6196. *It grows in banks of sand and mud,* which banks appear to be held together principally by the roots of this plant, which are strong and succulent, and throw out numerous lateral fibres. It grows at such depths as to be left nearly dry by the ebbing of spring tides. During the autumn and beginning of winter these leaves are thrown on shore in large quantities. They are of a very imperishable nature, and may be kept for any length of time in fresh or salt water, without any apparent decay. In the Orkney Islands this grass is thrown ashore during winter in large quantities, and collected by the inhabitants with other marine plants into heaps, for manure. In these heaps it is allowed to ferment, and sometimes, before being applied, it is mixed with earth or other matters. It is also used as thatch, and forms a more durable defence against the violent winds and heavy rains of that climate than straw. A few years ago, in consequence of premiums offered by the Highland Society, this grass was applied as a substitute for horse-hair, and stuffing mattresses and furniture: for this purpose it is carefully washed twice in fresh water, then dried quickly; and afterwards, any sea-weed that had got mixed with it picked out. In the Orkneys it is steeped in fresh-water lakes for a week, then taken out and spread wet on the ground, and picked, while in this state, from extraneous matters. Exposure to drought for one day will make it sufficiently dry for packing. When dry, care must be taken, if the weather is windy, to gather it into heaps or cocks, otherwise it may be blown away, being then extremely light. It is sent to market in large bags of sacking, or twisted into ropes of the thickness of a man's waist, and then compactly made up in nets, formed of ropes made of bent grass. It is sold at the Asylum for the Industrious Blind at Edinburgh, who employ it in stuffing mattresses. (*Highl. Soc. Trans.* vol. vi. p. 592.)

Chap. X.

Weeds or Plants injurious to those cultivated in Agriculture.

6197. *Every plant which appears where it is not wanted may be considered injurious,* though some are much more so than others. A stalk of barley in a field of oats is a weed, relatively to the latter crop, but a thistle is a weed in any crop; weeds, therefore, may be classed as relative and absolute.

6198. *Relative weeds,* or such cultivated plants as spring up where they are not wanted, give comparatively little trouble in extirpating them. The most numerous are the grasses when they spring up in fields of saintfoin or lucern, or among corn crops in newly broken up grass lands. The roots of chiccory, in fields that have been broken up after bearing that crop for some years, those of madder, liquorice, &c., are of difficult extirpation. When the potato crop has not been carefully gathered, or mustard has been allowed to shed its seed, they also occasion trouble. Other cases will readily occur to the practical man, and need not be mentioned.

6199. *Absolute weeds,* or such native plants as are considered injurious to all crops, are very numerous, and may be variously arranged. Some affect in a more peculiar manner corn-fields and tillage lands, and these are chiefly annuals, as wild mustard, wild radish, poppy, blue-bottle, cockle, darnel, &c.; or biennials, as the thistle; or perennials, as couch-grass, knot-grass, black-couch, polygonum, &c.; on lands laid down to grass for a few years, dock, ox-eye daisy, ragweed, &c. Others infest grass lands, and these are chiefly perennials, such as crowfoot, one of the most difficult of weeds to extirpate; thistles, docks, rushes, sedges, moss, and an endless variety of others. Some are more particularly abundant in hedges; of which the reedy and coarse grasses, as couch-grass, brome-grass; the climbing and twining plants, as goose-grass (*Gàlium Aparìne*); and the twiners, as bind-weed (*Convólvulus*), are the most injurious.

6200. *With regard to the destruction of weeds,* they may be classed first according to their duration.

6201. *All annuals and biennials,* as sau.d-wort (*fig.* 816. *a*), and sorrel (*b*), are effectually destroyed by cutting over the plant at any point below that whence the seed leaves originated, as this prevents them from ever springing again from the roots. Perennials of the fibrous-rooted kind may be destroyed in the same manner, as the crowfoot, ragweed, the fibrous-rooted grasses, and many others. Some fusiform-rooted perennials may also be destroyed by similar means; but almost all the thick-rooted perennials require to be wholly eradicated.

816

6202. *The perennial weeds,* which require their roots to be wholly eradicated, may be classed according to the kind of roots. The first we shall mention are the stoloniferous roots or surface shoots of plants, by which they propagate themselves. Of this kind are the creeping crowfoot, goosefoot or wild tansy, potentillas, mints, strawberries, black couch-grass, and most of the *Agrostideæ* and other grasses. The next are the under-ground creeping roots, as the couch-grass, *Convólvulus arvénsis*, and other species of bind-weed, coltsfoot (*fig.* 816. *c*), sowthistle, several tetradynamous plants, as toadflax, *Scrophulària*, nettle, hedge-nettle (*Stàchys*), *Làmium*, *Ballòta*, &c. Some of these, as the bindweed and corn-mint, are extremely difficult to eradicate: a single inch of stolone, if left in the ground, sending up a shoot and becoming a plant. The creeping and descending vivacious roots are the most difficult of all to eradicate. Of this class are the *Polýgonum amphíbium* (*fig.* 817. *a*), the reed (*Arúndo Phragmìtes*), the horse-tail (*Equisètum*, *fig.* 817. *b*), and some others. These plants abound in deep clays, which have been deposited by water, as in the carses and clay-vales of Scotland. In the Carse of Falkirk for example, the roots of the *Polýgonum amphíbium* are found

every where in the subsoil alive and vigorous. They send up a few leaves every year in the furrows and on the sides of drains; and when any field is neglected or left a year or two in grass, they are found all

over its surface. Were this tract left to nature for a few years, it would soon be as completely covered with the *Polýgonum* as it must have been at a former age, when it was one entire marsh partially covered by the Frith of Forth. The horse-tail is equally abundant in many soils, even of a drier desceiption; and the corn-thistle (*Serrátula arvénsis*, *fig.* 817. *c*) even in dry rocky grounds. Lightfoot (*Flòra Scótica*) mentions plants of this species dug out of a quarry, the roots of which were nineteen feet in length: it would be useless to attempt eradicating the roots of such plants. The only means of keeping them under, is to cut off their tops or shoots as soon as they appear; for which purpose, lands subject to them are best kept in tillage. In grass lands, though they may be kept from rising high, yet they will, after being repeatedly mown, form a stool or stock of leaves on the surface, which will suffice to strengthen their roots, and greatly to injure the useful herbage plants and grasses.

6203. *Tuberous and bulbous-rooted weeds*, are not very numerous; wild garlic, arum, and bryony are examples; and these are only to be destroyed by complete eradication.

6204. *Ramose, fusiform, and similarly rooted perennials*, of which rest-harrow, fern, and scabious are examples, may in general be destroyed by cutting over below the collar or point whence the seed-leaves have issued. Below that point the great majority of plants, ligneous as well as herbaceous, have no power of sending up shoots; though there are many exceptions, such as the dock, burdock, &c., among herbs, and the thorn, elm, poplar, cherry, crab, &c., among trees.

6205. *Holdich has taken a different view of the subject of weeds*, and classed them, not according to the modes by which they may be destroyed, but according to the injuries which they do to the soil or the crop. He has divided them into two classes, weeds of agriculture, or arable lands, and pasture weeds.

6206. *Arable weeds* are arranged as, 1. those which infest samples of corn; 2. root or fallow weeds, and such others as are hard to destroy; 3. those which are principally objectionable as they incumber the soil; 4. underling weeds, such as never rise with the crop, nor come into the sickle. Under these heads, each weed in its respective division is treated of as to its deteriorating qualities and mode of destruction.

6207. *The weeds which infest the sample* are, 1. Darnel (*Lòlium temuléntum*); 2. Cockle (*Agrostémma Githàgo*); 3. Tares (*E'rvum tetraspérmum*); 4. Melilot (*Trifòlium Melilòtus officinàlis*); 5. Wild oats (*Avèna fàtua*); 6. Hariff (*Gàlium Aparine*); 7. Crow needles (*Scándix Pécten*); 8. Black bindweed (*Polýgonum Convólvulus*); 9. Snake-weed (*Polýgonum lapathifòlium*); 10. Charlock seeds, (*Sinàpis, Ráphanus*, and *Brássica*) in barley sometimes.

6208. *Weeds which are principally objectionable as they encumber the soil* are, 1. Charlock, a name which is applied to four species of Crucíferæ (viz. *Sinàpis arvénsis* and *nìgra*, *Ráphanus Raphanístrum*, and *Brássica Nàpus*); 2. Corn poppy (*Papàver Rhœ'as*); 3. Blue-bottle (*Centaurèa Cyanus*); 4. Mayweed (*A'nthemis Cótula*); and 5. Corn marigold (*Chrysánthemum ségetum*.

6209. *The weeds called underlings*, or such as never rise in the crops, are, 1. Groundsel (*Senècio vulgàris*); 2. Annual meadow grass (*Pòa ánnua*); 3. Chickweed (*Stellària mèdia*); 4. Shepherd's purse (*Thlápsi búrsa pastòris* and *erécta*); 5. Spurry (*Spérgula arvénsis*); 6. Chamomile (*Matricària Chamomílla*); 7. Fat-hen (*Chenopòdium álbum*); 8. Common corn salad (*Fèdia olitòria*), 9. Flix-weed (*Sisýmbrium Sophìa*); 10. Common fumitory (*Fumària officinàlis*); 11. Sand mustard (*Sinàpis muràlis*).

6210. *Pasture weeds* are, 1. Dwarf-thistle (*Cárduus acaúlis*); 2. Common chamomile (*A'nthemis nóbilis*); 3. Star-thistle (*Centaurèa Calcítrapa*); 4. Ox-eye daisy (*Chrysánthemum leucánthemum*); 5. Great fleabane (*Conỹza squarròsa*); 6. Checse-rennet (*Gàlium vèrum*); 7. Long-rooted hawkweed (*Apárgia autumnàlis*); 8. Wild thyme (*Thỹmus Serpýllum*); 9. Sheep's sorrel (*Rùmex Acetoséllа*); 10. Knot-grass (*Polýgonum aviculàre*); 11. Yellow rattle (*Rhinánthus Crísta gálli*); 12. Common carline thistle (*Carlìna vulgàris*).

6211. *Pasture weeds which generally prevail in loamy soils*, and such also as are prevalent in clayey and damp soils, are principally as follows:—1. Yellow goat's-beard (*Tragopògon pratènsis*); 2. Marsh thistle (*Cárduus palústris*); 3. Melancholy thistle (*Cárduus heterophýllus*); 4. Meadow thistle (*Cárduus pratènsis*), 5. Common butter-bur (*Tussilàgo Petasìtes*); 6. Common ragwort (*Senècio Jacobæ'a*); 7. Common daisy (*Béllis perénnis*); 8. Common black knapweed (*Centaurea nìgra*); 9. Broad-leaved dock (*Rùmex obtusifòlius*); 10. Orchis (*O'rchis máscula, maculàta, latifòlia, mòrio*, and *pyramidàlis*); 11. Common cow-parsnep (*Heraclèum Sphondýlium*); 12. Sedge (*Càrex*), various species.

6212. *A catalogue of weeds* could be of little use to the agriculturist, as the mere names could never instruct him as to their qualities as weeds, even if he knew them by

their proper names. Besides, weeds which abound most, and are most injurious in one district, are often rare in another. Thus, the poppy abounds in gravelly districts, the charlocks on clays, the chickweed, groundsel, nettle, &c., only on rich soils. A local Flora, or any of the national Floras, as Lightfoot's *Flòra Scótica*, and Smith's *British Flora*, and, we may be allowed to add, our own *Encyclopædia of Plants* and *Hórtus Británnicus*, by pointing out the habits of indigenous plants, may be of considerable use to the agriculturist who has acquired a slight degree of the science of botany.

BOOK VII.

THE ECONOMY OF LIVE STOCK AND THE DAIRY.

6213. *The grand characteristic of modern British farming*, and that which constitutes its greatest excellence, is the union of the cultivation of live stock with that of vegetables. Formerly in this country, and in most other countries, the growing of corn and the rearing of cattle and sheep constituted two distinct branches of farming; and it was a question among writers, as, according to Von Thaer, it still is in Germany, which was the most desirable branch to follow. The culture of roots and herbage crops at last led gradually to the soiling or stall-feeding husbandry, in imitation of the Flemings; and afterwards, about the middle of the last century, to the alternate husbandry, which is entirely of British invention, and has been more effectually than any thing else the means of improving the agriculture of the districts where it is practised.

6214. *It is observed* by Brown, that "though horses, neat cattle, sheep, and swine are of equal importance to the British farmer with corn crops, yet we have few treatises concerning the animals, compared with the immense number that have been written on the management of arable land, or the crops produced upon it. But though so little has been written, the improvement of those animals has not been neglected; on the contrary, it has been studied like a science, and carried into execution with the most sedulous attention and dexterity. We wish it could be stated, that one half of the care had been applied to the selecting and breeding of wheat and other grains, which has been displayed in selecting and breeding the best proportioned and most kindly feeding sheep. A comparison cannot, however, be made with the slightest degree of success; the exertions of the sheep-farmers having, in every point of view, far exceeded what has been done by the renters of arable land. Even with cattle considerable improvement has taken place. With horses, those of the racing and hunting kinds excepted, there has not been correspondent improvement; and as to swine, an animal of great benefit to the farmer, in consuming offal which would otherwise be of no value, it is to be regretted that very much remains to be done."

6215. *The first important effort in the improvement of live stock* was made by Robert Bakewell, who was born on his father's estate of Dishley, in 1726. Mr. Bakewell wrote nothing himself; so the first scientific work on the subject was written by George Culley, in 1782, who had formed himself on Bakewell's model. The systematic improvements of Mr. Bakewell were developed in various agricultural reports, and consisted in attempts to lessen such parts of the animal frame of cattle and sheep as were least useful to man, as bone, cellular substance, and appendages; at the same time increasing such other parts, as flesh or muscle, and fat, as become more important in the furnishing man with food. These ends he endeavoured to accomplish by a judicious selection of individuals, possessing the wished-for form and qualities in the greatest degree; which being perpetuated in their progeny in various proportions, and the selection being continued from the most approved specimens among these, enabled him at length to establish breeds with the desired properties. Later improvements have been grafted on these, and we find excellent observations on the subject from the pens of Cline, Dr. Coventry, Sir J. Sebright, Hunt of Leicester, and the Rev. H. Berry; and we have witnessed the strenuous and successful efforts of a Russell, a Coke, an Ellman, and others. The improvement in the sciences of comparative anatomy and physiology has also led to an amended practice both in breeding and in pathology. The example of various opulent proprietors and farmers in all parts of the empire tended to spread this improvement, by which the pursuit became fashionable. Add to these the accounts of the management of live stock in almost every county of the British Isles, as contained in Marshal's *Works* and the *County Reports*. From these sources we shall draw the information we are about to submit, and shall adopt the arrangement of the horse, the ass, the mule and hinny, the bull family and the dairy, the sheep, the swine, minor stock, and injurious animals or vermin.

Chap. I.

The cultivated Horse. — E`quus Cabállus L.; *Mammàlia Bélluæ* L., and *Pachydérmes Solípedes* Cuvier. *Cheval*, Fr.; *Pferde*, Ger.; *Cavallo*, Ital.; and *Caballo*, Span.

6216. *The horse family*, by far the most important among the brute creation as a servant to man, includes several species both in a wild and cultivated state, as the *E`quus Hemìonus*, or wild mule, a native of Arabia and China, and which it is supposed would form an excellent race of small horses, could they be reduced to a state of domestication; the *E. Asìnus*, or ass, well known; the *E. Zèbra*, or striped ass; the *E. Quágga*, by some considered a variety of the zebra; and the *E.* bisúlcus, or cloven-footed horse, a native of Chile, and by many supposed to belong to a distinct genus.

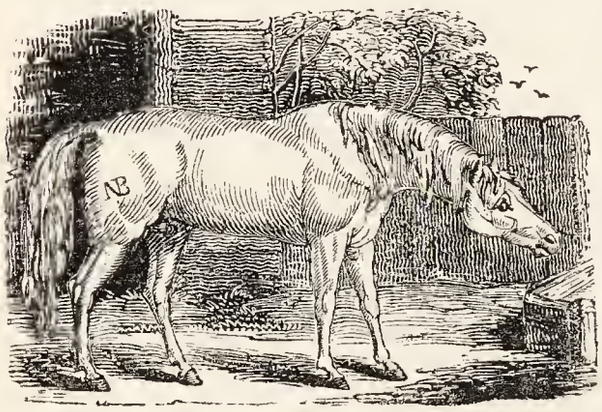
6217. *The common horse, justly considered as the noblest of quadrupeds,* is found in a wild state in the deserts of Great Tartary, in the southern parts of Siberia, and in other parts of Asia, and in the interior of Africa. He has long been domesticated and cultivated in most parts of the earth, for the various purposes of war, hunting, parade, the saddle, and draught; and in some places, partly for his flesh and the milk of the female. The parts of a horse, when no longer endued with life, are applied to various useful purposes. The blood is used as manure. The bones are broken and boiled, to produce oil, and are afterwards ground into an excellent manure; some of the bones are also employed in the mechanical arts. The flesh supplies food for the domestic carnivorous animals, the cat and dog; for carnivorous birds, kept for amusement or curiosity; for fish, &c. We shall consider the horse in regard to its varieties, organology, anatomy, physiology, diseases, breeding, rearing, training, feeding, and working

Sect. I. *Varieties of the Horse.*

6218. *The varieties of the domestic horse* are numerous. The indigenous horse of every country, operated on by climate, assumes that form best adapted to its locality. Man would soon, however, be led to mix with the native breeds that variety which presented in its aboriginal state the finest form and most valuable qualifications. This being found centred in the horses of Arabia, Persia, and Barbary, the inhabitants of Europe generally sought an amelioration of their own breeds by an admixture of oriental blood.

6219. *The Arabian horses* (*fig.* 818. is a portrait of one brought by Buonaparte from Egypt, and now living in the royal garden of Paris,) are reckoned the best, and the solicitude with which the Arabs preserve these horses pure and unmixed is remarkable. The care with which they are nurtured, and the skill displayed in their equestrian management, are no less admirable. None but stallions of the finest form and purest blood are allowed access to their mares, which is never permitted but in the presence of a professional witness or public officer, who attests the fact, records the name, and signs the pedigree of each. The *Persian horses* are considered next in value; and after them the horses of Andalusia in Spain. The *Barbary horses* are descended from the Arabians, and much esteemed. Jackson (*Empire of Morocco*, p. 42.) mentions one very fleet variety, used for hunting the ostrich, and fed entirely on camel's milk. The *horses of India*, though active and not ill formed, are small and vicious, the climate being unfavourable to their greater developement. *Those of Tartary* are of a moderate size; but strong, muscular, full of spirit, and active. The Tartars are considered skilful riders. Like the Kalmucks, they eat the flesh of horses as we do that of oxen, and use their milk either in curd or fermented.

818



6220. *Of the European varieties of the horse,* those of Italy were formerly in greater esteem than at present; but still those of the Neapolitans shine both under the saddle and in traces. Great numbers are bred in Sicily; those of Sardinia and Corsica are small, but active and spirited. The Swiss horses partake of the same qualities.

6221. *The Spanish horses* have long been highly esteemed. The invasion of the Moors, in 710, brought a vast influx of oriental blood into Spain; and the continuance of the Moorish yoke during several centuries produced altogether so improved a race there, that the best Spanish horses are preferred by some to the Barbs. The Spanish Genette has long been celebrated for its elegance, sprightliness, and durability. The best breeds of Spain are generally finely carcased, and well limbed, active, ready, and easy in their paces, docile and affectionate to their owners, full of spirit and courage, but tempered with mildness and good-nature; they are, for the most part, of a moderate size. Those which are bred in Upper Andalusia are deemed the most valuable. The Portuguese horses, or rather mares, were famous of old for being very fleet and long-winded; but of late, it is said, they are much degenerated.

6222. *France* abounds in horses of all kinds, whose origin may be traced to a mixture of their native breeds with the Asiatic introduced by the irruption of the Goths, and originally received from the Scythians, and the true eastern blood received from Spain, Barbary, and Arabia. With these admixtures, however, the horses of France have not yet borne a high character throughout Europe; and although under the dominion of Napoleon more than two hundred pure Arabian stallions were imported, and the northern states plundered of their choicest specimens, by which the breeds have been much improved; still France imports yearly vast numbers from this country, particularly hunters and high bred carriage horses. Of their own breeds, Limousin furnishes some good saddle horses, and hunters also. Next to those, Normandy claims precedence for a well-formed and useful breed. There are also very good *bidets*, or ponies, in Auvergne, Poitou, and Burgundy. Lower Normandy and the district of Cotentin furnish some very tolerable coach horses, and which are more active and appear more elastic in their motions than the Dutch horses. They have, however, a noble race of large draught horses equal to any seen in England, and among which the chesnut colour seems to prevail. The French horses generally are apt to have their shoulders although oblique, yet too loose and open, as those of the Barbs are usually too confined and narrow.

6223. *The Flemish horses* are inferior in value to the Dutch, having usually large heavy heads and necks; their feet also are immoderately large and flat, and their legs subject to watery humours and swellings.

6224. *Holland* furnishes a race of horses which are principally serviceable in light draught work: the best come from Friesland.

6225. *Germany* is not destitute of good horses. The native breeds, heavy and ill-formed, received their first improvement from admixture with the Asiatic horses In after-times the Germans obtained still

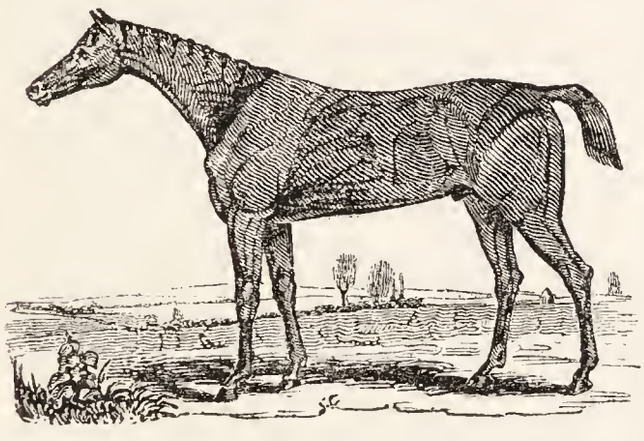
finer breeds from the Arabs, Turks, and the Barbary states, which they still preserve with some care as stallions: some good specimens are also obtained from Spain. In a general point of view, however, the German horses are more fitted for the manege than for racing or hunting; in which qualities they are inferior to the Hungarian and Transylvanian horses. The horses of Bohemia are not distinguished by any eminent qualities. The Hussars and Transylvanians are accustomed to slit the nostrils of their horses, under a notion of giving their breath a free passage, and improving their wind, as well as to render them incapable of neighing, which, in the field, would be often inconvenient. The Croatian horses are nearly allied in qualities and character to the Hungarian and Bohemian: these, as well as the Poles, are remarkable for being, as the French term it, *bégut*, or keeping the mark in their teeth as long as they live.

6226. *The Polish horses* are hardy, strong, and useful, but they are generally of a middling size. In the marshy parts of Prussia, and towards the mouth of the Vistula, there is a breed of tall strong horses, resembling those of Friesland, but of inferior value.

6227. *The horses of Russia* are not much regarded by other nations. They are small but hardy, and capable of enduring great fatigue. Great attention is, however, paid to such as are very fast in their trot; and such a breed is much encouraged for trotting matches on the snow and ice. Those of the Turkish breed are handsome and finely shaped, but too slight and weak for heavy cavalry. The Kalmuck horses are somewhat higher than the Russian common horses, and are so lasting and constitutionally strong as to be able to run three or four hundred English miles in three days. They subsist, summer and winter, solely upon grass in the great deserts which are between the rivers Don, Volga, and Yaik, where they are collected in great herds of four hundred, five hundred, or even a thousand. They are excellent swimmers, and pass the river Volga, where it is from one mile to two miles broad, with great ease.

6228. *The horses of Sweden* are low and small, and the Norway breed may be comprehended under the same description, but they are strong, hardy, and active. Denmark, and also Holstein and Oldenburg, boast a large variety of horses, which has long been esteemed as peculiarly adapted for heavy cavalry and carriage uses, though they are apt to fail with respect to elegance of limb and symmetry of parts; their heads being large, their shoulders heavy, their backs long, with croups too narrow to correspond with their fore parts. In the Islands of Feroe there is a race of horses of small growth, but strong, speedy, and very sure-footed. They are never shod, and feed abroad without shelter both summer and winter. In Suderoe, one of these islands, they have a peculiarly swift breed, of great use to the inhabitants, who catch their sheep, which are wild, by hunting them with a dog, pursuing them at the same time with their horses. The horses of Lapland are small of stature, but active and willing; they are used only in the winter season, in drawing sledges over the snow, and transporting wood, forage, and other necessaries; but in summer they are turned into the forests, where they form separate troops, strictly confined to their own quarters.

6229. *The British varieties of saddle horse* may be reduced to the racer, the hunter, the improved hack, the old English road horse, the galloway, and the pony; the two latter of which we shall consider in another place.

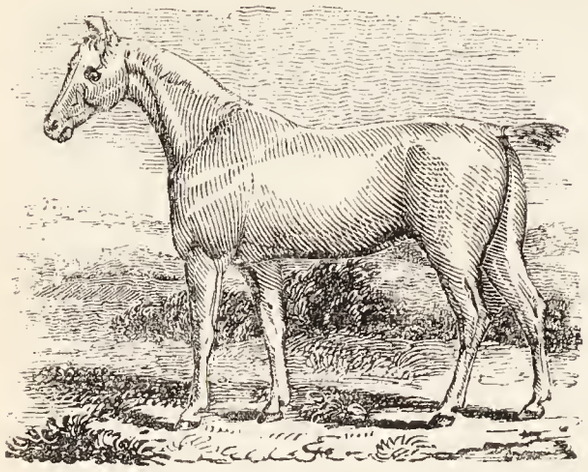


6230. *The race horse* (*fig.* 819.) is descended nearly in a direct line from the Arabian, the Persian, and the Barb. In an agricultural point of view, this celebrated breed might at first sight appear of little importance; but it is probable, that to the amusement afforded by it to the rich and powerful, we are indebted for the principal improvements in every other variety of this most valuable animal. Races or courses were very early a part of British sports; and it is natural to suppose that, on this account, endeavours would be made to improve and enlarge the breeds of the native horses. Roger de Bellesme, Earl of Shrewsbury, is the first on record who imported a Spanish stallion, the progeny of which was afterwards extolled by Michael Drayton, in his *Poly-olbion*; and, it is probable, the first amelioration of the native breeds was derived altogether from horses brought from Spain and the southern parts of Gaul. In the reign of Henry IV., public ordinances were made favourable to the improvement of the breeding of horses, which would tend still further to extend the search after better specimens. There is reason, however, to believe, that the courses of those times were little more than ordinary trials of speed between the *indigenæ*, or these slightly improved breeds; and it was not until the days of Henry VII. and VIII., that the true eastern blood was collected in any considerable quantities. During these reigns, however, it becoming very general to import stallions from Arabia, Barbary, and Persia, a new and highly improved race rapidly extended itself. This improvement was carried subsequently to its acmé by an equally careful selection of mares as of horses; and thus we find king James importing a set of mares of the purest blood, significantly called the royal mares. From these periods, the breeding of the race horse was pursued with the utmost care, as well in regard to purity of blood, as in the increase of his bodily powers, by the most nutritious food and duly apportioned exercise, during his training for the courses, then becoming so fashionable in England. Thus has been produced a breed unrivalled throughout the world for symmetry of form, swiftness of progression, and durability under exertion. The accounts on record of feats performed by some of our horses on the turf are truly astonishing. Bay Malton ran at York four miles in seven minutes and forty-three seconds. Childers, known by the name of the flying Childers, moved through a space equal to eighty-two feet and a half in a second. After these Eclipse, Highflyer, Matchem, Hambletonian, and others, have contributed to keep up the reputation of the English racer.

6231. *Climate has a great influence over the form of animals*, and that form is found indigenous to each which best fits it for the purposes required of it. In the arid plains of the east, where herbage is scarce, a form is given which enables its brute inhabitants to readily transport themselves from one spot to another; and as in every situation the flesh of the horse is greedily sought after by the predatory tribes, so here, where those are peculiarly strong and active, the horse is formed peculiarly agile and swift to escape their attack, as well as peculiarly light, that his weight might not sink him in the sandy plains, nor his bulk retard him in his flight. Removed, however, to more temperate climes, where vegetation affords by its luxuriance more nutriment, and where the restrictions of danger have ceased to operate, we no longer see him equally small and slender; but, with equal capacity for swift progression, we find him expanded into a form capable of keeping up that progression with a durability unknown to the original breeds from which he sprang. Symmetrically formed as we now see him, he at once evinces his claim to great speed. His bony skeleton exhibits a base founded on the justest geometrical principles, presenting a series of lengthened levers acting by means of a condensed muscular and tendinous organization of great power, on angles capable of great flexion and extension; while his pointed form fits him to cleave that atmosphere, from which his deep chest enables him to draw by extensive inspirations wind and vigour to continue his exertions. Purity of blood, by which is meant the result of confining to particular races or

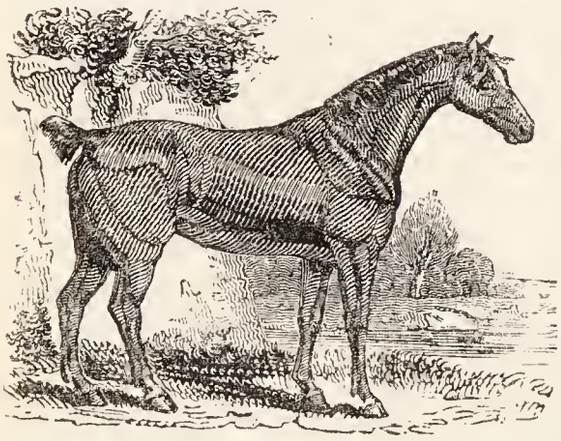
breeds the means of continuing their species, is observed with equal care and jealousy by the breeders of the English race, as by the Arabians; and turf jockeys assert they can discover a taint or departure from this purity to the sixteenth remove.

820



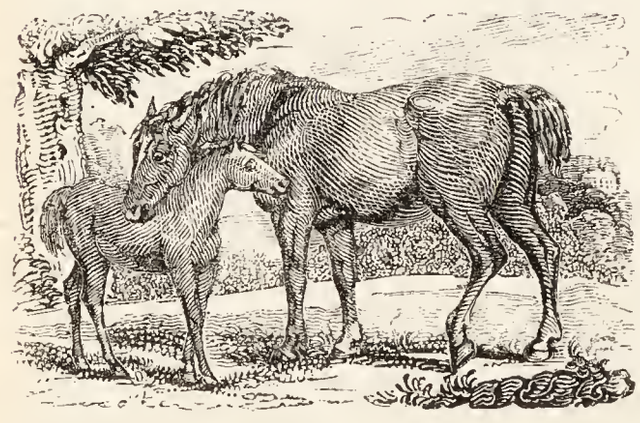
6232. *The hunter* (*fig.* 820.) is derived from horses of entire blood, or such as are but little removed from it, uniting with mares of substance, correct form, and good action. In some instances hunters are derived from large mares of the pure breed, propagating with powerful stallions of the old English road horse. This favourite and valuable breed is a happy combination of the speed of the Arabian, with the durability of the native horse. More extended in form, but framed on the same principles, he is able to carry a considerable weight through heavy grounds, with a swiftness equalled only by the animal he pursues, and with a perseverance astonishing to the natives of every other country. Hence the extreme demand for this breed of horses in every European country; our racing stallions being now sent to propagate in the eastern climes, whence they were some of them originally brought.

6233. *The improved hackney* (*fig.* 821.) is derived, like the former, from a judicious mixture of the blood breed with the native horse, but exhibiting a greater proportion of the latter. Hackneys are now, however, mostly bred from stallions possessing nearly the same proportion of blood with the hunter; but with a form and qualities somewhat different. In the hackney, as safety is as requisite as speed, we look particularly to the fore parts to see that they are high and well placed; that the head is not heavy, nor the neck disproportionately long or short; that the legs stand straight (that is, that a perpendicular line drawn from the point of the shoulder should meet the toe); and that the elbows turn out: and although a perfect conformation in the hinder parts is necessary to the hackney, it is in some measure subordinate to the same perfection in the fore parts; whereas in the racer and hunter, but particularly in the former, the form of the hinder is even of more consequence than that of the fore parts.



6234. *The old English road horse.* This most useful breed is now nearly extinct, although some northern agriculturists appear to be making efforts to revive the race. It has so long been known in this country that it might almost be reckoned among its *indigenæ*: although it is probable that it originally sprang from a judicious culture from horses of Norman, German, or Flemish extraction, which horses were very early imported to enlarge our small breeds, and to render them equal to the heavy loads they were accustomed to carry as pack-horses; and of which kind the old English road horse unquestionably is. (*fig.* 822.) Neither is it at all impossible, that, in the more fertile parts of the island, an original breed existed of considerable power and bulk. Athelstan expressly prohibited the exportation of English horses, and the "scythed chariots drawn by fiery steeds" of the ancient Britons struck terror even into Cæsar's legions. These accounts of the antiquity of the English horse, receive additional strength from the notices we obtain of the fossil bones of horses having been found, according to Parkinson, in various parts of the island. The old English road horse possessed great power, with short joints, a moderate shoulder, elevated crest, with legs and feet almost invariably good. The heights varied from fifteen hands to fifteen hands two inches; and the colours were frequently mixed.

822



6235. *The objection, however, to English horses*, both of the original and of the more early improved breeds, and which is even still seen among them, is, that they want grace or expression in their figure and carriage; that they are somewhat obstinate and sullen; and that a certain stiffness in their shoulders, and want of suppleness and elasticity in their limbs, render them unfit for the manege. As this is an important charge against the excellence of our breeds, it may be worth consideration how far it is founded in truth. Commerce requires despatch, and England as a great commercial country makes every thing subservient to an economical use of time. Conformably to these principles, many of the qualities of our horses, but principally those of flexibility and safety in progression, are certainly sacrificed to speed, in which they undoubtedly excel all horses in the world. It is well known that all animals intended by nature for quick progression, are formed low in their fore parts, and have usually narrow upright shoulders; which defects are too common in English horses in general. On the contrary, in most of the improved breeds of continental horses, the fore hands are elevated, and the shoulders wide and oblique; by which, flexibility and safety in progression are gained at some expense of celerity; for the strong lumbar muscles of horses so formed, operating on the lengthened spinous processes of the dorsal vertebræ with increased advantage, elevate the fore parts higher; and even in default of this form in the fore parts, yet a corresponding effect is produced in foreign horses by the great strength and expansion of their haunches and croups, and by the greater inclination in their hinder extremities towards the common centre of gravity of the body: for as speed depends first on the extent to which the angles of the limbs can be opened, and secondly, on the efforts of the body in its transit to counteract the tendency to the common centre of gravity, the earth; so it is evident that the form which is the most favourable to speed, is less so to safety or flexibility in progression.

6236. *The Irish road horse, or hunter*, coeval with, or probably in some measure subsequent to, the culture of the old English road horse, was a still more excellent breed. With similar properties, but an improved form, with a great acquired aptitude for leaping, it gained the name of the Irish hunter; and when the dogs of the chace were less speedy than they now are, this horse was equal to every thing required of him as a hunter; even now the possessors of the few which remain find, particularly in an enclosed and deep country, that what others gain by speed these accomplish by strength to

go through any ground, and activity sufficient to accomplish the most extraordinary leaps. As roadsters, these horses have ever proved valuable, uniting durability, ease, and safety with extreme docility. In form they may be considered as affording a happy mixture of an improved hack with our old English roadster.

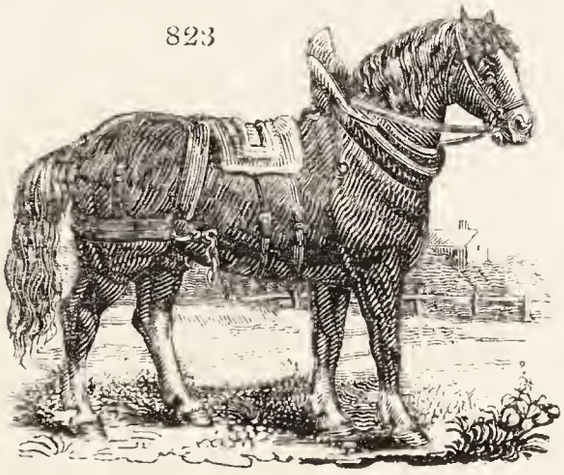
6237. *The British varieties of saddle horse of more inferior description* are very numerous, as cobs, galloways, and ponies. Cobs are a thick, compact, hackney breed, from fourteen hands to fourteen hands two inches high, in great request for elderly and heavy persons to ride, or to drive in low phaetons, &c. Galloways and ponies are lately in much request also for low chaises; a demand which will lead to a cultivation of their form; the number bred requires little increase, as several waste districts or moors throughout England are already appropriated principally to the purpose of rearing ponies.

6238. *The British varieties of war or cavalry horse, and of carriage and cart horse*, are considered to have been derived from the German and Flemish breeds, meliorated by judicious culture. Most of the superior varieties contain a mixture of Arabian or Spanish blood. Cavalry horses are found amongst the larger sort of hackneys; and the observations made in the late wars sufficiently show the justice of the selection. Except in a few unhappy instances, where a mistaken admiration of the Hulans had led to selecting them too light, the English cavalry horse possessed a decided superiority over the best French horses in strength and activity, as well as over the Germans, whose horses on the other hand, by their bulk and heavy make, were incapable of seconding the efforts of the British dragoons. The coach, chariot, and stage horses are derived many of them from the Cleveland bays, further improved by a mixture of blood. Others are bred from a judicious union of blood and bone, made by the breeders in Yorkshire, Lincolnshire, and other midland counties.

6239. *The varieties of draught horse* were originally as numerous as the districts in which they were bred, each having its favourite breed; but since the intercourse among farmers and breeders has been greater, those in common use are so mixed as to render it difficult to determine of what variety they partake the most. At present the principally esteemed draught horses are the Suffolk punch, the Cleveland bay, the black, and the Lanark or Clydesdale. The native breeds of draught horses of England, Scotland, Wales, and Ireland, are much too small for the purposes of agricultural draught as now conducted; but by cultivation, the improved breeds pointed out have furnished such animals as are equal to every thing required of them.

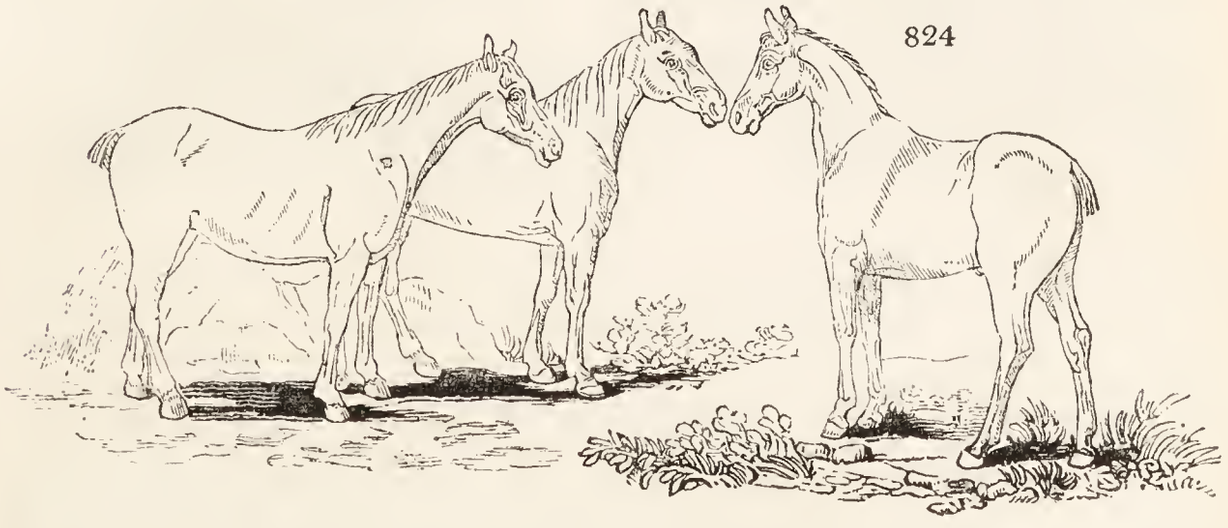
6240. *The black horse* (*fig.* 823.), bred in the midland counties of England, is a noble and useful animal; and furnishes those grand teams we see in the coal, flour, and other heavy carts and waggons about London; where the immense weight of the animal's body assists his accompanying strength to move the heaviest loads. But the present system of farming requires horses of less bulk and more activity for the usual agricultural purposes, better adapted for travelling, and more capable of enduring fatigue; consequently this breed is seldom seen in the improved farms. The black cart horse is understood to have been formed, or at least to have been brought to its present state, by means of stallions and mares imported from the Low Countries; though there appears to be some difference in the accounts that have been preserved, in regard to the places whence they were originally brought, and to the persons who introduced them. (*Culley on Live Stock*, p. 32., and *Marshal's Economy of the Midland Counties*, vol. i. p. 306.) Marshal, under too confined a view, and probably prejudiced against the breed on account of its fancied want of spirit, as well as for the alleged tendency to become flat and pommiced in the feet, is most unreasonably severe on it, when he says, "the breed of grey rats, with which this island has of late years been overrun, are not a greater pest in it than the breed of black fen horses; at least while cattle remain scarce as they are at present, and while the flesh of horses remains to be rejected as an article of human food." (*Marshal's Yorkshire*, vol. ii. p. 164.) The present improved sub-variety of this breed is said to have taken its rise in six Zealand mares, sent over from the Hague by the late Lord Chesterfield, during his embassy at that court.

823



6241. *The Cleveland bays* (*fig.* 824.), which owe some of their most valuable properties to crosses with

824

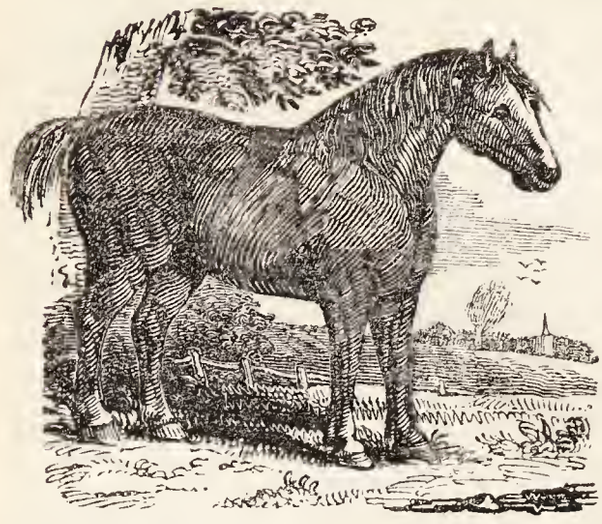


the race-horse, have been long celebrated as one of the best breeds in the island; but they are said to have degenerated of late. They are reared to a great extent in Yorkshire, the farmers of which county are remarkable for their knowledge in every thing that relates to this species of live stock. In activity and hardiness, these horses, perhaps, have no superior. Some capital hunters have been produced by putting full-bred stallions to mares of this sort; but the chief object latterly has been to breed coach-horses, and such as have sufficient strength for a two-horse plough. Three of these horses draw a ton and a half of coals, travelling sixty miles in twenty-four hours, without any other rest but two or three baits upon the road; and frequently perform this labour four times a week.

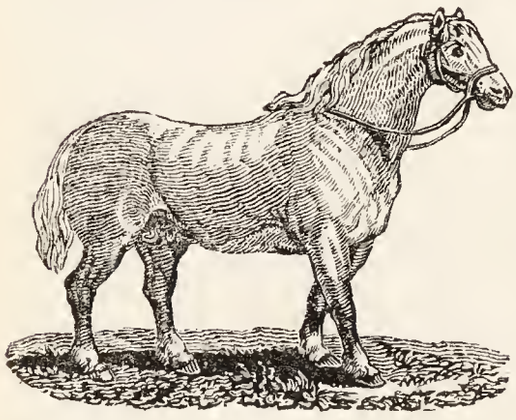
6242. *The Suffolk punch* (*fig.* 825.) is a very useful animal for rural labour, and is particularly esteemed by the farmers of Norfolk, Suffolk, and Essex, but the merit of this breed seems to consist more in constitutional hardiness than in any apparent superiority of shape. "Their colour is mostly yellowish or sorrel, with a white ratch or blaze on their faces; the head large, ears wide, muzzle coarse,

fore-end low, back long sometimes, but always very straight, sides flat, shoulders too far forward, hind-quarters middling, but rather high about the hips, legs round and short in the pasterns, deep-bellied, and full in the flank. Here, perhaps, lies much of the merit of these horses; for we know, from observation and experience, that all deep-bellied horses carry their food long, and consequently are enabled to stand longer and harder days' works. However, certain it is, that these horses do perform surprising days' works. It is well known, that the Suffolk and Norfolk farmers plough more land in a day than any other people in the island; and these are the kind of horses every where used in those districts." (*Culley on Live Stock*, p. 27.) Since Culley's time much pains have been taken to improve this useful breed, and to render them, by cultivation, fitted not only for heavy but for light work. It is no uncommon thing for a Suffolk stallion to fetch from 200*l.* to 300*l.* The best show of these stallions in England is at Woodbridge Lady-day fair, where Suffolk cart mares have brought from 100*l.* to 150*l.*, and one mare and her offspring a few years ago at this fair brought 1000*l.* The figure (825.) hardly does justice to the animal. (*M.*)

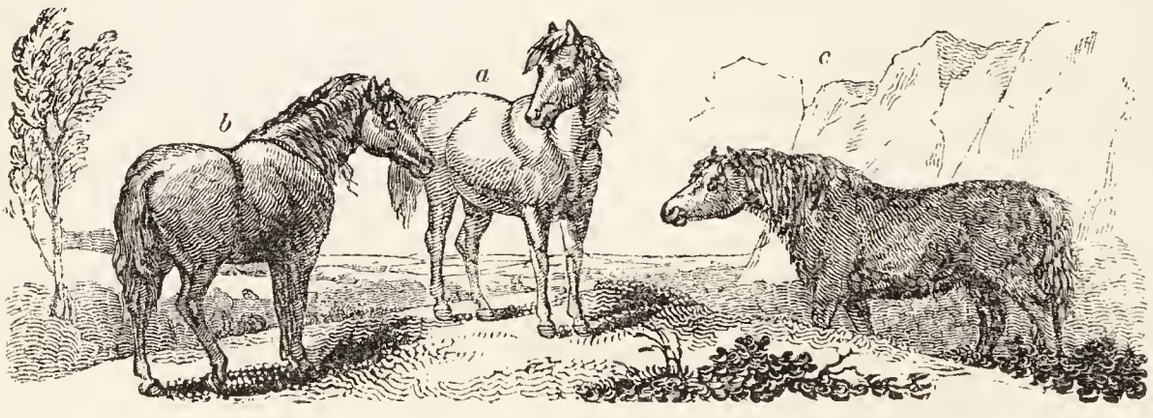
825



6243. *The Clydesdale horse* (*fig.* 826.) has been long in high repute in Scotland and the north of England; and, for the purposes of the farmer, is probably equal to any other breed in Britain. Of the origin of this race, various accounts have been given, but none of them so clear, or so well authenticated, as to merit any notice. They have got this name, not because they are bred only in Clydesdale or Lanarkshire, for the same description of horses are reared in the other western counties of Scotland, and over all that tract which lies between the Clyde and the Forth, but because the principal markets at which they are sold, Lanark, Carnwath, Rutherglen, and Glasgow, are situated in that district, where they are also preserved in a state of greater purity than in most other parts. They are rather larger than the Suffolk punches, and the neck is somewhat longer; their colour is black, brown, or grey, and a white spot on the face is esteemed a mark of beauty. The breast is broad; the shoulder thick, with the reaching cartilaginous portion of the blade-bone nearly as high as the withers, and not so much thrown backwards as in road horses; the hoof round, and usually black, with wide heels; the back straight and broad, but not too long; the hucks visible, but not prominent, and the space between them and the ribs short; the tail heavy, and well haired; the thighs meeting each other so near as to leave only a small groove for the tail to rest on. One most valuable property of this breed is, that they are remarkably true pullers, a restive horse being rarely found among them.



6244. *The Welsh horse* (*fig.* 827. *a*) bears a near resemblance, in point of size and hardiness, to the best of



the native breed of the highlands of Scotland, and other hilly countries in the north of Europe. It is too small for the present two-horse ploughs; but few horses are equal to them for enduring fatigue on the road. "I well remember," says Culley, "one that I rode for many years, which, to the last, would have gone upon a pavement by choice, in preference to a softer road." (*Observations on Live Stock*, p. 35.)

6245. *The galloway* (*b*), properly so called as being found chiefly in that province of Scotland, has now become very rare, the breed having been neglected from its unfitness for agricultural purposes. Galloway is, however, used as a term for any horse between the pony size and the hack; and in this point of view is sufficiently numerous, and very commonly bred by small farmers on commons and wastes. The true galloway is somewhat larger than the Welsh horse, and is said to resemble the Spanish horses; there is also a tradition, that some of the latter, that had escaped from one of the vessels of the Armada, wrecked on the coast of Galloway, were allowed to intermix with the native race. Such of this breed as have been preserved in any degree of purity are of a light bay or brown colour, with black legs, and are easily distinguished by the smallness of their head and neck, and the cleanness of their bone.

6246. *The still smaller horses of the Highlands and isles of Scotland*, (*c*) are distinguished from larger breeds by the several appellations of *ponies*, *shelties*, and in Gaelic of *garrons* or *gearrons*. They are reared in great numbers in the Hebrides, or western isles, where they are found in the greatest purity. Different varieties of the same race are spread over all the Highland districts, and the northern isles. This ancient breed is supposed to have been introduced into Scotland from Scandinavia, when the Norwegians and Danes first obtained a footing in these parts. "It is precisely the same breed that subsists at present in Norway, the Feroe Isles, and Iceland, and is totally distinct from every thing of horse kind on the continent of Europe, south of the Baltic. In confirmation of this, there is one peculiar variety of the horse in the Highlands, that deserves to be noticed: it is there called the *eel-backed* horse. He is of different colours, light bay, dun, and sometimes cream-coloured; but has always a blackish list that runs along the ridge of the back, from the shoulder to the rump, which has a

resemblance to an eel stretched out. This very singular character subsists also in many of the horses of Norway, and is nowhere else known." (*Walker's Hebrides*, vol. ii. p. 158.) "The Highland horse is sometimes only nine, and seldom twelve hands high, except in some of the southern of the Hebrides, where the size has been raised to thirteen or fourteen hands by selection and better feeding. The best of this breed are handsomely shaped, have small legs, large manes, little neat heads, and are extremely active and hardy. The common colours are grey, bay, and black; the last is the favourite one." (*General Report of Scotland*, vol. iii. p. 176.)

Sect. II. *Organology or exterior Anatomy of the Horse.*

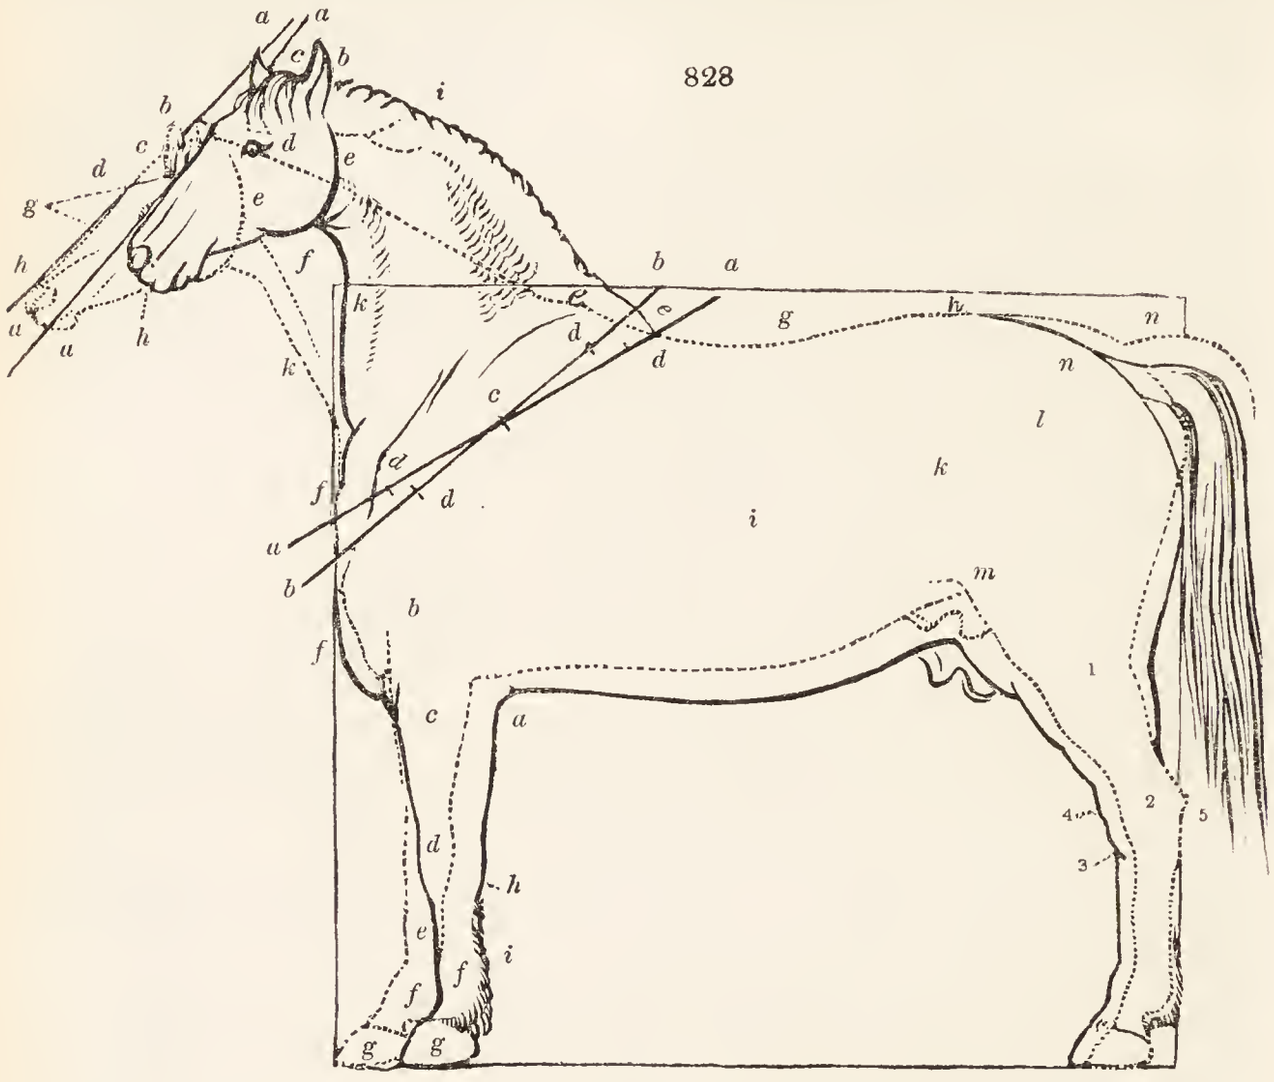
6247. *A just knowledge of the exterior conformation of the horse*, to be able to form a correct judgment on the relative qualities of the animal, forms the *ne plus ultra* of a scientific horseman's aim; but it is a branch of knowledge not to be obtained without much study and experience. In considering a horse exteriorly, his age, his condition, and other circumstances should be taken into the account; without which attention it is not possible to determine, with precision, the present or future state of a horse when he is seen under various peculiarities. A horse of five years old, though considered as full grown, yet experiences very considerable alterations of form after that period. He then becomes what is termed *furnished;* and all his points (*i. e.* his adult form), before hidden in the plumpness of youth, or disguised by extreme obesity, now show themselves. From the effects of muscular exertion promoting absorption, he becomes more angular, and to the painter's eye, would prove more picturesque, but less beautiful. A horse likewise low in flesh and condition, is hardly the same animal as one in full flesh and condition; and again, the sleekness acquired from relaxed labour, with full and gross feeding, is very unlike the robust form acquired from generous diet with correspondent exertion.

6248. *The examination of the subject of organology* is conveniently pursued by dividing it into head, neck, trunk, or body, and extremities or legs. The greater number of well proportioned horses, with the exception of the head and neck, come within a quadrangle; not one strictly equilateral as depicted by Lawrence (Richard) and Clark, but one whose horizontal dimensions are usually between a twenty-fourth and twenty-eighth greater than their perpendiculars. It must, however, be kept in mind, that with some considerable deviations from this quadrangular form, many horses have proved superiorly gifted in their powers; and that a deviation from these proportions appears in some instances, as in that of the race horse, not only favourable, but necessary also to his exertions. Nature will not be limited, and the perfection of her operations is not alone dependent on the arbitrary arrangement of parts, but on a harmony and accordance of the whole, internal as well as external. To the artist, however, such admeasurement is useful, inasmuch as it prevents any singular departure from a symmetrical appearance, which is but too common among our animal draughtsmen. To the amateur it also offers a convenient, though not an unerring guide. Our exemplification of the organology appears by placing a blood and a cart horse within the same square (*fig.* 828.), by which the differences between the various parts of the one and the other are readily contrasted.

6249. *The organs of the head.* The head of the horse is remarkable for its dimensions, formed by an elongation of the jaws; yet in him, as in most of the grazing tribes, its bulk is in an inverse proportion to the length of the neck, otherwise the muscles would not be able to lift it. It is an important part considered as relative to beauty alone, it being in the inferior heavy breeds but little marked by grace or expression; but in the improved varieties it presents lines worthy the painter's pencil and the poet's fancy. Neither is it too much to say, that in no part of the body is this amelioration of breed so soon detected as in the head. Can any thing be conceived more dissimilar than the small inexpressive features of the cart horse, and the bold striking ones that grace the head of the blood horse? The quick succession of movements in his pointed ears, the dilatations of his expanded nostrils, or his retroverted eyes, which give fire and animation to the character of his head when under the influence of any excitement. This is the more worthy of remark, when it is considered that some of the principal aids to expression in the human countenance are wanting in the horse. Man borrows much of his facial expression from his eyebrows, and when to these the varied action of the mouth is added, it amounts to more than a half of the total expression. A great accession of beauty is gained in the improved breeds by the increase of the facial angle, which in them is about 25°, but in the heavy breeds is usually only 23° (*a a a a*).

6250. *The ears* (*b b*) in the improved breeds are small and pointed; in the heavy they are not only large and ill shaped, but they frequently separate from each other: these defects gave rise to the barbarous custom of cropping, now happily in a great measure abolished. The ears are criteria of the spirit, as well as of the temper; we have seldom seen a horse which carried one ear forward and the other backward during his work that was not hardy and lasting. Being not subject to early fatigue, he is attentive to every thing around him, and directs his ears different ways to collect sound from every quarter. The ears are also indications of temper, and a horse is seldom either playful or vicious but his ears are laid flat on the neck. It is fortunate that we are provided with such a warning, by an animal that does not want craft to surprise us, nor strength to render his resentment terrible.

6251. *The forehead* next presents itself (*c c*), straight, and of a proper width in the improved breeds, adorned by nature with an elegant portion of hair, which, detaching itself from the rest of the mane, flows down the face to protect both that and the ears from the attacks of insects.



6252. *The eyes* (*d d*) deserve particular attention, not only for their utility, but as objects of beauty and expression. In the blood horse the orbitary fossæ, or eye-sockets, are more prominent and more inclined, by which the axes of his eyes diverge more from each other than those of the heavy breed; by which not only he is enabled to see further behind him, but the prominence of his eyes gives great beauty and expression to the blood head. The further consideration of the eyes, and their criteria of soundness, will be postponed to the anatomical detail. In old horses most of the fat of the body, which is more superficially placed in the young, becomes absorbed; in this way the eye, which is usually embedded in a vast quantity of this matter, losing its assistance, sinks within its orbits, and thus the cavities above, called eye-pits, shows themselves deeply in an aged horse.

6253. *From the ears to the angle of the jaws* (*e e*) large vessels and extensive glands are situated. Within these branches of the posterior jaw is lodged the throat, and it will be observed how necessary it is that these branches should expand sufficiently to admit of the motions of the head, particularly of those influenced by the reining-in of the bridle; otherwise the blood-vessels and other parts must be injuriously pressed upon.

6254. *The hollow between the jaws is called the channel*, and at the under part of it (*f*) a considerable branch of an artery proceeds from the inner side over and around the outer, which branch forms the most convenient situation for feeling the pulse of the horse.

6255. *The face* (*g*) of the improved breed of horses presents either a straight line, or one slightly curved inward towards the lower part; whereas, in the heavy breeds, it is very commonly found to be curved outward. This part comprises, as with man, from the forehead to the lips. When the face is covered with white, it is considered a blemish; but when a white spot only exists in the forehead, it is considered a beauty.

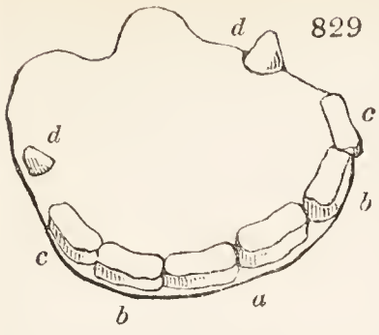
6256. *The markings in the face are useful to describe a horse by*, and frequently lead to the recovery of a strayed or stolen one. In regimental accounts these marks are carefully noted. When a spot extends down the face, it is termed a blaze; and when further continued into the muzzle, it is called blaze and snip. When a star is distinct, but with it there are white markings which begin some distance below it, and are continued downwards, it is called a race.

6257. *The muzzle* (*h h*) includes the lips, mouth, and nostrils; the darker the colour of this part the more is the horse esteemed: very dark brown horses are an exception, for in them it is usually of a tan colour, and is praised both as a beauty and indicative of excellence. It is both a beauty and an excellence that the nostrils be thin, angular, and large.

6258. *The lips* should be thin, firm, and by no means loose and pendulous, as is the case in the old and sluggish. The lips in the horse are the principal organs of touch and discrimination, and hence are exquisitely sensible.

6259. *The form of the mouth, as receiving the bit, is important.* It is also of more consequence than is usually supposed, that its commissure or opening be sufficiently deep; when shallow, it is not only inelegant, but it will not admit a bridle favourably into its proper resting place upon the bars. Within the mouth are situated the teeth, which are so placed as to have interrupted portions of jaw above and below of considerable extent. These vacancies are called *bars*, and are parts of extreme importance to the horseman, as it is by means of agents called bits resting on these parts, and operating on their sensibility by means of a lever, the long arm of which is in the hand of the rider, that he ensures obedience. In aid of this mechanism, to one portion of this lever is attached a chain, called a curb, which acting on the outer part of the chin, increases the pressure. This latter part has been called the *barb* or *beard*, but its situation is evidently above that.

6260. *The teeth* (*fig.* 829.), which present themselves on the lower parts of the jaws, are the incisive and canine. The two front incisives are popularly called nippers or gatherers (*a*); the two next adjoining, separators or middle teeth (*b*); and the outer, the corners (*c*); but it would be more definite to say the first, second, and third incisives, beginning at the corner. The tusks or tushes (*d d*) occupy part of the intermediate space between the incisive and grinding teeth. The teeth, as criteria of age, will be considered in another place, and as organs of mastication, they will be further noticed in the anatomical detail.



6261. *The organs of the neck.* The exterior parts which compose the neck are first the upper surface, which is furnished throughout its whole extent with an elegant assemblage of hair called mane (*fig.* 828. *e e*). In some instances, as in stallions, it is of enormous length and thickness. In dark-coloured horses it is commonly black, but in horses of colours approaching to a light hue the reverse is frequently seen, and the mane and tail are in these often lighter than the body.

6262. *To make the hairs of the mane and tail lie smooth* is an object with most horsemen, but the pulling the hair out in tufts by wrapping it round the fingers is a most erroneous practice, and not only at the time frustrates the end intended, but a mane so pulled will seldom hang well after. The writer of this has always made use of a three-pronged angular mane-puller, which, if used two or three times a week, will bring both mane and tail into perfect order, and will keep them so. This iron is manufactured and sold by Long, veterinary instrument maker in Holborn, London.

6263. *The upper surface of the neck* (*i*) should form a moderate but elegant curve, which is greatly favourable to beauty: this curve is, however, not so considerable in the pure eastern variety as in the better sort of northern horse.

6264. *The under surface of the neck* (*k k*) should be nearly straight; in the cock-throttled horse it arches outwards, and the upper surface in these instances is sometimes hollowed inwards in equal proportions, when such horse is called ewe-necked. When this deformity is considerable, it prevents the head from being carried in its true angle, and particularly so under the action of the bridle; in which case the nose being projected forwards, carries the axis of the eyes upwards: such horses are called star-gazers; and it is to be observed that they are seldom safe-goers. In mares and geldings a very just criterion of a sluggish disposition, may be formed from the presence of a considerable quantity of flesh on the upper surface of the neck: when the crest is very thick and heavy, it is almost an unerring prognostic of a decided sluggard. In stallions it, however, forms a distinctive sexual mark, and therefore is less to be depended upon in them. In a well-proportioned horse, the length of the neck, the length of the head, and of the angle uniting the two, should give the height of the withers from the ground. When the neck is too long, the head must of course gravitate by the increased length of the arm of the balance; it likewise seldom presents a firm or proper resistance to the bridle. When, on the contrary, the neck is too short, the head is frequently ill placed, and the lever in the hand of the rider will be too short also.

6265. *The organs of the trunk or carcase* are various. Considered as a whole, Clark has not unaptly likened it, when separated from the limbs, to a boat; within which are disposed various important viscera. The bony ribs he likens to the wooden ones encompassing the vessel, and the sternum or breast-bone, being perpendicularly deep and thin, carries the resemblance further, and fits the machine to cleave the air as the boat does the water. Within this animal vessel, according with the justest mechanical principles, the weightiest of the viscera, the liver, is placed in the centre, and the others follow nearly in the relative order of their gravity; so that the lungs, the lightest of the whole, are stowed in front, where great weight would have been most disadvantageous.

6266. *The shoulders* (*a a, b b*) are commonly considered as extending from the withers above to the point in front, and to the line behind formed from the elbow upwards: but a correct description considers them as those parts immediately concerned in motion; that is, the scapula or blade-bone, and its attachments. The shoulders are too apt to be confounded with the withers above, and with the arm below, erroneously called the point of the shoulders. From this confusion, great error is committed in appreciating their nature and action; but this is removed by recourse to the skeleton (*fig.* 830. *i, k, l*). The withers (*e e*) may be justly proportioned at the same time that the shoulders may be narrow, straight, and altogether badly formed, and *vice versâ*. The shoulders should be muscular and narrow, but not heavy; and to determine between these essential points, requires the eye of experience in the viewer, and the presence of condition in the viewed. A muscular shoulder is essentially necessary, when we consider that the fore extremities are wholly connected by muscle, and not as in man, by the intervention of the bony union of the clavicle or collar bone. In the horse, therefore, we find that large muscular masses unite the shoulder blade, by its upper and inner surfaces, to the chest; while other powerful muscles suspend as it were the machine between them. By this contrivance, elasticity is preserved and strength gained; for had the shoulders possessed a bony connection, when the body is propelled forwards, its weight and force being received by the fore extremities, painful and hurtful shocks would have been experienced at every step. Powerful muscles for the shoulders are also as necessary for progression as for attachment. It is not therefore with judgment that a very thin meagre shoulder is commonly preferred. It is by the union of strength with just proportions, and a proper situation of the parts, that the value of the animal is determined.

6267. *The centre of action in the shoulders* (*c*) is in their common centre, and the extent of action of any part moving on its centre, is dependent on the length of such part; the motion the shoulder enjoys is confined to the perpendicular backwards, and to as great an elevation of the muscles as they will admit of forwards. It will be therefore evident that the more oblique is the situation of the shoulder blade, the greater number of degrees it can go through; it must be as evident also that when the shoulder blade is long and deep, as well as oblique, that this advantage is increased. It is commonly observed, although it is not invariably the case, that when the shoulder is short, it is also upright (*b b*). Obliquity and length in the shoulder favour the safety of the progression also: for as the angles formed between the shoulder, the arm, and fore-arm, are consentaneous, and make, when in action, a bony arch; so the obliquity and length of the shoulders is favourable to a due elevation of the limb, on which, in a great degree, depends the safety of progression. Thus mares are, *ceteris paribus*, more unsafe than horses, their shoulders being short to correspond with the low mare-like forehand; and their decreased obliquity usually regulates an increased obliquity in the whole limb downwards, or as is familiarly expressed, they stand with their legs under them. Unfavourable as is this form of the mare, both for the speed and safety of their action, it was given for advantageous purposes: for, by such a position in the fore extremities, the hinder are raised higher to afford additional security against the evils of gravitation and dislodgement of the foal from the pelvis. Few rules can be laid down in the exterior conformation that are more important, or of such general application, as that a short and upright shoulder, particularly when united with an

inclined direction of the whole limb backwards, is a sure mark of an unsafe goer, and commonly, though not invariably, of a slow one also. It now and then happens indeed, that horses having defective shoulders prove speedy and good movers, which would appear to contravene these principles; but it will be found, that, wherever horses having these defects in their fore legs yet prove quick and safe in progression, they invariably have hinder parts of great strength and proportion to make up the deficiency. Indeed, it appears probable, that the hind and fore parts do not bear the same relative proportion in all horses alike; in blood horses, the withers are not always high, and although their shoulders are commonly deep and oblique, yet the fore limbs are altogether short in proportion to the hinder, in a great number of the fleetest racers: for, as speed appears to be a principal end in their formation, and as comparative anatomy furnishes us with abundant proof that all animals destined to make considerable leaps (and the full gallop is nothing more than a succession of leaps) are low before, the end of their formation is really best answered by this arrangement of parts; it is also more than probable that, although speed in the gallop may be found with a defective forehand, yet, in the slower paces of the canter, trot, and walk, a justly formed shoulder is more immediately requisite. This subject will be still further elucidated when we treat on the mechanical properties of the skeleton.

6268. *The withers* (*e e*) are formed by the long transverse processes of the dorsal vertebræ (*fig.* 830. *y*), and as their use is to serve as levers to muscles, so their length characterised by the height of the withers must be of great advantage, and enable such horses to go high above their ground; for the muscles of the back, acting to greater advantage, elevate the fore parts more forcibly. From this we may also learn that the elevation of the fore parts, or the horse's going above his ground, as elevated action is expressed, is not altogether dependent on the motion of the shoulders, nor on the height to which the animal may be inclined to lift merely his legs; but likewise, on the extent to which the fore half of the machine is altogether elevated by the action of the dorsal and lumbar muscles. When the withers are high, or the forehand well up, as it is termed, it is favourable to the celerity and to the safety of the action; but as these properties are less wanting in the heavy breeds, we find in them a considerable variation of form: in the cart horse, weight of forehand is an essential requisite to his exertions; for drawing being an effort of the animal to preserve himself from the tendency which his weight gives him to the centre of gravity when he inclines forward, so the more weighty and bulky he is before, and the nearer he approximates this centre, the more advantageously he will apply his powers. It is not here intended to be hinted that nature gave him this form purposely to enable him to draw: this, indeed, would be an argument of necessity; but this form has been judiciously imposed on him by men, by regulation of the sexual intercourse, and by a careful selection of specimens having some of the requisites to propagate from, until at last we have produced the massive weighty animal whose powers astonish as well as benefit us.

6269. *The breast or counter* (*f f*) is the part between the point of the arms or shoulders, and which should be moderately wide and extended: when it is otherwise, the horse is seldom durable, or even strong, although he may be speedy; neither have the lungs sufficient room for expansion, nor the muscles great extent of attachment; frequently too it accompanies a general flatness of ribs, and want of circular form in the carcase in general; all which experience has shown to be necessary to the perfection of the machine. The breast may, however, be too wide; it may also hang over or project beyond the perpendicular of the fore limbs, so as to overweigh the machine: this form, however, though unfavourable to the saddle horse, for the reasons just assigned, is much desired in the heavy draught horse.

6270. *The back.* Where the withers end the back commences (*g*); the length should be moderate only, for a long cylinder cannot be so strong as one of less length; long-backed horses are easy because the action and the reaction are considerable; but what is gained in elasticity is lost in strength. When the back is too short, the extremities are so much approximated that they frequently overreach each other, and the hind foot strikes that before it, in progression: the back should be nearly straight, it has naturally an inclination in the line of its gravity; but this exists in very different degrees in different horses. When the incurvation inwards is considerable, such horses are called saddle-backed, and are usually considered weak; but, to keep up the counterpoise, the crest in such horses is generally good; they also ride pleasantly, and commonly carry much apparent carcass; sometimes indeed too much. When the back is curved upwards, it is called roach-backed; when considerably so, it is unfavourable to the liberty of action, as well as to the elasticity of motion: in these cases, to counteract the curve outward, the head is also usually carried low. A short-backed horse is in considerable request with many persons, who do not consider that when it is too much so there is seldom great speed; for the hinder extremities cannot be brought sufficiently under the body to propel the mass forwards.

6271. *The loins* (*h*) may be considered as the part which extends from immediately behind the hinder edge of the saddle, when properly placed, to the rump. Anatomically it begins at the sacrum (*fig.* 830. *z*), whose processes being sometimes defective or interrupted, leave an indentation, as though the union between the back and loins were incomplete; and such horses are said to be badly loined: but although it may in some measure deprive the muscles of some slight attachments, yet the evil is not so considerable as is imagined. The width of the loins is of considerable import to the strength of the animal, as it affords a greater surface for the attachment of the powerful muscles of the back and loins; and the muscles themselves should be so prominent, as to seem to swallow the back-bone amongst them. When the protuberances of the ilium or haunch bone are very prominent, the horse is said to be ragged hipped; but it operates to his disadvantage only in appearance, as extent in these parts, being favourable to muscular attachment, is always beneficial.

6272. *The croup* extends from the loins to the setting on of the tail (*n n*). It should be long and only slightly rounded, which is another characteristic of the blood or improved breed. In the cart horse, on the contrary, it is seen short and much more considerably rounded (*n n*). A long croup is in every point of view the most perfect, for it affords a very increased surface for muscular attachment, and although the large buttocks of the cart horse would at first sight convey an idea of great strength and extent, yet, attentively viewed, it will be found that the early rounding of the sacral line, the low setting on of the tail, and the small space which necessarily exists between the hips and buttocks, all tend to lessen the surface of muscular attachment, compared with the broad croup, wide haunches, and deep spread thighs of the blood horse.

6273. *The flank* (*k*), is the space contained between the ribs and haunches; when too extensive it indicates weakness, because it is the consequence of too long a back; and such a horse is said not to be well ribbed up. When the transverse processes of the lumbar vertebræ are short, as in badly loined horses, this part is hollow. The flank is usually looked to also as indicative of the state of respiration: thus, when it rises and falls quicker than ordinary, unless violent exertion has just been used, it betokens present fever, or otherwise, chronic disease of the lungs.

6274. *The belly* (*i*). Having taken a tour round the upper parts of the carcase, we will carry the survey downwards and forwards. Anteriorly, the *ribs* should be wide upwards, and as much deepened below as possible, which affords what is termed great depth in the girth. This form greatly increases the surface of attachment of the motive organs, the muscles, and also allows room for the free expansion of the lungs, and consequently is favourable to the wind. Posteriorly, the ribs should form the body as much as possible into a circular figure, that being of all others the most extended, and affording the best surface for the absorption of nutriment; thus barrelled horses, as they are termed, are greatly esteemed, and found to be lasting in work and readily brought into condition, and more easily kept so. When the chest is too flat and straight, the belly is also small: hence, neither can the blood absorb its vital principle from the air, nor the lacteals the chyliferous juices from the intestines; these horses are therefore seldom durable. As less nutriment is taken up by the constitution, so less is eaten, thus also they are seldom good feeders;

and as the pressure on the intestines must be considerable from the small containing surface, so they are usually likewise what is termed washy; that is, easily purged, whereby an additional cause of weakness exists, from the too early passing off of the food. Such horses are, however, very commonly spirited and lively, although not lasting. A knowledge of the advantages gained by a circular form of carcass or belly, as affording the greatest capacity, is what constituted Bakewell's grand secret in the breeding of cattle: he always bred from such animals as would be most likely to produce this form, well knowing that no other would fatten so advantageously.

6275. *The whirlbone* (*l*), among the jockeys and grooms, is the articulation of the thigh bone, with the pelvis, or basin, and forms the hip joint. The ligaments of this powerful joint are sometimes forcibly distended by violence, and a very obstinate lameness is usually the consequence. The situation of the thigh (*l*, *m*) is in the horse, as in most quadrupeds, enveloped within the range of the trunk.

6276. *The stifle* (*m*) corresponds with the knee of the human figure, and is the point at the lower portion of the flank. It is evident that the part below this, which is generally called the thigh or gascoin, is erroneously so named. It should be very muscular and extended; it should also make a considerable angle with the femur or thigh, and form a direct line under the hip or haunch. Its length in all animals destined for speed is considerable.

6277. *The fore extremities or legs.* In treating of the mechanical properties of the skeleton, we shall have to point out the essential differences between the geometrical structure and functions of the fore and hinder extremities. We shall here content ourselves with a simple examination of the individual parts.

6278. *The arm of the horse* (*b*) is apt to be overlooked, nor, without some consideration, does it strike the observer, that the arm covered with muscles, and enveloped within the common skin of the chest, extends from the elbow (*a*) to the point of the shoulder, as it is termed, but correctly to its own point below and before the shoulder blade. (*fig.* 830.) The same reasons which render a muscular, oblique, and deep shoulder advantageous, also make it desirable that this part should be muscular and extensive in length and breadth, and that its obliquity should be proportionate to that of the shoulder: whence it results, that the more acute the angle between them, the greater will be the extent of the motion gained by the flexion and extension of the parts.

6279. *The fore arm* (*c*), which horsemen consider and call the arm, is placed upright to counteract the angular position of the real arm and shoulder bones. As it is always found long in animals destined for great speed, as we witness in the hare and greyhound, it should therefore be also of considerable length in the horse, when speed is a requisite quality; but for the cadences of the manege, where the elasticity is required to be distributed equally through all parts of the limb, it is chosen short. The fore-arm is broad and large, particularly upwards, for here the powerful muscles that operate the motions of the parts below, are almost all of them situated. To prevent incumbrance, and to give solidity, these muscles degenerate into tendons and ligaments below the fore-arm; but above, it is essentially necessary to strength that they should be large and well marked.

6280. *The knee* (*d*), so called, is properly, with reference to human anatomy, the carpus or wrist. It is composed of many bones to enable it to resist the jar arising from the action of the perpendicular parts above and below it. All the joints of the extremities, but particularly those of the knee and hock, should be broad, that the surface of contact may be increased, and the stability augmented; by this means, likewise, a more extensive attachment is afforded to muscles and ligaments; their insertions are also thereby removed farther from the centre of motion.

6281. *As criteria of safe going, the knees should be particularly examined* when it is contemplated to purchase a horse, to see whether the skin has been broken by falls; and in this, very minute attention is required; for sometimes the wound heals so perfectly, or otherwise so much art is used in shaving the hair, blistering, colouring, and rubbing it down, picking out the white or staring hairs, &c., that more than common nicety is required to detect a slight scar. It is, however, prudent to remember, that it is not every horse whose knees betray a scar, that is a stumbler: the best may have a fall in the dark. It is also necessary to caution persons against the admission of a very common prejudice, that when a horse has once been down, however little he may have hurt his knees, he is rendered more liable than before to a similar accident. If his limbs have not been weakened by the accident, or if the cicatrix be not sufficiently large to prevent the free bending of the knee, he is not at all more liable to fall than another horse. If, therefore, a horse with a scar on his knee have the forehand good, and if his action correspond thereto, he ought not to be refused on this ground: but with a different conformation he ought to be steadily rejected, let the tale told be ever so plausible. In gross heavy horses a scabby eruption often seats itself around the inner bend of the knee (*h*), which is called mallenders.

6282. *The canon or shank* (*e*) carries the limb down elegant, light, straight, and strong. Much stress is deservedly laid on the necessity that this part of the limb should be wide when viewed laterally. Viewed in front, its being thin is favourable, because made up as it is principally of bone and tendon, any addition to it beyond these must arise from useless cellular matter, or otherwise from matter worse than useless, being placed there by disease. Any thickening of the part generally or partially, should be looked on with suspicion; as, if natural, likely to interfere with motion without adding to strength; or if accidental, as a mark of acquired injury likely to remain. In the bony skeleton may be seen within and behind the knee an apparatus destined to remove the acting ligaments and tendons from the centre of motion, by which great advantage is gained in strengthening and facilitating their flexions. It is a default in this conformation that renders horses *tied in under the knee*, as it is usually termed. The limb below the knee, instead of proceeding downwards of a uniform width, is seen suddenly narrowing immediately as it leaves the knee. Such horses are invariably found to bear exertion badly; their legs at an early period become bowed or arched, and totter on the slightest exertion. In cart horses this conformation is very common; but in them it is of less consequence than in those destined for quicker motion, where the elevation of the limb is so extensively and so frequently repeated. To render this subject familiarly clear, we will recommend that a cord be placed round the ball of the thumb, and passed up close to the arm until it reaches the bend: with the other hand, by straightening and extending this cord, but held close to the arm, endeavour to flex the hand and wrist inwards: operated in this way it will require great force to do it; but remove the hand only two inches from the arm, and the bound hand will yield readily to a less force. Exactly the same happens to the ligaments and tendons called back sinews which flex or bend the fore legs; for by an apparatus, formed from the position of one of the carpal bones (*pisiformis*), they are, in well formed legs, set out wide from the knee.

6283. *The back sinews* should not only be large and firm, but they should, like the limb generally, be very distinct from the knee to the fetlock: in this course, if any thickening be observed, it betokens former injury, as extension or rupture of ligamentous fibres, which usually have a disposition to recurring weakness. If a hard swelling appear on the inner side, not on the tendon, but on the bone, a splint is present which is more or less injurious as it is nearer or farther from the knee, or distinct from or situated among the tendons and ligaments; but when it is considerable in size, hot to the feel, and extends inwards and backwards among them, it usually produces most injurious consequences. To detect these evils the eye alone should not be trusted, particularly where there is much hair on the legs, as on cart horses, and even on hackneys in the winter, but the hand should be deliberately passed down the shank before and behind. An enlargement or scar situated close to and on the inner side of the knee, must not be mistaken for a splint; it more frequently arises from a custom some horses have when trotting fast, of elevating their feet and cutting this part with their shoes, and it is thence called the *speedy cut.*

6284. *The pastern and fetlock* (*f f*). General usage has applied the term fetlock to the joint itself, and pastern to the part extending from the fetlock to the oot; properly speaking, the fetlock or footlock is only the posterior part of the joint, whence grows the lock or portion of hair, which, in many horses, flows over and around the hinder part of the foot; a short and upright pastern is inelastic, and such horses are uneasy goers; they are unsafe also, for the pastern being already in so upright a position, requires but little resistance, or only a slight shock, to bring it forwards beyond the perpendicular; and the weight of the machine then forces the animal over. Nor are these the only evils arising from this formation, for the ends of the bones being opposed to each other in nearly a perpendicular direction, receive at each movement a jar or shock, which leads to an early derangement of the joint, and to the appearance called overshot. On the contrary, when the pasterns are too long they are frequently too oblique also; and although their elasticity may he pleasant to the rider, such formation detracts from the strength of the limb. These joints both before and behind are very subject to what is called windgalls, which are swellings formerly supposed full of air, whence their name; but they are now known to contain an increased quantity of the mucus destined to lubricate the parts in their motions. These puffy elastic tumours are originally small and hidden between the lower end of the canon and the flexor tendon, or back sinew; but when hard work has inflamed all the parts, the secretion within increases, and then they become visible to the eye; but unless they are so considerable as to obstruct the due action of the parts, they are no otherwise objectionable than as they tell a tale of inordinate wear of the limbs generally.

6285. *The form of the pasterns influences the defect called cutting*, which arises from a blow given to either the fore or hind fetlocks by one leg to the other during its elevation. Horses narrow in the chest, or which turn their toes out, or have other peculiarities of form, cut permanently, and are then very objectionable; but others only cut when fatigued, or when very low in flesh. Horses often cut when young, who leavc it off when furnished, and of mature growth.

6286. *The feet* (*g g*). These essential and complex organs will be more fully examined in the anatomical detail, but much also presents itsèlf to the consideration in an exterior examination. Horses might be presumed to be naturally born with perfect feet; but experience shows that defects in these organs are hereditary. In some, the peculiarities of climate operate; and in others, a constitutional predisposition exists; dependent on some cause with which we are unacquainted.

6287. *Climate influences the form of the horse's foot.* In the arid plains of the east, where every impediment to an extensive search for food is removed, the feet are hard, dry, and small; this form, notwithstanding the alterations of breed and culture, in some degree still adheres to the blood or aboriginal eastern horse: artificial habits have extended the evil, and now small and contracted feet are to be seen in every variety, except in the coarse heavy breeds.

6288. *Constitutional and hereditary causes operate on the feet.* That a constitutional predisposition exists in the production of a particular form of foot, we know from the fact, that dark chesnut horses are more prone to contraction of the hoofs than any other coloured horse; and that the form of the foot is hereditary, may be gained from the known circumstance that some of the Lincolnshire stallions always get large flat-footed progeny; while some full bred entire horses entail small upright feet on all their offspring.

6289. *Local situation will also affect the form of the feet.* The effect of situation is remarkably exemplified in the horses which we used to obtain from Lincolnshire, Cambridgeshire, and some parts of Norfolk and Yorkshire, before the draining system was perfected. These horses had, almost invariably, large, flat, heavy feet; which, however convenient and natural they might prove to the animals while moving on the quaggy surface of marshy districts, yet were found very unfit for quick light movements in drier situations. Such horses go heavily and stumble: and as the horn of which these enormous feet are formed is always weak, the anterior or front part yields to the heat and inflammation brought on by exercise on hard roads, and falls inwards, which letting the weight of the body fall on the soles pushes that downward; and at last from a concave, it presents a convex surface. The feet cannot then bear shoeing, but with much art and difficulty: pain and tenderness bring on lameness and uselessness; and therefore horses with such feet should be rejected. Feet preternaturally small are equally objectionable, as betokening a disposition to contraction. Horses with a tendency to foundered feet stand with pain in the stable, first placing one foot before, and then shifting it to place the other in the same situation. The contraction usually begins in the heels, which are found higher than natural, and drawn inwards; the foot altogether is likewise narrower, and the solc hard and hollow. When a preternatural fulness is seen around the coronets, *ring-bone* may be suspected; and if heat and hardness be accompanied with any tenderness in going, its existence is certain. But although too much horn is to be avoided, too little produces a weak foot; in which the heels, quarters, and soles all participate: the thin horn cannot resist the impressions of the stones on the road, and then lameness ensues. The under surface of the foot should exhibit a full, healthy, wide frog, with bars prominent and properly inflected. The concavity of the sole should be particularly attended to; when less than natural, it is weak, when more, it indicates contraction; whence such feet have been called too strong. White feet are objectionable, because they are found more liable to this evil than others. *Corns* are an evil to which the under surface of the foot is liable, and which should always be looked for on the purchase or examination of a horse; for which purpose, it would be well that the fore shoes should be removed, and the foot carefully pared by a judicious and clever smith. Merely picking out the foot will often, also, detect the remains of former cuttings or parings out of the corns. Some hoofs are very brittle, and a horsc with this defect should, in every instance, be rejected. The evil may in general be easily detected by the marks of the fragile parts detaching themselves from every old nail-hole. This kind of foot, particularly in hot weather, breaks away till there is no room for the nails to hold; when the horse of course becomes useless. *Sandcracks* are also another evil to which the feet are liable; and which should engage the attention in the examination of a horse: they consist of longitudinal fissures; one only is usually present at once; but that one if deep is fully equal to produce lameness. The subject of the feet will be concluded by an observation on their general appearance, well worthy of attention. The eye should be directed to the degree and to the manner in which the shoes are worn; which will often save much useless trouble in trying a horse. A stumbling horse may be frequently, nay commonly, detected by simply lifting up one fore foot: for the unequal wearing away of the shoe at the toe, while the other parts remain good, is a full proof of his going unsafely and *digging his toes.*

6290. *On a review of the conformation of the fore extremities*, it may be remarked, that whereas the hinder may be considered as more particularly concerned in impelling the machine forwards with its requisite velocity; yet, that upon a proper form and a true direction of the various component parts of the fore limbs must depend the stability, the truth, and the safety of the movements. Viewed anteriorly, the fore legs should stand rather widest at the upper part, inclining a little inwards below; but when we view them latterly, they should present a perpendicular from the arm downwards; and the toe should place itself directly under the point of the shoulder, as it is called. If the foot should stand beyond this, which is seldom the case, the action will be confined, for the limb will have already passed over a point of its ground; such a horse, however, generally treads even, flat, and safe; and, in proportion as it stands in the direct line downwards, he generally inherits these desirable properties. When the foot stands behind the perpendicular line the defect is considerable, by the removal of the centre of gravity too much forward, by which an increased tendency to stumble and fall is entailed; and as this in general accompanies a want of extent and obliquity in the shoulder, so it likewise lessens the speed.

6291. *The hinder extremities.* We have already described the thigh, correctly so

called, which is so concealed by muscles as frequently to escape this consideration of it, by which the part immediately below it popularly receives the name of thigh, but which is, in fact, the leg.

6292. *The leg* (1, 2), commonly called *the thigh*, in well formed horses is powerfully furnished with muscles, and very extended in its figure; it should also make a considerable angle with the femur or real thigh, and form a direct line under the hip or haunch; for the same reasons that make it desirable to have a long arm in the fore extremities, it is also advantageous that the leg should be so likewise, and this is the form usual among all quadrupeds of speed.

6293. *The hock* (2) is the important joint immediately below the leg, or thigh commonly so called, and is interposed between the tibia and tarsal bones (*fig.* 830.), purposely to increase the extent of attachment, and to break the shock of great exertion; it may be considered as the most complex and important joint of the body: like the knee, it should be extended and broad; for, in proportion as the calcaneum or point of the hock (5), and which is the real heel, extends itself beyond the other bones, so the powerful tendo Achilles inserted into it, acts with a longer lever, and with a greater increase of power. This joint is subject to several important diseases, which, in the examination of a horse, require particular attention; when a soft puffy swelling is discovered in the ply or bend of the hock (3), it is termed a *blood spavin*, which will be noticed among the diseases; it is, in fact, a similar enlargement with the windgalls before mentioned, and what has been said on them equally applies to these. When similar mucous capsules become enlarged on each side of the hock, the enlargement receives the name of *thorough-pin*. A small bursal enlargement is sometimes found at the very point of the hock (5), and is then called a capulet; to all which what has been said on windgalls applies, that they are only to be deemed of consequence when so large as to interfere with the motion of the parts they are situated with or near; or, as indicative of an undue portion of work. The ligaments at the back of the hock sometimes become strained or extended, and heat, inflammation, and swelling follow, which is then called a *curb*. As rest or very mild treatment soon reduces it, it is not to be considered as of great consequence. The inner part of the joint at the ply or bend, is sometimes attended with a skin affection similar to the mallenders before alluded to, and is called *sellenders* (4); but the most serious disease to which the hock is liable, is a disease of the ligaments of some of the tarsal bones. Sometimes one or more of these bones, or the ligaments which unite them, inflame, and an exostosis or *splint* is formed: to detect the existence of this affection, the hocks should be attentively viewed from behind, when any enlargement in the spavin place (3, 4) may be easily detected. The mechanism of this joint will be further considered when we treat of the skeleton generally.

6294. *The colour of horses* does not depend on their real skin, as with man, but upon an exterior beautiful covering which nature has given them, called *hair*; nevertheless, the hair is, in some measure, influenced by the skin, as light-skinned horses have light hair, and when the hair is light, the eyes are usually so likewise: hair presents many varieties of tint, so horses are said to be of various colours. Buffon has conjectured that horses were originally of one colour, which he presumes to be bay; but such wild horses as have been seen, and which have been supposed to be pure originals, have not justified this opinion. This same author has divided the colours of the horse into simple, compound, and strange or extraordinary.

6295. *The simple colours* are bay, chestnut, dun, sorrel, white, and black; *bay* is a very prevailing tint among European horses, and admits of many shades, but is admired in all: there are bright bays, blood bays, dark and dappled bays; *brown bay* is a very esteemed colour, and consists of bay and black in unequal proportions in different horses: *brown* horses are highly prized; the darker varieties have usually beautiful tan markings, as about the muzzle, &c.: they have commonly also black manes and tails, with legs and feet of the same hue; and it may be here remarked, that horses of compounded colours, of whatsoever tint the mane and tail may be, will be found invariably formed of one of the compounding colours; thus light greys, which are a compound of black and white, have often white manes and tails: sorrels, again, which are formed of white, with a small proportion of red, have also frequently white manes and tails: *chestnut*, which is also a very common colour, admits of almost as many shades as the bay, from the lightest tint to the deepest tone. Very light chestnuts have frequently still lighter manes and tails, with mealy legs and light feet; so marked, they are certainly not to be chosen for strength, durability, or pliancy of temper: the Suffolk punch, however, may be considered in some degree an exception, although the true breed is hardly so light as those hinted at here. Dark chestnuts are considered, and with justice, as fiery in their dispositions; they are also more subject to contracted feet than horses of any other hue. *Dun* is a colour that has several varieties; it is sometimes accompanied with a white mane and tail, at others they are seen even darker than the rest of the hair. In some, a list or line of deeper tint extends along the back, which is regarded by some as an indication of hardihood: a similar line is sometimes seen in the bay. Dun horses do not appear to be at all influenced in their qualities by their colour, or rather no criteria are offered by it, for there are good, bad, and indifferent in all the varieties of shade. The *sorrel* is a variety of the chestnut, but not a favourite one. *White* as a native colour is not in much estimation, neither is it very common, for many horses are white only through age, as all light-grey and flea-bitten horses become so. *Black* is a very usual colour, and in the large heavy northern breed it seems to be an original tint; and perhaps it is to this their goodness may be attributed, for, among the lighter breeds, there are more indifferent black horses than of any other colour. The tempers of black horses are commonly in the extreme, either sluggish to stupidity, or fiery to excess. The colour itself admits of many shades; but a perfect black horse is more unusual than it is generally thought to be: a star on the forehead is common to relieve the ebon hue; and in the absence of that, a few white hairs on the breast frequently interrupts the uniformity. It is, perhaps, on this principle that black horses have white legs so often as they do.

6296. *The compound colours* may be considered as those in which the hairs are compounded, but not the colours themselves; otherwise the bay, the chestnut, brown, &c. might be considered as compounded colours. The *roan* is a mixture of red and white: its varieties are the common, the red, and the dark. All the roans are esteemed. *Grey* admits of a great number of shades and varieties, but all are compounded of black and white, except the iron grey, which receives a few bay hairs among the black and white; a considerable prejudice exists in favour of this colour. Greys are light or dark; there are also the dappled, the markings of which are extremely beautiful, and the silver grey. Grey horses become lighter by age: many old white horses have been grey until age overtook them. Grey horses, like black, admit of no settled character; though, unlike them, they are not to be generally disapproved of. They have, however, all the extremes within their range; the darker ones are usually good, the lighter ones not generally so.

6297. *The extraordinary colours* are not very numerous, and it may be remarked, that white is always the relieving tint, intermixed with distinct markings, in various proportions, of bay, brown, black, or chestnut. *Flea-bitten* is grey or white, with small bay spots. When these spots are very large, and have a marginal surface of lighter markings, they give the name *tiger coloured*; and although they are uncommon with us, they are not unfrequent in Germany and Barbary. Pied or pie-bald is one of the most numerous extraordinary colours, and is usually composed of two colours, in distinct large markings,

Now and then a third interferes: there are pies of all original colours with white, and all are held in estimation.

6298. *Colour, as a criterion of mental and personal qualities*, is laid much stress on by many persons, and long experience has shown that certain tints are usually accompanied by certain qualities of person or disposition. As a general rule, dark-coloured horses are certainly the best; but, as before observed, it is peculiar that black, as the darkest of all, should form an exception to this rule. Light shades appear unfavourable to strength and durability; they are also accompanied frequently with irritability and perverseness of temper. Something like a general law in the animal economy seems to prevail, to make white a distinctive mark of weakness. Age, which is the parent of weakness, brings with it white hairs, both in man and in horses, and most other quadrupeds. The hair formed after a wound has robbed a part of its original covering is often white, because the new formed surface is yet in a state of debility. It is likewise a fact well known among the observant, that the legs and feet when white are more obnoxious to disease than those of a darker tone. The Arabs remarks, that light chestnut horses have soft tender feet. It is the observance of these peculiarities that has at length guided our taste, and formed our judgment of beauty. With us much white on the legs is considered as a deformity, and is expressively called *foul marked*, whereas pied markings in other parts are reckoned beautiful. In Africa, however, Captain Lyon informs us a superstitious dependence is placed on horses with legs and feet stockinged with white. It does not appear that climate has the same influence on the colour of horses as on that of other domesticated animals. In all latitudes in which the horse can live, he is black or white indiscriminately; but as he cannot endure extreme rigour, it is not necessary that he should vary.

Sect. III. *The Bony Anatomy or Osseous Structure of the Horse.*

6299. *All quadrupeds* are formed on an earthy base called bone, and the assemblage of bony parts is called a skeleton. Bones are formed of earth and membrane (1881.); they are covered also by an investure called periosteum. The earthy part is the last formed, and consolidates the bones as the animal becomes fitted to exert all his powers. This deposit of earth in the bones appears to be hastened by any thing that permanently quickens the circulation: heat does this, and hence the human and brute inhabitants of warm climates come to perfection sooner than those of northern regions; but they are generally smaller, for by preternaturally hastening the earthy deposit before the membranous part of the bones becomes fully evolved or grown, they do not attain the bulk they would be otherwise capable of. Undue exertion has the same effect; and thus we learn why horses too early and too hard worked become stinted in their growth. Pressure likewise occasions an early, and also a preternatural ossification: in this way the parts of the spine which bear heavy loads present large masses of bone, brought on by this cause alone. For the same reasons, horses early worked put out splints, spavins, and other bony concretions. Bones are all of them more or less hollow: within their caverns an oily fluid is secreted, called medulla or marrow, which serves for their support, and that of the constitution generally. The bones have nerves, blood-vessels, and absorbents. Bones are capable of reproduction, as proved by their uniting when broken; and also by the yearly renewal of the antlers of the deer, which are not horn as in the ox or sheep, but pure bone. Bones are connected together by *articulation:* when such articulation is moveable, it is termed a joint. In some cases bones articulate by suture or indentation of parts, as in the skull. We shall consider, in succession, the anatomy of the head, trunk, and extremities.

Subsect. 1. *Osseous Structure of the Head.*

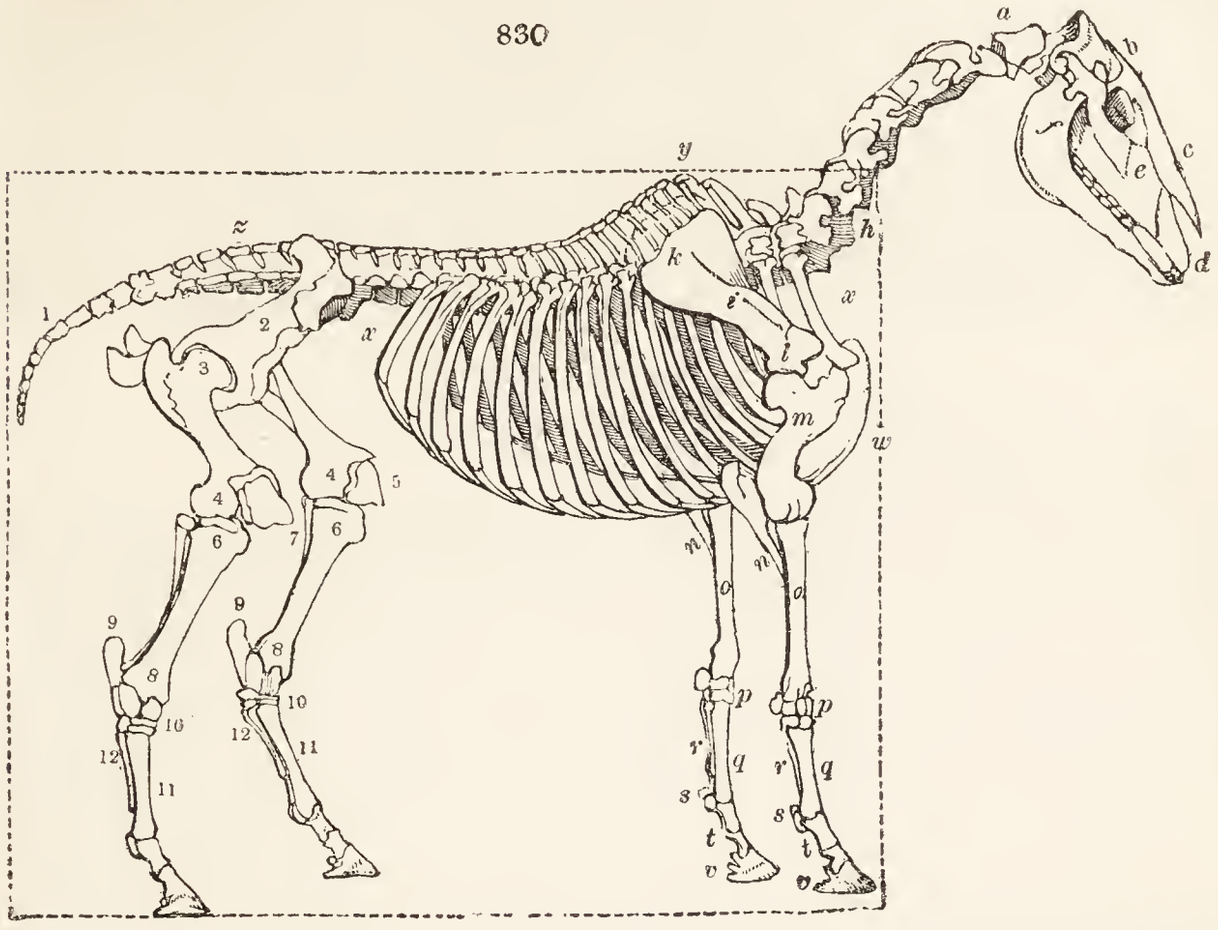
6300. *The bones of the head* are as follows. The *occipital* (*fig.* 830. between *a* & *b*), which is the largest bone of the skull, in the colt is composed of several pieces which unite by age; it articulates with the atlas (*a*) or first of the cervical or neck vertebræ. At its posterior surface it is perforated by a large hole, which gives passage to the spinal marrow. The two *frontal* bones (*b*) unite also by age; and behind them is lodged the anterior and inferior portion of the brain. A division of their bony surfaces forms two cavities called the frontal sinuses, which are lined by the nasal membrane throughout. The sagittal sature unites these two bones. The remainder of the bones of the skull are the *two parietals*, the *two temporals*, divided into a squamous and petrous portion, within the latter of which is situated the internal ear; and to the former the posterior or lower jaw articulates. The *sphenoid* and *ethmoid* bones are hollow and irregular, serving to intersect and attach the others; and also to assist by their cavities in extending the pituitary or smelling membrane.

6301. *The bones of the face* are ten pairs and two single bones. The *nasal* (*c*) pair, within their union, hold the séptum nàrium or long cartilaginous plate which separates one nostril from the other. These bones also greatly assist to extend the surface of the smelling organ. In the old heavy breeds, it was very common to see these bones arched outwards; but in the improved breed, particularly in those approaching full blood, it is not uncommon to find them slightly curved inward. The fossæ within these bones are the principal seat of glanders. The two *angulars* form a considerable portion of the orbits of the eyes. The two *malar*, *jugal*, or *cheek* bones occupy also a portion of the orbits. The *superior maxillary* bones (*e*) are the largest of the face bones, and contain all the upper molar teeth. The *inferior* or *intermaxillary* bones (*d*) are wanting in man, in whom the face is short: these bones concur with the former in forming alveoli or sockets for lodging the teeth. The *superior palatines*, the *inferior palatines*, the *pterygoids*, the two *anterior*, and the two *posterior turbinated* bones, with the *vomer* or *ploughshare*, make up the remaining facial bones, with the exception of the *posterior* maxillary or *lower jaw* bone (*f*), which on its anterior edge is pierced to lodge the teeth; at the upper part it extends itself into two angular branches, each of which ends in two processes and an intermediate groove. The superior of these processes articulates with the upper jaw. This bone throughout shows the most admirable mechanism; the molar or grinding teeth, on which most is dependent, and whose exertions are greatest, are placed near the centre of motion: and as the upper jaw in most animals is fixed, or nearly so, it was necessary that the lower should have considerable extent of motion for the purpose of grinding; and it is accordingly so formed as to admit of motion in every direction. The *os hyoìdes* is a bone situated within the head at the root of the tongue, to which it serves as a support, and for the attachment of muscles.

6302. *The teeth* of the horse are the hardest and most compact bones of the body. There are usually forty of them in the horse, and there are thirty-six in the mare; in which latter the tushes are usually wanting. In anatomical language, they are divided into *incisòres cuspidàti*, and *molàres*, or according to the language of farriers and horsemen, into twelve *nippers* (*fig.* 829. *a*, *b*, *c*), four *tushes* (*d d*), and

twenty-four *grinders*, which numbers are equally divided between the two jaws. The teeth are inserted into indentations or sockets between the bony plates of the jaw, called alveoli, by cone-like roots. The bodies of the teeth are principally composed of two substances, one of the nature of common bone, giving bulk and form, and one of extreme hardness, called enamel, placed in man and carnivorous animals wholly

830



without the teeth, to give strength and durability; but in the horse and other Granívora, the latter particularly, it is placed in the grinders, in perpendicular plates, within the body of the teeth; by which contrivance, a rough grinding surface is kept up; for the mere bony parts wearing faster than the lamellæ of enamel, it follows that ridges remain to triturate the vegetable matter that passes between the teeth.

6303. *There are two sets of teeth*, a temporaneous or milk set, and a permanent or adult set, in which wise provision man and most brutes participate. The milk set are some of them, as the molars, apparent at birth; there being usually six grinders in each jaw, three on each side in the new-born foal, and which number of this set is never increased. The nippers begin to appear soon after birth, and follow a regular order of succession until the animal is three or four months old; at which time he begins to require support from herbage as well as milk. The temporaneous set remove gradually one after another; had they all been displaced at the same time, or even had several of them fallen out together, the animal must have suffered great inconvenience, and perhaps have been starved. This removal, which commences at the age of two years and a half, and is completed between the fourth and fifth year, is effected by the action of the absorbents on their fangs, and appears to be occasioned by the stimulus of the pressure received from the growing teeth under them. For although these two sets appear with an interval of some years between them; yet the rudiments of both are formed at nearly the same period, and both sets may be thus seen in a dissected jaw. Regulated by the stimulus of necessity, as soon as the temporaneous set falls out, the permanent appears: and that such appearance follows the necessity is evident; for a premature or accidental removal of the colt's teeth is soon followed by the appearance of the others. Dealers and breeders, aware of this, draw the milk teeth to make their colts appear as horses. It was necessary there should be two sets of teeth; for, as they grow slowly in proportion to the jaws, had there been but one only, the disproportion of growth between the teeth and jaws must have separated them.

6304. *The forms of the teeth* vary more than their structure. The incisive or nippers are round, which is favourable for the pressure they undergo; the upper more so than the lower. On the upper surface a hollow is seen in the young tooth, which, not extending through the whole substance, naturally wears out with the wear of the tooth; and as a considerable degree of regularity occurs in this wearing away in all horses, it has gradually settled into the general criterion of age. The nippers are not all of them exactly similar; the corner teeth differ most in being nearly triangular, and in having an internal wall or side, which does not become level with the rest until long after those of the others. The cuspidate tusks or tushes are permanent, appearing at about five years or rather earlier; those in the front jaw are usually nearer the nippers than those below. Each presents a slight curve, which follows the direction of all the canine or pugnatory teeth of other Mammàlia. The pointed extremity wears away by age, leaving merely a buttoned process, which may serve as a guide to the age when a horse is suspected to be Bishoped, as it is called, from a man of that name who was peculiarly dexterous in imitating on old teeth the distinctive cavity of youth. The molar or grinding teeth are stronger in the upper than in the lower jaw; which was necessary, as they form the fixed point in the process of grinding. The upper surface presents nearly a long square, indented from the alteration of the enamel with the bony portions; and as the interior or upper teeth hang over the posterior, so the ridges of the one set are received into the depressions of the other.

6305. *Wear of the teeth.* The teeth, in a state of nature, would probably present a surface opposed to each other for mastication, to the latest period of the most protracted life; but the removal of the animal from moist food to that which is hard and dry, must occasion an unnatural wear in those organs; and hence, although the teeth of the horse, even in a domesticated state, are not subject to the caries of the human; yet the grinders are liable to become thus injured by continued exertion. In the young or adult horse, the upper and under grinders do not meet each other horizontally; on the contrary, they have naturally an inclination obliquely inwards; and those of the upper jaw present small spaces between each other, while those of the lower are more continuous; by which means, as the food, particularly its interrupted portions, as grain, becomes ground, it falls within the mouth to be replaced under the grinding sur-

face, if necessary, by the joint action of the tongue and muscles of the cheek. This arrangement becomes in a great measure frustrated in old horses, by the superior wear of the inner surface of the upper grinders, as well as by the general misapplication of the surfaces of both upper and under teeth, by constant attrition, when worn down nearly to the gums. The unfortunate animal feels sensible of this, and endeavours to remedy it by throwing the wear on the outer edge, by an inclination of the lower jaw and of the head in general; and which is so particular in its appearance as to engage the attention of the by-standers. This defect may be in a considerable degree remedied by casting the animal, and having opened and wedged the mouth so as to keep it so, removing the inequalities with a well tempered concave file, as much as may be. When the defect is considerable, and the horse is mild and quiet, it is better to file the inequalities every day, which will gradually but effectually wear them down. It however happens, that the inclination thus to wear is commonly resumed, and gradually the same loss of nutriment takes place: in which case, soft moist food, as carrots, mashes, soiling, or grazing, must be substituted for harder substances, and if corn be actually necessary, let it be bruised. Whenever an old horse betrays symptoms of want of condition, or weakness, and emaciation, that neither his mode of feeding, nor his ratio of work will account for, and particularly if whole grains should be found in his dung, his teeth should be examined carefully. This undue wearing of the teeth occasions another evil often, which is ulceration of the cheeks, by reason of the projecting ragged surface of the uneven teeth, which can only be remedied by the removal of such portions. These projecting portions are called by farriers *wolves' teeth.*

Subsect. 2. *Bony Anatomy of the Trunk.*

6306. *The trunk of the skeleton* consists of the spine, the pelvis, and the thorax or chest, composed of the ribs and sternum.

6307. *The bony column called the spine* is made up of seven cervical, eighteen dorsal, six lumbar, and five sacral vértebræ, with the addition of thirteen or fourteen small tail-bones. The spinal bones are thus divided on account of the varieties they present; they have, however, some characteristics in common. Each is composed of a spongy bony body, with protruded points called processes, which processes unite, to form a hollow through which the spinal marrow is transmitted; and by some of these processes the vértebræ are articulated with each other, as well as by their bodies, by which their strength as a column is much increased. Though but little motion exists between any two vértebræ, yet the flexibility of the whole spine is considerable.

6308. *The cervical or neck vértebræ* (*g*, *h*) are called, by farriers and butchers, the rack bones. It is remarkable, that, let the neck be long or short, the number of bones is the same in most quadrupeds. The first and second differ from the rest in figure, and present some other peculiarities. The first is the only one of them to which the great suspensory ligament of the neck does not attach itself, which would have interfered with freedom of motion. It articulates with the second by receiving its tubercular process within it, and from which process the second of these bones has been called *dentàta.* Between these two neck bones is situated a part, where the spinal marrow is exposed from any bony covering; at which part butchers plunge a pointed knife into what they call the pith of the neck, when they want to kill their animals instantaneously, and without effusion of blood; whence it is called pithing. The remaining five neck bones are not very dissimilar from each other.

6309. *The dorsal vértebræ* (*y*) are now and then, though rarely, nineteen in number; they do not differ materially from each other, but in the length of the spinous processes of the first seven or eight. It is to these elongated spines that we owe the height of the withers; and as the intention of these parts seems principally to serve as levers for the muscles of the back inserted into them, so we can readily understand why their increased or diminished height is favourable or unfavourable to progression. These like the former articulate with each other by processes, as well as by the anterior and posterior surfaces of their bodies; between each of which is interposed a substance, semi-cartilaginous in its structure, which is most compressible at its sides, these permitting the motion of the spine.

6310. *The six lumbar vértebræ* differ from the foregoing in having a longer body, and very long transverse processes to make up for the deficiency of ribs in the loins. These bones often unite by the pressure of heavy weights, and sometimes spontaneously by age, and thus we need not be surprised at the stiffness with which some old horses rise when down.

6311. *The five sacral vértebræ* (*z*) are united into one to give strength to the column, and to serve as a fixed support to the pelvis, or basin, with which it is interwedged. From this detail it will appear how admirably this spinal column is adapted to its important functions of serving as a flexible but powerful support to the machine; and how by the formation of a large foràmen within the substance of each vértebræ, a bony canal is offered for the safeguard of the spinal marrow, from which, through lateral openings in these vértebræ, the spinal nerves are given off in pairs. The *pelvis* or *basin* (2) is composed of the sàcrum, the two óssa innominàta and cóccygis. The *óssa innominàta* in the fœtal colt before birth are each composed of the ílium, the íschium, and the pùbis, all traces of which division are lost before birth. The *ílium* is the most considerable, and forms the haunches by a large unequal protuberance which, when very prominent, occasions the horse to be called ragged-hipped. The next largest portion is the *íschium* or *hip bone*, on each side. It forms a part of the cotyloid cavity, or cup for the thigh bone, and then stretches back also into a tuberosity which forms the points of the buttocks. The *pubis* or *share bone* is the least of the three: in conjunction with the former it forms the *acetábulum* or cup-like cavity in which the head of the thigh-bone lodges. The pelvis or basin is attached to the sacrum by ligaments of immense strength; but it has no bony union, by which means, as in the fore extremities, some play is given, and the jar of pure bony connection is avoided. The *óssa cóccygis*, or bones of the tail, vary from eight to sixteen, but are very commonly thirteen or fourteen.

6312. *The thorax or chest* comprises the sternum or breast bone, and the ribs. The *sternum* (*w*) of the horse is inclined like the keel of a ship, to which the ribs are attached by strong ties. The *ribs* (*x x*) are usually eighteen to each side, of which eight articulate with the sternum, and are called *true*, while the remaining ten, uniting together by intervening cartilages, are called *false ribs.* The centrals are the longest, those anterior, as well as posterior, are less so: the first is placed perpendicularly, the second less so; and their obliquity, as well as dimensions, increase as they advance, so as to enlarge the chest to an almost circular form, which is the most desirable; but when they are less arched, the belly partakes of the defect, and a flat-sided horse is commonly a bad carcased one also.

Subsect. 3. *Bony Anatomy of the Extremities.*

6313. *An examination of the bony parts of the limbs* excites our admiration at the wonderful mechanism displayed in their formation: osseous portions also present themselves, which may be regarded as principally subservient in keeping up that vast chain of continuity and similarity observable throughout Nature's works. In the following explanation we shall have occasion to notice several of these.

6314. *The scápula or shoulder blade* (*k*, *l*), is a broad, flat, and rather triangular bone. It is very unlike the human scapula, having neither acromion, coracoid, nor recurrent process: neither is its situation at all similar to the human blade bone applied to the back; for, in this instance, the horse may be said to

have no proper back, but to be made up of sides and chest. In man, the scápula is in a direct angle with the hùmerus, but in the horse it does not pass out of the plane of the arm. Its superior surface is furnished with a considerable cartilage (*l, m*), by means of which its surface is augmented without weight. The posterior surface ends in a superficial cavity called glenoid, which receives the head of the hùmerus or arm bone. It is divided in its upper surface by its spine. The shoulder blade, as has been already shown in the exterior conformation, has neither bony nor ligamentous union, but is held in its situation by very powerful muscles, as the serràtus màjor, pectoràlis, and others. Its usual situation is to a plane perpendicular to the horizon, at an angle of thirty degrees; and it has a motion in its greatest extent of twenty degrees: hence, as it does not pass beyond the perpendicular backwards, so the more oblique its natural situation, the more extensive are its motions.

6315. *The hùmerus or arm bone* (*m*) is so concealed by muscles as to be overlooked by a cursory observer, and hence the radius or next bone is popularly called the arm. It extends from what is called the point of the shoulder, but which, in fact, is a protuberance of its own to the elbow, forming an angle with the scápula, and extending obliquely backwards as that does forwards. Near its upper extremity it sends off a very powerful head to articulate with the shoulder blade. The motions of the hùmerus are necessarily confined to a removal from its inclined point backward to the perpendicular line of the body. When this bone is too long, it carries the fore legs too much under the animal, and if this defect is joined to a shallow upright shoulder, the evil will be increased. It, however, fortunately happens that both the angle and extent of these two parts are usually regulated by each other.

6316. *The fore-arm* (*n n, o o*) is composed of the *ràdius* (*o o*), and an appendage united to it, which, in man and some animals, forms the *úlna* (*n n*), but which, as the leg of the horse requires no rotatory motion, was unnecessary in him. Here, however, to keep the link of resemblance in all her children of the higher order, Nature has stretched out a large process; which in the colt is really distinct, and may then deserve the name of úlna; and in the adult horse unites with the ràdius, and serves as an attachment to muscles. On the slightest inspection of the skeleton, it will appear how much the motions of the fore leg must depend on the length and obliquity of this process; which, acting on the principle of a lever in the extension of the arm, must necessarily, as it is either long or short, make all the difference between a long and a short purchase. The breadth of the arm, as it is called, at this part, will, from this reasoning, be seen to be very important. This bone articulates with the knee by its inferior portion.

6317. *The cárpus*, or *wrist*, called the *knee* (*p p*), is composed of seven bones, whose principal uses appear to be to extend the surface of attachment of ligaments and tendons, and by their interruptions to lessen the shocks of progression. It may be remarked that all hoofed quadrupeds have the anterior extremities permanently in the state of pronation, or with what is called the back of the wrist turned outwards. The carpal bones articulate with each other, and have one investing capsular ligament, by which means the smallest wound of the knee which penetrates this ligament has the effect of opening the whole joint: hence the quantity of synovia or joint oil which escapes in these cases, and hence also the dangerous consequences which ensue.

6318. *The metacárpus* (*q q, r r*), *canon*, or *shank*, is formed of one large metacarpal bone (*q*), and two small ones (*r*). Here the wide palm of the human, and the paw of the digitated animal, is formed into one solid cylindrical bone, and two small additaménta, called *splint* bones; which are united with it by strong ligamentary attachment, converted by age into a bony one. Although these additions may somewhat increase the surface of attachment, their principal use appears to be to keep up the connection with the dígiti, of which they appear the rudiments. In the cow there are no splint bones, but the uniformity is more perfectly kept up by the divided hoof: in her, therefore, the canon branches at its inferior surface into condyles for the reception of the two claws.

6319. *The pastern* (*t t*). The rest of the extremity below the canon, consists of one phalange only, comprising all the mechanism, and a double portion of complexity of all the phalanges of the digitated tribes. Four bones enter into its composition with two small *sesamoids* (*s s*) to each fetlock; placed there not only to act as a spring and prevent concussion, but to throw the tendon of the foot which runs over them farther from the centre of motion. The pastern bone is situated obliquely forward, and on this obliquity depends the ease and elasticity of the motion of the animal: nevertheless, when it is too long, it requires great efforts in the tendons and ligaments to preserve it in its situation; and thus long-jointed horses must be more subject to fatigue and to strains than others.

6320. *The lesser pastern or coronary bone* (*t, v*) receives the great pastern, and below expands into a considerable surface articulating with the coffin and navicular bones.

6321. *The coffin bone* (*v v*) *forms the third phalange*, and corresponds in shape with the hoof. It is very porous, and laterally receives two prominent cartilages. It is around the outer surface of this bone that the sensible laminæ are attached; and the inferior surface receives the flexor tendon.

6322. *The navicular nut*, or *shuttle bone*, is situated at the posterior part of the coffin, and unites with that and the preceding bone.

6323. *The posterior extremities differ much from the anterior*, not only in their superior strength, and in the different lengths and directions of the parts, but also, in some degree, in their uses.

6324. *The fèmur*, or *thigh bone* (3, 4) is the largest of the body, its vast indentations and risings, almost peculiar to it, show the great strength of the muscles inserted into it. It articulates with the acetábulum or hip joint by a strong head called the *whirl-bone*. In this situation it is held not only by a powerful capsular ligament, and still more powerful muscles, but by an admirable contrivance resulting from a ligamentous rope, which springs immediately from the middle of its head, and is firmly fixed within the socket of the joint. In its natural situation it is not perpendicular as the human fèmur, but inclines to an angle of about forty-five degrees. This bone presents large protuberances for the attachment of very powerful muscles called trochanters. Throughout it exhibits a mechanism uniting the combined qualities of celerity and strength unknown to other animals. The inferior end of this bone is received by its condyles into depressions of the tíbia, while the patélla, or knee-pan, slides over the anterior portions of both bones.

6325. *The patélla* (5), which is by farriers called the stifle, is nearly angular, and serves for the insertion of some of the strongest muscles of the thigh, which are then continued down to the leg. It thus appears to act as a pulley.

6326. *The tíbia or leg bone* (6, 6) is usually, in horsemen's language, called the thigh. It is a bone formed of a large epiphysis, with a small attached part called the fíbula (7), a long body, and an irregular inferior end, adapted to the peculiarities in shape of the principal bones of the back, with which it articulates. The obliquity in the situation of this bone corresponds with that of the fèmur, being as oblique backwards as the former is forwards. The length of the tíbia is a prominent character in all animals of quick progression; in this respect it corresponds with the fore-arm, and the remarks made on that apply, with even more force, to this — that length is advantageous to the celerity, but less so to the ease, of the motion.

6327. *The fíbula* (7, 7) forms a prominent instance, in common with the splint bones, of what was remarked in the outset of our osteological detail of the extremities — that many parts, whose uses were not apparent, would be found to be organs of harmony, placed in the body to prevent interruption to the completing the general plan of animal organisation. In this way the *fíbula* appears but a process springing from the posterior part of the tíbia, forming but the rudiments of the human bone of that name.

In the ox it is wanting; in the dog and cat, as requiring numerous motions in their limbs, it is, on the contrary, perfect.

6328. *The társus, or hock of the horse* (10, 10), is a striking instance of the perfect mechanism displayed in the bony structure of this admired animal. It is formed by an assemblage of six bones, and sometimes of seven; while in the ox, sheep, and deer, there are seldom more than five. Between these bones there is little motion, yet there is sufficient to give a spring to the parts, and to preserve the joints from the effects of shocks, &c. As the human anatomy is generally received as the standard of comparison, we must, in order to a proper consideration of the hock, consider it as the instep and heel; and all the parts beyond it as the foot. The human társus, and that of some beasts, as the monkey and some varieties of the bear, makes a right angle with the tíbia in standing or walking; but, in the horse, the hock makes an open angle with the tíbia, and is far removed from the ground. In him, and the greater number of quadrupeds, all the bones, from the hock downwards, are much elongated, and form a part of the upright pillar of the limb. In the horse, therefore, the point of the hock is the true point of the heel, and, as in the human figure, the great twisted tendons of the gastrocnèmii muscles are inserted into it: but the appellation of téndo Achílles would be too forced here. A broad hock, as already observed in the exterior conformation, may be now still more plainly seen to be very important to strength and speed; for the longer the calcàneum or heel bone of the hock, the longer must be the lever that the muscles of the thigh act by; and a very slight increase or diminution in its length must make a very great difference in the power of the joint. It is by this tendon acting on this mechanism, that, when the animal has inclined the angle between the canon and the tíbia, or, in other words, when the extremities are bent under him in the gallop or trot, he is enabled to open it again. The bones of the hock, like those of the knee, are united together by strong ligamentous fibres; and it is to an inflammation of those uniting the calcàneum and cuboid bones, that the disease called *curb* is to be attributed; and to a similar inflammatory affection of the ligaments in the front of the hocks, that *spavins* of the first stage are owing: in the latter stages the periosteum and bones themselves become affected. The remainder of the bones below do not differ so essentially from the corresponding bones in the fore extremities as to need an individual description. It may, however, be remarked, that the hinder canon or shank bone is longer than the fore, and that the pastern is also the same, but is less oblique in its situation; by which wise provision the horse is enabled to elevate and sustain his body entirely on his hinder parts without danger; which would not have been the case if the obliquity of those parts had been considerable.

Subsect. 4. *General Functions of the Bony Skeleton.*

6329. *The skeleton of the horse* must be considered as a mechanism of admirable wisdom and contrivance, which having considered in detail, we offer the following summary of its functions generally as a whole. It will be found to present nearly a quadrilateral figure, having an inclined cylinder resting on four supporting pillars. The spinal column, as the inclined cylinder, serves as a base for the soft parts, and is found not truly horizontal, but dipping downwards over the fore legs; by which the propelling force of the hinder extremities is relieved by the maximum of strength thus transferred. The increased weight of the hinder part of the cylinder is admirably counterpoised by the head and neck, which are projected forwards; by these means leaving the line of direction near the centre of the whole. The length of a cylinder may be such as not to support its own weight; Nature, therefore, has limited the length of the spines of animals: hence, *ceteribus paribus*, a long-backed horse must be weaker than a short one; and thus, likewise, small horses can carry proportionably more than larger ones. The four pillars which support this cylinder are not perpendicular partially; but they are so totally: for a perpendicular drawn from their common centre of gravity will be found to fall nearly in their common base, by which means they are supported as firmly as though their individual axes had been in a line perpendicular to the horizon. Had they been perpendicularly opposed to each other, there could have been but little elasticity, and consequent ease in motion; every exertion would have proved a jar, and every increased effort would have produced luxation or fracture. To increase our admiration of this mechanism, we need only turn our attention to the contra-disposition of these angles in the fore and hinder supporting pillars. Had these angles presented themselves in the same direction, the body must have been precipitated forward or backward; but each offering a counteraction to the other, the body is firmly sustained within them.

6330. *The bony masses are operated on by muscles*, for this deviation from a perpendicular direction in the various bony portions of the limbs must necessarily have powers to correct it, which is effected by the muscles; and wherever the angles are found most extensive, the muscles will be found proportionally strong and large. This muscular exertion, to counterbalance the angular inclination, occasions fatigue; as the set of muscles immediately employed becoming weary, the animal is obliged to call another set into action, which change is necessarily more or less frequent as the animal is weaker or stronger.

6331. *The extent of the action of the bony portions of the extremities* is the produce of the length and direction of the various parts entering their composition, and of the different angles they are capable of forming; as progression itself is effected by these angles closing, and suddenly extending themselves again. The force of the action arises from the direction of the component parts of the ankles, in combination with the agency of the muscles. The repetition of the action is dependent on the muscles alone; but as the original action arose out of the length and direction of the parts, so it will be evident that in every subsequent repetition, it will be more or less extensive, as these are more or less perfect in their formation, even though the muscular exertions should be the same; thus, some strong animals cannot move so fast as others with less strength, as the cart-horse and racer, or greyhound and mastiff.

6332. *The bony mechanism of the fore and hinder extremities presents some differences.* That of the fore limb may be said to exhibit altogether a different character. The fore-leg bones are much less angular, and appear framed purposely to receive the weight imposed on them by the impulse of the hinder limbs. This weight they are destined to sustain, until the elevation is forced on them by the tendency the general inclined mass has to meet the ground, or to find its common centre in the earth. The fore extremities, under this view of the matter, could not have been placed with equal wisdom in any other situation, nor have taken any other form. The hinder extremities having less weight on them, and at no time bearing an increase of pressure, as the fore do by the impetus communicated from behind, are much more angular; and their angles, by being thrown into a backward direction, afford the necessary impetus for the projection of the body forward. This important operation of impelling the mass being almost wholly dependent on the hind extremities, as that of sustaining it is principally confined to the fore extremities; so the former are also much stronger in point of muscular apparatus; by which their angles can be advantageously opened and closed with superior effect in progression.

Sect. IV. *Anatomy and Physiology of the soft Parts.*

6333. *We shall include under appendages to bone,* the muscles and tendons, blood-vessels, absorbents, nerves and glands, integuments, head, ear, eye, nose, mouth, neck, chest, abdomen, organs of generation, and the foot.

Subsect. 1. *Appendages to Bone, the Muscles, and Tendons.*

6334. *The appendages to bone* are cartilages or gristle, periosteum, medulla or marrow, ligaments, and synovia or joint oil.

6335. *Cartilages* are of three kinds, *articular* (1887.), which cover the ends of the bones by a thin layer, enabling them to slide easily on one another; *non-articular*, or such as are placed between bones immoveably joined; *unattached*, as those of the ears and larynx; and *temporary*, as the ends of bones in very young animals before their earthy deposit is completed. The general nature of cartilage is smooth, white, solid, elastic, and hard.

6336. *The periósteum* is a general uniting membrane to bones and their appendages (1882.); on the skull it is called *pericrànium;* when it covers ligaments, *peridésmium;* and *perichóndrium*, when it invests cartilage. Its uses appear to be to furnish vessels to the bones. It is little sensible, except under inflammation, when it becomes highly so.

6337. *Medúlla*, or marrow, is a soft fatty substance deposited in the cavities of bones.

6338. *Ligaments* (1891.) are close, compact, fibrous substances, of immense strength in the horse, necessary to bones as a connecting medium; ligament is also a common membrane in every part of the body. Ligament is considered inelastic; there are, however, many exceptions, of which the cervical and metacarpal and metatarsal are instances. In some cases they are semicartilaginous. The *suspensory* ligaments attach and suspend parts, as that of the thigh bone to its socket, &c. *Capsular* ligaments surround the two opposed ends of jointed bones, and form a complete cavity.

6339. *The synòvia* or joint oil, being secreted from the inner surface of the capsular ligaments, fills up this cavity, and affords a slippery medium, which enables the bones to slide readily over each other.

6340. *Muscle* is that part of the body of the horse which we term flesh, to distinguish it from skin, gristle, bone, ligament, &c. Muscles appear composed of bundles of reddish fibres, the ultimate division of which it is impossible to trace; and as the motions of an animal are very various, and as almost all motion is operated through the agency of the muscles; so the peculiar shape they take on is very varied. To the generality of muscles, particularly to those ending in bones, is added a portion of a very different nature, called *tendon.*

6341. *Tendons* are insensible, inelastic, tough, fibrous substances, of a whitish colour: expanded into thin layers, they are called aponeuroses. The tendons are eminently useful to muscles, diminishing their size without decreasing their strength. What would have become of the light elegant limb, had the large muscular masses been continued to their terminations below in equal dimensions? Muscles are highly vascular, as their colour testifies; but the tendons are very little so, hence their powers of life are very different: one can regenerate itself with ease, the other with extreme difficulty. The muscles also possess a large share of nerves, and consequently of sensibility and irritability, to which properties the surprising phenomena they exhibit must be attributed; while their extreme vascularity furnishes them with powers to keep the energies requisite for these agencies. They contract and shorten at pleasure, acquire a power of acting dependent on their situation, and can change the fixed for the movable point, and *vice versâ.*

6342. *Muscles are voluntary and involuntary.* The former are immediately under the influence of the will, as those of the legs, eyes, mouth, &c. Involuntary muscles are such as are not under the guidance of the will, and whose functions go on without control, as the heart, the respiratory and digestive muscular organs. Muscles are many of them covered by a cellular or membranous covering, called *fáscia*, and their tendons by another, but stronger investure, called *théca* or *sheath.* At the tendinous extremity there is usually a *capsule* containing a quantity of lubricating mucus, the diseased increase of which forms what is termed windgall.

Subsect. 2. *Blood-vessels of the Horse.*

6343. *The arteries are long membranous canals*, composed of three strata, which are called *tùnicæ* or *coats*, as, an external elastic, a middle muscular, and an internal cuticular. Each of these coats is the cause of some important phenomena, as well in disease as in health. The *elastic* power enables them to admit a larger quantity of blood at one time than another, and thus they are turgid under inflammation: by this also they can adapt themselves to a smaller quantity than usual; otherwise a small hæmorrhage would prove fatal. The muscular tunic appears to exist in much greater proportion in the horse than in man, and this accounts for his greater tendency to inflammation, and also why inflammatory affections run to their terminations so much sooner in the horse than in man. The arteries gradually decrease in their diameter as they proceed from the heart. Our knowledge of the terminations of these vessels is very confined; we know they terminate by anastomosis, or by one branch uniting with another. They terminate in veins, and they terminate on secreting surfaces, in which case their contents become changed, and the secretion appears under a totally different form. Another common termination of the arteries is by exhalant openings, by which sweat is produced. The use of the arteries is evidently to convey blood from the heart to different parts of the body, and according to the part the artery proceeds from, or proceeds to, so does it receive an appropriate name.

6344. *The aórta* is the principal member of this system. Originating from the left ventricle of the heart it soon divides into two branches, one of which, the *anterior*, or *aórta ascéndens* (*fig.* 833. *p*), proceeds forward to be divided into two principal divisions: the *carotids* (*q*), by which the head is furnished, and the *axillaries*, by which the fore limbs receive their blood, under the names of humeral, radial, and metacarpal arteries; and the *posterior*, or *aórta déscendens* (*o*), which is distributed to the trunk and hinder extremities.

6345. *The pulmonary artery* is a trunk of five or six inches in length; arising out of the anterior ventricle of the heart, and continued by the side of the aórta. It soon divides and enters the lungs, through which it ramifies.

6346. *The veins* are also membranous canals which begin where the arteries end, and return that blood which has been distributed by their means. They have less solidity, and possess two tunics or coats only. They usually accompany the arteries in their course, but are more numerous, being wisely divided into a superficial and a deep-seated set, to avoid the dangerous effects of interruption. To prevent the return of the blood they are furnished with valves also.

6347. *The original venal trunks of the horse* are ten in number; the anterior càva, the posterior càva, and eight pulmonary, to which may be added the vèna pórtæ.

6348. *The vèna càva* passes out of the heart by two trunks from separate parts of the right auricle. The *anterior*, or *càva ascéndens* (*fig.* 833. *n*), opposite to the first rib, divides into four principal trunks; two axillaries, and two jugulars, (*fig.* 833. *r*). The axillaries furnish the fore limbs under the names of the humeral, the ulnar, and the metacarpals. The *jugulars* (*r*) run up one on each side of the trachea to return the blood of the head. The *posterior*, or *càva descéndens* (*o*), returns the blood from the body and hinder extremities.

6349. *The vèna pórtæ* is formed from the veins returning the blood from the víscera, which, uniting to enter a sac of that viscus, are ramified through all parts of the liver, where the blood having undergone some remarkable alterations is returned by the vèna hepática, and enters the heart by the posterior càva.

6350. *The blood is a homogeneous fluid*, contained in the heart, arteries, and veins, and constantly circulating through the whole body. It appears formed with the body; is red in the arteries, and purple in the veins. The component parts of the blood are the crùor or coágulum; the coagulable lymph, fibrin, or gluten; and the sèrum. The coágulum is composed of red globules, whose intensity of colour is less in the horse than in man. A red colour is not necessary to the essential properties of blood, seeing the blood of some animals is white; and even some parts of the horse's body are furnished with colourless blood, as the transparent part of the eye, &c. The coagulable lymph or fibrin (1941.) appears the most essential part of the blood, and that from which all the parts are formed. The sèrum seems to dilute the whole. The quantity contained in the body is uncertain: young animals possess more than older, and hence bear bodily injuries better. It is less in quantity in fat than in lean animals; and in

domesticated than in those which run wild. An animal will lose one fifteenth before he dies. A horse lost forty-four pounds without apparent injury. Probably the quantity contained in the body may vary according to circumstances: between one eighth and one tenth of the whole mass is a fair medium.

6351. *The pulse.* From the contraction of the heart and consequent dilatation of the arteries to receive the blood, and pass it onward to all parts of the body, which is called the *diastole*; so a dilatation of the heart and contraction of the arteries necessarily occurs, which is called the *systole*; and these two causes operating alternately produce the phenomena of circulation. The momentary increase in capacity in the diameter of the artery is called the *pulse.* As there is seldom disease present, without some alteration in the circulation also, so the pulse is attended to as an indication of health or disease. The circulation being carried on over the whole body, the pulse may be felt universally; but some situations are more favourable than others; as the heart itself, the pasterns, at the root of the ear, &c.: but the most convenient of all is at the branch of the posterior jaw, where the maxillary artery may be readily detected (*fig.* 833. *t*). The natural pulse in the horse is about 45 beats in a minute; in the ox the same; in man 75; in the dog 90. When the pulse is much accelerated, the circulation is accelerated also. If, with its quickness, fulness of vessels and hardness are apparent, the circulation is *morbidly* hurried, and inflammation general or partial is present.

Subsect. 3. *Absorbents of the Horse.*

6352. *The absorbent system* is a very extraordinary and a very important one; for if the blood builds up and repairs parts, the absorbents pull down, remove, and take them away again. They are eomposed of the *lymphatics* and *lacteals.* Both kinds, although thin and transparent, are strong, and appear to have a contractile power: where very minute they are called *capillaries.* The lacteal absorbents are situated in the mesentery and intestines, whence they draw the chyle, or nutritious fluid by which the blood is nourished and augmented. The chyle is carried forward from the mesentery into a tube called the *thoracic duct,* which, passing up by the side of the aórta, pours its contents into the heart through the medium of the jugular vein. The *lymphatic absorbents* differ from the latter only in being situated over the whole body, and being the recipients of the various matters of the body; whereas the lacteals appear to absorb the chyle only. From numerous facts, we know that the various organs are continually suffering a destruction and a removal of parts, and that what the absorbents take away, the arteries renew; and to this constant change, most of the alterations of the body are to be attributed with regard to the structure of parts. We use our power over these vessels in the horse medicinally. We stimulate the absorbents to take up diseased solutions of fluids from various parts of the body, as in watery swellings in the legs by mercury and by friction, or by pressure in the way of bandage. When deposits are made of hard matter, or ligament or bone, we stimulate them by blistering or by firing. It is by stimulating the absorbents that splints and spavins are removed. Exercise is a very powerful stimulus to absorbents; thus it is that swelled legs are removed by half an hour's exercise. In the horse, the lymphatics are more liable to disease than the lacteals, but in man the reverse. Farcy diseases the lymphatics irreparably.

Subsect. 4. *Nerves and Glands of the Horse.*

6353. *The nervous system of the horse* is composed of white medullary cords, springing from the brain and spinal marrow, whence they are generally distinguished into the cerebral and spinal nerves: the internal structure of these bodies is fibrous, and their ramifications extend to every part of the body; it is supposed that the brain is the seat of sensation and volition, and that the nerves are only the messengers of it. The sensibility of a part is usually proportioned to the number and size of its nerves; nervous influence occasions motion. From some cause, unknown to us, some motions are voluntary, and some involuntary; but both are brought about by nervous agency. As the nerves are the media of sensation; so a division of their cords has lately been attempted, with success, to relieve certain painful affections; the most prominent instance is, in the division of the pastern nerves for the relief of the painful affection of founder. Tetanus, or locked jaw, which seems a morbid irritation on the nerves, has been recommended to be treated in the same way.

6354. *The cerebral nerves,* arising in pairs immediately from the brain, are the olfactory, optic, motòres óculi, pathétici, trigémini, abducents, auditory, lingual, par vagum, and the pair called the intercostal or great sympathetic, from its extensive connection.

6355. *The spinal nerves* are those which arise immediately from the spinal marrow, as the cervicals, humerals, ulnar, metacarpal, and pastern nerves; the dorsal, the lumbar, crural, sciatic, popliteal, sacral, and the nerves to the posterior extremities, which correspond with those of the anterior.

6356. *The glands* are numerous, and placed in every part of the body; they may be characterised as secretory bodies, composed of all the different vessels enclosed in a membrane; their office appears to be to secrete or form some fluid, as the liver secretes bile, and the kidney urine. They are classed into follicular, globate, glomerate, and conglomerate; they also receive specific names according to their situations, or according to the fluid they secrete, as lachrymal, salivary, &c.

Subsect. 5. *Integuments of the Horse's Body.*

6357. *The common integuments* may be considered as the hair, the cuticle, the epidermis, or insensible or outer skin, the rète mucòsum, which is immediately under this, the cùtis, sensible or true skin, the cellular membranes, which contain fat and other fluids, and the pannículus carnòsus or fleshy pannicle; to these may be added, the únguis, nails or hoofs, which we shall describe separately.

6358. *Hair* is the clothing of brutes, and hence is very important to them, and as it enters largely into the arts, it is also important to us. (1851.) It appears to be a production of the true skin, arising from a bulbous end, which penetrates the rete and cuticle in the form of an elongated cone. In some parts hairs appear singly, as about the muzzle; in others in masses, as on the mane, tail, and over the body generally, as an inclined congregated mass; hair varies in colour, and therefore appears by nature intended both for ornament and use.

6359. *The cuticle is situated immediately under the hair* (1845.), and appears a hard insensible covering, purposely placed to guard or defend the sensible skin underneath. The cuticle lines many of the large openings of the body, as the mouth, whence it is continued into the stomach, lining one half of it. It is perforated by innumerable small vessels that give out and take in various matters; through these blisters act on the true skin, inflame it, and force it to secrete a quantity of fluid, which thus pushes the cuticle from the cutis. It exists before birth, and is speedily renewed after birth, when accidentally destroyed, and, like the true skin, thickens by pressure; it is constantly undergoing changes; it exfoliates in the form of powder, or little scales, over every part of the body, and is that substance called dandriff, which grooms are so careful to remove with the currycomb.

6360. *The rète mucòsum* is a mucilaginous substance placed like a net between layers of cuticle and cutis; and although very universal in animated nature, its use is unknown.

6361. *The cùtis, còrium, or true skin.* (1847.) This very general investure of the body is situated immediately under the two former; it is very vascular, and is furnished with innumerable small villous processes of exquisite sensibility, and which, without doubt, were intended to constitute it as the real organ of touch. It is much thickened by pressure; asses, from the beatings they are subjected to, have it of immense thickness on the rump. It naturally also exists in various degrees of density according to the wants of the animal. Like the cuticle it is perforated by numerous openings which correspond with those of the latter membrane. Its composition appears principally gelatine, and hence it is employed in the manufacture of glue; its gelatine uniting with the matter called tannin, becomes insoluble

in water, and then forms leather; and the value of the horse's hide in this particular is sufficiently known.

6362. *Adipose membrane and fat.* These form very considerable parts of the body of most animals. The adipose membrane is not so universal as the skin; some parts are completely without it, as the eyelids, ears, sheath, and some portions of the extremities. It is cellular, but the cells fortunately do not communicate or the fat would gravitate. The *fat* is the unctuous juice poured or rather secreted into these cells. It appears in greater quantities in some parts than in others, and in different degrees of consistence; in the belly of some it is lard, and suet in others; within the bones it is oleaginous in all. Different quadrupeds have their fat of different degrees of consistence, from the firm suet of the ox, and the tallow of the sheep, to the soft lard of the hog, and the intermediate state of the horse; it guards the parts, it preserves warmth; but above all, it is a depôt against occasional want: thus a fat animal can sustain itself without food much longer than a lean one. The torpid bear comes from his hibernation emaciated, because his constitution has been subsisting on his fat.

6363. *Cellular membrane.* (1849.) This complete investure of the body enters every part, and is formed of communicating cells; as we see by the practice of butchers who blow up their meat; and also by the emphysematous effects of a fractured rib, and the gaseous distention in some putrid diseases. It exists in different quantities, and under various modifications of density throughout the body, and is a very universal medium of connection in the form of ligament.

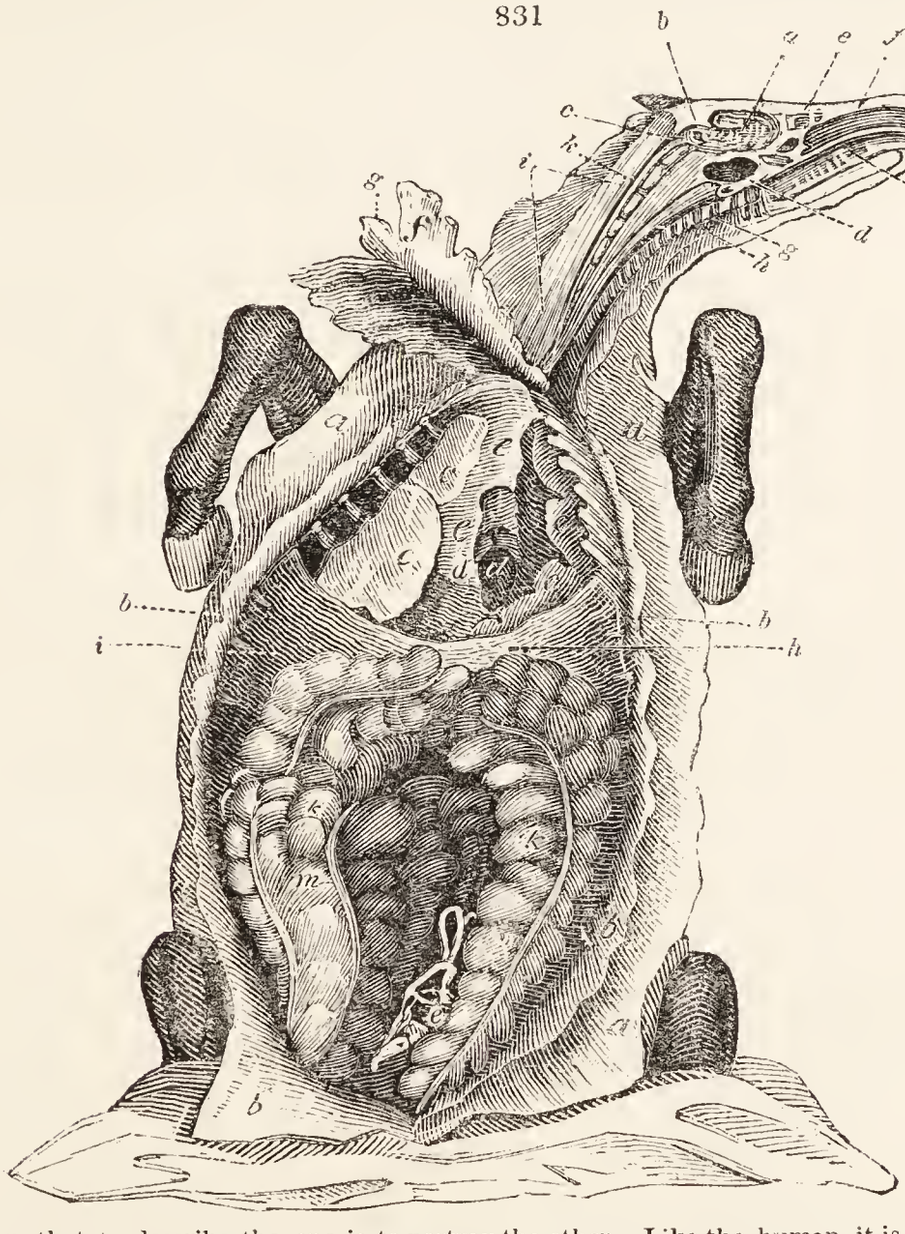
6364. *Pannículus carnòsus.* (1848.) The fleshy pannicle was kindly given to quadrupeds in lieu of hands, to enable them to corrugate or pucker the skin, and thus to shake off dust and insects. It is a thin muscular expansion peculiar to brutes, but not to all; the swine family being denied it. By its attachments it can operate variously, as we see by the uses the horse makes of it. It is very vascular and sensible, also, from the numerous nerves which enter it.

Subsect. 6. *The Head generally.*

6365. *The parts of the head* are external and internal; some of these have been touched on, as the integuments, &c.: such as have not will follow in the order of their magnitude or situation.

6366. *The brain of the horse* (*fig.* 831. *a*, *b*, *c*), contained within the hollow of the skull, is so similar to

831



that of man, that to describe the one is to portray the other. Like the human, it is composed of cérebrum (*a*), cerebéllum (*b*), and medúlla oblongàta (*c*). The medúlla spinàlis is a direct continuation of the brain in the form of a medullary cord, called the pith or spinal marrow (*k*), which passes out of the skull through the occipital foràmen. The brain appears to be the organ of consciousness, and the nerves which arise out of the medullary cord are the messengers by which sensation and volition are distributed to the various parts of the body.

Subsect. 7. *The Ear.*

6367. *The ears of the horse* are composed of inner and outer parts. The internal parts do not differ from those of the human, but the outer are adapted to his situation and habits. These exterior parts are composed of the skin, the outer hair, the cartilages, and the muscles by which they are moved. The skin within the ears is furnished with sebaceous glands, which secrete a bitter matter, noxious to insects: and further to guard against these, it is filled with hair; which the false taste of grooms induces them to remove, and thus to expose the animal to dust, hail, rain, and insects.

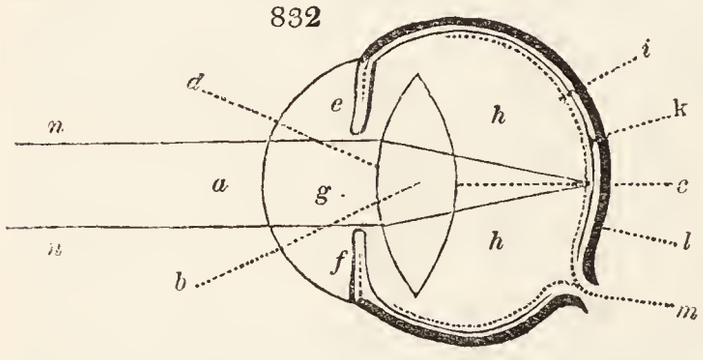
6368. *The form of the ear is dependent on the concha cartilage*, which is found pointed and small in the Arabian, but large and broad in the heavy breeds. The cavity within the concha is thrown into folds throughout, which increases its surface, and reflects the sonorous waves. This outer ear is attached to the internal, by connecting cartilaginous portions and appropriate ligaments. The parts of the internal ear are, the meàtus auditòrius intérnus, or passage; the membràna týmpani, or separating membrane between the external and internal parts; the týmpanum, drum, or barrel of the ear; and the labyrinth. The *Eustachian tube* is an opening at the upper and anterior edge of the hollow of the týmpanum, forming a duct which is in part bony, and in part cartilaginous; extending from the týmpanum to a large and peculiar cavity at the posterior part of the nasal fossa.

6369. *The sense of hearing* is formed through the medium of the expansion of the soft portion of the auditory nerve over the internal ear; sounds, therefore, entering the cavity of the concha, are reflected alternately from its sides into the týmpanum, whose oscillations are imparted to the brain.

Subsect. 8. *The Eye and its Appendages.*

6370. *The appendages to the eye* are, first, a funnel-shaped cavity formed by the concurrence of the bones of the skull, called the *orbit*, not placed directly in front as in man, but inclining laterally, to enable the animal to enbrace a larger field of view. The *eyelids* are an upper and under, of which the upper is the most considerable, and enjoys the greatest motion. United, they form an admirable curtain to defend the eye from dust, insects, and the light during sleep; and are moved by two appropriate muscles. Attached to the edge of each is a cartilaginous rim, called the tarsus. The *cilia*, or eyelashes, are not, as in man, above and below; the upper lid only is furnished with hairs, and these are not placed in one row, but in several smaller rows. The horse has no supercilia or eyebrows, unless we reckon as such the few long hairs over the orbits. The *lachrymal gland* is a body lodged within the upper part of the orbit; it is furnished with five or six excretory ducts, which secrete the làchrymæ or tears to lubricate the surface of the globe. The superfluous tears are carried off by two openings at the inner angle, called *pùncta lachrymàlia*, by which means the tears are at once carried into the nose, and not as in man first into a lachrymal sac. The *carùncula lachrymàlis* is a small black substance in view at the inner canthus, whose office appears to be to direct the tears aright in this course. The *haw*, or *nictating membrane*, is an important part, seen when the eye is drawn inwards, but which is at all other times hidden within the fatty matter surrounding the globe of the eye. Though called a membrane it is cartilaginous, and when the eye is forcibly withdrawn into the socket, it is pressed out from the inner angle, and passes completely over the surface of the globe, to which its shape is adapted. A moderate pressure only shows about half of it; and it is thus seen in tetanus or stag-evil, by the action of the retractor muscle; and under inflammation of the eye it also becomes visible, which has led ignorant farriers to cut it off, under a suspicion that it formed one cause of the disease. The use of this nictitating membrane cannot be for a moment dubious. It is denied to man and to monkeys, because they, having hands, can with their fingers remove dust and dirt from the eyes; but to the horse and most other quadrupeds it is essentially necessary for these purposes.

832



6371. *A diagram of the eye* (*fig.* 832.) displays the transparent cornea in front of its globe (*a*), the crystalline lens (*b*), its posterior convexity (*c*), its anterior convexity (*d*), the iris, or curtain (*e*, *f*), the anterior chamber occupied by the aqueous humour of the pupil (*g*), the posterior chamber filled with the vitreous humour (*h h*), the retina (*i*), the choroid coat (*k*), the sclerotic coat (*l*), and optic nerve (*m*), rays of light showing the different degrees of refraction they suffer in passing through the humours of the eye (*n n*).

6372. *The globe of the eye* is composed of coats, chambers, and humours, and is operated on in its movements by muscles. It may be considered as forming a large cup posteriorly, with a smaller cup applied to its margin anteriorly; or as though the segment of a large sphere were adapted to that of a smaller one. The substance which gives figure and consistence to the larger segment is the *sclerotic coat* (*l*), which is very firm and fibrous. The anterior cup or segment is supplied by the córnea, which is transparent, and formed of thin concentric plates of very different degrees of convexity in different animals, and often in similar animals; to a defect in which is ascribed the indistinct vision or starting of some horses. The *córnea* (*a*) is vascular and sensible, and in an inflamed state it admits the red blood, as we see by the universal redness over the whole; at other times it admits only the colourless parts of that fluid. Immediately within the sclerotic coat is a thin vascular membrane, called the *choröìdes* (*k*), which is spread over it nearly as far as the córnea, where it turns in and expands into the ciliary processes. It also by a peculiar fold forms a ligament, after which it produces another projection into the cavity of the eye, termed the ùvea. It is here continuous, and presents a veil perforated in the centre.

6373. *The pupil of the eye* (*g*) is the perforation which is seen annular in the human, oblong in the horse, ox, and sheep, and perpendicular in the cat. The anterior surface of the ùvea is covered with a membrane, termed ìris, on which the colour of the eye depends: in man it is grey, brown, black, or blue; in the horse it is usually brown, but now and then white, when the animal is said to be wall-eyed. At the central margin of the ìris are seen, in a strong light, some little globular bodies or bags, covered with a black pigment. They are usually attached to the upper margin only, but when any exist on the lower they are small; they have been mistaken for disease. The *ìris* (*e*, *f*) is capable of accommodating itself to circumstances; that is, it can enlarge the diameter of the central aperture or pupil (*g*), so as to admit or shut out the rays of light. Over the central surface of the choroid expansion is spread a dark mucous substance, called nìgrum pigméntum. In animals, whose vision is distinct at night, this pigment is found of a lighter colour: in man it is very dark, and his crepuscular vision is, therefore, indistinct. In the grazing tribes it is of a greenish cast, lost in azure blue; in the predaceous tribes it is still lighter. Under this pigment is the mucous expansion, peculiar to quadrupeds, called *tapètum*. The *optic nerve* (*m*) penetrates the sclerotic coat, and becomes expanded on its inner surface, in a membranous lamen of exquisite fineness, called *rétina*. On this, it is supposed, objects are painted, and thus taken cognizance of by the brain.

6374. *The humours of the eye* are the vitreous, the crystalline, and the aqueous. The vitreous humour (*h h*) is of a jelly-like consistence, and occupies all the globe, except those parts taken up by the other humours. *The crystalline humour* forms a lenticular body of moderate consistence, and is, therefore, more properly called a *lens* (*b*). It is doubly convex (*c*, *d*), its posterior side resting in a concavity of the vitreous humour. It is not of equal consistence throughout, being much firmer in the middle. Different animals have the lens of different figures, to suit the purposes of their existence: in fishes it is nearly spherical, but in quadrupeds, lenticular. It is a diseased opacity of this body that forms cataract. The *aqueous humour* is a limpid fluid which fills up the spaces not occupied by those already described.

6375. *The muscles of the eye.* The motions of the eyeball are operated by seven muscles; four recti or straight, which elevate, depress, and draw to and from; two oblique, which rotate the eye; and a retractor

or choanoid, peculiar to quadrupeds, to draw the eye within the socket and thus preserve it from danger, which draws the globe inwards.

6376. *The phenomena of vision.* If the diagram be examined, it will be evident that the eye of the horse presents an optical instrument of exquisite workmanship and mechanism, admirably fitted to collect the luminous rays from the various objects around, and to transmit them with truth to the brain. If the luminous rays reflected from objects passed through the eye in a rectilinear course, as they do through the atmosphere, no cognisance at all useful to the animal could be taken of them by the eye; all would be glare and indistinctness: but being refracted or bent by the media through which they pass, the rays finally meet at a point called their focus or focal point. Neither would one simple line of refraction have been sufficient to answer all the purposes of perfect vision, under its various modifications. It is necessary that the refraction should be increased in its passage by increased degrees of density in the media of its transit (*n n*). In the passage of the rays through the cornea and aqueous humour, they must encounter their first refraction; and it is evident, that the more convex the anterior portion of the eye may be, the more will this refraction be increased. We need not, therefore, be surprised that a goggler, or horse with this form of eye, should start. The next and largest degree of bending which the rays receive occurs in their passage through the crystalline lens, which from its lenticular form must necessarily be considerable; in their progress through the vitreous humour a farther refraction is effected, till meeting in a point on the rétina, a perfect representation of the object or objects viewed is obtained; the rays forming in their passage numerous cones, the bases of which will be the object viewed, and the apex of each a radiant point. Amidst the number of objects around, it appears that the eye has a capability of collecting rays from such only as are immediately necessary for the purposes of the animal it belongs to; hence, although the general field of view may fall under an angle of vision, yet such rays only as are immediately capable of this convergency produce effect, all others are lost in the black pigment of the eye, apparently placed there purposely to absorb the superfluous rays. As the eye must necessarily have a vast variety of objects painted on it whose distances are widely different, there must be some optical adjustment of the powers of the part to enable it to effect a distinct vision of all objects near or remote; but whether this takes place by means of the angle formed on the two opposite axes, or as has been more lately taught, by a muscular power in the lens itself, is not yet satisfactorily ascertained: certain it is that after the loss of one eye, time is required both in the human and brute subject for the remaining eye to learn to adjust itself to judge of relative distances; which fact is certainly in favour of the opinion that an angle formed between the eyes regulates the judgment of distances. In this way we can account for the well known fact, that hunters, which have before the loss of an eye been excellent and sure leapers, have afterwards lost the power of measuring their leaps. Were it not for some adjustment of the optical organ itself, the rays reflected from objects very near the eye would fall behind it, and those from distant ones would, from being almost parallel, meet together before the rétina. The mechanical adjustment of the focus is also assisted in some measure by the îris, which contracts almost to a point when we look at a very minute object; and by this means only permits such rays to pass through as penetrate the centre of the lens, by which such rays will be very much refracted; but when the eye regards distant objects, the îris becomes dilated, and the rays are then viewed through the edges of the lens, and their inclination is thereby lessened.

6377. *The criteria of soundness in the eyes* are gained by a careful examination of them; and which experience has shown to be best made by placing the horse within a stable, with his head nearly approaching the stable door, which should be fully open. Small eyes are found more prone to inflammation than large, and large goggling eyes are more liable to accompany a starting horse than lesser ones: and when the convexity is extreme, not only is the starting in proportion, but such eyes are more liable than others to become affected with the disease popularly called glass eyes, but medically gútta sèrena. It is not, however, to be understood that all starters have defective eyes; many are so from natural timidity, and still more from harsh usage. The eyes should be examined together, not only to observe whether each presents an equal degree of clearness in the transparent part and within the pupil, but also that an equal degree of contraction exists between each of the pupils. This is of much consequence: if any inequality in size or form be observable between the pupils, the least of them has been in some way affected, and will probably become so again. It is even more suspicious when a turbid milkiness appears on any part of the transparent portion; and equally so, when the inferior part looks other than clear; or, in a very strong light, with a lively bluish tinge. When it is at all turbid, viewed under various aspects, regard it attentively, and there may probably be found an inward speck of perfect white; which is the nucleus or central point of an incipient cataract.

6378. *A glassy greenish cast in the eye should occasion suspicion*, and the hand should be placed over such eye so as to exclude the light; remove the hand suddenly and watch the motions of the îris or curtain of the pupil. If it do not contract, carry the examination still further, and it will probably be found such eyes are totally blind. A blind horse usually carries his ears about, as though in alarm, on his leaving the stable; he also lifts his feet on such occasions, particularly in strange quarters, higher than a sound horse.

Subsect. 9. *The Nose and Sense of Smelling.*

6379. *The organ of smell* is, in most quadrupeds, the next in importance to that of vision, and in many points of view it is even of more consequence. With the herbivorous tribe, it forms their principal means of judging between the noxious and the innoxious. It is not therefore to be wondered at, that it should in these tribes form so large a portion of the head; nor that it should be so exquisitely gifted with sensibility, or so admirably formed to answer its important purposes. The external parts of the nasal organ are the two nostrils, and as much of their convolutions and linings as come into immediate view. Internally these two cavities are carried upwards into the pharynx, but completely divided by a cartilaginous septum (*fig.* 831. *f*). In this course they communicate with numerous openings and cavities, formed within the bones of the skull (6300.), the whole of which are lined by one continuous membrane of exquisite vascularity and sensibility; being largely furnished with blood-vessels, which gives them such a ready tendency to inflame and become red, as we witness under only a slight degree of exertion, and as we see more evidently when violent colds or inflammations on the chest are present. Its sensibility is derived from the olfactory nerves, which are spread over all its surface. It is this membrane which is the peculiar seat of glanders, becoming first inflamed, and next ulcerated throughout its extent; and as the membrane itself appears to be continued to the pharynx and larynx, so we need not wonder why the glanders proceeds to disease the lungs; nor why a common cold, which is at first a simple inflammation of this membrane, so readily degenerates into inflammation of the lungs. The common integuments or coverings of other parts are extended over the nose, but it is little furnished with fat. Of hairs it has a fine thin covering to the edges of the nostrils, and a longer set, which are carefully removed in trimming. By a fold of the skin, within which is a cartilage, the false nostril, as it is termed, is formed, whose use appears to be to keep open the canal for the transmission of air, and yet to offer an interruption to extraneous matter. When the nostrils are a little separated, a small canal may be seen, which is the nasal duct for the transmission of the superfluous moisture from the eyes. The horse breathes or respires wholly through his nostrils in all ordinary cases.

6380. *The sense of smelling.* The volatile particles from all odorous bodies are continually passing off from them, and consequently some must reach the olfactory organs, whose capability of taking cognizance of their qualities appears derived as before pointed out, by the expansion of nervous fibrillæ from the olfactory nerves which transmit impressions to the brain.

Subsect. 10. *The Cavity of the Mouth.*

6381. *The external parts of the mouth* are the lips, cheeks, and beard. The *lips* are made up of fleshy masses so disposed as to give them motion every way; they are covered over with a very fine expansion of skin almost devoid of hair, their exquisite sensibility forms them into an organ of touch; and in this point of view they may be considered as supplying the part of the points of the fingers in man. The *cheeks* are equally muscular and moveable, but are more furnished with hair; and the *beard*, in addition to this thin hairy expansion, has a set of long hairs.

6382. *The internal parts of the mouth* are the teeth already described (6260.), the gums, the alveolary edges, the palate, the tongue, and the parts of the great posterior cavity. The *gums* are a spongy substance which embraces and holds fast the teeth in their *alveolary sockets*. The membrane which covers the gums at the lower part of the channel forms a kind of fold to connect and confine the tongue on each side. These folds are called the *barbs*, and are apt to be mistaken and cut off as excrescences. The *bars* are the spaces in the jaw left between the grinders and nipper teeth; and which man, ever ready to take advantage of for his own purposes, has made use of to ensure obedience by placing on its sensitive surface the pressure of the bridle-bit. The *palate* forms a bony arch, covered by membranous folds, which are apt, when the stomach is affected, to become swollen, in which case the horse is said to have the lampas or lampers. (6446.) By means of these rugose folds, the food is retained within the mouth. The *curtain of the palate* or *vèlum palàti*, which is situated at the extreme end of the palatine arch, is stretched directly across the hinder mouth, and is not intercepted as in man by the pendulous body termed ùvula. This palate curtain is intended to shut out the communication between the mouth and the great cavity of the fauces, which it does at all times, except when the horse is swallowing, at which period the curtain is forced back and the food passes. From this cause likewise the horse is prevented from breathing but by his nostrils; and when any air does pass by the mouth, as in coughing, crib-biting, &c. it is only effected by a forcible displacement of the curtain.

6383. *The tongue is a long fleshy mass* (*fig.* 831. *e*), which adapts itself below to the form of the channel, and above to the arch of the palate: its external surface is rough by means of papillæ, which are inclined backwards, and thus resist the loss of the food received within the mouth. In some animals, as the ox, bear, &c., they are very large, and in the cat pointed. The tongue is a very principal organ in mastication, carrying, by its great mobility, the food into every direction until fully acted upon, and finally passing it into the pharynx.

6384. *Sense of tasting.* It is not observed that this sense is so diversified in brutes as in man; but it is instinctively so correct, that it seldom errs in the herbivorous tribes; and when it does, there is reason to suspect some present defect in the organ, arising from morbid sympathy, which (as in the instance of salt-water, of which at some times horses will drink immoderately,) prompts them to take in matters they are accustomed to refuse. Taste was given to brutes to regulate their other senses, and thus there are few plants or substances whose application to the tongue, under ordinary circumstances, produces an agreeable effect but such as are proper for food. Nature, therefore, stimulates her creatures to search for edibles by a double motive, the calls of hunger and the pleasures of taste; and these are usually in unison, for the nausea of repletion destroys the appetite of taste.

6385. *The pharynx.* The cavities of the mouth and nose terminate in the great cavity of the fauces called by this name, to which also is appended another lesser opening called the larynx, immediately appropriate to the entrance of the tràchea or windpipe. Within this great chamber, at the afterpart of the mouth, shut from it by a membrane only, is the Eustachian cavity, into which the Eustachian tube opens, and which great membranous hollow is unknown in man and most quadrupeds (*fig.* 831. *d.*) Its use is not understood, but it is probably connected with the voice.

6386. *The larynx* is situated at the posterior part of the former cavity, and appears as a cartilaginous box between the os hyöìdes, to which it is attached for support. This cartilaginous box, or entrance to the windpipe, is formed of several pieces, and is furnished with a kind of movable door, which, in ordinary cases, exactly fills up the cavity left by the arch of the palate curtain, thereby shutting the cavity of the mouth, and forcing the animal to breathe through his nasal openings. In extraordinary cases, as when the animal swallows food, this cartilage is forced down, and then it becomes a door to the glottis or funnel part of the tràchea, and thus prevents the entrance of extraneous matter into the lungs. All these parts are operated on by numerous muscles.

6387. *The voice.* The larynx has also another important office in being the organ of the voice. The cartilages of the larynx are very movable on one another, and are furnished with muscular cords, which tighten or relax them; besides which, they are also furnished with peculiar and appropriate sacs or cavities, independent of the tracheal opening, and which are of different magnitudes and directions in different animals. The cartilages of the larynx being acted on by the córdæ vocàles, produce different degrees of density, and consequently different degrees of expansion in the laryngeal sacs; by which, either in expiration or inspiration, are produced different degrees of vibration, and consequent intonation. *Neighing* appears produced wholly by expiration through the nose, as are most of the tones of the horse's voice. This is proved by slitting the nasal cartilage, which wholly stops it. *Knuckering*, as it is termed, is only a lesser neigh, with shorter, deeper, and less forcible tones. The former sound is used as a call, the latter as either call or recognition. It is likewise, when used mildly, significant of joy and affection, and is then beautifully sonorous. The horse has an acute sound produced by inspiration, usually descriptive of lust: in most other cases his intonations are accompanied by expirations; nor does it appear that the tongue or teeth of the horse are much concerned in the modulations of his voice.

6388. *The parotid glands*, or, in the language of farriers, the *vives*, are two considerable bodies on each side of the head, extended from the base of the ear around the angle of the jaw. Each parotid is a conglomerate gland, furnished with numerous little ducts, which unite into one, and enter the mouth about the second molar tooth. These glands furnish saliva for the use of the mouth, and it is an induration and gathering, either in them or the maxillary glands, which form the strangles of young horses. Assistant to these in the furnishing of saliva are the *maxillary* glands, situated within the branches of the lower jaw, and the *sublingual* also.

Subsect. 11. *The Neck.*

6389. *The external parts of the neck* are the common coverings which have been described; the cervical ligament, the muscles, and the jugular or neck veins, &c. The *cervical ligament* (*fig.* 831. *i*), is a very strong substance, in some parts semimuscular, and in all extremely elastic, stretched from the occipital bone along the back of all the cervical vértebræ except the first. Continued on the spinous processes of the dorsal vértebræ, it fills up the dip or depression of the spinal column of the neck, so completely as to form the neck either into a plane, or an elegantly convex line upwards. By its extreme tenacity, the ponderous mass of the head is preserved in its situation, without the necessity of an immense mass of muscle which would, without this contrivance, have been necessary. It is to an injury received at the upper and anterior part of this ligament, that the pole evil is owing. The muscles of the neck are too numerous to allow of particularisation; it is sufficient to say, they most of them run longitudinally. The jugular veins run one on each side of the neck superficially, on the side of the tràchea and windpipe, and form the vessel usually bled from (*fig.* 833. *r*). A few inches before they reach the angle of the jaw, each divides to furnish the head.

6390. *The internal parts of the neck* are the vértebræ, within which passes the spinal marrow. The *carotid arterics* pass up under the jugular veins, near the œsóphagus (*fig.* 833. *s*). The *tràchea* or wind-

pipe (*fig.* 833. *g*), is a large canal for the transmission of air, formed by alternate rings of membrane and segments of cartilage, rendering it at once flexible and cylindrically hollow. The *œsóphagus* (*figs.* 831. *h* & 833. *s*) is the continuation of the funnel-like cavity of the pharynx. It is externally muscular, and internally membranous and cuticular, by which formation it is elastic, to allow of distention in the act of swallowing. The œsóphagus penetrates the chest within the mediastìnum, and passing along the spine (*fig.* 833. *l*), through an opening in the diaphragm, terminates in the stomach.

Subsect. 12. *The Thorax or Chest.*

6391. *The chest* of the horse is bounded anteriorly by the matters filling up the space between the two first ribs, posteriorly by the diaphragm, laterally by the ribs, above by the vértebræ, and below by the sternum or breast bone. In dissecting the horse, after the interior membranes, muscles, &c. are thrown back (*fig.* 831. *b b b b*), there appear the lobes of the lungs (*c c c c*); the heart (*d*); mediastìnum or membranous division of the chest (*e e*); the sternum or breast-bone (*f*); the ensiform cartilage (*g*); and tendinous centre of the diaphragm (*h*, *i*).

6392. *When the chest is opened* a smooth polished membrane is seen, which covers the surface, and then is reflected over its contents; this is called the pleùra; and by a junction of the two pleùræ, a division of the chest into two nearly equal portions is effected, which membranous division is called the mediastìnum. By this division of the chest into two parts, very important benefits arise; as when one cavity is opened the lungs immediately collapse, but the respiration may be carried on by the other. In a similar manner ulceration may proceed to destroy the lobes of one side of the chest, as in glanders, but may be checked by the mediastìnum from proceeding to the other. The pleùra does not, as in man, appear to take on inflammation independently of the substance of the lungs; thus the horse is not subject to pleurisy. The thymus gland, which is a considerable body in the colt, and which forms the sweetbread in calves, is hardly discernible in the old horse. It is situated between the folds of the mediastìnum, but its uses are unknown.

6393. *The diaphragm or midriff* (*fig.* 831. *i*, *h*) is a very important part of the body of the horse, dividing the chest from the belly by its disk, but which is far from elliptical, extending much further backwards than forwards. Its fibres radiate from their origins to unite in one tendinous centre (*h*). In a state of rest it is anteriorly convex, and posteriorly concave; but at each inspiration these appearances are nearly reversed. (6398.) It is perforated for the passage of the vèna càva, the aórta, the vèna ázygos, thoracic duct, and œsóphagus, all which pass through it by means of three openings. It has been found ruptured in some desperate cases of broken wind.

6394. *The heart* (*fig.* 831. *d*) is the great agent of circulation, and is made independent of the will; were it otherwise, man and other animals might cease to live at their own discretion. The *pericárdium* is first seen surrounding the heart so completely, that it swims within it by means of a little fluid termed lìquor pericárdii. The heart is a composition of membranous and muscular fibres, having four principal cavities, and several openings. It is situated within the mediastìnum, so as to occupy a cavity of its own, distinct from either side of the chest. Its base is in a line with the dorsal vértebræ, and its apex is directed to the left of the sternum, between the eighth and ninth ribs. Its two ventricles are immediately within its body, and its two auricles are rather without, appended to it. The left ventricle contains arterial blood, and from it originates all the arteries except the pulmonary. The right ventricle is the reservoir of the venous blood, and it receives all the veins except the pulmonary. Within the ventricles are valves to prevent the return of the blood. The auricles are less muscular than the ventricles: the left, or pulmonary, opens into the left ventricle; and the right communicates with the right ventricle. Into the right and larger auricle the anterior and posterior cavas enter by two openings, and into the left, the pulmonary veins pass.

6395. *The circulation of the blood* may be shortly described as originating with the left ventricle of the heart, which sends its blood, by means of the great vessel called the aórta, to all parts of the body. The blood thus distributed is collected again by the veins from all parts, and is by them returned into the heart by means of the two cavas, which pour their contents into the right auricle, which immediately forces it into the right ventricle. From the right ventricle it is again forced out into the pulmonary artery, which carries it throughout the lungs to undergo a change, and to be finally returned by eight trunks into the left auricle, which immediately empties it into the left ventricle to renew the process described.

6396. *The lungs are spongy masses* divided into right and left, with less divisions called lobes. Their colour varies according to age: thus, in the colt they are of a light lively pink; in the full grown horse they approach to a greyer tint; and in the very old subject they are of a still deeper tone. The bronchia are continuations of the trachea or windpipe, which, dividing on its entrance into the chest, ramifies throughout the substance of the lungs, giving these masses their spongy cellular structure, in which distribution the air vessels are accompanied by ramifications of the pulmonary artery and veins. From the extreme vascularity of these parts they are very liable to inflammation.

6397. *The theory of respiration.* By some extraordinary sympathy, the colt at birth gasps, and air rushes into the lungs before collapsed: having once felt this stimulus, by a common consent between the diaphragm and intercostal muscles, the cavity of the chest is diminished to expel the air received, and to inspire a fresh quantity; and which process is then continued through life. The body appears vitally nourished by two sources: the one through the medium of digestion; the other by means of the blood itself, which, in its progress through the body, gives out its vital principles of heat to the mass, and vitality to the muscular fibre, for unless the blood effect its part in the contractile phenomena it will be in vain for nervous influence to exert its power. Having given out these principles, it is returned by the veins, and is passed forwards into the lungs, circulating throughout their substance, and imbibing, by their contiguity or continuity with the air vessels, oxygen gas from the atmospheric air contained in them. In return for the oxygen received, carbon is given out, which passes off in the form of aqueous vapour. As the blood is renovated, so the air it acted on is deteriorated, and is therefore expired from the chest to make room for a fresh inhalation, to oxygenate a fresh quantity of blood, and thus to renovate afresh the vital powers subservient to its influence.

Subsect. 13. *The Abdomen.*

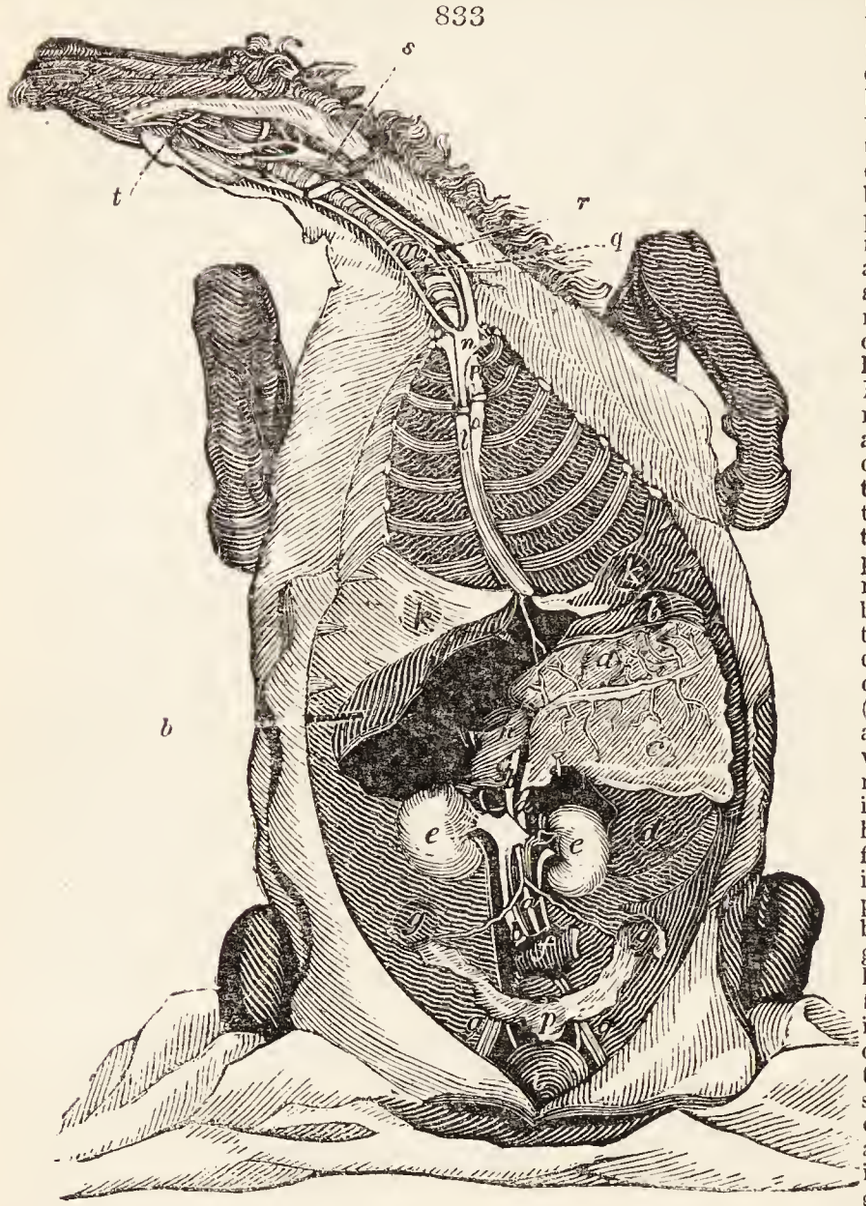
6398. *The víscera of the abdomen* include the stomach (*fig.* 833. *a*); lobes of the liver (*b b*); omentum or caul attached to the whole inferior curvature of the stomach (*c*); the spleen (*d*); the kidneys (*e e*); the rectum (*f*); the ovària (*g g*); the ùterus (*h*); the bladder distended with urine (*i*); the diaphragm or muscular partition dividing the belly from the chest (*k k*); œsóphagus or gullet proceeding to the stomach (*l*); tràchea (*m*); vèna càva ascéndens (*n*); aórta descéndens (*o*), which passes through the abdòmen (*a a*), as does the càva descéndens (*b*); the aórta ascéndens (*p*); carotid arteries (*q*); jugular veins (*r*); œsóphagus (*s*); and maxillary artery, forming the most convenient situation for feeling the pulse (*t*); which completes the víscera and general appearances of the horse when laid open.

6399. *The abdòmen or cavity of the belly* is the largest cavity of the body, and forms an extensive oval vault, containing very important víscera, which may be considered as the chylopoietic, the urinary, and the spermatic, all which are invested by a membrane called the peritonèum, which, after covering each of these organs separately, is reflected over the cavity of the belly itself. It is very strong, and very elastic, as we perceive by the effects of dropsy, great fatness, and likewise by the increase in pregnancy. The *omentum or caul* (*c*) is the fatty apron which first presents itself on opening an animal's

body, extending in some, as the dog, pig, &c. into the pelvis; but in the horse it is less considerable, from which he is not subjected to epiplocele as they are. Its uses are unknown.

6400. *The stomach and its digestive functions.* The horse has one stomach only, and that a very small one, drawing a very wide line of separation by this means between his family and the ruminants. In fact the stomach of the horse may be regarded as intermediate between the triturating muscular one of fowls, and the membranous one of the Graminívora. It is peculiarly constructed to keep up this intermediate character, being partly membranous, partly muscular, and partly cuticular; in which latter formation much of its peculiarity consists, and which it shares in common with asses, rats, and mice; whose habits of living on grain give them a like claim to this wise provision. In a state of rest, or only moderately distended, its direction is across the abdomen, with its two orifices directed upwards; but the cardiac or recipient orifice, to which the œsóphagus is attached, the most so; while the pyloric or expellent orifice is rather lower, and more inclined backward. The situation of the stomach is immediately contiguous to the diaphragm or great breathing muscle (*fig.* 833. *k k*), from which we are at no loss to understand why a very full meal obstructs respiration; and why it is so imprudent to gallop a horse very hard after drinking or eating fully. Small as the stomach is in a natural state, it is yet capable of great distention, as has been witnessed in stomach staggers, when upwards of half a hundred weight of undigested food has been extracted from it. The membranous portion of the stomach is gained from the peritonèum; within this is situated its muscular part, principally composed of longitudinal and transverse layers, by which its motions in digestion are regulated. Around the cardiac or recipient orifice, a strong band of circular fibres is very evident, which effectually constringes this part, and prevents regurgitation or vomiting in the horse, except under extraordinary circumstances of muscular relaxation and sympathy. It has been already shown that the anterior part of the alimentary canal, as the mouth, throat, and gullet, are lined with cuticle or skin. This cuticle is continued into the stomach, and lines nearly a half of its internal surface, whose office seems to be a more perfect comminution of the food, which the horse has no opportunity of remasticating like the ox, sheep, &c. The villous or sensible portion of the stomach is thrown into folds, so as greatly to increase its surface: here the comminuted food in its passage becomes saturated with the solvent *gastric* juice, and is then passed forward into the intestines.

833

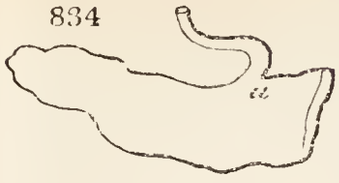


6401. *The derangements of the stomach* may be explained from its anatomy. Though small, and its sensible parts still smaller, yet it is subject to more diseases, and to more frequent derangement, than is generally supposed. It has been proved to be muscular, and that its digestive functions are performed by means of its muscularity. It has also been shown that the contractile energy of the muscular fibre, is mainly gained from the oxygen derived from the blood; whatever tends to interrupt this separation, as an unhealthy state of the lungs, too quick action of them, &c. must derange the action of the stomach also. The perfection of its digestive powers is also derived from its secreting healthy gastric juice, consequently whatever interrupts this process must likewise interfere with stomachic health; and that such health is more often impaired than is generally supposed, and that many ailments, attributed to other causes, are really dependent on an affection of this organ, experience and observation will fully evince. Out of condition is a most frequent complaint among horsemen; their horses are out of condition, and unfit for work: the appearances are various, but are all well known; yet it is seldom considered that it is owing, in every seven cases out of ten, to the stomach being morbidly affected. (6425.) It is evident that too full feeding must derange it, not only by keeping it constantly distended, and thus weakening its capacity; but by entrenching too much on its secreting office, and requiring an inordinate quantity of gastric fluid to saturate an undue quantity of farinaceous matter. The bots, that are frequently found on its cuticular coat, and are there probably harmless, sometimes displace themselves, and settle on the villous part, where they must occasion uneasiness and probable inflammation.

6402. *The intestines* (*fig.* 831. *k*, *l*) in the horse may be considered not merely as secerning organs alone, as in man and many animals, but as really digestive organs, and continuations of the stomachic viscera. This is more particularly the case with the small intestines, and may therefore entitle them to the term of alimentary canal, and the large to that of the excremental; the former measure from twenty-one to twenty-three yards in length, and the latter from seven and a half to eight yards and a half, according to the size of the animal. The duodènum is the first of the small intestines, commencing at the pyloric orifice of the stomach; the jejùnum, which is the next and larger portion, and the ílium (*fig.* 831. *e*), which is still longer, form the remainder. The alimentary canal in its structure does not differ from the sensible part of the stomach, having like that two plans of muscular fibres, a circular and a longitudinal, by which its peristaltic motions are regulated; the longitudinal shortening the canal, and the circular diminishing its size. The alimentary part of the intestinal canal ends with this small gut, which itself

terminates abruptly in the cœcum or first of the large intestines (*fig.* 834 *a*), and which intestine commences what has been termed the excrementitious canal. This entrance is effected in such a manner as to leave, by a protrusion of its surface inwards, a kind of valvular apparatus, which prevents the return of the contents.

834



6403. *The large intestines* (*fig.* 831. *k k*) in the horse are really deserving of that name, being very capacious; while in man and carnivorous animals they are little different from the small. They occupy and completely fill up the lower portion of the abdomen: the cœcum occupies the right side, and carries its blind end towards the diaphragm, which is not furnished with an appendix as in man. A careful inspection of this intestine will show that the appellation of excrementitious canal does not wholly apply to it; but that, on the contrary, it performs some of the offices attributed to the smaller intestines. The colon commences small from the side of the base of the cœcum; but soon enlarging, it makes a turn round the abdomen, when contracting it ends in the rectum, and passes backwards to the anus. Along the course of the large intestines are muscular bands, which throw their surfaces into folds, and also form them into a continuation of cells (*fig.* 831. *m*). By these means, the matters are detained to be acted on more fully, and finally they are expelled in dry hardened balls.

6404. *The digestive process* in the horse is one of the most curious as well as one of the most important which goes on in the body. The various actions of an animal body produce relaxation and waste, which are indicated by fatigue and hunger. To restore the one, rest is required, and to restore the other, food becomes necessary. For the herbivorous tribes, vegetable matter is sought for, which being collected, is masticated by the grinders and mixed with salìva, until it becomes a softened mass, when it is passed backwards by the tongue and molar muscles, through the arch of the palate, in the form of a bolus. Received into the pharynx, which rises to receive it, and the action of which forces down the epiglóttis, all impediment is removed to its falling in the open funnel of the œsóphagus; which having received it, the spiral fibres of the œsóphagus force it inwards into the stomach. While the food remains within the cuticular part, it is acted on by pressure; but being further removed, it meets the action of the gastric fluid, by which it is reduced to a pultaceous mass called chyme. In this state it is passed into the small intestines: for in the horse, as before observed, the process of digestion is by no means completed in the stomach, as in man and many animals. The exertions of the horse require that he should eat largely and nutritiously, but the bulky víscera of the ox would have ill suited with his necessities; for he is not only strong, but his motions are designed to be quick also: it was therefore necessary that some speciality should occur to meet these seeming discordances. This consists in the mode of digestion, which being but partially completed in the stomach, requires a less bulk in that organ, the intestines participating in the labour. A horse will eat two or three pecks of corn or ten pounds of hay at a meal, and yet in a natural state his stomach will not hold half of either. He will also drink two pails of water, when the same organ cannot hold one. What is taken into the stomach is therefore quickly passed through it, and more is required. A horse cannot fast long without injury and pain; his food does not produce a lasting effect in the constitution as animal food does on the Carnívora. A dog fed once a day will thrive, and, when fed every other day only, will not suffer materially; but no horse fed once a day would support himself: even oxen and sheep, as having a slower digestion and more intestinal room, can bear fasting better than the horse. As an animal destined for quick as well as great exertions, his wants prompt him to take in a moderate portion of food only at a time, which his digestive powers peculiarly fit him to convert into nutriment quickly and efficaciously, by distributing the task through a long tract of canal; instead of confining it, as in man and the Carnívora, to one simple organ, the stomach.

6405. *The chyme passes into the duodènum from the stomach*, where it receives the addition of the pancreatic and biliary fluids, whose ducts open into that part of the intestinal tracts. Conducted onwards by the creeping *peristaltic motion*, it passes through this long alimentary tract rather rapidly in the horse; but it remains sufficiently long to receive further additions from the secreting surfaces of the smaller intestines, and probably to have its work of division and absorption begun in it. Arrived at the larger part of the intestinal tract, it is purposely delayed to be fully strained and separated, the open mouths of the lacteals spread over the villous surface receiving the nutritious part under the name of chyle, and the residue being carried backward, and thrown out as dung. The chylous orifices belong to minute tubes termed *lacteals*, which pass onwards enveloped in membranous folds termed *mesentery*, until uniting in one trunk called *thoracic duct*, their contents are poured into the heart, whereby they become mixed with and converted into blood, producing an increase to its quantity; as the alteration it receives in the lungs is an amelioration of its quality, which it has been shown is equally necessary to the animal.

6406. *The liver may also be considered as a digestive organ* (*fig.* 833. *b b*), inasmuch as it secretes a fluid whose office appears to be to quicken the action of the intestines; at the same time that perhaps the very matter separated tends to purify that blood which has been already distributed to the chylopoetic víscera. All other animals, except the horse, ass, and deer, are furnished with a receptacle for the bile, where it may be retained and rendered more acrid: but the horse has no gall bladder, and, in his fœtal state, another speciality presents itself in this organ, which is, that he is deprived of a canàlis venòsus, and thus the whole of the abdominal blood flows through the liver. From this simplicity of structure in the horse he is seldom affected with obstructed or concrete bile; but the organ itself is liable to inflammation, and also to a chronic disease of it through the medium of the stomach.

6407. *The páncreas is an assistant to digestion* also, as we have reason to conclude by its pouring its contents into the duodènum with the bile. It is situated behind the liver, between the stomach and left kidney.

6408. *The spleen, or milt* (*fig.* 833. *d*), is a spongy body situated at the greater extremity of the stomach. Its use is likewise not clearly ascertained; but it has been supposed to be that of a reservoir of blood for the stomach.

6409. *The kidneys are two excremental glands* (*e e*) situated in the lumbar region, the right more forward than the left. The structure of the kidneys exhibits an external reddish part, an internal whitish part, and a cavity called the pelvis. From this cavity passes out the duct called the urèter, and brings with it the urine which is secreted within the kidney. The *urèters* convey the urine to the bladder.

6410. *The urine appears to be a fœcal separation from the blood*, and is in some measure connected with the skin in its office. Thus, when the perspiration is great, the urine is less; and on the contrary in winter, when the perspiration is small, the urine is more considerable. The kidneys of the horse are more easily stimulated into increased action by *diuretics* than those of man or of most other animals; and substances which would not appear potent act with violence on his urinary organs. Thus mow-burnt hay, kiln-dried oats, &c., will produce diabètes.

6411. *The bladder of the horse* (*fig.* 833. *i*) is a membranous sac for the reception of the urine. It rests on the pùbis, and is immediately under the rectum. It is in part muscular, by which it can expel its contents almost to the last drop. At its neck is a kind of sphincter to prevent the involuntary escape of urine, and at its posterior part it is pierced by the urèters. To the bladder is attached a membranous pipe called the *urèthra*, which passes through the penis, and by that means ejects the urine.

Subsect. 14. *The Fœtal Colt.*

6412. *The reproductive system* is one of the most important of nature's works; and, whether we examine the subject anatomically or physiologically, we shall be convinced that the utmost wisdom and care have

been displayed to perfect the continuance of the species. The tender embryo, produced by the mutual sympathies of both parents, becomes placed in a situation the best adapted to its necessities and safety.

6413. *Pregnancy and evolution of the fœtus.* In the pregnant womb, the rudiments of the future animal are covered with expansions from the neighbouring parts; and derive nourishment from a communication with the mother by means of the umbilical cord, and farther, by a surrounding fluid. In this state a speciality is observed in the fœtal sanguineous circulation; the whole of its abdominal blood passing through its liver (5733.) by which it gains a more early and perfect evolution to fit it at its first entrance into life for active exertions. Under these circumstances it daily acquires increase, until the distention it occasions becomes too great for the capacity, when the muscular fibres of the uterus, powerfully assisted by the diaphragm and abdominal muscles, contract, and thus force both the foal and the membranes into the world.

6414. *The new-born foal*, on its entrance into active life, finds its organs of immediate necessity in a full state of capacity. Unlike the infant, it is far from indigent, but can run and perform the common phenomena of an animal with dexterity and ease. Its powers are, however, not sufficiently developed to enable it to live independent: it has therefore a necessity for seeking support from the mother, in the form of milk; and it may therefore be now considered in some measure as carnivorous. The milk is derived from a bag furnished with two nipples, having excretory outlets and valves to prevent the accidental loss of the fluid. These valves the instinct of the foal teaches it to displace by its nose. The milk of the mare being highly nutritious, its evolution rapidly increases and becomes fitted to perform all the more matured functions, and when fully able to counteract its own wants, it sympathises only with itself; when the parent's care being no longer necessary, the lactiferous secretion ceases.

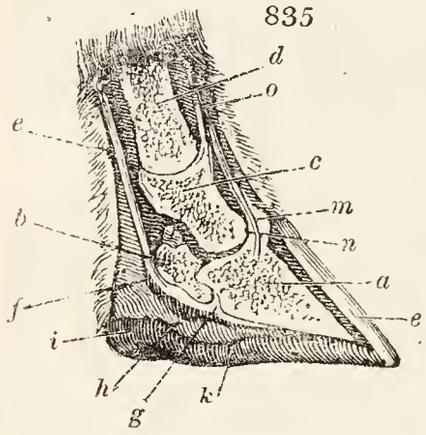
6415. *The period of gestation* varies in different mares: one hundred and two mares were observed by Tessier, of which 3 foaled on the 311th day, 1 on the 314th, 1 on the 325th, 1 on the 326th, 2 on the 333d, 47 from the 340th to the 350th, 25 from the 350th to the 360th, 21 from the 360th to the 377th, and 1 on the 394th day; which gives a latitude of 83 days in the time of gestation.

Subsect. 15. *The Foot.*

6416. *The feet of the horse present in their united functions a series of springs* with great complexity of structure. An unreflecting observer considers only the horny box, and perhaps attaches as little merit to its mechanism, as he would to a well turned wooden leg of a man. But a little examination will convince him that all the complexity, all the admirable mechanism displayed in the assemblage of four fingers and a thumb, are here concentrated within this horny box and its appendages. As the parts which compose the hind and the fore feet do not materially differ, a description of one foot will serve for the whole.

6417. *On examining a perpendicular section of the foot and pastern* (*fig.* 835.), there appears the coffin bone (*a*), the navicular or nut bone (*b*), the coronary or little pastern bone (*c*), the larger pastern bone (*d*), the back sinew or great flexor tendon of the foot (*e*), the same tendon sliding over the navicular bone (*f*), its termination or insertion into the bottom of the coffin bone (*g*), the elastic matter of the sensible frog (*h*), the insensible or horny frog (*i*), the horny sole (*k*), which includes the parts of the sensible foot; the outer wall of the hoof (*l*), the elastic processes (*m*), the attachment of the extensor tendon to the coffin bone (*n*), and its attachment to the coronary bone (*o*), which completes the section.

835

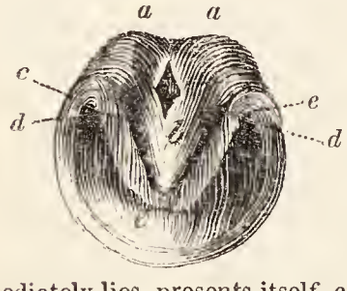


6418. *The coffin bone* (*fig.* 835. *a*) adapts itself to the form of the hoof, or rather is adapted by nature to this eligible form. The eminence in front receives the insertion of the tendon of the great extensor muscle of the foot, whose upper attachment is to the humerus or arm bone where it is fleshy, but as it passes onwards, it becomes tendinous, expanding over every joint, both to prevent friction, and to embrace and give attachments to each bone, by which a simultaneous movement of the whole limb is made. In the hinder limb, this extensor and its two less adjuncts arise from the tíbia and in part from the fèmur. To the sides of the coffin bone are attached the lateral cartilages, and around its surface are marks of the attachment of the laminated substance.

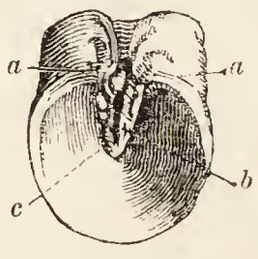
6419. *The coronary or small pastern bone* (*c*), articulates with the coffin at its posterior part, and articulating also with both these is the *navicular or nut bone* (*f*), whose attachments to them are effected by ligaments.

6420. *The hoof is conical*, or rather, as Clark observes, slightly truncated, and is a secretion as well from the vascular parts of the foot as from the skin, as our nails are from the portion of skin called the quick. The structure of the hoof is firm and fibrous; externally plane and convex, but internally concave and laminated. The *quarters* are the lateral parts. As the horn approaches the heels it becomes soft, and is reflected inwards. The heels are parted by the *horny frog* (*fig.* 836. *b*), and without the frog on each side, the hoof inflects its fibres to form the bars which are seen on the under surface (*fig.* 836. *c*). In a healthy foot (*fig.* 837.) the heels are round, wide, and smooth (*a a*), the frog fully expanded (*b*), the bars or binders distinct (*c*), no corns in the usual angle (*d*), the sole broad and concave (*d*). In a diseased foot (*fig.* 837.), the heels are high and drawn together by contraction (*a a*), the frog narrow and filled with fissures from contraction and thrush (*b*), and the sole greatly shortened in its transverse diameter, which is morbidly counterbalanced by the increased heights in the truncated form (*c*). When the hoof is removed, the *sensible or fleshy sole* (*fig.* 835. *k*), above which it immediately lies, presents itself, covering the whole of the horny sole, except so much as is taken up by the *sensible frog* (*h*). This part is exquisitely sensible and vascular; and thus we learn why injuries to it from punctures produce such serious effects, and why very slight pressure from contraction of the hoof gives so much pain. The sensible frog and the sensible sole form the insensible frog and sole; but when from pressure, too much moisture, or other causes, the sensible frog, instead of forming horn, secretes pus or matter as in thrush, the structure of the whole becomes injured; and the horny frog, thus losing its support, gradually wastes and decays. It is, therefore, evident that no thrush can be entirely harmless, as is erroneously supposed. Above the sensible frog and sole is the great flexor tendon, or back sinew, inserting itself into the vaulted arch of the coffin (*fig.* 835. *e*). This important tendon arising from its parent muscle above the knee, whose origin is taken from the hùmerus and ùlna, in its passage unites with an assistant flexor, but which latter is principally distributed to the pastern bones; while the *pérforans*, so called because it is perforated by the assistant flexor tendon, is inserted into the vault of the coffin. In the posterior extremities, the attachments of these two leading flexors, and a smaller *lateral* one, are from the fèmur and tibia.

836



837



6421. *The sensible láminæ.* Around the surface of the coffin bone it has been noticed that there are

linear indentations, to which about five hundred semi-cartilaginous leaves are attached. Each of these is received between two of the horny lamellæ which line the interior of the horny hoof: and when it is considered what a vast surface of attachment is formed by these means, the strength of the union will not be wondered at. No common violence can separate these parts, and their use, as so many springs to support the actions of an animal, at once weighty, strong, and extremely agile, must be apparent. The vessels and nerves of the foot are derived from the metacarpal arteries, veins, and nerves, which pass behind the pastern, when the main trunks divide to proceed to each side of the foot, and are ramified from thence throughout. It is a division of the metacarpal nerve on each side of the lesser pastern, or of the larger, as occasion suits, which forms the *nerve operation*, now in vogue as a remedy for founder.

Sect. V. *Diseases of the Horse.*

6422. *The diseases of the horse* are as numerous and as important as his complicated structure, and the artificial state of his present mode of life, would lead one to expect. Until of late the treatment of these diseases was confined to the hands of ignorant farriers, presumptive grooms, or shoeing smiths; and the fate of the animals was commensurate with the wretched treatment they were subjected to. The establishment of a school for the veterinary art has disseminated an improved practice, and spread improved practitioners throughout the country; and we would earnestly recommend an application to one of established reputation in all cases of difficulty and danger. But as it is not always that such a one is within reach, to enable the agriculturist to have in his own hands the means of informing himself, or of being a check on others, we submit a concise view of the diseases of the head, neck, trunk, and extremities, preceded by some general observations.

Subsect. 1. *General Remarks on the healthy and diseased State of the Horse.*

6423. *Condition of horses.* Being in condition, in stable language, signifies not only perfect health internally, but such an appearance externally as the philosopher would call unnatural, or at least artificial; while the amateur considers it as an essential requisite to the other qualities of the horse. This external condition is denoted by a sleek, short, shining coat, with a degree of flesh neither bordering on fatness nor emaciation. Even in this sense of the term, *condition* must be varied according to the uses of the animal. In the cart horse, provided there be sleekness of coat, looseness of hide, sound wind, freedom from grease or swelled legs, with good digestion; a fulness and rotundity of bulk, instead of detracting from his beauty or impeding his exertions, will add to the one and assist the other. In the coach horse, the hackney, the hunter, and the racer, a different *condition* is expected, varying in different degrees from that of the cart horse. In both cart horse and racer, it is equally necessary that the various internal organs should be in a state to act uninterruptedly for the benefit of the whole; but, in addition to this, it is necessary to the racer, that the greatest possible quantity of animal fibre should be condensed into the smallest possible bulk; and that the absorption of all useless fat and other interstitial matter should be promoted by every possible means, as essentially necessary to unite lightness of body with full strength and elasticity. It is in the attempts to produce such a state in its full perfection, that all the *secrets of training* consist: but whether a total departure from natural rules, by unnatural heat, deprivation of light, stimulating food, restraint from water, and excessive clothing, are best calculated to promote it, admits of much doubt; and it is to be observed, that the dawn of reason and science appears to be shining through the crevices of these darkened casements; for even at Newmarket the system has lately much relaxed from its artificial rigour.

6424. *To bring a horse into condition*, not only should the purposes he is intended for be taken into account, but also his previous state. If he be taken up from grass with much flesh on him, it is evident that what is required is, to remove the soft interstitial matter it may be supposed he has gained by green food, and to replace it by hard flesh; and also to produce a sleekness of coat and beauty of appearance. To accomplish these ends, the horse should be accustomed to clothing and the full heat of the stable by degrees only; and also by degrees only to the meditated change of food, which is best done by mashes. In two or three days a mild dose of physic may be given, during all which moderate exercise only should be allowed, as walking, but which may be continued two hours at a time. After the physic has set, begin to dress his coat, increase his exercise and his food, and accustom him to an increase of warmth. In four or five days' time again mash him for two days, and give a second dose of physic, a very little stronger than the first. (6544.) After this, still further increase his warmth, his exercise, and his food, by which his belly will be taken up, his flesh will harden, and his coat will begin to fall. A third dose of physic, or urine balls, &c., are only necessary in the training of hunters, &c., and even in these, a gradual increase of exercise, rather long continued than violent, with proper food, will effect the end, if not so quickly, more beneficially to the animal. *To bring a lean horse into condition*, a somewhat different plan should be pursued. If from grass, still mash him for a day or two, by no means stint him in his water, and with his mash let corn be also soaked. If corn be speared or malted, it will produce flesh sooner. But even here, give the horse moderate walking exercise, and if he be not too much reduced, add a mild dose of physic to prevent his heels flying, or his getting hide-bound by the increased food; but if great emaciation forbid the physic, give him nightly an alterative. (*Vet. Pharm.* 6550. No. 1.) As his appearance improves, gradually harden his food and increase his exercise.

6425. *Diseased condition of horses.* What has been already said relates to that alteration from one state to another, neither being an unhealthy one, which custom has rendered necessary; thus a man in training for running or fighting, and a man out of training, are both considered equally healthy. But there are circumstances that produce a *morbid state of condition*, different from all *these*. It is common to hear persons say, "My horse is sadly out of condition; and I cannot tell either what is the matter with him, or how to get him into better case." Various are the causes that may produce this: a sudden alteration of the food or temperature, or of habits altogether, may become a cause. Removing a horse from grass to a heated stable, full feeding, and hard exercise, will often do it: therefore these changes should always be gradual. Bad food, as mow-burnt hay, musty oats, beans, &c., likewise mineral waters, foul air, &c., are frequent causes. Diabètes, or profuse staling, is often brought on by these means, and the *condition* of the horse becomes greatly reduced. It is requisite, therefore, to enquire whether any of these errors are in existence, and to immediately remove them: but it often happens that the stomach has become relaxed and the hide become bound; neither of which readily remove, even though the original evil may be amended. When the relaxed stomach has produced lampas, treat the mouth as described under that disease (6446.); but the stomach itself must be principally attended to. First mash and give a dose of physic; after it has set, commence the treatment, if the horse be of a full habit, by a moderate bleeding and a nightly *alterative* (*Vet. Pharm.* 6550. No. 1. or 2.) But if he be not in full, but in low flesh, commence by a daily *tonic* (*Vet. Pharm.* 6551. No. 1. or 2.), which will gradually remove the swelling within the mouth, and loosen the hide. A sudden cold applied to the skin often brings on a want of *condition* with *surfeit*. In which cases bleeding, nightly alteratives (*Vet. Pharm.* 6550. No. 1. or 2.) with or without an assistant dose of physic, as the habit of the horse may require, constitute the proper treatment. *Worms* form another cause of morbid *condition*, which are to be removed as described. (6478.) *Excessive fatigue* is also productive of a bad state of *condition*, which often proves very obstinate. Turning out to very good grass is the quickest cure, and when that is impracticable, soiling in the stable, or feeding with carrots, parsneps, beet-root, &c. will be good restoratives; as medicines give tonics daily. (*Vet. Pharm.* 6551. No. 1. or 2.) It will be only necessary to add, that in considering the state of a horse's *condition*,

the effect is apt to be mistaken for the cause, and the symptoms for the disease. Hide bound and lampas are not in themselves any thing more than effects, or symptoms; the former being commonly, and the latter being always, dependent on a deranged state of the stomach: both are, therefore, to be treated accordingly. Exactly the same will apply to all the other symptoms of *morbid condition.*

Subsect. 2. *Inflammatory Diseases of the Horse.*

6426. *The inflammatory diseases of the horse* are numerous, but his fevers are few; a febrile state being generally brought on by the inflammation of some important organ. Inflammation may be considered as general or diffused, and local or confined, and both seem to arise from an affection of the blood-vessels, and perhaps from a peculiar state of the blood itself.

6427. *General or diffused inflammation* constitutes fever or extensive inflammatory affection, and appears to consist in an increased action of the heart and arteries, accompanied with an increase of heat. In some instances where the fever is purely symptomatic, and dependent on the inflammation of some important organ, as of the lungs or the intestines, the circulation appears retarded rather than increased, from interruption arising to its passage through the heart.

6428. *Local or confined inflammation* is also dependent on an affection of the blood-vessels, but confined principally to the blood vessels of the part affected. It is betokened by redness in the skin, tumour or swelling, heat, and tenderness, with pain. Inflammations, both diffused and local, are brought on by excitements, such as over-feeding, excessive heat, the reaction produced after cold, and the reaction produced by inordinate exertion. Those more exterior arise from injuries, the application of improper substances, &c. Inflammations *terminate* in various ways; but it is to be remarked, that in consequence of the very large circulatory system in the horse, his febrile affections rage higher, and terminate sooner, than in man. The usual termination of inflammatory affections in the horse is, by resolution, effusion, suppuration, and gangrene. Schirrus is not at all a common termination of inflammation in the horse.

6429. *Inflammation of the brain* (*phrenitis*), *brain fever*, *phrensy fever*, *staggers*, *mad and sleepy.* There are few diseases more likely to be mistaken by inexperienced farriers than this; it is not to be wondered at, therefore, if indifferent persons should be led into error by it. It appears in two forms, a violent frantic one, and a sleepy lethargic one; and the latter appearance is also common to a disease, not dependent, as this is, on idiopathic inflammation of the brain, but on a paralytic affection of the stomach, and thence it is called stomach staggers. This latter affection, however, may be distinguished from the former by attending to the colour of the eyelids, nose linings, mouth, &c., which, in stomach staggers, are usually more yellow than red; whereas, in sleepy staggers, they are more red than yellow. Inflammation of the brain shows itself, in general cases, by disinclination to food and motion, drowsiness, accompanied by a heaviness and closing of the eyelids, with moisture and redness of them; and also of the linings of the mouth and nose. Sometimes these symptoms increase until the horse becomes comatose, and after a few frightful struggles, he sinks to rise no more. In these cases the pulse is apt to be oppressed instead of increased; but most frequently after the first stages he becomes furious, plunges about, and is vicious to himself and others, approaching to a state of madness, in which state he continues till he sinks from his own exertions, when he rises again to renew his violence.

6430. *The causes of staggers may be various:* the immediate are either an original accumulation of blood within the brain, or the translation of the inflammation of some organ to the brain; as a remote cause it is often brought on by too full feeding, without sufficient exercise, and particularly in horses at one time working very hard, and at another suffered to remain inactive, but which horses, whether used or not, are equally fed. Sudden cold, violence, &c., may bring it on.

6431. *The treatment of staggers* should be begun by abstracting a very large quantity of blood promptly, by opening both jugulars, and letting the horse bleed to the amount of ten or even twelve quarts; repeating the same until the delirium ceases. After the first bleeding, back rake, throw up a laxative clyster (*Vet. Pharm.* 6564.), blister the head, promote a current of free air in the stable, and treat altogether as directed under other febrile affections.

6432. *Locked jaw*, *stag-evil*, *or tétanus*, arises from cold, excessive fatigue, sometimes perhaps from worms, but more often from a wound of some part, as pricks in shoeing, &c. Such wound is seldom in a recent state, but after two or three weeks' continuance, sometimes after it has healed even; it follows docking, gelding, and nicking frequently, and is preceded by a flabby unhealthy state of the wound. It is not always produced by an open wound; it is sometimes consequent on a bruise, strain, &c.; and is sometimes brought on by cold, violent exertions, &c. &c. It appears as an affection of the brain, which transmits its morbid irritation, particularly to the nerves attached to muscles, by which they become cramped, or may be considered as in a high state of action, giving the horse a peculiar look of energy, as though immediately stopped from full speed, with his nostrils extended, his head raised, and nose carried forward; his legs straddle wide, and his tail is cocked and quivers, as after violent exercise. The jaws will now be found, if not closed, yet nearly so, when he is called *jaw-set.*

6433. *The treatment* is not often successful; but, however, it is sufficiently frequent that it is so, to deserve the utmost attention. Blaine informs us that enormous bleedings have succeeded; but he places his principal dependence on the application of cold by the means of ice, or of constant dashing with cold water, with an active blister applied the whole length of the spine. Balls of camphor and opium, to the amount of two drachms of each, may be given every three hours. If any room remains in the mouth, the ball may be passed up by means of a stick, or it may be given as a drink by means of a syringe; and even when the mouth is entirely closed, he informs us we may give a drink by the nostrils. Moorcroft used cold also. Fearon, on the contrary, has experienced benefit from a bath, heated to ninety degrees, and kept at that temperature for three hours. White recommends camphor and opium. Wilkinson, of Newcastle, has been very successful by keeping up heat and stimulus over the skin in general, by means of newly stripped sheepskins put on hot. Perhaps if the body were previously rubbed with oil of turpentine one part, and common oil two parts, it might assist Wilkinson's plan. When locked jaw arises from nicking, it might be prudent for a veterinary surgeon to dissect down on the nerves of the tail, and divide them; and when from docking, it would be advisable at once to cut off another portion of the tail; which practices, in both instances, would afford a moderate chance of saving the animal. It is necessary further to remark, that it is of great consequence that the bowels be kept free from fæces, by raking and clysters. With regard to the latter they are very important in this disease, as a medium, commonly the only one, of giving support. A horse has been kept alive on nourishing clysters alone for seven or eight days. (*Vet. Pharm.* 6566.)

6434. *Catarrhal fever*, *epidemic catarrh*, *influenza*, *distemper*, *cold*, *morfoundering*, *&c.* These names apply to one common disease, which often in rainy, variable seasons appears as an epidemic, and affects thousands of horses at once. It is observed to be particularly prevalent in this form in the spring of some years, more than of others. It is not contagious, like the more malignant form, but is brought on as an epidemic by the same causes being applied to nearly all subjects alike; which are alternations of heat with cold, moisture, and dryness, &c. In crowded cities and large towns it is more prevalent than in more open situations, and it is more frequently found in the young than in aged horses. Where it does not exist as an epidemic, it is brought on by an accidental cold taken. It is of great consequence to distinguish it from pure inflammation of the lungs, with which it is very apt to be confounded; and which mistake is often a fatal one, from the treatment being in some essential particulars different. Inflammation of the lungs commences by a short cough, without much other disturbance to the health than the pain it gives the horse to cough; but which is often so considerable as to make him stamp his feet while coughing. If a horse in the distemper coughs early, it is not a hollow, harsh-sounding, and distressing cough of this kind; if he expresses uneasiness, it is principally from a sore throat, which is very common

in distemper, but by no means common in pneumonia. The sore throat in distemper gives the horse a disposition to refuse his food, or he chews it and lets the quid fall without swallowing it. He refuses water, particularly if it be placed on the ground. His cough is quick, short, and usually sounds more moist than harsh and dry; but though common, this is not invariably the case. His eyes are heavy and moist, his breathing is quickened, and his ears and legs are alternately hot and cold. His nose on looking into it is redder than usual, and sometimes his glands, as well submaxillary or jaw glands, as his parotid or vives, are tumified. On the second or third day excessive weakness comes on; the cough becomes more painful, the pulse is quickened, and the nose begins to run. After which the horse either runs off the disease by this suppuration, or it goes on to destroy him by the height of the fever, and degree of weakness produced, or by suffocation from water in the chest. Now and then, although recovery takes place, an obstinate cough is left; and in a few cases the disease terminates in glanders.

6435. *The treatment* may in some cases be cut very short; for as in almost every instance a shivering fit begins the disease, so when many horses are in a stable, and the disease is very prevalent, those who have not been attacked should be watched, and the moment such an attack does take place, give of *sweet spirit of nitre*, or when not at hand of *spirit of hartshorn*, an ounce, in a pint of sound ale. Exercise the horse briskly, then well hand rub him, clothe him warmly, and it is more than probable that the disease will be cut short. But should it proceed, or should the disease have gone on unobserved to the appearance of the symptom detailed, begin by bleeding moderately, if the horse be not already weak, or if there have not appeared the running of matter from the nose. If there have, the bleeding had better be dispensed with, unless the fever appear, from the quick full pulse and redness of the inner surface of the nostrils and eyelids, to be still so considerable as to require it; in which case we must not be deterred from one moderate bleeding; and which, if the febrile symptoms do not abate, may be even repeated. It will, however, in general cases, be advisable to avoid bleeding after the second day of the attack, or after the discharge has appeared from the nose, or after considerable weakness has come on. In all cases a very cool temperature is essentially requisite: hot stables or hot clothing is very pernicious, but particularly the former. A hood is not improper over the head, because it encourages the running to make an early appearance; and for this reason a warm mash may advantageously be hung round the neck three or four times a day. Before the discharge commences, give night and morning the fever powder (*Vet. Pharm.* 6578. No. 1. or 2.) in a mash or drink; after the running has come on, or as soon as the weakness has become considerable, give night and morning either of the fever drinks. (*Vet. Pharm.* 6579. No. 3. or 4.) Malt mashes, when the weakness is great, are proper; at other times bran mashes with plenty of chilled water are best. To relieve the throat, rub the outside with mild liquid blister (*Vet. Pharm.* 6563.); and if the weather be warm enough to allow it, two or three hours turning out in a field each day is proper. Green meat in the stable, when it can be procured, should likewise be given.

6436. *Malignant epidemic, murrain, or pest.* Now and then the distemper or influenza assumes a character of uncommon malignance; which is happily not frequent here, but not unfrequent in continental countries; sweeping off a third of the horses and kine, without any means being found sufficient to arrest its progress. In these cases it is highly contagious, attacking almost all the horses as well as cattle within its sphere of action, or which communicate with each other. Dr. Layard, and Osmer, English writers of established reputation, noticed the appearances of this disease long ago; and their descriptions are not different from the milder kind noticed (6434.) but in degree. The throat is intensely sore, and the mouth ulcerated; the glands of the head swell, and sometimes these and other parts suppurate and burst. The matter from the nose is bloody, and the stench intolerable; the weakness is also peculiarly great, and shows itself early.

6437. *The treatment* recommended by Blaine is the early use of malt mashes; even ale is indispensable. Green meat should be allowed, and a very cool stall is necessary, having a free communication with the open air. As medicine, three doses are necessary, every day, of the malignant epidemic fever drink (*Vet. Pharm.* 6582.); half a pint of yeast with a pint of ale has been given, with good effect, three times a day; also, to prevent the infection from spreading, fumigate the stables and all the outhouses with the preventive fumigation. (*Vet. Pharm.* 6583.)

Subsect. 3. *Diseases of the Head.*

6438. *Epilepsy, megrims, sturdy, or turnsick*, are epileptic attacks of greater or less violence, and which are apt to be confounded with the accidental strangulation that sometimes takes place, from a collar too tight, or from driving a horse hard up hill, &c. The epileptic fit makes its appearance by a sudden stop; if the horse be in action he shakes his head, looks wild and irresolute, but after some time he proceeds; when more violent, he suddenly falls down, is convulsed, dungs and stales insensibly, and remains some time before he recovers. This disease, like staggers, is generally the consequence of too full a habit; and is, therefore, best relieved by bleeding, and a more moderate diet; and, where it is convenient, a run at grass should be allowed to alter the habit.

6439. *The diseases of the horse's eyes* are not numerous, but they are very destructive. The principal are ophthálmia and gútta serèna.

6440. *The ophthálmia, lunatic, or moon-blindness*, is a very peculiar disease among horses, affecting their eyes generally about their full growth, but sometimes later, and seldom earlier. It is but little known among mules and asses, and unknown in oxen and sheep. It does not, however, appear to be a disease natural to the horse, as wild ones, or even those little subjected to artificial restraints, are not observed to be subject to it: but among others, it is become so common as to have the tendency handed down in the breed, the progeny of some stallions being more prone to it than others. It is often very sudden in its attack, the eyelids being found swelled and almost closed to avoid the light; they are also very red within, and the haw is half drawn over the surface; the tears flow down the face perpetually, and the whole head is hot: now and then these appearances come on gradually. The suddenness of the attack makes the complaint to be attributed to accident, as blows, hay-seeds within the eye, &c.; and it is frequently difficult to get the owner of such a horse to believe that a constitutional attack, as it usually is, can come on so suddenly. Sometimes as it comes on quickly, so it goes off, the eye, from being opaque and milky, in twenty-four hours becoming clear and almost well. When such an attack has taken place, even if nothing be done, the horse sooner or later amends, and the eye or eyes, — for it is sometimes one, and sometimes both that are so attacked, — become again clear and well, and remain so an indefinite period, from five or six weeks to as many months. Another attack, however, sooner or later follows, to which others succeed, each leaving increased milkiness on the outer coats, and some dimness within the pupil, either speck-like or diffused; and finally the horse becomes blind from *cataract*. When one eye goes blind totally before the other, it is often the means of preventing the future attack on the remaining one; which has given rise to a custom of putting out one eye to save the other, and which has succeeded. As this is a constitutional disease, brought on by artificial habits, as over-exertion, close unhealthy confinement, and heating food; so it is clear the abstraction of all these are necessary to remove the complaint, and to prevent a recurrence; but particularly the close, dark, and unventilated state of the stable should be attended to, as well as the removal of the litter, which retains the volatile alkali of the urine, and irritates the eyes most injuriously. The food should be mild and cooling, and the exercise moderate, but long continued. Under the height of the attack, however, rest is advisable, with moderate light, which may be still further moderated by keeping over the eye or eyes a thick cloth wet with goulard water. (*Vet. Pharm.* 6575.) Sometimes one quarter of vinegar to three quarters of water has been found a useful application; and whichever is used, the eyes and eyebrows should be kept continually wet with it, which

by exciting evaporation will keep the part cool. A seton may be introduced under the eye or jaw. In some cases, blistering the forehead or cheek is found useful; but in every instance bleeding is proper, which should be repeated until the disease lessens. When the horse is very full and gross, physic and alteratives assist the cure. When blistering is used in any part near the eye, the greatest care is requisite to prevent the blistering matter from being rubbed into it. A very peculiar ophthalmic affection is also sometimes occasioned, particularly to the horses of hot climates, by the entrance of a filària or thread-worm into the globe of the eye, which swimming about in the aqueous humour, eventually occasions violent inflammation. The cure consists in letting out the aqueous humour with a lancet, when, the filària escaping with the fluid, recovery follows.

6441. *Gútta serèna or glass eyes*, so called from the peculiar glassy appearance of the eye, arise from a paralysis of the optic nerve. As the eye is not materially altered in appearance, a horse often becomes blind without its being noticed, until his cautious stepping, quick motion of his ears, &c., give notice of the case. On examination it will be found that the pupil remains dilated, however great the light, and the eye is irrecoverably lost. In the very early stages, blisters to the forehead and stimulants to the eyes (as *white vitriol a drachm, water four ounces,*) may be tried, but with faint hopes of success.

6442. *Pole evil.* This complaint commonly requires the attendance of an experienced practitioner: but the prevention is often in the power of owners, and others about horses; and to this point we shall particularly direct their attention. Pole evil is commonly the effect of accident. Repeated small blows of the manger, or continued pressure from hanging back on the halter, &c., will, if not remedied, produce swelling at the nape of the neck, with some tenderness. In this early state, if the collar be removed, and the part be kept continually wet with vinegar and water, the swelling will often disperse; but if, in spite of this, it proceeds to suppuration, let a vent be made for the matter by a seton (6537.) so that it may readily flow out. Introduce nothing healing, but encourage a free discharge, and it may yet heal at once. When such is not the issue, the disease attacks the ligaments, sinuses form, and the matter burrows under the skin and muscles, when a seton must be introduced from the opening above and should be brought out at the bottom: the seton should be then daily wetted with the liquid blister. (*Vet. Pharm.* 6562.) Should this plan fail, escharotics will be required in the form of the *scalding mixture.* (*Vet. Pharm.* 6586.)

6443. *Strangles, vives, or ives.* This disease has been likened to the human measles; because it usually attacks every horse, and most of them at a young period, between three and five years. It is fortunate when it attacks colts at grass, as it seldom occasions inconvenience, which has led some persons into error by turning their horses out as soon as attacked; but it is not found that stabled horses, thus turned out, pass through the disease more mildly, but the contrary, except the disease exists under its very mildest form. White has conjectured that colts breeding the strangles while at grass are afterwards exempt from glanders, but this wants confirmation. Prosser has also affirmed, that inoculation by the matter of strangles is good; because it mitigates the complaint, and renders the horse not liable to any future attack: but the practice has never gained ground. When the strangles occurs in the stable, and now and then also in the field, it proves a severe disease, and shows itself under the appearance of a cold, with cough, sore throat, and swelling of the glands under the jaws, or behind and under the ears. Sometimes there is not much external swelling, and the tumours break inwardly, and nature effects a cure; at others they break outwardly, and the disease runs off that way; and sometimes the swellings disperse either by nature or art, which breeders think unfavourable, as they suppose it renders the animal liable to a future attack, but many so treated pass the remainder of their lives without more affection.

6444. *The treatment of strangles.* When the swelling lingers, and neither comes forward nor recedes, poultices are preferable to fomentations, which, by leaving the horse wet, promote evaporation and produce cold. Peal recommends blistering the part, as the best means of promoting suppuration. The horse should be kept very cool, and bran mashes with warm water should be his principle support, unless the complaint last long, and produce much weakness, when malt mashes should be substituted. Bleeding is only advisable when the early symptoms are violent, as heaving at the flanks, extreme soreness of throat, with much swelling around it, and considerable cough, in which case bleeding and fever medicines are proper.

6445. *Vives, or ives*, is supposed to be a relic of the latter complaint, and it does appear now and then that after the strangles the parotid or vive glands do remain enlarged (6463.), which occasions the disease in question: resolution may be attempted by mercurial frictions; suppuration should be avoided, otherwise the gland may be destroyed.

6446. *Diseases of the mouth, lampas.* All horses, but particularly very young ones, are liable to enlargement of the rugæ or ridges of the palate, dependent not on any local disease confined to the part itself, but occasioned by an affection of the whole passage of the mouth, throat, and stomach. It is usual to attend to the part only, which is scarified or burnt to little purpose, when a mild dose of physic, or gentle alteratives, would prove more certain expedients; to which may be added rubbing the rugæ themselves with bay salt, or with vinegar.

6447. *Bridle sores.* When the bit in colt breaking, or in hard-pulling horses, has hurt the bars, care is requisite to prevent the bone becoming carious. Touch daily with ægyptìacum, and cover the bit with leather, unless total rest can be allowed.

6448. *Diseases of the teeth* are fully treated of under the anatomical description of the bones. (6305.)

Subsect. 4. *Diseases of the Neck.*

6449. *Fistulous withers* are brought on usually by pressure from a saddle with too low or narrow a saddletree; and what has been said both with regard to prevention and cure on the subject of pole evil, will equally apply here also. (6442.)

6450. *Sore throat* is common to horses in colds, in influenzas, and in strangles. (6434. 6443.) It is discovered by the horse chewing his hay, but instead of swallowing he drops it from his mouth, or, as it is called quids it. He likewise shows a disinclination to drink. In every case, the horse finds great difficulty in reaching every thing that stretches his neck downarwds or upwards; his water therefore should be held to him, and his hay should be pulled for him: omission of these services greatly aggravates the sufferings of horses labouring under sore throat.

6451. *Swelled neck.* A very serious swelling sometimes follows on bleeding with a rusty or poisoned lancet, or fleam, and sometimes also from causes not apparent. (6547.)

Subsect. 5. *The Chest.*

6452. *Inflammation of the lungs* is a disease to which the horse is peculiarly liable; as we might *a priori* suspect, from the vast dimensions of his circulatory system, and the vast alteration from a natural state to which we subject him, and thereby increase his pulmonary circulation.

6453. *The causes* are these deviations remotely, but the immediate attack is generally brought on by sudden cold, acting on a heated surface; and thus it is that knackers and collarmakers in frosty weather expect a glut of horses that die from this disease. Hard riding is a very common cause, and high feeding also. It often commences slowly, a hard dry cough has been slightly noticed, but which has occasioned no alarm for two or three days: gradually, however, the cough appears to give the horse pain; he occasionally shivers, and his ears and feet feel colder than the rest of his body; he heaves at the flanks, and the lining of his nose is found to be much more red than usual, in the worst cases it is seen of a purplish hue; the

inside of the eyelids also are tinged with the inflammation. The appetite now becomes affected; and although there is not much apparent pain, except when the horse coughs, yet there is much anxiety of countenance present. The pulse is usually small but quick. If in this state the horse accidentally or erroneously be taken out and subjected to considerable exertion, it is almost always fatal to him: it likewise happens that this complaint is sometimes mistaken for distemper, and, from a fear of profuse bleeding, the only remedy that is to be depended on is omitted, and the horse is lost. At the veterinary college, in these cases, a small dose of aloes is given every six hours, and after being bled and rowelled, the horse is turned out in the open air; and it is affirmed that many recover from this treatment. Certain it is, that the stable in which a horse is placed in this disease can hardly be too cool; but when entirely turned out, his feet and legs cannot conveniently be hand-rubbed, or bandaged up to promote circulation; neither can we blister a horse when turned out, so conveniently; and on blistering we depend as the second source of cure.

6454. *The treatment* is to be commenced by attempts at lessening the action of the arterial system by early and large bleedings, as seven or eight quarts from a large horse, and which should be repeated in five or six hours if he be not relieved in his breathing. Immediately rub into the brisket, on the chest, and behind the fore legs, the blister. (*Vet. Pharm.* 6559. No. 1.) Give half a dose of physic, and assist it by mashes and warm water, which, if not readily taken, horn down. Back-rake also, and throw up the laxative clyster. (*Vet. Pharm.* 6564.) Avoid all exercise, clothe moderately, allow a free circulation of cool air through the stable, and rub the legs frequently; and when not under this process, keep them bandaged up to the knees with hay-bands or woollen cloths. When the bowels are opened, give the fever drink (*Vet. Pharm.* 6580.) three times a day. The terminations of this complaint are various. It is not uncommon for the horse to appear better, to eat and to drink, and to excite every hope of a perfect recovery; but on some sudden exertion he falls down and expires. On examination after death, it is found that effusion of a large quantity of serous fluid has taken place in the chest.

6455. *Thick wind is another termination of pneumònia*, by leaving the bronchial passages charged with coagulated blood. Moderate exercise and soiling in the stable, with mild mercurial physic, form the best mode of treatment; but frequently the cough resists all these, and terminates in broken wind.

6456. *Roaring is also a termination of pneumònia*, in which case the lungs are not affected, but congealed blood, under the name of coagulable lymph, remains in the trachea or windpipe, and obstructs the free passage of the air; by means of which the roaring noise is made. It is in vain to expect a cure: blistering the throat sometimes slightly relieves it.

6457. *Chronic cough is also a termination of pneumònia*, and appears dependent on a peculiar irritability the disease leaves in the bronchial passages, which are found afterwards incapable of bearing any sudden alteration of temperature: thus horses with this kind of cough are excited to it as soon as the stable door opens, and by every exertion, by drinking, by eating, and, in fact, by any thing that alters the situation of the body, or is new to the part. But, besides pneumonia or inflammation of the lungs producing it, it is often brought on likewise by gross feeding, which, weakening the stomach, impoverishes the blood, and thus injures the lungs which are fed by that blood. Worms also by the same means are a cause of chronic cough. It is thus that we expect to derive benefit by mediums acting on the stomach. Green food is often found useful, but particularly carrots. The hay should be excellent in quality and small in quantity; and it will be found that soiling in the stable, but particularly a course of carrots, forms a better plan of treatment than turning out. If worms be suspected, treat as under that head. (6478.) Formulæ of chronic cough balls are seen in the *Vet. Pharm.* (6569.)

6458. *Broken wind is also sometimes brought on by pneumònia*, and sometimes by occult causes. It is often occasioned by over-exertion after full meals, in which the lungs become permanently weakened, perhaps ruptured, in their air-cells. Inexperienced persons find some difficulty in detecting broken wind from other chest affections, as chronic cough, occasional colds, &c. &c.

6459. *Criteria of broken wind.* The cough which accompanies broken wind is a short deep hollow grunting noise, and the short grunting expiration is peculiarly excited by turning a horse quickly round, striking him smartly with a stick at the same time, which often produces the deep sound without the cough; and which is so significant as never to be mistaken when once heard and attended to: but the principal peculiarity arises from the beating of the flanks, which operate rather by three efforts than by two as usual. In the first, the air is drawn in, in the usual manner, and the flanks fill up as in common: but in the next, the falling of the flanks is by no means natural; for it is not done by a gradual sinking of the sides, but it takes place at once, with a kind of jerk, as though the horse were sighing; and then a third effort takes place by a more slow drawing up of the muscles of the belly and flanks, to press out the remaining air. Broken wind usually destroys the fecundity of the mare, and hence argues permanent alteration of structure; it is also always incurable, but horses may be rendered very useful that have it, by feeding them very nutritiously, but with their food much condensed in bulk. Little hay should be allowed, and that little should be wetted, water in any other way should be given but sparingly, for which they are however very greedy: from which circumstance, as well as that they are peculiarly flatulent, we learn, that the vitiation of the lungs is either aggravated by the deranged state of the digestive organs; or, which is more probable, that the digestive powers become weakened from the state of the lungs. In some few cases a partial rupture of the diaphragm or midriff has been observed in broken wind.

6460. *Diseases of the belly.* Inflamed stomach seldom attacks the horse as an idiopathic affection, but it is not unfrequent for the stomach to become inflamed by mineral poisons as well as rendered inert by vegetable ones. Over-distention may also inflame it.

6461. *Mineral poisons inflame the stomach* acutely, and produce excessive distress, and cold sweats; the animal lies down, rolls, gets up again, looks short round to his ribs, stamps with his fore feet, and his pulse beats quick and short. When arsenic or corrosive sublimate have occasioned the malady, a viscid mucus distils from the nose and mouth, and the breath is fetid. When copper in the form of vitriolic salts or verdigris has been given, to the foregoing symptoms are usually added ineffectual attempts to vomit. Immediately the poisoning is discovered, pour down two ounces of *sulphuretted potash*, in a quart of water; or in the absence of that, an ounce of common potash in the same quantity of water: or when no better substitute is at hand, even strong soap-suds are advisable. Mineral poisons have also another mode of acting, and are often received into the constitution, neither by design to do mischief, nor by mistake; but are purposely given as remedies. In this way, both mercury and arsenic are frequently given for worms, glanders, farcy, &c., in daily doses, which, when even of considerable magnitude, occasion for many days no inconvenience; all at once, however, the constitution becomes fully saturated with the poison, and although before diffused throughout the blood, it now appears to return and act on the stomach to the great surprise of the owner. In these cases the symptoms are not usually so violent as in the former instance, but they are equally fatal. A similar treatment with the one already prescribed is necessary; and as soon as the first symptoms are abated, give laxatives. In all these cases, large quantities of linseed tea should be horned down, the back should be raked, and clysters thrown up; blood should also be taken away plentifully. As a preventive to this latter mode of poisoning, whenever mineral agents are used, it is prudent every five or six days to stop a while, and then recommence, by which the constitution will part with the previous quantity.

6464. *Salivation is also another mode of poisoning;* and though not equally injurious to the stomach, it often proves distressing, and sometimes fatal. Whenever, therefore, mercurials are given, carefully watch the gums, and as soon as they look red, and the horse quids his hay, give him a mild purge instead of his mercurial.

6463. *Vegetable poisons also inflame the stomach;* but by no means in an equal degree with the mineral poisons; nor is it supposed that it is the inflammation they raise that proves destructive, but by an effect

communicated through the stomach to the nervous system. Digitàlis purpùrea or foxglove, *T*áxus baccàta or yew, *Œ*nânthe crocàta or water dropwort, *C*icùta virôsa or water hemlock, *P*hellándrium aquáticum or water parsley, *C*ònium maculàtum or common hemlock, are all poisonous in a high degree to horses, and may be taken accidentally by the animal as food, or given injudiciously as medicine. *Nicoti*àna or tobacco, and the vegetable acid or vinegar, are also poisonous, and are sometimes productive of injurious consequences by over-doses, when intended as remedies. It is little known that a pint of strong vinegar has destroyed a horse. As we cannot remove the matters from the stomach, we must endeavour to neutralise their effects by acids and demulcents, as oil, butter, &c.: thus, when narcotics have been taken, a drachm of sulphuric acid or oil of vitriol may be given in a quart of ale; or six ounces of vinegar, with six of gin, and a quart of ale, may be tried. An excellent domestic remedy might be found in two ounces of flour of mustard mixed with ale or other fluid.

6464. *Stomach staggers.* This peculiar complaint, which is even yet but little understood, appears dependent on a particular state of stomach, acting on particular foods; and not on what is taken in acting on the stomach, as was supposed by Coleman, White, and others. From later communications of White, he also now appears to consider it as originating in "a peculiar state of stomach." Blaine appears always to have characterised it as "a specific inflammation of the stomach." It appears among horses of every description, and at grass as well as in a stable; and there is reason to think it epidemic, as it is prevalent in some seasons more than in others. It may, perhaps, be regarded now and then as endemic also; under which circumstance it appears confined to low wet situations, where long marshy grass is abundant, and where noxious aquatic plants mix themselves with the grasses. When it occurs at grass, the horse is found stupidly dull or asleep with his head resting against something. This has occasioned the disease to be called the sleepy staggers: and it has often been confounded with the phrenìtis, or inflammation of the brain. (6429.) In the stable the horse dozes, and rests his head in the manger: he then wakes up and falls to eating, which he continues to do until the distention of the stomach becomes enormous; for the peculiarity of the complaint consists in the total stop that is put to digestion, and the uneasy feel of the distention consequent to such indigestion appears to deceive the horse, and by a morbid excitement to force him to take in more. In this way he continues eating until the distention prevents the return of the blood from the head, and the animal dies apoplectic, or his stomach bursts with over-distention. More frequently, however, the stomach becomes flabby, inert, and paralytic, and after death presents marks of inflammation towards the pylorus.

6465. *The treatment.* When recovery has taken place, it has occurred only when the disease has been very mild, and has been assisted by stimulating the stomach into action by purgatives, at once active and invigorating, as an ounce of aloes dissolved in half a pint of gin. When a horse of extreme value is attacked, croton oil might be tried to the amount of 20 or 25 drops in two ounces of tincture of aloes. Warm water in small quantities, or mixed with common salt, should be frequently passed down. Remove every eatable; rake, clyster, and hand-rub; and, if the determination to the head be extreme, bleed, otherwise avoid it.

6466. *Inflammation of the bowels, enterìtis, or red colic,* is a very distinct disease from the gripes, gullion, or fret, with which it is, however, very apt to be confounded to the destruction of many horses. The peritoneal inflammation of the bowels, the one here treated on, is an affection of their outer covering.

6467. *The causes are various.* It is not unfrequently brought on by a sudden translation of cold after great heats, as swimming during hunting, or from the removal of a horse from grass at once into heated stables; neglected gripes, or long-continued costiveness, excessive riding, and the immediate drinking of cold water, have brought it on. It begins by restlessness, loss of appetite, and some uneasiness; the mouth is hot and dry; the inner membranes of the mouth, nose, and eyelids are often redder than natural. As the disease advances, the pain, before not violent, now increases so as to force the horse to lie down and rise again frequently; and when very violent, he kicks at his belly, or looks round at his sides, pawing his litter very frequently. The pulse is usually small, quick, or hard; sometimes it is more full and small, but always hard. Breathing is quickened, and the flanks heave; the extremities are alternately hot and cold, but continue longer cold than hot; and the animal is costive: sometimes pain may force away a few hardened balls of fæces, but the principal contents are retained. Blaine has given the distinguishing features between this disease and colic, under which head we have stated them.

6468. *The treatment* must be active and immediate, or a fatal termination may be expected. Begin by abstracting a considerable quantity of blood, from a large horse to the amount of seven or eight quarts; proceed to back-rake; throw up a large clyster of warm gruel. Give by the mouth, if the expense be not considered an object, a pint of castor oil, mixed by means of the yolk of two eggs, with half a pint of broth or gruel. If the expense be objected to, give olive oil instead, following it up in half an hour by a gruel drench, in which six ounces of Epsom salts have been dissolved. A sheep-skin, immediately as it is removed from the sheep, may be applied to the belly, which should first be well rubbed with the stronger liquid blister. (*Vet. Pharm.* 6562.) In four hours repeat the bleeding; if a considerable improvement have not taken place, and if the bowels be not unloaded, give more oil, and clyster frequently, having first back-raked. Avoid exercise; first hand rub, and afterwards wrap up the extremities to the knees. As a clear passage for the dung is found, the symptoms mitigate, and the animal slowly recovers; but he must be fed at first very sparingly.

6469. *Inflammation of the inner surface of the intestines* is, in some measure, different from the former, which, as before stated, is an affection of their outer covering; whereas this is usually confined to their villous surface, and may be brought on by superpurgation from over-strong physic, or from mineral acids being taken in, particularly mercurials, which often exert more influence on the bowels than on the stomach. It differs from the former in the symptoms being generally accompanied with purging; neither is there usually so much pain or uneasiness present, nor such cold extremities; but where from the violence of the inflammation these symptoms are present, bleeding to the amount of three or four quarts is a proper preliminary, but can hardly be with propriety continued. The same stimulants to the outside of the belly should be used as in the last disease; but here, warm general clothing is recommended as well as warmth in the stable, as also hand-rubbing to keep up the circulation in the extremities. Give astringent drink (*Vet. Pharm.* 6552. No. 1. or 2.) with a pint of boiled starch every three hours, and give the same by clyster with two quarts of pot liquor, or tripe liquor, free from salt.

6470. *Dysenteric inflammation of the horse's bowels* is happily not very common, but now and then appears, and is then called by farriers molten grease; they mistaking the morbid secretion from the intestines, for the fat of the body melted down and passing off thus: but dysentery is a peculiar inflammation of the mucous surface of the intestines, not contagious as in the human, nor epidemic, nor exhibiting a putrid tendency; but is peculiarly confined to a diseased increase in the mucous secretions, yet very different from simple diarrhœa, which is a mere increase in the peristaltic motion, by which the common aliments are quickly passed through the intestines, and ejected in a liquid form by an increase in their watery secretion. Whereas in the dysentery of the horse, the mucous of the intestines separates from them in large quantities, and comes away with the dung surrounding it; but when it does not pass in this way it appears in membranous films like sodden leather, or in stringy evacuations, like morsels of fat floating in water; sometimes there is a little bloody appearance. The usual symptoms of fever are always present, but not in a very high degree.

6471. *The causes* are cold, over-riding, and not unfrequently acrid substances within the intestines: change of food has occasioned it, and now and then superpurgation from strong physic.

6472. *The treatment.* In the first stages bleed considerably, and give, as the first internal remedy, six ounces of castor oil, which will amend the fæcal evacuations considerably; afterwards administer the

following: — *Powdered ipecacuanha, a drachm; powdered opium, a scruple; liquid arrow-root, eight ounces.* Should this not check the evacuation, and should it continue as mucous as at first, again give castor oil, and then follow it up by either of the drinks directed for the cure of scouring or looseness. (*Vet. Pharm.* 6552.)

6473. *Diarrhœa or looseness.* This complaint originates in an increased peristaltic motion of the intestines, with an increase of their watery secretion, and is distinguished from dysentery by the purging being complete from the first, and seldom occasioning much fever or disturbance in the general health, unless exceedingly violent. The stools are merely solutions of the aliment, and unmixed with membranous films as in dysentery or molten grease. It sometimes succeeds to over-strong physic; at others the food itself enters into new combinations, and forms a purge. Some horses have their bowels constitutionally weak, as lank-sided small-carcased ones, where the mechanical pressure hurries the contents forwards. Salt mashes and sea water will purge horses violently sometimes. In violent cases, horn down liquid starch, and throw up the same by clysters. Give astringents (*Vet. Pharm.* 6552. No. 1.) two or three times a day; keep the animal warm and quiet. In the milder cases and in habitual scouring change the food. The change should be generally from one more moist to one less so, as beans, &c. Barley will sometimes stop looseness; malt usually increases it. Buck-wheat is often a check to habitual diarrhœa. Efficacious astringents will be found in the *Vet. Pharm.* (6552.) Repeat either of these night and morning. Give but little water and that little warm.

6474. *Colic, flatulent or spasmodic*, called also *gripes*, *fret*, or *gullion*, is an important, because a frequent, disease, and because it frequently destroys either quickly by its irritation, or by its degenerating into the red or inflammatory colic, when improperly treated or long continued. It is usually very sudden in its attack.

6475. *The causes of colic are not always apparent.* It is sometimes occasioned by intestinal stones, which accumulate to a great size, remaining for years in the cells of the colon, until some accidental displacement occasions an interruption to the peristaltic motion. Cold in its various forms is a parent of colic; but under the form of cold water given when a horse is hot it is most common. In some horses it is so frequent as to become a constitutional appendage.

6476. *The distinguishing marks between colic and inflammation of the bowels* are gained, according to Blaine, by attending to the following circumstances: — In gripes the horse has violent fits of pain, but they remit, and he has intervals of ease. The pain in red colic is more uniform and less violent. In gripes, the pulse is, in general, natural; in red colic it is quicker than natural, and commonly small. The extremities are not usually cold in gripes; in red colic they usually are. In gripes, the horse attempts to roll on his back, which in red colic he seldom does. There are no marks of fever with gripes, as red eyelids, inflamed nostrils, &c.; but in red colic they are always present. When spasmodic colic has continued some hours, it is always proper to bleed to prevent its ending in inflammation: bleeding in the mouth is quite useless. Back-rake, and throw up clysters of warm water, one after another, as fast as possible, which often overcomes the irritation. La Fosse recommends a curious remedy; but as it can always be obtained, and has the sanction of long experience, it may be tried. An onion is pounded and mixed up with some powdered savin; in default of which, use powdered ginger. This is to be introduced up the rectum as high as possible, and the horse is to be then moved briskly about. An onion put up the fundament whole has long been a domestic remedy. The following is recommended by Blaine: — *Spirit of vitriolic æther, an ounce; powdered opium, one drachm; oil of turpentine, three ounces; warm ale, a pint.* He also recommends the following more simple remedy as always at hand: — *The expressed juice of two or three large onions, common gin, common oil, of each half a pint;* mix and give. White recommends a pint of brandy, or of gin, with water, as an excellent carminative. Clark, who has expressly written on gripes, extols the virtues of a mixture thus made; which, if it have the qualities he attributes to it, and which there is no reason to doubt, no agriculturist, coach or post master should be without it: — *Pimento berry, called also allspice, ground fine, half a pound; spirits of wine, and of water, of each a pint and a half:* infuse these together, and keep for use. Give a quarter of a pint every hour until full relief is obtained; hand rubbing, wisping, or fomenting the bowels with hot water at the time.

6477. *Inflammation of the intestines from wounds in the belly* frequently occurs; and these injuries may happen in leaping over hedges or pale gates, or may be inflicted by the horns of a cow. Sometimes the strong tendinous covering of the belly is ruptured, while the skin remains entire; the gut then protrudes and forces out the skin into a tumour. The first thing to be done is to put the gut back, taking care at the same time, otherwise extensive inflammation follows, to remove any dirt or other matter that may be sticking to it; for which purpose, should it be found necessary, it may be washed with warm water, but with nothing stronger. If the gut cannot be returned, from its being full of air, and the opening in the belly be too small to put it back again, such opening may be carefully enlarged to the necessary size; but if the animal can be thrown upon his back conveniently, a great deal may be done that cannot otherwise be accomplished. After the gut is returned the skin only should be stitched up, and a cushion of several folds of old linen and tow being placed in the wound, it should be kept in its situation by means of a wide bandage rolled round the body, and carefully secured. The animal should then be copiously bled, and have his bowels emptied by clysters. The only food he should be allowed is grass, or bran mashes, and that only in moderate quantity. When the distention of the intestines wholly prevents their return, it would be prudent to puncture them with a very fine instrument, and thus to suffer the air to escape, which, although subjecting the horse to the risk of inflammation, is better than the certainty of death by having the intestines protruded.

6478. *Worms of horses* are of several kinds. First, bots in the stomach; but which, as they mostly attach themselves to the hard insensible part of that organ, seldom do harm. Clark fancifully supposes they do good, and devises means for furnishing them when not in existence. The *bot* is the larva of the *Œ*strus equi, a fly which deposits its eggs, it is supposed, on the grasses on which horses feed, and probably on parts of the horse himself, from whence they pass into the stomach by the food or by being licked off. Certain it is they get there, are hatched, and there remain hanging to the coats of it by two tentaculæ, receiving the juices of the masticated food as nutriment. After a considerable time they make their way out by the anus, drop on the ground, and are first transformed into chrysalids, and afterwards into parent flies. When bots fix themselves on the sensible portion of the stomach they may do harm; but no medicine that we know of will destroy them. The *tères*, or large round worm, sometimes occasions mischief, when it exists in great numbers, such as a staring coat, binding of the hide, irregular appetite, and clammy mouth. The best remedy is the Spigèlia marylándica or Indian pink, in daily doses of half an ounce. *Tæ'nia* are not common in the horse; now and then they exist, and are best combated by weekly doses of oil of turpentine, three ounces at a time, mixed by means of the yolk of an egg with half a pint of ale. The *A'scaris* or thread-worms are best removed by mercurial purgatives. The existence of worms may be known by the appearance of a yellow matter under the tail, and by the disposition the horse has to rub his fundament. Blaine recommends the following vermifuge: — *Powdered arsenic, eight grains; pewter or tin finely scraped; Venice turpentine, half an ounce:* make into a ball, and give every morning. He also recommends salt to be given daily with the food; which agrees with our own experience as one of the best vermifuges known. It is a fact acknowledged by the residents along the sea-coast, that horses troubled with worms will often voluntary drink largely of sea water, and thus cure themselves.

6479. *The diseases of the liver are acute inflammation or hepatìtis, and chronic inflammation or yellows.* *Hepatìtis* is the acute inflammation of this organ, which, like the lungs, stomach, and intestines, may spontaneously take on the affection. The symptoms are not unlike those which attend red colic, but with

less violence. If it be not, however, arrested, the termination will be equally fatal. About the third day the whites of the eyes turn yellow, and the mouth also. Bleeding, blistering, and purgatives form the methods of cure as practised in red colic.

6480. *Chronic inflammation or yellows.* The liver of horses is less complex than that of many other animals, and is therefore not very liable to disease; indeed some authors affirm that the horse is never affected with jaundice, but that the yellowness of skin is a mere stomach affection: this is, however, erroneous; and not only does the liver become hardened and thickened occasionally, but the bile becomes diseased and is thrown out in that state by the blood over the body. If fever be present, bleed, but if the symptoms present no token of active inflammation, give each night ten grains of calomel, and every ten days work it off with a mild dose of physic. It is, however, necessary to remark, that it is not every yellowness of the skin that betokens either an acute or chronic inflammation of the liver. It is the property of every serious inflammation of any of the important organs of the chest and belly, to communicate a portion of the evil to the other organs immediately in conjunction with the liver: thus an affection of the stomach or intestines, of the inflammatory kind, very often occasions redness of the membranes of the nose, eyelids, &c. &c.

6481. *Diseases of the urinary organs.* Inflammation of the kidneys is an idiopathic affection, not one of frequent occurrence; but as brought on by injuries, such as over-riding, heavy loads, or violent diuretics, it is not unfrequent: when idiopathic, it may be the effect either of cold, heating food, or a translation of some other inflammation; in which cases, it comes on suddenly, and assumes the same febrile appearances that other intestine inflammations produce; but there is not often great apparent pain, but a frequent inclination to stale, the quantity made being so small as almost to amount to a stoppage of urine, which is less or more complete, as one or both kidneys are affected. What little urine is made is also at first very thick, and then bloody. When the disease is the effect of external injury, the urine is not so scanty, but is more bloody; and this symptom precedes the other. There is usually much pain and stiffness about the loins; and we learn from Blaine, that a swelling and a paralytic affection of the hind leg, of the side of the affected kidney, sometimes is a feature in the complaint. To distinguish this inflammation from that of the neck or body of the bladder, with which it may be confounded, the same author recommends that the hand be passed up the rectum: when, if the affection belong to the kidneys, the bladder, whether full or empty, will not be hotter than usual; but the contrary occurs when any part of the bladder is the seat of the disease.

6482. *The treatment* must be active, and in most respects similar to what has been recommended for red colic, as regards emptying the bowels, and endeavouring to lessen the arterial action by bleeding; but here we must carefully abstain from irritating the kidneys by diuretics internally, or blisters externally. A newly stripped sheepskin placed over the loins, or active fomentations of hot water, are the only sources of counter-irritation that are proper; neither should diluting liquors be pressed, on account of the distention they occasion, but no evil can arise from frequent warm clystering.

6483. *Inflammation of the bladder.* When the body of the bladder becomes inflamed, there is frequent staling from the very first attack; but when the neck of the bladder is the seat of the evil, the squeezing out of a few drops will only take place when the bladder has become filled, which may be known by passing the hand up the rectum. The treatment will be alike in both cases, and is the same as recommended for the last affection. It must be evident, that warm, mild, and frequent clystering must here be peculiarly advisable.

6484. *Strangury or suppression of urine, incontinence of urine, bloody urine.* Strangury may arise from an injury done to the kidneys, or to the bladder, by strains, or by the absorption of irritating matters. In these cases, bleed if there be fever, and if not, merely give the horse absolute rest; mash him, give gruel, and warm his water for drink. *Bloody urine* should be treated in the same way; some horses have such a natural or acquired weakness of kidneys, as to stale blood with their urine on every occasion of over-exertion: the means frequently used for relief are such as aggravate the complaint, and indeed are often the occasion of it, which are diuretics. Strong diuretics injure horses more than strong physic, and benefit them less than any other of the popular means made use of. In retentions of urine, but particularly in the case of bloody urine, they are absolutely improper.

6485. *Diabètes, profuse staling, or pissing evil.* This disease is more frequently forced on the horse by long-continued diuretics, or from a similar effect brought on by kiln-dried oats, mow-burnt hay, and some green vegetables, than acquired from constitutional indisposition. The horse first stales often and profusely, he then becomes weak and faint, and sweats on any exertion. If it be at all constitutional, his hide is bound from the beginning, and his urine will have a sweet taste; but if his appetite were good, and his coat sleek, bright, and elastic when the urine was first observed to be immoderate, the evil arises from some fault in the feeding, clothing, exercise, or other management of the horse. Examine into these matters, particularly into the food, and next the water. Enquire whether diuretics have been given, under an erroneous supposition of increasing the condition, and alter what may be amiss. If this do not remove the complaint, try the following, after Blaine's directions: — *Liver of sulphur, two drachms; uva ursi, four drachms; oak bark, one ounce; catechu, half an ounce; alum, half a drachm:* give as a daily drink in a pint of water.

6486. *Stone and gravel.* Calculous concretions are not uncommon in the large intestines of horses, where they grow sometimes to an enormous size, lodged in one of the cells usually, and where they occasion but little inconvenience, except a displacement occurs, when serious evils, as colic, inflammation, or total stoppage, follow. In the bladder, stone is very seldom found; and there is reason to believe, that though gravel is a common term in the farrier's list, that it seldom if ever occurs; injuries of the kidneys and bladder being usually mistaken for it.

Subsect. 6. *Diseases of the Skin.*

6487. *Mange is a contagious disease* not uncommon among low-bred and badly kept horses, but which is seldom generated in those properly managed. When it is the effect of impoverished blood, a different course of feeding must be substituted, not heating, but cooling though generous; as, carrots, speared corn, malt mashes, stable soiling, &c. When it arises in full-fed horses, bleed twice, lower the feeding, substituting for corn soilings, carrots, or barn mashes. Give a nightly alterative (*Vet. Pharm.* 6550. No. 1. or 2.), and dress with either of the mange dressings. (*Vet. Pharm.* 6589.) After a cure has been effected, carefully clean all the apartments with soap and water.

6488. *Surfeit will now and then degenerate into mange,* but more generally it is brought on by a fulness of habit acted on by sudden transitions from cold to heat, or heat to cold; it is likewise not unfrequently the consequence of over-fatigue. If it show a disposition to spread, and the skin become scaly and scurfy, treat as under mange; otherwise treat as directed under want of condition. (6425.)

6489. *Warbles* are of the nature of surfeits in many instances, in others they are brought on by the pressure of the saddle, which either suppurate and burst, or become indolent and remain under the name of *sitfasts.* In the early state, bathe them with chamberlye or vinegar: if they proceed to suppuration, refrain; and when they neither go back nor come forward, put on a pitch plaster, and if this do not promote suppuration, let the sitfast be dissected out.

6490. *Warts are common to old horses,* and had better be put up with, unless they be situated in some inconvenient or very conspicuous part. In this case, tie a thread tightly around the root, and the wart will drop off, or it may be cut off. Blaine recommends the following, when warts are too numerous to be so removed: — *Crude sal ammoniac, two drachms; powdered savin, one ounce; lard, an ounce and a half.*

6491. *Hide bound is a state of the skin,* where the interstitial matter between that and the fleshy pan-

nicle is not in a state to allow of its pliancy and elasticity. The binding down of the hide thus closely acts on the hair, which it protrudes in a contrary direction to its naturally inclined position; and thus a staring coat usually accompanies hide binding. In considering the subject of condition (6425.), we have seen that it is not a disease of itself, but is in every instance a symptom only.

Subsect. 7. *Glanders and Farcy.*

6492. *The glanders* is the opprobium medicorum, for hitherto no attempts have succeeded in the cure of more than a few cases. By some peculiar anomaly in the constitution of the horse, although conclusive proofs are not wanting that this and farcy are modifications of one disease, and can each generate the other; yet the one is incurable, while the other is cured every day. When glanders has been cured, the time and labour necessary to accomplish the end has swallowed up the value of the horse; and has also, in many supposed instances of cure, left the animal liable to future attacks which have occurred. The experiments on glanders, pursued at the veterinary college and by White of Exeter, have thrown great light on the disease itself, its causes, connexions, and consequences; but have done little more. From these we are led to conclude that glanders will produce farcy, and that farcy can produce glanders; that glanders is highly infectious, and that such infection may be received by the stomach, or by the skin when it is at all abraded or sore; and it is also probable, that it is received by the noses of horses being rubbed against each other. White's experiments go to prove that the air of a glandered stable is not infectious; but this matter is by no means certain, and should not be depended on without a greater body of evidence.

6493. *The marks of glanders* are a discharge of purulent matter from ulcers situated in one or both nostrils, more often from the left than the right. This discharge soon becomes glairy, thick, and white-of-egg-like: it afterwards shows bloody streaks, and is fetid. The glands of the jaw of the affected side, called the kernels, swell from an absorption of the virus or poison; and as they exist or do not exist, or as they adhere to the bone or are detached from it, so some prognosis is vainly attempted by farriers, with regard to the disease; for in some few cases these glands are not at all affected, and in a great many they are not bound down by the affection to the jaw. As there are many diseases which excite a secretion of matter from the nose, and which is kept up a considerable time, so it is not always easy to detect glanders in its early stages. Strangles and violent colds keep up a discharge from the nostrils for weeks sometimes. In such cases a criterion may be drawn from the existence of ulceration within the nose, whenever the disease has become confirmed. These glanderous chancres are to be seen on opening the nostril a little way up the cavity, sometimes immediately opposed to the opening of the nostril; but a solitary chancre should not determine the judgment. The health often continues good, and sometimes the condition also, until hectic takes place from absorption, and the lungs participate, when death soon closes the scene.

6494. *The treatment of glanders*, it has already been stated, is so uncertain that it is hardly worth the attempt; however, when the extreme value of the horse or the love of experiment leads to it, it may be regarded as fixed by experience, that nothing but a long course of internal remedies, drawn from the mineral acids, can effect it. These have all been tried in their endless variety: White recommends the mildest preparations of mercury, as *æthiops mineral;* under the conviction that the more acrid preparations disturb the powers of the constitution so much, as to destroy as effectually as the disease. At the veterinary college the *sulphate of copper* (blue vitriol) has been long in use. Others have used the *sulphates of iron and zinc.* Clark recommends the daily administration of a drink or ball, composed of the following ingredients: — *Sulphate of zinc*, 15 *grains; powdered cantharides*, 7 *grains; powdered allspice* 15 *grains;* of the utility of which he gives one or two extraordinary proofs, and Mr. Sewell still attaches much importance to its use, in such daily doses as the stomach will bear. Blaine appears but little sanguine as to any medical treatment, but recommends a union of the mineral acids in the same proportions, and with the same cautions, as are detailed under farcy. (6496.)

6495. *The farcy is a disease more easily cured than the glanders*, of which our daily experience convinces us; farcy, or farcin, attacks under distinct forms, one of which affects the lymphatics of the skin, and is called the *bud or button farcy:* the other is principally confined to the hind legs, which it affects by large indurations, attended with heat and tenderness. A mere dropsical accumulation of water in the legs sometimes receives the name of *water farcy;* but this has no connection whatever with the true disease in question. Farcy is very contagious, and is gained from either the matter of farcy or from that of glanders.

6496. *Treatment of farcy.* The distended lymphatics or buds may often be traced to one sore, which was the originally inoculated part; and in these cases the destruction of this sore, and that of all the farcied buds, will frequently at once cure the disease, which is here purely local. But when the disease has proceeded farther, the virus must be destroyed through the medium of the stomach; although, even in these cases, the cure is rendered more speedy and certain, by destroying all the diseased buds, by caustic or by cautery. Perhaps no mode is better than the dividing them with a sharp firing-iron; or if deeper seated, by opening each with a lancet, and touching the inner surface with *lapis infernalis.* The various mineral acids may any of them be tried as internal remedies with confidence; never losing sight of the necessity of watching their effects narrowly, and as soon as any derangement of the health appears, to desist from their use. *Oxymuriate of quicksilver* (corrosive sublimate) may be given in daily doses of fifteen grains; *oxide of arsenic* may also be given in similar doses. The *subacetate of copper* (verdigris) may also be tried, often with great advantage, in doses of a drachm daily. Blaine joins these preparations, and strongly recommends the following: —*Oxymuriate of quicksilver, oxide of arsenic, subacetate of copper, of each eight rains; sulphate of copper, one scruple;* make into a ball and give every morning, carefully watching the effects; and if it be found to occasion distress, divide, and give half, night and morning. The same author professes to have received great benefit from the use of the following: — *The expressed juice of clivers or goose-grass, a strong decoction of hempseeds, and of sassafras, of each six ounces*, to be given after the ball. It remains to say, that whatever treatment is pursued either with respect to farcy or glanders will be rendered doubly efficacious if green meat be procured, and the horse be fed wholly on it; provided the bowels will bear such food: but if the medicines gripe, by being joined with green food, add to the diet bean-meal. When green meat cannot be procured, carrots usually can; and when they cannot, still potatoes may be boiled, or the corn may be speared or malted. As a proof of the beneficial effects of green meat, a horse, so bad with farcy as to be entirely despaired of, was drawn into a field of tares, and nothing more was done to him, nor further notice taken of him, although so ill as to be unable to rise from the ground when drawn there. By the time he had eaten all the tares within his reach, he was enabled to struggle to more; finally, he rose to extend his search, and perfectly recovered.

Subsect. 8. *Diseases of the Extremities.*

6497. *Shoulder strains* are very rare, most of the lamenesses attributed to the shoulder belong to other parts, and particularly to the feet. Out of one hundred and twenty cases of lameness in the fore extremities, Blaine found that three only arose from ligamentary or muscular extension of the shoulder. When a shoulder strain does happen, it is commonly the consequence of some slip, by which the arm is forced violently outwards. It is less to be wondered at than at first seems probable, that farriers mistake foot lameness for shoulder strains, when we reflect that a contracted foot occasions inaction, and a disposition to favour the limb by pointing it forward, which thus wastes the muscles of the shoulder. Seeing one shoulder smaller than the other, the evil is supposed to be there, and it is pegged, blistered, and fired,

or the horse is swam for it to his torture, and the increase of the foot's contraction by the confinement. In real shoulder strains, the toe is dragged along the ground while in motion; at rest it is planted forward, but resting on the point of the toe. When the lameness is in the foot, the horse points his foot forward also, but he does so with the whole limb unbent, and the foot flat. These differences are highly necessary to attend to, as well as the peculiar difficulty which is always apparent in moving down hill, which he does with reluctance, and by swinging his leg round to avoid flexing it. This lameness may be farther brought to the test by lifting up the fore leg considerably, which, if the evil be in the shoulder, will give great pain. The muscles between the fore legs are likewise tumefied and tender in these cases.

6498. *The treatment* consists, when it is recent, in bleeding in the plate vein, rowelling in the chest, and fomenting with hot water two or three times a day. When the heat and tenderness have subsided, first bathe daily with the astringent wash for strains (*Vet. Pharm.* 6555. No. 1.) for a week; and afterwards, if necessary, proceed to blister in the usual manner.

6499. *Strain in the whirl bone.* (6324.) This important joint is sometimes strained, or its ligaments and muscles unnaturally extended, from a greater force being applied to them than their structure is able to bear, or their powers to resist: a læsion takes place of some of their fibrillæ, or in lesser injuries their elasticity is injured by being put on the stretch beyond their power of overcoming again. In all such cases, the parts react, and inflammation follows; by which heat, tenderness, and swelling ensue.

6500. *Treatment.* The first indication is the same in this as in all ligamentary strains, which is to moderate the inflammation by fomentations, &c. &c., and when that has subsided, to endeavour by astringents and bracers to restore the tone of the parts: after which, if any swelling remains, from the extravasated blood becoming organised, to promote its absorption by mercurial frictions, and blistering. This applies to all strains, and will direct the treatment therefore of that of strain in the articulation of the thigh with the body also.

6501. *Strain in the stifle*, is treated in the same manner.

6502. *Strain or clap in the back sinews.* This is generally an injury done to the sheaths of the tendons, or of the ligaments which bind them down. In very aggravated cases, it sometimes occurs that even the tendons themselves are extended beyond their capacity. The heat, swelling, and tenderness are first to be combated by fomentations, and if these be extreme, bleed also, and give a dose of physic. Next proceed to poultice with saturnine applications, until the heat and swelling are reduced: then use tonics, *astringent wash* (*Vet. Pharm.* 6555. No. 1. or 2.): bandage and exercise very carefully. If swelling remain after heat, pain, and lameness are past; or when lameness only remains, after all heat is gone, proceed to blister mildly twice. In all cases of ligamentary extension when the heat has subsided, the part may be considered as in a state of atony; and bandages judiciously applied are then proper, particularly during the day.

6503. *Rupture of the tendons and ligaments of the leg.* It is very seldom that the tendons themselves are ruptured, but the suspensory ligaments are more often so, and the evil is called breaking down. It is usually very sudden, and the fetlock is brought almost to the ground. A perfect cure is seldom obtained; but the inflammation should be moderated by the means already described, and the heels should be raised. A laced stocking or firm bandage, when the inflammation has subsided, is necessary; and firing is often prudent as a permanent bandage.

6504. *Strains of the ligaments of the fetlock and coffin joints* often occur, and may always be distinguished by the heat, tenderness, and swelling. Treat as already described. In all strains of the leg, attended with inflammation, a goulard poultice is a convenient and useful application. The goulard water should be mixed with bran; and a worsted stocking being drawn over the foot, and up the leg, it is first tied around the foot; the poultice is then put in, and the stocking fastened around the leg above the injury. (6536.)

6505. *Mallenders and sellenders* are scurfy scabby eruptions, affecting the back of the knee, and ply of the hock; common only in coarse, low-bred, and in cart horses. Wash with soft soap every day, after which anoint with an unguent formed of equal parts of mercurial ointment, tar, and calamine cerate.

6506. *Broken knees.* The usual cases of broken knees are referrible to wounds in general; and the treatment of them in nowise differs therefrom, with this caution, that here it is more immediately necessary, both for appearance and safety, that if any flap of skin hang apart, to cut it off, or the wound will heal with rugosed edges. But when the joint of the knee is broken into by the violence of the injury, it becomes of a very different nature, and is known first by the extreme lameness and swelling that occur; and next, by the escape of a slippery mucus not unlike the white of an egg. If this continue to escape, violent inflammation follows, and either the horse or the joint are lost by it. Farriers are apt to attempt to stop the flow of the *joint oil*, as it is called, by oil of vitriol, or other escharotics, which treatment is usually followed by the most disastrous consequences. It is, however, necessary to stop the immediate flow, by other means; the best of which is by a fine budding-iron heated. Should the laceration be considerable, this cannot be done; but the treatment must then consist of saturnine poultices, bleeding, low diet, and the other antifebrile remedies, until the swelling has subsided, when apply the astringent paste recommended by Clark, made of pipe-clay and alum, every day; but by no means introduce any escharotics.

6507. *Splints and bone spavins.* The former are usually situated on the inner side of the canon or shank bone; and as they are situated, so they are more or less injurious. When buried, as it were, within the tendons or back sinews, they are very apt to lame the horse seriously; but when situated on the plain bone, unless they be very large, they seldom do much injury. If a splint be early attended to, it is seldom difficult to remove. Blaine recommends the swelling to be rubbed night and morning for five or six days, with a drachm of mercurial ointment, rubbing it well in; after which to apply a blister, and at the end of a fortnight or three weeks to apply another. In very bad cases, he recommends firing in the lozenge form.

6508. *Bone spavin* is an exostosis of the hock bones, the treatment of which in nowise differs from that of splint; except that as a spavin in general is more injurious than a splint, so it is more necessary to commence the treatment early, and to continue it energetically. From the greater complexity of structure in the hock, spavin is not so easily removed as splint, and more usually requires the application of firing.

6509. *Ring bone* is of the same nature, being an exostosis or bony circle formed around the coronet, the treatment of which is the same with that of splint and spavin.

6510. *Blood spavin, bog spavin, and thoroughpin*, are all of them originally of the nature of windgalls, and are nothing more than enlargements of the bursal capsules described in the anatomy, as surrounding tendons, ligaments, and bones, to furnish them with a lubricating medium. By over-exertion or hard work these bursal bags become extended, and their contents increased and distended into puffy swellings in the hock, called, when on the ply, *bog spavin*. The pressure of this sometimes occasions a varicose state of the superficial vein, which passes directly over it on the inner side of the hock, and which enlargement then receives the name of *blood spavin*. When the bursal enlargement extends through the hock, it is called *thoroughpin*. When it is situated below, in the bursæ of the flexor tendons, near the fetlock joint, it receives the name of *windgall*.

6511. *The treatment* of all these cases must be similar in principle, and consists in lessening the distended sac; not as was formerly practised, to the destruction of the horse often, by letting out the contents of these windgalls; but by strengthening the sides of the tumours by stimulants or by pressure. The more active stimulants are the liquid blister (*Vet. Pharm.* 6562.), milder ones are found in the astringent wash. (*Vet. Pharm.* 6555. No. 1.) Bandages assist greatly, when well applied to the part, and in desperate cases firing has been resorted to, which is nothing more than a more violent stimulant, and a more permanent bandage.

6512. *Capulet* is a bursal enlargement of the point of the hock, and is to be treated by friction, astringents, and bandage.

6513. *Curb* is an inflammation of the ligaments at the back of the hock, and is usually removed by astringents. (*Vet. Pharm.* 6555.) When it does not give way to these, the sweating liquid blister may be applied. (*Vet. Pharm.* 6563.)

6514. *Cracks and grease* may be considered as modifications of one and the same affection, and are commonly brought on by some neglect in all horses; but when they occur in any but the thick-heeled low-bred animals, they are invariably so. Over-feeding or under-feeding, but much more frequently the former, will bring it on. A very frequent cause of it is the practice of washing the legs of horses, and suffering them to dry of themselves. In every case, without exception, washing the legs should be avoided, unless they be rubbed perfectly dry afterwards. When horses have long hairs about their heels, and are washed and then left wet, the evil must be doubled; as the evaporation going on, cools and chills the heels, and thus produces a species of chilblain: and we well know how difficult these are to heal when broken. Cracks in the heels very often occur in horses removed too suddenly into full keep from previous straw or grass, or from these to a hot stable; which, by the heat and moisture of the litter, occasions a determination of blood and humours to the legs, and they break out into cracks or scabs, from which issue a bloody ichor, or a more thick matter. Between the sores the hair stares and gets pen-feathered, and the horse finds difficulty and pain in moving.

6515. *The treatment* must depend on the state in which the animal is at present. If there be reason to suspect the horse to be full and foul, bleed, lower his food, soil him in the stable; or mash and give a mild dose of physic. But when some mismanagement is the sole cause, remove that, and if the case be a severe one, by means of an old stocking drawn over the foot, bury the whole heel in a poultice, made of scraped carrots or turnips; which will subdue the irritation, and bring the parts into a state to bear the application of the astringent paste (*Vet. Pharm.* 6557. No. 2.), or if more convenient, of the astringent wash. (*Vet. Pharm.* 6555. No. 1. or 2.) Moderate exercise should be continued, and the heels carefully cleaned from dirt by soft soap and water on each return therefrom; after which, always again apply the astringent.

6516. *Grease* is nothing more than an aggravated state of the same affection, and is more common to the hind than to the fore legs. Coarse fleshy-legged horses are peculiarly prone to the affection, from the great accumulation that takes place in their legs; and from the difficulty that the capillaries find in carrying the increased quantity of lymph upwards. In these, long stable confinement should be avoided, and when that is impossible, it should be counteracted by exercise frequently and judiciously administered. Many cart horses never go out but to work: they often work three days incessantly, or nearly so; and they perhaps rest two days entirely. Can it be wondered at, that the change occasions swelling, acting on the weakness and exhaustion of previous fatigue? and could not this be avoided by turning out for an hour, or walking for half an hour night and morning? Stable soiling should be used; bleeding and physicking also in very bad cases; and when the inflammation and irritation or soreness are great, the poultices recommended for cracks should be applied until these circumstances are removed: afterwards commence the use of some of the astringents recommended. (*Vet. Pharm.* 6555.) White has stated two remarkable cases of grease cured by the application of corrosive sublimate, in the form of a wash, as of *two drachms of sublimate to ten ounces of water*; increasing it to three drachms, if the pain occasioned by the first be not too considerable. Blaine says that the clivers or goose-grass has been known to be of great service in bad cases of grease: half a pint of the expressed juice to be given daily as a drink; and a poultice of the herb to be applied to the heels. In some cases of long standing when the running has ceased, a thickened state of the limb remains, which is best removed by firing, and which likewise is a preventive to a return.

Subsect. 9. *Diseases of the Feet.*

6517. *Founder of the feet is of two kinds*, acute and chronic. *Acute founder* is a disease that, until lately, was less understood than almost any other. After a very severe day's work, or when very much heated, if a horse get a sudden chill by standing in snow or cold water, it is not uncommon for him to be seized with universal stiffness and every symptom of great fever. Such a horse is said to be *body foundered*. By degrees, however, it is observed that the animal has an extreme disinclination to remain on his feet; from whence it will appear that the whole of them are affected. When the horse draws his hind feet under him, his fore only are affected: and when he draws his fore feet under him, the hinder feet are the seat of the complaint; but which is seldom the case. On feeling the feet they will be found intensely hot, and the pastern arteries will beat with great violence. After a few days, unless the disease abate, a separation of the hoofs from the coronet takes place, and at last they fall entirely off.

6518. *The treatment.* At the commencement of the disease bleed largely, as well by the neck as from the toe of each affected foot, by paring, until the blood flows freely. After which immerse each foot in a goulard poultice (6536.), give the fever powder or drink (*Vet. Pharm.* 6578 and 6579.), litter up to the belly; and if amendment do not take place, renew the bleedings, and blister round the pasterns.

6519. *Chronic founder, contraction or fever in the feet.* The artificial life that horses lead subjects them to many diseases; one of the principal of which is that of contracted feet. Blaine considers a neglect of sufficient paring of hoof, the application of artificial heat from hot stables, and hotter litter, the deprivation of natural moisture, constitutional liability, and the existence of thrushes, as among the principal causes of this evil. It is more common to blood horses than to others; and he observes, that dark chestnuts are of all others most prone to it. The appearances of a contracted foot, as contrasted with a healthy one, we have already displayed. (6420.) It is there shown that the contracted hoof becomes longer, higher, and narrower: the heels (*fig.* 837. *a a*) particularly are drawn in, and seem to screw the frog between them, which becomes wasted and thrushy from this pressure. The hinder hoofs are seldom affected.

6520. *The treatment of contraction in the feet.* It is better to prevent, than to be under the necessity of attempting to cure, the evil. Prevention may be practised by avoiding the acting causes. As soon as at all suspected to be likely to occur, keep the hoofs pared low; never suffer the horse to stand on litter, nor allow the stable to be too hot; feed moderately, and never allow the horse to go without daily exercise; whatever increases the general fulness of habit, flies to the feet. Above all, keep the feet moist by means of wet cloths tied loosely around the coronet, falling over the whole hoof, but not extending beyond the edge. Then moisten repeatedly, and stop the feet (6587.) every night. When contraction has already taken place, many plans have been recommended; as jointed shoes by Coleman, Clark, and others; but it is not found that mechanical expansion in this way produces permanent benefit. The most effectual mode is to obviate all previous causes of contraction; and then to thin the hoofs around the heels from each quarter so thin as to be able to produce an impression by means of the thumb: in fact, to remove so much of the horn as is consistent with safety, from the coronet downwards. It is also prudent to put in a score or two from above downwards, drawn a quarter of an inch deep on each side towards the front of the hoof; but whether this be done or not, the front of the hoof should be rasped thin about an inch in width; by which means a hinge is formed, which operates most advantageously in opening the heels. After this is done, tips should be put on, and the horse should be turned out to grass, where he should remain three months, by which time the new formed heels will have reached the ground, and will bear a shoe. This process is fully described by Blaine in his *Veterinary Outlines*, where a plate completely elucidates the operation, and to which we would recommend the reader.

6521. *The pumiced foot* is a very common consequence of acute founder, in which the elasticity of the laminæ becoming destroyed, the support of the coffin bone is removed, and it rests wholly on the sole,

which it gradually sinks from a concave to a convex surface, drawing with it the front of the hoof inwards. In weak, broad, heavy feet, this evil comes on sometimes without founder; the treatment can be only palliative, a wide-webbed shoe exactly fitted to the foot, without at all pressing on it, prevents the lameness consequent to the disease. A shoe exactly the contrary to this has been tried in some cases with benefit, the form of which has been one with a web so narrow as only to cover the crust, but so thick as to remove the feet from accidental pressure. In other cases, no shoe answers so well as a strong bar shoe. (6601)

6522. *Corns* are most troublesome ailments, to which horses are very liable, and which injure and ruin thousands. They are wholly accidental; no horse having any peculiar tendency to them, but being always brought on them by some improper pressure, usually of the shoe, or from something getting in between the shoe and the horny heel. A shoe too long worn is a very common cause, and a still more frequent one is the clubbing the heels of the shoe; neither is it necessary to the production of corns, that the shoe itself should press on the sole; but they are equally produced when the outer horn of the heels or of the bars is the immediate offending part, rendered so by too luxuriant growth, by unequal wear, or by secondary pressure from the shoe, or by gravel working in. (*fig.* 836.) It is the fleshy sole itself that is bruised, from which a speck of extravasated blood follows; and if not immediately relieved, it gathers, or the part becomes habitually defective, and instead of forming healthy horn, it always afterwards forms a spongy substance of extreme sensibility, and thus is always liable to produce pain and lameness when exposed to pressure.

6523. *The treatment of corns* is seldom difficult or unsuccessful at their first appearance, but afterwards it can be only palliative. Blaine directs that, by means of a fine drawing-knife, every portion of diseased horn should be pared away, and the extravasation underneath likewise. Having done this, he advises to introduce some *butter of antimony* into the opening, to place over this some tow, which should be kept in its place by means of a splint. If any contraction of the heels (*fig.* 836. *a a*) be present, it will materially assist the cure to lower them, and to thin the hoof a little around the quarters, and afterwards to put on a shoe without heels opposed to the corn, or a shoe chambered opposite the weak part; or a bar shoe may be applied, so framed as completely to leave the heel untouched. Introduce the butter of antimony once or twice more, with the interval of two days between, and then turn the horse out to grass: in about six weeks' time the foot will be sound. The treatment of corns, when of long standing, does not materially differ; for although they are never wholly eradicated, they may be rendered but little troublesome. The diseased part must be carefully pared out at each shoeing, and such a shoe put on as will completely free the heel from pressure.

6524. *Running thrush is always a dangerous disease*, and few errors in horse management are more glaring than the common one of supposing they are necessary to carry off humours. If less food, more exercise, cool stables, and dry standings, were substituted to correct the fulness, instead of thrushes, which invariably contract the feet whenever they continue any length of time, many valuable horses would be saved to the community. To the cure, begin by clearing out all the fissures of the frog (*fig.* 836. *a a*) from loose ragged horn, and then introduce to the bottom of the sinuses, by means of a thin piece of wood, some of the *thrush paste* (*Vet. Pharm.* 6554.), smeared on tow, which will enable it to be held within the cleft, especially if it be guarded by splints of wood passed under the shoe; renew the dressing daily: turning out to grass may be practised to great advantage for thrushes by this mode of dressing; but without it the disease is sometimes aggravated.

6525. *Sandcracks are fissures in the hoofs*, commonly of those before, and usually towards the inner, but now and then towards the outer quarter also, from above downwards: from the crack, a little oozing of blood or moisture is seen; and the sensible parts underneath getting between the edges of horn, become pressed on and lame the horse. Fire the fissure crossways, so as to destroy the connection between the divided and the undivided parts of the hoof. With melted pitch close up the origin if the oozing be moderate, and bandage tightly. Watch the foot, and if inflammation succeed this plan, remove the dressing.

6526. *Pricks or punctures in the feet* are often very serious evils, either when received by nails in shoeing, or by one picked up on the road, &c. The danger arises from the inflammation, which is always great from any injury done to the sensible and vascular parts within the foot. This inflammation quickly proceeds to suppuration; and the matter is apt to make its way upwards, unless it find a ready vent below. When it does not break out at the coronet, it will often penetrate under the sole, and finally disease the bones, ligaments, or cartilages, and produce quittor. It is very seldom that a horse is pricked in shoeing, but that the smith is aware of it by the peculiarity of the feel on the hammer, and by the flinching of the animal. At such times were he to immediately withdraw the nail a little, enlarge the opening, and introduce some spirit within the puncture, nothing would occur; but on the contrary, he sends the horse home to avoid trouble, who, the next or following day, is found lame, and with his foot hot. If the nail be only driven too near the sensible laminæ, it will only require to be removed, to free the horse from his evil; but if it have been driven through, and have wounded them, then suppuration ensues, and on examining the foot by the pincers when the shoe is removed, he will flinch at the pressure on the diseased part. It is probable, on the removal of the shoe, that matter will at once flow out at the immediate nail hole; if not, the drawing-knife will soon detect the injury. If the heat be great, and instead of matter bloody dark ichor flows out, wrap the foot up in a poultice; but if healthy matter flows out, this will not be necessary: sometimes it is requisite to detach all the horn that is underrun by the matter; but when the injury has not proceeded to this extent, apply over the part a pledget of tow steeped in friar's balsam; tack on the shoe lightly, and retain the dressing by means of *splints*, which are thin pieces of wood (the withy which binds birch brooms is convenient for the purpose) passed under the shoe; repeat the dressing daily, and avoid moisture, which would encourage quittor. A nail picked up on the road, and which passes through the sole, below or through the frog, is to be treated in the same manner, and also when the matter breaks out at the coronet; but when a nail is picked up, and penetrates the coffin joint, which is known by the synovia or joint oil appearing, such opening should be immediately stopped by paring towards the wounded joint, and then applying a heated budding-iron, not to the capsular ligament itself, but to the skin immediately near it; if this be inconvenient, put a pledget dipped in a little butter of antimony just within the opening, but do not press it into the cavity of the joint: if this be insufficient to stop the flow, but more particularly if the original wound penetrated to the bone, it is probable that the bone itself will become, in some measure, diseased, which is known by the rough grating felt at the point of the probe when passed. In this case, enlarge the opening so as to be able to scrape the diseased bone away. *Bruises of the sole*, from whatever cause, will all fall under some of these points of view, according as the case may be.

6527. *Quittor and canker are the consequences of these injuries* when neglected, or originally extensive. In these cases either the bones, ligaments, or cartilages, or all, become diseased; and a cure can only be obtained by removing the diseased parts by the knife or by caustic.

6528. *Treads, over-reach, &c.* A wound on the coronet is not uncommon from one foot being placed on the other; or the hinder foot may strike it, &c. First wipe away the dirt, and remove any loose edges that cannot unite: avoid washing, unless stones and dirt are suspected to be within, and bind up, having first placed over the wound a pledget of lint or tow moistened with balsamic tincture, or tincture of myrrh, or of aloes, &c. *Over-reaching*, or *over-stepping*, is often an injury done to the fetlock joint before, by the hinder foot, or to the back sinew higher up. Sometimes it is simply a violent bruise, at others the laceration is extensive, in which cases treat as a tread; and when no laceration has taken place treat as a bruise or strain.

6529. *Cutting* is a defect to which some horses are liable from their form, as when they turn their toes

out, or have bent legs. Others cut only when they are lean, which brings their legs nearer together. Weak horses cut because they cross their legs when fatigued, and young unfurnished horses cut at youthful periods, and grow out of it afterwards. The part in which a foot interferes with the opposed limb is very different. When it strikes the shank high up it is called *speedy cut*, and is best remedied by wearing knee-boots or rollers. When it is at the fetlock the cutting is at the side, or rather backward, according to circumstances. Some horses cut by the edge of the shoe, others by the hoof at the quarters; and some by the point of the heels. It is to be remarked, that it is better to put up with the evil of cutting, than to do as is too frequently done, which is, to pare away the hoof until it excites contraction. The shoe may be feather edged, or it may be set a little within the cutting quarter; but by no means alter the size or the form of the hoofs themselves, and particularly avoid taking liberties of this kind with the fore feet. Boots, or rollers, are but little trouble to put on, and when not buckled too tight never injure: whereas, to allow a horse to continue to cut produces a callus, and often throws the animal down.

Sect. VI. *Veterinary Operations.*

6530. *The general practices* to be here enumerated are chiefly the treatment of wounds, the application of fomentations, setons, blisters, clysters, and physicking; and the operations of castrating, nicking, bleeding, &c.

Subsect. 1. *Treatment of Wounds.*

6531. *A wound* must be treated, in some measure, according to the part of the horse's body in which it happens; but there are some principles to be observed alike in all horse surgery. There are likewise a few, which, as they differ from the principles of human surgery, should be first noticed, and which should guide the practice of those who might be misled by analogy. The wounds of horses, however carefully brought together and confined in their situation, as well as shut out from the stimulus of the external air, are seldom disposed to unite at once, or, as it is called in surgical language, by the *first intention*. It is always, therefore, necessary to expect the suppurative process: but as the adhesive inflammation does now and then occur, we should never wash a mere laceration with water or other liquids, if no foreign matter, as dirt, &c., be suspected to be lodged within it, still less should we stuff it with candle tow, or tents of any kind. On the contrary, it should be carefully and smoothly brought together, and simply bound up in its own blood; and if it do not wholly unite at once, and by the *first intention*, perhaps some portion of it may; and, at all events, its future progress will be more natural, and the disfiguration less than when stuffed with tents, tow, &c., or irritated with heating oils or spirits. When an extensively lacerated wound takes place, it is common, and it is often necessary to insert sutures, or stitches, into the lips of the wound: and here we have to notice another considerable variation from the principles of human inflammation, which is, that these stitches in the horse, ox, and dog, soon ulcerate out, seldom remaining longer than the third or fourth day at farthest. It therefore is the more necessary to be careful, that by perfect rest, and the appropriation of good bandages, we secure the wound from distortion. In this we may be assisted by strips of sticking plaster, made with diachylon and pitch; but these strips should be guarded from touching the wound itself by means of lint or tow first put over it. When, in addition to laceration in a wound, there is a destruction of substance, then the caution of washing will not apply, as it will be necessary to bathe with some warming spirit, as *tincture of myrrh*, *tincture of aloes*, or *friar's balsam*, to assist in restoring the life of the part, and in preventing mortification. Bleeding must be stopped by pressure and astringents, as powdered alum: when it is very considerable, the vessel from whence the blood comes must be taken up. When great inflammation follows wounds or bruises, counteract it by bleeding, a cooling temperature, opening medicines, and continual fomentations to the part itself.

Subsect. 2. *Balls and Drinks.*

6532. *Mode of giving a ball.* Back the horse in his stall, and being elevated on a stool (not a bucket turned upside down), gently draw the tongue a little out of the mouth, so as to prevent its rising to resist the passage of the hand; the tongue should however not be laid hold of alone, but it should be held firmly by the fingers of the left hand against the jaw. The ball previously oiled, being taken into the right hand, which should be squeezed into as narrow a shape as possible, must be passed up close to the roof of the mouth, and the ball placed on the root of the tongue, when both hands being withdrawn, it will readily pass down. This mode is much preferable, when a person is at all handy, to using a balling iron. At Long's, veterinary surgeon's instrument maker, is sold a clever machine for this purpose.

6533. *Mode of giving a drink.* Exactly the same process is pursued, except that a horn holding the liquid matter is forced up the mouth; the passage being raised beyond the level line, the liquid is poured out from the larger end of the horn, and when the tongue is loosened it is swallowed. Clark, however, ingeniously proposes to substitute the smaller end of the horn, the larger being closed, by which, he says, the horn can be forced up the mouth between the teeth, and poured farther back so as to ensure its not returning.

Subsect. 3. *Fomentations and Poultices.*

6534. *Fomentations* are very commonly recommended of various herbs, as rue, chamomile, St. John's wort, wormwood, bay leaves, &c.; but the principal virtue is to be found in warmth and moisture, which unload the vessels: but this warmth ought not to be too considerable, except when the inflammation is within, as in inflamed bowels. Here we foment to stimulate the skin, and cannot foment too hot: but when we do it at once to an inflamed part, it ought not to be more than of blood heat; and it should be continued long, and when removed the part should be dried or covered, or cold may be taken, and the inflammation increased instead of diminished. *Anodyne fomentations* are made of poppy heads, and of tobacco, and are frequently of great use.

6535. *The method of applying fomentations* is conveniently done by means of two large woollen cloths wrung out of the heated liquors; as one is cooling the other should be ready to be applied.

6536. *Poultices* act in the same way as fomentations in allaying irritation and inflammation; but are in some respects more convenient, because they act continually. It is an error to suppose that poultices, to be beneficial, should be very hot: however hot they may be applied, they soon become of the temperature of the surrounding parts. When poultices are applied to the extremities, a stocking, as has been before stated, is a convenient method of application. When it is drawn over the leg and bound around the lower part of the hoof, or of the pastern, or otherwise, the matter of the poultice may be put within, and it may be then kept in its situation, if high up on the extremity, by means of tape fastened to one part of it, and passed over the withers or back to the other side, and again fastened to the stocking. In this way, also, loose bandages may be retained from slipping down. *Cold poultices* are often useful in the inflammations arising from strains, &c. In these cases bran and goulard water form a convenient medium; but when the poultice is necessarily hot, a little linseed meal added to the bran will render it adhesive, and give it consistence. It is a very necessary caution in this, as in every instance where bandages are wanted around the extremities, to have them broad, and only so tight as to secure the matters contained, as in a poultice, or as in common bandaging.

Subsect. 4. *Setons and Rowels.*

6537. *Setons* are often useful in keeping up a drain to draw what are termed humours from parts; or by their irritations on one part, they lessen the inflammation in another part not very remote, as when applied in the cheek for ophthalmia or inflamed eyes. They also in the same way lessen old swellings by exciting absorption. Another useful action they have is to make a dependent or convenient orifice for the escape of lodged matter: thus a seton passed from the upper part of the opening of pole evil, through the upper part of the integuments of the neck, as low as the sinuses run, will often effect a cure without farther application. The same with fistulous withers, which sometimes run under the shoulder blade, and appear at the arm point; in which cases a blunt seton needle, of sufficient length to be passed down to that point, and to be then cut down upon, will form the only efficient mode of treatment. Setons may be passed in domestic farriery with a common packing needle and a skein of thread, or piece of tape; but in professional farriery they are made by a proper needle armed with tape or lamp cotton, or skeins of thread or silk smeared over with digestive ointment. When the seton needle is removed, the ends of the tape should be joined together, or otherwise knotted, to prevent them from coming out.

6538. *Rowels* in their intention act as setons, and as irritating a larger surface, so when a general drain is required they act better; as in grease, &c.: but when their action is confined to a part only, setons are more convenient. Any person may apply a rowel by making an incision in the loose skin about an inch, separating with the finger its adherences around, and then inserting in the opening a piece of round leather with a hole in the middle smeared with a blistering ointment. Then plug the opening with tow; and in three days, when the suppuration has begun, remove it. The rowel leather is afterwards to be daily moved and cleaned.

Subsect. 5. *Blistering and Firing.*

6539. *Blistering* answers the same purpose as setons; and is practised by first cutting or shaving the hair from the part, when the blistering ointment (*Vet. Pharm.* 6559.) should be well rubbed in for ten minutes, or a quarter of an hour. Some of the ointment after the rubbing may be smeared over the part. The head of the horse should now be tied up to prevent his gnawing or licking. If a neck cradle be at hand, it may also for safety be put on; in which case the head may be let down the third day.

6540. *A neck cradle for blistered horses* is very convenient for other occasions also, when the mouth is to be kept from licking or biting other parts; or to keep other parts from being rubbed against the head. It is of very simple construction, and may be made by a dozen pieces of wood of about an inch and half in diameter, as old broom handles, &c. These bored at each end admit a rope to be passed through; and as each is passed on, a knot may be tied to the upper part of the pieces of the cradle, two inches apart; and those which form the lower part, four inches: by which means the neck will be fitted by the cradle when it is put on; and the horse will be prevented from bending his head to lick or gnaw parts to be protected. When the lower parts of the legs, particularly of the hinder, require blistering, it is necessary to bear in mind that in gross full horses, particularly in autumn, grease is very apt to follow blistering; and almost certainly if the back of the heels below the fetlock be blistered. First, therefore, smear this part over with lard or suet; and afterwards avoid touching it with the ointment. After blistering in summer, the horse is often turned out before the blistered parts are quite sound; in this case guard them from flies by some kind of covering, or they may become fly-blown: and likewise the fourth or fifth day rub into the blistered part some oil or lard to prevent the skin from cracking.

6541. *Sweating or liquid blisters* (*Vet. Pharm.* 6563.) are only more gentle stimulants, which are daily applied to produce the same effects on a diseased part without removing the hair. Of course less activity is expected; yet as the action is repeated, they are often more beneficial even than blistering itself: as in old strains and stiffnesses.

6542. *Firing*, as requiring the assistance of an experienced practitioner, we shall not describe; it will be only prudent to point out that it is a more active mode of blistering; and that it acts very powerfully as a stimulant, not only while its effects last as blisters do, but also after its escharotic effect is over, by its pressure; and in this way it is that it operates so favourably in bony exostosis, as splints and spavins; and in this way it is so useful in old ligamentary weaknesses; because by lessening the dilatibility of the skin it becomes a continual bandage to the part.

Subsect. 6. *Clystering and Physicking.*

6543. *Clystering* should always be preceded by *back-raking*, which consists in oiling one hand and arm, and passing them up the fundament, and by that means to remove all the dung balls that can be reached. The large pewter syringe for clystering is neither a useful nor safe machine. A much better consists in a turned box pipe, to which may be attached a large pig or ox-bladder, by which four or five quarts of liquid can be administered at one time. (*Vet. Pharm.* 6564. to 6567.) The pipe should be previously oiled, by which means it passes more easily: the liquor should then be steadily pressed up; and when the pipe is removed, the tail should be held down over the fundament a little to prevent the return of the clyster. In some cases of a spasmodic nature, as gripes and locked jaw, great force is made by the bowels to return the clyster, and nothing but continued pressure over the fundament can enable it to be retained. *Clysters* not only act in relaxing the bowels, but they may be used as means of nutriment when it cannot be taken by the mouth; as in locked jaw, wounds of the mouth, throat, &c. &c. In locked jaw, it was observed by Gibson, that he kept a horse alive many days by clysters alone: and by clysters also many medicines may be given more conveniently than by the mouth.

6544. *Physicking of horses.* It is equally an error to refrain altogether from giving horses physic, as it is to give it on every occasion, as some do. Neither is it necessary for horses to be bled and physicked every spring and autumn, if they be in perfect health, and the less so, as at this time they are generally weak and faint from the change going on in their coats. Nor is it always necessary to give horses physic when they come from grass or a straw yard; provided the change from the one state to the other be very moderately brought about. But on such a removal, it certainly expedites all the phenomena of condition (6423.), and such horses are less likely to afterwards *fall to pieces*, as it is termed. (6424.) In various morbid states physic is particularly useful, as in worms, hide-bound from too full a habit, &c. &c. It is not advisable to physic horses in either very cold or very warm weather. Strong physic is always hurtful: all that physic can do is as well operated by a mild as by a strong dose, and with infinitely less hazard. No horse should be physicked whose bowels have not been previously prepared by mashing for two days at least before. By these means the physic will work kindly, and a moderate quantity only is requisite. Most of the articles put into the purging balls for horses, to assist the aloes, are useless. Jalap will not purge a horse, nor rhubarb either. Aloes are the only proper drug to be depended on for this purpose, and of all the varieties of aloes the socotorine and Cape are the best. (*Vet. Pharm.* 6584.) Barbadoes aloes are also not improper, but are thought more rough than the socotorine. For formulæ of purging balls, see *Vet. Pharm.* 6584. Blaine gives the following as the process: —

6545. *Physicking process.* The horse having fasted an hour or two in the morning from food, but having had his water as usual, give him his purge, and two hours after offer him a little chilled but not warm water, as is often done, by which horses are disgusted from taking any: it may be here remarked that in this particular much error is frequently committed. Many horses will drink water with the chill taken off, provided it be perfectly clean, and do not smell of smoke from the fire, kettle, or saucepan: but few, very few, will drink warm or hot water; and still fewer, if it be in the least degree greasy or smoky.

After the ball has been given two hours, a warm bran mash may be offered, and a very little hay. He should have walking exercise as usual, moderate clothing, and altogether he should be kept rather more warm than usual. At noon mash again, and give a little hay, which should be repeated at night, giving him at intervals chilled water. On the following morning the physic may be expected to work; which if it do briskly, keep the horse quiet: but should it not move his bowels, or only relax them, walk him quietly half an hour, which will probably have the desired effect. Continue to give mashes and warm water, repeating them every two or three hours to support him. When physic gripes a horse, give him a clyster of warm water, and hand-rub the belly, as well as walk him out. If the griping prove severe, give him four ounces of gin in half a pint of sound ale, which will soon relieve him. On the next day the physic will probably *set*, but should it continue to work him severely, pour down some boiled starch; and if this fail, turn to the directions under diarrhœa. (6473.) The horse should return to his usual habits of full feeding and full exercise by degrees; and if more than one dose be to be given, a week should intervene. It is often requisite to make the second and third doses rather stronger than the first. A very mild dose of physic is likewise often given to horses while at grass in very warm weather, and without any injury. When worms or skin foulness are present, and mercurial physic is deemed necessary, it is better to give two drachms of calomel in a mash the previous night, than to put it into the purging ball.

Subsect. 7. *Castration, Nicking, Docking, &c.*

6546. *The operations of castration, docking, nicking, and that of cropping* (which is now seldom practised), all require the assistance of a veterinary surgeon; and it is only necessary to remark of them, that the after treatment must be the same as in all other wounds. To avoid irritation, to preserve a cool temperature and a moderate diet; and if active febrile symptoms make their appearance, to obviate them by bleeding, &c. &c. It likewise is proper to direct the attention of the agriculturist who attends to these matters himself, that the moment the wound following any of these operations looks otherwise than healthy, locked jaw is to be feared, and no time should be lost in seeking the best assistance that can be obtained. (6432.)

Subsect. 8. *Bleeding.*

6547. *Bleeding* is a very common, and to the horse a very important operation, because his inflammatory diseases, on account of the great strength of his arterial system, run to a fatal termination very soon, and can only be checked in the rapidity of their progress by abstracting blood, which diminishes the momentum of circulation. Bleeding is more particularly important in the inflammatory diseases of the horse; because we cannot, as in the human frame, lower the circulation by readily nauseating the stomach. Bleeding also lessens irritation particularly in the young and plethoric, or those of full habit: hence we bleed in spasms of the bowels, in locked jaw, &c., with good effect. Bleeding is general or topical. *General*, as from the neck, when we mean to lessen the general momentum. *Topical*, when we bleed from a particular part, as the eye, the plate vein, the toe, &c. Most expert practitioners use a large lancet to bleed with; and when the habit of using it is acquired, it is by far the best instrument, particularly for superficial veins where a blow might carry the fleam through the vessel. In common hands the fleam (*fig.* 838.), as the more general instrument, is best adapted to the usual cases requiring the agriculturist's notice. Care should, however, be taken not to strike it with vehemence; and the hair being first wetted and smoothed down, it should be pressed close between the hairs, so that its progress may not be impeded by them. A ligature should be first passed round the neck, and a hand held over the eye, unless the operator be very expert, when the use of the fingers will dispense with the ligature. The quantity of blood taken is usually too small. In inflammatory diseases, a large horse, particularly in the early stage of a complaint, will bear to lose eight or ten quarts: and half the quantity may be taken away two or three times afterwards, if the violence of the symptoms seem to require it; and the blood should be drawn in a large stream to do all the good it is capable of. After the bleeding is finished, introduce a sharp pin, and avoid drawing the skin away from the vein while pinning, which lets the blood escape between the vein and skin: wrap round a piece of tow or hemp, and next day remove the pin, which might otherwise inflame the neck. In drawing blood, let it always be measured: letting it fall on the ground prevents the ascertaining the quantity; it also prevents any observation on the state of the blood, which if it form itself into a cup-like cavity on its surface, and exhibit a tough yellow crust over this cavity, it betokens an inflammatory state of body that will require further bleedings, unless the weakness forbid. After the bleeding, it now and then happens, from rusty lancets, too violent a stroke with the blood stick, or from drawing away the skin too much while pinning up, that the orifice inflames and hardens, and ichor is seen to ooze out between its edges. Immediately this is discovered, recourse must be had to an able veterinary surgeon, or the horse will lose the vein, and perhaps his life.

838

Sect. VII. *Veterinary Pharmacopœia.*

6548. *The following formulæ for veterinary practice* have been compiled from the works of the most eminent veterinary writers of the present day, as Blaine, Clark, Laurenee, Peel, White, &c.; and we can, from our own experience also, confidently recommend the selection to the notice of agriculturists, and the owners of horses in general. It would be prudent for such as have many horses, and particularly for such as live at a distance from the assistance of an able veterinarian, to keep the more necessary articles by them in case of emergence: some venders of horse drugs keep veterinary medicine chests; and where the compositions can be depended on, and the uncompounded drugs are genuine and good, one of these is a most convenient appendage to every stable. The best arranged veterinary medicine chest we have seen was in London, at the veterinary elaboratory of Youatt of Nassau Street, Middlesex Hospital.

6549. *The veterinary pharmacopœia for oxen, calves, and sheep* has been included in the arrangement. When any speciality occurs, or where distinct recipes are requisite, they have been carefully noticed; it will therefore only be necessary to be kept in mind, that with the exception of acrid substances, as mineral acids, &c., which no cattle bear with equal impunity with the horse, the remedies prescribed require about the following proportions: — A large ox will bear the proportions of a moderate-sized horse; a moderate-sized cow something less; a calf about a third of the quantity; and a sheep about a quarter, or at most a third of the proportions directed for the cow. It is also to be remarked, that the degrees in strength in the different recipes are usually regulated by their numbers, the mildest standing first.

6550. *Alteratives.*

1.

Levigated antimony, 2 drachms.
Cream of tartar,
Flower of sulphur, each half an ounce.

2.

Cream of tartar,
Nitre, of each half an ounce.

3.

Æthiops mineral,
Levigated antimony,
Powdered resin, each 3 drachms.

Give in a mash, or in corn and bran a little wetted, every night, or make into a ball with honey.

6551. *Tonic Alteratives.*

1.

Gentian,
Aloes,
Ginger,
Blue vitriol, in powder, of each 1 drachm.
Oak bark in powder, 6 drachms.

2.
Winter's bark, in powder, 3 drachms.
Green vitriol, do., one and a half drachm.
Gentian, do., 3 drachms.
Make either of these into a ball with honey, and give every morning.
3.
White vitriol, 1 drachm.
Ginger or pimento ground, 2 drachms.
Powdered quassia, half an ounce.
Ale, 8 ounces.— Mix, and give as a drink.
4.
Arsenic, 10 grains.
Oatmeal, 1 ounce.
Mix and give in mash or moistened corn nightly.

6552. *Astringent Mixtures for Diarrhœa, Lax, or Scouring.*

1.
Powdered ipecacuanha, 1 drachm.
Do., opium, half a drachm.
Prepared chalk, 2 ounces.
Boiled starch, 1 pint.
2.
Suet, 4 ounces; boiled in
Milk, 8 ounces.
Boiled starch, 6 ounces.
Powdered alum, 1 drachm.
3.
The following has been very strongly recommended in some cases, for the lax of horses and cattle: —
Glauber's salts, 2 ounces.
Epsom do., 1 ounce.
Green vitriol, 4 grains.
Gruel, half a pint.
4.
When the lax or scouring at all approaches to dysentery or molten grease, the following drink should be first given: —
Castor oil, 4 ounces.
Glauber's salts (dissolved), 2 ounces.
Powdered rhubarb, half a drachm.
Powdered opium, 4 grains.
Gruel, 1 pint.

6553. *Astringent Balls for Diabetes or Pissing Evil.*

Catechu (Japan earth), half an ounce.
Alum powdered, half a drachm.
Sugar of lead, 10 grains.
Conserve of roses to make a ball.

6554. *Astringent Paste for Thrush, Foot-rot, Foul in the Foot, &c.*

Prepared calamine,
Verdigris, of each half an ounce.
White vitriol,
Alum, of each half a drachm.
Tar, 3 ounces: mix.

6555. *Astringent Washes for Cracks in the Heels, Wounds, Sprains, &c.*

1.
Sugar of lead, 2 drachms.
White vitriol, 1 drachm.
Strong infusion of oak or elm bark, 1 pint: mix.
2.
Green vitriol, 1 drachm.
Infusion of galls, half a pint.
Mix, and wash the parts three times a day.

6556. *Powder for Cracks, &c.*

3.
Prepared calamine, 1 ounce.
Fuller's earth, powdered,
Pipe clay, do., of each 2 ounces.
Mix, and put within gauze and dab the moist surfaces of the sores frequently.

6557. *Astringent Paste for Grease.*

1.
Prepared calamine,
Tutty powdered,
Charcoal, do. of each 2 ounces.
Yeast enough to make a paste.
2.
To the above, if more strength be required, add of alum and verdigris each a drachm.

6558. *Astringent Wash for Do.*

3.
Corrosive sublimate, 2 drachms.
Spirit of wine or brandy, 1 ounce.
Soft water, 10 ounces.
Rub the sublimate in a mortar with the spirit till dissolved, then add the water. This is a strong preparation, and has often proved successful in very bad cases of grease, which have resisted all the usual remedies.

6559. *Blisters.*

1. A general one.
Cantharides powdered, 2 ounces.
Venice turpentine, do.
Resin, do.
Palm oil or lard, 2 lbs.
Melt the three latter articles together, and when not too hot stir in the Spanish flies.

2.
6560. *A strong cheap Blister, but not proper to be used in Fevers or Inflammations, as of the Lungs, Bowels, &c.*

Euphorbium powdered, 1 ounce.
Oil of vitriol, 2 scruples.
Spanish flies, 6 ounces.
Palm oil or lard,
Resin, of each 1 lb.
Oil of turpentine, 3 ounces.
Melt the resin with the lard or palm oil. Having previously mixed the oil of vitriol with an ounce of water gradually, as gradually add this mixture to the melted mass; which again set on a very slow fire for ten minutes more: afterwards remove the whole, and when beginning to cool, add the powders previously mixed together.

3.
6561. *A mercurial Blister for Splints, Spavins, and Ringbones.*

Of either of the above, 4 ounces.
Corrosive sublimate, finely powdered, half a drachm.

4.
6562. *Strong Liquid Blister.*

Spanish flies in gross powder, 1 ounce.
Oil of origanum, 2 drachms.
Oil of turpentine, 4 ounces.
Olive oil, 2 ounces.
Steep the flies in the turpentine three weeks, strain off, and add the oil.

5.
6563. *Mild Liquid or Sweating Blister.*

Of the above, 1 ounce.
Olive oil or goose grease, one and a half ounce.

6564. *Clysters, a Laxative one.*

1.
Thin gruel or broth, 5 quarts.
Epsom or common salts, 6 ounces.

6565. *Clyster for Gripes.*

2.
Mash two moderate-sized onions.
Pour over them oil of turpentine, 2 ounces.
Capsicum, or pepper, half an ounce.
Thin gruel, 4 quarts.

6566. *Nutritious Clyster.*

3.
Thick gruel, 3 quarts.
Strong sound ale, 1 quart.
or 4.
Strong broth, 2 quarts.
Thickened milk, 2 quarts.

6567. *Astringent Clyster.*

5.
Tripe liquor, or suet boiled in milk, 3 pints.
Thick starch, 2 pints.
Laudanum, half an ounce.
or 6.
Alum whey, 1 quart.
Boiled starch, 2 quarts.

6568. *Cordial Balls.*

Gentian powdered, 4 ounces.
Ginger, do., 2 ounces.
Coriander seeds, do., 4 ounces.
Carraway do., 4 ounces.
Oil of aniseed, a quarter of an ounce.
Make into a mass with honey, treacle, or lard, and give one ounce and a half for a dose.

6569. *Chronic Cough Balls.*

1.
Calomel, 1 scruple.
Gum ammoniacum,
Horse radish, of each 2 drachms.
Balsam of Tolu,
Squills, each 1 drachm.
Beat all together, and make into a ball with honey, and give every morning fasting.

6570. *Drink for the same.*

2.
Tar water,
Lime water, of each half a pint.
Tincture of squills, half an ounce.

6571. *Powder for the same.*

3.
Tartar emetic, 2 drachms.
Powdered foxglove, half a drachm.
Powdered squill, half a drachm.
Calomel, 1 scruple.
Nitre, 3 drachms.
Give every night in a malt mash.

6572. *Diuretic Balls.*

Resin, yellow, 1 lb.
Nitre, half a pound.
Horse turpentine, half a pound.
Yellow soap, quarter of a pound.
Melt the resin, soap, and turpentine over a slow fire; when cooling, add the nitre. For a strong dose, an ounce and a half; for a mild one, an ounce. It should be kept in mind, that mild diuretics are always equal to what is required; and that strong diuretics are always hurtful.

6573. *Diuretic Powders.*

Yellow resin, powdered, 4 ounces.
Nitre, do., 8 ounces.
Cream of tartar, ditto, 4 ounces.
Dose — 6, 8, or 10 drachms nightly, which some horses will readily eat in a mash.

6574. *Urine Drink.*

Glauber's salts, 2 ounces.
Nitre, 6 drachms.
Dissolve in a pint of warm water.

6575. *Embrocations. — Cooling for Inflammations.*

1.
Goulard's extract, half an ounce.
Spirit of wine or brandy, 1 ounce.
Soft water, 1 quart.
2.
Mindererus spirit, 4 ounces.
Water, 12 ounces.

6576. *For Strains.*

Bay salt, bruised, half a pound.
Crude sal ammoniac, 2 ounces.
Sugar of lead, quarter of an ounce.
Vinegar, 1 pint and a half.
Water, 1 pint.

6577. *For the Eyes.*

1.
Sugar of lead, 1 drachm.
White vitriol, 2 scruples.
Water, 1 pint.
2.
Brandy, 1 ounce.
Infusion of green tea, 4 ounces.
Tincture of opium, 2 drachms.
Infusion of red roses, 4 ounces.
3.
Rose water, 6 ounces.
Mindererus spirit, 3 ounces.
4.
Corrosive sublimate, 4 grains.
Alkohol, 1 ounce.
Lime water, 1 pint.
5.
Alum, powdered, 1 drachm.
Calomel, half a drachm.
Mix and insert a little at one corner of the eye. The custom of blowing it in alarms the horse.

6578. *Fever Powders.*

1.
Tartar emetic, 2 drachms.
Nitre, 5 drachms.
2.
Antimonial powder, 2 drachms.
Cream of tartar,
Nitre, of each 4 drachms.

6579. *Fever Drink.*

3.
Sweet spirit of nitre, 1 ounce.
Mindererus spirit, 6 ounces.
Water, 4 ounces.

6580. *Epidemic Fever Drink.*

4.
Sweet spirit of nitre, 1 ounce.
Simple oxymel, 6 ounces.
Tartar emetic, 3 drachms.

6581. *Malignant Epidemic Fever.*

5.
Simple oxymel,
Mindererus spirit,
Beer yeast, of each, 4 ounces.
Sweet spirit of nitre, 1 ounce.

6582. *Fumigations for purifying infected Stables, Sheds, &c.*

Manganese, 2 ounces.
Common salt, ditto.
Oil of vitriol, 3 ounces.
Water, 1 ounce.
Put the mixed manganese and salt into a bason; then, having before mixed the vitriol and water very gradually, pour them by means of tongs, or any thing that will enable you to stand at a sufficient distance, on the articles in the bason gradually. As soon as the fumes rise, retire and shut up the door close.

6583. *Hoof Liquid.*

Oil of turpentine, 4 ounces.
Tar, 4 ounces.
Whale oil, 8 ounces.
This softens and toughens the hoofs extremely, when brushed over them night and morning.

6584. *Purging Medicines*

Balls — very mild.
Aloes, powdered, 6 drachms.
Oil of turpentine, 1 drachm.

Mild.

Aloes, powdered, 8 drachms.
Oil of turpentine, 1 drachm.

Strong.

Aloes, powdered, 10 drachms.
Oil of turpentine, 1 drachm.

The aloes may be beaten with treacle to a mass, adding, during the beating, the oil of turpentine. All spices, oil of tartar, cream of tartar, jalap, &c. are useless, and often hurtful additions.

6585. *Liquid Purge.*

Epsom salts, dissolved, 8 ounces.
Castor oil, 4 ounces.
Watery tincture of aloes, 8 ounces.

Mix. — The watery tincture of aloes is made by beating powdered aloes with the yolk of egg, adding water by degrees; by these means half an ounce of aloes may be suspended in eight ounces of water; and such a purge is useful when a ball cannot be got down, as in partial locked jaw.

6586. *Scalding Mixture for Pole Evil.*

Corrosive sublimate, finely powdered, 1 drachm.
Yellow basilicon, 4 ounces.

6587. *Foot Stoppings.*

Horse and cow dung, each about 2 lbs.
Tar, half a pound.

6588. *Wash for coring out, destroying Fungus, or proud Flesh, &c. &c.*

Lunar caustic, 1 drachm.
Water, 2 ounces.

6589. *Wash for Mange.*

Corrosive sublimate, 2 drachms.
Spirit of wine or brandy, 1 ounce.
Decoction of tobacco,
Ditto of white hellebore, of each 1 pint.

Dissolve the mercury in the spirit, and then add the decoctions.

6590. *Ointments for Healing.*

1.

Turner's cerate, 4 ounces.
White vitriol, powdered, half a drachm.
Lard, 4 ounces.

6591. *For Digesting.*

2.

Turner's cerate, 2 ounces.
White vitriol, 1 drachm.
Yellow basilicon, 5 ounces.

6592 *For Mange.*

Sulphur vivum, 8 ounces.
Arsenic in powder, 2 drachms.
Mercurial ointment, 2 ounces.
Turpentine, 2 ounces.
Lard, 8 ounces.

Mix, and dress with every morning.

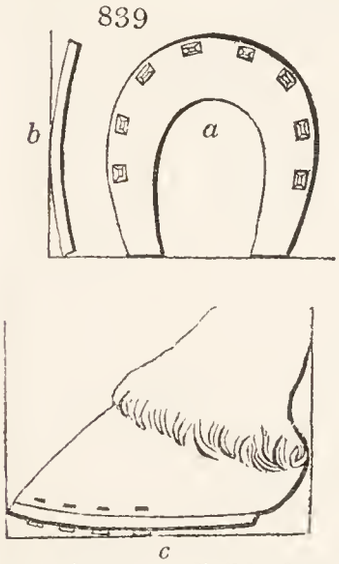
6593. *For Scab or Shab in Sheep, Mallenders and Sellenders in Horses, and foul Blotches and Eruptions in Cattle in general.*

Camphor, 1 drachm.
Sugar of lead, half a drachm.
Mercurial ointment, 1 ounce.

Sect. VIII. *Shoeing of Horses.*

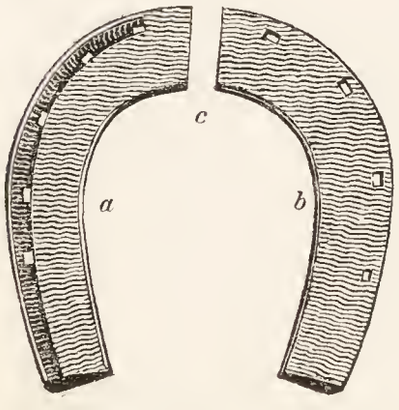
6594. *The importance of the subject of shoeing* to the agriculturist is sufficiently attested by the immense number of inventions which the ingenuity of philosophers and artists are every day devising, to render the system complete. Almost every veterinary professor has his favourite shoe; and we find one of the most ingenious of the present day endeavouring to force on our notice, and introduce into our stables, the French method; which, with the exception of the mode of nailing on, White observes, is the very worst he ever saw. The French shoe (*fig.* 839 *a*) has a wide web towards the toe, and is concave above and convex below (*b*), on the ground surface, by which neither the toe nor heel touch the ground (*c*); but the horse stands pretty much in the same way with an unhappy cat, shod by unlucky boys with walnut shells. But as Blaine observes, in reference to these inventions, "No one form of foot defence can be offered as a universal pattern." It is, he continues, plain that the principles of shoeing ought to be those that allow as little departure from nature as circumstances will justify. The practice also should be strictly consonant to the principles; and both ought to consist, first, in removing no parts but those which, if the bare hoof were applied to natural ground, would remove of themselves. Secondly, in bringing such parts in contact with the ground (generally speaking) as are opposed to it in an unshod state; and above all, to endeavour to preserve the original form of the foot, by framing the shoe thereto; but never to alter the foot to the defence. The shoe at present made at the forges of the most respectable smiths in the cities and large towns throughout the kingdom, if it have not all the requisites, has however, by degrees, been so improved, that with a few additional alterations, neither difficult to direct or adopt, it is the one we shall hold up as the most eligible for general shoeing. It is not that a better might not be offered to notice; and, in fact, such a one we shall present to our readers; but so averse are the generality of smiths from having any improvements forced on them, and so obstinately determined are they to adhere to the forms handed down to them by their forefathers, that their stupidity or malevolence, or both, frequently makes the improvement itself, when seemingly acquiesced in, a source of irreparable injury. It is for these reasons we would recommend to agriculturists in general a modified shoe of the common stamp.

839



6595. *The improved shoe for general use* (*fig.* 840.), is rather *wider* than what is usually made. Its nail holes (*a*) extend no further towards the heels than is actually necessary for security; by which the expansion of these parts is encouraged, and contraction is avoided. To strengthen the attachment, and to make up for this liberty given to the heels, the nails should be carried around the front of the shoe (*c*). The nail holes, on the under or ground surface of the shoe (*a*), are usually formed in a gutter, technically called the *fullering;* but in the case of heavy treading powerful horses this gutter may be omitted, or if adopted, the shoe in that part may be steeled. The web should be quite even on the foot or hoof surface (*b*), and not only be rather wider, but it should also have rather more substance than is common: from half an inch to five eighths in thickness, according to circumstance, forms a fair proportion; when it is less it is apt, in wearing, to bend to pressure and force out the clinches. A great error is committed in setting shoes out so much wider than the heels themselves: this error has been devised to correct another, which has been that of letting horses go too long without shoeing; in which case, if the heels of the shoe were not too wide originally, as the foot grew, they became lost within the heels; and were thus bruised and produced corns: but as we will suppose that few will wish to enter into a certain error to avoid an uncertain one, so we recommend that the heels of the shoe should stand only wide enough to prevent the expansion of the quarters pushing the heels of the feet over the outer edge of the heels of the shoe: for which purpose, if the iron project rather less than a quarter of an inch, instead of three eighths, or even half an inch, as it frequently does, many advantages will be gained. Whoever attentively examines a shoe *well set off* at the heels, as it is termed, will find only one third of its flat surface protecting the heels; the remainder projects beyond, and serves but to form a shelf to lodge dirt on; or as a convenient clip for another horse to tread on; or for the wearer to cut his own legs with; or to afford a more ready hold for the suction of clayey grounds to force off the shoe by. The heels of the common shoe are likewise not in general sufficiently long for the protection of the foot; and which defect, more than a want of width, causes the tendency to press on the crust of the heels. It is further to be observed, that if the decreased width of the outer standing of the heels, and the increased width of the web, should make the inner angle of the shoe heel in danger of interfering with the frog, the corner may be taken off. In forging this shoe, it may be bevelled, or left plain on both surfaces, or rather nearly so, for it is usual with most smiths to thin it in some degree towards the inner edge. This shoe is applicable to most feet, is easily formed, and as such, in country places is all that can be expected.

840



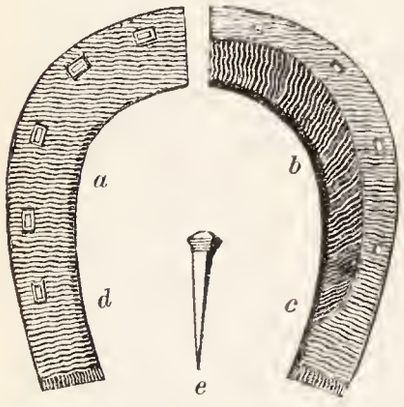
6596. *The injurious effects of bad shoeing* would only require to be known to excite every endeavour to obviate them; and there are some circumstances in the more common shoes of country smiths that ought

to be impressed on the mind of every agriculturist, and guarded against by every one who possesses a horse. It is too frequently observed that the ground side of their shoe is convex, and that the inward rim, when the foot is on the ground, is the lowest part; on which it is evident the weight must first press; and by which pressure, the crust will be forcibly thrust on the extreme edge of the shoe; and the only resistance offered to its being forced from it, depends on the nails and clinches, instead of its just application to the ground, and the support derived from the uniform pressure of the whole. Every shoe should therefore be perfectly level on its ground surface: nor should any shoe be put on that has not been tried on a *plane iron* purposely made for such trial; which irons are kept in some smithies, but are absent from too many. The substance of the shoe should be the same throughout, forming two parallel lines of upper and under surface; in plain language, the heels, instead of being clubbed as is too frequent, should be the exact thickness of the toe. Neither should the width at the heels diminish in the proportion it usually does; on the contrary, for a perfectly formed foot, the web should present a uniform width throughout.

6597. *Varieties in form of foot, differences in size, weight, and uses of horses,* will necessarily make deviations in the form and substance of shoes. The very shoe recommended may be considered as a variation from what would be immediately necessary, were the feet generally perfect; but it is to be considered that there are but very few feet but what have undergone some unfavourable alteration in their form, which makes them very sensible to concussion. It is for this reason, therefore, that it is recommended that a shoe be used, for general purposes, somewhat wider and thicker than the common one. In weak, tender, flexible feet, it will be found particularly advantageous; and here the benefit of wide heels to the shoe will be most apparent. Good as the roads now are, yet most horses are occasionally subjected to travel on bad ones; some know no other: to these the addition of one, or at the most, two ounces to each shoe is nothing; but the ease to the horse, and its superior covering, as well as support, is incalculable. In very young, very light, and very firm feet, the width and substance may be somewhat diminished at pleasure, and particularly in situations where the roads are uniformly good; but a very long and extensive experience has assured us, that the shoe portrayed is one well calculated to meet the ordinary purposes of travelling, and the present state of the art of horse-shoeing.

6598. *An improved shoe on the present plan* (*fig.* 841.), would be found to unite all the perfections of the modern English improvements, with some derived from our neighbours the French. What has since been called a *seated shoe* was introduced by Osmer; but from the obstinacy and ignorance of smiths, as it could not be brought into general use, it became little thought of, until revived by Clark of Edinburgh; by whom it was patronised and recommended. It finally was taken up by Moorcroft, and has ever since attracted some attention, and continues to be forged in some shops where the work is superiorly done; and where the employers have liberality enough to pay for such work, and judgment enough to discriminate between its advantages and those of the common shoe. If to this shoe were added the French mode of fastening it to the foot, we think the improvement would almost shut out all others. On examining the figure it will be seen that this shoe presents a flat surface opposed to the ground (*a*), but a concave one towards the sole (*b*); but that this concavity does not begin, as in some seated shoes, near the outer edge, but embraces two thirds only of the web, leaving by this means a sufficient surface for the crust: but this bevelling is not intended to reach the heels; it stops short of them (*c*), leaving the web at this part plain for the heels to rest upon. The great advantages of this seating are, first, that as the crust rests on a flat surface instead of an inclined plane, as most of the common forged shoes present, so its position is maintained entire, and the inclination to contraction is in a great degree avoided. The nailing on of this shoe we would recommend to be after the French method, which consists in conical nail holes, punched with a square countersink (*d*), into which are received conical nails (*e*); which exactly fill up the countersink; by which means so long as any part of the base of the nail remains, the shoe must be held firmly on, and which is not the only advantage gained; for the nail holes being obliquely formed, and at some distance from the outer rim, act less detrimentally on the crust of the foot.

841



6599. *To prepare the foot for the application of the shoe* is also an important consideration. Avoid taking off more than one shoe at a time; otherwise the edges of the crust become broken away. Observe that the clinches are all carefully removed. Let the rough edges of the crust be rasped away; after which, the sole should be pared throughout until a strong pressure with the thumb can produce some yielding: too strong a sole tends to heat and contraction, too weak a one will not require paring. In this paring imitate the natural arch of the sole as much as possible. The line of concavity should not begin, as it usually is made to do, from the extreme margin of the foot, but should begin from the inner line of the crust only; by which means the crust, or outer wall of the hoof, will have a firm bearing on the flat surface of the shoe. Let no heated shoe be applied to correct the inequalities that may be left, unless it is for a moment, only to observe, but not burn them; but still more carefully avoid putting a plane shoe on an uneven foot. The portion of sole between the bars and quarters (*fig.* 836. *d*) should be always pared out as the surest preventive against corns. The heels also should be reduced to the general level of the foot, never allowing their hardness to serve as an excuse for being left; neither suffer the inner heel to be lowered more than the outer. After all the rest has been done, the frog should be so trimmed as to remain on an exact level with the returns of the heels, and no more. The custom of taking away the point or angle of the horny inflexions of the heels, under the false term of opening the heels, is to be carefully avoided. Let all these operations be performed with the drawing knife. The butteris should never be allowed to come near the foot of any horse but the largest and coarsest of the cart breed.

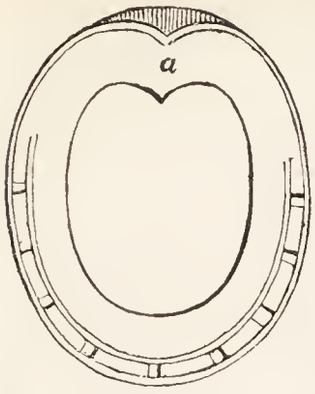
6600. *The shoes for the hind feet are somewhat different to the fore,* being a little squarer at the toe for about an inch; to which squareness the hoof is to be also adapted by rasping it slightly so, avoiding, however, to do it injuriously. By this mode a steady point of bearing is afforded to the hinder feet in the great exertions they are often called upon to make in galloping, leaping, &c. They are, when thus formed, less liable, also, to interfere with the fore shoes by clicking. When horses *click* or *over-reach* very much, it is also common to square, or rather to shorten the toes of the hinder shoes; but not to do so by the horn; by which, the hoof meets the middle of the fore shoe instead of the shoe itself; and the unpleasant noise of the stroke or click of one foot against the other is avoided.

6601. *Varieties which necessarily occur in shoeing.* The *bar shoe* (*fig.* 842.) is the most important variety; and it is to be regretted that so much prejudice prevails against the use of this shoe, which can only arise from its supposed unsightly appearance as betokening unsoundness. As a defence to weak thin feet it is invaluable, as it removes a part of the pressure from the heels and quarters, which can ill bear it, to the frog which can well bear it; but a well formed bar shoe should not have its barred part raised into an edge behind, but such part should be of one uniform thickness throughout the web of the bar, which, instead of being the narrowest, should be the widest part of the shoe. The thickness of the bar should be greater or less (*a*), so as to be adapted to take only a moderate pressure from the frog. When the frog is altogether ulcerated away by thrush, the bar may be altogether plain; but this form of shoe is still the best for these cases, as it prevents the tender surface from being wounded. In corns this shoe is invaluable, and may then be so made as to lie off the affected part, which is the great desideratum in corns.

6602. *The hunting shoe* is made lighter than the common one, and it is of consequence that it is

made to sit as flat to the foot as it can safely do without pressing on the sole; by which the great suction in clayey grounds is much lessened. Hunting fore-shoes should also be as short at the heels as is consistent with safety to the foot, to avoid the danger of being pulled off by the hinder shoes: nor should the web project at all. It is the custom to turn up the outer heel to prevent slipping; which is done sometimes to both fore and hind feet, and sometimes only to the latter. As this precaution can hardly be avoided in hilly slippery grounds, it should be rendered as little hurtful as possible by making the tread equal; to which purpose, thicken the inner heel and turn up the outer. This is better than lowering the outer heel to receive the shoe, which still leaves both the tread and foot uneven.

842

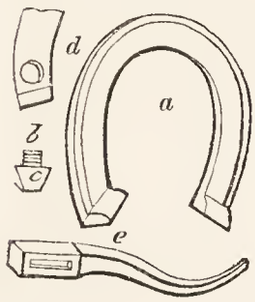


6603. *The racing shoe, or plate*, is one made as light and slender as will bear the weight of the horse, and the operations of forging, grooving, and punching; to enable it to do which, it ought to be made of the very best Swedish iron. Three, or at most four, nails are sufficient on each side; and to avoid the interfering of the hind with the fore feet, the heels of the fore shoes are made as short as they can safely be. As racers are shod in the stable, the owners should be doubly careful that the plate is an exact fit. Many pairs ought to be brought and tried before any are suffered to be put on, and this is more important than is at first considered.

6604. *Grass shoes or tips* are very short pieces placed on the toe alone, in horses turned to grass in summer; at which time they are essentially necessary to guard the fore feet, which otherwise become broken away, and irretrievably injured. They should be looked at occasionally to see that they do not indent themselves into the soles.

6605. *Frost shoes* (*fig.* 843 *a*) have the ends turned up to prevent the foot from sliding; unless the turning up or calkin be hardened, they soon wear level and require to be renewed, to the injury of the foot by such frequent removals. To remedy this, many inventions have been tried; one of the best of these is that of Dr. Moore, in which the frost clip is made distinct and moveable by means of a female screw (*b*) worked in it, to which a knob or wedge (*c*) and male screw (*d*) are adapted; a key (*e*) being used for fixing or removing it.

843



6606. *High calkins*, or turn-ups, however objectionable in general shoeing, yet, in precipitous counties, as those of Devonshire, Yorkshire, and of Scotland, &c., are absolutely necessary for their draught horses. It greatly obviates the evils of uneven pressure, if a calkin be also put to the toe; and it would be still better were these calkins steeled, particularly the fore ones.

6607. *The shoeing of diseased feet* is necessarily very various, and is too often left to the discretion of the smith, by which the evils themselves are greatly aggravated, if he be ignorant. The most prominent alterations for these purposes will be found described under the respective diseases of the feet requiring them.

6608. *Horse pattens* are in use by some cultivators who occupy soft or mossy soils. Those esteemed the best are constructed of alder or elm, and are fixed to the hoof by means of three links and a staple, through each of which passes a leathern strap that goes twice round the hoof, and is fastened by a buckle. The staple is placed behind the patten, which is ten inches one way, by ten and a half the other. The links are about three inches in length, and rivetted through pieces of hoop iron to prevent the wood from splitting. After numerous trials, it has been found that pattens made in this way answer the purpose better than any other kind. (*Farm. Mag.*)

Sect. IX. *Criteria of the Qualities of Horses for various Purposes.*

6609. *The general criteria of the qualities of a horse* are derived from inspection and trial. His outward appearance among judges affords a pretty just criterion of his powers, and a moderate trial usually enables the same judgment to decide on the disposition to exercise such powers.

6610. *The criteria of a horse derived from his colour* have been already noticed. (6298.) As a general principle dark are preferable to light horses, except in the instance of black, which has fewer good horses within its range, particularly in the lighter breeds, than any other. Grey horses are also, in some degree, an exception to the rule; for there are many good greys. Bay and brown are always esteemed colours.

6611. *The criteria of action* are derived from a due consideration of the form generally, and of the limbs particularly; as well as from seeing the horse perform his paces in hand.

6612. *The criteria of hardihood* are derived from the form of the carcase, which should be circular, or barrelled; by which food is retained, and strength gained to perform what is required. Such horses are also generally good feeders.

6613. *The criteria of spirit, vigour*, or mettle, as it is termed, are best derived from trial. It should always be kept in mind, that a hot fiery horse is as objectionable as a horse of good courage is desirable. Hot horses may be known by their disinclination to stand still; by their mettle being raised by the slightest exercise, especially when in company. Such horses seldom last long, and under accident are impetuous and frightened in the extreme. A good couraged horse, on the contrary, moves with readiness as well alone as in company: he carries one ear forward and one backward; is attentive and cheerful, loves to be talked to, and caressed even while on his journey; and if in double harness, will play with his mate. Good couraged horses are always the best tempered, and, under difficulties, are by far the most quiet, and least disposed to do mischief.

6614. *The criteria of a race-horse*, derived from form, are, that he have the greatest possible quantity of bone, muscle, and sinew, in the most condensed form. There should be a general length of parts to afford stretch, scope, and elasticity, with great muscles hardened by condition, to act on the length of these parts advantageously. In particular his hind limbs should be furnished with ample thighs and broad hocks, which should be low set. His fore-arm ought also to be broad, and the knee, like the hock, should be near the ground.

6615. *The criteria of a hunter* are, that he have somewhat similar proportions with the racer, but with more bulk to enable him to continue his exertions longer, and to carry more weight. In him, a good carcase is essentially necessary to fit him to go through a long chase; and the more, if he be required to hunt more than one or two days in the week. Some light carcased horses will do one day's hunting work a week very well, but knock up at more. The hunter should be well formed in his loins, and well let down in his thighs to propel him forward in his gallop, and give him strength to rise sufficiently to cover his leaps. It is also of great use to a hunter to be a good trotter; many such horses, when fatigued, break out of the gallop and relieve themselves by trotting, particularly over heavy ground.

6616. *The criteria of a hackney.* If it be necessary that the hackney be well formed behind to give him strength, and to propel him forward, it is even of more consequence that he be well formed before; and in this kind of horse the hind parts are in some measure subordinate to the fore, as safety is preferable to speed. The head in the hackney should be small, and well placed on a neck of due length and substance to make a proper *appui* for the bridle, and that proper resistance to the hand, so pleasant to the feel, and

so necessary for ease and safety. The shoulders should be oblique and well furnished with muscle, but not heavy; and the withers in particular should be high. The elbows should be turned rather out than in, and the legs should stand out straight, and by no means fall under the horse, or it betokens a stumbler. The pasterns should neither be too oblique, which bespeaks weakness; nor too straight, which wears the horse out, and is unpleasant to the rider. The carcase should be round, or the horse will be washy and weak; the loins straight, wide, and ribbed home; the thighs of good substance; and although the being cat-hammed, or having the hocks turned inwards, is defective in beauty, it often bespeaks a trotter.

6617. *The criteria of a cavalry horse* are, that he have considerable extention of bulk or size, to enable him to carry weight, with good carcase to allow him to feed coarsely, and yet thrive at picket or on service. He should have also liberty of action; but great speed is not requisite. The best cavalry horses are those formed of the united properties of hackneys and very light draught horses.

6618. *The criteria of road horses for quick draught*, or coach, chariot, stage and post chaises, &c., are derived from the immediate purposes for which they are intended; as requiring either strength or speed in greater proportions. To make them safe, the fore-hand should rise, the back should be straight, the step should be short but quick, which fatigues least. As they approach the hunter in form, they are best fitted for quick work; and as they resemble the best kind of light agricultural horses, they are calculated for heavy draught, as coaches, &c. But in all, a portion of blood gives courage, durability, and condenses strength into lessened bulk; by which activity is gained. It is of great consequence to a coach-horse that the neck and head be so formed as to be enabled to rein-in well to the bridle.

6619. *The criteria of a dray-horse* are, that he be very broad-breasted and muscular, and thick in the shoulders, which should not lie backward. Nor should the fore-hand be up, as recommended in the road-horse; for, by holding up their heads, such horses may be choked by the collar, as they would, if so formed, draw too much by the throat, and their wind being thus stopped, would be in danger of falling down. The neck of a dray-horse is not the better for being long, and the head should be proportionate to it. Like all horses, he should be chosen with short legs, and good strong hoofs. He ought to be thick in his thighs, and large in bone; but above all, he ought to be a steady collared horse, with courage to make him true to a severe pull; and yet, without a hot fiery spirit to make him fretful.

6620. *The criteria of a waggon horse* are, in some respects, different from those of the dray-horse. He should be more weighty, and altogether larger. Rapidity of motion is greatly subordinate, in the heavy stage-waggons usually seen on our roads, to strength. It is all collar work; nothing is gained from the momentum of the dragged mass, which, the instant the pull ceases, stands still. The waggon horse should be patient in the extreme; willing to lie to his collar up-hill, and yet settle into his share of work on level ground. As his exertions are constant, it is of the greatest consequence that he be a good feeder.

6621. *The criteria of a horse peculiarly adapted to the labours of agriculture*, are thus given by Culley: — His head should be as small as the proportion of the animal will admit; his nostrils expanded, and muzzle fine; his eyes cheerful and prominent; his ears small, upright, and placed near together; his neck, rising out from between his shoulders with an easy tapering curve, must join gracefully to the head; his shoulders, being well thrown back, must also go into his neck (at what is called the points) unperceived, which perhaps facilitates the going much more than the narrow shoulder; the arm, or fore-thigh, should be muscular, and tapering from the shoulder, to meet a fine, straight, sinewy, and bony leg; the hoof circular, and wide at the heel; his chest deep, and full at the girth; his loins or fillets broad and straight, and body round; his hips or hooks by no means wide, but quarters long, and the tail set on so as to be nearly in the same right line as his back; his thighs strong and muscular; his legs clean and fine-boned; the leg-bones not round, but what is called *lathy* or flat.

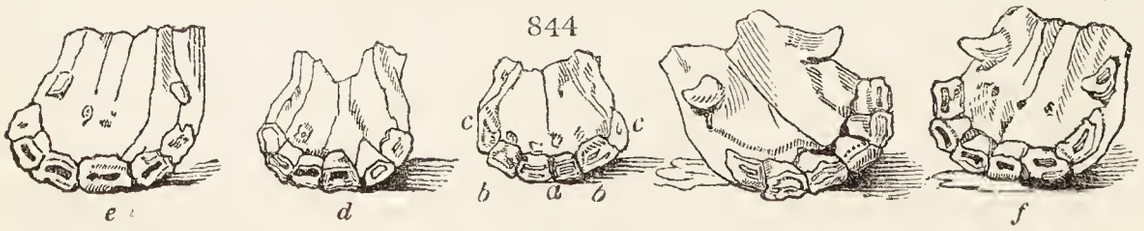
6622. *The chief points in a farming cart-horse*, in the opinion of the author of the *New Farmer's Calendar*, are, "neck not long, nor too thick; short legs, rather flat than round and gummy; fore-feet even, not too distant; wide chest; strong, but not high, shoulders; considerable length of waist, supported by a wide loin; quarters full, and rather raised; strong muscular thigh; size, fifteen hands one inch to sixteen hands high. Being somewhat forelow gives them an advantage in draught; and a moderate length of waist insures speed in the walk.

6623. *The horse used in husbandry*, according to the writer of the *Experienced Farmer*, ought to be larger, but in other respects like the road horse: and, instead of walking two or three miles an hour, be able to walk four or five. In that case he would be able both to plough more land in a given time, and work in the cart or waggon with more despatch, when wanted. In harvest time, a nimble and strong horse is valuable. In drawing manure into the field, or corn to the market, the farmer will also find his account in strength and activity; for, as the draught in all these cases is light one way, such horses would do their business with speed. The small farmer need not with this kind of horse keep an idle one; he might carry his master to market, and plough the remainder of the week.

6624. *In a horse for the plough*, according to Brown, both strength and agility are required; a dash of blood, therefore, is not disadvantageous. It is not size that confers strength, the largest horses being often soonest worn out. A quick even step, an easy movement, and a good temper, are qualities of the greatest importance to a working horse; and the possession of them is of more avail than big bones, long legs, and a lumpy carcase. To feed well is also a property of great value; and this property, as all judges know, depends much upon the shape of the barrel, deepness of chest, strength of back, and size of the hips or hooks with which the animal is furnished. If straight in the back, and not over short, high in the ribs, and with hooks close and round, the animal is generally hardy, capable of undergoing a great deal of fatigue, without lessening his appetite, or impairing his working powers; whereas horses that are sharp pointed, flat ribbed, hollow backed, and wide set in the hooks, are usually bad feeders, and soon done up when put to hard work.

6625. *The criteria of a horse's age* are derived from the appearance of the teeth. According to La Fosse the younger, there are these appearances. The horse is foaled with six molar or grinding teeth in each jaw (*fig.* 844. *a*); the tenth or twelfth day after, the two front nippers (*a*) appear above and below, and in

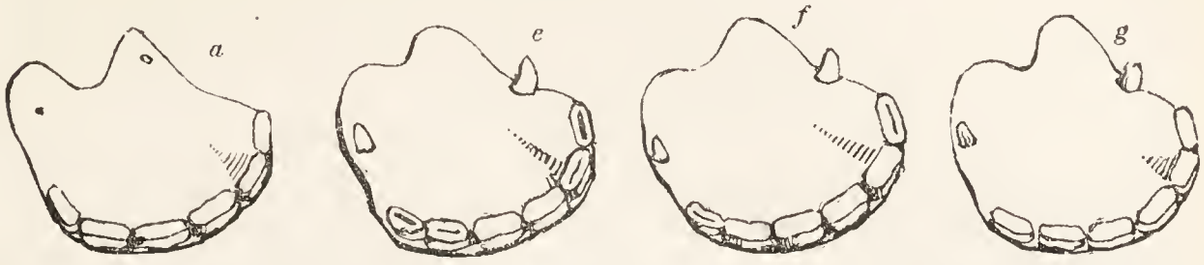
844



fourteen or fifteen days from this, the two intermediate (*b b*) are pushed out; the corner ones (*c c*) are not cut till three months after. At ten months the incisive or nippers are on a level with each other, the front less than the middle, and these again less than the corners; they at this time have a very sensible cavity (*d*). At twelve months this cavity becomes smaller, and the animal appears with four molar teeth on each side, above and below, three of the temporaneous or colts', and one permanent or horse tooth: at eighteen the cavity in the nippers is filled up, and there are five grinders, two of the horse, and three temporaneous: at two years (*fig.* 845.), the first of the colt's molar teeth in each jaw, above and below, are displaced. at two years and a half, or three years, the front nippers fall and give place to the permanent ones: at three and a half the middle nippers are likewise removed, at which period the second milk-molar falls: at four years the horse is found with six molar teeth, five of his new set, and one of his last: at four years and a half the corner nippers of the colt fall and give place to the permanent set

(*fig.* 844. *e*), and the last temporaneous grinder disappears: at five years old the tushes in the horse usually appear. at five and a half they are completely out, and the internal wall of the upper nippers, which

845



before was incompletely formed, is now on a level with the rest; at this period the incisive or nippers have all of them a cavity formed in the substance between the inner and outer walls (*fig.* 844. *f*), and it is the disappearance of this that marks the age: at six years those in the front nippers below are filled up (*fig.* 845. *e*), the tushes are likewise slightly blunted: at seven years the mark or cavity in the middle nippers is filled up, and the tushes a little more worn (*fig.* 845. *f*): at eight years old the corner nippers are likewise plain, and the tushes are round and shortened (*fig.* 845. *g*). In mares, the incisive or nippers alone present a criterion (*fig.* 845. *a*); at this period the horse is said to be aged, and to have lost his mark; but among good judges the teeth still exhibit sufficient indications. At nine the groove in the tushes in worn away nearly, and the nippers become rather rounded: at ten these appearances are still stronger: at twelve the tushes only exhibit a rounded stump, the nippers push forward, become yellow, and as the age advances, appear triangular and usually uneven.

6626. *M. St. Bel*, the late professor of the English Veterinary College, used to assert, that after eight years the cavities in the anterior or upper incisive teeth are filled up with equal regularity; thus from eight to ten the front ones were filled up, from ten to twelve the two middle, and from twelve to fourteen those of the corner; but though some pains have been taken to ascertain this, it does not appear that the disappearance of the cavities in these teeth is attended with sufficient regularity to warrant implicit confidence.

6627. *To make a colt appear older than he really is*, both breeders and dealers very commonly draw the nippers, particularly the corner ones; by which means the permanent set which are underneath immediately appear, and the animal is thus fitted for sale before he otherwise would be.

6628. *To make a horse look younger than he really is*, dealers perform an operation on the teeth called bishopping (from the name of a noted operator); which consists in making an artificial cavity in the nippers, after the natural one has been worn out by age, by means of a hard sharp tool; which cavity is then burned black by a heated instrument. But no art can restore the tushes to their form and height, as well as their internal grooves. It is, therefore, common to see the best judges thrust their finger into a horse's mouth, contenting themselves with merely feeling the tush. To less experienced judges other appearances present themselves as aids. Horses, when aged, usually become hollow above the eyes, the hoofs appear rugged, the under lip falls, and if grey, they become white. In this country, where horses are so early worked before the frame is consolidated, and where afterwards they continue to be exerted unceasingly on hard roads, it is not uncommon to find a horse at six years old feeble, debilitated, and exhibiting all the marks of old age, except in his mouth; on the contrary, when the animal falls into other hands, at ten or twelve he has all the vigour of youth, and his teeth are the only parts that present an indication of age: it is, therefore, more useful to examine the general appearance of the animal, than to be guided altogether by the marks in the teeth; a too strict adherence to which, Blaine observes, lead into great error on the subject of the age of horses. The commonly received marks, he says, grant not a criterion of a third of the natural life of the animal, nor of one half of the time in which he is perfectly useful. Many good judges will not purchase a horse for hunting earlier than eight years old, and regard him only in his prime at twelve. A gentleman at Dulwich has a monument to the memory of each of three several horses which died in his possession at the age of thirty-five, thirty-seven, and thirty-nine years; the latter of which was suddenly taken off by a fit of colic, having been in harness but a few hours before. Culley mentions a horse of forty-five; and an instance lately occurred of one which lived to fifty. Blaine, in continuation, draws the following comparison between the relative situations of the state of the constitution, between the horse and man, under the ordinary circumstances of care towards each: — The first five years of the horse may be considered as equivalent to the first twenty of a man; a horse of ten as a man of forty; of fifteen as a man of fifty; of twenty as a man of sixty; of twenty-five as a man of seventy; of thirty as a man of eighty; and of thirty-five as a man of ninety. (*Vet. Outlines*, p. 35.)

Sect. X. *Breeding of Horses.*

6629. *The general principles of breeding* we have already laid down at length (2023.), and have here to notice what are considered the best practices in the choice of stallions and mares, and in the treatment of the latter during pregnancy. Unfortunately, however, much less attention has been paid to breeding horses, than to breeding cattle or sheep; though, as Brown has observed, a pound of horse-flesh is worth two of that of any other stock; and it costs just as much to breed a bad horse as a good one. Every one, an eminent writer observes, exercises some degree of judgment in regard to the stallion; but there are few breeders, comparatively, who hesitate to employ very ill-formed and worthless mares, and often solely because they are unfit for any thing else than bringing a foal. All the best writers on agriculture reprobate this absurd and unprofitable practice. "In the midland counties of England, the breeding of cart horses is attended to with the same assiduity as that which has of late years been bestowed on cattle and sheep; while the breeding of saddle horses, hunters, and coach horses is almost entirely neglected; or left almost wholly to chance, even in Yorkshire, — I mean as to females. A breeder here would not give five guineas for the best brood mare in the kingdom, unless she could draw or carry him occasionally to market; nor a guinea extraordinary for one which could do both. He would sooner breed from a rip, which he happens to have upon his premises, though not worth a month's keep. But how absurd! The price of the leap, the keep of the mare, and the care and keep of her progeny, from the time they drop to the time of sale, are the same, whether they be sold from ten to fifteen, or from forty to fifty pounds each." (*Marshal's Economy of Yorkshire*, vol. ii. p. 166.) A little consideration will show this error in a still stronger light, when we consider, that united with the characteristic marks common to the breed in general, the progeny of two individuals always exhibits traits of resemblance to each; and as the defects are as certainly propagated as the excellencies, so a neglect in being equally careful in our selection of the female as the male parent is actually bespeaking deformity. It being also now and then observed, that a stronger resemblance is borne to the mother than to the father; so the chances of a worthless colt are increased. It having likewise been remarked, that every variety has a tendency to breed back towards its original, so a breed thus constituted can hardly admit of amelioration, but remains stamped by its original erroneous selection. These remarks, it is hoped, will encourage our breeders to be less indifferent to the choice of their breeding mares.

6630. *In those districts where the breeding of horses is carried on upon a large scale and a regular plan*, the rearing of stallions forms in some degree a separate branch; and is confined, as in the case of bulls

and rams, to a few eminent breeders. These stallions, which are shown at the different towns in the vicinity, sometimes sent to be exhibited at a considerable distance, are let out for the whole season, or sold to stallion men, or kept by the breeder himself, for covering such mares as may be offered, at a certain price per head; and this varies according to the estimation in which the horse is held, and sometimes according as the mare has more or less of what is called blood. For farm mares, the charge for covering by a stallion of the same kind is commonly about a guinea, with half-a-crown to the groom; and it is a common practice in the North, to agree for a lower rate if the mare does not prove with foal; sometimes nothing more is paid in that case than the allowance to the groom.

6631. *In choosing the parents*, or stallion and mare, regard must be had to the kind of stock desired to be bred. Whatever may be the particular purpose of the breed, a stallion ought first to possess all the general properties of a good horse, and next the characteristic criteria of the desired stock. The produce, whether a male or female, much more frequently acquires and retains the form, make, marks, and disposition of the sire than the dam. On this account, stallions with the least appearance of disease, blemish, or bodily defect of any kind, where there is the slightest probability of its being transmittted to the offspring, should be rejected as improper. And it is even considered by some necessary to descend to the minutiæ of symmetry in the head, neck, shoulder, forchead, ribs, back, loins, joints, and pasterns, attending even to a strict uniformity in the form, make, and texture of the hoofs: it is also of importance to ascertain the temper and disposition of both sire and dam, in order to avoid the procreation of vices or imperfections. But provided either parents be free from hereditary infirmities, disorders which arise from accident are of no consequence.

6632. *The general properties required in a breeding mare*, are a good shape, a gentle disposition, a large carcase conformably to her height, and belly well let down; she must be perfectly free from all sorts of blemishes and defects. The size, frame, bone, strength, and blood, will of course be regulated by the purposes of the breeder.

6633. *The mare which is intended to supply draught colts* should, according to the author of the *Synopsis of Husbandry*, be large-limbed, close-jointed, short-docked, wide-chested, home-ribbed, with a capacious body; her eyes good, and her nostrils large and open; in disposition she ought to be gentle and tractable; of a constitution healthy and vigorous, free from any blemishes either hereditary or acquired. The horse should be bold and spirited, well made, and of a kindly disposition; his constitution should be strong, his temper good, and, in short, neither in mind or body ought he to be contaminated with vices or disease of any kind; since on the good qualities and strength of constitution in the sire and the dam depends, in a great measure, the future welfare of the colt.

6634. *The age at which horses should be allowed to breed* is not determined by uniform practice; and is made to depend, in some measure, on the degree of maturity, which, in animals of the same species, is more or less early, according to breed and feeding. Yet it would seem, in general, to be an improper practice to allow animals of any kind to propagate, while they are themselves in a raw unformed state, and require all the nutriment which their food affords, for raising them to the ordinary size of the variety to which they belong. It may, therefore, be seldom advisable to employ the stallion till he is about four years old, or the mare till she is a year older, and if the stallion be five also it is better, and still more so if he be six or seven. But the greater number of mares left for breeding are not very young; being in many cases not allowed to bring foals till they are in the decline of life, or otherwise unable to bear their full share in rural labour.

6635. *Three months before a stallion is sexually employed*, he should be fed with sound oats, peas, or beans, or with coarse bread, and a little hay, but a good quantity of wheat straw; he should be watered regularly, and have long continued walking exercise every day, but he should not be over-heated. If he be not prepared and put in condition, the colts will be likely to be weakly, and the horse himself will become injured, begetting humours, or becoming broken-winded. If he be put to too many mares, he will not last long; his mane and tail will begin to fall off through weakness, and it will be difficult to get up his flesh again by the next year. The number of mares should be proportioned to his strength, and twelve, fifteen, or at the most twenty, are as many as a horse will well serve for in a season. This number, indeed, is thought by many too few, and in Suffolk, we are informed on the best authority, the stallions serve from fifty to seventy, and even eighty mares in a season.

6636. *The usual season for the generative process* is from the beginning of April to the beginning of July. The month of June is considered the best season in this country; although from the middle to the end of May is more approved of on the Continent, particularly in Normandy, where the farmers devote much of their attention to this branch of husbandry; and in which, especially in regard to useful farm horses, they have succeeded, perhaps, beyond those in any other part of Europe. This difference, as to the time when a mare should be allowed to take the horse, in the different countries, is easily reconcileable: a mare goes eleven months and a few days with foal; and the great object with all farmers, where practicable, is to have her covered at such a period as to ensure abundance of grass, and the return of warm and comfortable weather at the period of foaling. An early colt is always to be preferred to one that falls late in the season. It is generally understood, and is an opinion that is believed to be well founded, that a mare may be covered on the ninth day after she has foaled, with a greater degree of success than at any other period. This practice is, of course, often followed; but in such cases the mare ought, Donaldson thinks, to be fed in an extraordinary manner, otherwise it is impossible she can do justice to her present and her future foal. But modern farmers would probably, he says, come nearer their purpose, were they to follow the example of the Romans, and content themselves with one foal in the two years.

6637. *At the season of parturition, there should be a suitable supply of food for the mother and young.* The time of covering mares ought, therefore, to be partly regulated by a due regard to this circumstance, and may be earlier in the south than in the north, where grass, the most desirable food both for the dam and foal, does not come so early by a month or six weeks. In Scotland, it is not advantageous to have mares to drop their foals sooner than the middle of April; and as the period of gestation is about eleven months, they are usually covered in May, or early in June. But if mares are intended to bring a foal every year, they should be covered from the ninth to the eleventh day after foaling, whatever may be the time; and the horse should be brought to them again nine or eighteen days afterwards.

6638. *In breeding horses on a large scale* it is easy to contrive so that all the foals may be brought forth at a time when there is plenty of grass. About the end of May the mares are to be put into an enclosure capable of feeding them as long as the stallion is to be with them, or that they are in season. In this enclosure all the mares are to be put together, as well those which are barren as others. The stallion's hind shoes are to be taken off, but the fore shoes should be left, or tips put on to preserve his feet; then lead him forth, and let him cover a mare twice in hand, to render him more tame and gentle. After this take off the bridle and turn him loose among the rest, where he will become familiar with them, and not one of them will be horsed but when they are in season. There should be a little lodge built up in some part of the enclosure, and peas, beans, oats, bread, and other good food, put into the manger in it, that the horse may retire into it in the scorching heats, and eat what he likes best. He must be thus entertained during the whole time he is with the mares, which is to be about six or seven weeks. Mares that are very fat and gross do not hold well; but those which are moderately fat conceive with the greatest success and ease.

6639. *To bring a mare in season*, it is a common thing to give her a quart of hemp-seed, or twice that quantity, night and morning for eight days before she is brought to the horse. If she refuse it alone, it may be mixed with beans or oats, and will go down; and if the stallion eat of it, it will force him also; but it must be remembered that these provocatives are unnatural, and often defeat their own purposes. They

are therefore seldom now resorted to among intelligent breeders. Still more improper is it to attempt an early horsing, by injecting stimulating fluids up the vagina as is sometimes done; for when it succeeds, the future progeny seldom answers the expectation.

6640. *The treatment of a pregnant mare* is in general little different from that of any other horse. Mares of draught are worked in summer as usual, and more moderately in the ensuing winter, till near the time of foaling; when, if the season be somewhat advanced, even though the pasture be not fully sufficient for their maintenance, they should be turned out to some grass field near the homestead, and receive what additional supply of food may be necessary under sheds adjoining. It is both inconvenient and dangerous to confine a mare about to foal in a common stable, and still more so to leave her loose in a close stable among other horses; and confinement is not much less objectionable after dropping her foal.

6641. *Breeding mares are usually worked through the greatest part of the year*, laying them aside only for a week or two before foaling, and during the summer season, when giving suck to the young foal. In this way, Brown observes, the strength and vigour of the mother is not only weakened, but the size and power of the foal stand a great chance of being diminished, by the exertions of the mother when kept at work. Under these impressions we are led to consider the working of breeding mares as an unprofitable practice. Were they suffered to remain at ease, to roam upon coarse pastures, where sheds were erected in which they might find shelter during inclement weather, we are almost certain that their progeny would enter upon action with increased abilities. The expense of a breeding mare kept in this way would not be great, whilst the advantages would be innumerable. In Yorkshire, and in those midland counties where the breeding and rearing of horses is better understood than in any other part of the island, they are often worked till the very time of foaling. Great care, however, is necessary in working and managing a mare heavy with foal: an over-heat, too severe exercise, a fright, or a sudden and violent jerk, are very apt to cause an untimely birth, whereby the foal is lost, and the life of the mare very much endangered.

6642. *In the mountains of Wales, and in the Highlands of Scotland*, the breeding mares are never worked during the summer. They are driven to the hills and mountains at the close of the barley-seed season, where they remain till the inclemency of the weather forces them to return for shelter. But their scanty subsistence, the labour they are subjected to in procuring their food, and the moistness and coldness of the climate in the latter part of the season, render both themselves and their progeny of but little value and importance.

6643. *Farms*, consisting chiefly of pasture land unfit for feeding, are the situations where breeding is generally carried on. Arable farmers may breed occasionally; but the inconvenience of wanting any part of their working stock at the time of foaling operates almost as a prohibition to the breeding of horses. The greater number of horses are bred in situations where a small portion of arable land is attached to farms chiefly occupied with cattle or sheep; or where the farms are so small as not to afford full and constant employment to the number of horses that must, nevertheless, be kept for the labour of particular seasons.

Sect. XI. *Rearing of Horses.*

6644. *Rearing includes the treatment of the foal till it is fit to work*, or to be put in training for use, and also the treatment of the mother till she has weaned her foal.

6645. *In regard to the treatment of the mare till she has weaned her foal* in England, and in the improved parts of Scotland, a mare after having foaled is turned, together with the foal, into a pasture field, and is allowed two or three weeks' rest, before she is again worked, either in plough or cart; the foal being allowed to suck at pleasure during the time. After having had a few weeks' rest, she is again worked in the usual manner; the foal being commonly shut up in a house during the hours of working. In Yorkshire, some farmers are particularly careful not to allow the mare to go near the foal, after her return from labour, till her udder has been bathed with cold water, and not till most of the milk is drawn from it. These precautions are used with a view of preventing any bad consequences from the foal's receiving over-heated milk. Another practice, and which is superior to the above, is also common in Yorkshire, and in many parts of Scotland: — After the foal is a few weeks old, and has acquired strength and agility enough to follow its mother, it is allowed to attend her in the field during the hours of labour, and to suck occasionally. By this means, not only does the foal receive sufficient exercise; nor can any prejudicial effect happen from the over-heated state of the milk, as the foal is allowed to draw it off repeatedly, and at short intervals; but the little animal becomes hardy, and loses all timidity, and afterwards requires less breaking: these may be considered as the general modes of management in those parts of the kingdom mentioned above, during the period while the foal is allowed to suck its dam, which is usually about six months; that is, from the time of foaling till Michaelmas, which is the period at which foals are generally weaned, or prevented from sucking. Breeding mares are evidently unable to endure the fatigue of constant labour, for some months before and after parturition: this has led a few farmers to rear foals upon cow-milk; but the practice is neither common nor likely ever to become so; and as it is a philosophical fact, well established, that all animals partake, in some measure, of the nature of their foster parent, so there is great reason to fear this practice would prove injurious to foals so reared.

6646. *In weaning the foal* at the end of six or seven months, great care should be taken to keep the mare and foal from the hearing of each other, that neither may fret or pine after the other. The best method will be to confine the foal in a small stable by itself, which should be furnished with a rack and manger, where it may be fed with clean shaken hay, and clean sifted oats, bruised a little in a mill, or chopped carrots, or boiled potatoes. With this management, he will quickly forget his dam, and become gentle and familiarised to his keeper, and in fair weather may be suffered to exercise himself in a pasture adjoining to the stable; but this should be only for a little while in the middle part of a sunny day; the tenderness of the young animal rendering it dangerous to keep him out in the night.

6647. *The treatment of weaned foals* in England, is to put them immediately into a good fresh pasture, where they remain as long as the winter continues moderate. On the approach of winter, they are fed with a sufficient quantity of hay, placed in a stable or hovel, erected in the field for the purpose, and into which they have free access at all times. The next summer they are put into other pastures, commonly the most indifferent on the farm, where they remain till the beginning of the following winter, when they are either allowed to range in the pasture fields, or brought home to the straw-yard. The inclemency of the winter in Scotland, and the great falls of snow which generally take place, render it necessary always to house the foals there during that season.

6648. *During the first winter* foals are fed on hay with a little corn, but should not be constantly confined to the stable; for even when there is nothing to be got on the fields, it is much in their favour to be allowed exercise out of doors. A considerable proportion of succulent food, such as potatoes, carrots, and Swedish turnips (oil-cake has been recommended), should be given them through the next winter, and beans and peas meal has been advantageously substituted for oats; but which, if allowed in a considerable quantity, are injurious to the thriving of the young animal, from their heating and astringent nature.

6649. *During the following summer* their pasture depends upon the circumstances of the farms on which they are reared. In the second winter they are fed in much the same manner as in the first, except that straw may be given for some months instead of hay; and in the third winter they have a greater allowance of corn, as they are frequently worked at the harrows in the ensuing spring. (*General Report of Scotland*, vol. iii. p. 183.) When about three years old, the author of the *New Farmer's Calendar* advices

foals to be fed all winter with a little corn twice a day, with hay, oat-straw, &c. Where carrots can be procured, they form a most excellent feed for colts of every age, on which they will thrive surprisingly. With the use of carrots, no corn is necessary, nor any caution requisite against an over-heating effect from a more stimulating diet. Care should, however, be taken to cut them properly, allowing a well littered shed, or warm straw-yard. Colts fed at home with green meat, cut during summer, should have a daily range on a common, or elsewhere, for exercise. Yearlings to be carefully kept separate from the milch mares.

6650. *The time for gelding colts* is usually the same in both parts of the kingdom, which is, when they are about a year old; although, in Yorkshire, this operation is frequently suspended till the spring of the second year, especially when it is intended to keep them on hand, and without employing them in labour till the following season. Parkinson disapproves of delaying this operation so long, and recommends twitching the colts, a practice well known to the ram-breeders, any time after a week old, or as soon after as the testicles are come down; and this method, he says, he has followed himself with great success. (*Parkinson on Live Stock*, vol. ii. p. 74.) Blaine's remarks on the subject of castration appear worthy of notice: he says, when the breed is particularly good, and considerable expectations are formed on the colt, it is always prudent to wait till twelve months: at this period, if his fore parts are correspondent with his hinder, proceed to castrate; but if he be not sufficiently well up before, or his neck be too long and thin, and his shoulders spare, he will assuredly improve by being allowed to remain whole six or eight months longer. Another writer suggests for experiment, the *spaying* of mares, thinking they would work better, and have more wind than geldings. (*Marshal's Yorkshire*, vol. ii. p. 169.) But he does not appear to have been aware that this is by no means a new experiment: for Tusser, who wrote in 1562, speaks of *gelding fillies* as a common practice at that period. The main objection to this operation is not that brood mares would become scarce, as he supposes, but that, by incapacitating them from breeding in case of accident, and in old age, the loss in this expensive species of live-stock would be greatly enhanced. An old or lame mare would then be as worthless as an old or lame gelding is at present.

6651. *The rearing of horses* is carried on in some places in so systematical a manner, as to combine the profit arising from the advance in the age of the animals, with that of a moderate degree of labour, before they are fit for the purposes to which they are ultimately destined. In the midland counties, the breeders sell them while yearlings, or perhaps, when foals; namely, at six or eighteen months old, but most generally the latter. They are mostly brought up by the graziers of Leicestershire, and the other grazing parts of the midland counties, where they are *grown* among the grazing-stock until the autumn following. At two years and a half old they are bought up by the arable farmers, or dealers of Buckinghamshire, Berkshire, Wiltshire, and other western counties, when they are broken into harness, and worked till they are five, or more generally, six years old. At this age the dealers buy them up again to be sent to London, where they are finally purchased for drays, carts, waggons, coaches, the army, or any other purpose for which they are found fit. (*Marshal's Economy of the Midland Counties*, vol. i. p. 311.)

6652. *In the west of Scotland, a similar mode of transferring horses* from hand to hand is common. The farmers of Ayrshire, and the counties adjacent, who generally grow corn on not more than one fourth, or at the most, one third of their arable land, and occupy the remainder with a dairy stock, purchase young horses at the fair of Lanark and Carnwath before mentioned; work them at the harrows in the following spring when below two years old; put them to the plough next winter, at the age of two and a half, and continue to work them gently till they are five years old, when they are sold again at the Ruther-glen and Glasgow markets at a great advance of price, to dealers and farmers from the south-eastern counties. A considerable number of horses, however, are now bred in the Lothians, Berwickshire, and Roxburghshire, the very high prices of late having rendered it profitable to breed them, even upon good arable ground; but many farmers of these counties, instead of breeding, still prefer purchasing two and a half or three and a half year old colts, at the markets in the west country, or at Newcastle fair, in October: they buy in a certain number yearly, and sell an equal number of their work horses before they are so old as to lose much of their value. (*General Report of Scotland*, vol. iii. p. 182.)

Sect. XII. *Training of Horses.*

6653. *Horses are trained for various purposes*, but principally for carrying our persons or drawing our burdens. Formerly, burdens were principally borne on the back by pack-horses, but the improvements in our roads have removed them from the back, to machines called carriages, drawn by means of harness applied over the person of the horse. Under saddle, we train horses as racers, hunters, hackneys, or troop horses. In harness we use them in coaches, stages, chariots, and various lighter vehicles, or we employ them in waggons, carts, ploughs, and various other agricultural or commercial machines. Horses are held in obedience by means of bridles, with appendages called reins, which are long or short, as used in riding or driving. Horses are directed and urged forward by whip, spur, and language, and they are chastised by the same means.

6654. *The directive language used to horses* ought to be every where the same, which is the more easily accomplished, as words or phrases are sufficient for giving every requisite direction to a horse. The first of these words may be "on," or go on, or merely the common chuck of the tongue, &c. as used by all coachmen in the world; the second to make the horse go to the right-hand side, "right-hand;" the third, to the left-hand side, "left-hand;" the fourth to make them stop, may be "stop," or "stand-still." Any attempt to modify these directions ought to be given in the correct language of the country, and not in provincial words, as go on, slowly, briskly, right-hand, a little round, or turn, left-hand, a little, or left-hand and round, stop, or stand gently, &c. As a proof that only four words are requisite for giving every requisite direction to horses, we may mention that foreigners in Stockholm, Petersburgh, and Moscow, who know nothing of the language, require only four corresponding words of Swedish or Russian to direct the native coachmen and sledge drivers to any street, house, or place, the situation of which they know by the maps, or otherwise.

6655. *The three natural and ordinary movements of horses* are, walking, trotting, and galloping, to which some horses naturally add another, which is known by the name of "ambling," or "pacing." The trot is, perhaps, the most natural motion of a horse, but the pace, and even the gallop, are most easy to the rider.

6656. *In training saddle horses*, the first thing is to make them familiar with man, and other general objects, and which is best effected at the earliest periods, which then saves almost all the trouble of breaking, and docility follows as a matter of course: to effect this, the greatest kindness should be used to the colts from the moment they are dropped: they should be accustomed to be handled, should be fed with bread, patted in various parts of the body, have light matters put on their heads and backs, and subjects of different colours and forms should be shown them with caution. While at foot, the mare and foal should be led out into roads, and where carriages pass, during which time nothing should be allowed to intimidate the foal. By this management, the animal will be easily prepared for the future operations; and it is thus that the single foal the ploughed-land farmer breeds, and which daily follows the mother in her work, as it were breaks itself.

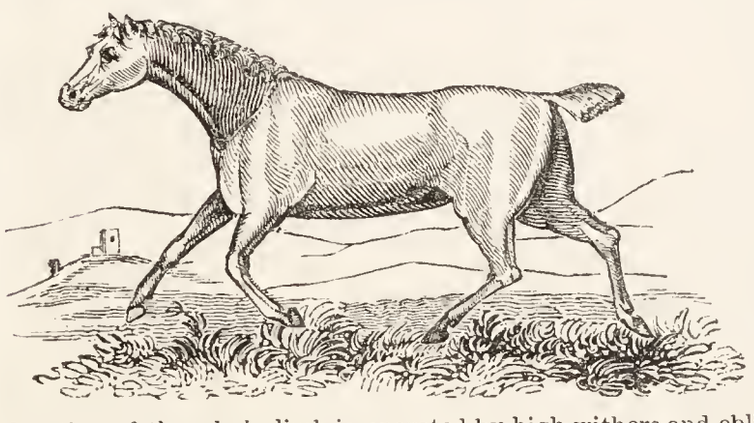
6657. *Backing* is the next operation, and if the colt has been judiciously used, and taught familiarity and docility by early handling and kindness, it is by no means difficult. It should be commenced before the colt is two and a half or three years old. The first backing of a horse is a thing of great consequence, as his value afterwards very much depends of it. The application of the saddle should be gradually done, and without alarm to the horse. After a colt has become habituated to the saddle and bridle, and has been exercised some time, morning and evening in them, and become somewhat obedient, it is usually

recommended that he be taken to some ploughed land, where he is to be walked and trotted until he be slightly fatigued. If the colt be very high spirited or refractory, or if he be not inclined to lift up his legs sufficiently, it may be admissible to practise him on some very light-ploughed lands; but if otherwise, it is better to dispense with this, and a field and a road alternately used will, in general cases, be found preferable. It would be well that this preliminary practice should be performed in a cavesson to ensure obedience. When he is perfectly tractable during his exercise, let a person used to him lay himself gently and by degrees across his back; and if he seem not to be alarmed, let him proceed at a foot-pace with his burden. When this occasions no alarm, let one leg gradually be slid over his back, the person at his head engaging his attention during the time, and encouraging him. The rider may then gradually raise himself up. The next step will be to mount him at once in the usual way, still having a judicious attendant at his head: this must likewise by no means be done suddenly, or at a jerk, but very gradually and slowly, by several risings and heavings. If he bear this patiently, the person is to seat himself firmly on his back; but if he be troublesome and not tame enough, the person is to forbear the attempt to mount, and he is to be trotted in the hand over the same ploughed lands or other ground again, till he is more fatigued, and willing to receive the rider quietly on his back: when this is done, the person who is on his back must encourage him, and the man who has his head must lead him a few paces forward; all the while encouraging him. The feet are to be fitted well in the stirrups, and the toes turned out; afterwards the rider is to shrink and move himself in the saddle, and the person who holds his head is to withdraw his hand a little farther from the mouth. As the rider moves his toes forward, the holder must move him forward with the rein, till he is made to apprehend the rider's motion of body and foot, which must always go together, and with spirit, and will go forward without the other's assistance, and stay upon the restraint of the rider's hands. When this is accomplished, let him be cherished, and again have grass and bread to eat; and then let the rider mount and alight several times, encouraging him between each time, and thus he is to be managed till he will go on, or stand still at pleasure. This being done, the long rein may be laid aside, and the band about the neck, which are always used on this occasion, and nothing will be necessary but the trenches and cavesson, with the martingal. A groom must lead the way before; or another horse going only straight forwards, and making him stand still when desired. In this manner, by sometimes following, and sometimes going before another horse on the trot, the creature will by degrees be brought to know that it is his business to be quiet and governable.

6658. *To teach a horse the different movements of walking, trotting, galloping, and ambling,* comes next in order.

6659. *Walking* is the slowest and least raised of all a horse's movements. It is performed, as any one may observe, by the horse's lifting up its two legs on a side, the one after the other, beginning with the hind leg first. Thus, if he leads with the legs of the right side, then the first foot he lifts is the far hind foot; and in the time he is setting it down (which in a step is always short of the tread of his fore foot on the same side) he lifts his far fore foot, and sets it down before his near fore foot. Again, just as he is setting down his far fore foot, he lifts up his near hind foot, and sets it down again just short of his near fore foot; and just as he is setting it down, he lifts his near fore foot, and sets it down beyond his far fore foot. This is the true motion of a horse's legs in a walk; and this is the pace in which many things are best taught; for instance, when the horse is to be taught to turn to the right and left, or from one hand to another, he is first to be taught it on the walk, then on the trot, and finally on the gallop. The walk is a pace to which team, carriage, and road horses should constantly be well broke, as being of great use in all such cases and intentions. It is an excellent pace too in a saddle horse, when well performed by being properly taught.

6660. *In trotting,* the limbs are diagonally employed; but their tenses or times, or rising and falling, are very different, as it is conducted slow or fast. In the slow trot the diagonal legs are elevated and replaced simultaneously; while those on the ground are preparing to elevate themselves, and the horse is for a moment on tiptoe; but until the original diagonal legs are set down, these are not wholly elevated: therefore the horse is during the moderate trot at no time without support. But it is very different when the trot is accelerated, as to nine or ten miles an hour; for then there is a period in every spring made by the diagonal members, when all the feet are in the air at the same time; and the body completely suspended from the ground by these means. Thus during this accelerated action, the off fore leg and near hind leg having been elevated in the air, before they meet the ground, the near fore leg and the off hind one are not only prepared, as in the slow trot, to elevate themselves, but actually do so before the others are set down; consequently, the feet, at this precise time, must be all in air. (*fig.* 846.) To speed in the trot, it is necessary that a horse pick up his feet quick, and extend them far forward. To the safety also, it is necessary he elevate his knee particularly; at the same time the general elevation of the whole limb is operated by high withers and oblique shoulders.



6661. *Three qualities are essentially necessary to make the trot useful.* It ought to be extended, supple, and even, or equal: these three qualities mutually depend upon each other, so that you cannot pass to the supple trot without having first worked upon the extended trot; and you can never arrive at the even and equal trot without having practised the supple. The *extended* trot (*fig.* 846.) is that in which the horse trots out without retaining himself, going directly forwards; and this consequently is the kind of trot with which you must begin. The *supple* trot is that in which the horse, at every motion he makes, bends and plays his joints by the elasticity of the organs composing them; which no colts or raw horses can execute, who have not had their limbs suppled by exercise. The *even* or *equal* trot is that in which the horse moves so equally and exactly, that his legs never cover more ground one than the other nor at one time more than another. To go from the extended trot to the supple, you must gently and by degrees hold in your horse; and when by exercise he has attained sufficient ease and suppleness to manage his limbs readily, you must insensibly hold him in still more and more, and by degrees you will lead him to the equal trot.

6662. *The manner of trotting a colt who has never been backed* is as follows: — Put a plain snaffle in his mouth; fit a cavesson to his nose, to the ring of which tie a longe of a reasonable length. Let a groom hold this longe, who having got at some distance from the colt, must stand still in the middle of the circle which the horse will make. Let another follow him with a long whip or chambrière in his hand. The colt being alarmed, will be forced to go forward, and to turn within the length of the cord, the groom must hold it tight in his hand; by this means he will draw *in*, or towards the centre, the head of the colt, and his croupe will of consequence be without the circle. In working a young horse after this manner do not press or hurry him. Let him walk first, and afterwards put him to the trot. If you neglect this method his legs will be embarrassed: he will lean on one side, and be more upon one haunch than the other; the inner fore foot will strike against the outer one, and the pain which this will occasion will drive him to seek some means of defence, and make him disobedient. If he refuses to trot, the person who holds

the chambrière will animate him by trotting him, or striking the ground with it. If he offers to gallop instead of trotting, the groom must shake or jerk the cord that is tied to the cavesson, and he will fall into his trot. (*Berenger's Art of Horsemanship*, vol. i. chap. 4.) The value of this longing in a circle is incalculable, inasmuch as it supples the shoulders, and gives them a greater extent of action. It also increases the action of the whole limb downwards, and accustoms the horse to effect other movements, to be performed with an elevated hand.

6663. *The gallop* is the swiftest natural pace of a horse, in which the two fore feet become elevated almost at the same moment, but one slightly takes the lead of the other, and must therefore be set down beyond and somewhat after it: previous to this, however, the hinder legs have become elevated, with also a little precedence in the leg of that side which has been led by the fore. Such is the natural gallop of the horse; when it is performed with its utmost velocity the limbs are simultaneous and synchronous. (6664.) In galloping the horse may lead with which fore leg he pleases; the most usual way is that with the right, in which case the gallop is said to be *just;* but whichsoever it be, the hind leg of the same side must follow it next, which forms an even or equal gallop; otherwise the legs are said to be disunited, and the gallop to be *false;* to remedy which disorder, the rider must stay the horse a little on the hand, and help him on the spur on the contrary side to that on which he is disunited. However, this rule has not been always strictly observed; for hunting horses have been trained to lead indifferently with both legs, because it has been found, that a horse which has never been suffered to gallop but with his right fore leg, has been worn out on one side, when he has been fresh and sound on the other. In order to make a stop in a gallop straight forwards, the rider should carefully put his horse together, without altering or disturbing the appui, and throw his body back a little to accompany the action, and to relieve the horse's shoulders. In doing this he should seize the time of making the stop, keeping the hand and body quite still, exactly when he feels the horse put his fore feet to the ground, in order that by raising them immediately by the next motion which he makes, he may be upon his haunches. When horses do not answer to the lessons in the gallop, they should be galloped briskly, and then slowly again by turns, and they will thus be compelled to obey the hand and heel. In the slow gallop, as well as in the trot, it is sometimes necessary to close the heels to the horse's sides, which is called *pinching;* but this should be done in such a manner as not to make the horse abandon himself upon the hand, and care must be taken that he be upon his haunches, and not upon his shoulders; and therefore, when he is pinched, he should be kept in the hand. To put a horse well together, and make him bring his hinder legs under him, the rider must close his legs upon him, putting them very much back; this will oblige him to slide his legs under him; at the same instant let the hand be raised a little to support him before, and yielding again immediately. Let him be thus supported, and have the rein again from time to time, till he begins to play and bend his haunches, and gallops leaning and sitting down, as it were, upon them; let the rider then press him with the calves of his legs, and he will thus become quick and sensible to the touch. If a horse has too fine a mouth, gallop him upon sloping ground; this will oblige him to lean a little upon the hand, in order the better to put himself upon the haunches; and through fear of hurting his bars, he will be prevented from resisting the operation of the bit. If the horse is heavy in hand, gallop him up sloping ground; and when his appui is too strong, this will lighten him. The gallop serves to assure and make steady a weak and delicate mouth, and also to supple a horse, and make him steady and active in his limbs. (*Berenger's History and Art of Horsemanship*, vol. ii. p. 104., &c.) In galloping in a circle, the horse is confined always to lead with his fore leg within the turn; otherwise he is said to gallop *false.*

6664. *The varieties of gallop* may be reduced to the *gallop of speed*, the ordinary or *hand gallop*, and the *canter:* all others are but compounds of these. The *gallop of full speed* is the most simple of all the paces, being nothing more than a succession of leaps; but it requires repeated efforts to acquire its full celerity: the fore parts being first raised and thrown forwards are followed by the hinder immediately; as the velocity increases, the fore and the hind legs become opposed to the ground at almost the same instant, thus forming a repetition of leaps. The *ordinary or hand gallop* does not differ from the gallop (6663.), except that the leading leg being elevated still earlier, and being carried still more forward, is followed also by an earlier and a more considerable displacement of its fellow leg behind, which of course retards the velocity considerably, and lessens the exertion. The school gallop is formed of this, with the haunches drawn more under, and the fore hand more thrown up.

6665. *The canter is different from the gallop* in some essential particulars. Whether the gallop be fast or slow, still the legs are at one period wholly removed from the ground, and the horse is all in air. In the canter, on the contrary, at no period is the horse completely elevated from the ground, but has always one or more points of contact with it. Blaine describes its operation thus: — When performed on the right, the horse commences by first placing his off hind leg a little beyond the other; at nearly the same instant he elevates the fore hand, and places first the near fore leg on the ground; the off doubling over and beyond, is placed in an instant after it. In the next movement the hind legs are thrown in, and, while elevated, the off fore leg becomes raised from the ground; but the near fore leg is not elevated until the hinder ones are replaced. The near fore leg is, therefore, the whole point of support in cantering at each remove, and thus it is that cantering horses always first fail on that leg.

6666. *The amble* is a peculiar kind of pace, by which the horse changes sides at each remove; two legs of a side being always in the air, and two on the ground. An amble is usually the first natural pace of young colts, which, as soon as they have strength enough to trot, they quit. There is no such thing as an amble in the modern manege; the riding-masters allowing of no other paces besides walk, trot, and gallop; their reason is, that a horse may be put from a trot to a gallop, without stopping him; but not from an amble to a gallop without stopping.

6667. *The training of cavalry horses* is exclusively performed in the military establishments, and therefore can never be required of the farmer or breeder.

6668. *The training of coach horses* commences with taming, walking, trotting, and repeated longing; and next with yoking and driving in a break or four-wheeled frame, with no other load than that of the coach box or seat placed in the usual position, the driver and his assistant sitting on a board fixed to the perch or hind axle, in order to be ready at a moment's notice to descend and restrain or direct the horses. Coach horses, from fifteen to sixteen hands high, should walk light five miles an hour, and trot twelve. They should be first accustomed to this exercise in the country, next in the outskirts of a large city, and lastly in the most crowded streets.

6669. *The age at which a horse is fit to be worked in a coach* is four and a half or five years; but by the fraudulent practice both of the country and town dealers, horses of three and four years old are frequently employed. The first business of the Yorkshire dealer, who has three or four years old colts to dispose of, is to draw their corner teeth, in order to make them have the mouths of those of five. The also undergo the operation of docking and nicking; and after having been kept two or three months on mashes, made of bran, ground oats, or boiled corn, they are sold to the London dealers, who, it is said, sell these three or four years old horses as if they were five years old. They are then taken into immediate work, either for the coach or saddle; and in a few months are completely destroyed by this premature and too severe labour. The drawing of the teeth is not a fraud practised on the London dealers; they *know* the deception, and *insist* upon its being done by the country dealers. It is requisite to be done some months before the London dealers finally sell them for use, or the tooth which denotes a horse to be five years old would not be grown, consequently the deception could not have taken place.

6670. *The training of cart and plough horses* commences with taming before they are a year old, with walking and rubbing them down in the stable when they are two, and with training to work when they are of three years' growth. They should be placed under the charge of a very steady careful servant, who

will teach them to back, and to go into the shafts. They ought not, however, to be made to draw any other than a very light empty cart till their fourth or fifth year; nor ought they to be put into the shafts of a threshing machine before their fifth year. The first work to which an agricultural horse may be applied is harrowing; but this during the fourth year only half a day at a time, or with a light harrow the whole day. Next he may be put to plough with similar care and caution in regard to strength. In general, agricultural horses require very little training; but one thing is too often neglected, and that is, teaching plough horses a quick step, and keeping them at that step ever after in working them. By not attending to this, and leaving the step to be regulated by lazy spiritless ploughmen, the loss to many farmers is very considerable.

Sect. XIII. *The Art of Horsemanship.*

6671. *Horsemanship, as an art,* is unquestionably of very ancient date, and it is curious how very different are the modes by which it is practised in different countries; but which differences are yet principally confined to the situation of the legs of the rider; for wherever the horse is used to carry the person, it is by the rider placing himself astride the animal. Horses were used in this way for centuries before any apparatus was used or applied to their bodies to spare fatigue to the rider; and we know that the first saddles were mere pads strapped round the body, but without the appendages of stirrups. In England, riding is systematically divided into two kinds, which are manege and jockey riding.

6672. *Manege riding*, called also *riding the great horse*, in the strict application of the term, was formerly more practised than at present; and required a system of education for both horse and rider long and severe. Horses perfectly broke for the manege were formerly taught several paces and motions, as ambling, pacing, passaging, yerking, capriole, and cornetti. The practice of these artificial cadences, it is supposed, injures the natural pace of the horse; and this circumstance, united to a particular form of horse (defective for other purposes) being required for the elasticity of these actions, has tended to bring manege riding, as formerly practised, into disrepute. Manege riding also taught the constant application of the seat of the body of the rider to the seat of the saddle, during all the motions of the horse; and as a severe education, and a particular form, had bestowed ease and elasticity to the rudeness of the manege horse, the inconveniences of this seat were not felt. But when another form of horse, capable of great speed over excellent roads, was in general use, this kind of riding was found hurtful to both horse and rider; fatiguing the one, and injuring the other.

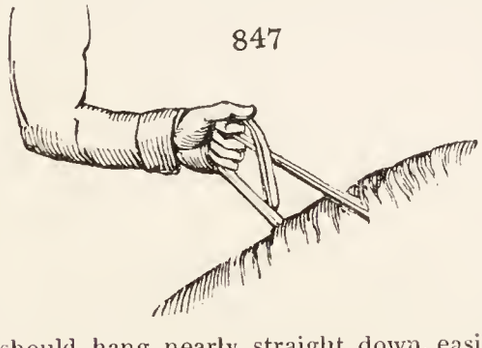
6673. *The art of proper riding*, as practised among experienced horsemen, is derived from a knowledge of the judicious application of the aids of the bridle, as taught in our schools, and as practised in the army generally; and also from a proper application or placing the body on the horse. These we certainly owe to manege riding; and a knowledge of them is as essential to the safety of the rider, as it is to the grace of his appearance as a horseman. The proper art of riding embraces all that is taught in the best schools, or practised on the road; and is equally applicable to both. This is allowed to its fullest extent by those who have possessed themselves of the requisite information and practice on the subject; but is denied by those who, wedded to field riding, contend that the perfection of horsemanship consists in a snaffle bridle and a jockey seat.

6674. *The use of the curb bridle* is considered in the schools to be essential to good riding: by it the horse is not only restrained, but he is also aided and assisted. He is alternately thrown on his haunches, or forced on his forehand, by which changes fatigue is prevented to both. Great nicety, however, is required in the use of the curb; and without an inclination and ability to use it lightly and dexterously, a snaffle is the best and safest bridle. The curb is to be operated by a gentle turn of the wrist only; and the action of the hand in this respect should be as fine and as pliable as the fishing rod and line. The force of the curb should in every instance be proportioned to the mouth of the horse.

6675. *The best form of saddle* for general riding is one in which the cantle is not so high as the military, nor so low as the racing saddle. The pommel should be no more raised than is necessary to keep the whole completely free from the withers. The stirrups should be substantial, not only to prevent breaking, but also that by their weight they may fall to the foot when accidentally slipped away; which is of more consequence than at first sight may appear. If they are of the spring kind, it is also desirable: but it is still more so, that the spring stirrup leather should be used; which prevents the danger arising from horses catching the leather in the projections of doors, gates, &c. Having saddled and bridled our horse, we will proceed to mount our rider.

6676. *If you would mount with ease and safety*, says Hughes, stand rather before the stirrup than behind it; then, with the left hand, take the bridle short, and the mane together, help yourself into the stirrup, with your right, so that, in mounting, your toe do not touch the horse. Your foot being in the stirrup raise yourself till you face the side of the horse, and look directly across the saddle; then, with your right hand, lay hold of the hinder part of the saddle, and, with your left, lift yourself into it. When mounted, let your position on the saddle be square, and the purchase of your bridle such as not to pull your shoulders: and let your body be in such an even posture as if you held a rein in each hand. In holding the bridle, grasp the reins with your hand, which should be held perpendicular with the reins passed, the lower within the hand, and the upper between the fore and next fingers (*fig.* 847.). The reins are then brought over the fore finger and firmly held by the thumb. It is often directed to place the little finger between the lower reins; the practice of this may be optional with the rider, and in a very fine hand is desirable. The bridle should be held at such a length as to enable you if your horse stumbles, to raise his head and support it with your arms; and by throwing your body backwards at the same time you frequently save a horse that would otherwise fall.

847



6677. *A graceful and proper seat* on horseback is greatly dependent on a right disposition of the legs and thighs, which should hang nearly straight down, easily, and without force or constraint: all which is brought about from above; by placing the body flat and evenly on the saddle, and opening the knees, whereby the fork will come lower on the saddle. (*fig.* 848.) The thighs should be applied to the saddle and to the sides of the horse by their inner surfaces, so as to bring in the knees and toes; and although the line may be properly broken by some little irregularities, yet the foot, the knee, the hip, and shoulder, should deviate but little from one perpendicular line. The ball of the foot should rest within the stirrup, and should be even with the heel, or very slightly elevated above it. Avoid any stiffness in the legs, thighs, or body; all should be lax, but in a state to be able to embrace the horse, either for support, or as aids to him. The loins, particularly, should be lax and pliable, as a coachman's on his box; and for the same reasons: for by sitting thus loosely, the rough motions of both are broken. To depend on the embrace of the knees for support is to lose the benefit of a true equipoise of body, and is rather to stick on a horse than to sit on one.

848

6678. *When you are troubled with a horse that is vicious*, which stops short, or, by rising or kicking, endeavours to throw you off, you must not bend your body forward, as is commonly practised in such cases; because that motion throws the breech backward, and moves you from your fork, or twists and casts you out of your seat; but the right way to keep your seat, or to

recover it when lost, is to advance the lower part of your body, and to bend back your shoulders and upper part. In flying or standing leaps, a horseman's best security is the bending back of the body. The rising of the horse does not affect the rider's seat; he is chiefly to guard against the lash of the animal's hind legs, which is best done by inclining the body backwards. But the usual method of fixing the knees in all cases of danger only serves, in great shocks, to assist the violence of the fall. To save yourself from being hurt, in these cases, you must yield a little to the horse's motion; by which means you will recover your seat, if displaced, or keep it at such times as would dismount an unskilful horseman.

6679. *If your horse grows unruly*, take the reins separately, one in each hand, put your arms forward, and hold him short, but do not pull hard with your arms low; for, by lowering his head, he has the more liberty to throw out his heels: but if you raise his head as high as you can, this will prevent him from rising behind. Is it not reasonable to imagine, that, if a horse is forced towards a carriage which he has started at, he will think he is obliged to attack or run against it? Can it be imagined that the rider's spurring him on, with his face directly to it, he should understand as a sign to pass it? These rational queries are submitted to the serious consideration of such as are fond of always obliging their horses to touch those objects at which they are, or affect to be, frightened.

6680. *Indifferent horsemen*, Lawrence observes, should never venture on horseback without spurs. Those who reflect upon the predicament of being placed between a deep ditch and a carriage, at which their horse shies, will see the necessity of this precaution.

6681. *Previously to mounting*, every person will find his account in examining the state of both horse and furniture with his own eyes and hands; for, however good and careful his groom may generally be, it is a maxim, that too much ought not to be expected from the head of him who labours with his hands. Besides, all such sedulously avoid trouble, particularly in nice matters. For example, see that your curb is right; that your reins are not twisted; that your girths, one over the other, still bear exactly alike; that the pad be not wrinkled up; but, above all, that your saddle lies exactly level upon the horse's back.

6682. *On getting off the horse's back*, hold the bridle and mane in the same manner as when you mounted, hold the pommel of the saddle with your right-hand; to raise yourself, bring your right leg over the horse's back, let your right-hand hold the hind part of the saddle, and stand a moment on your stirrup, just as when you mounted. But beware that, in dismounting, you bend not your right knee, lest the horse should be touched by the spur.

849

6683. *The jockey mode of riding* is practised in its fullest extent in racing. With some modification it is also in use by many who esteem themselves excellent fox-hunters. With still greater modification it is by its advocates practised also on the road. English post-boys unite these two kinds of riding in a manner at once easy to themselves and horses. True jockey riding consists in the use of a snaffle bridle, which is held firmly; and, as an advocate for it expresses himself, to enable the rider to give his horse the proper pulls. To this end, the same writer recommends a firm seat, upright, and as you would sit in a chair, with the knees nearly as much bent, and turned inward; the toes somewhat out and upward; the leg falling nearly straight, and the foot home in the stirrup (*fig.* 849.); elbows close to the sides; hands rather above the horse's withers, or pommel of the saddle; and the view directed between his ears. The same writer further advocates the jockey mode, by commenting on the decline of riding-house forms, and the universal preference given to expedition, which, as he says, fully confirm the superior use and propriety of a jockey-seat. Indeed, our riding-schools are now, he continues, considerably reformed from the stiffness of ancient practice in all respects. It was the custom formerly in the schools, and indeed pretty generally upon the road, to ride with the tip of the toe only in the stirrup; as if it were of more consequence to prepare for falling with safety, than to endeavour to sit securely. Those who preserve a partiality for this venerable custom, we would advise to suspend a final judgment, until they have made a few more essays upon a huge cock-tail half-bred, of that kind which 'cannot go, and yet won't stand still,' and will dart from one side of the road to the other, as if he really desired to get rid of his burden. Nor is the ball of the foot a proper rest; chiefly because inconvenient to that erect, or rather almost kneeling, posture, which is required in speedy riding. The riding-house seat is preserved by the balance or equipoise of the body solely; that recommended here by the firm hold of the knee, which is obviously strengthened by the opposite directions of the knee and toe, the one in, the other outward.

Sect. XIV. *Feeding of Horses.*

6684. *The feeding of horses generally* is an important feature in their management. In considering the food for horses, we are apt to locate our notions to the matters around us, without taking into account that every country has its peculiar products. White observes, that the best food for horses is hay and oats; and had he added for English horses, it might have been just, but without such notice the assertion is much too confined. "In some sterile countries, horses are forced to subsist on dried fish, and even vegetable mould; in Arabia, on milk, flesh balls, eggs, broth, &c. In India, horses are variously fed. The native grasses I judge very nutritious. Few, perhaps no oats are grown in India. Barley is not commonly given to horses; indeed, it is rarely grown. In Persia, barley is a common food for good horses. In some parts of India (in the Mahratta country), salt, pepper, and other spices are made up into balls, as big as billiard balls, with flour and butter, and thrust down the animal's throat. It is supposed to give them animation and fine coats: no doubt it promotes digestion. Meat broth (especially sheep's head) is also given to horses. English gentlemen sometimes adopt these usages. Different kinds of grain are given to horses in different parts of India. In Bengal, a vetch, something like the tare, is used. On the western side of India, a sort of pigeon pea, called gram (*Cicer arietinum L.*), is the usual food; with grass in the season, and hay all the year. Indian corn or rice is, I think, seldom if ever given to horses in India as ordinary food. In the West Indies they are fed on maize, Guinea corn, and sugar-cane tops; and, in some instances, on the sugar itself, in the form of molasses. In France, Spain, and Italy, besides the grasses, the leaves of limes, vines, the tops of acacia, the seeds of the carob tree, &c. are used."

6685. *The food of British horses* may be divided into herbage, grain, roots, and mixtures. Of *herbage*, the principal kind is the proper gramina, eaten either moist or dried into hay. When eaten moist in their natural state, such a horse is said to *graze;* but when these matters are cut, and carried into the stable to a horse, he is said to be *soiled.* Hay is herbage cut during its flowering and seeding processes; which being subjected to the action of the sun and air a proper time, are then collected into large masses called ricks, where a certain degree of fermentation takes place before the matter is fitted to become wholesome or nutritious, or before it receives such alteration as fits it for resisting further decomposition and decay. The judicious management of this fermentative process forms one of the greatest desiderata in hay-making. Pursued to a proper extent, the remaining moisture acting on the farinaceous parts, as the seeds, &c., in conjunction with the heat evolved during the process, as it were malts the whole, and sugar is produced. Pushed beyond this, the hay becomes carbonised, and mow-burnt; its nutritive properties are lessened, and its noxious qualities increased, it being found in this state to excite diabetes, sweating, and extreme weakness and emaciation. (6425.) The quality of the hay is too little attended to, but which is of very great importance; and more particularly so where little corn but much hay is given. Hay should therefore be of the best, whether meadow, clover, or mixed. Many horses thrive best on clover hay, particularly draught horses. It is very grateful to horses, and it saves much waste of saliva; to sprinkle hay with water has the same effect, but it should only be done as it is wanted.

6686. *Hay should never be given in large quantities at a time;* horses breathe on it, become disgusted, and then waste it. They also, when it is good, eat too much, and distend their stomachs, and then become crib-biters. Hay should not be kept in the stable in great quantities, otherwise it becomes impregnated with the volatile alkali of the stable, and is then spoiled. As substitutes for hay, the straw of wheat, barley, oats, and rye are used; but these are much less nutritive, and rather serve to excite mastication by mixing them with other matters, than to be depended on for animalisation. On hay, when good, many horses subsist; and when no exertions are required of them they are sufficiently nourished by it.

6687. *The grain used as horse food* is of various kinds, possessing, it is supposed, different degrees of nutriment, according to their different proportions of gluten, sugar, or farinaceous matter. In South Britain, oats are almost exclusively used as horse grain; and which, according to the experiments of Sir Humphry Davy, as we have seen (§ 5000.), contain 748 parts of nutritious matter out of 1000. In wheat, 955 parts of 1000 are nutritious; but wheat is seldom given with us except to racers and hunters, or on extraordinary occasions when great excitement is required, when it is sometimes given in the form of bread. Barley is more frequently given than wheat, and contains 920 parts in 1000 of nutritious particles. Made into malt, where its sugar is evolved, it becomes still more highly nutritious. Barley appears to have been the principal horse food of the ancients.

6688. *The pulse used as horse food*, are the seeds of beans, peas, vetches, &c. Beans are seldom given alone on account of their heating and astringent qualities, but are mixed with straw or hay, cut into chaff, either whole or broken.

6689. *The roots used as horse food*, are such as contain much sugar, but in which the gluten is in small proportion only. Carrots stand deservedly high on this list. They are favourable to condition, as the skin and hair always look well under their use. They are highly nutritious we know, from the fattening that occurs from them. They also generate good flesh, as we know horses can work on them, and have their wind increased by their use; indeed, so favourable are they to the proper action of the lungs, that a course of carrots will frequently remove the most obstinate coughs. The parsnep has similar properties. Swedish turnips, as having the saccharine particles in abundance, are also found good. Beet-root likewise.

6690. *Mixtures, or mixed food*, is formed of several kinds among agriculturists; and it possesses many advantages, as it can be varied to every taste, and made either cooling as an alterative, or nutritious and stimulating as a tonic. Although it is principally used for waggon, post, and farm horses, it would be better were its use more universal. Of this manger feeding, one of the best is formed from a chaff made of one part best meadow or clover hay, and two parts wheaten straw; to three bushels of this mixture add one of bruised oats. The importance of bruising or flattening the oats is very great. When used whole, the grains are apt to slip between the teeth or the chaff in mastication. In fact, corn when either given alone, or with chaff, would, in most instances, benefit by bruising. To horses under great exertion, the stomach must be, to a certain degree, weakened also; in such cases, by bruising their corn, not only the work of mastication is much of it spared, but that of the stomach also. In old horses with worn teeth, bruised oats are of great consequence. Fast-eating horses do not properly masticate more than one half of their corn; much of it remains in the dung so perfectly unaltered, that it will afterwards vegetate; and an experienced agriculturist states, that during his residence in India, in a season of scarcity, half-famished wretches actually followed the cavalry, and drew their principal subsistence from the unchewed grains of corn extracted from the excrement of the horses. Of this manger food, three, four, five, or six pecks may be given daily, according to size and exertions required; and as but little hay is required, so hard-worked horses are enabled to lie down much more, instead of standing on their already fatigued limbs to eat hay.

6691. *Cooked food* is also now much used by practical agriculturists for horses. The articles made use of are potatoes, carrots, turnips, or parsneps. To horses with their digestion weakened by hard work, old age, or other causes, food in sufficient quantities, thus already reduced to a pultaceous mass, resembling chyme, without the loss of time, or the waste of saliva, may be very important: for, as Curwen very judiciously observes, a horse will consume nearly six hours in eating a stone of hay, whereas he will eat a stone of steamed potatoes in twenty minutes. Horses are observed of themselves to lie down after eating cooked food sooner than other times.

6692. *The quantity of food* to be given to a horse must be regulated by circumstances, the principle of which is the exertions or nature of the work required of him. If this be simply laborious, as drawing of loads, or carrying of weights, all that is requisite is that the food be sufficiently nutritious. The bulk from whence such nutriment is gained is not a matter of import: but if such exertions are to be combined with celerity, as in our racers, hunters, &c., it is evident that such feeding is best adapted to the end required which combines nutriment without bulk; and which increases the durability by increasing the mental irritability, and thus giving tone and courage. These are found to be better derived from a proportionate allowance of grain or corn, than any other mode of feeding at present known. It remains only to add, that although experience has fully proved this, in all cases where the exertions are extreme, yet it has also led to another evil, by introducing a plan of treating all horses of value alike. Thus, most of the more valuable hackneys, the carriage horses of the wealthy, &c., are accustomed to be fed, not as though their exertions were moderate, but as though they were unceasing, to the destruction of a vast quantity of valuable corn. From thousands of such horses, at least one third of their hay and corn might be advantageously abstracted.

6693. *Too great a quantity of food* injures not only the community but the horse also. The stomach becomes distended by over-feeding, and it then becomes weak and incapable of a healthy digestion; crib-biting, hide-bound, and pursiveness follow; or when the stomach does digest this undue quantity, it generate fulness, which shows itself in inflammations or foulness, appearing in the form of cracks and grease.

6694. *A horse in full work*, of whatever kind, will require, according to his size, a peck of sound oats in twenty-four hours; and when the work is unremitting, as in post, stage-waggon, or other very large and hard-working horses, even more may be required. Some post horses have an unlimited quantity given them; but this practice is always erroneous. If they eat more, it serves only to distend the stomach unduly, and also to require stronger digestive powers: if they blow on it they leave it, and it is wasted, or a more greedy one swallows it up without mastication; and both stomach, horse, and master are thereby robbed. It is of consequence that the oats, as an important part of horse food, should be perfectly sweet, free from must, and not kiln-dried. The skin should be thin, but the grain plump and heavy, yielding from thirty-eight to forty pounds the bushel. To encourage a slow and thorough mastication, sprinkle them with water and spread them well over the manger. The quantity of hay required for saddle horses which are corn-fed is from six to eight pounds in twenty-four hours: if the quantity of corn be small, and the horse large, ten or twelve pounds is not too much. This quantity is also sufficient for carriage or coach horses, as they usually have either corn or mixed food in sufficient plenty also. For waggon and the larger agricultural horses, from fifteen to twenty pounds may be requisite. When it can be conveniently done, the quantity of both hay and corn should be divided into four portions. The largest portion both of hay and corn should be given at night; the next in quantity in the morning; the other two portions at noon, and about four in the afternoon. This, however, must depend on the work of the horse, and other circumstances.

6695. *Watering of horses* is an important part of their management, and many errors are committed relative to it. It is equally erroneous to debar them from it, as it is to allow them too much; and the former is much the most common evil. In summer, or when from great perspiration the animal juices

are wasted, it generates fevers, and wastes the strength and spirits. All horses prefer soft water, and as nature is unerring, there is no doubt but that it is the most wholesome. As some horses drink quicker than others, it is not a good custom to take riding horses to a pond, unless at night, when the quantity cannot injure them; or when not intended for early work the next morning, as hunting, &c.

6696. *The necessary quantity of water* for a horse should be regulated by circumstances, as the weather, the work, &c. In common cases, a large horse requires rather more than the half of a large stable pail full twice in the day. At night a full pail should be allowed. Horses should never be galloped after drinking; it has destroyed thousands, by gripes, inflammations, and broken wind. This custom also uses horses to expect they are to run away directly they are accidentally watered at any time. Others, expecting they are to be fatigued with a gallop, will avoid drinking at all. The most that should ever be done, is to suffer no horse to drink his fill at a river or pond; but having given him half what is necessary, walk him ten minutes, and then give him all that is required, and walk him again.

Sect. XV. *Stabling and Grooming of Horses.*

6697. *The stabling of horses* is likewise a most important point in their management, the more so as being wholly a deviation from nature; hence, under the most judicious management, it is liable to produce some departure from health; and as sometimes managed, is most hurtful to it. Clothing, dressing, or combing, and exercise, are also highly important.

6698. *Every stable should be large, cool, and airy.* It is too common to suppose that warmth is so congenial to horses, that they cannot be kept too hot; but there is reason to suppose that many of the diseases of horses are attributable to the enervating effects of unnatural heat, and of an air breathed and rebreathed over again. Blaine says, Is it not alike repugnant to reason and experience, to expect to keep animals in health, that from stables heated to sixty degrees, and further protected by warm clothing, are first stripped, and then at once exposed to a temperature at the freezing point? If it be argued that habit and exercise render these less hurtful, it will be easy to answer that their original hardihood is lost by confinement and artificial treatment; and that neither does exercise always tend to obviate the effects of this sudden change: for our best carriage horses, and hackneys also, have often to wait hours in roads and streets the convenience of their owners, or the pleasure of the groom.

6699. *The heat of a stable* should be regulated by a thermometer, and the heat shown by it should never exceed 50° of Fahrenheit in winter, or 62° or 63° in summer. To renew the air, the stable should be well ventilated; and which is best done by trunks or tubes passing from the ceiling through the roof.

6700. *A stable should not only be well ventilated, but it should be light also;* and the windows should be so constructed as to admit light and air, without producing a current of wind on the bodies of the horses. Darkened stables are very hurtful to the eyes; neither do they, as was formerly supposed at Newmarket, tend to the condition or rest of a horse.

6701. *A stable should have a close ceiling* to keep the dust and dirt from the hay-loft from entering the horse's eyes. It is also necessary to prevent the ammoniacal gases from ascending and lodging in the hay. It is preferable that the hay-loft be altogether removed from over the stable; and if a very high ceiling even to the roof were substituted, it would be for the benefit of the horses.

6702. *The form of the rack and manger* should be attended to. Sloping racks are disadvantageous, as encouraging dust in the eyes. They should therefore be upright, and by no means so high as they usually are, by which the head and neck are put injuriously on the stretch. As a proof that this is unpleasant to horses, many of them first pull out all the hay, and then leisurely eat it. The manger should be wide at the bottom, and of a proper height: care should be taken that no splinters are present to endanger the lips, nose, and mouth. The halter reins should, in good stables, be suffered to run within a groove within the manger post, to prevent the rein entangling the legs. It is become the practice in some stables appropriated to post, stage-waggon, and other hard-worked horses, to abandon hay-racks altogether; but the hay being placed on the ground before the horse encourages him to lie down and eat it; by which much rest is afforded to the weary limbs, and much improvement to the feet.

6703. *The stalls of a stable should be wide.* Strains in the back, and sometimes even worse evils, are the consequence of the standings being too narrow. Bails are objectionable from the ease with which horses can kick over them; and also from the quickest feeder getting most food, when several horses stand together bailed.

6704. *The acclivity of the stalls* is a matter of much dispute: when too much raised, as in dealers' stables, they put the back sinews on the stretch, and fatigue horses much. It is more natural that they should be even; or that a very slight slope only be allowed to carry off the urine. The best mode, however, of carrying off the urine is by means of a small grating to each stall, communicating with a cesspool without doors, which should be closed up, that a current of air may not come through the grating. Such a contrivance will effectually carry off the water, and prevent the volatile alkali of the urine from impregnating the air around. For the same reasons, the dung should be removed, if possible, wholly without the stable as soon as dropped; for the exhalations from that are also ammoniacal, and consequently hurtful. To this cause alone we may attribute many diseases, particularly the great tendency stabled horses have to become affected in the eyes. The pungency of this effluvia is familiar to every one on entering a close stable in the morning, and when the long-soiled litter is removed, it is absolutely unbearable.

6705. *The litter of horses* should be kept dry and sweet, and should be often removed. When it is suffered to remain, under the notion of making better dung, the horse may be ruined; neither does the manure benefit as is supposed; for when it is removed to the dung pit, the close confinement does it more good than the open exposure in the stable, when it parts with its salts, on which its properties as manure partly depend.

6706. *Horses should not stand on litter* during the day, although very generally suffered to do so. Litter is thought to save the shoes and even the feet, by preventing the uneven surface of the stable from hurting them: but it holds the urine; it injures the feet; and is very apt to encourage swelling at the heels: as we know by removing it, when they immediately subside. A little litter may be strewed behind to obviate the effect of kicking, or the splashing of urine in mares.

6707. *The clothing of horses* is apt to be carried to as erroneous an extent as the heat of their stables. When horses go out in cold weather, and are intended to have merely a long walking exercise, then clothing is very proper: but it must be evident, that when taken clothed from a stable and exercised briskly so as to produce perspiration, it is erroneous; for not only are the clothes wetted and thus liable to give cold, but the horse is unfitted to go out afterwards with a saddle only. Saddle horses kept in condition stand clothed in a kersey sheet, and girted with a broad roller, with occasionally the addition of a quarter-piece; the breast-plate is sometimes put on when going out to exercise; the hood is used to race horses only, except in case of sickness. All horses, except racers, are best without clothing in the summer season; at the most a linen sheet only should be allowed to avoid the dust and flies.

6708. *The grooming or dressing of horses* is generally thus practised: — Having tied up the horse's head, take a currycomb, and curry him all over his body, to raise the dandriff or scurf, beginning first at his neck, holding the left cheek of the head-stall in your left hand, and curry him from the setting on of his head, all along his neck, to his shoulder, and so go all over his body to the buttocks, down to his hocks; then change your hands, and curry him before on his breast, and laying your right arm over his back, join your right side to his left, and curry him all under his belly to his chest, and so all over very well, from the knees and shoulders upwards: after that, go to the far side, and do in like manner. Then take a dead horse's tail, or a dusting-cloth of cotton, and strike that dust away which the curry-comb has

raised. Then take a round brush, made of bristles, and dress him all over, both head, body, and legs, to the very fetlocks, always cleansing the brush from that dust which it gathers, by rubbing it upon the curry-comb. After that, take a hair-cloth, and rub him again all over very hard, both to take away the loose hairs, and to help to lay his coat; then wash your hands in fair water, and rub him all over with wet hands, as well head as body; for that will cleanse away all those hairs and dust the hair-cloth left. Lastly, take a clean cloth, and rub him all over till he be very dry; for that will make his coat smooth and clean. Then take another hair-cloth (for you should have two, one for his body and another for his legs), and rub all his legs exceedingly well, from the knees and hocks downwards to his very hoof, picking and dressing them very carefully about the fetlocks from gravel and dust, which will lie in the bending of his joints.

6709. *The curry-comb should not be too sharp*, or, at least, not used in a rude and severe manner, so as to be an object of torture and dread, instead of delight and gratification to the horse. It is too often the fate of thin-skinned horses to suffer much from the brutality of heavy-handed and ignorant fellows, who do not recollect that the unhappy animal is suffering, every time he writhes and attempts to escape from the comb or brush, the same tortures that they themselves experience when tickled on the soles of their feet.

6710. *The care of the legs and feet* forms a most important branch of stable discipline. The legs must be kept perfectly dry and clean. Dirt suffered to form a lodgment, or wet remaining upon the legs in cold weather, will fret the skin, and cause cracked heels, grease, mallenders and sellenders, rat's-tail, crown-scab, and such a train of stable plagues, as may baffle the most vigorous efforts during a whole winter. If any disposition to swellings, cracks, &c. make their appearance on the legs, particularly in winter, moderate bandaging, which every good groom knows how to perform, will contribute to remove the evil; if it, however, increase, have recourse to the veterinary directions. It forms a part of the constant attention of a good horse-keeper to see that the feet of his horses be well cleansed beneath the shoe with the picker from all small stones or gravel, at every return from abroad. The shoes must be examined, that their ends do not press into the crust, and that the nails be fast, and that the clinches do not rise to cut the horse. In these cases, instant application must be made to the farrier: horses ought by no means to remain in old shoes until the toe is worn away, or the webs become so thin that there is danger of their breaking, unless in case of brittle hoofs, when it is an object to shoe as seldom as possible. Upon the average, good shoes will wear near a month. Steeling the toes is, in general, a useful practice, but less necessary when the best iron is made use of. Where any tendency to dry hoofs exists, the feet should be stopped with equal parts of clay, cow-dung, and chamberlye every night; otherwise, twice or three times a week will be sufficient. A still better stopping is made by adding a little tar to the other matters. It is also prudent, when the hoofs have any tendency to hardness and contraction, to water the front part of the stall a little; and also occasionally, or constantly, to hang around the hoofs an apparatus, made by doubling a circle of woollen cloth over a tape, which should be tied around the fetlocks loosely: the two segments of the cloth will then fold around the hoof, and correspond to it in shape. This may be dipped in water, and will be found very convenient in keeping the feet moist and cool. Very brittle hoofs are greatly benefited by brushing them over with a mixture of whale oil and tar. It is considered as beneficial, in general, to take off the shoes of a horse who is necessitated to stand long in the stable, and who does no work, and to substitute tips; the growth of the crust and the enlargement of the heels being thereby promoted.

6711. *The care of the furniture and trappings* is another part of the duty of a horse-keeper. These are best kept in order by being instantly rubbed clean after use, and placed in a dry situation; by which method, neither oil nor scouring-paper is often found necessary. Great care should be taken to dry the pads of the saddles after journeys, and never to put a hardened and damp saddle upon the horse's back. The same is also necessary with regard to the body-clothes. The pads of the saddles ought to be kept perfectly soft, and free from dirt and sweat; and, after use, should be dried either in the sun or by the fire, and hung in a dry place: the body-clothes also should be washed much oftener than they generally are, and ever kept perfectly dry, and in a sweet state.

6712. *The exercising of horses* is essentially necessary for their health, as it counteracts the effects of the artificial life we force on them. High feeding, heated stables, and unnatural clothing are, particularly the first, counteracted by proper exercise; and without it, horses become pursive, fat, heavy, and greased; for, when the secretions do not find themselves natural vents by perspiration, &c., they will find themselves artificial ones. Exercise keeps down the fat, and it also hardens and condenses the muscles by drawing their fibres nearer together; it likewise enlarges the muscles. Thus the appearance, as well as the feel, when we handle the flesh of a horse in condition by proper exercise, is totally different from those of one merely full of flesh by fat, &c. Exercise increases the wind by taking up the useless fat, and by accustoming the lungs to expand themselves.

6713. *The quantity of exercise necessary for a horse* must be regulated by a variety of circumstances; as age, constitution, condition, and his ordinary work. A young horse requires more exercise than an old one, but it should be neither very long, nor very fatiguing. Some colts are observed to come out of the breaker's hands with splints and spavins, owing to the severe exercise they have undergone. When horses are in general work, a little walking exercise in the morning in body-clothes, if the condition be very high, or the weather be very cold, is all that is necessary: but, on days when their common work is not expected to occur, a full-fed horse should be exercised twice a day, an hour at each time; or, if only once a day, then an hour and a half or two hours' exercise should be given; two thirds of which ought to be passed in walking; the other should be passed in a moderate trot in the hackney, and divided into galloping and trotting in the hunter. The racer has his regular gallops at stated periods; but the exercise of each should always finish with a walk of sufficient length, to bring the horse in cool, both in person and temper.

Sect. XVI. *Management and Working of Horses.*

6714. *The working of horses* includes the racing, hunting, and journeying of saddle horses; and the treatment in harness of coach, waggon, cart and farm horses.

Subsect. 1. *Management and Working of Race Horses.*

6715. *In the managing and working of race horses*, three things are to be considered, the preparation of the horse, the conduct of the rider, and the after-treatment of the horse. The preparation of a race horse for running a race is not the work of a few days, if there be any great dependence on the success. A month at least is required to harden his muscles in training, by proper food and exercise, and to refine his wind, by clearing his body to that degree of perfection that is attainable by art. It is first necessary to ascertain correctly the present state of the horse, as whether he be low or high in flesh; and in either case a proper estimate should be formed of the time and means required to bring him into true running condition.

6716. *If a race horse be low in flesh*, it is necessary to judge of the cause of such state, and to act accordingly, the necessary proceedings for which were detailed in treating of condition. (6425.) It is to be remarked, that spices are less to be depended on for this purpose than generous food, as malt mashes; and if any thing of the kind be used, let it be the simple cordial ball. (*Vet. Pharm.* 6568.) Feed frequently, and by little at a time: while he is thus low, let his exercise be walking only, and by no means spare his water, or he will become hide-bound: carefully watch him, that full feeding may not disagree

by making his heels swell, or his coat unthrifty; and if such appearances occur, mash him, and begin his scourings, otherwise abstain from physicking until he is in better health. As he improves in condition, increase his exercise, but not to such a degree as to make him sweat. His food must now be the best oats and beans, with wheaten or barley bread; the beans and oats are to be put into a bag, and beaten till the hulls are all off, and then winnowed clean; and the bread, instead of being chipped in the common way, is to have the crust clean off.

6717. *If the horse be in good flesh and spirits* when taken up for his month's preparation, cordials are altogether unnecessary; and the chief business will be to give him good food, and so much exercise as will keep him in wind, without over-sweating or fatiguing him. When he takes larger exercise afterwards, towards the end of the month, it will be proper to have some horses in the place to run against him. This will put him upon his mettle, and the beating them will give him spirits. This, however, is to be cautiously observed, that he has not an injurious, or in the language of jockeys, a bloody heat given him for ten days or a fortnight before the plate is to be run for; and that the last heat that is given him the day before the race must be in his clothes: this will make him run with greatly more vigour when stripped for the race, and feeling the cold wind on every part. In the second week, the horse should have the same food and more exercise: and in the last fortnight he must have dried oats, that have been hulled by beating; after this jockeys wet them with the whites of eggs, beaten up, and then laid out in the sun to dry; and when as dry as before, the horse is to have them: this sort of food being considered by them as very light of digestion, and very good for the creature's wind. The beans in this time should be given more sparingly and the bread should be made of three parts wheat and one part beans, or of wheat and barley in equal parts. If he should become costive under this course, he must then have bran-water to drink, or some ale and whites of eggs beaten together; and keep his body moist. In the last week all mashing is to be omitted, and barley-water given him in its place; and every day, till the day before the race, he should have his fill of hay; then he must have it given him more sparingly, that he may have time to digest it; and in the morning of the race-day, he must have a toast or two of white bread soaked in ale, and the same just before he is led out of the field. This is an excellent method, because the two extremes of fulness and fasting are at this time to be equally avoided; the one affecting his wind, and the other occasioning a faintness that may make him lose. After he has had his food, the litter is to be shook up, and the stable kept quiet, that he may be disturbed by nothing till he is taken out to run.

6718. *In the choice of a rider* for winning a race, it is necessary, as far as possible, to select one that is not only expert and able, but honest. He must have a very close seat, his knees being turned close to the saddle skirts, and held firmly there; and the toes turned inwards, so that the spurs may be turned outward to the horse's belly; his left hand governing the horse's mouth, and his right the whip. During the whole time of the race, he must take care to sit firm in the saddle, without waving or standing up in the stirrups. Some jockeys fancy the last a becoming seat; but it is certain, that all motions of this kind do really incommode the horse. In spurring the horse, it is not to be done by sticking the calves of the legs close to the horse's sides, as if it were intended to press the wind out of his body; but, on the contrary, the toes are to be turned a little outwards, that the heels being brought in, the spurs may just be brought to touch the sides. A sharp touch of this kind will be of more service toward the quickening of a horse's pace, and will sooner draw blood than one of the common coarse kicks. The expert jockey will never spur his horse until there is great occasion, and then he will avoid striking him under the fore bowels between the shoulders and the girt; this is the tenderest part of a horse, and a touch there is to be reserved for the greatest extremity.

6719. *As to whipping the horse*, it ought always to be done over the shoulder, on the near side, except in very hard running, and on the point of victory; then the horse is to be struck on the flank with a strong jerk; for the skin is the most tender of all there, and most sensible of the lash. When a horse is whipped and spurred, and is at the top of his speed, if he clap his ears in his pole, or whisk his tail, it is a proof that the jockey treats him hard, and then he ought to give him as much comfort as he can by sawing the snaffle backwards and forwards in his mouth, and by that means forcing him to open his mouth, which will give him wind, and be of great service. If there be any high wind stirring in the time of riding, the artful jockey will let his adversary lead, holding hard behind him, till he sees an opportunity of giving a loose; yet, in this case, he must keep so close behind, that the other horse may keep the wind from him; and that he, sitting low, may at once shelter himself under him, and assist the strength of the horse. If the wind happen to be in their back, the expert jockey is to keep directly behind the adversary, that he may have all the advantage of the wind to blow his horse along, as it were, and at the same time intercept it in regard to his adversary.

6720. *When running on level smooth ground*, the jockey is to beat his horse as much as the adversary will give him leave, because the horse is naturally more inclined to spend himself on this ground; on the contrary, on deep earths, he may have more liberty, as he will there spare himself.

6721. *In riding up hill* the horse is always to be favoured, by bearing him hard, for fear of running him out of wind; but in running down hill, if the horse's feet and shoulders will bear it, and the rider dares venture his neck, he may have a full loose. If the horse have the heels of the rest, the jockey must always spare him a little, that he may have a reserve of strength to make a push at the last post.

6722. *On the jockey's knowing the nature of the horse that is to run against him*, a great deal depends; for by managing accordingly, great advantages are to be obtained: thus, if the opposite horse is of a hot and fiery disposition, the jockey is either to run just behind him, or cheek by joul with him, making a noise with the whip, and by that means forcing him on faster than his rider would have him, and consequently, spending him so much the sooner; or else keep him just before him, in such a slow gallop, that he may either overreach, or by treading on the heels of the fore-horse, endanger tumbling over. Whatever be the ground that the adversary's horse runs worst on, the cunning jockey is to ride the most violently over; and by this means it will often happen, that in following he either stumbles or claps on the back sinews. The several corrections of the hand, the whip, and the spur, are also to be observed in the adversary, and in what manner he makes use of them: and when it is perceived by any of the symptoms of holding down the ears, or whisking the tail, or stretching out the nose like a pig, that the horse is almost blown, the business is to keep him on to this speed, and he will be soon thrown out or distanced. If the horse of the opponent looks dull, it is a sign his strength fails him; and if his flanks beat much, it is a sign that his wind begins to fail him, and his strength will soon do so too.

6723. *The after-management of a horse who has run* includes the treatment between the heats, and the treatment after the race is over. After every heat for a plate, there must be dry straw, and dry clothes, both linen and woollen, ready to rub him down all over, after taking off the sweat with what is called a sweat-knife; that is, a piece of an old sword-blade, or some such thing. After the horse has been well rubbed, he should be chafed all over with cloths wetted in common water, till the time of starting again. When it is certainly known that the horse is good at the bottom, and will stick at the mark, he should be rid every heat to the best of his performance; and the jockey is as much as possible to avoid riding at any particular horse, or staying for any, but to ride out the whole heat with the best speed he can. If, on the contrary, he has a fiery horse to ride, and one that is hard to manage, hard-mouthed, and difficult to be held, he is to be started behind the rest of the horses with all imaginable coolness and gentleness; and when he begins to ride at some command, then the jockey is to put up to the other horses; and if they ride at their ease, and are hard held, they are to be drawn on faster; and if it be perceived that their wind begins to rake hot, and they want a sob, the business is to keep them up to that speed; and when they are all come within three quarters of a mile of the post, then is the time to push for it, and use the utmost speed in the creature's power.

6724. *When the race is over*, the horse is immediately to be clothed up and rode home; and immediately

on his coming into the stable, the following drink is to be given him: — Beat up the yokes of three eggs, and put them into a pint and a half of sound ale, made warm; and let it be given with a horn. After this, he is to be rubbed well down, and the saddle-place rubbed over with warm water and vinegar, and the places where the spurs have touched, with the same; after this he should have a feed of rye-bread, then a good mash, and at some time after these as much hay and oats as he will eat. His legs, after this, should be bathed some time with a mixture of vinegar and water.

Subsect. 2. *Management and Working of the Hunter.*

6725. *The managing and working of the hunter* includes his preparation for hunting, his condition, and his treatment while taking his regular day's work in the field, whether after buck, fox, or hare hounds.

6726. *The preparation of the hunter* must, like that of the race horse, be commenced by an estimate of his state and condition. If taken fresh from grass, it should be in due time: first, that he may be well prepared; and next, because the grass does not yield much nutriment in the heat of summer. A still better method is to continue to let him run out in the day and graze, having a shed to house himself from heat and rain. He is also to be fed and exercised, nearly as in the common training, for hunting condition. In this way he is sure to be free from cracks, hide-bound, or surfeit; and he will prove infinitely more hardy afterwards. It is even the practice with some of the best sportsmen to allow their horses to run out all the hunting season, unless the weather be very severe; when they are only stabled in a loose place. They are allowed as much corn as they can eat, and are found, if a little rougher in their coats, infinitely superior in hardihood, and exemption from the dangers of cold.

6727. *A hunter taken from grass* or in very low case should be treated as already fully detailed under condition. (6424.) Great care must be taken that all the alterations in heat of stable, clothing, feeding, &c., are gradually brought about; by which means his flesh will harden gradually, and by using first walking exercise, and increasing it as he advances in flesh and strength, his wind also will become excellent.

6728. *In the physicking of hunters*, particularly when they are low in flesh, much caution is requisite that it be not over-done. It is the practice with some, and by no means a bad one, to give no physic; but to give more time in the preparation. Others, again, give mild grass physic, which is an excellent plan, when the weather is fine. (See *Physicking*, 6544.)

6729. *The preparation of a hunter in full flesh and not from grass* depends principally on regular exercise, and the best hard food; physicking him or not, according as he may be suspected to be foul, or as his wind may seem to want mending; but above all, whatever is done, should be done regularly; and his exercise should be rather long continued than violent. Oats with beans are the proper hard food for hunters, taking care that the beans do not constipate the bowels; which must be obviated by bran mixed with the other food, if such should be the case. Bread is not necessary, but for tender delicate horses; but every thing should be of the best.

6730. *The day before a horse is to hunt* it is common to treat him somewhat differently, but this is seldom necessary. It is evident he should be well fed, and that not late at night, that he may lie down early. Some feed in the morning, which others avoid; but when it is considered, as has been fully explained (6404.), how ill a horse bears fasting, it will be at once seen, that if very early in the morning, as by five o'clock, he could be fed with a moderate quantity of corn wetted, it would tend to support him through the day.

6731. *On the return of a horse from hunting*, the care bestowed on him should be extreme; as on it depends the immediate recovery of his strength. If he have fasted very long, and particularly if he be disinclined to eat of himself, horn down a pint of ale, with two pints of thick gruel. No prudent sportsman will bring in a horse hot; but if unavoidable accidents prevent this caution, let the horse be again led out for a few minutes, hooded and clothed; but he must have fresh clothes when afterwards dressed. Encourage him to stale as quickly as possible, after which proceed to hand-rub him all over carefully, placing before him a little of the best hay well sprinkled with water. If he refuse this, offer him three quarts of very clean chilled water. When perfectly cleaned, let his feet be carefully examined, that stubs have not pierced them, or that his shoes have not been forced awry by over-reaching, or by the suction of clayey ground; or that thorns be not lodged in his knees, hocks, and sinews. After all these matters have been well attended to, remove him from his stall to a loose box, well bedded up. A loose box is invaluable to a hunter; it gives room for stirring to prevent the swelling of the legs; and is better than bandaging when it can be avoided, which gives a disinclination to lie down. If the horse be off his food the next day, give him a cordial ball (*Vet. Pharm.* 6568.) and a malt mash, and afterwards a few cut carrots, which will assist to bring him round more speedily.

Subsect. 3. *Working and Management of Riding Horses.*

6732. *The working and managing of hackney or riding horses* include what is required for them as pleasure horses for ordinary airings; and what they require when used for purposes of travelling or long journeyings. It embraces also their stable management in general, with the proper care of horse and stable appointments: all which are usually entrusted to a servant, popularly called a groom, whose qualifications should be, moderate size, light weight, activity and courage, joined with extreme mildness and good temper; and above all, a natural love of horses, by which every thing required is done as a pleasure for the animal he loves, and not as a task for those he is indifferent to.

6733. *The hackney for gentlemen's airings* should be in high condition, because a fine coat is usually thought requisite; and here the groom ought to be diligent that he may keep up this condition by regularity and dressing, more than by heat, clothing, and cordials. Whenever his master does not use his horse, he must not fail to exercise him (but principally by walking) to keep up his condition, and to keep down useless flesh and swellings of the heels. The horse appointments are to be peculiarly bright and clean. The bridle should be billetted and buckled, that the bits may be removed to clean them without soiling the leather, which cleaning ought not to be done with rough materials, but fine powder and polishing. On the return from exercise, they should be wiped dry and then oiled. Two pair of girths should be used, that a clean pair may always be ready, and the same if saddle cloths are used.

6734. *The preparation for, and the care of a horse on, a journey* involve many particulars which should not escape the eye of the master. The first is, Is the horse in hard travelling condition? Next, Do his appointments all fit, and are they in proper order? The bridle for journeying should always be a double curbed one. The snaffle can be ridden with, certainly; but the snaffle cannot do the work of the curb, in staying a horse, in saving him from the ground under stumbling or fatigue, or throwing him on his haunches, or in lightening his mouth. The bridle should not be new, but one to which the horse is accustomed. It is of still more consequence that the saddle be one that the horse has worn before, and that fits him thoroughly. The girths should also be of the best materials to prevent accidents; and if the saddle be liable to come forward, however objectionable the appearance, a crupper had better be used. Some days before a long journey is attempted, if the shoes are not in order, shoe the horse; but by no means let it be done as you set off, otherwise having proceeded on the journey a few miles, you find that one foot is pricked, and lameness ensues; or, if this be not the case, one or more shoes pinch, or do not settle to the feet; all which cannot be so well altered as by your own smith.

6735. *It is always best to begin a long journey by short stages*, which accustoms the horse to continued exertion. This is the more particularly necessary if he have not been accustomed to travel thus, or if he be not in the best condition. The distance a horse can perform with ease depends greatly on circumstances.

Light carcassed horses, very young ones, and such as are low in flesh, require often baiting, particularly in hot weather; horses in full condition, above their work, and well carcassed, and such as are from seven to ten or twelve years old, are better when ridden a stage of fifteen or twenty miles, with a proportionate length of baiting time afterwards, than when baited often, with short stoppages: the state of the weather should also be considered; when it is very hot the stages should be necessarily shorter.

6736. *To a proper consideration of the baiting times on a journey*, the physiology of digestion should be studied. (6400.) Fatigue weakens the stomach; when we ourselves are tired, we seldom have much inclination to eat, and fatigue also prevents activity in the digestive powers. To allay these consequences, ride the horse gently the last two or three miles. If a handful of grass can be got at the road-side, it will wonderfully refresh your horse, and not delay you three minutes. In hot weather, let the horse have two or three go-downs (gulps), but not more, of water occasionally as you pass a pond; this tends to prevent excessive fatigue. Occasionally walk yourself up-hill, which greatly relieves him, and at such time remove the saddle, by shifting which, only half an inch, you greatly relieve him; and during this time, perhaps, he may stale, which also is very refreshing to him. It may be as well, in a flinty country, to take this opportunity of examining that no stones are got into the feet likewise.

6737. *When a horse is brought into an inn from his journey*, if he be very hot, first let him be allowed time to stale; let his saddle be taken off, and with a sweat knife draw the perspiration away; then, with a rug thrown over him, let him be led out and walked in some sheltered place till cool, by which means he will not afterwards break out into a secondary and hurtful sweat: but by no means let an idle ostler hang him to dry without the stable. Being now dried, remove him to the stable, where let some good hay, sprinkled with water, be placed before him: if very thirsty, give three or four quarts of water now, and the remainder in half an hour, and then let him be thoroughly dressed, hand-rubbed, foot-picked, and foot-washed; but by no means let him be ridden into water; or, if this practice is customary, and cannot be avoided, let it be not higher than the knees, and afterwards insist on the legs being rubbed perfectly dry; but good hand-rubbing and light sponging is better than washing. Having thus made him comfortable, proceed to feed him with corn and beans according as he is used.

6738. *To feed a horse when very hard ridden, or if weakly and tender*, it is often found useful to give bread, or bread with ale: if this be also refused, horn down oatmeal and ale, or gruel and ale. It is of the utmost consequence if the journey is to be of several days' continuance, or if it is to consist of a great distance in one or two days, that the baitings are sufficiently long to allow the horse to digest his food: digestion does not begin in less than an hour, and is not completed in less than three; consequently any bait that is less than two hours fails of its object; and such a horse rather travels on his former strength than on his renewed strength, and therefore it cannot continue. After a horse is fed he will sometimes lie down; by all means encourage this, and if he is used to do it, get him a retired corner stall for the purpose.

6739. *The night baiting of a journeying horse* should embrace all the foregoing particulars, with the addition of foot stopping; and care that his stable be of the usual temperature to that to which he is accustomed; and that no wind or rain can come to him. Give him now a full supply of water: if he has been at all exposed to cold, mash him, or if his dung be dried by heat, do the same; otherwise, let a good proportion of oats and beans be his supper, with hay, not to blow on half the night, but enough only to afford nutriment.

6740. *When returned home from a journey*, if it has been a severe one, let the horse have his fore shoes taken off, and, if possible, remove him to a loose box, with plenty of litter; but if the stones be rough, or the pavement be uneven, put on tips, or merely loosen the nails of those shoes he has on; keep the feet continually moist by a wet cloth, and stop them at night if the shoes be left on; mash him regularly, and if very much fatigued, or reduced, let him have malt or carrots, and if possible, turn him out an hour or two in the middle of the day to graze: bleeding or physicking are unnecessary, unless the horse shows signs of fear. If the legs be inclined to swell, bathe them with vinegar and chamberlye, and bandage them up during the day, but not at night, and the horse will soon recover to his former state.

Subsect. 4. *Horses in Curricles and Coaches.*

6741. *In working and managing horses in curricles*, two-wheeled chaises, and similar cases, great feeling and nicety is required, not to overload or overdrive the animal; to see that the weight is duly proportioned between the wheels and horse's back, and that the harness does not pinch; but no directions on this head can be of much use, unless the driver be a humane and considerate person, and one who sets a just value on the services of the noble animal committed to him. In Russia, the drivers of two-wheeled carriages, as droscheys, sledges, and others, corresponding to our gigs and curricles, have a barbarous custom of teaching the horses to turn round their heads, the one to the left, and the other to the right (*fig.* 850.), the sight of which is very offensive to a stranger.

850

6742. *In working and managing coach horses*, the same attention to grooming in all its departments is required as for saddle horses. Coach horses should never be brought into full work before they are five years old: when well fed on hard food, they may be worked at an average of thirty miles a day at twice. In general they should not be longer than five or six hours in the yoke at a time. Their principal meals should be in the morning and after their work is over for the day, as the action of trotting fast materially impedes digestion.

Subsect. 5. *Working of Cart, Waggon, and Farm Horses.*

6743. *In working and managing cart and waggon horses*, a similar attention is requisite as for coach horses, though perhaps in a somewhat less degree, the animal being hardier.

6744. *The working and managing of farm horses* includes the age at which they are put to work, the quantity of work they should perform, and their feeding and general management.

6745. *The age at which horses are put to full work, in the labours of a farm*, is usually when four or five years old, according to the nature of the soil, and the numbers of the team; but they are alway understood to be able to pay for their maintenance after they are three years old, by occasional work in ploughing and harrowing. Brown thinks it probable they might be put to work at four years old, were the same attention paid to their breeding and rearing that is paid to cattle and sheep.

6746. *The work which a farm horse ought to perform* is evidently a question of circumstances, which does not admit of any precise solution: a two-horse plough may, on an average, work about an English acre a day throughout the year; and, in general, according to the nature of the soil, and the labour that has been previously bestowed on it, a pair of horses, in ploughing, may travel daily from ten to fifteen

miles, overcoming a degree of resistance equal to from four to ten hundred weight. On a well made road, the same horses will draw about a ton in a two-wheeled cart for twenty or twenty-five miles every day; and one of the better sort, in the slow movement of the carrier or waggoner, commonly draws this weight by himself on the best turnpike roads. In some places horses are in the yoke, when the length of the day permits, nine hours, and in others ten hours a day; but for three or four months in winter, only from five to eight hours. In the former season they are allowed to feed and rest two hours from mid-day, and in the latter they have a little corn on the field, when working as long as there is day light, but none if they work only five or six hours. (*Sup. Enc. Brit.* art. *Agr.*)

6747. *The feeding of farm horses* is a subject of great agricultural importance, and has excited considerable discussion among speculative agriculturists, who have generally urged the great expenses attending it as an argument against horses, in favour of oxen. Others, without preferring oxen to horses, have, instead of corn and hay, proposed to feed them on roots, leaves, whins, and even haws from the hedges. The latter have been given in large quantities by West of Hampshire, and, it is said (*Complete Farmer*, art. *Team*), were found to answer. That horses as well as men may live on very inferior food is evident; but that either will be able to perform their work under such treatment, as well as if they were properly nourished, is contrary to reason and experience. It is observed by the judicious writer so often quoted, that horses can never perform their labour, according to the present courses of husbandry, on carrots, turnips, potatoes, or other roots alone, or as their chief food. They will work and thrive on such food; but they will work as much more, and thrive as much better, with oats or beans in addition, as fully to repay the difference in expense. One of the three meals a day, which farm horses usually receive, may consist of roots; and a few of them, every twenty-four hours, are highly conducive to the health of the animals: but we have never had occasion to see any horse work regularly throughout the year, in the way they are usually worked in the best cultivated districts, without an allowance of at least an English peck of oats, or mixed oats and beans, daily, less or more at particular periods, but rather more than this quantity for at least nine months in the year.

6748. *Brown* does not approve of giving much grain to young horses, thinking it expensive, and not so conducive to their health as when they are supported on green food. In the winter and spring months, a few turnips are eminently beneficial to young horses, by keeping their blood in good order, swelling their bone, and hastening their growth. A plentiful supply of grass in summer ought always to be allowed, as their condition through the winter depends greatly upon that circumstance. It is an object deserving of attention, that flesh once gained ought never to be lost, but that every animal whatever should be kept in a progressive state of improvement, and not suffered to take a retrograde course, which afterwards must be made up by extra feeding, or a loss be sustained, in a direct proportion to the degree of retrogradation that has actually occurred.

6749. *The leanness of a farmer's working cattle*, and their reluctant movements, clearly mark his unprosperous condition. There are particular operations, indeed, such as turnip-sowing, seeding, fallows, harvest-work, &c., which require to be executed with so great despatch in our variable climate, that unusual exertions are often indispensable. At these times, it is hardly possible, by the richest food and the most careful treatment, to prevent the animals from losing flesh, sometimes even when their spirit and vigour are not perceptibly impaired. Such labours, however, do not continue long, and should always be followed by a corresponding period of indulgence. It is particularly dangerous and unprofitable to begin the spring labour with horses worn down by bad treatment during winter. (*Sup. Enc. Brit.* art. *Agr.*)

6750. *Donaldson* observes, that the coarse garbage with which farm horses are commonly stuffed, profitably or otherwise, is the real cause of the frequent occurrence among them of blindness, grease, and colic; more particularly the last, which, with care, might be prevented from happening so frequently. The remedy lies in physic, once or twice a year; either the regular aloetic dose, or salts given in pails of warm water, or sulphur and cream of tartar; one third of the latter mixed in the corn. All horses kept in the stable become, more or less, internally loaded; and it is an error to suppose cart-horses are not equally benefited with others by purging physic.

6751. *The cleaning and dressing of farm horses* was formerly very little attended to; but at present its importance to the health of the animal is better understood. Donaldson recommends that the heels, legs, bend of the knee, and hock, the twist under the flanks; in short, all parts out of sight, of cart horses, whilst standing in the house, should be kept perfectly free from dirt and scurf, and the skin supple; the parts more in sight will take care of themselves. In a deep country, it is much the better practice, notwithstanding the prejudice to the contrary, to trim their legs coach-horse fashion. It is now well understood, the editor of *The Farmer's Magazine* observes, that the liberal use of the brush and the currycomb twice a day; frequent but moderate meals, consisting of a due proportion of succulent joined to more solid food; abundance of fresh litter, and great attention to method and cleanliness, are as indispensable in the stable of a farmer (as far as is consistent with a just regard to economy) as they have always been held to be in the treatment of horses kept for pleasure. Good dressing, with all well informed and attentive men, is considered to be no less necessary to the thriving of the horses than good feeding; according to a common expression, it is equal to half their food.

6752. *The general management of farm horses in the improved districts of the north* may be presented as a good example. There, for about four months in summer, horses are fed on pastures; or on clover and rye-grass, and tares cut green, and brought home to the stable or fold-yard; the latter method being by far the most economical and advantageous. For the other eight months, they are kept on the straw of oats, beans, and peas, and on clover and rye-grass hay. As soon as the grass fails towards the end of autumn, they have hay for a few weeks, and when the days become so short as to allow of no more than from six to eight hours' work, they are very generally fed with different kinds of straw, according to the circumstances of the farm; in the month of March they are again put to hay till the grass is ready for being cut. Throughout all the year they are allowed more or less corn, when constantly worked; and during the time they are on dry fodder, particularly when on straw, they have potatoes, yams, or Swedish turnips, once a day, sometimes boiled barley, and, in a few instances, carrots. A portion of some of these roots is of great importance to the health of horses, when succulent herbage is first exchanged for hay at the end of autumn; and it is no less so towards the latter end of spring, when hay has become sapless, and the labour is usually severe. At these two periods, therefore, it is the practice of all careful managers to give an ample allowance of some of these roots, even though they should be withheld for a few weeks during the intermediate period.

6753. *The quantity of these different articles of food* must depend on the size of the horses, and the labour they perform; and the value upon the prices of different seasons, and, in every season, on the situation of the farm with respect to markets, particularly for hay and roots, which bring a very different price near large towns, and at a few miles distant. It is for these reasons that the yearly expense of a horse's maintenance has been estimated at almost every sum, from 15*l.* to 40*l.* But it is only necessary to attend to the expense of feeding horses that are capable of performing the labour required of them, under the most correct and spirited management. Such horses are fed with oats, sometimes with beans, three times a day, for about eight months; and twice a day for the other four, when at grass; and, at the rate of eight feeds per bushel, each horse will eat fifteen quarters of oats, or twenty bolls Linlithgow measure in the year. When on hay, he will require about one stone of twenty-two pounds *avoirdupoise* daily, and five pounds more if he does not get roots. One English acre of clover and rye-grass, and tares, may be necessary for four months' soiling; and a quarter of an acre of potatoes, yams, or Swedish turnips, during the eight months he is fed with hay or straw. The use of these roots may admit of a small diminution of the quantity of corn in the winter months, or a part of it may be, as it almost always is, of an inferior quality.

6754. *The expense of feeding a horse throughout the year* may therefore be estimated, in regard to quantity, as follows: —

Oats, fifteen quarters.
Soiling, one acre of clover and rye-grass, and tares.
Hay part of October and November, March, April, and May, 1¼ ton.
Straw for other four months, half the price of hay.
Potatoes, yams, or Swedish turnips, ¼ acre.
(*Sup., &c.* art. *Agr.*)

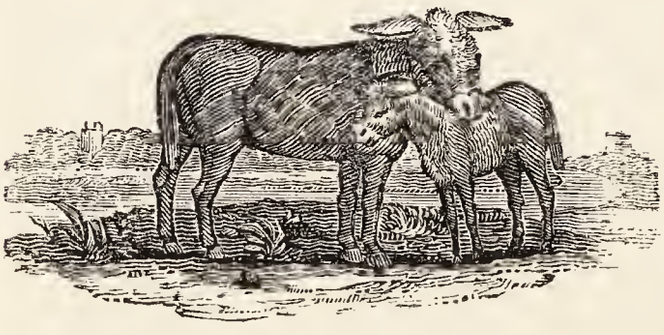
6755. *The extent of land required for a horse's maintenance, supposing the soil to be of a medium quality*, may be about five acres; that is, for oats three acres, soiling one, and one more for hay and roots. On rich soils four acres will be sufficient; but on poor soils, and wherever horses are kept at pasture, the produce of six acres and a half, or seven acres, will be consumed by one of them, when worked in the manner already mentioned. The straw of about two acres must be allowed for fodder and litter, the last of which has not been stated above; because, at a distance from towns, what is allowed for litter must, at any rate, be converted into dung. If sixty acres, therefore, should be assumed as the average extent of land that may be kept in cultivation by two horses, according to the best courses of modern husbandry, the produce of ten acres of this will be required for their maintenance; or, a horse consumes the produce of one acre out of every six which he cultivates, according to a four or six years' course, and something more than one acre out of every five which he ploughs annually. (*General Report of Scotland*, vol. iii. p. 192.)

Chap. II.

The Ass. — E`quus Asìnus L. *Ane*, Fr.; *Esel*, Ger.; *Asno*, Span.; and *Asino*, Ital.

6756. *The ass* is a native of the mountainous deserts of Tartary, of Arabia, Persia, and other parts of the Asiatic continent; and at present is very generally domesticated throughout most civilised countries. The wild ass feeds chiefly on the most saline or bitter plants of the desert, as the kalis, atriplices, chenopodium, &c.; and also prefers the saltest and most brackish water to that which is fresh. Of this the hunters are aware, and usually station themselves near the ponds to which they resort to drink. Their manners greatly resemble those of the wild horse. They assemble in troops under the conduct of a leader, or sentinel; and are extremely shy and vigilant. They will, however, stop in the midst of their course, and even suffer the approach of man, and then dart off with the utmost rapidity. They have been at all times celebrated for their swiftness. Their voice resembles that of the common ass, but is shriller.

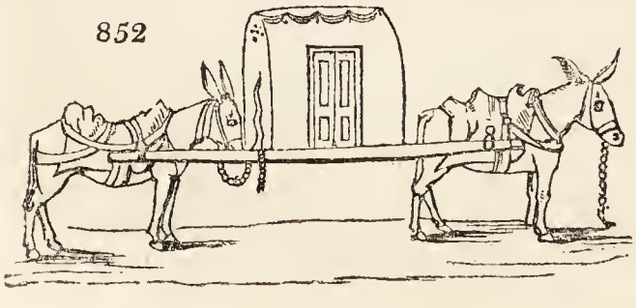
6757. *The excellencies and defects of the common ass* have amply engaged the lively pens of several descriptive writers on the history of animals; and of none with more happy effect than those of the eloquent Buffon, and the ingenious Abbé la Pluche. The ass, in his natural temper, is humble, patient, and quiet, and bears correction with firmness. He is extremely hardy, both with regard to the quantity and quality of his food, contenting himself with the most harsh and disagreeable herbs, which other animals will scarcely touch. In the choice of water he is, however, very nice; drinking only of that which is perfectly clear, and at brooks with which he is acquainted. He is very serviceable to many persons who are not able to buy or keep horses; especially where they live near heaths or commons, the barrenest of which will keep him; being contented with any kind of coarse herbage, such as dry leaves, stalks, thistles, briers, chaff, and any sort of straw. He requires very little looking after, and sustains labour beyond most others. He is seldom or never sick; and endures hunger and thirst longer than most other kinds of animals. The ass may be made use of in husbandry to plough light lands, to carry burdens, to draw in mills, to fetch water, cut chaff, or any other similar purposes. The female (*fig.* 851.) is also useful in many cases for her milk, which is excellent; and she might be of more advantage to the farmer if used, as in foreign countries, for the breeding of mules. The skin of the ass is extremely hard, and very elastic, and is used for various purposes; such as to cover drums, make shoes, or parchment. It is of the skin of this animal that the Orientals make the fagri, or, as we call it, shagreen. The milk of the ass is the lightest of all milks, and is recommended by medical men to persons of delicate stomachs; the flesh, and the hair of the tail and mane, are used as those of the horse.



6758. *The ass attains his full growth* in three or four years, and may then be put to work. Like the horse, he will live to 25 or 30 years: it is said the female lives longer than the male; but, perhaps, this happens from their being often pregnant, and at those times having some care taken of them, instead of which the males are constantly worn out with fatigue and blows. They sleep less than the horse, and do not lie down to sleep, except when they are exceedingly tired. The male ass also lasts much longer than the stallion; the older he is, the more ardent he appears; and, in general, the health of this animal is much better than that of the horse; he is less delicate, and not nearly so subject to maladies. Ophthalmia, which may be reckoned among the indigenæ of the cultivated horse, is almost unknown to the ass. Contraction of the feet also is very seldom observed in him.

6759. *The different breeds or races of the ass* are much less known than those of the horse; because in this country they have not been taken the same care of, or followed with the same attention. Travellers inform us that there are two sorts of asses in Persia; one of which, being slow and heavy, is used for burdens; and the other is kept like horses for the saddle. The latter have smooth hair, carry their heads well, and are much quicker in their motion; but when they ride them they sit nearer the buttocks than when on horseback. They are dressed like horses, and like them are taught to amble; and they cleave their nostrils to give them more room for breathing. According to Dr. Russell, there are two sorts in Syria, one of which is like ours, and the other very large, with remarkably long ears; but both kinds are employed for the purpose of carrying burdens and sedan chairs. (*fig.* 852.)

852



6760. *In breeding from the ass*, the same general rules should be attended to as in the horse breeding. The male ass will procreate at the age of two and a half years, and the female still earlier. The stallion ass should be chosen from the largest and strongest of his species; he must at least be three years old, but should not exceed ten; his legs should be long, his body plump, head long and light, eyes brisk, nostrils and chest large, neck long, loins fleshy, ribs broad, rump flat, tail short, hair shining, soft to the touch, and of a deep grey. Those are reckoned the best shaped that are well squared, have large eyes, wide nostrils, long necks, broad breasts, high shoulders, a great back, short tail, the hair sleek, and of a blackish colour.

6761. *The best time for covering* is from the latter end of May to the beginning of June, nor must the female be hard worked whilst with foal, for fear of casting; but the more the male is worked, in moderation, the better he will thrive. She brings forth her foal in about a twelvemonth, but, to preserve a good breed, she should not produce more than one in two years. She should be covered between the months of March and June. The best age to breed at is from three years old to ten. When the foal is cast, it is proper to let it run a year with the dam, and then wean it by tying up and giving it grass, and sometimes milk; and, when it has forgot the teat, it should be turned out into a pasture; but if it be in winter, it must then be fed at times, till it be able to shift for itself.

6762. *The ass may be broken and trained* at the end of the second year; but should not be worked sooner than the third year. Breaking is easily effected when two years old, or it may be let alone still longer, as till three years. It is easily done by laying small weights on his back, and increasing them by degrees; then set a boy upon him, and so increase the weights as may be proper, till they are sufficiently heavy.

6763. *The age of the ass* is known by his teeth in the same manner as the horse. At two years and a half old, the first middle incisive teeth fall out, and the other on each side soon follow; they are renewed at the same time, and in the same order.

6764. *The anatomy and physiology of the ass* do not differ from those of the horse essentially. The concha cartilages of the ears are, however, considerably more elongated; the spinous processes of the dorsal vertebræ forming the withers are less extensive; and the bones of the extremities in general are less angularly placed, from whence results his inferiority in speed. It is also to the unbending lines of the spine, that his motions are rendered so uneasy to a person placed on the middle of his back. Some specialty occurs in the feet, which, like the horses of arid climes, are small and upright. His laryngeal sonorous sacs and córdæ vocàles are not altogether like those of the horse, from whence his aptitude to bray instead of neighing. In the ass there are three laryngeal sacs as in the horse; but instead of a wide opening into them, there is a small round hole, and the interior sac is a real bag of considerable size. In the horse there is also, at the commissure of the cordæ vocales, a slight membranous fold not visible in the ass. These organs in the mule are compounded of these forms. Braying appears produced through the mouth, whereas neighing is principally effected by the nose. There is a hollow membranous cavity at the back of the mouth that is greatly assistant to this trumpet-like noise, which is effected by convulsively displacing the vèlum palàti by alternate inspirations and expirations.

6765. *The diseases of the ass*, as far as they are known, bear a general resemblance to those of the horse. As he is more exposed, however, and left to live in a state more approaching to natural, he has few diseases. Those few, however, are less attended to than they ought to be; and it is for the veterinary practitioner to extend to this useful and patient animal the benefit of his art, in common with those of other animals. The ass is seldom or never troubled with vermin, probably from the hardness of its skin.

6766. *The ass is shod* with a narrow web, and with heels projecting beyond the heel of the foot, and slightly turned up, for he seldom overreaches; but much care is required in using small nails, and in very carefully driving them. The hinder shoes differ little from those used for the fore feet.

Chap. III.

The Mule and Hinny, Hybrids of the Horse and Ass.

6767. *The mule* (E`quus Asìnus var. γ Mùlus L. *Grand Mulet* Fr.; *Grosser Maulessel*, Ger.; *Mula*, Span. and Ital.) is the hybrid produce of an ass with a mare; having a large clumsy head, long erect ears, a short mane, and a thin tail.

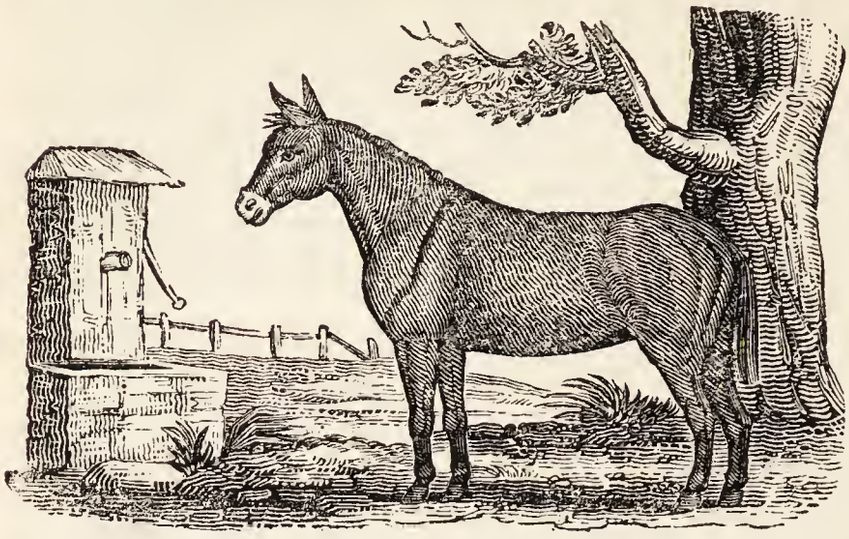
6768. *The hinny* (E`quus Asìnus, var. δ Hínnus L. *Bardeau* or *Petit Mulet*, Fr.; *Kleiner Maulessel*, Ger.; *Mulo*, Span. and Ital.) is the hybrid produce between the she-ass and a stallion; the head is long and thin, the ears are like those of a horse, the mane is short, and the tail is well filled with hair. The hinny is much less common than the mule; because, being less hardy and useful than the other, he is never cultivated.

6769. *The mule*, commonly so called, is much valued for the saddle, and for drawing carriages in Spain, Portugal, Italy, and the East, and in the warmer parts of America. In those countries where great attention is paid to the breed, it is as tall as the horse, exceedingly well limbed, but not so handsome, especially about the head and tail. These animals are mostly sterile; some, indeed, have thought that they are altogether incapable of producing their kind; but some few instances have occurred in which female mules have had foals, and in which even the male has impregnated females both of the ass and horse species, though such instances are exceedingly rare.

6770. *The mules made use of in the southern parts of Europe* are now brought to an astonishing perfection as well as great size. (*fig.* 853.) They are usually black, strong, well-limbed, and large, being mostly bred out of fine Spanish mares. They are sometimes fifteen or sixteen hands high, and the best of them worth forty or fifty pounds. No creatures are so proper for large burdens, and none so sure-footed. They are much stronger for draught than our horses, and are often as thickset as our dray-horses, and will travel several months together, with six or eight hundred weight upon their backs. Some think it surprising that these animals are not more propagated here, as they are so much hardier and stronger than horses, less subject to diseases, and capable of living and working to twice the age of a horse. Those that are bred in cold countries are more hardy and fit for labour than those bred in hot; and those which are light made are fitter for riding than horses, as to the walk and trot; but they are apt to gallop rough; though these do it much less than the short-made ones. The general complaint made against them is, that they kick and are stubborn; but this is owing to neglect in breeding them, for they are as gentle as horses in countries where they are bred with proper care.

6771. *In the breeding of mules*, mares that are of a very large breed and well made should be employed. They should be young, full of life, large barrelled, but small limbed, with a moderate-sized head, and a good forehand. It is found of advantage to have the foals from the time of their being dropped often

handled, to make them gentle: it prevents their hurting themselves by skittishness and sudden frights; and they are much easier broken at the proper age, and become docile and harmless, having nothing of that viciousness which is so commonly complained of in these animals. They may be broken at three years old, but should never be permitted to do much hard work till four, as they are thus secured from being hurt by hard labour, till they have acquired strength enough to bear it without injury. An expert breeder of these animals found, that feeding them too well while young, was not only incurring a much larger expense than was any way necessary, but also made them wonderfully nice and delicate in their appetites ever after. He therefore contented himself with giving them food enough to prevent their losing flesh, and to keep up their growth without palling their appetites with delicacies, or making them over-fat: he also took care to defend them from the injuries of the weather by allowing them stable-room, and good litter to sleep on, besides causing them every day to be well rubbed down with a hard wisp of straw by an active groom. This was scarcely ever omitted, particularly in cold, raw, wet weather, when they were least inclined to exercise themselves. When three years old, mules are proper for use.



6772. *The shoe for the mule* is by some made not unlike the bar shoe before, and the common shoe behind; by some both fore and hind shoes are made to project considerably beyond the toe, under an idea of increasing the points of contact with the ground: but the most usual shoe is one formed between the usual horse and ass shoe.

Chap. IV.

Neat or Horned Cattle. — *Bós* L.; *Mammàlia Pécora* L., and *Ruminàleæ* Cuv. *Bêtes à corne*, Fr.; *Vieh*, Ger.; *Ganado*, Span.; and *Bestiame*, Ital.

6773. *The neat or horned cattle used in agriculture* are included under two species of *Bós*; the *B. Taúrus* or ox, and the *B. bùbulus* or buffalo; the latter less used in Britain than on the Continent and in other countries. These animals are more universally used as beasts of draught and burden than the horse, and have the additional advantage of furnishing excellent food and other valuable products. There is scarcely a country in which the ox or the buffalo is not either indigenous, or naturalised and cultivated; while in many parts of the world the horse is either wanting, or reserved for the purposes of war or the saddle.

Sect. I. *The Ox.* — *Bós Taúrus* L.; *Ochs*, Ger; *Bœuf*, Fr.; *Buey*, Span.; and *Bue*, Ital.

6774. *The male ox* is the bull (*Taureau*, Fr.; *Stier*, Ger.; *Toro*, Span. and Ital.) and the female the cow (*Vache*, Fr.; *Kuh*, Ger.; and *Vaca*, Span. and Ital.). The bull and cow inhabit various parts of the world, and, as already observed, are domesticated every where. In most countries, however, they are the mere creatures of soil and climate, the same attention in breeding and rearing that is bestowed on the horse being withheld; the natural habits little restrained or the form little improved for the purposes of milking, fattening, or for labour. It is almost exclusively in Britain that this race of animals has been ameliorated so as to present breeds for each of these purposes, far superior to what are to be found in any other country. Notwithstanding this, however, much certainly remains to be known regarding the nutriment afforded by different kinds of herbage and roots; the quantity of food consumed by different breeds, in proportion as well to their weight at the time, as to the ratio of their increase; and the propriety of employing large or small animals in any given circumstances. Even with regard to the degrees of improvement made by fatting cattle generally, from the consumption of a given weight of roots or herbage, no great accuracy is commonly attempted; machines for weighing the cattle themselves and their food, from time to time, not being yet in general use in any part of Britain. We shall consider this valuable family as to variety, criteria, breeding, earing, feeding, working, fattening, and milking: the manufacture of milk will be treated of in a succeeding chapter.

Subsect. 1. *Varieties and Breeds of the Bull.*

6775. *The varieties of the wild ox* are the bonasus and the bison (*fig.* 112.); the first with a long mane, and the last with a gibbous back. They inhabit the woods in Madagascar and many other countries of the East; and the bison is even said to be found in Poland.

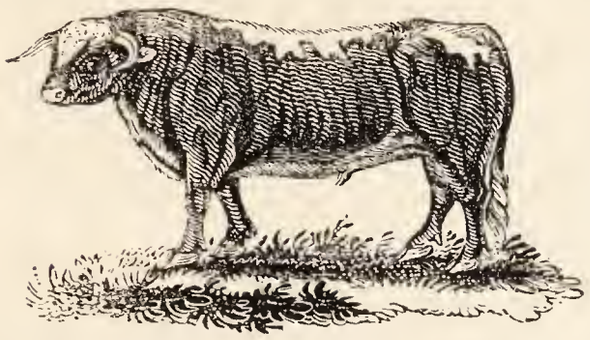
6776 *The varieties of the European cow*, according to Aiton, are innumerable. The pliancy of their nature is such, that they have been formed into many diversities of shape, and various qualities have been given them, very different from the original stock. The *uris*, or cows of Lithuania, are almost as large as the elephant; while some of those on the Grampian hills are little above the size of a goat; and cows are found of every diversity of size between the one and the other. They are not less varied in their shapes. The *bison*, which is a species of the cow family, and which readily propagates with our cows, wears a strong shaggy mane, like the lion; a beard, like the goat; as much hair under its neck and breast as covers its fore legs; a hump upon its shoulders, nearly as large as that worn by the camel (sometimes forty or fifty pounds in weight), with a tail that scarcely reaches the top of its buttock; and it resembles the lion much more than it does our domesticated cows, or other varieties of its own species. (*Aiton.*)

6777. *The diversity of qualities in the cow family* is also very great. Our cows are so grovelling and inactive, that they scarcely know the road from their stall to their pasture; while those of the Hottentots are so tractable as to be intrusted with the charge of other animals, and keep them from trespassing on the fields of grain, or other forbidden ground. They also fight their master's battles, and gore his enemies with their horns. Our dairy cows are so feeble and inactive, that they are hurt by travelling twice a day, even slowly, one mile from the byre to their pasture; while those of Tartary are used as riding animals, and in drawing carriages. Those of Hindostan draw the coaches, and maintain their rates with horses at the full trot; and the Hottentots teach their cows to hunt down the elk antelope. Cows of the wild neglected breed can with difficulty be removed from one enclosure or one hill to another; while those on whom due attention has been bestowed are docile, and submit to perform all sorts of labour. Some cows will yield upwards of twenty Scots pints of milk per day, while others will not give so much in ten, perhaps not in twenty days. These are not so many different species of animals, but all of them one and the same species, all capable of generating with each other a perfect offspring. All these varieties have been formed from the parent stock, partly by the diversity of soil and climate, or other accidental or adventitious circumstances; and partly of late by human skill and industry. (*Dairy Husbandry*, p. 17.)

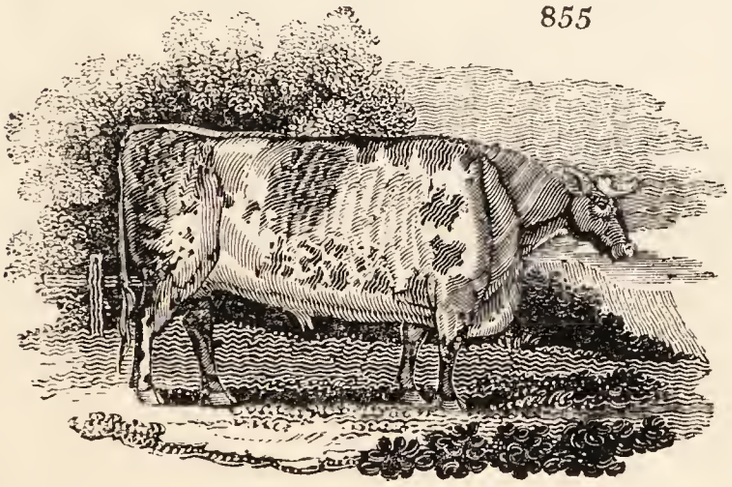
6778. *The varieties of the cultivated ox* are the European, Indian, Zebu, Surat, Abyssinian, Madagascar, Tinian, and African. From the European variety have been formed the different breeds cultivated in Britain. They are very numerous, but we shall only notice such as are in most esteem. These different breeds are generally distinguished by the length or flexure of their horns; by the absence of horns; by the districts where they are supposed to have originated, or in which they abound, or exist in the greatest purity; or by the name of the breeder.

6779. *The long-horned or Lancashire breed of cattle* (*fig.* 854.) is distinguished from others by the length of their horns, the thickness and firm texture of their hides, the length and closeness of their hair, the large size of their hoofs, and their coarse, leathery, thick necks: they are likewise deeper in their fore quarters, and lighter in their hind quarters, than most other breeds; narrower in their shape, less in point of weight than the short horns, though better weighers in proportion to their size; and though they give considerably less milk, it is said to afford more cream in proportion to its quantity. They are more varied in their colour than any of the other breeds; but, whatever the colour be, they have in general a white streak along their back, which the breeders term finched, and mostly a white spot on the inside of the hough. (*Culley*, p. 53.) In a general view, this race, notwithstanding the singular efforts that have been made towards its improvement, remains with little alteration; for, except in Leicestershire, none of the subvarieties (which differ a little in almost every one of those counties where the long horns prevail) have undergone any radical change or any obvious improvement.

854



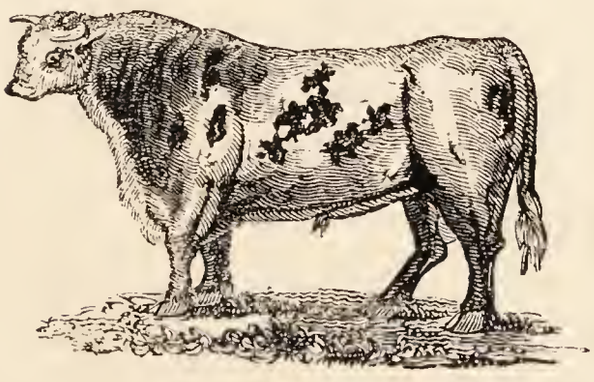
855



The improved breed of Leicestershire (*fig.* 855.) is said to have been formed by Webster, of Cauley, near Coventry, in Warwickshire, by means of six cows brought from the banks of the Trent, about the beginning of the present century, which were crossed with bulls from Westmoreland and Lancashire. Bakewell of Dishley, in Leicestershire, afterwards got the lead as a breeder, by selecting from the Cauley stock; and the stocks of several other eminent breeders have been traced to the same source. (*Marshal's Midland Counties*, vol. i. p. 318.)

6780. *The short-horned*, sometimes called the Dutch breed (*fig.* 856.), is known by a variety of names, taken from the districts where they form the principal cattle stock, or where most attention has been paid to their improvement: thus, different families of this race are distinguished by the names of the *Holderness*, the *Teeswater*, the *Yorkshire*, *Durham*, *Northumberland*, and other breeds.

856



The Teeswater breed, a variety of short horns, established on the banks of the Tees, at the head of the vale of York, is at present in the highest estimation, and is alleged to be the true Yorkshire short-horned breed. Bulls and cows from this stock, purchased at most extraordinary prices, are spread over all the north of England, and the border counties of Scotland. The bone, head, and neck of these cattle are fine; the hide is very thin; the chine full; the loin broad; the carcase throughout large and well fashioned; and the flesh and fatting quality equal, or perhaps superior, to those of any other large breed. The short-horns give a greater quantity of milk than any other cattle; a cow usually yielding twenty-four quarts of milk per day, making three firkins of butter during the grass season: their colours are much varied, but they are generally red and white mixed, or what the breeders call flecked. The heaviest and largest oxen of the short-horned breed, when properly fed, victual the East India ships, as they produce the thickest beef, which,

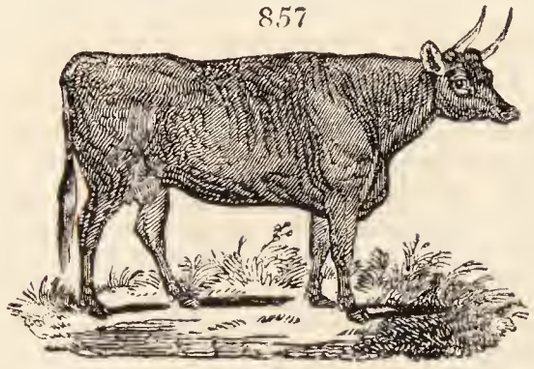
by retaining its juices, is the best adapted for such long voyages. Our royal navy should also be victualled from these; but, from the jobs made by contractors, and from other abuses, it is feared our honest tars are often fed with beef of an inferior quality; however, the coal ships from Newcastle, Shields, Sunderland, &c., are wholly supplied with the beef of these valuable animals. These oxen commonly weigh from 60 to 100 stone (14 lbs. to the stone); and they have several times been fed to 120, 130, and some particular ones to upwards of 150 stone, the fore-quarters only. (*Culley*, p. 48.)

6781. *In comparing the breeds of long and short horned cattle*, Culley observes that the long-horns excel in the thickness and firm texture of the hide, in the length and closeness of the hair, in their beef being finer-grained, and more mixed and marbled than that of the short-horns, in weighing more in proportion to their size, and in giving richer milk; but they are inferior to the short-horns, in giving a less quantity of milk, in weighing less upon the whole, in affording less tallow when killed, in being generally slower feeders, and in being coarser made and more leathery or bullish in the under side of the neck. In few words, says he, the long-horns excel in the hide, hair, and quality of the beef; the short-horns in the quantity of beef, tallow, and milk. Each breed has long had, and probably may have, its particular advocates; but if he may hazard a conjecture, is it not probable that both kinds may have their particular advantages in different situations? Why not the thick firm hides, and long close-set hair, of the one kind, be a protection and security against those impetuous winds and heavy rains to which the west coast of this island is so subject; while the more regular seasons and mild climate upon the east coast are more suitable to the constitutions of the short-horns.

6782. *The middle-horned breeds* comprehend, in like manner, several local varieties, of which the most noted are the *Devons*, the *Sussexes*, and the *Herefords*; the last two, according to Culley, being varieties of the first, though of a greater size, the Herefords being the largest. These cattle are the most esteemed of all our breeds for the draught, on account of their activity and hardiness; they do not milk so well as the short-horns, but are not deficient in the valuable property of feeding at an early age, when not employed in labour.

6783. *The Devonshire cattle* (*fig.* 857.) are of a high red colour (if any white spots they reckon the breed impure, particularly if those spots run one into another), with a light-dun ring round the eye, and the muzzle of the same colour, fine in the bone, clean in the neck, horns of a medium length, bent upwards, thin-faced, and fine in the chops, wide in the hips, a tolerable barrel, but rather flat on the sides, tail small, and set on very high; they are thin-skinned, and silky in handling, feed at an early age, or arrive at maturity sooner than most other breeds. (*Culley*, p. 51.) Another author observes, that they are a model for all persons who breed oxen for the yoke. (*Parkinson on Live Stock*, vol. i. p. 112.) The weight of the cows is usually from 30 to 40 stone, and of the oxen from 40 to 60; the North Devon variety, in particular, from the fineness in the grain of the meat, is held in high estimation in Smithfield. (*Dickson's Practical Agriculture*, vol. ii. p. 120.)

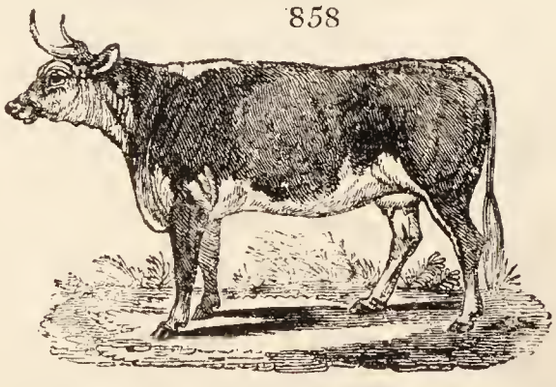
857



6784. *Lawrence* says that the race of red cattle of North Devon and Somerset is doubtless one of our original breeds, and one of those which have preserved most of their primitive form: the excellence of this form for labour is best proved by the fact, that the fashionable substitution of horses has made no progress in the district of these cattle, by their high repute as feeders, and for the superior excellence of their beef, which has been acknowledged for ages. They are, he says, the speediest working-oxen in England, and will trot well in harness; in point of strength, they stand in the fourth or fifth class. They have a greater resemblance to deer than any other breed of neat cattle. They are rather wide than middle-horned, as they are sometimes called; some, however, have regular middle-horns, that is, neither short nor long, turned upward and backward at the points. As milkers, they are so far inferior to both the long and short horns, both in quantity and quality of milk, that they are certainly no objects for the regular dairy, however pleasing and convenient they may be in the private family way.

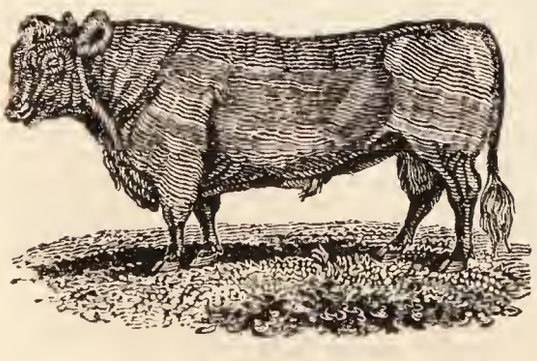
6785. *The Sussex and Herefordshire cattle* (*fig.* 858.) are of a deep red colour, with fine hair and very thin hides; neck and head clean, the face usually white; horns neither long nor short, rather turning up at the points; in general, they are well made in the hind quarters, wide across the hips, rump, and sirloin, but narrow in the chine; tolerably straight along the back, ribs too flat, thin in the thigh, and bone not large. An ox, six years old, will weigh, when fat, from 60 to 100 stone, the fore-quarters generally the heaviest: the oxen are mostly worked from three to six years old, sometimes till seven, when they are turned off for feeding. The Hereford cattle are next in size to the Yorkshire short-horns: both this and the Gloucester variety are highly eligible as dairy stock, and the females of the Herefords have been found to fatten better at three years old than any other kind of cattle except the spayed heifers of Norfolk. (*Marshal's Economy of Gloucestershire.*)

858



6786. *The polled or hornless breeds.* The most numerous and esteemed variety is the Galloway breed (*fig.* 859.), so called from the province of that name, in the south-west of Scotland, where they most abound. The true Galloway bullock "is straight and broad on the back, and nearly level from the head to the rump, broad at the loins, not, however, with hooked bones, or projecting knobs, so that when viewed from above, the whole body appears beautifully rounded; he is long in the quarters, but not broad in the twist; he is deep in the chest, short in the leg, and moderately fine in the bone, clean in the chop and in the neck; his head is of a moderate size, with large rough ears, and full but not prominent eyes, or heavy eyebrows, so that he has a calm though determined look; his well proportioned form is clothed with a loose and mellow skin, adorned with long soft glossy hair." (*Galloway Report*, p. 236.) The prevailing colour is black or dark brindled, and, though they are occasionally found of every colour, the dark colours are uniformly preferred, from a belief that they are connected with superior hardiness of constitution. The Galloways are rather undersized, not very different from the size of the Devons, but as much less than the long-horns, as the long-horns are less than the short-horns. On the best farms,

859



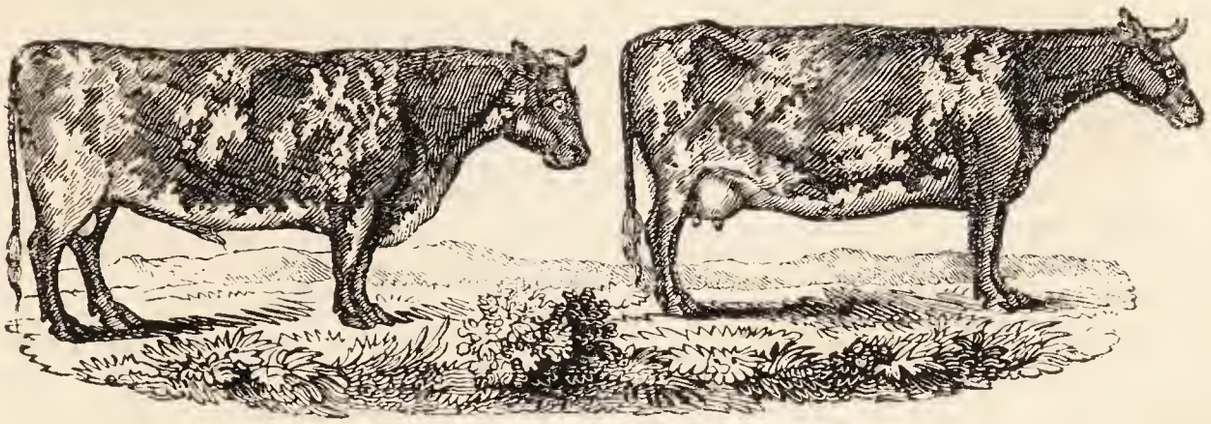
the average weight of bullocks three years and a half old, when the greater part of them are driven to the south, has been stated at about 40 stone, avoirdupois; and some of them, fattened in England, have been brought to nearly 100 stone.

6787. *The general properties of this breed* are well known in almost every part of England, as well as in Scotland. They are sometimes sent from their native pastures directly to Smithfield, a distance of four hundred miles, and sold at once to the butcher; and in spring they are often shown in Norfolk, immediately after their arrival, in as good condition as, or even better than, when they begin their journey; with full feeding, there is perhaps no breed that sooner attains maturity, and their flesh is of the finest quality. Culley was misinformed about the quantity of milk they yield, which, though rich, is by no means abundant. It is alleged not to be more than seventy or eighty years since the Galloways were all horned, and very much the same in external appearance and character with the breed of black cattle which prevailed over the west of Scotland at that period, and which still abounds in perfection, the largest-sized ones in Argyleshire, and the smaller in the Isle of Sky. The Galloway cattle at the time alluded to were coupled with some hornless bulls, of a sort which do not seem now to be accurately known, but which were then brought from Cumberland, the effects of which crossing were thought to be the general loss of horns in the former, and the enlargement of their size: the continuance of a hornless sort being kept up by selecting only such for breeding, or perhaps by other means, as by the practice of eradicating with the knife the horns in their very young state. (*Coventry on Live Stock*, p. 28.)

6788. *The Suffolk duns*, according to Culley, are nothing more than a variety of the Galloway breed. He supposes them to have originated in the intercourse that has long subsisted between the Scotch drovers of Galloway cattle, and the Suffolk and Norfolk graziers who feed them. The Suffolks are chiefly light duns, thus differing from the Galloways, and are considered a very useful kind of little cattle, particularly for the dairy. (*Culley*, p. 66. *Parkinson*, vol. i. p. 116.)

6789. *The Ayrshire breed* (*fig.* 860.), according to Aiton (*Agriculture of Ayr*, p. 421.), is the most improved breed of cattle to be found in the island; not only for the dairy, in which they have no parallel,

860



under similar soil, climate, and relative circumstances; but also in feeding for the shambles. They are, in fact, a breed of cows that have, by crossing, coupling, feeding, and treatment, been improved and brought to a state of perfection, which fits them, above all others yet known, to answer almost in every diversity of situation, where grain and grasses can be raised to feed them, for the purposes of the dairy, or for fattening them for beef. (*Aiton.*)

6790. *The origin of the Ayrshire breed of cattle* is to be found in the indigenous cattle of the county of Ayr, "improved in their size, shapes, and qualities, chiefly by judicious selection, cross-coupling, feeding, and treatment, for a long series of time, and with much judgment and attention, by the industrious inhabitants of the county, and principally by those of the district of Cunningham." (*Aiton.*) The whole dairy breed in the county of Ayr is of mixed white and brown colours.

6791. *The size of the Ayrshire improved dairy cows* "varies from 20 to 40 stones English, according to the quality and abundance of their food. If cattle are too small for the soil, they will soon rise to the size it can maintain; and the reverse, if they are larger than it is calculated to support." (*Aiton.*)

6792. *The shapes most approved of* are as follows:—"Head small, but rather long and narrow at the muzzle; the eye small, but smart and lively; the horns small, clear, crooked, and their roots at considerable distance from each other; neck long and slender, tapering towards the head, with no loose skin below; shoulders thin; fore-quarters light; hind-quarters large; back straight, broad behind, the joints rather loose and open; carcass deep, and pelvis capacious and wide over the hips, with round fleshy buttocks; tail long and small; legs small and short, with firm joints; udder capacious, broad, and square, stretching forward, and neither fleshy, low hung, nor loose; the milk veins large and prominent; teats short, all pointing outwards, and at considerable distance from each other; skin thin and loose; hair soft and woolly; the head, bones, horns, and all parts of least value, small; and the general figure compact and well proportioned." (*Aiton.*)

6793. *The form of the Cunninghame Ayrshire cow*, according to Robertson, is "very elegant, but must be seen to be well understood. So far as it may be explained in words, it is thus:—The neck is small, the head little, the muzzle taper, the horns short, curved, and bending upwards; the countenance mild; the body straight along the back from shoulder to tail; the limbs slender; the udder shaped like a well turned punch-bowl, and the paps widely set. The head, the neck, and the udder are the chief distinguishing points. The colour is generally brown, of many hues, from dark to yellow, intermixed and mottled in many a varied form and proportion with white. Some few have a black ground, without any change in character; but almost none are of one colour only. In a whole hirsel of forty or fifty, there will not two of them be alike in colour, in this respect exhibiting a diversity not unlike to a bed of tulips, and of as many hues and shades, in an endless variety of beauty. The bulls are generally good tempered, and, like the cows, are also mild in the countenance. The usual produce of butter from these cows is ascertained to be about half their own weight (meaning the four quarters) in a year; but this requires that the pasture be good, and the cow otherwise well kept the whole season over." The produce of such a cow so kept will equal 242 lbs. imperial weight per annum of butter, and double that quantity of cheese. The medium produce in butter from Ayrshire milk is from five imperial quarts. (*Rural Recollections*, p. 565.)

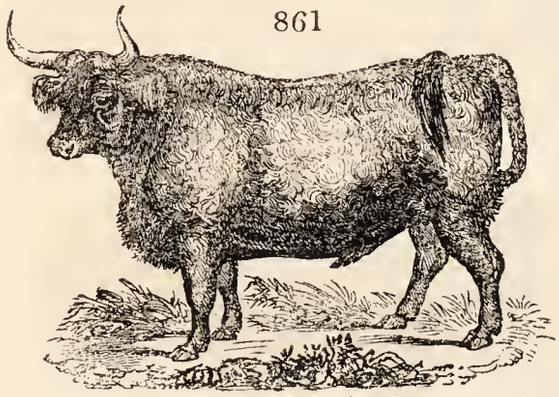
6794. *The qualities of an Ayrshire dairy-cow* "are of great importance. Tameness and docility of temper greatly enhance the value of a milch cow. One that is quiet and contented feeds at ease, does not break over fences, or hurt herself and other cattle, will always yield more milk, and is easier to manage, than those that are of a turbulent disposition. To render them docile, they ought to be gently treated; frequently handled when young, and never struck or frightened. Some degree of hardiness, a sound constitution, and a moderate degree of life and spirits, are qualities to be wished for in a dairy cow, and what those of Ayrshire generally possess. The most valuable quality which a dairy cow can possess is that she yields much milk. A cow in Ayrshire that does not milk well will soon come to the hammer. I have never seen cows any where that, under the same mode of feeding and treatment, would yield so much milk as the dairy breed of that district. Ten Scotch pints per day is no way uncommon. Several cows yield, for some time, twelve pints, and some thirteen or fourteen pints per day. Another quality of the

dairy breed of Ayrshire is, that, after they have yielded very large quantities of milk for several years, they are as valuable for beef as the Galloway cow, or any other breed of cows known in Scotland. They fatten as well, and their beef is not inferior to that of any other breed of cattle known in Britain." (*Aiton.*)

6795. *The cattle of the Highlands of Scotland* are divided into a number of local varieties, some of which differ materially from others, probably owing to a difference in the climate and the quality of the herbage, rather than to their being sprung from races originally distinct, or to any great change effected either by selection or by crossing with other breeds. It is only of late that much attention has been paid to their improvement, in any part of this extensive country; and in the northern and central Highlands the cattle are yet, for the most part, in as rude a state, and under management as defective, as they were some centuries ago. These cattle have almost exclusive possession of all that division of Scotland, including the Hebrides, marked off by a line from the Frith of Clyde on the west, to the Murray Frith on the north, and bending towards the east till it approaches in some places very near to the German Ocean. Along the eastern coast, north of the Frith of Forth, the Highland cattle are intermixed with various local breeds, of which they have probably been the basis. There are more or less marked distinctions among the cattle of the different Highland counties; and, in common language, we speak of the Inverness-shire, the Banffshire, &c., cattle, as if they were so many separate breeds; but it is only necessary in this place to notice the two more general varieties, now clearly distinguishable by their form, size, and general properties.

6796. *The most valuable of these are the cattle of the Western Highlands and Isles*, commonly called the *Argyleshire breed* (*fig.* 861.), or the breed of the Isle of Skye, one of the islands attached to the county of Argyle. The cattle of the Hebrides are called *kyloes*, a name which is often applied in the south to all the varieties of the Highland cattle, not as a late writer (*Dickson's Practical Agriculture*, vol. ii. p. 1124.) has imagined, from the district in Ayrshire called Kyle, where very few of them are kept, but from their crossing, in their progress to the south, the *kyloes* or ferries in the mainland and Western Islands, where these cattle are found in the greatest perfection. (*General Report of Scotland*, vol. iii. p. 26.)

861



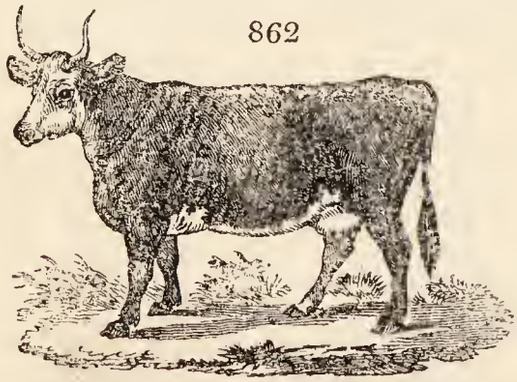
6797. *The cattle of Orkney and Zetland* are of a most diminutive size; an ox weighing about sixty pounds a quarter, and a cow forty-five pounds. They are of all colours, and their shapes are generally bad: yet they give a quantity of excellent milk; fatten rapidly when put on good pastures; and, in their own district, are considered strong, hardy, and excellent workers, when well trained to the yoke, and so plentifully fed as to enable them to support labour.

6798. *Of the Fifeshire cattle*, Culley observes, "You would at first imagine them a distinct breed, from their upright white horns, being exceedingly light-lyered and thin-thighed; but I am pretty clear that it is only from their being more nearly allied to the kyloes, and consequently less of the coarse kind of short horns in them. (*Culley*, p. 69.) Notwithstanding this opinion, the cattle of the north-eastern counties of Scotland require, for every useful purpose, to be mentioned separately from the Highland herds; and as all of them have a general resemblance, it will only be necessary in this place to notice the Fife cattle in particular. There are various traditions about the origin of this variety. It is said to have been much improved by English cows sent by Henry VII. to his daughter, the consort of James IV., who usually resided at the palace of Falkland, in that county; and as there is some resemblance between the cattle of Fife and Cambridgeshire, they are supposed to have been brought originally from the latter county. Others ascribe the origin of the present breed to bulls and cows sent by James VI. (James I. of England), in payment of the money which his obliging neighbours in Fife are said to have advanced for his equipment, when he went to take possession of the English throne. (*Report of Nairn and Moray*, p. 305.)

6799. *The prevailing colour of the Fife cattle* is black, though sometimes spotted or streaked with white, and some of them are altogether grey. The horns are small, white, generally pretty erect, or at least turned up at the points, bending rather forward, and not wide spread like the Lancashire long-horned breed. The bone is small in proportion to the carcass; the limbs clean, but short; and the skin soft. They are wide between the hook-bones; the ribs narrow, wide set, and having a great curvature. They fatten quickly, and fill up well at all the choice points; are hardy, fleet, and travel well, and are excellent for labour, both at plough and cart. A good cow of this breed gives from eighteen to twenty-four quarts of milk per day, yielding from seven to nine pounds of butter, and from ten to twelve pounds of cheese per week (twenty-four ounces to the pound), for some months after calving. (*Fife Report*, p. 251. and 253.)

6800. *The cattle of Aberdeenshire*, the largest of which are said to have been produced by crossing with Fife bulls, have been long highly esteemed in the southern markets. It is observed, that every succeeding generation of them has increased in size for the last thirty years; and that the native breed has doubled its former weight since the introduction of turnips. (*Aberdeenshire Report*, p. 468.) The colour is commonly black, but there are many of a red and brindled colour. They are thinner in the buttock, in proportion to their weight; and deeper in the belly, in proportion to their circumference, than the west Highlanders, and they yield a much larger quantity of milk. Many of them are brought to the south of Scotland, and kept during winter in the straw-yards, for which they suit better than smaller cattle, as they are not so impatient of confinement. The ordinary weight of middle-sized oxen, at from three to five years old, is from forty to fifty stone; but after being worked for some time, and thoroughly fattened, they have been known to reach double this weight.

862



6801. *Of the Welsh cattle* (*fig.* 862.) "there seem to be two distinct kinds. The large sort are of a brown colour, with some white on the rump and shoulders, denoting a cross from the long-horns, though in shape not the least resembling them. They are long in the legs, stand high according to their weight, are thin in the thigh, and rather narrow in the chine; their horns are white and turned upwards; they are light in flesh, and next to the Devons, well formed for the yoke; have very good hoofs, and walk light and nimbly. The other sort are much more valuable; colour black, with very little white; of a good useful form, short in the leg, with round deep bodies; the hide is rather thin, with short hair; they have a likely look, and a good eye; and the bones, though not very small, are neither large nor clumsy; and the cows are considered good milkers." (*Parkinson on Live Stock*, vol. i. p. 135.)

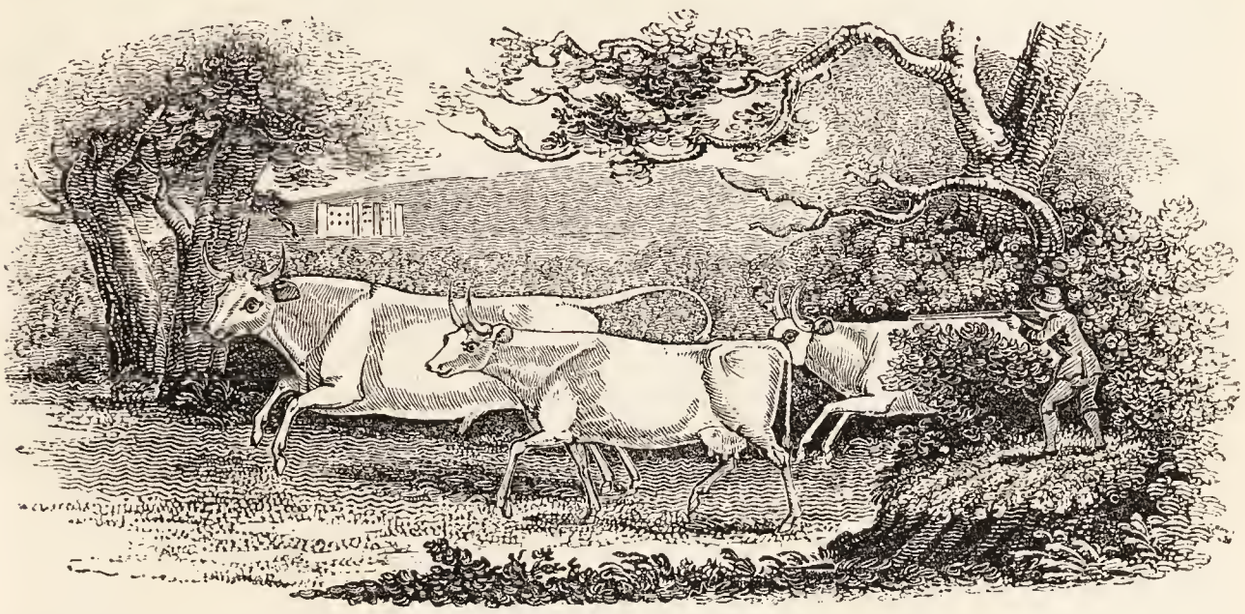
6802. *The Alderney cattle* are to be met with only about the seats of a few great landholders, where they are kept chiefly for the sake of their milk, which is very rich, though small in quantity. This race is considered, by very competent judges, as too delicate and tender to be propagated to any extent in Britain, at least in its northern parts. Their colour is mostly yellow or light red, with white or mottled faces; they have short crumpled horns, are small in size, and very ill-shaped; yet they are fine-boned in

general; and their beef, though high-coloured, is very well flavoured. I have seen, says Culley, some very useful cattle bred from a cross between an Alderney cow and a short-horned bull.

6803. *The Irish cattle*, Culley thinks, are a mixed breed between the long-horns and the Welsh or Scotch, but more inclined to the long-horns, though of less weight than those in England.

6804. The last variety of cattle we shall mention is one entirely of luxury, it is the *wild breed* (*fig.* 863.) which is found only in the parks of a few great proprietors, who preserve the animals as curious and

863



ornamental, or for the sake of their high-flavoured beef. Those kept at Chillingham Castle, in Northumberland, a seat belonging to the Earl of Tankerville, have been very accurately described in the *Northumberland Report*, and in Culley's book on live stock, so often quoted. Their colour is invariably of a creamy white; muzzle black; the whole of the inside of the ear, and about one third of the outside, from the tips downward, red; horns white, with black tips, very fine, and bent upwards; some of the bulls have a thin upright mane, about an inch and a half or two inches long. The weight of the oxen is from thirty-five to forty-five stone, and the cows from twenty-five to thirty-five stone the four quarters (fourteen pounds to the stone). The beef is finely marbled, and of excellent flavour. From the nature of their pasture, and the frequent agitation they are put into by the curiosity of strangers, it is scarcely to be expected they should get very fat; yet the six years old oxen are generally very good beef, from which it may be fairly supposed that, in proper situations, they would feed well.

6805. *The habits* of these animals are entirely rude; at the first appearance of any person they set off in full gallop, and at the distance of about two hundred yards, make a wheel round and come boldly up again, tossing their heads in a menacing manner; on a sudden they make a full stop, at the distance of forty or fifty yards, looking wildly at the object of their surprise, but, upon the least motion being made, they all again turn round, and fly off with equal speed, but not to the same distance, forming a shorter circle, and again returning with a bolder and more threatening aspect than before; they approach much nearer, probably within thirty yards, when they again make another stand, and again fly off: this they do several times, shortening their distance, and advancing nearer and nearer till they come within such a short distance, that most people think it prudent to leave them, not choosing to provoke them farther.

6806. *When the cows calve*, they hide their calves for a week or ten days in some sequestred situation, and go and suckle them two or three times a day. If any person comes near them, the calves clap their heads close to the ground, and lie like hares in form, to hide themselves. This is a proof of their native wildness, and is corroborated by the following circumstance that happened to the writer of this narrative (Bailey of Chillingham), who found a hidden calf, two days old, very lean and very weak: — On stroking its head it got up, pawed two or three times like an old bull, bellowed very loud, stepped back a few steps, and bolted at his legs with all its force; it then began to paw again, bellowed, stepped back, and bolted as before; but knowing its intention, and stepping aside, it missed him, fell, and was so very weak that it could not rise, though it made several efforts: but it had done enough; the whole herd were alarmed, and, coming to its rescue, obliged him to retire; for the dams will allow no person to touch their calves without attacking him with impetuous ferocity.

6807. *When a calf is to be castrated*, the park-keeper marks the place where it is hid, and when the herd are at a distance, takes an assistant with him on horseback; they tie a handkerchief round the calf's mouth to prevent its bellowing, and then perform the operation in the usual way, with as much expedition as possible. When any one happens to be wounded, or is grown weak and feeble through age or sickness, the rest of the herd set upon it and gore it to death. (*Culley*, p. 73.)

6808. *The mode of killing them* was, perhaps, the only remains of the grandeur of ancient hunting. On notice being given that a wild bull would be killed on a certain day, the inhabitants of the neighbourhood came mounted and armed with guns, &c. sometimes to the amount of a hundred horse, and four or five hundred foot, who stood upon walls or got into trees, while the horsemen rode off the bull from the rest of the herd, until he stood at bay, when a marksman dismounted and shot. At some of these huntings, twenty or thirty shots have been fired before he was subdued. On such occasions, the bleeding victim grew desperately furious from the smarting of his wounds, and the shouts of savage joy that were echoing from every side; but, from the number of accidents that happened, this dangerous mode has been little practised of late years, the park-keeper alone generally shooting them with a rifled gun at one shot.

Subsect. 2. *Criteria of Cattle for various objects and purposes.*

6809. *The criteria of a well-made bull*, to whatever breed he may belong, are, according to Culley, as follows: — The head should be rather long, and the muzzle fine; his eyes lively and prominent, his ears long and thin, his horns wide, his neck rising with a gentle curve from the shoulders, and small and fine where it joins the head; the shoulders moderately broad at the top, joining full to his chine or crops and chest backwards, and to the neck-vein forwards; his bosom open, breast broad, and projecting well before his legs; his arms or fore-thighs muscular, and tapering to his knee; his legs straight, clean, and very fine-boned; his chine and chest so full as to leave no hollows behind the shoulders; the plates strong, to keep his belly from sinking below the level of his breast; his back or loin broad, straight, and flat; his ribs rising one above another in such a manner that the last rib shall be rather the highest, leaving only a

small space to the hips or hooks, the whole forming a round or barrel-like carcass; his hips should be wide placed, round, or globular, and a little higher than the back; the quarters from the hip to the rump long, and instead of being square, as recommended by some, they should taper gradually from the hips backward, and the turls or pott-bones not in the least protuberant; rump close to the tail, the tail broad, well haired, and set on so high as to be in the same horizontal line with his back. Bulls should be constantly well fed, and kept in proper enclosures, never being suffered to ride before they are three years old, as when the contrary is the practice they never attain so perfect a growth. It is observed by Lawrence, that the above description delineates that barrel-shape which Bakewell supposed most advantageous for all kinds of animals intended to be fed for slaughter, or even used for labour.

6810. *The criteria of excellence in neat cattle in general* are thus given by John Wilkinson of Linton, near Nottingham, an eminent breeder. (*Remarks on Cattle, &c.* 1820.) "The head ought to be rather long, and muzzle fine; the countenance calm and placid, which indicates a disposition to get fat; the horns fine; the neck light, particularly where it joins the head; the breast wide and projecting well before the legs; the shoulders moderately broad at the top, and the joints well in, and when the animal is in good condition, the chine so full as to leave no hollow behind it; the fore flank well filled up, and the girth behind the shoulders deep; the back straight, wide, and flat; the ribs broad, and the space between them and the hips small; the flank full and heavy; the belly well kept in, and not sinking low in the middle, but so formed that a cross section of it would resemble an oval, whose two ends are of the same width, and whose form approaches to that of a circle, or of an ellipsis whose eccentricity is not great (the whole forming, not a round or barrel-like carcass as some have expressed it, for this would leave a deficiency both in the upper and lower part of the ribs); the hips globular, wide across, and on a level with the back itself; the hind quarters, that is, from the hips to the extremity of the rump, long and straight; the rump points fat, and coming well up to the tail; the twist wide, and the seam in the middle of it so well filled that the whole may very nearly form a plane perpendicular to the line of the back; the lower part of the thigh small; the tail broad and fat towards the top, but the lower part thin; the legs straight, clean, and fine-boned; and when the animal is in high condition, the skin of a rich and silky appearance. These appear to be the most material points for the formation of true symmetry in cattle: there are others of a minor consideration, which will readily be suggested by attention and experience."

6811. *The criteria of an ox well adapted to labour* differ from the above only in requiring long and strong legs, and broad hardy feet and hoofs.

6812. *The criteria of a beautiful cow*, according to Wilkinson, may be thus expressed: —

She's long in her face, she's fine in her horn,
She'll quickly get fat, without cake or corn,
She's clear in her jaws, and full in her chine,
She's heavy in flank, and wide in her loin.

She's broad in her ribs, and long in her rump,
A straight and flat back, with never a hump;
She's wide in her hips, and calm in her eyes,
She's fine in her shoulders, and thin in her thighs.

She's light in her neck, and small in her tail,
She's wide in her breast, and good at the pail,
She's fine in her bone, and silky of skin,
She's a grazier's without, and a butcher's within.

6813. *Culley's marks of a good cow* are these: —Wide horns, a thin head and neck, dewlap large, full breast, broad back, large deep belly; the udder capacious, but not too fleshy; the milk-veins prominent, and the bag tending far behind; teats long and large, buttocks broad and fleshy, tail long and pliable, legs proportionable to the size of the carcass, and the joints short. To these outward marks may be added a gentle disposition, a temper free from any vicious tricks, and perfectly manageable on every occasion. On the other hand, a cow with a thick head and a short neck, prominent back-bone, slender chest, belly tucked up, small udder or fleshy bag, short teats, and thin buttocks, is to be avoided as totally unfit for the purposes either of the dairy-man, the suckler, or the grazier. The most valuable cows are those which are bred in Yorkshire, Staffordshire, and upon the strong lands in other part of England, and in Ayrshire in Scotland.

6814. *The criteria of excellence in cattle, as derived from colour*, are of no importance; and all that can be said is, that white and red cattle are less hardy than the black-haired.

6815. *The criteria of age in cattle* are derived from the teeth and horns. At the end of about two years they shed their first four teeth, which are replaced by others, larger, but not so white; and before five years all the incisive teeth are renewed. These teeth are at first equal, long, and pretty white; but, as the animals advance in years, they wear down, become unequal, and grow black. These animals, according to some, likewise shed their horns at the end of three years; and they are replaced by other horns, which, like the second teeth, continue; this, however, is totally or partially denied by practical men, and our statement of it as a fact without qualification has been objected to in the "*American Farmer.*" The manner of the growth of these horns is not uniform, nor the shooting of them equal. The first year, that is, the fourth year of the animal's age, two small-pointed horns make their appearance, neatly formed, smooth, and towards the head terminated by a kind of button. The following year this button moves from the head, being impelled by a horny cylinder, which, lengthening in the same manner, is also terminated by another button, and so on; for the horns continue growing as long as the animal lives. These buttons become annular joints or rings, which are easily distinguished in the horn, and by which the age of the creature may be easily known; counting three years for the point of the horn, and one for each of the joints or rings. The cow continues useful for more than twenty years, but the bull loses his vigour much sooner. It is common with dealers to obliterate these rings, by shaving the horns, in order to conceal the age of the beast.

6816. *The terms applied to different ages* are as follows: — A young castrated male, after the first year, is called a stirk; when a year older, a stot, or steer; at five years old, an ox. A female, after the first year, is called a heifer, or quey; when about to bring a calf, she is called a young cow. A castrated female is called a spayed heifer. Certain of the Welsh and Scots cattle, of rather a coarse and sturdy kind, are denominated runts. Bullock is the general term for any full-grown male cattle, fat or lean.

6817. *The natural duration of life with the bull and cow* may be stated at upwards of twenty years, to nearly the end of which the latter is useful with her milk, but the former generally loses his vigour, consequently his use, many years sooner.

Subsect. 3. *Breeding of Horned Cattle.*

6818. *The objects to be kept in view* in breeding cattle are, forms well adapted for fattening, for producing milk, or for labour. These three objects have each of them engaged the attention of British agriculturists; but experience has not hitherto justified the expectation that has been entertained of combining all these desirable properties, in an eminent degree, in the same race. That form which indicates the property of yielding the most milk, differs materially from that which we know from experience to be combined with early maturity and the most valuable carcass; and the breeds which are understood to give the greatest

weight of meat for the food they consume, and to contain the least proportion of offal, are not those which possess, in the highest degree, the strength and activity required in the beasts of labour.

6819. *A disposition to fatten, and a tendency to yield a large quantity of milk, cannot be united.* The form of the animal most remarkable for the first, is very different from that of the other; in place of being flat in the sides, and big in the belly, as all great milkers are, it is high-sided and light-bellied: in a word, the body of the animal well adapted to fatten is barrel-formed, while that of the milker is widest downwards. It is not probable, therefore, that the properties of two breeds of cattle, so opposite in form and general appearance, can ever be united in the same animal.

6820. *The long and short horned breeds* have hitherto been in possession of the best part of the island; but various others, as the Ayrshire, the Galloway cattle, and kyloes, might be bred with advantage in many situations, so as to be more profitable than either the short-horns or the long-horns. These breeds of cattle, as true quick-feeders, and being kindly-fleshed, or excellent eating beef, have established their character in the first market in the island. The Scotch or kyloes are better adapted to cold, exposed, heathy, mountainous situations, than any other breed we have. Particular breeds are probably best adapted to particular situations; on which ground, breeders of cattle should endeavour to find out what breed is the most profitable and best suited to their situations, and to improve that breed to the utmost, rather than to try to unite the particular qualities of two or more distinct breeds by crossing. The latter is a precarious practice; for we generally find the produce inherit the coarseness of both breeds, and rarely attain the good properties which the pure distinct breeds individually possess. In order to have good cattle of any breed, particular regard must be paid in selecting those that are the most complete and perfect in their form, shape, and other qualities, and to breed from them.

6821. *An extraordinary degree of attention* has been paid to the breeding of cattle in England since the time of Bakewell, and some illustrious names might be mentioned in addition to those of professional farmers. Pedigrees of the best cattle have been preserved with no less care, in several places, than those of race horses; and, in the selection of breeders, the properties of the family from which they have descended are matters of scarcely less importance than the form of the young animals themselves. The extraordinary prices paid for the best-bred bulls and cows show that this attention has not been without its reward.

6822. *The best bulls* are either let out for the season, or cows are brought to them at a certain rate per head. The practice of letting bulls is said to have originated with Bakewell (*Marshal's Midland Counties*, vol. i. p. 334.), who, early in his career, let a bull for one hundred and fifty-two guineas, to be used only four months (*Parkinson*, vol. ii. p. 469.); and five guineas per cow were about that time commonly paid to him and other eminent breeders.

6823. *The age at which bulls should begin to be employed*, and the number of seasons they should be allowed to serve, as well as the age at which the females should begin to breed, are points regarding which practice is by no means uniform. In the midland counties, the bulls are pretty commonly allowed to leap while yearlings; and if good stock-getters are kept on as long as they will do business, perhaps till they are ten or twelve years old. In other places they are employed only three seasons, for the first time at two years old. The females, in many instances, bring their first calf at the age of two years, but more commonly, perhaps, not till they are a year older; and in some of the Highland districts, where, owing to a want of proper nourishment in their infancy, they are later in coming to their full growth, the females do not often become mothers till they are about four years old.

6824. *The period of gestation with cows* has been found, upon an average of a great number of experiments, to be about forty weeks. M. Tessier communicated to the National Institute of France the following observations on this subject: — Of 160 cows, 14 calved from the 241st to the 266th day; 3 on the 270th; 50 on the 280th; 68 on from the 280th to the 290th; 20 on the 300th; and 5 on the 308th. Cows seldom bring more than one calf at a time. When they produce twins, one of them a male and the other a female, the latter, which is called a free martin, is commonly considered to be incapable of procreation; yet there seem to have been well authenticated instances to the contrary. (*Farmer's Magazine*, vol. vii. p. 462.; and vol. viii. p. 466.)

6825. *The most desirable period for putting cows to the bull* is midsummer, in order that they may be dropped in spring, and have the whole of the grass season before them. Where no regular system is followed, and cows are sent to the bull merely because they are in heat, calves will be dropped at all seasons; but, except in those districts where the fatting of calves is an object of importance, spring is probably the most advantageous time; as the calves, having all the grass season before them, become sufficiently strong for enduring the change to a less agreeable food in the ensuing winter. A calf newly weaned seldom thrives well during that period, unless it is pampered with better food than usually falls to the share of young animals. By midsummer the cows are readier to take the bull than at any other season, and will bring calves in proper time. If a cow goes till after May before she calves, the calf will be too weak in the winter following; and the dam will not be so ready to take the bull again, but will often grow barren.

6826. *It is not always the best milch cow that has the best calf*, even though the external circumstances should be similar; and *vice versâ*, a *sorry* cow may have a *good* calf. These remarks apply to this breed as well as to others. The immediate progeny of a good milker may be an indifferent milch cow; but in the second remove, the good milking quality of the grandam returns. This has often been observed, and without any of the causes being imputable to the size. (*Robertson*, p. 571.)

Subsect. 4. *Rearing of Horned Cattle.*

6827. *The mode of rearing calves* is various. There can be little doubt but that the best and most natural mode is that of allowing them to suck their dams, at least for some length of time after they are brought forth.

6828. *In Yorkshire, and most parts of Scotland*, the usual method is to give them milk to drink, there being few instances where they are allowed to suck. For the first two or three weeks, they mostly get milk warm from the cow; but for the next two or three weeks, half the new milk is withdrawn, and skim-milk substituted in its stead; and at the end of that period, the new milk is wholly withdrawn: they are then fed on skim-milk alone, or sometimes mixed with water, till they are able to support themselves by eating grass, or other food of that sort.

6829. *In Cheshire*, the practice is to allow the calves to suck for the first three weeks. They are then fed on warm new whey, or scalded whey and buttermilk mixed; with the green whey water is frequently mixed, and either oatmeal or wheat and bean flour added. A quart of meal or flour is thought sufficient to mix with forty or fifty quarts of liquid. Oatmeal gruel and buttermilk, with an addition of skimmed milk, are also used for the same purpose. Some one of these prepared kinds of food is given, night and morning, for a few weeks after the calves are put on that diet, but afterwards only once a day till they are three months old or more.

6830. *In Gloucestershire* the calves are not allowed to suck above two or three days; they are then fed on skim-milk, which is previously heated over the fire. When they arrive at such an age as to be able to eat a little, they are allowed split beans, or oats and cut hay, and water is mixed with the milk.

6831. *In Sussex* it is common to allow the calves to suck for ten or twelve weeks, or to wean them at the end of three or four, and give them a liberal allowance of skim-milk for six or eight weeks longer.

6832. *In Middlesex* it is usual, in rearing calves, to give them a pailful, containing about a gallon, of milk warm from the cow, morning and evening, for eight or ten weeks; or, which is certainly the most

agreeable to nature, and therefore to be preferred to any other that can be adopted, to allow the calf to suck its dam, as it is sometimes done in the county of Sussex, and generally in Wigtonshire.

6833. *According to Marshal*, the best method is this: — The calves suck a week or a fortnight, *according to their strength* (a good rule); new milk in the pail, a few meals; next, new milk and skim-milk mixed, a few meals more; then, skim-milk alone, or porridge made with milk, water, ground oats, &c. and sometimes oil-cake, until cheese-making commences; after which, whey porridge, or sweet whey, in the field; being careful to house them in the night, until warm weather be confirmed. (*Midland Counties*, vol. i. p. 338.) This method of suckling is not, however, free from objection; and, in the ordinary practice of rearing calves, it is held to be a preferable plan to begin at once to teach them to drink from a pail. The calf that is fed from the teat must depend upon the milk of its dam, however scanty or irregular it may be; whereas, when fed from a dish, the quantity can be regulated according to its age; and various substitutes may be resorted to, by which a great part of the milk is saved for other purposes, or a greater number of calves reared upon the same quantity. (*General Report of Scotland*, vol. iii. p. 51.) Yet it would seem to be a good practice to allow calves to suck for a few days at first, if there were no inconvenience to be apprehended, both to themselves and their dams, from the separation afterwards.

6834. *When fed from the pail*, the average allowance to a calf is about two English wine gallons of milk daily, for twelve or thirteen weeks; at first, fresh milk as it is drawn from the cow, and afterwards skim-milk. But after it is three or four weeks old, a great variety of substitutes for milk are used in different places, of which linseed-oil cake, meal, and turnips, are the most common.

6835. *Where calves are reared with skim-milk*, it should be boiled, and suffered to stand until it cools to the temperature of that first given by the cow, or a trifling degree more warm, and in that state it should be given to the calf. Milk is frequently given to calves warm only; but that method will not succeed so well as boiling it. If the milk be given over-cold, it will cause the calf to skit or purge. When this is the case, put two or three spoonfuls of rennet in the milk, and it will soon stop the looseness. If, on the contrary, the calf is bound, bacon-broth is a very good and safe thing to put into the milk. One gallon of milk per day will keep a calf well at first. The usual allowance is about double after the first eight or ten days, and this is increased with the age of the animal. After it is thirteen weeks old, it will do very well upon grass or other food, without any milk at all. A calf may then be supported without milk, by giving it hay, and a little wheat-bran, once a day, with about a pint of oats. The oats will be found of great service as soon as the calf is capable of eating them. The bran and oats should be given about mid-day; the milk in portions, at eight o'clock in the morning, and four in the afternoon. But whatever hours are chosen to be set apart for feeding the calf, it is best to adhere to the particular times, as regularity is of more consequence than many people think. If the calf go but an hour or two beyond his usual time of feeding, he will find himself uneasy, and pine for food. It is always to be understood, that calves reared in this manner are to be enticed to eat hay as early as possible; and the best way of doing this is to give them the sweetest hay that can be got, and but little at a time. Turnips or potatoes are very good food, as soon as they can be eaten by them; and they are best cut small, and mixed with hay, oats, bran, and such articles. It may be observed, that it is not absolutely necessary to give milk to calves after they are one month old: to wean them gradually, two quarts of milk, with the addition of linseed boiled in water to make a gruel, given together, will answer; and by diminishing the milk gradually, the calf will soon do without it. Hay tea will do, with the like addition of two quarts of milk; but it is not so nutritious as linseed. It is a good method of making this, to put such a proportion of hay as will be necessary into a tub, then to pour on a sufficient quantity of boiling water, covering up the vessel, and letting the water remain long enough to extract the virtues of the hay. When bacon or pork is boiled, it is a good way to preserve the liquor or broth, and mix it with milk for the calves.

6836. *In summer, calves may sometimes be reared on whey only;* but, when reared in winter, they must be fed with hay; and clover-hay is probably the best of any for this use. Calves may also be raised with porridge of different kinds, without any mixture of milk. It is sometimes a good and convenient plan, the author of the *New Farmer's Calendar* says, to bring up calves under a step-mother; an old cow, with a tolerable stock of milk, will suckle two calves, or more, either turned off with her, or at home, keeping them in good condition, until they are old enough to shift: they ought to suck the first of their mother's milk for two or three days, although many are weaned without ever being suffered to suck at all. Calves, whether rearing or fattening, should also always suck before milking, the cow being milked afterwards, as the first and thinnest of the milk is sufficiently rich. Old milk will, perhaps, scour a very young calf; but the effect will go off without any ill consequences. He observes, that the Duke of Northumberland's recipe is to take one gallon of skimmed milk, and to about a pint of it add half an ounce of common treacle, stirring it until it is well mixed; then to take one ounce of linseed-oil cake, finely pulverised, and with the hand let it fall gradually, in very small quantities, into the milk, stirring it in the mean time with a spoon or ladle, until it be thoroughly incorporated; then let the mixture be put into the other part of the milk, and the whole be made nearly as warm as new milk when it is first taken from the cow; and in that state it is fit for use. The quantity of oil-cake powder may, from time to time, be increased as occasion may require, and as the calf becomes inured to the flavour of it. Crook's method is to make a jelly of one quart of linseed, boiled ten minutes in six quarts of water, which jelly is afterwards mixed with a small quantity of the best hay tea. On this he rears many calves without milk: he thinks many calves are annually lost by artificial rearing, and more brought up with poor and weak constitutions.

6837. *When calves are dropped during the grass season*, Donaldson observes, they should be put into some small home-close of sweet rich pasture after they are eight or ten days old, not only for the sake of exercise, but also that they may the sooner take to the eating of grass. When they happen to be dropped during winter, or before the return of the grass season, a little short soft hay or straw, or sliced turnips, should be laid in the trough or stall before them.

6838. *Castration* is performed both on male and female calves, when neither are intended for procreation. On cow calves, however, it is generally omitted: but in Norfolk no distinction is made as to sex; males and females are equally objects of rearing, and are both occasionally subject to castration, it being a prevailing custom to spay all heifers intended to be fatted at three years old; but such as are intended to be finished at two years old are, it is believed, pretty generally left "open;" as are, of course, those intended for the dairy. There are two reasons for this practice: they are prevented from taking the bull too early, and thereby frustrating the main intention; and by this precaution may lie more quietly, and are kept from roving at the time of fatting. This may be one reason why spayed heifers are thought to fatten more kindly at three years old, and to be better fleshed, than open heifers.

6839. *The time of performing the operation of castration* in horned cattle, as in all kinds of live stock, is while the animals are yet very young, and just so strong as to endure this severe operation without any great danger of its proving fatal. The males, accordingly, are cut commonly when about a month old, and the females at the age of from one to three months; but in Galloway, where more heifers are *spayed* than perhaps in all the island besides, this is seldom done till they are about a year old.

6840. *The best time for rearing calves* is the spring; but that operation must depend in some degree on the time when the calf was dropped. Such as are weaned during autumn or winter, however, seldom do any good. At the season when the calf is weaned from the teat, it ought to be turned abroad, in the day-time, into a small close or orchard near the yard where there is a good bite of grass, which may be expected at the time of the year when the weaning-calves are of this age; and, as there will generally be more than one calf weaned in a season, they will each be company for the other and become in a short time reconciled to their situation. It is to be observed, that this pasture should be at some distance from that whereon the dams are turned, and that there be neither ponds nor ditches, nor any annoyance which might endanger the lives of these youthful animals; and, in order to habituate them still more

to their pasture, milk-pottage should be carried to them at each of their feeding hours. For the first month or six weeks, the calves ought every night to be brought out of the meadow, and lodged in the pens; but after this time they may be left in the pasture as well in the night season as in the day; and at this time their food may be lowered by degrees, till it be at length reduced to simple water only; for, when the calves get to the age of twelve or fourteen weeks, they will no longer require the aid of this sustenance, but will be able to satisfy their appetites with grass. Care, however, must be taken throughout the summer that they be frequently shifted from one pasture to another, in order that they may be kept up in good flesh, and enabled to grow away with the utmost celerity. At Michaelmas, or soon after, the calves should be taken into the yard; and if they were allowed the indulgence of a small close to themselves it would be still better.

6841. *The treatment of young cattle*, from the time they are separated from their dams or are able to subsist on the common food of the other stock, must entirely depend upon the circumstances of the farm on which they are reared. In summer, their pasture is often coarse, but abundant; and in winter all good breeders give them an allowance of succulent food along with their dry fodder. The first winter they have hay and turnips; the following summer coarse pasture; the second winter straw in the fold-yard, and a few turnips once a day, in an adjoining field, just sufficient to prevent the straw from binding them too much; the next summer tolerably good pasture; and the third winter as many turnips as they can eat, and are in every respect treated as fatting cattle. (*Culley*, p. 47.)

6842. *The method of managing young cattle* during the first winter is, according to Donaldson, pretty generally the same in every part of the island. They are generally housed: sometimes bound up to the stall; but more frequently allowed to remain at freedom. The way of feeding them in England is chiefly with hay or hay and straw mixed; and in Scotland sometimes with hay, but more frequently straw and turnips. They are mostly turned out on some of the inferior pastures on the farm in the following summer, and maintained the second winter on straw in the straw-yard, or in houses or sheds erected for the purpose. Some farmers in the more northern parts of the kingdom, from being situated at a distance from any market at which they can dispose of stall-fed beef, very frequently give a considerable part of their turnip-crop to their young cattle. This is, he thinks, an excellent practice; and one that ought to be followed, even by those who, from being better situated with regard to markets, can adopt other methods of using turnips to advantage. The benefit of green winter food for live-stock is so great, that there is probably, he says, no way in which turnips can be used, by which the farm or the farmer would reap greater benefit, than by giving the young cattle a daily allowance during the first two or three winters.

Subsect. 5. *Fattening Calves by Suckling.*

6843. *The most advantageous stock for suckling calves* for the butcher is that sort of cow which gives the greatest quantity of milk, richness of quality being not so great an object, or so well adapted to the desired purpose. The Holderness cows are to be preferred in this view; not, however, to suckle calves of the same, but of a smaller breed: perhaps Devon calves surpass all others as sucklers, whether for quickness of proof, or beauty of the veal; they are not, however, to be procured but in or near their own country.

6844. *The method most commonly employed in fattening calves* is, to allow them to suck; as by this method the object is probably not only sooner, but more effectually attained than by any other means. The period which is necessary for fattening calves in this way must be different, according to circumstances, but it is generally from seven to nine weeks; however, in the dairy districts, where milk is considered a valuable article, scarcely half that time is allowed. These is another method, which is, to give them the milk to drink; and when that is done, it is given them morning and evening warm from the cow, and the quantity increased according to their age and strength. In whatever way they may be managed, they should be kept in pens in a close house, and well littered. The author of the *Synopsis of Husbandry* observes, that as it is necessary that the calves should lie always quiet, in order that they may indulge in sleep at those times when they are not employed in sucking, it seems proper that the cow-house should be situated in the most retired part of the yard, and that the pens should be kept as dark as possible. But notwithstanding this caution, the calves should by no means be suffered to lie too hot in the summer time, which would be apt to produce a sickness amongst them. To admit, therefore, an occasional draught of fresh air, let a window be cut in each pen, with shutters adapted to the same, and let these windows be opened whenever the closeness of the atmosphere indicates it to be necessary. In the summer season, they should rarely, if ever, be closely shut; and when it is required, the stream of air may be increased by opening the cow-house door at the opposite end of the building. Each calf should have a collar round his neck, with which the attendant may direct him in his sucking, but should never be fastened up in the pen. It is necessary that the pens be kept constantly well littered with the cleanest wheat straw, a proportion of which should be thrown in to them every day; cleanliness being a most essential article in the fattening of every animal, and not more necessary to any than to the calf, which, but for this precaution, would in a short time demonstrate the ill effects of lying on his accumulated dung, which of all animals is the most offensive and of a quality highly septic. As the calves are yeaned, they are to be taken into the pens, and suckled by their own dams, which at first will yield a far greater quantity of milk than is necessary for their offspring, so that another calf may be suckled thereon; or the cow may be milked, and the cream be reserved for butter, or applied to any other use that the owner may think proper. As the calf increases in size, it will require a larger quantity of milk; but whilst calves are young, one good cow will yield a noble supply for two; and when the whole produce is demanded for one calf, another new milch cow should be provided, and these two cows will abundantly supply the three calves with milk till the oldest is fit for the butcher; after which, if necessary, a fresh suckler may be brought in, and the business be carried on progressively by keeping the house constantly supplied with calves, so that the whole milk may be sucked, as the dairy and the fattening of calves by suckling cannot be conveniently united.

6845. *The only advantage which suckling can have, over giving calves milk to drink*, is, that the action of sucking induces "a greater secretion of saliva, which, by promoting digestion, accelerates the growth and fattening of the young animal, cannot be doubted; but the secretion of that fluid may be likewise promoted, by placing an artificial teat in the mouth of the calf, and giving it the milk daily and at the natural temperature. In the dairy districts of Scotland, the dairy-maid puts one of her fingers into the mouth of the calf when it is fed, which serves the purpose of a teat, and will have nearly the same effect as a natural teat, in inducing the secretion of saliva. If that, or an artificial teat of leather, be used, and the milk given slowly before it is cold, the secretion of saliva may be promoted to all the extent that can be necessary; besides that secretion is not confined to the mere period of eating, but, as in the human body, the saliva is formed, and part of it swallowed at all times. (*Aiton's Dairy Husb.* p. 87.)

6846. *Young calves, when permitted to suck their fill*, are often seized with a lax or scouring: to prevent which, the calves for the first fortnight or three weeks may be stinted in their allowance; and at the same time due care should be taken that they do not pine or decrease in flesh for want of milk. But after this age they should be allowed to suck as long as they choose; and every means ought to be made use of to increase their appetite, and render them more eager after their food. Chalk may be given for this purpose, as well as for giving to the flesh a delicate whiteness. An excellent astringent remedy has been already given. (6552.) Salt sprinkled in the trough will likewise act as a stimulus to the appetite; besides which, it is a common practice with some people to cram their calves with balls compounded of flour, pounded chalk, and milk, with the addition of a small quantity of common gin. Of these balls they give

two, about the size of a walnut, once a day, or oftener, to each calf. These balls, being very nutritious, in some degree supply the place of milk, and at the same time the spirituous mixture operates on the creatures as a soporific, and thus, by composing them to sleep, increases their disposition to fatten; but where milk can be had in sufficient abundance, it is never worth while to have recourse to these factitious aids. When the demands of the calf, however, are beyond the ability of the cow, these balls come seasonably to their relief. In order that the calves may be provided with sufficient store of milk, the pastures should be changed, whenever the cows are found to be deficient in this particular; and in the winter time, such food as is of a succulent nature, as grains, turnips, &c., should be always at hand to supply the want of grass; and these, with a due allowance of the sweetest hay, should be their constant aliment during the time that the cows are confined to the yard.

6847. *The prices of suckling calves* vary according to the goodness of the young animal, and the time of year wherein the purchase is made. In general, sucklers fetch the largest price in summer, when veal sells the cheapest; and the reason of this arises from the smaller number to be met with at that time than in the spring. When calves are slaughtered at six weeks or two months old, the veal is seldom of a good colour; neither has the flesh of these young calves a taste equal to that of animals suffered to live a few weeks longer. To attain colour and flavour, it is necessary that the calves should be maintained with plenty of milk, and managed as before directed, till they arrive at the age of eight or ten weeks, according to the season of the year, the more or less kindly state of the calf, the particular demand of the markets, or other accidental circumstances. In the summer season, it may be proper to dispose of them at an earlier period than in the winter; not only on account of their growing away with greater celerity in warm weather, but likewise because of the increased demand for small veal, which is then most saleable. During the last three or four weeks, blood should frequently be drawn from the calf, which will be a likely means towards rendering the veal of a colour delicately white; a circumstance so much attended to by the butcher, that he will commonly depreciate such calves as, from the appearance of their eyes, are likely to die black, as they term it, though in other respects not to be despised.

6848. *Calves suckled on their own dams* will, generally speaking, fatten in a shorter time than those afterwards brought in to supply their places. The first obvious reason for this difference in their favour is, their having been permitted to remain in the place where they were first dropped, and having always continued to suck the milk of their dam, which must in all reason be supposed of a more nutritious quality to them than that of any other cow. Secondly, the cow having so lately calved, the aliment nourishes and fattens in a higher degree than when the animal becomes stale-milched. Cow calves are observed to fatten more kindly than the male or bull-calves; and the latter are much coarser grained than the former, and their flesh less delicate in taste. Calves of the largest size are fattened in Essex, where the business of suckling seems to be better understood, and more properly conducted, than in any other county, and where the farmer keeps the calves to a greater age than in any other part of the kingdom.

6849. *Marshal* is clearly of opinion, that to suckle calves in general after they are ten weeks old is bad management; for his account in this respect is uniform, those of nine or ten having paid as much a week as those of twelve or thirteen; and, although a calf of six weeks old may suck nearly as much milk as a calf of twelve weeks old, yet for the first month or five weeks the quantity is considerably less, and this advantage of their infancy is doubly as valuable to nine as it is to twelve weeks. There can be no doubt but that the profit of this system of fattening depends materially upon the quickness of return.

6850. *In some districts*, barley-meal, linseed boiled into a kind of jelly, and similar articles, are given to calves in the course of fattening; but the methods above described are greatly superior, although it must be allowed that they may sometimes be considerably more expensive.

6851. *The art of fattening calves for the butcher* is practised in the parish of Avondale or Strathaven, with a degree of success, according to Aiton, which has had no parallel in Scotland. The superior excellence of the Strathaven veal has long been proverbial in the Glasgow and Edinburgh markets, where Strathaven veal and that of the best quality have become synonymous terms. The mode of feeding them is easy and natural. They are fed on milk, with seldom any admixture; and they are not permitted to suckle their dams, but are taught to drink the milk from a dish. The only art used in feeding calves in the vicinity of Strathaven is, to give them, after the first two or three weeks, *abundance of milk*; to keep plenty of dry litter under them, in a place that is *well aired*, neither too hot nor too cold; and *to exclude the light*, as they are apt to become too sportive when exposed to much light. If a calf becomes *costive*, a little bacon or mutton broth will give it ease; and if it begins to purge, a small quantity of the rennet used in coagulating milk will cure the disease. (*Aiton's Dairy Husb.* p. 89.)

Subsect. 6. *Fattening Horned Cattle.*

6852. *The fattening of cattle demands considerable and constant attention*, and the grand object is to fatten quickly. An animal when in a state of rearing may be considered as a vessel open at both ends, in which the supply and the waste being nearly equal it can never be filled: fattening an animal may be considered as an attempt to fill the vessel, and this can only be done by excess of supply. The waste being the same as before, this excess must be great; if it is not so, the vessel may be filled to a greater height than before without ever becoming full. An important hint might be taken from this simile by many farmers, who know little of the difference between feeding and fattening. We have known cattle, sheep, and swine kept for months, and fed with a view to fattening them, without their gaining a pound of meat.

6853. *The food on which cattle is fatted* in summer is grass, commonly on pastures, but, in a few instances, cut and consumed in feeding-houses or fold-yards: in winter by far the greater number are fatted on turnips, along with hay or straw; oil-cake, carrots, potatoes, and other articles of food, are used occasionally, and in particular districts, oil-cake chiefly for feeding the larger animals; but few, comparatively, are fatted on any of these without the addition of turnips of one or other of the varieties generally cultivated. A considerable number of cattle are also fatted on the offals of distilleries, when distilling from corn; a source of supply, the frequent interruption of which has been much felt in those situations where the soil does not permit the extensive cultivation of turnips. It is seldom or never the practice of the best managers to fatten cattle with roots or other winter food on the field, during that season; but to confine them to houses or fold-yards, where they are well littered, regularly fed, not liable to be disturbed, and sheltered from the inclemency of the weather, and where the manure they make is an object of very considerable importance, and of much greater value than if it were dropped at random over a whole field.

6854. *The age at which cattle are fatted* depends upon the manner in which they have been reared; upon the properties of the breed in regard to a propensity to fatten earlier or later in life; and on the circumstances of their being employed in breeding, in labour, for the dairy, or reared solely for the butcher. In the latter case, the most improved breeds are fit for the shambles when about three years old, and very few of any large breed are kept more than a year longer. As to cows and working oxen, the age of fattening must necessarily be more indefinite; in most instances the latter are put up to feed after working three years, or in the seventh or eighth year of their age. In general, it may be said, that the small breeds of cattle are fatted on pastures, though sometimes finished off on a few weeks' turnips; and that large cattle, at least in the north, are chiefly fatted in stalls or fold-yards, by means of turnips, and the other articles before mentioned

6855. *Stall-feeding* is the most common, and, when judiciously conducted, probably the most eligible method, in regard to the cattle themselves, the economy of food, and the expense of farm buildings. The small shed and fold-yard, called a hammel (2831.), are used only for the larger breeds; but they do not

seem well calculated for an extensive system of fatting by those who do not breed, but purchase stock every year from different parts. (*Sup. E. Brit.* art. *Agr.*)

6856. *The two great points in feeding animals to proof*, according to the author of the *Farmer's Calendar*, are, regularity, and a particular care of the weaker individuals. On the latter account there ought ever to be plenty of trough or rack room, that too many may not feed together; in which very common case the weaker are not only trampled down by the stronger, but they are worried, and become cowed and spiritless, than which there cannot be a more unfavourable state for thriving; besides, these are ever compelled to shift with the worst part of the meat. This domineering spirit is so remarkably prevalent amongst horned cattle, that he has a hundred times observed the master-beasts running from crib to crib, and absolutely neglecting their own provender for the sake of driving the inferior from theirs. This is, much oftener than suspected, the chief reason of that difference so visible in a lot of beasts, after a winter's keep. It is likewise, he says, a very common and very shameful sight, in a dairy of cows, to see several of them gored and wounded in a dozen places, merely from the inattention of the owner, and the neglect of tipping the horns of those that butt. The weaker animals should be withdrawn and fed apart; and, in crib-feeding in the yard, it is a good method to tie up the master-beasts at their meals.

6857. *Fattening cattle*, Donaldson observes, are usually put to grass in May or June, according to the season and situation in regard to climate. The period necessary for fatting an ox for the butcher depends on several circumstances; as the condition he was in when put to grass, the nature of the pasture, and many others; but, in ordinary cases, an ox will be completely fattened in three months. There is, he says, one method of fattening, connected with the grazing system, that the farmers in England are, from the superior excellence of the climate, enabled to adopt with success, which can never be attempted with propriety in Scotland. It is very common, at the close of the grass season, when the fattening stock happen not to be fully in condition for the butcher, to render them so, by giving them hay two or three times a day in the field, or in hovels erected for the purpose, into which they have access at pleasure.

6858. *When turnips are employed for the purpose of fattening cattle*, especially if they are put up to the stalls in proper condition, which, considering the season of the year (November), must, with ordinary attention, always be the case, from ten to thirteen weeks is fully sufficient to render them fit for market.

6859. *The fattening of cattle with grains* may, in some respects, be considered as a branch of the distillery business; but yet there are some instances wherein those who cultivate farms practise it with a double view—the obtaining of a profit on the sale of cattle, and the acquisition of a valuable treasure of useful manure. Adam, the renter of the farm of Mount Nod, near Streatham, in the county of Surrey, erected a very complete building, for the purpose chiefly of fattening cattle on grains. In this building might sometimes be seen several hundred head of cattle.

6860. *The method of fattening cattle with oil-cake*, corn, cut chaff, &c. is practised in many of the English counties, with a degree of success sufficient to warrant farmers in other parts of the island to follow the same practice. The cattle are commonly put up to fatten at the end of the grass season. The usual allowance of oil-cake, after it is broken in a large mortar, or, in the fruit districts, in a cyder-mill, is about half a peck per day, one half in the morning, and the other in the evening; to which is added hay, and in some cases ground corn, that is, oats or barley of inferior quality, and cut straw, provincially "chaff." As bullocks fattened in this manner get regularly five, and sometimes six, meals a day, it is sufficiently evident that, although it may be, upon the whole, an expensive mode of fattening, yet it must be both expeditious and effectual.

6861. *Booth's establishment for fattening cattle at Brentford* is one of the most extensive in the neighbourhood of London. It was formed for the purpose of consuming on the spot the grains and wash of the extensive distillery of that family. The building is 210 feet long, and 180 feet wide; and calculated to contain 600 head of cattle. It cost 8000*l*. The side walls are about 10 feet high, with 20 windows on each side, and 8 windows at each end, not glazed, and a few glazed skylights in the roof. The roof forms one ridge, and the centre part of it affords space for an ample hay-loft; it is supported by cast-iron and wooden pillars, so numerous as to have the appearance, on first entrance, of a forest of columns. A passage of six feet, the centre of which is paved with plates of cast-iron, is continued round the whole building, and between every two rows of cattle are passages of the same width and description. The whole is lighted by thirty-six gas-lights. The cattle stand in stalls seven feet and a half wide; and the space from the manger to the gutter behind the cattle is about ten feet: the gutters have an inclination to one end, and there are also underground drains having a similar inclination, into which the liquid from the gutters runs through iron gratings. There is a common manger which extends the whole length of each row of cattle, the bottom of which is on a perfect level. The portion of this manger contained in every double stall has a second bottom, with two ends let into it, the second or upper bottom descending to within three inches of the bottom common to the whole manger. In the upper trough so formed, and which, in length, occupies about half of the length of the portion of the manger belonging to each stall, is put the grains, or other solid food; the common manger being for the reception of the wash, or other liquid food or drink. The immense quantity of wash produced by the distillery is kept in a cistern or tank above the level of these mangers, and in a different part of the premises; but pipes from this tank are conducted under the surface and communicate with each of them, so that by turning a cock the whole of the cattle in any one of the ranges are instantly supplied with wash. This article serves both as food and drink, as it contains the finer particles of the ground malt, and the greater part of the barley meal used in the mashing process. The grains are kept in deep pits about twelve feet square, and ten or twelve feet deep, somewhat narrower at bottom than at top, lined with brick set in cement; and when the grains are trodden in, and raised like the ridge of a house, they are covered with road stuff to exclude the air, and protect them from the weather. Little or no litter is used, and neither green food nor hay uncut is ever given. Oil-cake is used, but not always; it being found that rough clover chaff mixed with the grains and wash will fatten to any extent.

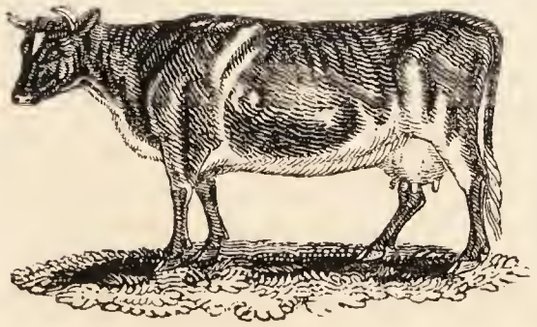
6862. *This building*, though erected at great expense, is very unsightly, and far from complete. It is much too cold in winter from the openness of the roof, and, exteriorly, very unpleasing to the eye from its great height. Within, the view is utterly disfigured by seemingly innumerable posts, three fourths of which are of little or no use. For one third part of the cost an equally useful, and much handsomer structure might have been erected. It has never paid a profit to its owners, who, if they could sell their wash and grains at the present market price, calculate that their profits would be considerably greater than by consuming it on the premises.

Subsect. 7. *Management of Cows kept for the Dairy.*

6863. *Milch cows* are kept for the manufacture of butter and cheese, for the suckling of calves for the butcher, and for the immediate use of the milk.

6864. *The kind of cow used by the dairyists* who supply the London market is chiefly the Holderness, a variety of the short-horned breed, with large carcasses and short horns. They are bred chiefly in Yorkshire and Durham; but in part in most counties. The Edinburgh dairies are supplied by short-horned cows from Roxburghshire, and other pastoral districts in the south of Scotland. For private dairies, the variety bred in Ayrshire (*fig.* 864.) have a decided preference, as giving a rich milk and large proportion of butter; and the cheese made from the milk of this breed, known as Dunlop, is decidedly celebrated. In Lancashire, the native long-horned breed is said, in the Report of that county, to obtain the general preference: but in Hodgson's dairy at Caton, in the same district, it was found that a short-horned cow, upon an average of twelve months, will yield nine quarts of milk in the day, and four and a half pounds of butter in the week; and a long-horned cow gives eight quarts of milk in the day, and four pounds of butter in the week, for the same period. The cows of both kinds had constantly the same kind of food; but, in order to have the clear result, the quantity of food consumed by each cow of the different breed should have been fully ascertained. The produce of milk and butter is on the side of the short-

864



horned sort; but it is not ascertained whether the neat balance is in favour of the short or long-horned. (*Lancashire Rep.* 561.) The Guernsey breed is valued by some for the richness of the cream and butter; but, both for the dairy and butcher, it is very unprofitable.

6865. *Where butter is the principal object*, such cows should always be chosen as are known to afford the best milk and cream, and in the largest quantity, of whatever breed they may be. But the weight of butter to be made from a given number of cows must always depend on a variety of contingent circumstances: such as the size and goodness of the beasts; the kind and quantity of the food; and the distance of time from calving. As to the first, it need scarcely be mentioned that a large cow will give greater store of milk than one of a smaller size; though cows of equal size differ as to the quantity of cream produced from the milk of each: it is, therefore, on those cows whose milk is not only in large abundance, but which, from a peculiar inherent richness, yields a thick cream, that the butter dairyman is to place his chief dependence; and where a cow is deficient in either of these, she should be parted with, and her place supplied by one more proper for this use. As to the second particular, namely, the kind and quality of the food, those who would wish to profit by a dairy ought to provide for their cows hay of a superior goodness, to be given them in the depth of winter, and this in an unlimited degree, that they may always feed till they are perfectly satisfied: and, when the weather will permit, the cows should be indulged with an outlet to marshes or low meadow-grounds, where they may feed on such green vegetables as are present; which is far preferable to the practice of confining them the whole day on dry meat, will enable them to yield greater plenty of milk, and will give a fine yellow colour to the butter even in the winter season.

6866. *In the vales of Buckinghamshire and Oxfordshire*, very great numbers of cows are kept for the purpose of butter. These fertile lands maintain a breed of large cows, which yield great store of milk; so that it is no uncommon circumstance for one farmer to keep a herd of fifty or sixty, and to collect a quantity of cream sufficient to fill a barrel-churn of sixty gallons in a week. The butter made from this cream is sold by the farmer or dairyman to persons who make it their business to purchase this article at a stated price from Michaelmas to Lady-day, and at an inferior rate from Lady-day to Michaelmas. The butter thus collected is sent to London every week in waggons. It is consigned to the dealers, who retail it to the consumer; and no small profit from this traffic accrues to the waggoner and the butter-merchant. This butter is mostly made up in lumps of two pounds each, and for that reason it has obtained the name of lump-butter. Its flavour is peculiarly sweet and agreeable, which is chiefly owing to the goodness of the pasture whereon the cows are fed; for this intrinsic merit would in vain be sought for in butter made from ordinary pastures, how great soever may be the skill of the dairy-woman. Though the grass should be equally luxuriant, the cows of the same breed, and the cream in like abundance, yet would a decided preference still remain in favour of the vale-fed cows; for, as a fattening beast on rich land will thrive much quicker than on thin soils, though the herbage be shorter on the former than on the poor ground, so will cows give a larger store of milk, and that of a more nutritious quality, when fed on deep fertile meadows, than if depastured on those of inferior goodness or quality.

6867. *Epping butter* has long been held in the highest estimation; and great quantities are manufactured in Cambridgeshire and the adjoining counties. The Cambridge butter is sent in small pans; it has an additional quantity of salt mixed with it, to insure its keeping for ten days or a fortnight; and is generally perfectly free from any rancid taste. Yorkshire, Lincolnshire, and other neighbouring counties, where the land is rich and fertile, likewise supply large quantities of butter, which is salted and put into tubs for the southern markets.

6868. *Where cheese is the principal object*, the management in respect to the cows must be the same.

6869. *When the object is the suckling of calves*, the farmer should provide himself with a breed of cows suited to the quality of his land. Where the farm abounds with fertile pastures, watered with wholesome streams, and not far distant from the yard, so that the cows may be turned immediately out of the suckling house upon their feed, the benefit will be in every respect superior to what can be expected from an arable farm, or where the green land is in a small proportion to the ploughed; for, in this latter case, the cows must depend for their sustenance chiefly on artificial fodder; such as clover, rye-grass, turnips, and other roots and herbage.

6870. *The cow-house* should be of a size adapted to the number of the beasts. Each cow should be driven into the house at suckling-time, and her head confined in a proper manner, having some fodder lying constantly before her, and a space left between every beast. When they become accustomed to this kind of restraint, they will without any trouble come into the places destined for them, when the calves may be suckled with the greatest ease and facility.

6871. *The time cows should become dry before their calving* is not agreed on, some contending that they may be milked almost to the time of their dropping the calf without injury; while others maintain that it is absolutely necessary that they should be laid dry from one month to two, both for the advantage of themselves and their calves. It is probable that much in this business must depend on the manner in which they are kept; as when well fed they may be continued in milk till within a week or two of their calving, without suffering any injury from it; but in the contrary circumstances it may be better to let them run dry for a month, six weeks, or more, according to their condition, in order to their more fully recruiting their strength. It appears not improbable, but that the longer the milking is continued, the more free the cows will be from indurations and other affections of the udder; which is a circumstance deserving of attention. Where only one or two cows are kept for the supply of a family, it is likewise useful to know, that by good feeding they may be continued in milk without any bad consequences till nearly the time of calving.

6872. *Cows sometimes slip their calves* before they are sufficiently grown. Where this occurs, it is essentially necessary to remove such cows immediately from the cow-yards, or from mixing with the other cattle, for a few days. But where cows are much subject to such accidents, it is the best method to get quit of them as soon as possible, as they will seldom turn out profitable afterwards.

6873. *Cows should be kept constantly in good condition*; as where they are ever suffered to become very lean, and that in the winter season, it is impossible that they can be brought to afford a large quantity of milk, by getting them into perfect condition in the summer months. Where cows are lean at the period of calving, no management afterwards is ever capable of bringing them to afford for that season any thing near the proportion of milk that they would have done if they had been supported in proper condition during the winter. Food of the most nourishing and succulent kinds should therefore be regularly given in suitable proportions in the cold inclement months, and the animals should be kept warm, and well supplied with pure water. Some advise their being cleaned by combing and other means; but this is a practice which, though useful in making them yield their milk more freely, can perhaps seldom be advantageously employed on an extensive scale.

6874. *Where the herd of cows is extensive*, an account should always be kept of the time when each cow takes the bull, that she may be dried off at a reasonable distance of time before the expected term of gestation be completed. The usual time when the cow is dried off is two months before her calving, when she ought to be suffered to lie quiet, and should not be brought up with the other cows at milking or suckling-time. According to some, if a cow be continued in milk nearer to the time of calving than the period above allotted, it will not only greatly injure her future progeny by rendering it weakly and stunted, but will also have an ill effect on her own health: while others, as we have seen (6871.), consider ten days or a fortnight as sufficient. When a cow is four months gone with calf, the fact may easily be ascertained by pressing upon her off-flank, when the calf will be felt to kick against the hand.

6875. *Cows may be known to be near the time of calving*, by springing at the udder or at the bearing. By springing at the udder is meant the collection of liquid in the bag, which, a few weeks before the time

of gestation is accomplished, assumes, in some degree, the appearance of milk, and may be drawn from the teats. To spring at the bearing, is when this part is more than ordinarily large and distended. Heifers are said to spring soonest at bearing, and old cows at the udder. Some cows are peculiarly given to abortions; and where this happens, they should never be continued long in the herd, as being unlikely to yield any considerable degree of profit to their owners.

6876. *Cows which are expected shortly to calve* ought to be lodged at night in a large convenient outhouse, or some other place, for a week or two previously to calving, as it may be the means of saving the life of the calf, and perhaps that of its dam: for, when a calf drops in the yard or field under such circumstances, the hazard of its perishing through the inclemency of the weather is very great, and it may considerably endanger the life of the cow. But if, from inattention or other causes, the creature should catch cold by calving abroad in sharp winter nights (which may be perceived by a refusal of her food, and by her trembling joints), she ought immediately to be driven into a warm shed, together with her calf, and fed with sugar-sops and ale, and with the best and sweetest hay, and should not be suffered to drink any cold water. By this treatment she will mostly recover in a few days; but should the disorder hang about her, balls composed of aromatic cordial substances may be given.

6877. *A milch cow is in her prime at five years old*, and will generally continue in a good milking state till ten years old or upwards; but this depends greatly on the constitution of the animal, some cows, like other animals, exhibiting marks of old age much earlier than others.

6878. *Cows of large size* yield great store of milk when turned on pastures where the grass is in sufficient abundance, or fed with a constant supply of such food as, from its succulency, conduces much towards the nutriment of the creature, and enables her to give large quantities of milk, such as turnips, grains, garden vegetables, &c. But as these large cows require a more ample provision than would fall to their share on the generality of farms, it would seem that they should not be kept by those farmers whose land is not of the most fertile kind; for, on ordinary keep, a small cow will yield a fairer profit than one of the Yorkshire or Staffordshire breed, which, having been bred on the best kind of land, would be starved where a Scotch or a Welsh cow would find an ample supply of food.

6879. *Those who would make the utmost advantage from cows*, either as calf-sucklers, dairymen, or milk-sellers, should always provide a bull to run in the herd, to obviate the perpetual trouble of driving them perhaps a mile or more to the bull, and in order to prevent the loss and inconvenience of their becoming frequently barren. One bull will generally be sufficient for twenty cows. These animals are in their prime at two years old, and should never be suffered to continue longer in a state of virility than to the fifth year; as, after that time, bulls which before were gentle and lay quiet in the cow pastures, are mostly apt to contract vicious dispositions, and become very unmanageable. Whenever this happens, they should be immediately castrated. In the principal town dairies of Scotland, such as Edinburgh, Glasgow, &c. the cows are never allowed to take the bull, but are sold off, after being kept a year or less, to the butcher, and fresh cows bought in their place. This is one very remarkable difference between the management here and in the town dairies of England.

6880. *For feeding of stalled cows*, the following directions are given to the cow-feeder in an improved dairy establishment near Farnham, in Surrey: — "Go to the cow stall at six o'clock in the morning, winter and summer; give each cow half a bushel of the field beet, carrots, turnips, or potatoes cut; at seven o'clock, the hour the dairy-maid comes to milk them, give each some hay, and let them feed till they are all milked. If any cow refuses hay, give her something she will eat, such as grains, carrots, &c. during the time she is milking, as it is absolutely necessary the cow should feed whilst milking. As soon as the woman has finished milking in the morning, turn the cows into the airing ground, and let there be plenty of fresh water in the troughs; at nine o'clock give each cow three gallons of a mixture composed of eight gallons of grains and four gallons of bran or pollard; when they have eaten that, put some hay into the cribs; at twelve o'clock give each three gallons of the mixture as before; if any cow looks for more, give her another gallon; on the contrary, if she will not eat what you give her, take it out of the manger, never at one time letting a cow have more than she will eat up clean. Mind and keep your mangers clean, that they do not get sour. At two o'clock give each cow half a bushel of carrots, field beet, or turnips; look the turnips, &c. over well before you give them to the cows, as one rotten turnip, &c. will give a bad taste to the milk, and most likely spoil a whole dairy of butter. At four o'clock put the cows into the stall to be milked; feed them on hay, as you did at milking time in the morning, ever keeping in mind that the cow whilst milking must feed on something. At six o'clock give each cow three gallons of the mixture as before. Rack them up at eight o'clock. Twice in a week put into each cow's feed, at noon, a quart of malt dust."

6881. *Directions to the dairy-maid:* — "Go to the cow stall at seven o'clock; take with you cold water and a sponge, and wash each cow's udder clean before milking; dowse the udder well with cold water, winter and summer, as it braces, and repels heat. Keep your hands and arms clean. Milk each cow as dry as you can, morning and evening; and when you have milked each cow, as you suppose, dry, begin again with the cow you first milked, and drip them each; for the principal reason of cows failing in their milk is from negligence in not milking each cow dry, particularly at the time the calf is taken from the cow. Suffer no one to milk a cow but yourself, and have no gossiping in the stall. Every Saturday night give in an exact account of the quantity of milk each cow has given in the week." (*Farm. Mag.* vol. xv. p. 314.)

6882. *Harley's dairy establishment at Glasgow* has been celebrated since 1813. The object of the proprietor, who is engaged in various extensive concerns, is to supply the public with new milk free from adulteration, and to have the cow-house, cows, and milk kept in a more cleanly state than by the usual mode.

6883. *Harley's cow-house* is fitted up upon a new construction. The cattle stand in rows, twelve in arow, across the house, head and head, and tail and tail, alternately; there is a passage behind for cleaning, and one in front for feeding. In front of each cow is a wire grating, hung like a window sash, which lifts up when giving the soft food and cleaning the cribs, and is put down when they get hay, &c. The contrivances for washing the cribs, collecting the urine, ventilating the house, &c., give peculiar advantages to the establishment, which may be summed up in the following items: — The health of the cattle; the preservation of the timbers; the diminished danger from fire, there being no hay-loft above the cattle; the preservation of the provender; and the flavour of the milk. The heat is regulated by thermometers. A circulation of air can be produced, so as to keep the cattle comfortable in the hottest weather, by which their health is promoted. The ventilation also prevents the timber from rotting; makes the cows eat their fodder better, as their breath is allowed to escape, instead of being thrown back upon the food, as is the case when their heads are placed opposite a wall. It is well known that milk easily takes a taste from any other substance; of course, if the cow-house is filled with bad air, the milk, while passing from the teat to the pail, and during the time it may stand in the house, will be impregnated with the foul atmosphere.

6884. *In feeding, and preparing the food*, Harley has made many experiments: and by the mode he now follows, the cattle fatten and milk better, than by the ordinary process; and the milk has no taste from turnips or other vegetables.

6885. *The arrangement for milking*, insures the cow to be clean milked, and also prevents fraud; and the mode of locking up the milk, and at the same time of admitting air, prevents adulteration by the retailer. The cows are not farmed out to milkmen as in London.

6886. *The stock of cows* for some time back has been 120, averaging eleven English quarts each per day; but both quality and quantity depend much upon the kind of food. Harley gives a decided preference to the Ayrshire breed of cows. They are bought chiefly at country fairs, either newly calved, or a few weeks before calving, and never turned out till they go to the butcher.

6887. *The food of the cows during summer* consists of cut grass and green barley mixed with old hay; and during winter Harley uses a good many turnips and potatoes, all of which are steamed and mixed with cut hay and straw; also grains and distillery wash, when these can be got.

6888. *When there is more new milk than supplies the demand*, part is put in the milk-house till next day, when the skimmed milk is sold at half price, and the cream sold at 1*s.* 6*d.* per quart. When any cream is left, it is put in a churn, and made into butter once a week or fortnight.

6889. *A table of regulations* has been adopted for the times of feeding, milking, currying the cattle, cleaning the house, &c. Each person has a currycomb and a hair cloth for cleaning the cows twice a day, and a mop and pail for the house, which is washed and sanded twice a day.

6890. *The cleanly state of the cattle and house* makes it a treat for visitors to see the establishment; and the way the vessels and milk-house are kept has made some people fond of milk who formerly were disgusted at it, from the manner in which many town dairies are conducted.

6891. *The advantage of irrigating grass lands with the cow's urine* almost exceeds belief. Last season some small fields of old grass were cut six times, averaging fifteen inches in length at each cutting, and the sward very thick. The soap-suds of a public washing-house are applied to the same purpose with considerable advantage.

6892. *The advantage of this system* to the owner of the cattle is shown by the following abstract, in Harley's own words; but the benefit of a liberal supply of genuine milk to the community at large, particularly to children, it is not easy to estimate: —

To the *general health* of the cattle by ventilation - - - - -	15 per cent.	
To the *prevention of a disease* called grain sickness, when fed on grains - -		
To the *prevention of swelling*, by eating young and wet grass - - - -		
To the *prevention of choking*, when feeding on turnips or potatoes, &c. - -	15	do.
To *saving in the expense* of feeding, by improved modes of cooking, &c. - -	20	do.
To *saving of labour* in feeding, dunging, &c. 50 per cent, as one person will do as much as two on the old plan; but allow 25 of this for draining, &c., leaves 25 per cent. profit on servants' wages - - -	25	do.
To *saving of timber* in the building, as they will last more than double the time	50	per cent.

6893. *Harley has a steam-engine* for driving the following machinery: —

A small threshing-mill.
A straw-cutter.
A turnip and potato slicer.
The churning apparatus.
Pumping water, &c.
The same boiler that drives the engine steams the food, warms water, &c.

6894. *After much study, labour, and expense*, the establishment is now brought to such a state of perfection, that it receives the cordial approbation of all who have seen it; furnishing the community with genuine milk at a comparatively low price. It is admitted, that the greater part of the system is original, and is not to be met with in any part of the kingdom. (*Farm. Mag.* xv. 189.)

6895. *The merits of Harley's system* are now considered to be greatly exaggerated in the above account. Taking the system altogether, it may be described as essentially that employed by the dairy-farmers in Holland and the Netherlands, described at length by Radcliff and Sinclair, and noticed in preceding sections of the present work from the above and other writers.

6896. *The London dairies* of most eminence are the two at Islington, belonging to Mr. Laycock and Mr. Rhodes, and the Metropolitan Dairy in the Edgeware Road. From 1822 to 1829, a number of other dairies sprang up, and made a conspicuous figure for a time; but, like other bubbles of those years, they have nearly all burst, and none now remain worth notice. We examined the Islington and Metropolitan dairies in October 1830, and the following is a brief outline of the result: —

6897. *Rhodes's Islington dairy* is the most complete of the three establishments. It has been in existence for upwards of thirty years, having been commenced by the father of the present possessors, and carried on for a considerable time in the neighbourhood of Greenwich. The number of cows kept by the present Messrs. Rhodes exceeds, on an average of the year, four hundred: at one time these individuals are said to have had upwards of a thousand cows in their different establishments. The surface on which the buildings are placed is a slope of two or three acres, facing the east; and its inclination is about one inch in six feet. The sheds run in the direction of the slope; as well for the natural drainage of the gutters, and the more easily scraping, sweeping, and wheeling out of the manure, as for supplying water for drinking to small cast-iron troughs, which are fixed in the walls, at the heads of the cattle, in such a manner as that the one trough may be supplied from the other throughout the whole length of the shed. The sheds are twenty-four feet wide; the side walls about eight feet high; the roof of tiles, with rising shutters for ventilation, and with panes of glass, glazed into cast-iron skeleton tiles, for light. The floor is nearly flat, with a gutter along the centre; and a row of stalls, each seven feet and a half wide, and adapted for two cows, runs along the sides. The cows are fastened by chains and rings, which rings run on upright iron rods, in the corners of the stalls; the common mode being departed from only in having iron rods instead of wooden posts. A trough or manger, formed of stone, slate, or cement, of the ordinary size of those used for horses, and with its upper surface about eighteen inches from the ground, is fixed at the head of each stall. Four sheds are placed parallel and close to each other, and in the party walls are openings, about a foot in breadth and four feet high, opposite each cow. The bottom of these openings is about nine inches higher than the upper surface of the troughs, and is formed by the upper surface of the one-foot-square cast-iron cisterns, which contain the water for drinking. Each cistern serves two cows, which of course are in different sheds, but adjoining and opposite each other. All these troughs are supplied from one large cistern by pipes, in a manner which can be so readily conceived, that we shall not stop to offer a description. Each of these troughs has a wooden cover, which is put on during the time the cows are eating their grains, to prevent their drinking at the same time and dropping grains in the water. At the upper end, and at one corner of this quadruple range of sheds, is the dairy, which consists of three rooms about twelve feet square: the outer, or measuring room; the middle, or scalding room, with a fireplace and a boiler; and the inner, or milk and butter room, separated by a passage from the last. At the lower end of the range is a square yard, surrounded by sheds; one for fattening the cows when they have ceased to give milk, and the others for store and breeding pigs. The pigs are kept for the purpose of consuming the casual stock of skim milk which occasionally remains on hand, owing to the fluctuations in the demand. This milk is kept in a well, walled with brick laid in cement, about six feet in diameter, and twelve feet deep. The milk becomes sour there in a very short time; and, as it is well known, is found most nourishing to the pigs when given in that state. Breeding swine are found most profitable; the sucking pigs being sold for roasting. Beyond this yard is a deep and wide pit or pond, into which the dung is emptied from a platform of boards projecting into it. The only remaining building wanted to complete the dairy establishment is a house or pit for containing the exhausted malt (grains), on which the cows are chiefly fed. Messrs. Rhodes have a building or pit of this description at some distance, where they have a smaller establishment. There are a stack-yard, sheds, and pits for roots, straw, and hay, a place for cutting hay into chaff, cart-sheds, stables, a counting-house, and other buildings and places common to all such establishments, which it is not necessary to describe.

6898. *The cows in Rhodes's dairy* are purchased newly calved in the cow market held in Islington every Monday. They are kept as long as they continue to give not less than two gallons of milk a day, and are then fattened on oil-cake, grains, and cut clover hay, for the butcher. The short-horned breed is preferred, partly for the usual reason of being more abundant milkers than the long horns, partly because the shortness of their horns allows them to be placed closer together, and partly because this breed is more frequently brought to market than any other. The Ayrshire breed has been tried to the number of 150 at a time, and highly approved of, as affording a very rich cream, as fattening in a very short time when they have left off giving milk, and as producing a beef which sold much higher than that of the short horns. The difficulty, however, in procuring this breed was found so great, that Mr. Rhodes was obliged to leave it off. The length of time during which a cow, treated as in this establishment, continues to give milk, varies from six months to the almost incredible period of two years. We were assured of there being at this moment several cows among the 390 which we saw, that had stood in their places even more than two years, and continued to give upwards of one gallon of milk daily.

6899. *The treatment of the cows in Rhodes's dairy* differs from that in most other establishments. The cows are never untied during the whole period that they remain in the house. In most other establishments, if not in all, stall-fed cows or cattle are let out at least once a day to drink; but these animals have clear water continually before them. They are kept very clean, and the sheds are so remarkably well ventilated, by means of the openings in the roofs, that the air seemed to us purer than that of any cowhouse we had ever before examined; probably from its direct perpendicular entrance through the roof, this, in moderate weather, being certainly far preferable to its horizontal entrance through the side walls.

6900. *The principal food of the cows in Rhodes's dairy*, as in all the other London establishments, consists of grains; that is, malt after it has been used by the brewer or the distiller. As the brewing seasons are chiefly autumn and spring, a stock of grains is laid in at these seasons sufficient for the rest of the year. The grains are generally laid in pits bottomed and lined with brickwork set in cement, from ten to twenty feet deep, about twelve or sixteen feet wide, and of any convenient length. The grains are firmly trodden down by men, the heaps being finished like hay-ricks, or ridges in which potatoes are laid up for the winter, and covered with from six to nine inches of moist earth or mud, to keep out the rain and frost in winter, and the heat in summer. As a cow consumes about a bushel of grains a day, it is easy to calculate the quantity required to be laid in. The grains are warm, smoking, and in a state of fermentation when put in, and they continue fit for use for several years; becoming somewhat sour, but they are, it is said, as much relished by the cows as when fresh. It is common to keep grains two or three years; but in this establishment they have been kept nine years, and found perfectly good. The exclusion of the air almost prevents the increase of the fermentation and consequent decomposition. What is called distiller's wash, which is the remainder after distillation of a decoction of ground malt and meal, is also given to cows, but more frequently to such as are fattening than to those in milk. The present price of brewers' grains is four-pence half-penny per bushel; of distillers' grains, on account of the meal which they contain, nine-pence a bushel; of wash, thirty-six gallons for sixpence.

6901. *Salt* is given to the cows in Rhodes's dairy at the rate of two ounces each cow a day. It is mixed with the grains which are supplied before milking, about three o'clock in the morning; and in the afternoon, about two o'clock, just before milking.

6902 *Of green food or roots* portions are supplied alternately with the grains; and in winter, when tares or green grass cannot be procured, after the turnips, potatoes, or mangold wurzel have been eaten, a portion of dry hay is given.

6903. *The produce of this dairy* is almost entirely milk and cream for private families and for public hospitals and other institutions. A number of the public establishments are supplied directly from the dairy, by contract; but private families are principally supplied by milk-dealers: these have what are called milk-walks; that is, a certain number of customers whom they call upon with supplies twice a day; and they are thus enabled to ascertain the average of what their customers consume, and to contract with Messrs. Rhodes for this average. The latter calculate the number of cows sufficient to give the dealer the supply wanted, and this number the dealer undertakes to milk twice a day, to wit, at three o'clock in the morning and at three o'clock in the afternoon. The milk is measured to the dealer, and should he have milked more than his quantity it remains with the dairy-man; but should the cows have been deficient in the quantity, it is made good from the milk of other cows milked on account of the contracts of the establishment. As the supply of the cows and the demand of the dealers are continually varying, it often happens that considerable quantities of milk remain on the dairy-man's hands, frequently, we are told, as much as sixty or seventy gallons a day. This quantity is placed in shallow earthen vessels, to throw up the cream in the usual manner; this cream is churned, and the butter sold, and the skim-milk as well as the butter-milk is put in the cesspool for the pigs.

6904. *The management of Rhodes's dairy* is committed to three persons:—A clerk, who keeps the books, collects debts, pays and receives; a man, who superintends the feeding and the treatment of the stock, and has the general care of the premises; and a dairy-woman, who sees the milk measured to the dealers, and superintends the dairy. The cows are purchased and sold by regular salesmen.

6905. *Laycock's dairy establishment* is also situated at Islington, and covers a number of acres. The cows vary in amount from 400 to 700; but there are open sheds sufficient to shelter from 8000 to 9000 head of cattle, and these sheds are accordingly appropriated to taking in cattle for the nights previous to the days on which Smithfield market is held. We shall only notice those particulars in which this establishment differs from that of Messrs. Rhodes. The cows are fed in the same manner, with the exception of not receiving any salt among their grains; but the hay is salted when put into the rick. They are turned out once a day to drink from troughs in the yards, remaining out from half an hour to three hours, according to the weather and the season of the year. From the end of June till Michaelmas, the cows are turned into the fields from six o'clock in the morning till eleven o'clock, and from two o'clock in the afternoon till about three o'clock in the following morning. The remaining hours of the twenty-four they are in the cow-houses for the purpose of being milked. The cows are kept in use much longer than at Messrs. Rhodes's establishment. Those which become barren are fattened in the same manner on grains, oil-cake, and, what is rather uncommon, boiled linseed. This linseed is boiled in a common boiler, and when reduced to a pulp, let out by tubes into large wooden cisterns, where it is mixed with clover-chaff, roughly cut, and sometimes with grains, and afterwards given to the cattle. Those cows which are good milkers are allowed to take the bull, for which purpose eight bulls are kept. The usual period of keeping the cows is three or four years; the calves are sold in Smithfield, when only a few days old, to those whose business it is to take them to the country and feed them for the butcher. Mr. Laycock has an extensive farm at Holloway, another at Enfield, and one at Clapton; at one or other of these farms the cows in calf are kept when dry. The hair of the tails is kept short to avoid the risk of dirtying the milk, and their bodies are sometimes curry-combed. The fattening cows stand with their hind feet on planks, laid as part of the pavement, the latter consisting of rather small sharp stones. The pigs, in addition to milk kept till it becomes sour, are fattened with ground linseed and grains. The manure made by the cattle and pigs is very considerable, and is all used on Mr. Laycock's own farms. The establishment here, as well as a dairy and cattle repository, may be considered as a central farm-yard to three hay-farms, and there are, accordingly, implements of various kinds, stables, a carpenter's shop, smith's shop, wheel-wright, &c. &c. Mr. Laycock himself seems to take the entire management, assisted by a clerk and a very active house-keeper, with a dairy-woman.

6906. *The Metropolitan Dairy establishment* is situated in the Edgeware Road; it was founded by the late Mr. Rhodes fifteen years ago, and after undergoing various changes, and among others being possessed by one of the bubble companies, from which its present name is derived, is now the property of Mr. Wilberforce. It stands on less than an acre of ground, and is well arranged. It is calculated for 360 cows, and it now contains 320, most of which are in milk, but some are fattening. The cowhouses are in parallel ranges twenty-four feet wide, the side walls eight feet high, the space allowed for each cow about three feet nine inches, and the greater number of cowhouses without stalls. There is one gutter in the centre, and no raised foot-path there; it being found that the latter is very apt to make the cows stumble, when turned out upon any occasion. It is true, these occasions are rare, for the cows here, as in Messrs. Rhodes's establishment, are never untied from the day they are put into the milking shed till they are removed to the fattening sheds, or till they are taken out to be sold, or to be sent into the country to remain till calving time. A cow so treated seldom produces more than two calves, remaining after each calf, at an average, eighteen months in milk. There is one cow here, however, which has given milk upwards of three years since she calved, still producing a gallon and a half a day. The cows are milked at three o'clock in the morning, and two o'clock in the afternoon, and the milk disposed of to dealers. The food consists of grains, which, instead of being kept in pits in the open air, are preserved in the cellar, or lower part of a building, about fourteen feet deep, the upper floor serving as a hay-loft, or chaff-cutting room. To protect the grains from the influence of the air, they are covered to the depth of a foot with cow-dung. Grass and roots constitute the rest of their food; dry hay being seldom given, and the chaff of clover hay being always mixed with grains or wash. The cows are never turned out to water; but from a large cistern pipes are conducted to every cow-house, and at a certain hour every day (one o'clock) the water is turned into the manger, which is on a perfect level, and it runs slowly past each cow, who drinks at pleasure. When any cow becomes sick, she is bled, and purged by giving her one pound of Epsom salts, with two ounces of flower of sulphur, and abundance of warm water. This mode of treatment seldom or never fails. Four bulls are kept for the cows; and as there is no farm belonging to the establishment, when a cow in calf becomes dry or nearly so, she is sent to any grass farm in the country, till near her calving time. To render a cow dry, it is only necessary to give two or three extra-doses of salt in her food. The quantity of salt given here daily with the grains is not much more than an ounce a day, on account of its drying quality. Manure has been sent from this establishment to Yorkshire; but this is found not to pay; and of so little value is it considered as manure, that as much as possible of the fluid part is discharged by the common sewer; and the present proprietor contemplates to compress the more consistent material into small squares like peats for fuel. By a hydraulic press we have no doubt that a two-horse cart load of any common cow-dung might be reduced to the size of a cubic foot. The cows in this establishment, as in the two others, are very sparingly littered; what is given is chiefly laid about their fore legs, and in consequence the other parts of the cowhouse, for want of under-ground gutters, as in Holland and Germany, are always watery and dirty.

6907. *The defects of the London dairy establishments* appear to us to be chiefly want of cleanliness, and imperfect ventilation. The first is to be removed by under-ground gutters, covered with oak plank pierced with numerous holes; and by the more abundant supply of litter: the second by openings in the roof as at Messrs. Rhodes's establishment, which, as we have said before, seems the most perfect in that respect of the three just examined. Compared with the Dutch and German dairies (p. 525. 587. and 611.), and with that of Harley of Glasgow (p. 6882.), they are very deficient both in original design and in management. It is a great mistake to suppose that they are lucrative concerns; and the idea is by no means pleasing of consuming milk chiefly manufactured from grains and distiller's wash, and produced by cows deprived of all exercise in the open air. Not more agreeable is the knowledge of the fact that the London market is supplied with so large a proportion of cattle fattened chiefly on oil-cake. According to a calculation we formed, the three establishments mentioned must supply, at an average of the year, nearly thirty fat cattle weekly. Booth's establishment, already described (6861.), probably furnishes half that number at the average of the year; and taking into consideration other establishments for fattening on oil-cake and grains, local and provincial, we shall probably not be far wrong in estimating that this description of beef is at all times the prevalent one in the London market. The cattle fed in pairs in hammels, (§ 2831.) that is, permitted to walk about in an open shed, as in Berwickshire and East Lothian, must produce a very different description of beef. The time will no doubt arrive when oil-cake beef will not find a market in England, but when the cattle so fed will be sent alive in steam boats to the Continent, or other parts of the world, where the taste of the inhabitants in the article of butcher's meat is less refined. Already country dairies have sprung up at the distance of from five to twenty miles from London, and the milk and cream are sent to town in close vessels in spring carts, which go at a rapid trot. When, instead of these spring carts, rail-roads are established, on which carriages may go at the rate of thirty miles an hour, the milk and butter used by the commonest people of London will be of as good a quality as that now used almost exclusively by gentlemen who have country seats.

Subsect. 8. *Working of Horned Cattle.*

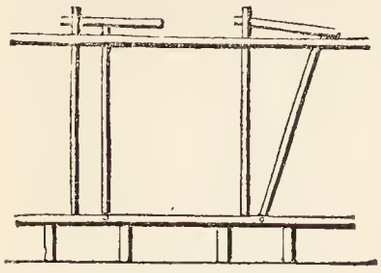
6908. *The arguments for and against the working of oxen* have been already stated. (4828.) Though horned cattle are gradually disappearing as beasts of labour, it is probable they will in many places be occasionally used as a substitute for horses, or to get up one or two additional teams on extraordinary occasions. Indeed we see no objection to the occasional use of both oxen and cows for this purpose; more especially in cases likely to occur in the farming of an extensive proprietor, such as breaking up his park, or cutting down and carting away timber, earth, gravel, &c. to a greater extent than can be readily performed by the ordinary teams of the establishment. For these and similar purposes of amateur farmers, and probably for some purposes on the farms of rent-paying cultivators, the horned cattle of the farm may afford a valuable resource. For these reasons, it seems fitting in this work not to consider the working of oxen as altogether an obsolete practice; and we shall, therefore, notice the training, harnessing, shoeing, age of being put to work, and general treatment of these animals so employed.

6909. *The training* of the calf intended for labour, according to some, should commence at an early period; and after being accustomed to be handled, he should be taught to present his foot to the shoeing smith, as readily as the horse, which is partially the practice in some places. No animal, however, is so easily broke as the ox at any age; and in most countries, where they are used in labour, they are never handled till harnessed and put in the plough, or to drag a tree. This is the case both in Devonshire and

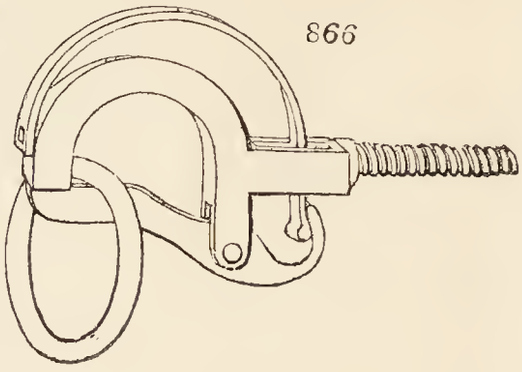
Herefordshire, and as they are only worked a few years it does not seem desirable to be at any great expense in their training. The Roman practice, in this particular, may deserve imitation. (99.)

6910. *Working oxen when kept in a house* are generally confined to their places by the same sort of fastening used for cows, (*fig.* 865.), in which their neck has free play between two upright spars; but in some establishments a ring of a particular description (*fig.* 866.) is used, to which they are tied by a halter attached to a head strap or bridle. The ring is generally screwed into the front of the manger or eating trough. The cattle fastening used in Devonshire is a wooden bow put on their necks and fastened to a round post. The bow consists of two pieces; the yoke, which has two slits terminating in round holes; and the bow, which is made of split ash, and has a knob at each end. These knobs being put through the round holes, the elasticity of the bow forces it along the slit and prevents it from returning.

865



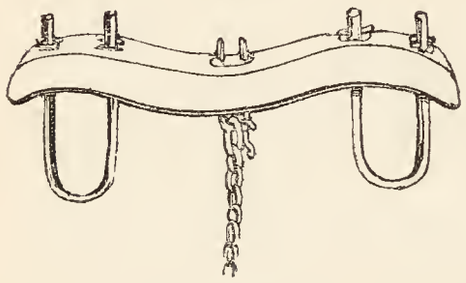
866



6911. *Harness for labouring cattle* is of three kinds: that for bearing as saddles some sorts of oxen yokes; that for drawing or pushing, as traces, brechins of saddles, &c.; and that for guiding the animals, as bridles, halters, reins, &c. These articles are of considerable expense, but when taken care of, kept dry, and the iron joints and leathers oiled occasionally, they will last a long time. In making all harness for beasts of labour great care ought to be taken to avoid superfluous materials which only encumber, and ornaments which only add to the expense. The London harness is much too heavy for agricultural purposes; that of Berwick or Newcastle is much more light and sufficiently strong.

6912. *The most approved kind of harness* for the ox is little different from that of the horse, except in the shape of the collar. In many places however, and especially on the Continent, the ox draws solely by the withers, by means of what is called a yoke and bow. (*fig.* 867.)

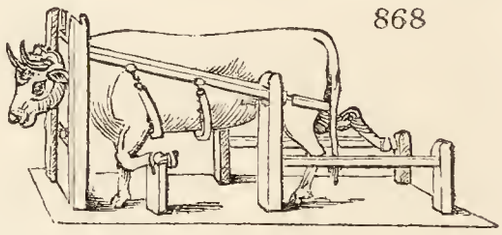
867



6913. *The shoeing of oxen* is a practice which is yet far from being performed in a perfect manner. Clark says, that in many parts of France, where the ox is used for draught, it is sometimes necessary to employ eight shoes, one under each nail; or four, one under each external nail; and sometimes only two, one under the external nail of each fore foot. In this country two pieces or shoes to each foot are generally made use of, being mostly fixed on, especially in the northern districts, with three or four large-headed nails to each shoe. They are fitted on in a similar manner to those of the horse. But, as the shoes of these animals from the smallness of the pieces are so liable to break, it has been suggested to have them shod with whole shoes in the manner of the horse; but how far this practice would answer, must depend upon future trials. As there is much trouble in the shoeing of oxen, from the necessity for casting them each time, it has been found requisite to have recourse to contrivances for shoeing them standing (*fig.* 868.)

869

868



6914. *An ox shoe* (*fig.* 869.) consists of a flat piece of iron, with five or six stamp holes on the outward edge to receive the nails; at the toe is a projection of some inches, which, passing in the cleft of the foot, is bent over the hoof, so as to keep the shoe in its proper place. This projection is not, however, employed in the general practice of making these shoes.

6915. *The age at which an ox may be worked* is from two and a half to three and a half years. Some begin at two, but it ought to be for very light operations, and such as are not of long duration. The period to which the ox is worked varies from his fifth to his tenth year.

6916. *Parkinson's father* used to make up occasionally an ox team for the plough of four oxen and one horse as a leader, which he found did about two thirds of the labour of two horses. There are, he says, great objections to ox-teams in the plough. He has, however found them useful in some sorts of farm-work, from their slow, steady pace; as in scarifying, leading dung, &c., as the work suits them from its being easy, and having a great deal of standing: they are, says he, much more cheaply kept than horses, and eat straw in the winter, and are valuable for making dung. He never saw this practice injure their growth. They may be worked from two till five years old, without any loss of time, as they grow to that age, and are then both larger and better beef than three-year-old steers. He therefore recommends ox-teams for leading dung and the other odd jobs, but not to plough and harrow. If they are worked to the age of eight or ten years, it is, he thinks, a real injury to the public, and an unprofitable practice to the farmer.

6917. *Bakewell* used to work his heifers moderately, whilst carrying their first calves; an unobjectionable practice, provided they are well fed. Bulls are generally allowed to be good labourers, and capable, if high fed, of vast exertions.

6918. *The length of time per day which an ox is kept in the yoke* varies according to the kind of labour, and the age and keep of the ox. If an ox is fed on hay, oats, and some roots, he will plough four days a week; but if on straw and roots only, not above three days. In the former case he is worked two whole days and two half days, and in the latter case six half days. The latter is the best plan, for which reason, where oxen are regularly worked, two pairs should be kept for each ploughman.

6919. *The most desirable breeds of oxen to work* are the Devonshire and Herefordshire varieties, which are long-legged, quick-stepping animals. Lord Somerville, who has carried the working of oxen to greater perfection than any one else, prefers the Devon breed, which most cultivators consider the quickest walkers in England. When horned cattle are only worked occasionally, whatever sort of animals are on the farm, whether bulls, cows, or oxen, of good or bad breeds, will necessarily be employed.

6920. *The food of horned cattle employed in labour* must be substantial. It is a great mistake to suppose they can work on straw alone. Unless they have roots added to straw in winter, and green food in summer, it will be an idle attempt to harness animals so nourished. The best and indeed the only way is to feed them well with straw, coarse hay, roots, green herbage, or pasturage, as the season and other circumstances may indicate.

Subsect. 9. *Anatomy and Physiology of the Bull and Cow.*

6921. *The general structure of the bull and cow* presents some peculiarities when compared with the horse, whose anatomy having been fully explained, will be taken as the subject of comparison. The ox, as an animal machine, displays less complexity of structure than the horse; but the principal differences between the two will be found to arise from the evident intention of nature to bound the locomotion of horned cattle: the limbs of the ox are therefore not found favourable to speed; nor does his general mass betray that symmetrical proportion and mechanical composition that would fit it to be acted on to advantage, as it regards quick motion, by the powerful muscles he evidently possesses; for strength alone will not produce speed.

6922. *The skeleton of the ox* is formed under the above view; and though the number of his bones differs little from that of the horse, the general form differs materially; — the frontal, the occipital, and indeed most of the bones composing the skull are broad and extended, while to the former are appended the horns. These, as we have seen (1859.), partake of the nature of true bone, placed within a membranous envelopment of a mixed nature between cuticle and cartilage. The ox has no upper nippers; the grass being cropped into a tuft by means of the tongue, is cut off by the under nippers; whereas in the horse it is nipped off by the approximation of both incisive teeth.

6923. *The vértebræ or neck bones* are the same in number and form as in the horse; but from the diminished elevation of the head, and the peculiarity of attachment of the great suspensory ligament, the ox has no cervical crest. The dorsal vértebræ are thirteen, with spinous processes, or withers less high. The lumbar vértebræ are six, and the sacral four; the coccyx or bones of the tail are indefinite in number, from eighteen to twenty-five. The pelvic bones in the ox are very large; and the rugged outline of the rump in cattle arises from the great rising of the spine of the ílium, and tuberosity of the íschium: the ribs are thirteen, eight of them true, and five false; and upon the former rest the scapulæ, which do not materially differ from those of the horse.

6924. *The fore-limb bones* are, the arm, and the fore-arm, which, as in the horse, is composed of the ràdius and úlna, and bears a general resemblance to that of the horse. The knee is composed of four bones in the first row, and two in the second, which renders that joint inferior to that of the horse in complexity and elasticity: the same holds good with regard to the hock, where the bones entering its composition are also less numerous than in the horse. The canon or shank has no splint bones attached to it, but it is lower, and enlarges into two articular portions corresponding with the metacarpal before, and metatarsal bones behind: thus, from the pastern downwards, the limb is double, and ends in two separate hoofs, which present, individually, a similarity of structure and design to the single hoof of the horse, but less developed; to the posterior part of each are appended two imperfect phalanges or claws, thus keeping a connection with the dígiti.

6925. *The hinder limbs* present nothing remarkable, but preserve the same increased simplicity of structure with the fore.

6926. *The víscera of the chest* offer no peculiarities from those of the horse to deserve notice; neither is the economy of the organs concerned different.

6927. *The viscera of the belly of the ox* have some specialities, the principal of which consist in the digestive organs, which differ in form, structure, and economy, in some essential particulars, from the same system in the horse.

6928. *The ox has four stomachs*, in which formation the goat, sheep, camel, and deer participate. As it is necessary that these animals should collect much herbage for their support; and as it would fatigue and keep them too long in motion to gather and masticate such a quantity at the same time, so a peculiar provision has been made for them, by which they first hastily collect their food, pass it into a reservoir, and afterwards commence the mastication of it at their leisure.

6929. *The first stomach, rùmen, or paunch*, is a very large membranous and muscular bag, principally occupying the left side, and extending, when full, from the middle of the ribs to the haunch, into which the unruminated food is received; consequently, it is the over-distention of this which occasions the malady called hoven: it is in this stomach also that the concretions called hair balls are found. It presents numerous processes to assist in the retention of the food.

6930. *The second stomach*, called also retículum, bonnet, or kingshood, would appear as a globular appendage to the paunch merely, were it not for its peculiarity of structure, which resembles the cells of the honey-comb, and which is well known to the eaters of tripe. The œsóphagus, or gullet, enters at the junction of this with the first stomach, and is continued in the form of a muscular ridge, or segmental tube along the line of junction between these two stomachs, which is thence continued into the *many-plies*. In the hornless ruminants, the second stomach is exclusively designed as a reservoir for water, and is capable of holding and preserving a vast quantity of it. A little of this water is passed up, as wanted, to be mixed with the dry matters chewed during rumination. In the deserts of Arabia, where water is met with only at long distances, this reservoir is peculiarly advantageous to the camel and dromedary; and the Arabian travellers, when famishing for water, save themselves frequently at the expense of their camels, by killing of which, and taking out this stomach, they find a supply.

6931. *The third stomach* is named after its foliated structure *many-plies;* there are about eighty or ninety of these septa or folds, which are covered with cuticle, in common with the two former stomachs, by which some resemblance is kept up between the digestive processes of the horse and ruminants. By the comparative insensibility of these stomachs, they can also bear potent medicines, which would be destructive to the Carnívora. By this curious extension of surface, the ruminated food is applied and reapplied to the sides of the bag, to be acted upon in its early stage of digestion.

6932. *The fourth stomach*, called also the *red bag*, abomàsum, falíscus, and ventrículus intestinàlis, is about two feet nine inches long in an ox, and resembles the simple digestive stomach of the Mammàlia. It is in this stomach that the pultaceous mass of the chyme undergoes a more perfect animalisation by being mixed with the gastric fluid, which appears to be wholly secreted here, and thus it is that this stomach only produces rennet. The red bag, to increase its secreting surface, has likewise about nine longitudinal plìcæ to each side, with an intervening rugose structure.

6933. *Rumination, or chewing the cud*, is the process whereby the ruminant animals having collected their food, and having passed it into the paunch, with little or no mastication or expense of saliva, begins a new operation. The paunch being full, the animal is stimulated to seek rest and quiet, and he usually lies down. The paunch begins now to exert its extraordinary powers of separating a portion from the contained mass, and to return it into the mouth, where it undergoes a complete mastication and mixing with the saliva. It is then again passed down the throat; but instead of again entering the first stomach, the muscular gutter forms itself into a tube, and carries it at once into the third stomach, where, having to undergo a further change, it is passed into the red bag, or fourth stomach; to undergo a further solution by means of the gastric fluid, preparatory to its being converted into nutriment under the name of chyle.

6934. *The intestines of the ox* have not their divisions into great and small so well marked as in the horse; yet the tract is very extended, to admit of a perfect separation of all the chylous particles. In the intestines of the horse it has been shown (6402.) that much of the digestive as well as the operative process goes on; but the chymous mass is more broken down in the stomachs of a cow than by the united forces of the stomachs and intestines of the horse. Grass, containing less organical moléculæ than grain, requires to be minutely acted on to afford nutriment; and thus the well-fed horse, after having been sufficiently nourished, passes off dung containing much of the original principles of his farinaceous food, and which forms excellent manure; while that of the ox, becoming almost wholly decomposed and nearly feculent, is very inferior for that purpose.

6935. *The liver of the ox* is large, and presents a gall-bladder, which that of the horse does not. This gall bag is furnished by several hepatic ducts leading into the neck of the gall duct. By the existence of a gall bladder the bile is evidently more concentrated; but it is difficult to understand why this should be necessary to the ruminants and not to the horse.

6936. *The páncreas of the ox* is of a lozenge form. The *spleen* is very large, and is placed on the left side of the paunch. The biliary and pancreatic ducts unite together. The principal fold of the *oméntum* is very large, and incloses the four stomachs, and part of the intestines. The *renal capsules* are flat and triangular. The kidneys are *lobulated.*

6937. *The organs of generation* in the cow differ but little from those of the mare and other Mammàlia. The penis of the bull is more pointed and taper than that of the horse. The vesículæ seminàles are wanting, but have a small ligamentous bridge instead. The prostàtæ are two.

Subsect. 10. *Diseases of Horned Cattle.*

6938. *Cattle are subject to some very dangerous diseases;* but as their life is less artificial, and their structure less complex, they are not liable to the variety of ailments which affect the horse. The general pathology of the horse and the ox being little different, the fundamental rules for veterinary practice, and the requisite medicines, when not particularised, will be found in the *Veterinary Pharmacopœia*, already given. (6548.)

6939. *Mild fever,* pantas or pantàsia. Cattle sometimes appear affected with heat, redness of the nostrils and eyelids; they refuse food, are dull, evacuate and stale with difficulty; and the urine is high coloured. These symptoms are often aggravated every other day, giving it the appearance of an intermittent affection. The complaint is often brought on by over-driving in very hot weather, occasionally by pushing their fattening process too fast. If there be no appearance of malignancy, and the heaving be considerable, bleed, and give half an ounce of nitre in a drink night and morning; but unless the weather be cold do not house the animal.

6940. *Inflammatory fever* is called, among farriers, cow-leeches, and graziers, by the various names of black quarter, joint felon, quarter evil, quarter ill, showing of blood, joint murrain, striking-in of the blood, &c. Various causes may bring this on. It is sometimes epidemic, and at others it seems occasioned by a sudden change from low to very full keep. Over-driving has brought it on. No age is exempt from it, but the young oftener have it than the mature. Its inflammatory stage continues but a few days, and shows itself by a dull and heavy countenance, red eye and eyelids: the nostrils are also red, and a slight mucus flows from them. The pulse is peculiarly quick; the animal is sometimes stupid, at others watchful, particularly at first; and in some instances irritable. The appetite is usually entirely lost at the end of the second day, and the dung and urine either stop altogether, or the one is hard, and the other red. About the third day a critical deposit takes place, which terminates the inflammatory action: and it is to the various parts on which this occurs that the disease receives its various names. The deposit is, however, sometimes universal, in the form of a bloody suffusion throughout the whole skin. In others, swellings form on the joints, or on the back or belly; and in fact, no part is exempt from their attack. Sometimes the animal swells generally or partially, and the air being suffused under the skin, crackles to the feel. After any of these appearances have come on, the disease assumes a very malignant type, and is highly contagious.

6941. *Treatment of inflammatory fever.* Before the critical abscesses form, or at the very outset of the disease, bleed liberally, and purge also: give likewise a fever drink. (6579.) If, however, the disease be not attended to in this early stage, carefully abstain from bleeding, or even purging; but instead, throw up clysters of warm water and salt to empty the bowels, and in other respects treat as detailed under malignant epidemic. (6436.) It may be added, that four drachms of muriatic acid in three pints of oak bark decoction, given twice a day, has proved useful. The swellings themselves may be washed with warm vinegar, both before and after they burst. The cowhouse should be fumigated daily.

6942. *Catarrh or influenza* in cattle, also known by the name of *felon*, is only a more mild form of the next disease. Even in this mild form it is sometimes epidemic, or prevalent among numbers; or endemical by being local. Very stormy wet weather, changing frequently, and greatly also in its temperature, are common causes. We have seen it brought on by change of food from good to bad; and from too close pasturage. It first appears by a defluxion from the nose; the nostrils and eyelids are red; the animal heaves, is tucked up in the flanks, and on the third day he loses the cud. There is a distressing and painful cough, and not unfrequently a sore throat also, in which case the beast almost invariably holds down his head. The treatment does not at all differ from that directed under the same disease in horses. (6434.) Bleeding only the first two days, carefully sheltering, but in an open airy place, and littering well up.

6943. *The malignant epidemic influenza* is popularly called the *murrain* or *pest;* and has at various times made terrible havoc among cattle. Ancient history affords ample proof of its long existence; and by the accounts handed down, it does not seem to have varied its types materially. In 1757 it visited Britain, producing extreme fatality among our kine. From 1710 to 1714 it continued to rage on the Continent with unabated fury. (*Lancisi's Disputatio Historica de Bovilla Peste.*) The years 1730 and 1731, and from 1744 to 1746, witnessed its attack, and produced many written descriptions of it, among which stand pre-eminent that of Sauvages, the celebrated professor of medicine at Montpelier. The British visitation of the malady in 1757, elicited an excellent work from the pen of Dr. Layard, a physician of London, which was afterwards translated into several other languages.

6944. *Symptoms of the murrain.* Dr. Layard describes it as commencing by a difficulty of swallowing, and itching of the ears, shaking of the head, with excessive weakness and staggering gait, which occasioned a continued desire to lie down. A sanious fetid discharge invariably appeared from the nostrils, and eyes also. The cough was frequent and urgent. Fever exacerbating, particularly at night, when it usually produced quickened pulse. There was a constant scouring of green fetid dung after the first two days, which tainted every thing around: even the breath, perspiration, and urine were highly fetid. Little tumours or boils were very commonly felt under the skin, and, if about the seventh or ninth day these eruptions become larger, and boils or buboes appeared with a lessened discharge of fæces, they proved critical, and the animal often recovered; but if, on the contrary, the scouring continued, and the breath became cold, and the mouth dark in colour, he informs us, mortality followed. Sauvages describes the murrain as showing itself by trembling, cold shivers, nose excoriated with an acrid discharge from it; purging after the first two days, but previous to which there was often costiveness. Great tenderness about the spine and withers was also a characteristic, with emphysema, or a blowing up of the skin by air discharged underneath it.

6945. *Dissections of those that have died* of this disease, according to Sauvages, have shown marks of great inflammation, and of a great putrid tendency; but the solid parts seldom ran into gangrene. The fluid secretions, however, always were sufficiently dissolved and broken down by putridity. The paunch, he says, was usually filled with undigested matter, and the other stomachs highly inflamed; the gall bladder was also commonly distended, with acrid thick brown bile. Goelich, who likewise dissected these subjects, describes the gall as particularly profuse and intolerably fetid. According to him the whole alimentary canal, from the mouth to the anus, was excoriated; and Lancisi, contrary to Sauvages, found the víscera of the chest and belly, in some cases, sphacelated and gangrenous. Gazola describes the murrain as accompanied with pustulous sores; and so great was the putrid tendency, that even the milk, before it dried up, which it usually did before the fourth day, became fetid.

6946. *The treatment of the murrain.* In the very early stages, all eminent authors recommend bleeding; but which should not only be confined to the very early periods, as to the first two days, but also to such subjects as by their previous health and condition can bear it. The animals should be placed in an open airy place; the litter should be frequently renewed; and the place itself should be fumigated with the preventive fumigation. (6582.) It has been recommended to burn green boughs with pitch as a substitute: even charcoal fires occasionally carried round the place would be useful. Dr. Layard advised the body to be washed with aromatic herbs in water; but vinegar would have been better. In the early stages, saline purgatives, as from ten to twenty ounces of Epsom salts, are to be invariably used. If the scouring have already come on, still, however, purge; but with only half the quantity: an artificial purge will carry off the morbid bile; and if excessive weakness do not come on, the same may be advantageously repeated. Setons are also recommended in the dewlap. When abscesses appear, they may be opened, and their contents discharged, washing the wound with brandy or vinegar, if putrid sloughing takes place. The emphysematous swellings or cracklings may also be opened, and the air discharged. The other essentials of medical treatment, as detailed under malignant epidemic among horses, is here applicable in every particular. When recovery takes place, it is usually a very slow process, and requires care to prevent other diseases supervening. The animals should continue to be housed, and neither exposed to sun or wind for some time, and the feeding should be nutritious.

6947. *The prevention of the murrain*, or the prevention of its spreading, in many respects is even more important than its medical treatment. Where it has already appeared, all the out-buildings, but particularly the ox-lodges or stalls, should be daily fumigated with the preventive fumigation (6582.); and even the whole of the infected districts should have frequent fires of green wood made in the open air, and every such district should be put under a rigorous quarantine. The cattle on every farm should be carefully examined three or four times every day, and the moment one is found to droop, he should be removed to a distance from the others. In very bad weather, while it is prevalent, the healthy cattle should be housed, and particularly well fed; and their pasture should also be changed. The bodies of those who die of the disease should be buried with their skins on, very deep in the earth, and quick-lime should be strewed over them.

6948. *Phrenzy fever*, or inflammation of the brain, called also *sough*, now and then, but by no means frequently, attacks cattle. The symptoms differ but little from those which attack horses. The *treatment* must be exactly similar.

6949. *Inflammation of the lungs* occasionally occurs in cattle, in which also the symptoms, progress, and proper *treatment* are similar to those detailed under that head in horse pathology.

6950. *Inflammation of the stomach* sometimes occurs from poisonous matters; and in such cases, when the nature of the poison is discovered, the *treatment* detailed under poison in horse pathology must be pursued. But there is a species of indigestion to which cattle are liable in the spring, from eating voraciously of the young sprouts of wood; to which some woods are more conducive than others. The symptoms are heat, thirst, costiveness, lessened urine, quick and hard pulse, with heat and redness in the mouth and nose; the belly is hard and painful, and the stools, when they appear, are covered with glair. When the mouth and nose discharge a serous fluid, the animal usually dies.

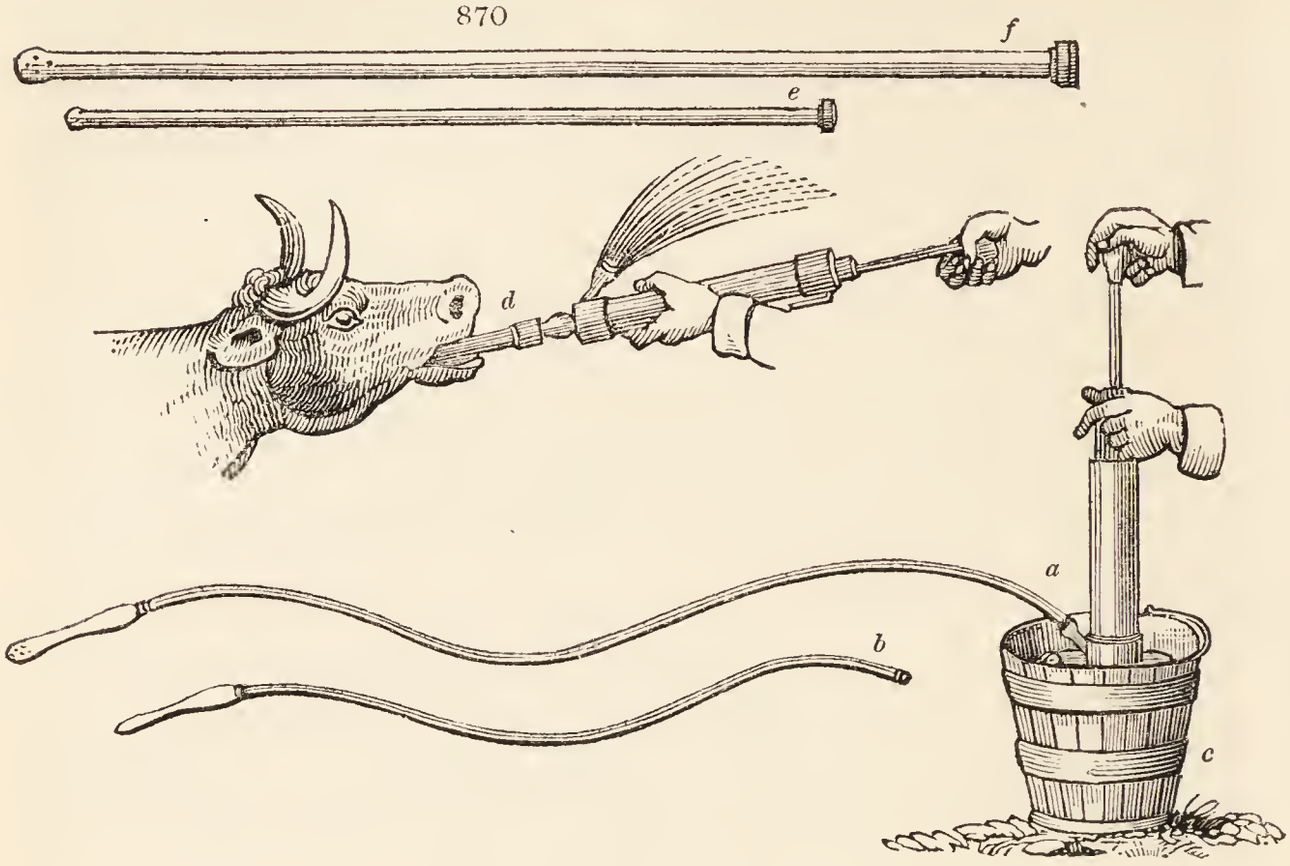
6951. *Treatment.* Bleed at first, open the bowels by saline purgatives. (6585.) After this give large quantities of nitrated water, and glister also largely.

6952. *The hove or blown* in cattle is also an inflammatory affection of the paunch, ending in paralysis and rupture of its substance. From the frequency of its occurrence, it has become a subject of investigation with almost every rational grazier, and a particular matter of enquiry with every agricultural body; whence it is now very successfully treated by the usual attendants on cattle, when skilful; but when otherwise, it usually proves fatal. It is observed to be more frequent in warm weather, and when the grass is wet. When either oxen, cows, or sheep meet with any food they are particularly fond of, or of which they have been long deprived, — as potatoes, turnips, the different grasses, particularly red clover, — they eat greedily, and forget to lie down to ruminate, by which means the first stomach, or paunch, becomes so distended as to be incapable of expelling its contents. From this inflammation follows, and fermentation begins to take place: a large quantity of air is let loose, which still adds to the distention, till the stomach either bursts, or, by its pressure on the diaphragm, the animal is suffocated. The situation of the beast is known by the uneasiness and general swelling of the abdomen; with the circumstances of the animal being found with such food, or the presumption that it has met with it.

6953. *Treatment.* There are three modes of relieving the complaint, which may be adverted to according to the degree of distention, and length of time it has existed. These are internal medicines; the introduction of a *probang* of some kind into the paunch by the throat; and the puncturing it by the sides. Dr. Whyatt, of Edinburgh, is said to have cured eighteen out of twenty hoved cows, by giving a pint of gin to each. Oil, by condensing the air, has been successfully tried. Any other substance, also, that has a strong power of absorbing air may be advantageously given. Common salt and water, made strongly saline, is a usual country remedy. New milk, with a proportion of tar equal to one sixth of the milk, is highly spoken of. A strong solution of prepared ammonia in water often brings off a great quantity of air, and relieves the animal. Any of these internal remedies may be made use of when the hoven has recently taken place, and is not in a violent degree. But when otherwise, the introduction of an instrument is proper, and is now very generally resorted to. The one principally in use is a species of probang, invented by Dr. Monro, of Edinburgh. Another, consisting of a cane of six feet in length, and of considerable diameter, having a bulbous knob of wood, has been invented by Eager, which is a more simple machine, but hardly so efficacious. It is probable that, in cases of emergency, even the larger end of a common cart-whip, dexterously used, might answer the end. But by far the best instrument for relieving hoven cattle, as well as for clystering them, is Read's énema apparatus, which is alike applicable to horses, cattle, and dogs. It consists of a syringe (*fig.* 870. *a.*), to which tubes of different kinds are applied, according to the purpose, and the kind of animal to be operated upon. There is a long flexible tube for giving an énema to horses and cattle (*a*), and a smaller one for dogs. (*b*) To relieve hoven bullocks effectually, it is necessary not only to free the stomach from an accumulation of gas, but from the fermenting pultaceous mixture which generates it; for this purpose a tube (*f*) is applied to the extremity of the syringe, and then passed into the animal's stomach through the mouth (*d*), and being put in action, the offending matter is discharged by a side opening. When the same operation is performed on sheep, a smaller tube (*e*) is made use of. The characteristic excellency of Read's instrument is, that there is no limit to the quantity of fluid that may be injected or extracted. The same syringe is used for extracting poison from the stomach of man, for smoking insects, extinguishing fires, and syringing fruit trees. (*Encyc. of Gard.* 2d edit. 1419.) The introduction of any of these instruments may be effected by the help of an assistant, who should hold the horn of the animal by one hand, and the dividing cartilage of the nose with the other; while the operator himself, taking the tongue in his left hand, employs his right in skilfully and carefully introducing the instrument; the assistant bringing the head and neck into such an attitude as to make the passage nearly straight, which will greatly facilitate the operation. But when no instruments can be procured, or as cases may occur when indeed it is not advisable to try them, as when the disease has existed a considerable time, or the animal has become outrageous, or the stomach so much distended with air that there is danger of immediate suffocation or bursting; in these instances the puncture of the maw must be instantly performed, which is called *paunching.* This may be done with the greatest ease, midway between the ilium, or haunch-bone, and the last rib of the left side, to which the paunch inclines: a sharp penknife is frequently used; and persons in veterinary practice should always keep a long trochar, which will be found much the most efficacious, and by far the most safe, as it permits the air escaping certainly and quickly, at the same time that it prevents its entrance into the cavity of the

abdomen, which would occasion an equal distention. As soon as the air is perfectly evacuated, and the paunch resumes its office, the trochar may be removed; and, in whatever way it is done, the wound

870



should be carefully closed with sticking plaster or other adhesive matter. It is necessary to observe, that this operation is so safe, that whenever a medical assistant cannot be obtained, no person should hesitate a moment about doing it himself. After relief has been afforded by means of either the probang or the paunching, a stimulant drink may yet be very properly given, such as half a pint of common gin; or one ounce of spirit of hartshorn in a pint of ale, or two ounces of spirit of turpentine in ale, may any of them be used as an assistant stimulus. When also the cud is again chewed, still some relaxation of the digestive organs may remain; at first, therefore, feed sparingly, and give, for a few mornings, a tonic. (6551. No. 1.)

6954. *Inflammation of the bowels, or red colic*, is by no means unknown in cattle pathology; the symptoms of which do not differ from those common to the horse, and the *treatment* also is in every respect the same. (6466.)

6955. *Inflammation of the liver, or hot yellows*, sometimes occurs, in which case, in addition to the symptoms detailed under hepatitis in the horse (6479.), there is, from the presence of cystic bile in the ox, a more determined yellowness of the eyelids, mouth, and nostrils; the *treatment* must be similar. (6479.)

6956. *Inflammation of the kidneys*, called *red water* by the cow-leeches, is not uncommon among cattle, and is, perhaps, dependent on the lobulated form of these parts in them. The animal, to the other symptoms of fever, adds stiffness behind, and often straddles, but always shrinks on being pinched across the loins, where frequently increased heat is felt; the urine is sometimes scanty, and now and then increased in quantity, but it is always first red, then purple, and afterwards brown or black, when a fatal termination may be prognosticated. The treatment has been fully detailed under nephritis, in the horse pathology (6481.), and it consists in plentiful bleedings, &c., carefully abstaining from the use of diuretics, as advised by ignorant cow-leeches.

6957. *The black water* is only the aggravated and latter stages of the above.

6958. *Inflammation of the bladder* also now and then occurs, and in nowise differs from the cystitis of the horse in consequences and treatment. (6483.)

6959. *The colics of cattle* arise from different causes: they are subject to a *spasmodic colic*, not unlike that of horses, and which is removed by the same means. (6474.) *Costiveness* also brings on a colic in them, called *clue bound, fardel bound*, &c. which often ends in the *red colic*, unless early removed; the *treatment* of this we have fully detailed. (6476.) Another colic is accompanied with relaxation of bowels.

6960. *Diarrhœa, scouring, or scouring cow*, is common in cattle, and is brought on by exposure to rain, improper change of food, over-driving, and other violences. It is essentially necessary that the animals be taken under cover, kept warm and dry, and have nutritious food allowed them. The medical *treatment* has been detailed. (6473.)

6961. *Dysentery, or braxy, bloody ray, and slimy flax*, differs from simple scouring, in a greater degree of fever attending it, and in its being an inflammation of a particular kind, and part of the intestines. It is frequently dependent on a vitiated putrid state of the bile, brought on by over-driving in hot weather, low damp pastures in autumn, &c. The discharge is characterised by its bad smell, and by the mucous stringy patches in it, and also by its heat and smoking when voided: all which are very different from the mere discharge of the aliments in a state of solution in diarrhœa, and which differences should be carefully marked, to distinguish the one from the other: *treat* as under dysentery in the horse. (6470.)

6962. *Yellows.* When active fever is not present, and yet cattle are very dull, with great yellowness of eyelids, nostrils, &c., it arises from some biliary obstruction, to which oxen and cows are more liable than horses, from their being furnished with a gall bladder; it is a more common complaint in some of the cold provinces on the Continent, where they are housed and stall-fed all the year round, than it is in England. The *treatment* is the same as detailed for chronic inflammation of the liver in horses, (6480.) adding in every instance to it a change of pasturage, and if convenient, into salt marshes, which will alone often effect a cure.

6963. *Loss of the cud.* This enters the list of most cow-leeches' diseases, but is less a disease than a symptom of some other affection; indeed it is evident that any attack sufficient to destroy the appetite, will generally occasion the loss of the cud. It is possible, however, that an occasional local affection or paralysis of the paunch may occur, particularly when it is distended with unhealthy substances, as acorns, crabs, the tops of some of the woody shrubs, &c. The *treatment*, in such cases, consists in stimulating

the stomach by tonics, as aloes, pepper, and gin mixed: though these, as liquids, may not enter the stomach in common cases, yet in this disease or impaired action of the rùmen they will readily enter there.

6964. *Staggers, daisey, or turning*, are sometimes the consequences of over-feeding, particularly when from low keeping cattle are suddenly moved to better pasturage. *Treat* with bleeding and purging.

6965. *Tétanus, or locked jaw*, now and then attacks cattle, in which case it presents the same appearances and requires the same *treatment* as in horses. (6432.)

6966. *Cattle surgery* is in no respect different from that in practice among horses, the wounds are treated in the same manner. Goring with the horns will sometimes penetrate the cavity of the belly, and let out the intestines: the *treatment* of which is the same as in the horse. (6477.) Strains, bruises, &c. are also to be *treated* like those of horses.

6967. *Foul in the foot.* This occasionally comes on of itself, but is more often the effect of accident: cleanse it well, and keep it from dirt: — apply the foot paste. (6587.)

6968. *Wornals, or puckeridge*, are tumours on the backs of cattle, occasioned by a dipterous insect which punctures their skin, and deposits its eggs in each puncture; these tumours are erroneously attributed to the fern owl or goat-sucker (*Caprimúlgus europæ'us L.*). When the eggs are hatched, and the larvæ or maggots are arrived at their full size, they make their way out, and leave a large hole in the hide, to prevent which the destruction of the eggs should be attempted by nipping the tumour, or thrusting in a hot wire.

6969. *Cattle obstetrics* are not very varied; young cows of very full habits have sometimes a superabundant secretion of milk before calving, which produces fever and heat; sometimes, from cold taken; the same will occur after calving also: in either case, give mild dry food, or hay; bathe the udder also with vinegar and water: in some cases, warm fomentations do best. If the fever run high, treat as under fever in horse pathology.

6970. *The process of calving* is usually performed without difficulty; sometimes, however, cross presentations take place, and sometimes a constriction of parts prevents the natural passage of the calf. To act properly on these occasions, great patience is required, and much mildness: many cows have been lost by brutal pulling; we have seen all the men and boys of the farm mustered to pull at a rope affixed about a calf, partly protruded, which, when it was thus brought away, was forced to be killed, and the mother soon died also from the protrusion of parts this brutal force brought with the calf. A steady moderate pull, during the throes of the animal, will assist much; having first directed the attention to the situation of the calf, that the presentation is such as not to obstruct its progress; if it does, the calf must be forced back, and turned or placed aright.

6971. *Whethering, or retention of the after-birth or burden.* — It sometimes happens that this is retained; for which no better remedy has been hitherto discovered than warm clothing and drenching with ale, administered as a forcer.

6972. *The diseases of calves* are principally confined to a species of *convulsions* which now and then attacks them, and which sometimes arises from worms, and at others from cold. When the first cause operates, it is then relieved by giving a mild aloetic purge, or in default of that, a mild dose of oil of turpentine, as half an ounce, night and morning. In the second, wrap up the animal warm, and drench with ale and laudanum a drachm. Calves are also very subject to diarrhœa or *scouring*, which will readily yield to the usual medicines. (6552.)

Sect. II. *The Buffalo.* — Bós bùbulus L. *Buffle*, Fr.; *Buffalo*, Span.; *Büffilochs*, Ger.; and *Bufle*, Ital.

6973. *The buffalo* is found wild in India, America, and various parts of the globe, and is in some degree domesticated in many countries. He is gregarious, docile, alert, and of surprising strength; his carcass affords excellent beef; and the horns, which are jet black, and of a solid consistence, take a polish of wonderful beauty: they can be converted into fabrics of use and ornament, such as mugs, tumblers, knife-handles, &c. In this way they sometimes apply them; and when ornaments of silver or mother-of-pearl are employed, the contrast with the polished black of the horn is agreeably striking. The boss on the shoulders is, as well as the tongue, extremely rich and delicious, and superior to the best English beef. It is usual to cure the tongues for sale. The buffalo far surpasses the ox in strength. Judging from the extraordinary size of his bones, and the depth and formation of his chest, some consider him twice as strong as the ox; and, as an animal of labour, he is generally preferred in Italy. In this country the ingenious physiologist, Hunter, has caused buffaloes to be trained to work in a cart. At first they were restive, and would even lie down; but afterwards they became steady, and so tractable, that they were driven through the streets of London, in the loaded cart, as quietly and steadily as in Italy or India.

6974. *The buffalo is kept in several gentlemen's parks* as an object of luxury, and has been trained and worked by Lords Sheffield, Egremont, and some other amateur agriculturists. Many prefer his flesh, and some his milk, to that of the bull family.

6975. *The breeding, rearing, and general treatment* of the buffalo may be the same as those of the bull family.

Chap. V.

The Dairy and its Management.

6976. *The manufacture of butter and cheese* is of necessity carried on where the milk or raw material is at hand. The subject therefore forms a part of farm management, more or less on every farm; and the principal one in dairy farms. In most of those counties where the profit of the cow arises chiefly from the subsequent manufacture of the milk, the whole care and management of the article rests with the housewife, so that the farmer has little else to do but to superintend the depasturing of his cattle; the

milking, churning, and in short the whole internal regulation of the dairy, together with the care of marketing the butter, where the same is made up wholly for home consumption, falling alone upon the wife. In this department of rural economy, so large a portion of skill, of frugality, cleanliness, industry, and good management, is required in the wife, that without them the farmer may be materially injured. This observation will indeed hold good in many other parts of business which pass through the hands of the mistress in a farm-house; but there is none wherein he may be so greatly assisted, or so materially injured, by the good conduct or want of care in his wife, as in the dairy. The dairy husbandry is more extensively and successfully pursued in England than in Scotland or in Ireland. "As to dairy husbandry on any thing like an improved plan," says Aiton, "it is still confined to a mere corner of Scotland." This corner is the district of Cunninghame, in Ayrshire, of which he observes: "The excellence of the improved breed of cows in Ayrshire, as well as the superior quality of Strathaven veal, the Glasgow butter and milk, and Dunlop cheese, to all others in Scotland, are things that cannot be disputed." (*Aiton's Dairy Husbandry, Pref.* p. 18.) We shall in giving the dairy husbandry of England glance, at the same time, at the peculiarities of the Ayrshire dairy husbandry, as given by the author last quoted.

6977. *The operations of the dairy* in all its branches are still conducted perhaps more empirically than those of any other department of husbandry, though it would appear that science, chemistry in particular, might be applied to discover the principles, and regulate the practice, of the art, with facility and precision. We have heard it admitted, an eminent author observes, even by experienced dairymen, that the quality of their cheeses differs materially in the same season, and without being able to assign a reason. Every one knows how different the cheese of Gloucester is from that of Cheshire, though both are made from fresh milk, the produce of cows of the same breed, or rather, in both counties, of almost every breed, and fed on pastures that do not exhibit any remarkable difference in soil, climate, or herbage. Even in the same district, some of what must appear the most important points are far from being settled in practice. Marshal, in his *Rural Economy of Gloucestershire*, has registered a number of observations on the heat of the dairy-room, and of the milk when the rennet was applied in cheese-making; on the time required for coagulation, and the heat of the whey after, which are curious, only because they prove that no uniform rule is observed in any of these particulars. The same discrepancy is observable in all the subsequent operations till the cheese is removed from the press, and even afterwards in the drying room. One would think the process of salting the cheeses the most simple of all; and yet it is sometimes, as in the west of Scotland, mixed with the curd; in other instances poured into the milk, in a liquid state, before being coagulated; and still more commonly, never applied at all till the cheeses are formed in the press, and then only externally. In treating of the dairy, we shall first offer a few remarks on the nature of milk, and the properties of that of different animals; and next consider the dairy house and its furniture, milking, churning, cheese-making, and the different kinds of cheese, butters, creams, and other products of the dairy.

Sect. I. *Chemical Principles of Milk, and the Properties of the Milk of different Animals.*

6978. *The milk* used by the human species is obtained from various animals, but chiefly the cow, ass, ewe, goat, mare, and camel; that in most general use in British dairying is the milk of the cow, which in modern times has received great improvement in quantity as well as quality, by ameliorations in the form of milch cows, in their mode of nourishment, and in the management of the dairy. Whatever be the kind of animal from which milk is taken, its external character is that of a white opaque fluid, having a sweetish taste, and a specific gravity somewhat greater than that of water. Newly taken from the animal, and allowed to remain at rest, it separates into two parts; a thick white fluid called cream, which collects on the surface in a thin stratum; and a more dense watery body, which remains below. The quantity and quality of cream, and the time it requires to separate from the milk, vary according to the nature of the milk and the temperature of the atmosphere. Milk which has stood some time after the separation of the cream, first becomes acescent, and then coagulates. When the coagulum is pressed gently, a serous fluid is forced out, and the remainder is the caseous part of milk, or pure cheese.

6979. *Butter*, or solidified cream, one of the most valuable products of milk, is obtained artificially by churning; an operation analogous in its effects to shaking or beating, by which the cream separates from the caseous part and serum, in a more solid form than when left to separate spontaneously. It is afterwards rendered still more solid by beating with a wooden spatula.

6980. *Cheese* is obtained by first coagulating the milk, either with, or deprived of, its cream, and then expressing the serum or whey; the consolidated curd so produced forms cheese. The milk may be coagulated in various ways, but that effect is chiefly produced by the use of rennet, which is prepared by digesting the coat of young ruminating animals, especially that of the calf. The rennet is poured into the milk when newly brought from the cow, or the milk is warmed to 90° or 100° for that purpose. The richness of cheese depends on the quantity of cream which the milk may have contained; its quality of keeping on the quantity of salt added; and the degree of pressure used to exclude the whey.

6981. *Whey* expressed from coagulated milk, if boiled, and the whole curd precipitated, becomes transparent and colourless. By slow evaporation it deposits crystals of sugar, with some muriate of potash, muriate of soda, and phosphate of lime. The liquid which remains after the separation of the salts is converted by cooling into a gelatinous substance. If whey be kept it becomes sour, by the formation of an acid, which is called the lactic acid; and it is to this that the spontaneous coagulation of milk, after it remains at rest, is owing. Milk may, after it is sour, be fermented, and it will yield a vinous intoxicating liquor. This is practised by the inhabitants of the most northerly islands of Europe, with buttermilk, and by the Tartars with the milk of the mare. Milk is likewise susceptible of the acetous fermentation.

6982. *The constituent parts of milk* are found to be oil, curd, gelatine, sugar of milk, muriate of soda, muriate of potash, phosphate of lime, and sulphur. These substances enter into the milk of all animals, but the proportions vary in different species. The various milks in use as food are thus distinguished:—

6983. *Cow's milk* produces a copious, thick, and yellow cream, from which a compact consistent butter is formed; the curd is bulky, and retains much serum, which has a greenish hue, a sweet taste, and contains sugar of milk and neutral salts. The milk of the buffalo is essentially the same as that of the cow.

6984. *Ass's milk* throws up a cream resembling that of woman's milk; the butter made from it is white, soft, and disposed to be rancid; the curd is similar to that of the woman, but not unctuous; the whey is colourless, and contains less salts, and more sugar, than that of the cow.

6985. *Ewe's milk* throws up as much cream as that of the cow, and of nearly the same colour; the butter made from it is yellow and soft; the curd is fat and viscid; the whey is colourless, and contains the smallest quantity of sugar of any milk, and but a small portion of muriate and phosphate of lime.

6986. *Goat's milk* produces abundance of cream, which is thicker and whiter than that from the cow;

the butter is white and soft, and equally copious, and so is the curd, which is of a firmer consistence than that of the cow, and retains less whey.

6987. *Mare's milk* produces a very fluid cream, similar in colour and consistence to good cow's milk before the cream appears on the surface; the butter made from it has but little consistence, and is readily decomposed. The curd is similar to that obtained from woman's milk, and the whey has little colour, and contains a large proportion of saccharine matter, and of saline substances.

6988. *Camel's milk* throws up little cream, which is whitish and thin, affording insipid whitish butter; the curd is small in quantity, and contains but little whey, which is colourless and somewhat saccharine.

6989. *Sow's milk.* In China, especially about the city of Canton, no other milk can be had but that of the sow. It is rather sweeter than cow's milk, but very similar in all other respects.

6990. *In the use of these milks*, that of the camel is chiefly confined to Africa and China, and that of the mare to Tartary and Siberia. In India the milk of the buffalo is preferred by the natives to that of the domestic cow. The milk of the goat is more generally used in Italy and Spain than in any other countries in Europe; they are driven into Leghorn, Florence, Madrid, and other towns, in flocks early in the morning, and milked in the streets. The goat will allow herself to be sucked by the young of various other animals, and a foal which has lost its mother has been suckled by a goat, placed on a barrel to facilitate the operation. As the butter of goat's milk contains a larger proportion of gelatine, and less oil than that of the cow, it is recommended by physicians as nearly equally light as ass's milk; it is the most prolific of all in curd, and forms excellent cheese; but it is an error to suppose that the Parmesan (a skim-milk cheese) is made from it. Ewe's milk is gradually wearing out of use, though it makes excellent cheese, and some milking ewes as well as goats might be kept for that purpose, by those who have extensive upland grass-lands. The milk of the ass comes the nearest to that of the woman, and being the lightest of any is much recommended in pulmonary and hepatic affections. Soda water and warm cow's milk is taken as a substitute, and found almost equally light. The milk in universal use, as an article of food in Britain, is that of the cow.

6991. *Lactometers* for ascertaining the value of milk, relatively to butter and cheese, will be described among the utensils of the dairy in the succeeding section.

Sect. II. *The Dairy House, its Furniture and Utensils.*

6992. *The dairy house, for general purposes,* consists of at least three separate apartments, the milk room, the dairying or working room, and the cheese or store-room. The two former are generally separated by a passage or lobby; and the latter is very frequently a loft over the whole, entered by a stair from the lobby.

6993. *The properties requisite in a good milk-house* are, that it be cool in summer, and moderately warm in winter, so as to preserve a temperature nearly the same throughout the whole year, or about 45 degrees; and that it be dry, so as to admit of being kept clean and sweet at all times. For these reasons a northern exposure is the best, and this as much under the shade of trees or buildings as possible; if it can be so situated that the sun can have no influence either on the roof or walls, so much the better.

6994. *A well constructed butter dairy* should consist of three apartments; a milk-house, a churning-house, with proper boiler, as well as other conveniences for scalding and washing the implements, and a room for keeping them in, and for drying and airing them, when the weather will not permit of its being done without doors.

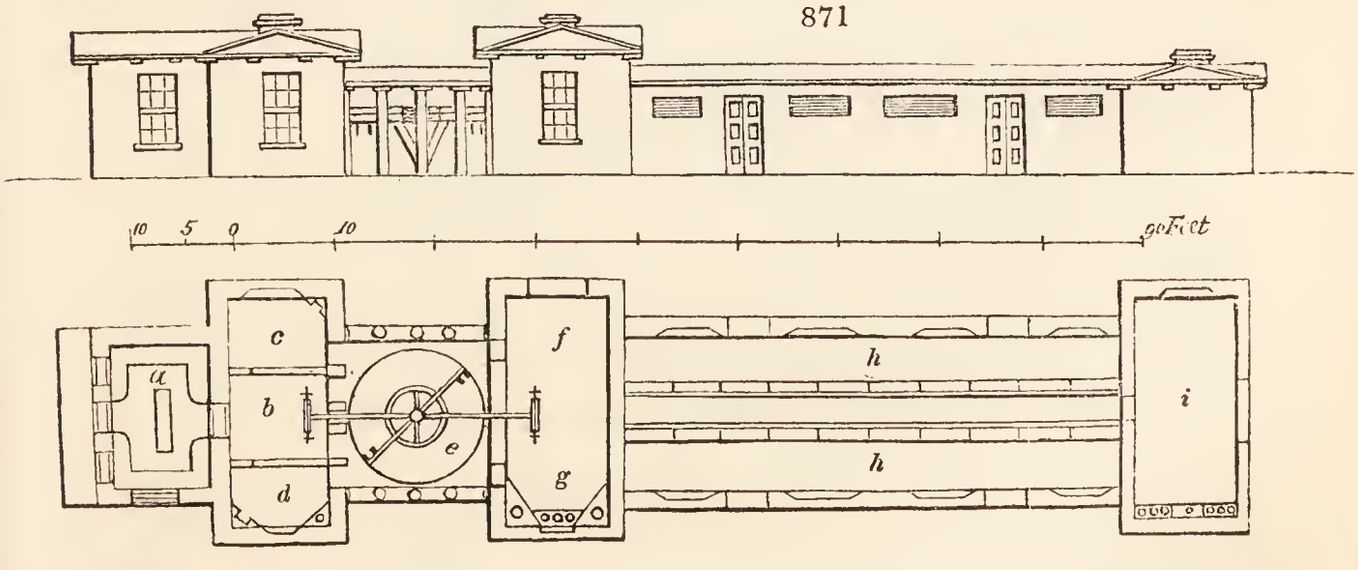
6995. *The cheese dairy* should likewise consist of three apartments; a milk-house, a scalding and pressing-house, and a salting-house. It is essential to the cheese dairy to have a command of heat during the cold season. When milk is exposed to a degree of cold below 50° at any time, from the moment it is drawn from the cow, till the cheese is not only pressed, but, to a great extent, dried, the cheese will not be good. "It is not enough that the milk be again heated; it must never be allowed to become too cold at any time, not even in the press; or if it is, the quality of the cheese will be much injured." (*Aiton's Dairy Husb.* p. 82.) To these should be added a cheese-room or loft, which may with great propriety be made above the dairy. This is, however, generally separate from the dairy. But a milk dairy requires only a good milk-house, and a room for scalding, cleaning, and airing the utensils. The size of the milk-house, according to Aiton, ought to be sufficient to contain one day's milk of all the cows belonging to it.

6996. *A dairy for the private use of any farmer* or family need not be large, and may very economically be formed in a thick walled dry cellar, so situated as to have windows on two sides, the north and east in preference, for ventilation; and in order that these windows may the better exclude cold in winter, and heat in summer, they should be fitted with double sashes, and on the outside of the outer sash should be a fixed frame of close wire netting, or hair cloth, to exclude flies and other insects.

6997. *Of dairies for dairy farmers* there are different sizes and shapes.

6998. *A dairy-house connected with a cow-house*, and mill for preparing food for the cows, churning, and washing the family linen, is thus arranged. (*fig.* 871.) The dairy (*a*, *b*, *c*, *d*) is at the north end, has

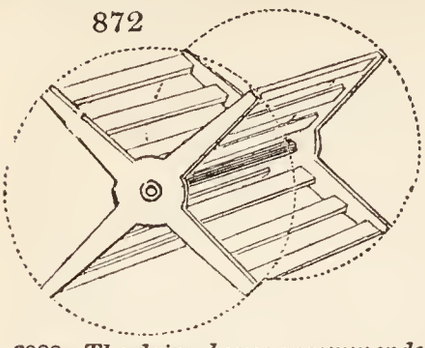
871



hollow walls, double doors, double sashed windows, and an ice-house under. The milk room (*a*) is surrounded by milk coolers, and has a butter slab and jet in the centre. The jet is supplied from a cistern over the steaming house (*f*, *g*), to which the water is raised from a well by a forcing-pump worked by the

gin wheel. Besides supplying the jet, it furnishes, by cocks and pipes, water for the usual dairy purposes, the steaming or boiling of food for the cows, their drink, and washing out the cow-house, the washing machine, &c. The churning room (*b*), is separated from the milk-room by double doors, as is the latter from the cheese-room (*c*) and store closet (*d*). The gin wheel (*e*) is worked by one or two horses, or oxen or asses, according to the work to be done. The steaming and washing room (*f*, *g*) is a large roomy apartment properly fitted up, and furnished with two boilers, a machine for steaming cattle food, another for washing linen by steam; one impelled by the gin wheel operating on an axle with beaters or lifters (*fig.* 872.), and a cylinder of open spars, which turns round in a box of water for washing potatoes or other roots. The cow-house (*h*, *h*) is calculated for forty cows to be fed from a broad passage in the centre. At the south end is a large apartment (*i*) open to the roof for hay, straw, green herbage for soiling, turnips, and other food; and under it is an urinarium vaulted, and from which the liquid is drawn by a Buchanan pump (4494.) outside of the building, and some yards distant.

872



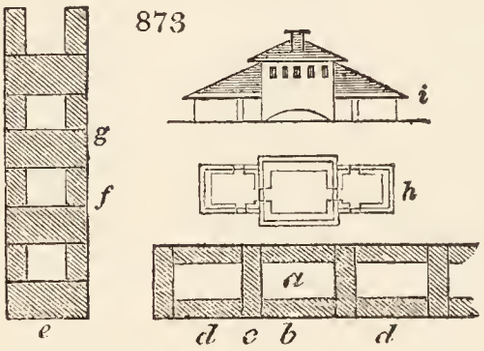
6999. *The dairy-house recommended by Dr. Anderson* is surrounded by double walls, the inner of brick or stone, nine inches or a foot in thickness; and the outer about two feet distance, built of stone or turf; or a bank of earth faced with turf may be placed against the inner walls.

7000. *The size of the dairy house* should vary according to that of the number of cows. Marshal found in Gloucestershire one for forty cows to be twenty feet by sixteen, and one for one hundred, thirty by forty. The North Wiltshire dairy-rooms have in general, he says, outer doors, frequently opening under a pent-house or open lean-to shed; which is a good conveniency, affording shade and shelter, and giving a degree of coolness to the dairy room. In one instance he observed two doors: a common close-boarded door on the inside, and an open-paled gate-like door on the outside; giving a free admission of air in close warm weather, and, at the same time, being a guard against dogs and poultry. A conveniency which, he thinks, would be an improvement to any dairy room in the summer season. The inside wall may be seven or eight feet high in the sides, on which may be placed the couples to support the roof, and the walls at the gables carried up to the height of the couples. Upon these should be laid a roof of reeds, or thatch, that should not be less than three feet in thickness, which should be produced downward till it covers the whole of the walls on each side to the ground: but here, if thatch or reeds be not in such plenty as could be wished, there is no occasion for laying it quite so thick. In the roof, exactly above the middle of the building, should be placed a wooden pipe of a sufficient length to rise a foot above the roof, to serve occasionally as a ventilator. The top of this funnel should be covered, to prevent rain from getting through it, and a valve fitted to it, that by means of a string could be opened or shut at pleasure. A window also should be made upon one side for giving light, to be closed by means of two glazed frames, one on the outside, and the other on the inside. The use of this double sash, as well as the great thickness of the wall, and of the thatch upon the roof, are to render the temperature of this apartment as equal as possible at all seasons of the year, by effectually cutting it off from having any direct communication with the external air.

7001. *The dairy-house made use of by Wakefield of Liverpool* contains three apartments; a milk-house, churning-room, and the room for the utensils. In the milk-house were the coolers; a slab for laying butter on after it is made up; cocks for drawing off the milk from the coolers; a large cock to throw water on the floor, which slopes a little from that part; cocks at the back part of the coolers, for letting in water; a door, latticed; and another door most commonly used, but panelled. In the churning-room is a fire-place, a boiler, a large copper, also used when brewing. The room for drying or airing the utensils is also used occasionally as a laundry. Over the whole are apartments for the servants.

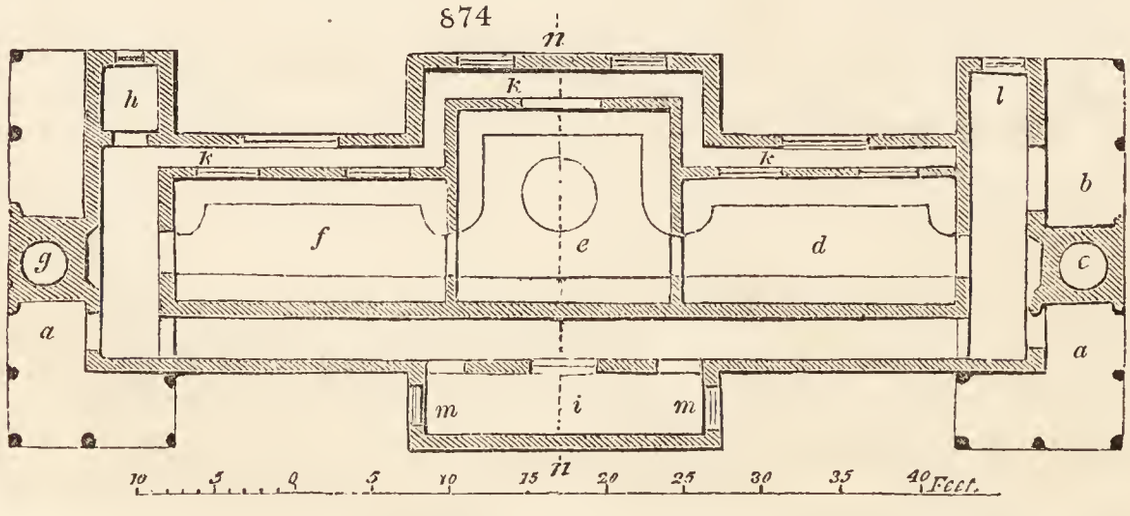
7002. *A very neat dairy for a private family* may be made under the shade of two or three tall trees, in the following manner: — Build the walls of bricks, and hollow in Silverlock's manner, by which every course of brick-work is laid on edge, and forms oblong cavities (*fig.* 873. *a*), the bricks of the one course being laid alternately lengthways (*b*), and crossways (*c*), and those of the next breaking joint with these, by the cross ones being placed on the middle of the long ones (*d*). The elevation of such a wall (*e*, *f*, *g*) should of course be founded on solid work, of breadth and thickness according to the height of the wall, and nature of the foundations. The plan of a dairy with such walls should contain the three usual apartments for milk, churning, and utensils (*h*), and should have double doors and windows: the latter guarded by fly-wire. The elevation (*i*) may be of any style of simple architecture.

873



7003. *As a complete dairy on a large scale*, we submit the following. The plan (*fig.* 874.) is of an oblong form, and consists of the three usual principal apartments, enclosed by walls of four inches in thickness, and surrounded by a passage two feet wide to the north, and three feet to the south, which is again surrounded by a nine-

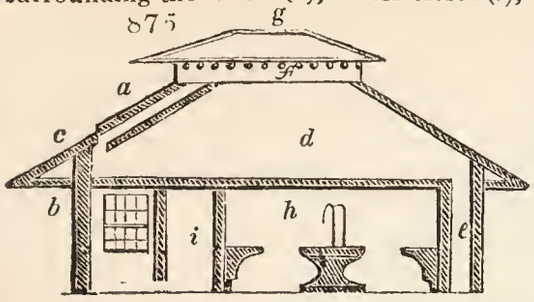
874



inch wall. The passages communicate with the roof by covered openings, in the ridge of which and by the windows ventilation is completely effected. In detail, the plan exhibits two principal entrance porches (*a*), back entrance (*b*), copper for heating water (*c*), churning-room (*d*), milk-room (*e*), utensils

and cheese-press (*f*), boiler for heating milk (*g*), store closet or butter-room (*h*), cheese-room (*i*), passage surrounding the whole (*k*), water-closet (*l*), and windows to cheese-room (*m*).

875

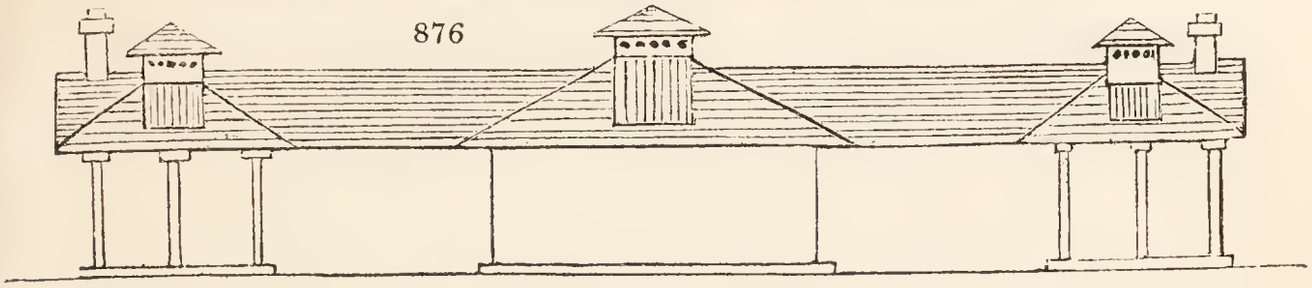


7004. *A section* (*fig.* 875.) taken across the milk-room (*fig.* 874. *n n*) exhibits the ventilating funnel in the roof (*a*), projecting eaves (*b*, *c*), cheese-room (*d*), passage on the north side (*e*), raised part of the roof for ventilation (*f*, *g*), fountain in the centre of the dairy (*h*), and south passage (*i*).

7005. *The elevation* (*fig.* 876.) presents a simple shed roof, varied, however, by projections and recesses: it presents no windows or doors to the south, and therefore that side, if other circumstances permit, may be covered with vines or other fruit-trees, or with ornamental creepers.

7006. *The fixtures of the dairy* are, in the scalding-room, a copper boiler fixed over a

876

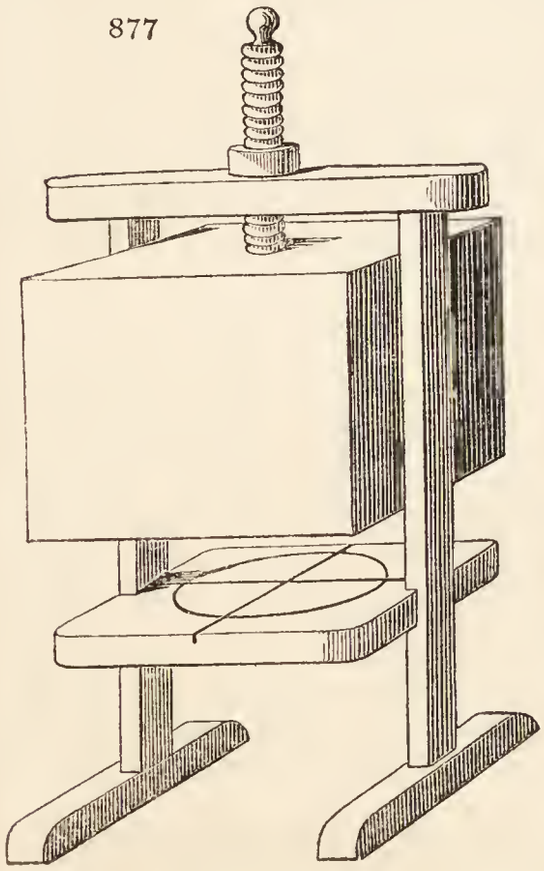


fire-place, for boiling water to wash and scald the utensils; next, some benches and shelves in this room and the cheese-room; and a bench or table not more than two feet wide surrounding the milk-room. It is very desirable, also, that there should be a jet, or fountain, or pump, or spring, in the centre of the milk-room, in order to cool down the air in summer, and to supply clear water at a moderate temperature at all times.

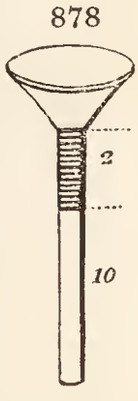
7007. *The utensils* of the dairy are, pails for milking into; sieves of hair-cloth or silver wire-cloth for passing the milk through, to free it from hairs and other impurities; milk dishes, or coolers, for holding the milk till it throws up its cream; a cream-knife of ivory for separating, and skimming dishes of willow or ivory for removing, the cream; bowls and barrels for holding it, or other preparations of milk-churns, butter-makers, butter-prints; one or more tubs for hot or cold water, in which to immerse vessels that require extraordinary purification; and a portable rack for drying dishes in the open air. All these utensils are requisite where butter only is to be produced.

7008. *The utensils requisite if cheese is to be made*, are the cheese-tub, in which the curd is broken, and prepared for being made into cheese; the cheese-knife, generally a thin spatula of wood, but sometimes of iron, used for the purpose of cutting or breaking down the curd while in the cheese-tub. The cheese-cloth is a piece of thin gauze, like linen cloth, in which the cheese is placed in the press; the cheese-board is circular, and on it the cheeses are placed on the shelves of the cheese-room; their diameter must be somewhat less than that of the interior or hoop part of the vat. The vat is a strong kind of wooden hoop with a bottom, which, as well as the sides, is perforated with holes to allow the whey to escape while the cheese is pressing: the size of vats must depend on that of the cheese and the number required, as of most of the other implements on the extent of the dairy. The cheese-press (*fig.* 877.) is a power generally obtained by a screw, though sometimes by a dead weight, and is used for forcing the whey from the curd while in the vat. The cheese-tongs is a wooden frame, occasionally placed on the cheese-tub, when the vat is set on it in order to drain the whey from the curd. To these implements some add a lactometer, one kind of which (*fig.* 878.), is a glass tube a foot long with a funnel at top. The upper two inches of the tube are marked in small divisions, and when the instrument is filled to the height of one foot with milk, the depth of cream it yields is noted by the gradations on the upper part. Another lactometer "for ascertaining the richness of milk from its specific gravity, by its degree of warmth taken by a thermometer, on comparing its specific gravity with its warmth," was invented by Dicas, of Liverpool, but never came into use. Another invention for the same purpose was made by Mrs. Lovi, of Edinburgh, in 1816. It consists of aereometric beads, by which the specific gravity of the milk is tried first when new-milked, and next when the cream is removed. When milk is tried as soon as it cools, say to 60°, and again, after it has been thoroughly skimmed, it will be found that the skimmed milk is of considerably greater gravity; and as this increase depends upon the separation of the lighter cream, the amount of the increase, or the difference between the specific gravity of the fresh and skimmed milk, will bear proportion to, and may be employed as a measure of, the relative quantities of the oily matter or butter contained in different milks. The specific gravity of skimmed milk depends both on the quantity of the saccharo-saline matters, and of the curd. To estimate the relative quantities of curd, and by that determine the value of milk for the purpose of yielding cheese, it is only required to curdle the skim-milk, and ascertain the specific gravity of the whey. The

877



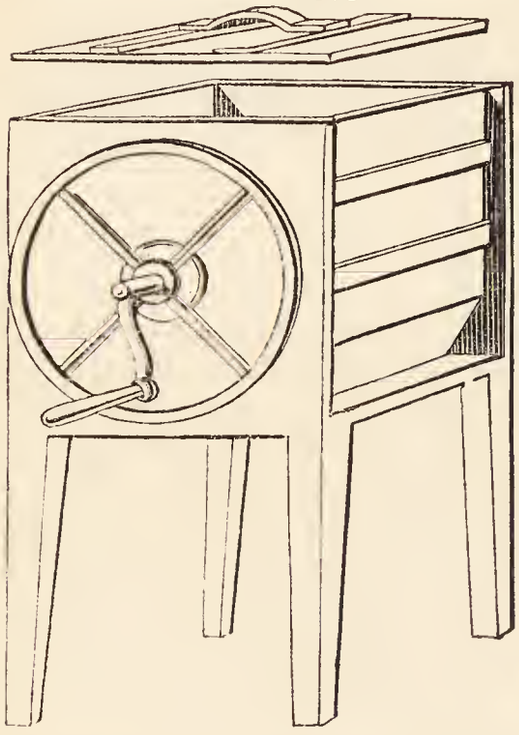
878



whey will, of course, be found of lower specific gravity than the skimmed milk, and the number of degrees of difference affords a measure of the relative quantities of the curd. According to this hypothesis, the aereometric beads may be employed to ascertain the qualities of milk, relatively both to the manufacture of butter and cheese. (*Trans. of the High. Soc.* sect. v. part i.)

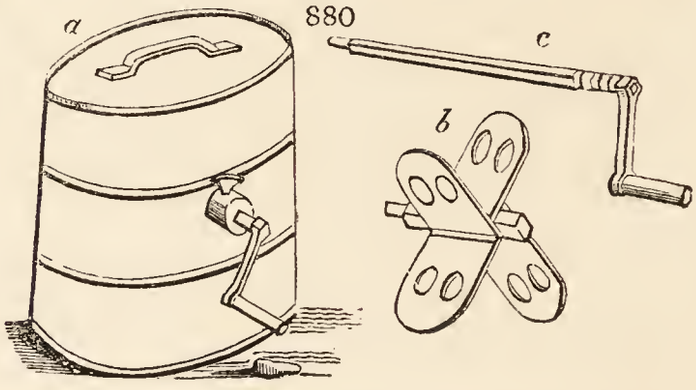
7009. *In milk coolers and churns* there is considerable variation of form. Milk coolers are generally made of earthenware or wood; but of late years they have been formed of lead, marble, slate, and cast-iron. Their general form is round, and diameter from one to two feet; but in extensive dairies they are often made several feet or yards in length, and from two to three feet wide, with holes at one or more corners to admit the escape of the milk after the cream is removed. The safest dish is wood, though it requires most labour to keep it sweet; next is earthenware or China, though on the leaden glaze of the former the acid of the milk is apt to operate. Leaden dishes or troughs, though very general in Cheshire, are the most dangerous; and the objection to slate coolers is the joinings of the plates, which are always unsightly, imperfect, and liable to be operated on by the lactic acid. The annealed and tinned cast-iron dishes of Baird's invention (in 1806), and which are now becoming universal in Scotland (*Aiton's Dairy H.*, p. 81.), are perhaps the best for such as do not choose to go to the expense of China dishes. They are durable from the nature of the material, not liable to be broken by falls by being annealed, easily kept clean from being turned smooth, and also very economical, and said to throw up more cream from a given quantity of milk than any other.

879



7010. *Besides the common plunge and barrel churns*, there are various improved sorts. One of the best for using on a small scale is the patent box churn (*fig.* 879.); and on a large scale, the plunge churn, worked by levers put in motion either by a man or horse. The Derbyshire churn (*fig.* 880.), which works on the principle of the barrel churn, is an excellent implement on a large scale. The bottom is a segment of a circle, and the advantage of the plan is, that when the butter is made, the lid (*a*) being

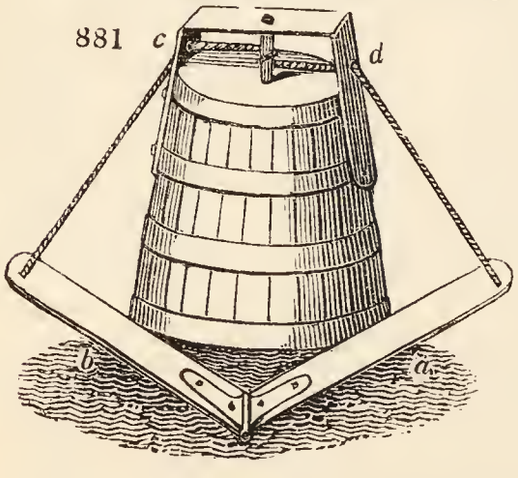
880



removed, the beaters (*b*) may be taken out at pleasure by withdrawing the spindle (*c*) to admit the removal of the butter, or the cleaning and scalding of the churn.

7011. *The Lancashire plunge churn* (*fig.* 881.) is a simple and effective implement, worked by the operator standing on the levers (*a*, *b*), throwing his whole weight alternately on each, so as by means of the line (*c*, *d*) connected with the churn staff to raise it and turn it round, and lower it and turn it round alternately.

881



7012. *The most exquisite cleanliness in the dairy* is an essential requisite, as to the walls, floor, shelves, benches, and in the different utensils.

7013. *The milk coolers* and all the dishes in which milk is put, as well as the churn, must be scalded, scrubbed, rinsed, and dried every time they are used. Scalding is less frequently requisite in the cheese utensils, but they also must be almost daily washed in hot water, dried, and aired. When any vessel becomes tainted with the acidity of milk, it operates like leaven on what is put into it: if this taint cannot be removed by ordinary scalding, it may by boiling or immersing in water impregnated with alkali; but afterwards it must be well boiled, or a day or two immersed in pure water.

Sect. III. *Milking and the general Management of Milk.*

7014. *The times of milking* vary greatly in different districts. In most places cows are milked twice in twenty-four hours throughout the year; but in the best managed dairies where they are abundantly fed, they are milked at morning, noon, and the approach of night: the additional quantity thus obtained is very considerable, but according to the experiments of Parmentier it must be inferior in quality; for he found twelve hours requisite for the due preparation of the milk in the cow. Where quantity of milk or cheese is an object, three times milking must be decidedly preferable; but it is certain that in the best butter districts of England the cows are only drawn twice a day, between five and six o'clock morning and evening. Whatever may be the times of milking, it is essential that the milk be drawn off clear; for if the milk which the cow can be made to yield at the time be not completely taken away, the quantity left will be reabsorbed into the system, and no more will be generated than is necessary to supply the quantity actually drawn off.

7015. *The operation of milking* is performed by men in many districts, but taking Britain generally it is more commonly the work of women. The milker, whether a man or woman, ought to be mild in manners and good tempered. If the operation be performed harshly, it becomes painful to the cow, who in this

case often brings into action her faculty of retaining her milk at pleasure; but if gently performed, it seems rather to give pleasure, as is exemplified on a large scale in Tiviotdale, and Switzerland, where the cows come to be milked at the call of the milkers. Many instances have occurred, Dr. Anderson observes, in which cows would not let down a single drop of milk to one dairy-maid, which let it flow in abundance whenever another approached them; exhibiting unequivocal marks of satisfaction in the one case, and of sullen obstinacy in the other. For the same reason, when cows are ticklish, they should be treated with the most soothing gentleness, and never with harshness or severity; and, when the udder is hard and painful, it should be tenderly fomented with luke-warm water, and stroked gently, by which simple expedient the cow will be brought into good temper, and will yield her milk without restraint. Lastly, as it sometimes happens that the teats of cows become scratched or wounded, so as to produce foul or corrupted milk, whenever this is the case, such milk ought on no account to be mixed with the sweet milk, but should be given to the pigs, without being carried into the milk-house; lest, by continuing there, it should taint the atmosphere, and consequently prove injurious to the rest of the milk.

7016. *To promote cleanliness in regard to milking*, cows are in some places curried, combed, brushed, and clothed like horses; before milking, their udders and teats are washed and dried, and their tails trussed up. It would be well if a part of this refinement were adopted in all dairies; that of using the comb and brush, and washing the udder, is indispensable in every establishment where clean milk is an object. According to Mowbray, snuff-takers, sluts, and daudles are unfit to be dairy-women, and no milker should ever be suffered to enter the dairy in a dirty apron covered with hairs from the cow-house.

7017. *The following aphorisms respecting the management of milk* in the dairy are from the "Recreations" of Dr. Anderson, one of the most scientific writers on this subject.

1. Of the milk drawn from any cow at one time, that part which comes off at the first is always thinner, and of a much worse quality for making butter, than that afterwards obtained; and this richness continues to increase progressively to the very last drop that can be obtained from the udder.

2. If milk be put into a dish, and allowed to stand till it throws up cream, the portion of cream rising first to the surface is richer in quality, and greater in quantity, than that which rises in a second equal space of time: and the cream, which rises in the second interval of time, is greater in quantity, and richer in quality, than that which rises in a third equal space of time; that of the third is greater than that of the fourth, and so of the rest; the cream that rises continuing progressively to decrease in quantity, and to decline in quality, so long as any rises to the surface.

3. Thick milk always throws up a much smaller proportion of the cream which it actually contains than milk that is thinner; but the cream is of a richer quality: and if water be added to that thick milk, it will afford a considerably greater quantity of cream, and consequently more butter than it would have done if allowed to remain pure; but its quality is, at the same time, greatly debased.

4. Milk, which is put into a bucket or other proper vessel, and carried in it to a considerable distance, so as to be much agitated, and in part cooled before it be put into the milk-pans to settle for cream, never throws up so much, or so rich cream, as if the same milk had been put into the milk-pans directly after it was milked.

7018. *From these fundamental facts*, the reflecting dairyist will derive many important practical rules. Some of these we shall enumerate, and leave the rest to be discovered. Cows should be milked as near the dairy as possible, in order to prevent the necessity of carrying and cooling the milk before it is put into the creaming dishes. Every cow's milk should be kept separate till the peculiar properties of each is so well known as to admit of their being classed, when those that are most nearly allied may be mixed together. When it is intended to make butter of a very fine quality, reject entirely the milk of all those cows which yield cream of a bad quality, and also keep the milk that is first drawn from the cow at each milking entirely separate from that which is last obtained, as the quality of the butter must otherwise be greatly debased without materially augmenting its quantity. For the same purpose, take only the cream that is first separated from the first drawn milk. Butter of the very best quality can only be economically made in those dairies where cheese is also made; because in them the best part of each cow's milk can be set apart for throwing up cream, the best part of this cream can be taken in order to be made into butter, and the remainder, or all the rest of the milk and cream of the dairy, can be turned into cheese. The spontaneous separation of cream, and the production of butter, are never effected but in consequence of the production of acid in the milk. Hence it is that where the whole milk is set apart for the separation of cream, and the whole of the cream is separated, the milk must necessarily have turned sour before it is made into cheese; and no very excellent cheese can be made from milk which has once attained that state.

Sect. IV. *Making and Curing of Butter.*

7019. *The milk from which butter is to be made* may either be put at once into the churn, and left there till it send up the cream; or it may be made to cream in milk dishes, and the cream alone churned.

7020. *The last is generally* considered the best mode, and in carrying it into effect, the milk being drawn from the cow, is to be strained into the creaming dishes, which should never be more than three inches deep, and of about a gallon and a half or two gallons in capacity. In general the best cream will be fit for removal in seven or eight hours, though for ordinary good butter it may stand twelve hours; but where the very best butter is wished, and such arrangements are formed as admit of converting the milk to cheese, or some other use while it is sweet, it may be separated after standing only two or three or four hours. In performing the operation, first pass the cream knife round the edges of the vessel, to separate the adhering stratum of cream, and then draw it to one side, lift it off with the skimming dish, and put it in the cream bowl to be carried to the cream barrel.

7021. *Cream* may be kept from three to seven days before it is churned. Where quantity more than quality is desired, the whole of the milk is churned, without separating any cream; the milk is kept in the churn or in large barrels for two or three days, till it begins to get sour. The operation of churning, where the cream and milk are both to agitate, is necessarily tedious and laborious; but a great weight of butter is undoubtedly obtained, the quality and flavour of which will depend a good deal on the peculiar properties of the milk. The milk of Galloways, Ayrshires, and Alderneys, so treated, makes excellent butter.

7022. *In the process of churning* great nicety is required; a regular stroke in plunge or pump churns, and a regular motion in those of the barrel or turning kind, must, if possible, never be deviated from. A few hasty irregular strokes or turns has been known to spoil what would otherwise have been excellent butter. Twamley (*Essays on the Dairy*) recommends the selection of a churner of a cool phlegmatic temper, of a sedate disposition and character; and advises never to allow any individuals, especially the young, to touch the churn without the greatest caution and circumspection. To those who have been accustomed to see cream churned without being properly prepared, churning may, perhaps, appear to be severe labour for one person in a large dairy; but nothing is more easy than the process of making butter, where the cream has been duly prepared.

7023. *The best time for making butter, during summer*, is early in the morning, before the sun acquires much power; and if a pump churn be used, it may be plunged a foot deep into a tub of cold water, where

it should remain during the whole time of churning; which will very much harden the butter. During winter, from the equality of temperature, which (if it be properly managed) will generally prevail in a dairy, it will very rarely, if ever, be necessary to churn near the fire. Should any circumstance, however, require this, care should be taken not to churn so near the fire as to heat the wood; as it would impart a strong rancid taste to the butter. As soon as the butter is made, it must be separated from the milk, and be put into a clean dish; the inside of which, if of wood, should previously be well rubbed with common salt, to prevent the butter from adhering to it. The butter should then be pressed and worked with a flat wooden ladle or skimming-dish, having a short handle, so as to press out all the milk that may be lodged in the cavities of the mass. A considerable degree of dexterity, as well as of strength, is requisite in this manipulation: for, if the milk be not entirely removed, the butter will infallibly spoil in a short time; and if it be much worked, the butter will become tough and gluey, which greatly debases its quality. In some places it is the practice to beat up the butter with two flat pieces of board, which may, perhaps, answer very well. In this operation, some persons pour cold water upon the butter, for the purpose of washing it: this practice, however, is not only useless, for the butter can be perfectly cleared of the milk without it, but it is also pernicious, and debases the quality of the butter in an astonishing degree. Nothing is so detrimental in a dairy as water improperly used; which, if mixed in any way, either with milk or butter, tends greatly to debase the quality of the latter.

7024. *The best temperature for churning butter* has been very satisfactorily determined by a number of experiments, sanctioned by the *Highland Society of Scotland*, and published in their *Transactions*. From these experiments it is concluded, that the most proper temperature at which to commence the operation of churning butter is from 50° to 55°; and that at no time in the operation ought it to exceed 65°: while, on the contrary, if at any time the cream should be under 50° in temperature, the labour will be much increased, without any proportionate advantage being obtained; and a temperature of a higher rate than 65° will be injurious, as well to the quality as the quantity of the butter. (*Highl. Soc. Trans.* vol.vii. p. 198.)

7025. *The making up of butter* is the next process.

7026. *Before being sent to table or market*, sweet or fresh butter is made up into various forms; sometimes into rolls or cylinders, six or eight inches long, and from half an inch to two inches in diameter; at other times into small round figures, or casts, with impressions in relief from butter moulds. When the butter is too soft for the last purpose, it may be put into small wooden vessels, which may be allowed to swim in a tub or cistern of cold water; or they may be set in an ice-house for an hour or two; or the water in which the small vessels float may be iced. At all events, whatever mode is adopted, no water ought to be allowed to touch the butter. When formed into the desired shapes, it may be placed in dishes, and set in the margin of the central cistern of water till wanted.

7027. *In salting or curing butter* the use of wooden vessels is preferable; and these vessels should be made from timber which has been previously boiled for four hours, to free it from the pyroligneous acid; or they should be formed from the lime tree, which is confidently asserted (*Highl. Soc. Trans.* vol. vii. p. 355.) to be without this acid. Whatever description of casks are used, they should previously be rendered as clean and sweet as possible, well rubbed with salt, and the cavity between the bottom and sides filled in with melted butter.

7028. *An excellent composition for preserving butter* may be made, by reducing into a fine powder, and carefully mixing together, sugar and nitre, of each one part, and two parts of the best common salt. Moir to each pound weight of salt adds four ounces of raw sugar. Of this composition, one ounce should be thoroughly mixed with every sixteen ounces of butter, as soon as the latter has been freed from the milk; and the butter must be immediately put into the firkin, being pressed so close as to leave no air-holes, or any kind of cavities, within it. The surface must be smoothed; and, if a day or two be expected to elapse before more can be added, the vessel must be closely covered up with a piece of clean linen, upon which should be laid a piece of wetted parchment, or (if this be not procurable) with a piece of fine linen dipped in melted butter, that is exactly fitted to the edges of the vessel all round, so as to exclude the air as much as possible. When more butter is to be added, these coverings are to be removed; the butter is to be applied close upon the former layer, pressing it down, and smoothing it as before, till the vessel be full. The two covers are then to be spread over it with the greatest care; and a little melted butter is to be poured all round the edges, so as to fill up every part, and effectually to exclude the air. A little salt may then be strewed over the whole, and the cover be firmly fixed down. Butter thus cured does not taste well till it has stood at least a fortnight after it has been salted; but after that period it acquires a rich marrowy taste, and will continue perfectly sweet in this climate for many years. As, however, its quality is liable to be impaired by being improperly treated while it is using, it will be necessary, when the firkin is opened, first to pare off a small portion of the whole surface, especially near the edges, in case the air should, by any accident, not have been entirely excluded. If it is to be quickly consumed, it may be taken up as it is wanted, without any other precaution than that of keeping it carefully covered up; but, on the contrary, if it is to be used very slowly, and if the person employed to take it up be not very careful in closing it up each time with the covers, the part which is thus exposed to the air will be liable to contract a small degree of rancidity. To prevent the occurrence of this inconvenience, when the vessel is opened, a strong brine of common salt (strong enough to float an egg) should be poured, when cold, upon the surface of the butter; and although the quality of the latter will be slightly injured by the action of the water upon it, yet that is a much less evil than the slightest rancidity would occasion.

7029. *Butter casks.* The following is the plan adopted by Moir: — "Cut the wood into deals of the lengths wanted; have a boiler of a square form, the length of the wood, full of water: put in the wood with a weight or pressure, to keep it immersed in the water, and have a wooden cover on the boiler, as it must be done by close evaporation. When thus boiled for *four hours*, the whole of the pyrolignous acid will be extracted. The wood is then dried for use. It becomes closer and more condensed, from the fibres being contracted. By this method, while the wood continues hot, it can be easily brought to any shape, and used for various purposes; and this is the only mode by which barrels for salted butter should be made. (*Highl. Soc. Trans.* vol. vii. p. 356.)

7030. *When butter is to be exposed to the heat of a warm climate*, it should be purified by melting before it is salted and packed up. For this purpose, let it be put into a proper vessel, and this be immersed into another containing water. Let the water be heated till the butter be thoroughly melted: let it continue in this state for some time, when the impure parts will subside, leaving at the top a perfectly pure transparent oil. This, when it cools, will become opaque, and assume a colour nearly resembling that of the original butter, being only somewhat paler, and of a firmer consistence. When this refined butter is become a little stiff, but while it is still somewhat soft, the pure part must be separated from the dregs, and be salted and packed up in the same manner as other butter; it will continue sweet much longer in hot climates, as it retains the salt better than in its original state. It may also be preserved sweet, without salt, by adding to it a certain portion of fine honey, perhaps one ounce to a pound of butter, and mixing them together thoroughly, so that they may be perfectly incorporated. A mixture of this sort has a sweet pleasant taste, and will keep for years without becoming rancid: there is no doubt, therefore, but that butter might thus be preserved in long voyages without spoiling.

7031. *As winter-made butter* is mostly pale or white, and, at the same time, of a poorer quality than that made during the summer months, the idea of excellence has been associated with the yellow colour: hence, various articles have been employed in order to impart this colour. Those most generally used, and certainly the most wholesome, are the juice of the carrot, and of the flowers of the marigold, carefully expressed, and strained though a linen cloth. A small quantity of this juice (and the requisite proportion is soon ascertained by experience) is diluted with a little cream, and this mixture is added to the rest of the cream when put into the churn. So small a quantity of the colouring matter unites with the butter, that it never imparts to it any particular taste.

7032. *The butter most esteemed in London* is that of Epping and Cambridge; the cows which produce the former feed during summer in the shrubby pastures of Epping forest, and the leaves of the trees and numerous wild plants which there abound are supposed to improve the flavour of the butter. It is brought to market in rolls from one to two feet long, weighing a pound each. The Cambridgeshire butter is produced from the milk of cows that feed one part of the year on chalky uplands, and the other in rich meadows or fens; it is made up into long rolls like the Epping butter, and generally salted, not cured, before brought to market. By washing it, and working the salt out of it, the London cheesemongers often sell it at a high price for fresh Epping butter.

7033. *The Suffolk and Yorkshire butter* is often sold for that of Cambridgeshire, to which it is little inferior. The butter of Somersetshire is thought to equal that of Epping; it is brought to market in dishes, containing half a pound each, out of which it is taken, washed, and put into different forms by the butter-men of Bath and Bristol. The butter of Gloucestershire and of Oxfordshire is very good; it is made up in half-pound packs or prints, packed up in square baskets, and sent to the London market by waggon.

7034. *The butter of the mountains* of Wales and Scotland, and the moors, commons, and heaths of England, is of excellent quality, when it is properly managed; and though not equal in quantity, it often is confessedly superior to that produced from the richest meadows. Bad butter is more frequently the result of mismanagement, want of cleanliness, and inattention, than of any other cause. Ireland would produce the finest butter in the empire, were it not for the intolerably filthy state of their cows, and the want of cleanliness in their dairies.

7035. *In packing fresh butter*, or butter salted only for immediate use, the leaves of cabbage, white beet, or of the garden orache (*Atriplex hortensis*) are to be preferred. The bottom of the basket should be bedded with a thick cloth, folded two or three times; then a thin gauze, dipped in cold water, spread over it, on which the prints or rolls of butter are to be placed, each with one or more leaves beneath, and smaller ones over it. The lowermost layer being adjusted, fold half of the gauze cloth over it, put in another layer in the same way, and then cover with the remainder of the gauze. The butter should be put into the basket, as well as taken from thence, without being touched.

7036. *Whey butter*, as its name implies, is butter made from the whey which is taken from the curd, after the milk is coagulated for the manufacture of cheese. It is chiefly made in those counties where cheese is manufactured, and where it forms no inconsiderable part of the profits of the dairy. In the county of Derby more butter is said to be made from whey than from the cream of milk, or from milk churned altogether.

7037. *Whey is divided into two sorts*, green and white, the former escaping readily from the curd, while the latter is freed from it by means of pressure. "There are different methods of extracting the whey. In some dairies the whole whey, when taken from the cheese-tub, is put into pails or other vessels, where it remains for about twenty-four hours; when it is creamed, and the whey is applied to the use of calves and pigs, which are said to thrive as well on it, after the cream has been taken from it, as before. The cream, when skimmed off the whey, is put into a brass pan and boiled, and afterwards set in pans or jars, where it remains till a sufficient quantity for a churning be procured, which, in large dairies, happens generally once, but sometimes twice, in the week." In Ayrshire whey is given to horses.

7038. *Butter forming an important article of commerce as well as food*, the legislature has passed various statutes respecting its package, weight, and sale. The principal of these are the 36th and 38th of Geo. III.

Sect. V. *Process of Cheese-making.*

7039. *The production of cheese* includes the making of rennet, the selection of a colouring matter, the setting of the curd, and the management of the cheese in the press.

7040. *The milk fresh drawn* from the cow is to be immediately strained into the dishes or shallow troughs, if these are used, in order to promote cooling, as the surest guard against fermentation. The same object may be attained by repeatedly drawing off the milk from the coolers, and pouring it back again.

7041. *To understand what rennet is, and its uses*, it is necessary to premise that milk is no sooner taken into the stomach, than it becomes curdled by the operation of the gastric juice, as every one who has seen much of infant children must have observed. What is called rennet is nothing more than the stomach of an animal in which the gastric juices are preserved by means of salt.

7042. *The application of any kind of acid* will cause milk to coagulate, as well as the infusion of several plants, as ladies' bedstraw (*Gàlium vèrum*), butter-wort (*Pinguícula vulgàris*), and others. With the former plant the Jews coagulate the milk for all their cheese; the Mosaic law prohibiting them to mingle meat with milk, and rennet they consider as meat.

7043. *The maw or stomach of ruminating animals*, which admit of obtaining the gastric juice in a less mixed state than those of others, and chiefly of a young calf that has been killed before the digestion is perfected, is almost universally preferred as rennet. This bag or maw is cleaned and salted in different ways in different districts; but the following method, described by Marshal in his *Rural Economy of Norfolk*, is considered as one of the best. "Take a calf's bag, maw, or stomach; and having taken out the curd contained therein, wash it clean, and salt it thoroughly inside and out, leaving a white coat of salt over every part of it. Put it into an earthen jar, or other vessel, and let it stand three or four days; in which time it will have formed the salt and its own natural juice into a pickle. Take it out of the jar, and hang it up for two or three days, to let the pickle drain from it. Re-salt it, place it again in a jar, cover it tight down with a paper pierced with a large pin, and in this state let it remain till wanted for use. In this state it ought to be kept twelve months; it may, however, in case of necessity, be used a few days after it has received a second salting; but it will not be so strong as if kept a longer time."

7044. *In order to prepare this rennet for use*, Marshal gives the following directions: — "Take a handful of the leaves of sweet-briar, the same quantity of the leaves of the dog-rose, and the like quantity of bramble leaves; boil them in a gallon of water, with three or four handfuls of salt, about a quarter of an hour; strain off the liquor, and, having let it stand till perfectly cool, put it into an earthen vessel, and add to it the maw, prepared as above. To this is added a good sound lemon, stuck round with about a quarter of an ounce of cloves, which give the rennet an agreeable flavour."

7045. *The strength of the rennet thus prepared* will increase in proportion to the length of time during which the bag remains in the liquor; the quantity to be used for the purpose of coagulating milk can, therefore, be ascertained only by daily use and occupation. In general, however, it may be stated, upon the average, that somewhat less than half a pint of wine measure will suffice for fifty gallons of milk, for which quantity, in Gloucestershire, the practice is to employ about one third of a pint. Throughout the whole process of preparing and preserving rennet, too much attention cannot be given to its clean-

liness and sweetness; for if it be kept too long, so as to become foul or tainted, the cheese will invariably become affected by it, and will prove unfit for use.

7046. *In Holland* a small quantity of the muriatic acid is used instead of rennet; and it is the use of this article which gives to the Dutch cheese that pungent relish which induces so many persons to prefer it.

7047. *Colouring matter.* As cheese in its native state, that is, such as is well manufactured, being put together in proper time, the milk being of a proper degree of warmth, and in all other respects properly pressed, salted, and dried, is uniformly of a bright yellow cast, the idea of excellence is generally attached to cheese of such a colour. Hence it has become necessary for the dairyman, who would dispose of his cheese to advantage, to impart a light yellow orange colour to it by artificial means.

7048. *Turmeric, marigolds, hawthorn buds*, and other vegetables, were formerly employed for this purpose; but these have long since been rejected for the *Spanish Arnotto*, which is unquestionably the best ingredient of the kind that can be used for the colouring of cheese. It is a preparation of the *roucon* or arnotto tree (*Bixa Orellàna* Lin., *fig.* 166.), which is a native of America. The red pulp, that covers the seeds of this tree, is suspended in hot water, and allowed to subside, and when dry, is formed into cakes or balls, which are further set aside, until they become completely dry and firm. One ounce of this substance, when genuine, will be sufficient to colour an hundred weight of cheese; and this is the common allowance in the county of Gloucester; in Cheshire, the weight of a guinea and a half is considered to be sufficient for a cheese of sixty pounds weight. The usual mode of applying the arnotto is to dip a piece, of the requisite size and weight, in a bowl of milk, and rub it on a smooth stone until the milk assume a deep red colour. This infusion is to be added to the milk, of which cheese is intended to be made, in such a quantity as will impart to the whole a bright orange colour, which will become the deeper in proportion to the age of the cheese. The mixing of the arnotto in no respect affects either its taste or smell.

7049. *In the county of Cheshire*, however, a somewhat different practice obtains. There, when the colouring matter is wanted, it is usual to tie up as much of the substance as may be deemed sufficient in a linen rag; putting it into half a pint of warm water, to let it stand over night. In the morning, immediately before the milk is coagulated, the whole of this infusion is mixed with it in the cheese-tub, and the rag is dipped in the milk, and rubbed on the palm of the hand, until all the colouring matter is completely extracted. A more simple method is directed by Parkinson: — "Take," says he, "a piece about the size of a hazel nut, put it into a pint of milk the night before you intend to make cheese, and it will dissolve. Add it to the milk at the time the rennet is put in. The quantity will suffice to colour a cheese of twenty pounds weight." (*Parkinson on Live Stock*, vol. i. p. 62.)

7050. *Setting the curd.* The proper season for making cheese is from the beginning of May till the close of September, or in favourable seasons till the middle of October. Very good cheese, however, may be made in winter, provided the cows be well fed. A certain elevation of temperature is requisite to the coagulation of milk, and it may naturally be supposed to be nearly that of the stomachs of milk-taking animals. Marshal is of opinion that from 85 to 90 degrees of heat, and two hours of time, are the fittest for coagulation.

7051. *Climate, season, weather, and pasture* may require that these limits should sometimes be violated. Milk produced from poor clays will require to be coagulated at a higher temperature than that which is procured from rich pastures. In some dairies the milk is heated to the proper temperature; but the most approved practice is to mix boiling water in such a proportion as shall render the milk of a proper degree of heat to receive the rennet; this the thermometer should be used to determine. In hot weather the milk in the cows' udders is liable to become very much agitated by their running about, or being driven to too great a distance: so that if rennet be put to it in this state, the curd, instead of coming in one or two hours, will require three, four, or five hours, and will be so spongy, tough, and in every respect so imperfect, as to be scarcely capable of being confined in the press or vat; and when released from the press, it will heave or split, and be good for little. Whenever, therefore, cows are discovered to be in this state, which perhaps can scarcely be avoided during very hot weather, where cows are pastured abroad, in unsheltered grounds, or where water is not within their reach; it will be advisable to add some cold fresh spring water to the milk as soon as it is brought into the dairy. The quantity to be mixed, in order to impart the proper degree of heat, can in this case only be regulated by experience and the use of the thermometer. The effect of the water thus added will, in both cases, be to make the rennet take effect much sooner, and consequently to accelerate the coagulation of the milk.

7052. *The proportion of rennet and time requisite for coagulation* have been already mentioned (7045. 7050.): too much rennet ought not to be put in, otherwise the cheese will be ready to heave, as well as become rank and strong; the same effects will also be produced if the rennet be made with bad or foul materials, or if it be too strong to operate in the given time (two hours). During the process, the milk ought to be covered so as not to lose more than five or seven degrees of its original heat. One or two handfuls of salt added previously to mixing the rennet will promote coagulation. Some put in a bowl, which is an absurd ancient custom, and injurious rather than useful.

7053. *When the coagulation has taken place*, the curd is broken or cut with a cheese-knife, which causes the whey to rise through the incisions, and the curd sinks with more ease. After a short time the cutting is repeated, still more freely than before; and is continued until the curd is reduced to small uniform particles. This operation will require about three quarters of an hour: the cheese-tub is again covered with a cloth, and is allowed to remain for the same time. When the curd has sunk to the bottom of the vessel, the whey is taken off by the hand, or by means of a skimming-dish; another quarter of an hour should now be allowed for the curd to settle, drain, and become solid, before it is broken into the vat, as it prevents the fat from being squeezed out through the fingers, and of course contributes to improve the quality of the cheese. Sometimes, in addition to the skimming-dish, a semicircular board and weight, adapted to the size of the tub, are employed. The curd is again cut as before, in order to promote the free separation of the whey, and pressure is again applied till it be wholly drawn off. Great attention is requisite in conducting this part of the business; and if any particles of slip curd should be seen floating in the whey, it ought to be carefully laded off with the whey; as it will not incorporate with the solid curd, but dissolving in the cheese, causes whey-springs, as already mentioned, and materially impairs its soundness. If the whey be of a green colour, when loaded or pressed out, it is a certain criterion that the curd has been properly formed: but if it be of a white colour, it is equally certain that the coagulation is imperfect, the cheese will be sweet, and of little value, and much valuable caseous matter will be completely thrown away. In the counties of Norfolk and Suffolk, the cheese manufacturers have recourse to a somewhat different method for extracting the whey, which is worthy of notice: when they think the milk sufficiently coagulated, they lay a strainer in a basket made for the purpose; into which they put the curd, and suffer it to remain there for some time to drain, before they break the curd. When the curd is sufficiently drained, it is put into two or three separate vessels, and is broken with the hand as small as

possible. During this part of the process salt is scattered over the curd, and intimately mixed with it; the proportion, however, has not been correctly ascertained, and is regulated by experience.

7054. *Management in the press.* The breaking and salting completed, a cloth is spread over the cheese vat, and the broken curd being packed into it, and covered up with the cloth, a smooth round board is laid over the vat, which is usually filled to the height of one inch above the brim, to prevent the curd from shrinking below its sides, when the whey is squeezed out.

7055. *The whole is then put into a press* for two hours, and as it is of the utmost importance that every drop of whey should be expressed, skewers are thrust into the cheese through the holes in the lower part of the vat to facilitate its escape. The two hours expired, the cheese is taken out and put into a vessel of warm or hot whey for an hour or two, in order to harden its skin. On taking the cheese out of the whey it is wiped dry, and when it has become cool, is wiped in a clean dry cloth, of a finer texture, and again submitted to the press for six or eight hours. The cheese is now turned a second time, and is taken to the salting room, where it is rubbed on each side with salt; after which it is wrapped in another dry cloth, of a finer texture than either of the preceding cloths, and is again pressed for twelve or fourteen hours; if any edges project these are paired off, and the cheese being laid upon a dry board, is turned every day. In the salting-room cheese should be kept warm until it has had a sweat, or has become regularly dry and somewhat stiff; as it is warmth that ripens cheese, improves its colour, and causes it when cut to have a flaky appearance, which is the surest sign of superior excellence.

7056. *Management in the cheese-room.* After the processes of salting and drying are completed, the cheeses are deposited in the cheese-room or loft, which should be airy and dry; but on no account should hard and soft cheeses be placed in the same room, for the dampness or moisture arising from the latter will cause the hard cheese to chill, become thick coated, and often spotted. Throughout the whole process of cheese-making, the minutest attention will be requisite; for if the whey be imperfectly expressed, or the rennet be impure, or the cheese be not sufficiently salted, it will become rank and pungent. For this defect there is no remedy. The imperfect separation of the whey will cause cheese to heave or swell, as well as to run out at the sides.

7057. *In order to prevent as well as to stop this heaving*, the cheese must be laid in a moderately cool and dry place, and be turned regularly every day. If the heaving be very considerable, the cheese must be pricked on both sides in several places, particularly where it is most elevated, by thrusting a skewer into it: by this pricking, though the heaving will not be altogether prevented, a passage will be given to the confined air, the heaving or swelling will consequently be considerably reduced, and the cavities of the cheese will be less offensive to the eye. Another remedy for *heaving* in cheese consist in applying a composition of nitre and bole armoniac, which is vended in the shops under the name of *cheese-powder*. It is prepared by mixing one pound of saltpetre with half an ounce of bole armoniac thoroughly together, and reducing them to a very fine powder. About a quarter of an ounce of this is to be rubbed on a cheese, when put a second and third time into the press, half on each side of the cheese at two different meals, before the salt is rubbed on, that the cheese may be penetrated with it. This preparation is very binding, and sometimes proves serviceable, but the nitre is apt to impart an acid taste; and if too much be applied, and the cheese should be exposed to too great heat, the quantity of air already confined in it will be increased by fermentation, and the cheese will swell much more than it would if no powder had been rubbed in. The greatest care, therefore, will be necessary whenever this remedy is adopted.

7058. *Hard and spoiled cheese* may be restored in the following manner: take four ounces of pearlash, and pour sweet white wine over it, until the mixture ceases to effervesce. Filter the solution, dip into it clean linen cloths, cover the cheese with them, and put the whole into a cool place, or dry cellar. Repeat this process every day, at the same time turning the cheese, and, if necessary, continue it for several weeks. Thus the hardest and most insipid cheese, it is affirmed, has frequently recovered its former flavour.

Sect. VI. *Catalogue of the different Sorts of Cheeses and other Preparations made from Milk.*

7059. *Of cheeses,* we shall first enumerate the British sorts, and next those peculiar to foreign countries: the description of each will be such as to enable any ingenious dairyist to imitate them.

7060. *The brick-bat cheese* is so named from the form of the mould; it is formed of new milk and cream in the proportion of two gallons of the former to a quart of the latter. It is principally made in Wiltshire, in the month of September, and should not be cut until it is twelve months old.

7061. *Chedder cheese,* so named from the vale of that name in Somersetshire, where it is exclusively made. It is made in cheeses about thirty pounds each, which have a spongy appearance, and the eyes are filled with a limpid and rich, but not rancid oil.

7062. *Cheshire cheese* is in universal esteem; it is made from the whole of the milk and cream, the morning's milk being mixed with that of the preceding evening, previously warmed. The general weight is sixty pounds each cheese.

7063. *Dunlop cheese* (so called from its having been first brought to the Glasgow market by a carrier who lived in the parish of Dunlop, in Ayrshire,) has been made in the district of Cunningham in Ayrshire, from time immemorial. The quality of this cheese has certainly not been equalled in any other part of Scotland, and scarcely surpassed in England. According to Aiton, it is "milder in its taste, and fatter, than any English cheese whatever." The following directions are from this author's *Dairy Husbandry.*

7064. *When as many cows are kept on one farm as that their milk will form a cheese of any tolerable size every time they are milked (twice a day),* the milk, as it comes from the cows, is passed through a sieve (provincially termed a *milsey*) to remove impurities into a boyn (vat), and when the whole is collected, it is formed into curd by a mixture of rennet. As milk requires to be coagulated as nearly as possible at the temperature of animal heat, and as it must cool considerably during the operation of milking from several cows, and in passing through the sieve, it is necessary for those who set their curd in the natural heat to make up some part of that which is lost, by mixing a quantity of hot water into the curd vat.

7065. *When the cows on a farm are not so numerous as to yield milk sufficient to make a cheese every time they are milked,* the milk is stored about six or eight inches deep in the coolers that have been described, and placed in the milk-house till as much is collected as will form a cheese of a proper size. When the cheese is to be made, the cream is skimmed from the milk in the coolers, and without being heated is, with the milk that is drawn from the cows at the time, passed through the sieve into the curd-vat; and the cold milk from which the cream has been taken is heated, so as to raise the temperature of the whole mass to near blood heat; and the whole is coagulated by means of rennet carefully mixed with the milk. The cream is put into the curd-vat, that its oily parts may not be melted, and the skimmed milk is heated as much as to raise the whole to near animal heat. The utmost care is always taken to keep the milk in all stages of the operation free, not only from every admixture or impurity, but also from being hurt by foul air arising from acidity in any milky substance, putrid water, the

stench of the byre, dunghill, or any other substance; and likewise to prevent the milk from becoming sour, which when it happens greatly injures the cheese.

7066. *The temperature* at which the milk is kept from the time it is drawn from the cows till it is formed into cheese, ready to be put up to dry, is a matter of great importance, and should be carefully attended to. The milk, when taken from the cow, ought to be as soon as possible cooled to below 55°, or between that and 50° on Fahrenheit's scale: to cool it speedily, and to facilitate the separation or rising of the cream, a small quantity of clean cold water is generally mixed with the milk in each cooler; and when the stone or iron coolers that have been described are used, the milk will cool in them much sooner than in the wooden dishes formerly in use. If the milk is kept warmer than 55° of temperature, it will not properly cast up the cream, which it is thought necessary it should do even when the whole is to be formed into cheese, and the milk will soon become sour, and acquire a bad taste, if it is not brought to near that degree of temperature; but if it gets into a lower temperature than about 50° the milk acquires an insipid and unpleasant taste, of which it cannot be again divested; it does not coagulate nearly so well, and the cheese made from it is soft and inadhesive, the curd difficult to be separated from the whey, and the milk and cheese are never well tasted.

7067. *Milk ought to be coagulated at nearly its natural heat when drawn from the cow*, or from 90 to 95 degrees of temperature, and for that pupose a thermometer ought to be used in the milk-house. If coagulated much warmer, the curd is tough, harsh, and too adhesive; much of the butteraceous matter is melted, and goes off with the whey, and the cheese becomes hard, dry, tough, and tasteless; and if the milk is too cold when coagulated, the curd is soft, does not part with the serum, and the cheese continues to be so soft that it is with difficulty that it can be kept together. Even when the utmost pains are taken to extract the whey, and to give it solidity and firmness, putrifying holes, which in dairy language are termed "eyes," whey-drops, or springs, frequently break out on the cheese; and it is always soft, tough, and of an insipid taste.

7068. *Whenever the milk is completely coagulated*, the curd is broken, in order to let the serum or whey be separated and taken off. Some break the curd slightly at first, by making cross-scores with a knife or a thin piece of wood, at about one or two inches distance, and intersecting each other at right angles; and these are renewed still more closely after some of the whey has been discharged. But others break the whole curd rather more minutely at once with the skimming dish, the hand, or any thing convenient; but they do not break or churn it, as is done in England. When this last method is pursued, the whey comes off rather too white and rich, or with too much of the cream at first; but it comes most copiously, and it is only for a few minutes at first that the whey is too rich. By the method first mentioned, the whey does not come off so copiously nor so rich at first, as when the curd is more minutely broken.

7069. *When the coagulum has been formed at a proper temperature*, neither too cold nor too hot, breaking the curd minutely, but gently and softly, seems to be most proper: for though the whey is a little too white at first, that is soon over; it comes off abundantly pure in a few minutes after; and it flows more copiously than when the curd is slightly broken at first. The advantage of a speedy discharge of the whey, as it saves time, and prevents the curd from becoming too cold and acquiring any bad taste or flavour (which it often contracts when neglected at that stage of the operation), is an ample compensation for any small quantity of the oily parts that may come off at first breaking.

7070. *But if the milk has been either too cold or too hot when coagulated*, I would recommend breaking the curd as slightly and easily as possible at first: if too hot, the whey naturally comes off copiously, but it is too white, and contains a portion of the butteraceous matter in the curd; and the complete breaking at first adds to that evil, and brings off still more of the oily substance from the curd, to the impoverishment of the cheese. Such quick agitation too tends to render the warm curd still more tough and adhesive. When the milk has been too cold at the time the curd was formed, it will be by far too soft to be minutely broken at first; and when that is done, some of the curd will come off with the whey: in that case the curd should be dealt with as gently as possible.

7071. *After the curd has been broken*, the whey ought to be taken off as speedily as it can be done, and with as little further breaking or handling the curd as possible. It is still necessary, however, to turn it up, cut it with a knife, or break it gently with the hand, in order to facilitate the separation of the whey from the curd.

7072. *When the curd has consolidated a little*, it is cut with the cheese knife, gently at first, and more minutely as it hardens, so as to bring off the whey. When the whey has been mostly extracted, the curd is taken up from the curd-boyn, and being cut into pieces of about two inches in thickness, it is placed into a sort of vat or sieve with many holes; a lid is placed over it, and a slight pressure, say from three to four stones avoirdupoise; and the curd is turned up and cut small every ten or fifteen minutes, and occasionally pressed with the hand so long as it continues to discharge serum. When no more whey can be drawn off by these means, the curd is cut as small as possible with the knife, the proper quantity of salt minutely mixed into it in the curd-boyn, and placed in the chessart within a shift of thin canvass, and put under the press.

7073. *All these operations ought to be carried on with the least possible delay*, and yet without precipitation. The sooner the whey is removed after the coagulation of the milk, so much the better. But if the curd is soft, from being set too cold, it requires more time, and to be more gently dealt with; as otherwise much of the curd and of the fat would go off with the whey. And when the curd has been formed too hot, the same caution is necessary. Precipitation, or handling the curd too roughly, would add to its toughness, and expel still more of the oily matter: and, as has been already mentioned, hot water or whey should be put on the curd when it is soft and cold; and cold water put on when the curd is set too hot.

7074. *After the cheese is put into the press* it remains for the first time about an hour, or less than two hours, till it is taken out, turned upside down in the cheese-vat, and a new cloth put round it every four or six hours till the cheese is completed; which is generally done in the course of a day and a half, two, or at most three days after it was first put under the press.

7075. *The process of salting* is very differently conducted in the Scotch dairies from what it is in England. In Scotland, the salt is minutely mixed into the curd after it has been rendered as dry as possible, and cut very small by means of the cheese-knife, as has been already mentioned. This seems to answer the purpose just as well as the mode pursued in England, to be afterwards described, which is far more troublesome, and must be much more expensive, both in waste of salt, in apparatus, and in labour. The greatest defect I can perceive in the salting in Scotland is, that the salt is generally applied to the cheese merely by guess, whereas it ought to be more carefully regulated. Half an ounce of salt to every English pound of cheese, or at most thirteen ounces to twenty-four pounds English, is a sufficient quantity. Too much salt renders the cheese dry, tough, and hard; and if a sufficient quantity is not given, the cheese will become putrid.

7076. *Cheeses made in Scotland* are never washed or greased with butter, as is done in Cheshire. The Scots cheeses contain the grease internally, and not on the outside.

7077. *When the cheeses in Scotland are ultimately taken from the press*, and which is generally after two or three days from the time they were first placed under it, they are exposed for a week, to the drought and heat of the farmer's kitchen; not to excite sweating, but merely to dry them a little before they are placed in the store, where a small portion of heat or drought is admitted. While they remain in the kitchen, they are turned over three or four times every day; and whenever they begin to harden a little on the outside, they are laid up on the shelves of the store, where they are turned over once every day or two days for a week or so, till they are dry; and twice every week afterwards.

7078. *The store-houses for cheese in Scotland* are in proportion to the size of the dairy, generally a small place adjoining the milk-house, or at the end of the barn or other buildings, where racks are placed, with as many shelves as hold the cheeses made for the season. Where no particular place is prepared, the racks are placed in the barn, which is generally empty during summer; or some lay the cheeses on the floor of a garret over some part of their dwelling-house.

7079. *Wherever the cheeses are stored*, they are not sweated or put into a warm place, but kept cool, in a place in a medium state between damp and dry, without the sun being allowed to shine on them, or yet a great current of air admitted. Too much air, or the rays of the sun, would dry the cheeses too fast, diminish their weight, and make them crack; and heat would make them sweat or perspire, which extracts the fat, and tends to induce heaving. But when they are kept in a temperature nearly similar to that of a barn, the doors of which are not much open, and but a moderate current of air admitted, the cheeses are kept in proper shape, neither so dry as to rend their skins, nor so damp as to render them mouldy on the outside, and no partial fermentation is excited, but the cheese preserved sound and good.

7080. *On the comparative taste* of the Scots and English cheese it is difficult to offer any opinion: there is not only such a diversity in the taste, not only of cheeses made in different dairies, at the different seasons of the year, stages of the cow's milk, state of the weather, and many slighter accidents; but there is also such a diversity in the taste of the consumers, that it is impossible to speak with any degree of precision as to the standard of perfection of the taste of cheese. The taste of mankind as to cheese varies so much that it is found necessary to bring forward both Scots and English cheeses, of different sorts and ages, some sound and others unsound or putrid, and to ask each lady and gentleman at table which they prefer. Do you eat Scots or English? coloured or white? old or new? sound or unsound? &c. The taste of some is so vitiated, as to like best the putrid parts, which abound with animalcula, and touch the olfactory nerves before they reach the mouth; others prefer that which is sound. The Scots cheese is generally less smart, acrid, and pungent in the taste than the English cheese. It is not so high flavoured, owing probably to the inferiority of the pasture and climate, or partly to the mode of manufacturing it. It is milder in the taste, and generally fatter, than the English cheese. A small morsel of English cheese after a good dinner may be better felt in the mouth than the softer and milder cheese of Scotland; but if any considerable quantity is to be eaten, the latter will not be felt so hot and heavy in the stomach as the same quantity of English cheese.

7081. *Gloucester cheese* is in very considerable demand from its mild taste, which suits most palates, especially those of the young and of simple habits: there are two kinds, double and single, the first made from the milk and cream, and the latter with the milk deprived of about half the cream: the latter are of course the least valuable; but as they may be often mistaken for the former, upright dairymen, Marshal observes, impress a heart-shaped stamp upon them to distinguish them from the former. They are made of various sizes, from twenty to seventy, or even eighty pounds weight, but generally from fifty to sixty pounds.

7082. *Green, or sage-cheese*, is made by steeping over night in a proper quantity of milk, two parts of sage, one part of marigold leaves, and a little parsley, after they have been bruised. On the following morning, the *greened* milk is strained off, and mixed with about one third of the whole quantity intended to be run or coagulated. The green and white milks are run separately, the two curds being kept apart until they be ready for vatting: these may be mixed, either evenly and intimately, or irregularly and fancifully, according to the pleasure of the manufacturer. The management is the same as for common cheese. Green cheeses are made in the vale of Gloucester, as also in Wiltshire.

7083. *Lincolnshire cheese* is made by adding the cream of one meal's milk to that which comes immediately from the cow; it is pressed gently two or three times, and is turned for a few days previously to being used. It is chiefly made in spring, but the richest is that made in autumn. It will not keep above three months.

7084. *Norfolk cheese* is made from the whole of the milk and cream; the size is from thirty to fifty pounds; it is generally coloured yellow, and is reckoned a good keeping cheese.

7085. *Soft, or slip-coat cheese*, is made from new milk hot from the cow, and the afterings; and what is required to make one pound of butter, will, in general, make one pound of cheese: this is a small soft rich cheese, which must be used immediately.

7086. *Stilton cheese*, which, from its peculiar richness and flavour, has been called the Parmesan of England, is made in the following manner:—The night's cream is put to the morning's milk with the rennet; when the curd is come, it is not broken as is usual with other cheese, but is taken out whole, and put into a sieve to drain gradually; while draining, it is gently pressed till it becomes firm and dry, when it is placed in a vat, a box made exactly to fit it; as it is so extremely rich, that without this precaution it is apt to bulge out, and break asunder. It is afterwards kept on dry boards, and turned daily, with cloth binders round it, which are tightened as occasion requires. After being taken out of the vat, the cheese is closely bound with cloth till it acquires sufficient firmness to support itself: when these cloths are removed, each cheese is brushed once every day for two or three months, and if the weather be moist, twice every day; the tops and bottoms are treated in a similar manner daily before the cloths are taken off. Stilton cheese derives its name from the town where it is almost exclusively sold; it is made principally in Leicestershire, though there are also many who manufacture it in the counties of Huntingdon, Rutland, and Northampton. Sometimes the cheeses are made in a net, resembling a cabbage net, which gives them the form of an acorn; but these are neither so good nor so richly flavoured as those made in vats, having a thicker coat, and being deficient in that mellowness which causes them to be in such general request. (*Bath Papers*, vol. iii. p. 152, 153.) Stilton cheese is not reckoned to be sufficiently mellow for cutting until it is two years old, and it is not saleable unless it is decayed, blue, and moist. In order to mature them the more rapidly, it is a frequent practice to place the cheeses in buckets, which are covered over with horse-dung. Wine is also reputed to be added to the curd, in order to accelerate the ripening of the cheese.

7087. *Cottenham cheese*, from the town of that name in Cambridgeshire, is a thicker kind of cream cheese than the Stilton: its superior delicacy and flavour are attributed to the fragrant nature of the herbage on the commons on which the cows are pastured, and, according to Professor Martyn, to the prevalence of *Poa aquática* and *praténsis*.

7088. *Suffolk, or skim cheese*, is made of skimmed milk; it forms a part of every ship's stores, not being so much affected by heat as richer cheese, nor so liable to decay in long voyages.

7089. *Wiltshire cheese* is made of new milk coagulated as it comes from the cow: sometimes a small quantity of skimmed milk is added. In some dairies it is manufactured in winter as well as summer; in the former case it is liable to become scurfy and white coated; the last of which defects is frequently concealed by a coat of red paint.

7090. *Of foreign cheeses*, the most common is the *Dutch cheese;* this is prepared much in the same manner as the Cheshire cheese, excepting that muriatic acid is used instead of rennet, which renders it pungent, and preserves it from mites; that of Gouda is preferred.

7091. *Parmesan cheese* (formaggio di grana, cheese used in a granular form,) is made in the Duchy of Parma, and in various places in Lombardy. It was formerly supposed to be made from the milk of goats, but it is merely a skim-milk cheese, the curd hardened by heat, well salted, pressed, and dried, long kept, and rich in flavour from the rich herbage of the meadows of the Po, where the cows are pastured.

7092. *The process*, according to Pryce, (*Bath Papers*, vol. vii.) is as follows:—The evening's milk, after having been skimmed in the morning, and standing till ten o'clock, and the morning's milk skimmed about two hours after it is drawn from the cow, are mixed together. The mixture is then suspended in a copper cauldron over a wooden fire (*fig.* 33.), and frequently stirred till it attains about 82° of Fahrenheit; the rennet is then put in, and the copper being removed from the fire, the coagulation quickly takes place, and the curd is afterwards worked with a stick till it is reduced to a small grain. The whey now occupies the surface, and a part of it being taken out, the cauldron is again turned over the fire, and its contents brought to nearly a boiling heat. A little saffron is now added to impart colour, the whole being all the while well stirred, and the superintendant examining it from time to time with his finger and thumb, to ascertain the exact moment when the curd shall have become sufficiently solid. When this is the case, the cauldron is removed from the fire, and the curd allowed to subside; three fourths of the whey is then drawn off, water poured round the bottom of the cauldron outside to cool it, so as to admit of a cloth being passed below the curd, which is thus brought up and placed in a tub to clear. When drained, it is put into a wooden hoop, and about half a hundred weight laid on it for half an hour; the cloth is then removed, and the cheese being replaced in the hoop is laid on a shelf; here it remains for two or three days, at the end of which, it is sprinkled over with salt; this sprinkling is repeated every second day for about thirty days if it be summer, and for about forty or fifty-five days if it be winter, after which no further attention is required. The best Parmesan cheese is that which has been kept for three or four years, but none is ever carried to market for sale until it has been kept at least six months. A short account of a Parmesan cheese dairy, situated thirteen miles from Milan, is given in Cadell's Journey in Carniola, 8vo, 1818, and quoted in *Farm. Mag.* vol. xxi. p. 161. The process is there carried on in conformity with what is above stated.

7093. *Swiss cheese* is of several varieties, mostly of skimmed or partially skimmed milk, and manufactured like the Parmesan. Its varied and rich flavour is more owing to the herbage of the pastures than the mode of making; and some sorts, as the Gruyère (so called from the bailiwick of that name in the canton of Fribourg), are flavoured by the dried herb of *Melilòtus officinàlis* (*fig.* 43.) in powder. Gruyère cheeses weigh from forty to sixty pounds each, and are packed in casks containing ten cheeses each, and exported to the most distant countries. This cheese requires to be kept in a damp place, and should frequently be washed with white wine, to preserve it from the depredations of insects. Neufchâtel is celebrated for a very fine sort of cheese made there, which, in shape, resembles a wash-hand ball.

7094. *Westphalia cheese* is of the skim-milk kind, and of a different character from any of those hitherto described. The cream is allowed to remain on the milk till the latter is in a sub-acid state; it is then removed, and the milk placed near a fire spontaneously to coagulate. The curd is then put into a coarse bag, and loaded with ponderous stones to express the whey: in this dry state it is rubbed between the hands, and crumbled into an empty clean milk vat, where it remains from three to eight days, according as the cheese is intended to be strong or mild. During this part of the process, which is called mellowing, the curd undergoes the putrid fermentation, and acquires a coat or skin on the top, before it is taken out of the vessel, and kneaded into balls or cylinders, with the addition of a considerable portion of carraways, salt, and butter; or occasionally a small quantity of pounded pepper and cloves. When over-mellowed, a third part of fresh curds, likewise crumbled into small pieces, is superadded, to prevent or correct its putrid tendency. As the balls or cheeses do not exceed three or four ounces each in weight, they soon dry in the open air, and are then fit for use. When nearly dry they are sometimes, for the palate of epicures, suspended in a wood-fire chimney, in a net, for several weeks or months; and both their taste and flavour are said to be remarkably improved, whether kept in a dry air, or subjected to the action of smoke. This sort of cheese M. Hochheimer, who describes it, affirms to be preferable to the Dutch, Swiss, and even Parmesan cheese. It is sometimes to be had in London, but is not very common.

7095. *Blue milk cheese* is made in the neighbourhood of Edinburgh, by Mr. Johnston, of Hill House. It is similar to the Stilton, to which it is said to be not inferior. Mr. Johnston never puts his curd into a cheese press, but into a bag or net, in which it is suspended, and frequently shifted, till it is sufficiently dry and solid. The cheeses are small; about five or six pounds each.

7096. *Potato cheese* is a German manufacture, of which there are three sorts. One of the best is thus prepared: — Select mealy potatoes, and only half dress them in steam; for by bursting their flavour and efficacy are diminished. Peel them, and then grate or beat them into a fine pulp. To three parts of this mass add two parts of sweet curd, knead and mix them, and allow them to stand three days in warm, and four or five days in cold, weather; form into small pieces like the Westphalia cheeses, and dry in the same manner. A still better sort of potato cheese is formed of one part of potatoes and three of the curd of sheep's milk. This sort is said to exceed in taste the best cheese made in Holland, and to possess the additional advantage that it improves with age, and generates no vermin.

7097. *The preparations of milk*, which can neither be included under butter nor cheese, are various, and constitute a class of wholesome luxuries or rural drinks. We shall do little more than enumerate them, and refer for further details to the cookery books.

7098. *Curds and whey* is merely coagulated new milk stirred up, and the curd and whey eaten together, with or without sugar and salt.

7099. *Curds and cream;* here the whey is removed and cream substituted, with or without sugar. The milk coagulated is often previously skimmed.

7100. *Sour cream;* cream allowed to stand in a vat till it becomes sour, when it is eaten with fresh cream and sugar, or new milk and sugar, and is found delicious.

7101. *Corstorphin cream*, so named from a village of that name, two miles from Edinburgh, from which the latter city is supplied with it. The milk of three or four days is put together with the cream, till it begins to get sour and coagulated, when the whey is drawn off and fresh cream added. It is, therefore, simply *sour curd* and *fresh cream*. It is eaten with sugar as a supper dish, and in great repute in the north.

7102. *Devonshire cream* is a term applied in the county of that name, sometimes to sour curd, and sometimes to sour cream; in either case mixed with new milk or fresh cream, and eaten with sugar like the Corstorphin cream.

7103. *Devonshire scalded or clouted cream.* The milk is put into tin or earthen pans, holding about ten or twelve quarts each. The evening's meal is placed the following morning, and the morning's milk is placed in the afternoon, upon a broad iron plate heated by a small furnace, or otherwise over stoves, where, exposed to a gentle fire, they remain until after the whole body of cream is supposed to have formed upon the surface; which being gently removed by the edge of a spoon or ladle, small air bubbles will begin to rise that denote the approach of a boiling heat, when the pans must be removed from off the heated plate or stoves. The cream remains upon the milk in this state until quite cold, when it may be removed into a churn, or, as is more frequently the ease, into an open vessel, and then moved by hand with a stick about a foot long, at the end of which is fixed a sort of peel from four to six inches in diameter, and with which about twelve pounds of butter may be separated from the buttermilk at a time. The butter in both cases being found to separate much more freely, and sooner to coagulate into a mass, than in the ordinary way, when churned from raw cream that may have been several days in gathering, and at the same time will answer a more valuable purpose in preserving, which should be first salted in the usual way, then placed in convenient-sized egg-shaped earthen crocks, and always kept covered with a pickle, made strong enough to float and buoy up about half out of the brine a new-laid egg. This cream, before churning, is the celebrated clouted cream of Devon. Although it would be reasonable to suppose that the scalding the milk must have occasioned the whole of the oily or unctuous matter to form on the surface, still experience shows that this is not the case, and that the scalded skim-milk is much richer and better for the purposes of suckling, and makes far better cheese than the raw skim-milk does. The ordinary produce of milk per day, for the first twenty weeks after calving, is three gallons, and is equal to the producing of one pound and a quarter of butter daily by the scalding process. The scald skim-milk is valued at one penny farthing per quart, either for cheese-making or feeding hogs. The sum of the trials procured to be made on the milk in several parts of this district gives an average of twelve pints of milk to ten ounces of butter (less than ten quarts to a pound of sixteen ounces). When cheese is to be made, great care is taken that the milk is not heated so far as to produce bubbles under the cream. (*Vancouver's Survey of Devon*, p. 214.)

7104. *Clotted cream.* The milk, when drawn from the cow, is suffered to remain in the coolers till it begins to get sour and the whole is coagulated. It is then stirred and the whey drawn off, or the cream (now in clots among the curd) and the curd removed.

7105. *Hatted kitt.* A gallon of sour buttermilk is put in the bottom of the milk-pail, and a quart or more of milk drawn from the cow into it by the milk-maid. The new warm milk, as it mixes with the acid of the sour milk, coagulates, and being lighter, rises to the top and forms a creamy scum or hat over the other; whence the name. This surface stratum is afterwards taken off and eaten with sugar.

7106. *Milk syllabub* is formed in a similar manner over a glass or two of wine, and the whole is then eaten with sugar. Both sorts may be formed by those who have no cow, by warming the sweet or new milk, and squirting it into the wine or sour milk.

7107. *Skim-milk* is milk from which the cream has been removed. When this has been done within twelve or fifteen hours from the time of milking, it is sweet and wholesome, and fit either for being heated or coagulated in order to make cheese, &c., or used as it is with other food; but if allowed to remain twenty or thirty hours, it becomes sour, coagulates spontaneously, the whey separates from the curd; and if it remain a certain period, generally three weeks longer, in a warm temperature, the vinous fermentation takes place, and a wine or a liquor, from which ardent spirit may be distilled, is produced.

7108. *Buttermilk* is that which remains in the churn after the butter has been taken off. When butter has been made from cream alone, it is seldom of much value; but where the whole milk has been churned, and no water poured in during the process, it is a very wholesome cooling beverage. Some prefer it when it has stood a few days and become sour. In England it is chiefly given to pigs; but in Ireland it forms a very common diluter to porridge, potatoes, oat cakes, peas cakes, and other food of the labouring classes, and especially of the farm servants. In the Orkney Islands and other northern parts of Britain, as well as in Ireland, buttermilk is sometimes kept till it undergoes the vinous fermentation, when it is used to procure intoxication.

7109. *Sour milk*, Aiton observes, requires considerable care in the manufacturing, and the use of the thermometer ought never to be omitted. "When the operation is carried on at a low temperature, the milk swells when agitated in the churn, appears of a white colour, throws up air bubbles, and makes, when agitated or churned, a rattling noise. But when it is in proper temperature the milk does not swell or rise in the churn, it is of a straw or cream colour, emits a much softer sound, and does not cast up air bubbles so plentifully as when colder. When milk is either overheated or churned too hastily, the butter is always soft and of a white colour. From two to three hours is a proper time for performing the operation of churning. In the manufacture of sour milk, and in every branch of dairy husbandry, the utmost attention to cleanliness is indispensably necessary. The milk must no doubt become sour, and even coagulate before it is churned; but if that souring is not natural, but brought on by any foulness in the vessels through which the milk passes, or by any sort of admixture, or even by the milk being kept in a damp place, in one too hot or too cold, or even by exposure to an impure atmosphere, the acidity will not be a natural one, nor the taste of the milk or butter agreeable, but acrid and unpalatable. Every vessel through which the milk passes must be as clean, and every part where it is kept before being churned must be as free from dampness, and every species of impurity or bad air, as if it were intended to keep the

milk long sweet for skim-milk cheese. Buttermilk is used more or less by the labouring classes in all parts of Scotland, and in particular in the city of Glasgow; on the authority of the secretary to the Board of Agriculture, it is adjudged to the pigs in England; but in the western counties of Scotland, as well as in Ireland, it is used to a vast extent as human food. It is used as drink, and is certainly far superior to the miserable table-beer generally drank in England. It serves as kitchen to pottage, bread, potatoes, &c.; and when a linen bag like a pillow-slip is filled with it, and hung up till the serum drop, and a small quantity of sweet cream is mixed with what remains in the bag, and a little sugar when the milk is too sour, it forms a dish that might be placed on the table of a peer of the realm.

7110. *The method of making butter and buttermilk* in Holland is somewhat different from the mode in the vicinity of Glasgow. After the milk is cold it is put into a pan or vat, and well stirred with a wooden spoon or ladle two or three times a day, to prevent the cream from separating from the milk; and this sort of stirring or partial churning is continued till the milk becomes so thick and clotted that the ladle or spoon stands erect in the milk: after which it is put into the churn, and beat or churned for one hour or so. Cold water is poured in, to help to collect the butter and separate the milk from it; after which the butter is washed in cold water. By this method the Hollanders imagine they obtain more butter from the milk than they can do any other way. They also say, that both the butter and buttermilk are better when made in that way than when churned as is done in England.

7111. *Whey*, when new and of a pale green colour, forms an agreeable beverage, and with oatmeal makes an excellent gruel or porridge. Left till it gets sour, it undergoes the vinous fermentation as readily as buttermilk; and man, who in every state of civilisation feels the necessity of occasionally dissipating the cares of his mind, when he cannot find tobacco, opium, malt liquors, or ardent spirit, has recourse to sour whey.

Chap. VI.

The Sheep. — O`vis A`ries L.; *Mammàlia Pécora* L, and *Ruminàleæ* Cuv. *Brébis*, Fr.; *Schaf*, Ger.; *Oveja*, Span.; and *Pecora*, Ital.

7112. *The sheep* is an inhabitant of every part of the globe, from Iceland to the regions of the torrid zone. The varieties of form and clothing necessary to fit it for existing in so many climates are of course numerous. In most of these countries it is cultivated for its wool or flesh, and in many for both; but it is most cultivated in Europe, and especially in France, Spain, and Britain. In the latter country its culture has attained an astonishing degree of perfection. Besides the *O. A`ries*, or common sheep, there are three other species; the *O. A'mmon* or Siberian sheep, the Pudu or South American, and the *Strepsíceros* or Cretan sheep. By some these are considered mere varieties. The Cretan and Siberian are cultivated in Hungary and Siberia.

7113. *The common sheep in a wild state* prefer open plains, where they herd together in small flocks, and are in general active, swift, and easily frightened by dogs or men. When completely domesticated, the sheep appears as stupid as it is harmless. It is characterised by Buffon as one of the most timid, imbecile, and contemptible of quadrupeds. When sheep, however, have an extensive range of pasture, and are left in a considerable degree to depend on themselves for food and protection, they exhibit a more decided character. A ram has been seen in these circumstances to attack and beat off a large and formidable dog. Sheep display considerable sagacity in the selection of their food; and in the approach of storms they perceive the indications with accurate precision, and retire for shelter always to the spot which is best able to afford it. The sheep is more subject to disorders than any of the domesticated animals; giddiness, consumption, scab, dropsy, and worms frequently seizing upon and destroying it. That popularly called the rot is the most fatal, and is supposed to arise from the existence of animals called fluke worms, of the genus Fascìola, which inhabit the vessels of the liver. Other parasitic animals attack and injure them, as the hydatids within the skull, producing symptoms called sturdy, turnsick, staggers, &c. Frontal worms, deposited by the sheep fly, in some cases prove very injurious also.

7114. *Of all the domestic animals of Britain*, Brown observes, *sheep are of the greatest consequence*, both to the nation and to the farmer; because they can be reared in situations, and upon soils, where other animals would not live, and in general afford greater profit than can be obtained either from the rearing or feeding of cattle. The very fleece, shorn annually from their backs, is of itself a matter worthy of consideration, affording a partial return not to be obtained from any other kind of stock. Wool has long been a staple commodity of this island, giving bread to thousands who are employed in manufacturing it into innumerable articles for home consumption and foreign exportation. In every point of view, sheep husbandry deserves to be esteemed as a chief branch of rural economy, and claims the utmost attention of agriculturists. For many years back it has been studied with a degree of diligence and assiduity not inferior to its merits; and the result has been, that this branch of rural management has reached a degree of perfection favourable to those who exercised it, and highly advantageous to the public.

Sect. I. *Varieties of Sheep.*

7115. *The varieties of the* O. A`ries, *or common sheep*, dispersed over the world are, according to Linnæus, the hornless, horned, blackfaced, Spanish, many-horned, African, Guinea, broad-tailed, fat-rumped, Bucharian, long-tailed, Cape, bearded, and morvant; to which some add the Siberian sheep, cultivated in Asia, Barbary, and Corsica, and the Cretan sheep, which inhabits the Grecian islands, Hungary, and Austria; by Linnæus considered as species.

7116. *The varieties of British sheep* are so numerous that at first sight it appears almost impossible to reduce them into any regular classes. They may, however, be divided in two ways: first, as to the length of their wool; and secondly, as to the presence or absence of horns. A third classification might be made after the place or districts in which such species are supposed to abound, to be in greatest perfection, or to have originated.

7117. *The long-woolled British sheep* are chiefly the * Teeswater, the * old and * new Leicester, the * Devonshire nots, Exmoor, and the Heath sheep.

7118. *The short-woolled sheep* are chiefly the Dorsetshire, * Hereford or Ryeland, the * South Down, the Norfolk, the * Cheviot, the * Shetland sheep, and the * Merinos.

7119. *The hornless breeds* are those in the above classes marked (*), the others have horns. These breeds, and their subvarieties, may be further arranged according as they are suited to arable or enclosed lands, and to open or mountainous districts.

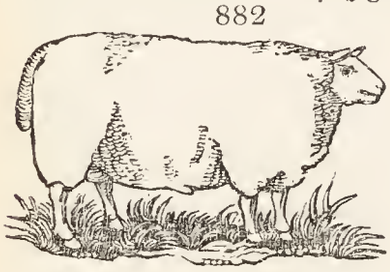
7120. *The sheep best suited to arable land,* an eminent writer observes, in addition to such properties as are common in some degree to all the different breeds, must evidently be distinguished for their quietness and docility; habits which, though gradually acquired and established by means of careful treatment, are more obvious, and may be more certainly depended on in some breeds than in others. These properties are not only valuable for the sake of the fences by which the sheep are confined, but as a proof of the aptitude of the animals to acquire flesh in proportion to the food they consume.

7121. *The long-woolled large breeds are those usually preferred on good grass-lands;* they differ much in form and size, and in their fatting quality as well as in the weight of their fleeces. In some instances, with the Lincolns or old Leicesters in particular, wool seems to be an object paramount even to the carcass; with the breeders of the Leicesters, on the other hand, the carcass has always engaged the greatest attention: but neither form nor fleece, separately, is a legitimate ground of preference; the most valuable sheep being that which returns, for the food it consumes, the greatest marketable value of produce.

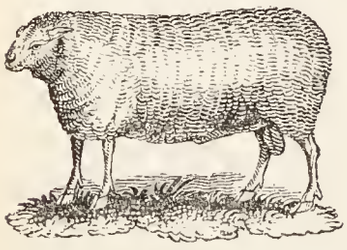
7122. *The Lincolnshire, or old Leicestershire breed,* have no horns, the face is white and the carcass long and thin; the ewes weighing from 14 to 20 lbs., and the three-year-old wethers from 20 to 30 lbs. per quarter. They have thick, rough, white legs, bones large, pelts thick, and wool long, from ten to eighteen inches, weighing from 8 to 14 lbs. per fleece, and covering a slow-feeding, coarse-grained carcass of mutton. This kind of sheep cannot be made fat at an early age except upon the richest land, such as Romney Marsh, and the richest marshes of Lincolnshire; yet the prodigious weight of wool which is shorn from them every year, is an inducement to the occupiers of marsh-lands to give great prices to the breeders for their hogs or yearlings; and though the buyers must keep them two years more, before they get them fit for market, they have three clips of wool in the mean time, which of itself pays them well in those rich marshes. Not only the midland counties, but also Yorkshire, Durham, and Northumberland, can send their long-woolled sheep to market at two years old, fatter in general than Lincolnshire can at three. Yet this breed, and its subvarieties, are spread through many of the English counties.

7123. *The Teeswater sheep* (*fig.* 882.) differ from the Lincolnshire in their wool not being so long and heavy; in standing upon higher, though finer boned legs, supporting a thicker, firmer, heavier carcass, much wider upon their backs and sides; and in affording a fatter and finer grained carcass of mutton: the two-year-old wethers weighing from 25 to 35 lbs. per quarter. Some particular ones, at four years old, have been fed to 55 lbs. and upwards. There is little doubt that the Teeswater sheep were originally bred from the same stock as the Lincolnshire; but, by attending to size rather than to wool, and constantly pursuing that object, they have become a different variety of the same original breed. (*Culley on Live Stock*, p. 122.) The present fashionable breed is considerably smaller than the original species; but they are still considerably larger and fuller of *bone* than the midland breed. They bear an analogy to the short-horned breed of cattle, as those of the midland counties do to the long-horned. They are not so compact, nor so complete in their form, as the Leicestershire sheep; nevertheless, the excellence of their flesh and fatting quality is not doubted, and their wool still remains of a superior staple. For the banks of the Tees, or any other rich fat-land county, they may be singularly excellent.

882



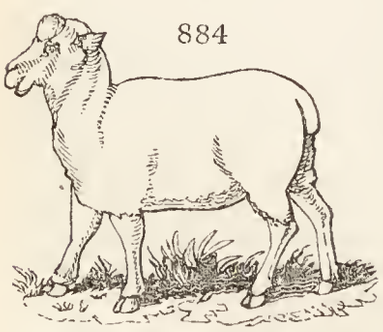
883



7124. *The Dishley, or new Leicester breed* (*fig.* 883.), is distinguished from other long-woolled breeds by their clean heads, straight, broad, flat backs, round barrel-like bodies, very fine small bones, thin pelts, and inclination to make fat at an early age. This last property is most probably owing to the before-specified qualities, and which, from long experience and observation, there is reason to believe extends through every species of domestic animals. The Dishley breed is not only peculiar for its mutton being fat, but also for the fineness of the grain, and superior flavour, above all other large long-woolled sheep, so as to fetch nearly as good a price, in many markets, as the mutton of the small Highland and short-woolled breeds. The weight of ewes, three or four years old, is from 18 to 26 lbs. a quarter, and of wethers, two years old, from 20 to 30 lb. The wool, on an average, is from 6 to 8 lbs. a fleece. (*Culley*, p. 106.)

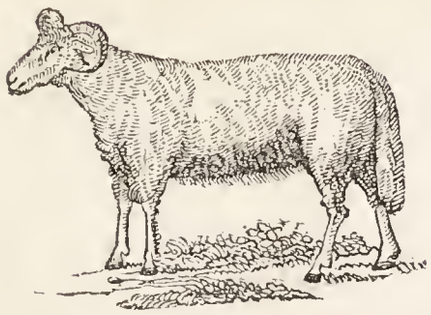
7125. *The Devonshire Nots* (*fig.* 884.) have white faces and legs, thick necks, narrow backs, and backbone high; the sides good, legs short, and the bones large; weight much the same as the Leicesters; wool heavier, but coarser. In the same county, there is a small breed of long-woolled sheep, known by the name of the *Exmoor* sheep, from the place where they are chiefly bred. They are horned, with white faces and legs, and peculiarly delicate in bone, neck, and head; but the form of the carcass is not good, being narrow and flat-sided. The weight of the quarters, and of the fleece, about two thirds that of the former variety.

884



7126. *The shorter-woolled varieties, and such as, from their size and form, seem well suited to hilly and inferior pastures,* are also numerous. Generally speaking, they are too restless for enclosed arable land, on the one hand; and not sufficiently hardy for heathy mountainous districts, on the other. To this class belong the breeds of Dorset, Hereford, Sussex, Norfolk, and Cheviot.

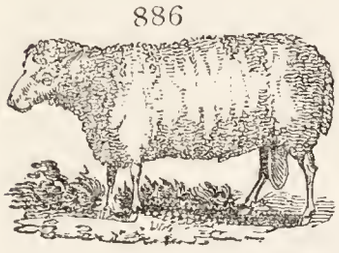
7127. *The Dorsetshire sheep* (*fig.* 885.) are mostly horned, white faced, stand upon high small white legs, and are long and thin in the carcass. The wethers, three years and a half old, weigh from 16 to 20 lbs. a quarter. The wool is fine and short, from 3 to 4 lbs. a fleece. The mutton is fine grained and well flavoured. This breed has the peculiar property of producing lambs at almost any period of the year, even so early as September and October. They are particularly valued for supplying London and other markets with house lamb, which is brought to market by Christmas, or sooner if wanted, and after that a constant and regular supply is kept up all the winter.



7128. *The Wiltshire sheep* are a variety of this breed, which, by attention to size, have got considerably more weight; viz. from 20 to 28 lbs. a quarter. These, in general, have no wool upon their bellies, which gives them a very uncouth appearance. The variations of this breed are spread through many of the southern counties, as well as many in the west, viz. Gloucestershire, Worcestershire, Herefordshire, &c.; though some of them are very different from the Dorsetshire, yet they are, Culley apprehends, only variations of this breed, by crossing with different tups; and which variations continue northward until they are lost amongst those of the Lincolnshire breeds. (*Culley*, p. 131.)

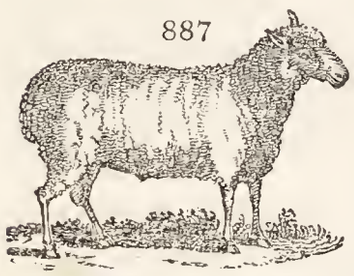
7129. *The Herefordshire breed* (*fig.* 886.) is known by the want of horns, and their having white legs and faces, the wool growing close to their eyes. The carcass is tolerably well formed, weighing from 10 to 18 lbs. a quarter, and bearing very fine short wool, from 1½ to 2½ lbs. a fleece: the mutton is excellent. The store or keeping sheep of this breed are put into cots at night, winter and summer, and in winter foddered in racks with peas-straw, barley-straw, &c., and in very bad weather with hay. These cots are low buildings, quite covered over, and made to contain from one to five hundred sheep, according to the size of the farm or flock kept. The true Herefordshire breed are frequently called *Ryeland* sheep, from the land formerly being thought capable of producing no better grain than rye; but which now yields every kind of grain. A cross between this breed and the merinos was extensively cultivated by the late Dr. Parry, of Bath, an eminent wool-grower, and promoter of agricultural improvement.

886



7130. *The South Down sheep* (*fig.* 887.) are without horns: they have dark or black-grey faces and legs, fine bones, long small necks; are low before, high on the shoulder, and light in the fore quarter; the sides are good, and the loin tolerably broad, back-bone too high, the thigh full, and twist good. The fleece is very short and fine, weighing from 2½ to 3 lbs. The average weight of two years old wethers is about 18 lbs. per quarter, the mutton fine in the grain, and of an excellent flavour. These sheep have been brought to a high state of improvement by Elman, of Glynd, and other intelligent breeders. They prevail in Sussex, on very dry chalky downs, producing short fine herbage.

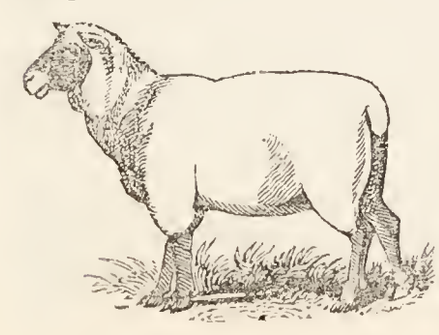
887



7131. *In the Norfolk sheep* the face is black, horns large and spiral; the carcass is very small, long, thin, and weak, with narrow chines, weighing from 16 to 20 lbs. per quarter; and they have very long dark or grey legs, and large bones. The wool is short and fine, from 1¾ to 2 lbs. per fleece. This race have a voracious appetite, and a restless and unquiet disposition, which makes it difficult to keep them in any other than the largest sheep-walks or commons. They prevail most in Norfolk and Suffolk, and seem to have been retained chiefly for the purpose of folding. As fatteners, they are not profitable; but the mutton produced is inferior to none. A three or four year old Norfolk wedder will produce a haunch, which, if kept two or three weeks, will vie with that of any animal excepting a buck.

7132. *The Cheviot breed* are without horns, the head bare and clean, with jaws of a good length, faces and legs white. The body is long, but the fore-quarters generally want depth in the breast, and breadth both there and on the chine; though, in these respects, great improvement has been made of late. They have fine, clean, small-boned legs, well covered with wool to the hough. The weight of the carcass, when fat, is from 12 to 18 lbs. per quarter; their fleece, which is of a medium length and fineness, weighs about 3 lbs. on an average. Though these are the general characters of the pure Cheviot breed, many have grey or dun spots on their faces and legs, especially on the borders of their native districts, where they have intermixed with their black-faced neighbours. On the lower hills, at the extremity of the Cheviot range, they have been frequently crossed with the Leicesters, of which several flocks, originally Cheviot, have now a good deal both of the form and fleece. The best kind of these sheep are certainly a very good mountain stock, where the pasture is mostly green sward, or contains a large portion of that kind of herbage, which is the case of all the hills around Cheviot, where those sheep are bred. Large flocks of them have been sent to the Highlands of Scotland, where they have succeeded so well as to encourage the establishment of new colonies; yet they are by no means so hardy as the heath or black-faced kind, which they have, in many instances, supplanted.

7133. *Of those races of sheep that range over the mountainous districts of Britain*, the most numerous, and the one probably best adapted to such situations, is the *heath* breed, distinguished by their large spiral horns, black faces and legs, fierce wild-looking eyes, and short, firm carcasses, covered with long, open, coarse shagged wool. Their weight is from 10 to 16 lbs. a quarter, and they carry from 3 to 4 lbs. of wool each. They are seldom fed until they are three, four, or five years old, when they fatten well, and give excellent mutton, and highly flavoured gravy. Different varieties of these sheep are to be found in all the western counties of England and Scotland, from Yorkshire northwards, and they want nothing but a fine fleece to render them the most valuable upland sheep in Britain.



7134. *The Herdwick sheep* (*fig.* 886.) are peculiar to that rocky mountainous district at the head of the Duddon and Esk rivers, in the county of Cumberland. They are without horns, have speckled faces and legs, wool short, weighing from 2 to 2½ lbs. per sheep, which, though coarser than that of any of the other short-woolled breeds, is yet much finer than the wool of the heath sheep. The mountains upon which the Herdwicks are bred, and also the stock itself, have, time immemorial, been farmed out to herds, and from this circumstance their name is derived.

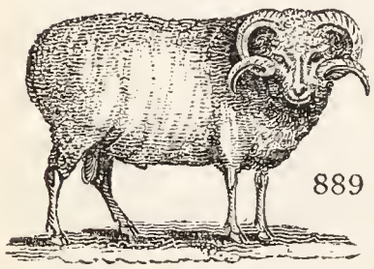
7135. *The dun-faced* breed, said to have been imported into Scotland from Denmark or Norway at a very early period, still exists in most of the counties to the north of the Frith of Forth, though only in very small flocks. Of this ancient race there are now several

varieties, produced by peculiarities of situation, and different modes of management, and by occasional intermixture with other breeds. We may, therefore, distinguish the sheep of the mainland of Scotland from those of the Hebrides, and of the northern islands of Orkney and Zetland.

7136. *The Hebridean sheep* is the smallest animal of its kind. It is of a thin, lank shape, and has usually straight shorn horns. The face and legs are white, the tail very short, and the wool of various colours; sometimes of a bluish grey, brown, or deep russet, and sometimes all these colours meet in the fleece of one animal. Where the pasture and management are favourable, the wool is very fine, resembling in softness that of Shetland; but, in other parts of the same islands, the wool is stunted and coarse, the animal sickly and puny, and frequently carries four, or even six horns. The average weight of this poor breed, even when fat, is only 5 or 5½ lbs. per quarter, or nearly about 20 lbs. per sheep. It is often much less, only amounting to 15 or 16 lbs.; and the price of the animal's carcass, skin and all, is from 10*s.* to 14*s.* Fat wedders have been sold in the Long Island at 7*s.* a head, and ewes at 5*s.* or 6*s.* The quantity of wool which the fleece yields is equally contemptible with the weight of the carcass. It rarely exceeds one pound weight, and is often short of even half that quantity. The quality of the wool is different on different parts of the body; and inattention to separating the fine from the coarse, renders the cloth made in the Hebrides very unequal and precarious in its texture. The average value of a fleece of this aboriginal Hebridean breed is from 8*d.* to 1*s.* sterling. From this account it is plain, that the breed in question has every chance of being speedily extirpated. (*Macdonald's Report of the Hebrides*, p. 447.)

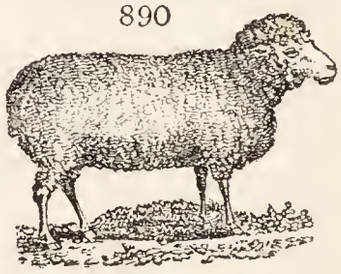
7137. *Of the Zetland sheep* it would appear that there are two varieties, one of which is considered to be the native race, and carries very fine wool; but the number of these is much diminished, and in some places they have been entirely supplanted by foreign breeds; the other variety carries coarse wool above, and soft fine wool below. They have three different successions of wool yearly, two of which resemble long hair more than wool, and are termed by the common people *fors* and *scudda*. When the wool begins to loosen in the roots, which generally happens about the month of February, the hairs, or scudda, spring up; and when the wool is carefully plucked off, the tough hairs continue fast until the new wool grows up about a quarter of an inch in length, then they gradually wear off; and when the new fleece has acquired about two months' growth, the rough hairs, termed *fors*, spring up and keep root until the proper season for pulling it arrives, when it is plucked off along with the wool, and separated from it, at dressing the fleece, by an operation called forsing. The scudda remains upon the skin of the animal as if it were a thick coat, a fence against the inclemency of the seasons, which provident nature has furnished for supplying the want of the fleece. The wool is of various colours; the silver grey is thought to be the finest, but the black, the white, the *mourat*, or brown, is very little inferior, though the pure white is certainly the most valuable for all the finer purposes in which combing wool can be used. (*Sir John Sinclair on the different Breeds of Sheep, &c. Appendix, No.* 4. *Account of the Shetland Sheep, by Thomas Johnston*, p. 79.) In the northern part of Kincardineshire, as well as in most other of the northern counties, there is still a remnant of this ancient race, distinguished by the yellow colour of the face and legs, and by the dishevelled texture of the fleece, which consists in part of coarse, and in part of remarkably fine wool. Their average weight in that county is from seven to nine pounds a quarter, and the mutton is remarkably delicate and highly flavoured. (*Kincardineshire Report*, p. 385. *Sup. E Brit.* art. *Agr.* 176.) The Highland Society of Scotland have offered premiums for the improvement of this breed, and some experiments are now in progress. See vol. vi. of their *Transactions;* and for a particular account of the breed itself, and its management, see Shirreff's *Survey of Orkney and Shetland.*

7138. *The Spanish, or Merino breed*, bears the finest wool of the sheep species; the males (*fig.* 889.) usually have horns of a middle size, but the females (*fig.* 890.) are frequently without horns; the faces and legs are white, the legs rather long, but the bones fine. The average weight per quarter of a tolerably fat ram is about seventeen pounds, and that of ewes about eleven pounds.



889

890



7139. *The shape* of this race is far from being perfect, according to the ideas of English breeders, with whom symmetry of proportion constitutes a principal criterion of excellence. The throatiness, or pendulous skin beneath the throat, which is usually accompanied with a sinking or hollow in the neck, presents a most offensive appearance, though it is much esteemed in Spain, as denoting both a tendency to fine wool, and a heavy fleece. Yet the Spanish sheep are level on the back, and behind the shoulders; and Lord Somerville has proved that there is no reason to conclude that deformity in shape is, in any degree, necessary to the production of fine wool.

7140. *The fleece of the Merino sheep weighs*, upon an average, from three to five pounds; in colour, it is unlike that of any English breed: there is on the surface of the best Spanish fleeces a dark brown tinge, approaching almost to a black, which is formed by dust adhering to the greasy properties of its pile; and the contrast between this tinge and the rich white colour below, as well as that rosy hue of the skin which denotes high proof, at first sight excites much surprise. The harder the fleece is, the more it resists any external pressure of the hand, the more close and fine will be the wool: here and there, indeed, a fine pile may be found in an open fleece, though this occurs but rarely. Nothing, however, has tended to render the Merino sheep more unsightly to the English eye than the large tuft of wool which covers the head: it is of a very inferior quality, and classes with what is produced on the hind legs; on which account it does not sort with any of the three qualities, viz. *rafinos*, or prime; *finos*, or second best; and *tercenos*, the inferior sort; and, consequently, is never exported from Spain.

7141. *Merinos were first brought into England in* 1788, but did not excite much interest before his Majesty's sales, which began in 1804: the desirable object of spreading them widely over the country, and subjecting them to the experiments of the most eminent professional breeders, has been greatly promoted by the institution of the Merino Society in 1811, to which belonged some of the greatest landholders, and the most eminent breeders in the kingdom. For some years past, this breed has been on the decline. (*Sup. E. Brit.* art. *Agr.*) A considerable importation was made by Colonel Downie, of Paisley, which distributed the breed throughout different parts of Scotland. See the *Renfrewshire Survey.* It is not understood that they have answered the expectations that were once formed of them; and I am not aware that there are any flocks in the possession of rent-paying farmers. The only successful experiment in Scotland seems to have been that of the late Mr. Malcolm Laing, in the Orkney Islands; and it is not the pure race, but crosses into other breeds. See the *General Report of Scotland*, vol. iii.

Sect. II. *Criteria of Properties in Sheep.*

7142. *The criteria of an excellent ram*, as given by Culley, combines qualities which ought to be found in every breed of sheep cultivated for its flesh and wool. His head should be fine and small; his nostrils wide and expanded; his eyes prominent, and rather bold or daring; ears thin; his collar full from his breast and shoulders, but tapering gradually all the way to where the neck and head join, which should be very

fine and graceful, being perfectly free from any coarse leather hanging down; the shoulders broad and full, which must, at the same time, join so easy to the collar forward and chine backward as to leave not the least hollow in either place; the mutton upon his arm or fore-thigh must come quite to the knee; his legs upright, with a clean fine bone, being equally clear from superfluous skin and coarse hairy wool, from the knee and hough downwards; the breast broad and well formed, which will keep his fore-legs at a proper wideness; his girth or chest full and deep, and instead of a hollow behind the shoulders, that part, by some called the fore-flank, should be quite full; the back and loins broad, flat, and straight, from which the ribs must rise with a fine circular arch; his belly straight, the quarters long and full, with the mutton quite down to the hough, which should neither stand in nor out; his twist, or junction at the inside of the thighs, deep, wide, and full, which, with the broad breast, will keep his four legs open and upright; the whole body covered with a thin pelt, and that with fine, bright, soft wool.

7143. *The criteria* of a sound healthy sheep are, a rather wild or lively briskness; a brilliant clearness in the eye; a florid ruddy colour on the inside of the eyelids, and what are termed the eyestrings, as well as in the gums; a fastness in the teeth; a sweet fragrance in the breath; a dryness of the nose and eyes; breathing easy and regular; a coolness in the feet; dung properly formed; coat or fleece firmly attached to the skin, and unbroken; the skin exhibiting a florid red appearance, especially upon the brisket. Where there are discharges from the nose and eyes, it indicates their having taken cold, and should be attended to by putting them in dry sheltered situations. This is a necessary precaution also in bringing them from one situation to another while on the road.

7144. *The criteria of the age of sheep* is the state of their teeth; by their having, in their second year, two broad teeth; in their third year, four broad teeth; in their fourth year, six broad teeth; and in their fifth year, eight broad teeth before. After which, none can tell how old a sheep is while their teeth remain, except by their being worn down. About the end of one year, rams, wethers, and all young sheep, lose the two fore-teeth of the lower jaw; and they are known to want the incisive teeth in the upper jaw. At eighteen months, the two teeth joining to the former also fall out; and at three years, being all replaced, they are even and pretty white. But as these animals advance in age, the teeth become loose, blunt, and afterwards black. The age of all horned sheep may also be known by their horns, which show themselves in their very first year, and often at the birth, and continue to grow a ring annually to the last period of their lives.

7145. *The different ages and conditions of sheep* have different names in different districts. After being weaned, the ram, or wedder lamb, is sometimes termed hog, hoggit, or tag, during the whole of the first year; and the female lamb, an ewe, or gimmer lamb, and ewe tag. The second year the wedder has the title of shear hog, or a two-toothed tag; and the ewe is called a thaive, or two-toothed ewe. In the third year, a shear hog, or four-toothed wedder; and a four-toothed ewe or thaive. The fourth year, a six-toothed wedder, or ewe; and in some places, from the time of lambing till that of salving, the males are called tup-lambs; and from that period, till the time of shearing, tup-hogs, and ever afterwards, tups: the females in the same order being termed, ewe-lambs, ewe-hogs, gimmers, young ewes, old ewes. The gelded male lambs, castrated wedder lambs, wedder hogs, dummonds, wedders. Crones also signify old ewes; and there are several other provincial names, which are explained in their proper places.

Sect. III. *Breeding of Sheep.*

7146. *In the breeding of sheep* a greater degree of perfection has been attained than in any other live stock; and in this branch, in particular, the breeders of England stand higher than those of any other country.

7147. *Bakewell*, by careful selection during several generations, raised his stock to a state of excellence, in regard to fattening at an early age with a moderate consumption of food, and with the smallest proportion of offal, which has been with difficulty equalled, certainly has not been exceeded, by the most skilful of his successors. It is a striking instance of the division of labour and skill, that there are breeders who devote themselves entirely to the breeding of rams for the purpose of letting out on hire. This practice originated in Lincolnshire, where, in the early part of the last century, rams were let out at from 10*s.* to 20*s.* each; but so great has been the improvement since that period, that they are now let out to common graziers at from 1 to 10 guineas, and to breeders of rams at from 20*l.* to 200 guineas. The breeding rams are shown for hire at certain times and places during the summer, where every one may select such as promise to maintain or improve the particular state of his flock, and at such prices as his means and experience may justify. Two or more individuals frequently join together in the hire of one ram, to which they put the best of their ewes, for the purpose of obtaining superior males for the future service of the rest of their flocks; and in particular cases, when the owner of the ram does not choose to part with him, even for a season, ewes are sent to him to be covered at a certain price per head; superior animals of this class being very seldom sold altogether. Much as this mode of doing business has been reprobated as a monopoly, and much as there sometimes may be of deception in *making up* rams for these shows, all intelligent practical men must agree, that there can be no better method of remunerating eminent breeders, and of spreading their improvements most widely, in the shortest period, and at the least possible expense. A single ram thus communicates its valuable properties to a number of flocks, often in distant parts of the country, without distracting the attention of ordinary breeders from their other pursuits.

7148. *The two methods of breeding* common to all animals are also adopted in breeding sheep. Breeding from different families of the same race, commonly called breeding *in and in;* and breeding from different races, generally called *cross breeding*. Bakewell, according to Sir J. Sebright (*On improving the Breeds of domestic Animals, &c.*), effected his improvements by breeding from the same family; but according to Hunt, who has written an able answer to Sir J. Sebright's pamphlet (*A Letter, &c. to Sir J. Sebright, &c.*), he bred from different relationships of the same family; it being out of his power to breed from different families of a race which he was at the time employed in forming, and cross breeding he did not approve of. Breeding *in and in* is so repugnant to human feeling, that it is difficult to avoid considering it an unnatural practice; for it does not follow that a flock of sheep in a wild state must necessarily breed in the nearest relationships, as father and daughter, &c.; on the contrary, it is more probable that remoter relationships would be chiefly bred from, as these must necessarily be much more numerous. In a flock of sheep, or a herd of savage men, springing each from one pair, every parent must necessarily have many more cousins, and cousins many times removed, than he can have mothers or daughters.

7149. *Breeding from different families of the same race* is the more general and approved practice. When a number of families of any breed have been for some time established in a variety of situations, and have had some slight shades of difference impressed upon them, by the influence of different soils and treatment, it is found advantageous to interchange the males, for the purpose of strengthening the excellencies, or remedying the defects of each family. Of this advantage Bakewell could not avail himself; but it has been very generally attended to by his successors. Culley, for many years, continued to hire his rams from Bakewell, at the very time that other breeders were paying a liberal price for the use of his own; and the very same practice is followed by the most skilful breeders at present. In large concerns, two or more streams of blood may be kept distinct for several generations, and occasionally intermixed with the happiest effects, by a judicious breeder, without having recourse to other flocks. (*Sup. E. Brit.* art. *Agr.* 177.)

7150. *In breeding from two distinct races*, the object is to acquire new properties or remove defects. The mode of effecting this by cross breeding is attended with greater difficulties than in breeding from the same race. The very distinction of breeds implies a considerable difference among animals in several respects; and although the desirable property be obtained, it may be accompanied by such others as are by no means advantageous to a race, destined to occupy a situation which had excluded that property from one of its parents. To cross any mountain breed with Leicester rams, for example, with a view to obtain a propensity to fatten at an early age, would be attended with an enlargement of size, which the mountain pasture could not support; and the progeny would be a mongrel race, not suited to the pastures of either of the present breeds. If the object be to obtain an enlargement of size, as well as a propensity to fatten, as is the case when Cheviot ewes are crossed with Leicester rams, the progeny will not prosper on the hilly pastures of their dams, and will be equally unprofitable on the better pastures of their sires. But the offspring of this cross succeeds well on those intermediate situations on the skirts of the Cheviot hills, where, though the summer pasture is not rich, there is a portion of lowland for producing clover and turnips. (*Supp. Encyc. Brit.* art. *Agr. &c.*)

7151. *As general rules in crossing breeds*, it is to be noticed that in every case where the enlargement of the carcass is the object, the cross breed must be better fed than its smaller parent. The size of the parents should also be but little disproportioned at first; and when some increase has been produced, one or more crosses afterwards may raise the breed to the required size. With these precautions, there is little reason to fear disappointment, provided both parents are well formed. (*General Report of Scotland*, vol. iii. p. 14. 18.)

7152. *The most advantageous and proper age for ewes taking the ram* in the different breeds has not been fully shown; but from a year to a year and a half old may be sufficient, according to the forwardness of the breed and the goodness of the keep. Some judge of this by the production of *broad* or sheep's teeth. It should not be done while too young in any case. Ewes commonly bring their first lamb when two years old; in the hilly and mountainous districts of Scotland commonly not for a year after. Of course, they are usually eighteen or nineteen months old when they take the ram, throughout all the lowland districts.

7153. *In regard to the season of putting the rams to the ewes*, it must be directed by the period at which the fall of the lambs may be most desirable, which must depend on the nature of the keep which the particular situation affords; but the most usual time is about the beginning of October; except in the Dorsetshire ewes, where the intention is suckling for house-lamb, in which case it should be much earlier, in order that the lambs may be sufficiently forward. But, by being kept very well, any of the breeds will take the ram at a much earlier period. Where the rams are young, the number of ewes should seldom exceed sixty for each ram; but in older rams a greater number may be admitted without inconvenience, as from one to two hundred; but letting them have too many should be cautiously avoided, as by such means the farmer may sustain great loss in the number of the lambs.

7154. *With respect to the period of gestation*, the ewe goes with lamb about the space of five months, consequently the most common lambing season is March, or the early part of April; but "it has been observed that in many of the more southern districts, where sheep-husbandry is carried on to a considerable extent, some parts of the ewe-stock are put to the rams at much earlier periods, so as to lamb a month or six weeks sooner; a practice which is attended with much profit and advantage in many situations where early grass-lamb is in great demand. It is usual for the rams to remain with the ewes for a month or six weeks, and in some cases longer, in order to complete the business of impregnation, which in some districts is ascertained by smearing the fore-bows of the rams with some colouring substance."

7155. *The practice of turning a number of rams among the flocks* formerly adopted is highly exceptionable, as tending to prevent the main object and injure the rams. A better way is to let each ram have a proper number of ewes, and with very choice stock to keep the ram in an enclosed small pasture, turning a few ewes to him, and as they are served replacing them with others. By this means there is more certainty, and more ewes may be impregnated. In such sort of fine stock, it is likewise of great utility to keep the rams during this season in a high manner. In this view a little oats in the straw, or a mixture of barley and pea meal, are excellent. Where ewes are backward in taking the ram, the best means to be employed are those of good stimulating keep. The rams should always be continued with the ewes a sufficient length of time.

7156. *The ewe will breed twice a year*, if it be made a point to produce such an effect by attention and high keep; since she will receive the male indifferently at any season, and, like the rabbit, very soon after bringing forth. Lisle gives an instance of three of his ewes, well kept, lambing at Christmas, fattening off their lambs at Lady-day, and producing lambs again the first week in June. It seems they stole the ram immediately after lambing, but brought the second time only single lambs, although of a breed that generally produces twins. There is no doubt but the sheep would produce young thrice a year were the bad practice resorted to, which has been so currently recommended with the rabbit, of allowing the male immediately after parturition; the ready way to render both the female and her progeny worthless. Could the lambs be advantageously weaned at two months, sufficient time would, he conceives, remain for the ewe to bring forth twice within the year. For example, suppose the young ewe tupped in August, the lamb would be dropped in the middle of January, and might be weaned in mid March, the ewe again receiving the ram on the turn of the milk, like the sow, perhaps in or before April, she would then bring forth within the twelve months or in August. This plan would, continues Lisle, at least injure the dam infinitely less than suckling during gestation.

7157. *When ewes are in lamb they should be kept in the pastures, and as free from disturbance as possible*, being carefully attended to in order to prevent accidents which are liable to take place at this time, such as those of their being cast in the furrows, &c. Where any of the ewes slip their lambs, it is advised by Banister that they should be immediately removed from the flock. They also require, under these circumstances, to be kept as well as the nature of the farm will admit, in order that there may be less loss at lambing-time from the ewes being stronger, and the lambs more healthy and better capable of contending with the state of the season at which they may be dropped. The shepherd should at this period be particularly careful and attentive to afford his assistance where it may be necessary. He should constantly have regard to the suckling of the lambs, and to see that the udders of the ewes are not diseased. His attendance will often be required in the night as well as the day. At this season covered sheep-folds are often of very great advantage in saving and protecting both ewes and their lambs.

7158. *In respect to the number of lambs* at a birth it is remarked by Lawrence, that the ewe brings most commonly one, next in degree of frequency two, rarely from three to five lambs at a birth. This property of double birth is, he says, in some instances specific; the Dorset sheep usually yeaning twins, and the large polled Belgic sheep, with their descendants our Teeswater, doing the same, and producing occasionally more at a birth. Other breeds bring twins in the proportion of one third of the flock, which is supposed to depend considerably on good keep. A certain number of ewes per centum prove barren annually: the cause very rarely natural defect; sometimes over-fatness, a morbid state of body from poverty or neglect of the ram; in other words, want of system in the shepherd.

7159. *The keep of sheep after lambing*, where rich pastures or other kinds of grass lands cannot be reserved, should consist of turnips or other kinds of green food provided for the purpose, and given them in a suitable manner; but where it can be done, it is always better to leave this sort of food untouched till about the period of lambing, when it should be regularly supplied in proportion to the necessity there may be for it. The ewes also demand at this time much care to see that they are put upon a dry sheltered pasture, free from disturbance, and that neither they nor their lambs sustain injury from the too great

severity of the season. Whenever this is the case, they should be carefully removed into a proper degree of warmth and shelter till perfectly restored. It is likewise a necessary as well as useful practice, as they lamb down, to take them and their lambs away from the common stock, putting them into a piece of turnips or fresh dry pasture where there is shelter when necessary, as by this means much fewer lambs would be lost than would otherwise be the case. It is also found, that by a proper supply of turnips or other similar green food at this period, the milk of the ewes is much increased, and the growth of the lambs greatly promoted; which is of much future importance, as when they are stinted at this early period of their existence, they never turn out so well afterwards for the farmer. With the green and root crops and preserved after-grass, hay, straw, corn, and oil-cake are in some cases made use of in the winter support of sheep stock. With turnips, where the soil is not sufficiently dry to admit the sheep, it is the practice to draw them and convey them to a sound firm pasture, that the ewes may be baited upon them once or twice in the day as there may be occasion, care being taken that they are eaten up clean, as the circumstance of their being thus eaten may serve as a guide to the farmer for the supply that may be daily necessary. In this way this sort of food will be consumed with the greatest economy. Where the land is perfectly dry, and the intention is to manure it for a grain crop, eating the turnips on the land, by means of portions hurdled off as wanted, is a good practice. With this sort of food, especially where it produces scouring in the ewes, green rouen hay, cut straw, or peas haulm should constantly be given, and also with rape, &c.

7160. *The castrating lambs* may be performed any time from the age of a fortnight or three weeks to that of a month or six weeks, and in some districts it is deferred to a considerably later period. It is, however, the safest method to have it executed early, as there is less danger of too much inflammation taking place. But in all cases the lambs should be in a healthy state when it is done, as under any other circumstances they are liable to be destroyed by it. The operation is usually performed by the shepherd, by opening the scrotum or cod and drawing out the testicles with the spermatic cord. This he often does with his teeth in the young state of the animal; but where the operation is performed at a later period, it is usual to have recourse to the knife, the arteries being taken up and secured by means of ligatures, or the searing iron. The business, if possible, should be done in fine weather, when not too warm, and the gelded lambs be kept in a dry, sheltered, quiet situation for a few days, until the inflammation is gone off. If it should happen to be wet at the time, it may be advisable to have them under some sort of shelter where they can have room to move freely about.

7161. *The weaning of lambs* should be effected when they are three or four months old, as about July; but it is done more early in some districts than in others. A proper reserve of some fresh pasture grass, where there may be a good bite for the lambs to feed upon, should be had recourse to, as it is of much consequence that an ample provision of this sort be had, in order that the growth of this young stock may not suffer any check on being taken from the mother. Where they have been continued so long as to graze with the dams, little check will be sustained in their separation if turned upon such good feed. Some advise clover in blossom as the most forcing sort of food in this intention, and with others saintfoin rouen is highly valued for the same purpose. When good feed is not provided of some of these kinds, the lambs soon decline in flesh, or, in the technical language of the flock, are said to pitch; and when once this happens they never afterwards thrive so well, however good the management may be. With regard to the ewes, they should be removed to such distant pastures or other places as that they may not be heard by the lambs, which would cause them to be disturbed in their feeding; and where the ewes sustain any inconvenience from their milk, as by their udders swelling, it should be drawn once or twice, as by this means bad consequences may be prevented: and as soon as the lambs have been removed, the ewes are returned upon the pastures destined for their summer support. There is, however, one caution to be attended to in first turning the lambs upon rich keep, which is that of letting them be in some degree satisfied with food previously, that they may not be surfeited by too quick and full feeding, and *heave* or *hove* as it is termed; keeping them gently moving about the field has also been advised in this intention. In some places, where the lands are of the more poor kind, it is a custom to send the lambs to the more rich vale or marsh districts, to be brought forward in condition or fattened. In those cases where the lands of the male kind are reared on the home lands as wethers, they are usually restored to the flock in the latter end of the year, but which is not by any means a good practice, as they often suffer for want of proper keep in the winter, and lose what they had previously gained in growth and condition. A practice the reverse of this has long been in use among the store-masters of Scotland. They send their lambs, as soon as weaned, to some rough coarse pasture, often at a distance of several miles, where they remain for six or eight weeks. The opinion is, that this renders them more hardy. Some grounds are occupied chiefly for this purpose, being kept for summering lambs, as it is called, the owner of the lamb paying a penny or three halfpence a week for each. The practice, it is believed, is not now so common as it has been.

Sect. IV. *Rearing and general Management of Sheep.*

7162. *In the practice of sheep husbandry different systems are had recourse to*, according to the extent and nature of the farms on which they are kept, and the methods of farming that are adopted on them; but under all circumstances the best sheep-masters constantly endeavour to preserve them in as good condition as possible at all seasons.

7163. *With the pasture kinds* of sheep this is particularly the case; and with the view of accomplishing it in the most complete manner, it is useful to divide them into different parcels or lots in respect to their ages and sorts, as by that practice they may be kept with greater convenience and benefit than in large flocks together under a mixture of different kinds; as in this way there is not only less waste of food, but the animals thrive better, and the pastures are fed with much more ease. The advantage of this management has been fully experienced in many of the northern districts, where they usually divide the sheep stock into lambs, yearlings, wethers, and breeding ewes: and in this method it appears not improbable that a much larger proportion of stock may be kept, and the sheep be preserved in a more healthy condition. With a breeding stock the sheep-master must act according to his circumstances, situation, and capital which he possesses, either selling the lambs to go to keep, fattening them for grass lamb, suckling them for house lamb, or keeping them on to be grazed and sold as store or fat wethers; the ewes being sold lean or in store condition, or fattened, as circumstances, profit, and convenience may point out.

7164. *Another practice*, but which requires much capital as well as knowledge, experience, and attention, is that of breeding and fattening off all lambs, both wethers and ewes, especially where markets for their sale when fat are conveniently situated; or this system may be partially acted upon, varying the plan according to capital, circumstances, and the nature of the times. In which case, whenever store stock become extravagantly high, it is mostly a good way to sell.

7165. *The sheep farming of the arable or low warm districts* of the kingdom consequently differs in various particulars from that of the hilly and mountainous districts; we shall, therefore, first give a general view of the sheep management of arable lands, and next of mountainous districts.

Subsect. 1. *Rearing and Management of Sheep on rich grass and arable Lands.*

7166. *The most general sheep husbandry* on rich lands, or where turnips and other green food is raised for winter consumption, is to combine the breeding and feeding branches, leaning to each according to the returns of profit.

7167. *A method very common among arable farmers*, and which is attended with the least trouble and hazard, is that of purchasing a store flock, as lambs, wethers, and what are termed crones, or old ewes; some of the last sort often proving with lamb, may be fattened off with them to good account. It is likewise often the case that ewes are disposed of in lamb, or with lambs by their sides, in what are termed couples, in which circumstances it is frequently a good practice to make annual purchases of them, in order to the fattening of both, and selling them in that state within the year. In the purchasing of sheep, which is often done from very distant fairs and markets, much care and circumspection is necessary, whatever the sort or intention with which they are bought may be. In these cases much advantage, especially when at a considerable distance, may be derived by employing a salesman on the spot.

7168. *The treatment of the lambs* is the first consideration in the mixed sheep husbandry.

7169. *Lambs are either suckled or fattened on grass*, or sold in autumn as lean stock. With regard to those that have been suckled or fattened in the house, much attention is required to have them early, to their being well, regularly, and very cleanly kept and suckled, as well as to the ewes being of the right sort, and the best milkers that can be provided, and to their being fully supplied with food of the most nourishing and succulent kinds. Their tails and udders should have the wool well clipped away from them, in order that they may be preserved in a perfectly clean state. The lambs also require, especially towards the close of their fattening, to have regular supplies of barley, wheat, and peas-meal, ground together in combination with fine green rouen hay. When these have been sold off, the lambs which have been fattened on the best grass land will be ready to succeed them at the markets, in the spring and summer months, and these will be followed by the sale of the store lambs, at the different autumnal fairs.

7170. *The selection or setting of the lamb-stock* is the first business of sheep management after the lambs have been weaned.

7171. *It is generally performed in the month of July or August*, at which period the fairs for the sale of lambs mostly take place. And as at this time the whole are collected together for drawing into different lots, it is a very suitable period for selecting or choosing those that are to supply such deficiencies in the breeding flocks. In his *Calendar of Husbandry*, Young has remarked, that in making this selection the farmer or his shepherd usually (whatever the breed may be) rejects all that manifest any departure from certain signs of the true breed: thus, in a Norfolk flock, a white leg, and a face not of a hue sufficiently dark, would be excluded, however well formed; in the same manner a white face on the South Downs; in Wiltshire, a black face would be an exclusion, or a horn that does not fall back; in Dorsetshire, a horn that does not project, &c.

7172. *The selection of the grown stock* generally takes place after the lambs are weaned, or, at all events, before tupping season, though wethers may be drawn out of the flock at any time. A certain number of old ewes or crones are removed every year, and these as well as the wethers are fed off for the butcher, either on grass, artificial herbage, or roots, according to the situation and circumstances of the farm, and season of the year.

7173. *The shearing of sheep* is an annual operation, which includes several preparatory measures and after-processes. These are, washing, separation, catching, clipping, marking, and tail-cutting.

7174. *The proper time for clipping or shearing sheep* must be directed by the state of the weather and the climate in the particular district, as by this means the danger of injury by cold from depriving the sheep of their coats at too early a season, and from heat by permitting them to continue on them too long, may be avoided in the best manner: but another circumstance that should likewise be attended to in this business, is that of the wool being fully grown or at the state of maturity; as where the clipping precedes that period, it is said in the *Annals of Agriculture* to be weak and scarcely capable of being spun, and if protracted later, it is yellow, felted, and of an imperfect nature. It has been stated, that for the more warm sheltered situations in the southern parts of the kingdom, the beginning or middle of June, when the weather is fine, may be in general the most proper; but in the more exposed districts in the northern parts of the island, the middle or latter end of the same month may be more suitable, provided the season be favourable. But with the fattening sheep in the enclosures, it will mostly be necessary to perform the work at an earlier period in every situation, as the great increase of heat from the setting in of the summer weather, added to the warmth of the fleece, becomes very oppressive and injurious to them in their feeding. There never can be any difficulty in ascertaining the proper time for shearing, because the separation of the old wool from the new is always distinctly marked in a thriving sheep; and this happens earlier or later according to the age and condition of the animal. Hence, from the beginning of May, or earlier, till the first week of July, shearing goes on in different districts; beginning with the fat Leicester wedders, and ending with the small nursing ewes of the Highland districts. From the middle of May to the middle of June is the busiest period.

7175. *Sheep-shearing in Romney Marsh* commences about midsummer, and finishes about the middle of July. Those who shear first think they escape the effects of the fly, and those that shear late apprehend they gain half a pound weight in every fleece, by the increased perspiration of the sheep. In early shearing, the wool has not the condition which it afterwards acquires; but the hot weather occasions a good deal of trouble in detecting the fly. The lambs that are sold in Smithfield market are, we believe, seldom or ever shorn. All over the north of England, and throughout Scotland, lambs are never shorn. They lose their first fleece when about fifteen months old.

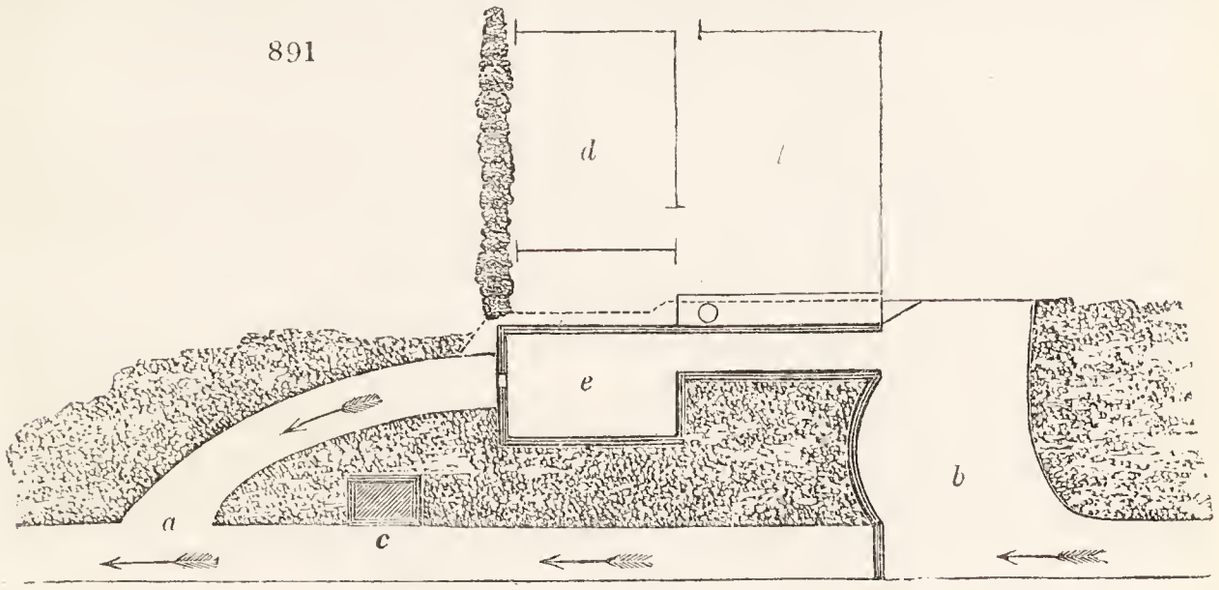
7176. *Clipping off the coarse soiled wool* about the thighs and docks, some weeks before the usual time of washing and clipping the sheep, is an excellent practice; as by this means the sheep are kept clean and cool when the season is hot, and with ewes the udders are prevented from becoming sore.

7177. *In separating for the purpose of washing*, the flock is brought to the side of the washing-pool, and there lambs and sheep of different kinds, fit to be washed, are put into separate fields; and such lambs as are too young to be clipped are not washed, but confined in a fold or enclosure of any kind, at such a distance from the washing place as that they may not disturb their mothers by their bleating. The object of washing is simply

to free the fleece from dust and dirt of various kinds. In Devonshire and Spain, the short-woolled sheep are not washed.

7178. *In performing the operation of washing*, it was formerly the method, and it still exists in the north, to have the washers standing up to the breast in the water; but from the inconvenience and danger of it, the men requiring a large supply of spirituous liquors, and being liable to be attacked with colds, rheumatisms, and other diseases, as well as being apt to despatch the work with too much expedition, so as to leave the wool insufficiently clean, it has been proposed by Young, in his *Calendar*, to rail off a portion of the water in a stream or pond (*fig.* 891.), for the sheep to walk into by a sloping mouth at one end (*a*),

891



and to walk out by another at the other end (*b*), with a depth sufficient at one part for them to swim; and to pave the whole: the breadth need not be more than six or seven feet. At one spot on each side of this passage, where the depth is just sufficient for the water to flow over the sheep's back, a cask or box (*e*), water tight, should be fixed, for a man to stand in dry; the sheep being in the water between them, they wash in perfection, and pushing them on, they swim through the deep part, and walk out at the other mouth, where a clean pen (*d*), or a very clean dry pasture, is ready to receive them; of course there is a bridge railway to the tubs, and a pen at the first mouth of the water (*e*), whence the sheep are turned into it, where they may be soaking for a few minutes before being driven to the washers. But other more cheap contrivances may be provided, where there is clean water at hand for the purposes.

7179. *After sheep are washed*, they should on no account be driven on dry or dusty roads; but should have a clean hard pasture for a few days, until they are perfectly dry and in a proper condition to be shorn.

7180. *The common method of catching the sheep*, in order to lay it on its back to be shorn, is by the hinder leg, drawing the animal backward with a crook (*fig.* 892. *a*, *b*, *c*) to the adjacent shearing place; the hand holding the leg to be kept low, when at the place it is turned on its back; or they are moved bodily, or one hand placed on the neck, and another behind, and in that manner walked along: the first or common mode he thinks the most safe. Sheep fed on rich pastures, and fleshy, if handled hard and bruised, the parts are liable to fatal mortifications; an accident which often happens, on which accounts pens upon some lands are obliged to be lined with woollen, or many would die from bruises.

892

7181. *In performing the operation of shearing*, the left side of the sheep is placed against the shearer's left leg, his left foot at the root of the sheep's tail, and his left knee at the sheep's left shoulder.

7182. *The process commences* with the shears at the crown of the sheep's head, with a straight cut along to the loins, returning to the shoulder, and making a circular shear around the off side to the middle of the belly; the off hinder leg next: then the left hand holding the tail, a circular shear of the rump to the near *huck* of the sheep's hind leg; the two fore feet are next taken in the left hand, the sheep raised, and the shears set in at the breast, when the remaining part of the belly is sheared round to the near stifle; lastly, the operator kneeling down on his right knee, and the sheep's neck being laid over his left thigh, he shears along the remaining side.

7183. *The method in Northumberland*, introduced by the Messrs. Culley, is to begin at the back part of the head, in order to give room for the shears to make their way down the right side of the neck, to the middle of the breast. The man then sits down upon his right knee, laying the head of the sheep over his left knee bent, and beginning at the breast, clips the underside of the throat upwards to the left cheek; then takes off the back of the neck, and all the way down below the left shoulder. He then changes to the contrary side, and makes his way down to the open of the right flank. This done, he returns to the breast, and takes off the belly, after which it matters not which side he clips, because being able to clip with either hand, he meets his shear points exactly at the middle of the back, all the way, until he arrive at the thighs or legs. He then places the sheep on its left side, and putting his right foot over the neck, and the other forward to the undermost hind leg, clears the right side; then turning the sheep over, finishes the whole.

7184. *The fleece being removed, is wound up*; that is, deprived of any clotted wool or dirty part, and lapped with the shorn side outwards, beginning at the breech and ending at the shoulders, where the neat wool serves as a bandage.

7185. *Marking* is performed on each sheep about a week after the fleece is removed. The object is to identify the individuals as the property of the master. Sometimes initials are impressed, and at other times other marks. They are impressed by stamps, or merely chalked or painted on. A stamp dipped in warm tar is the most durable mode. Some place the mark on different parts of the sheep, according to its age; others cut the margin of the ears in different ways.

7186. *Shortening the tails of the sheep* is performed in almost all the sheep districts of the kingdom except in Dorsetshire, which seems to be a useful practice, especially with long-woolled sheep, in keeping the animals more clean behind, and of course less liable to be stricken with the fly.

7187. *It has, however, been suggested* in the ninth volume of *Annals of Agriculture*, that by this custom the sheep may be rendered less able to drive away the flies. The general prevalence of the practice would, however, seem to prove its being of advantage. There is much difference in the manner of performing the business in different districts in respect to the length, but four or five inches being left is quite sufficient. It is usually done while the animals are young. In all sheep pastures the hedges should be well cleared from briars, as their coats are often injured by being torn by them. And all sorts of pernicious reptiles should be as much as possible destroyed, and removed from such land.

7188. *The mode of pasturing sheep, or of feeding them* on herbage or roots having been described when treating of these crops, the more general practices of rearing and management of lowland sheep husbandry may be considered as developed. Some peculiar practices and the mode of fatting lambs will be found in subsequent sections.

7189. *The practice of giving salt to sheep* deserves to be generally recommended. It is given in small long troughs every day throughout the year, and in rainy weather twice a day, or under cover, that it may not be washed away. The practice is particularly recommended, when sheep are first put to turnips. As to the quantity for each sheep, it is said that any quantity may be laid before them, and that no danger, but the reverse, will result from their having at all times as much as they will voluntary take.

Subsect. 2. *Rearing and general Management of Sheep on Hilly and Mountainous Districts, or what is generally termed Store Sheep Husbandry.*

7190. *The best store farmers* in Britain are unquestionably those on the Cheviot hills, which border the two kingdoms; and an account of their management may be considered as applicable to the mountainous districts of the whole kingdom. It is, indeed, applied by the migrations of the Cheviot and Teviotdale farmers, both in the North Highlands, on the Sutherland estate, and in Wales. No regular system of store farming, as observed by Napier (*Treatise on Store Farming*), appeared previously to his own; and accordingly from this work, and an excellent account published in the *Supplement to the Encyclopædia Britannica*, we have extracted what follows.

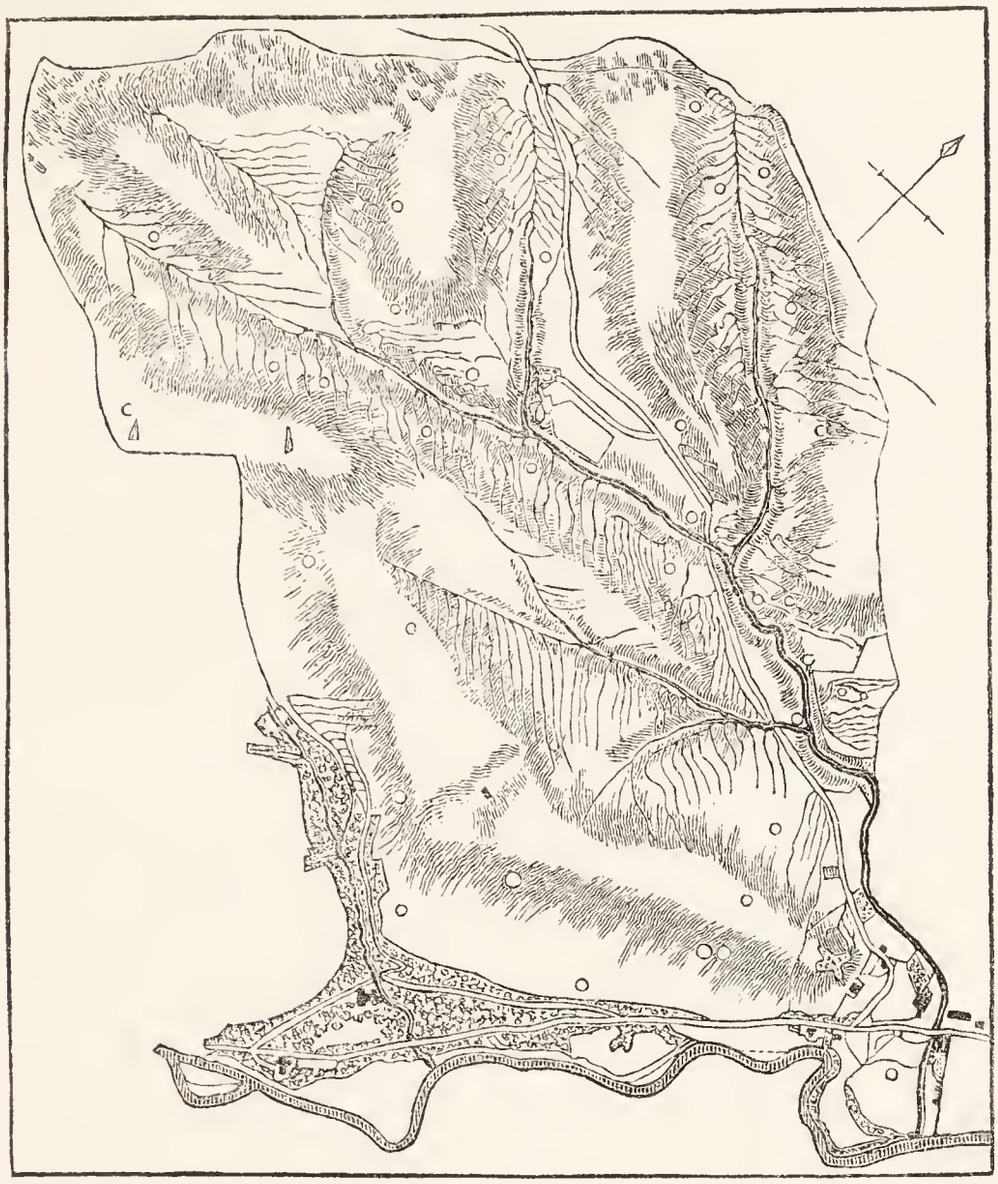
7191. *A general idea of the extent and nature of a store farm* may be obtained by referring to that of Thirlstane in Ettrick forest, a plan of which (*fig.* 893.) is given by Captain Napier. It contains one thousand six hundred and fifty-one acres; of which one thousand four hundred and sixty-four acres are in open hill pasture, seventy in plantation, forty in arable and meadow, about sixty in six enclosures, and the rest in shepherds' and other cottagers' houses, with their allowance of ground for a garden and cow. What distinguishes this farm from most others is the number of stells, or small circular enclosures (○) for sheltering and feeding sheep during storms of snow, which are distributed over it; being no fewer than thirty-seven. The advantages of these stells in districts where sheep are liable to be buried by snow Captain Napier considers very great, and to promote their more general introduction seems to have been one principal inducement for publishing his book. We shall recur to the subject in the following section, when treating of cotting, folding, housing, &c. In the mean time, we are informed that Captain Napier's round stells are not generally approved of, but that one is preferred which has four concave sides. See *Fairbairn's Treatise on Store Farming*, Edin. 8vo. 1825.

7192. *In the practice of store farming* the rams are put to the ewes for the purpose of copulation in November, a little earlier or later, according to the prospect of spring food, but seldom before the eighth or tenth of that month. The number of rams required is more or less, according to the extent of the pasture, and their own age and condition. If the ewes are not spread over an extensive tract, one ram to sixty ewes is generally sufficient. It is usually thought advisable to separate the gimmers (sheep once shorn) from the older ewes, and to send the rams to the latter eight or ten days before they are admitted to the former. Notwithstanding this precaution, which retards their lambing season till the spring is farther advanced, ewes which bring their first lamb when two years old, the common period on the best hill farms, are often very bad nurses, and in a late spring lose a great many of their lambs, unless they are put into good condition with turnip before lambing, and get early grass afterwards. This separation, and difference in the time of admitting the rams to the ewes and gimmers, should therefore be always attended to. When a farm under this description of stock has the convenience of a *few good enclosures* (as in Thirlstane farm for example), still more minute attention is paid by skilful managers. It is not sufficient that the rams are carefully selected from perhaps double the number, the ewes also are drawn out and assorted, and such a ram appropriated to each lot as possesses the properties in form or fleece in which the ewes are deficient. In other cases, the best ram and the best lots of ewes are put together. When neither of these arrangements can be adopted, owing to the want of enclosures, it is the practice to send the best rams to the ewes for a few days at first, and those of an inferior descriptions afterwards. In every case, when the farmer employs rams of his own flock, he is careful to have a few of the best ewes covered by a well-formed and fine-woolled ram, for the purpose of obtaining a number of good ram-lambs, for preserving or improving the character of his stock.

7193. *The stock through winter*, in a mere breeding farm, consists of ewes and gimmers, which should have lambs in spring; ewe lambs or hogs; and a few young and old rams. All these are sometimes allowed to pasture promiscuously; but on the farms around Cheviot the ewes and ewe hogs are kept separate, and the ewe hogs are either put on rough pastures, which have been lightly stocked in the latter end of summer, or get a few turnips once a day, in addition to the remains of their summer pasture. The most effectual preventive of the desolating distempers to which sheep of this age are liable is turnips; and though they should never taste them afterwards, a small quantity is frequently given them during their first winter. After the rams have been separated from the ewes, they are usually indulged with the same feeding as the hogs.

7194. *The ewes, during winter*, are seldom allowed any other food than what their summer pasture affords, except that a small part of it may sometimes be but lightly eaten, and reserved as a resource

893



against severe storms. When these occur, however, as they often do in the Cheviot district, there is little dependence on any other food than hay. When the snow is so deep as completely to cover the herbage, about two stones *avoirdupois* of hay are allowed to a score of sheep daily, and it is laid down, morning and evening, in small parcels on any sheltered spot near the house, or under the shelter of *stells* or clumps of trees, on different parts of the farm.

7195. *The ewes in March*, at least the gimmers or young ewes, are commonly allowed a few turnips once a day, on farms on which there is any extent of arable land; which are either carted to their pastures, or eaten on the ground, by bringing the sheep to the turnip field through the night. A part of the field, in the latter case, is cut off by nets, or by hurdles, which enclose the sheep in the same way as if they were intended for fattening. When they are ready to drop their lambs, they are no longer kept on the turnip field, and get what turnips may be left on their pastures. But it is seldom that the turnips last so long, though it is desirable to have a few remaining to be given to the weakest ewes, or to such as have twins in a separate enclosure.

7196. *A few days before the time of lambing*, the ewes are collected for the purpose of being udder-locked. The sheep are raised upon their buttocks, their backs next to the operator, who then bends forward and plucks off the locks of wool growing on or near the udders, for the purpose of giving free access to the expected lambs. At the same time he ascertains the condition of the ewes, and marks such as do not appear to be in lamb, which may then be separated from the others. This operation is not without danger, and several premature births are usually the consequence. It is therefore not so general a practice as it was formerly, though still a common one on many, if not on most farms.

7197. *The separation of the hogs from the ewes*, where these have been allowed to pasture promiscuously, should always take place at the commencement of the lambing season, and the lowest and finest part of the pasture be exclusively appropriated to the nursing ewes. On the Cheviot hills the hogs are generally pastured apart on the coarser herbage.

7198. *The lambing season* commences with the first or second week of April, according to the time at which the rains were admitted; and such as have twins, generally lamb among the first of the flock. At this season, the most constant attention is indispensable on the part of the shepherds, both to the ewes in labour and to the newly dropped lambs. Though the Cheviot ewes are not so liable to losses in parturition as some larger breeds which are in higher condition, and though they make good nurses, unless they are very lean, and their food scanty, yet, among a large flock, there are always a number that need assistance in lambing, and in a late spring not a few who have not milk sufficient for their lambs, particularly among the gimmers or young ewes. A careful shepherd at this time always carries a bottle of milk along with him, which he drops from his own mouth into that of the lamb that may need it; brings the ewes that have little milk to a better pasture, or to turnips, and confines such as have forsaken their lambs in a small pen, or barrack as it is called, temporarily erected in some part of the farm-steading. The same confinement is necessary when it is wished to make a ewe that has lost her own lamb, nurse that of another ewe that has had twins, or that has perished in lambing, or is from any other cause incapable of rearing her lamb. The ewe, after being shut up a few hours with the strange lamb, usually admits it to the teat, and ever after treats it as her own; though sometimes a little deception is necessary, such as covering the stranger with the skin of her own lamb. At this important season, an enclosure of rich early grass, near the shepherd's cottage, is of vast advantage. Thither he carries the ewes and twins,

such as have little milk; those that have been induced to adopt another's offspring; and, generally, all that need to be frequently inspected, and are in want of better treatment than the rest of the flock. (*Supp. &c.* 178.)

7199. *Castration* is performed in the male lambs when a few days old, the ewe lambs are never spayed: mild weather is chosen, and the operation performed in a fold on small quantities at a time.

7200. *The late lambing ewes* are separated from the ewes and lambs at the end of the lambing season, and kept by themselves, that they may be more under the eye of the shepherd, than if scattered over all the pasture. It is desirable to allow them fine grass for a few weeks after lambing, that their lambs may come to be nearly equal to the rest of the flock when weaned; or if they are too late for this, that they may get ready for the butcher by the month of August, beyond which period the ewes must be much injured by suckling them. (*Supp. &c.*, art. *Agr.* 179.)

7201. *Washing*, in store-farming, is performed when the wool has risen sufficiently, which is easily known by the appearance of a new growth. The barren sheep are first brought to the washing pool. Sometimes they are hand-washed by men who stand in the pool, and have the sheep forced towards them singly; but more commonly, the Cheviot sheep, especially if the flock be numerous, are compelled to leap into the pool in a body for three or four times successively; and it is desirable that they should have room to swim a little, and come out on a green low bank on the opposite side. After being washed, the sheep are preserved as far as possible from rubbing against earthen dykes or banks, and from lying down on any dirty spot which might soil their wool. (*Supp. &c.*)

7202. *Marking*, as in general sheep-farming (7185.), takes place before the shorn sheep are turned out to pasture: they are marked, commonly with the owner's initials, by a stamp, or *boost* in provincial language, dipped in tar heated to a thin fluid state; and it is not unusual to place this mark on different parts of the body, according to the sheep's age.

7203. *The weaning of lambs* takes place when they are about three months old, sometimes sooner. When the ewes are gathered to be washed or shorn, the ewe lambs to be kept for supplying the place of the old ewes occasionally sold are stamped in the same way as the ewes. The store-lambs are sent to some clean grassy pasture for a few weeks; and where the farm does not afford this accommodation, they must be *summered*, as it is called, at a distance. Several farms near Cheviot, and on the Lammermuir hills in Berwickshire, are appropriated to this purpose, the owner of the lambs paying so much a head for six or eight weeks. In the mean time the ewe hogs, or gimmers, as they are denominated after shearing, have joined the ewe stock, and the lambs, when brought home, go to the pasture which they had occupied. Wherever they may be kept in winter, it is always desirable to allow them a few turnips, along with a full bite of coarse herbage.

7204. *The practice of milking ewes* after the separation of the lambs is still continued in a few places. This very objectionable management is generally continued for six or eight weeks. The value of the milk of each ewe for this time may not exceed from one shilling to one shilling and sixpence a head, and the sheep are injured to at least three times that amount, independent of accidents at the milking fold. The cream is separated from the ewe milk, and made into butter for smearing, and the milk itself mixed with cow milk, and converted into cheese. The most skilful store-masters, however, have either laid aside milking, unless for a few days, or have shortened the period to two or three weeks.

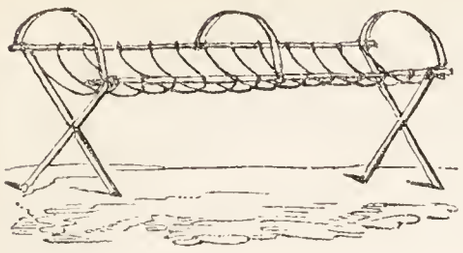
7205. *The selection of the crones or old ewes* to be sold generally takes place in September or October, when they are sold to the feeder, and replaced by lambs of the current year. On the lower hills, ewes are generally disposed of after having lambed three seasons, or under four and a half years of age. In some situations they are kept on till a year older; but when they are purchased, as they usually are, to be kept another year on lower grounds, it is commonly for the interest of the store-farmer to sell them when still in their full vigour. Skilful managers do not content themselves with drafting them merely according to age; for as there is no disadvantage in keeping a few of the best another year, they take this opportunity of getting rid of such of the flock of other ages as are not of good shapes, or are otherwise objectionable. As soon as the ewes to be disposed of are drawn from the flock, they are kept by themselves on better pasture, if the circumstances of the farm will admit of it. Sometimes they are carried on till they are fattened, and turnips are often purchased for them at a distance. When this is the case, it is not thought advisable to keep them longer than till between Christmas and Candlemas, as an old ewe does not improve like a wether in the spring months. (*Supp. &c.*)

7206. *The salving or smearing of sheep* is an operation scarcely known in England, and not practised by the Welsh: some store-farmers in the milder districts of the northern counties consider it unnecessary, but in all very cold situations it is still employed. The object of this operation is to destroy vermin, to prevent cutaneous diseases, and to promote the warmth and comfort of the animal during the storms of the ensuing winter. It is not necessary with sheep kept on low grounds, and well fed during winter, and it may occasionally be omitted for one season, particularly with old sheep, without material injury; but notwithstanding the ridicule that speculative writers have attempted to throw upon the practice, it is almost universally considered necessary and beneficial on high exposed situations, by the store-farmers of the border hills. Smeared wool does not sell so high as white wool, but the greater weight of the former more than compensates for the difference in price. (*General Report of Scotland*, vol. iii.) The season of salving or smearing is usually towards the end of October or beginning of November, before the rams are sent to the ewes. The most common materials are butter and tar, mixed in different proportions; a greater proportion of tar being employed for the hogs or young sheep than for the older ones. The proportions are also different on almost every farm, and more tar is thought to be necessary, according to their greater elevation and exposure. In Roxburghshire, some mix two gallons of tar with thirty-six pounds of butter, as a sufficient allowance for three score of sheep; but for the same number it is more common to allot only one stone (twenty-four pounds) of butter to two gallons of tar. (*Roxburghshire Report*, p. 155). A common proportion of late has been about fourteen pounds of butter to two Scotch pints of tar (nearly 3½ quarts English wine measure), for ewes, and eleven pounds to the same quantity of tar for hogs. This mixture should smear from twenty to twenty-five of each, which is the number one man can do in a day. The expense, according to present prices, will be about nine-pence for each sheep: other articles, such as oil, palm-grease, tallow, &c., have been recommended in place of butter; but none of them are in general use, and the only addition that is approved of is a little butter-milk. The butter is slowly melted and poured upon the tar, and the mixture is constantly stirred till it becomes cool enough for use. The wool is accurately parted into rows from the head to the tail of the animal, and the salve is carefully spread upon the skin with the point of the finger at the bottom of each row. (*Supp. En. Brit.* art. *Agr.* 180.) The practice of salving has undergone a change within these four years, and is not so general now as formerly, the low price of smeared wool having forced the store-masters to try other ingredients than tar. In the *Farmer's Magazine*, vol. xxv. are some notices of these experiments on smearing; which have not, however, been so long in use as to afford certain results. The object at present is as far as possible to dispense with tar, by which the wool is rendered unfit for certain sorts of manufacture.

7207. *The care of sheep during storms* is a business requiring constant attention. In storms of wind and rain, or what are called *black storms* by the shepherds, the sheep will, in a great measure, take care of themselves, by pasturing in situations naturally sheltered. All that is required is to remove any of the more delicate into a covered fold or sheep-house; though such conveniencies are seldom to be found on mountain farms. But in a storm of snow the natural shelter to which the sheep have recourse becomes the great receptacle of drift, and the harbinger of death to the flock. It is in such situations that Captain Napier purposes to place his stalls, or circular folds (*fig.* 893. ○), into which the sheep should be driven, or will naturally enter on the commencement of the storm. The round form for these stalls or folds is decidedly preferable to any figure with straight lines, as these invariably harbour drift. Where no

artificial shelter is provided immense losses sometimes take place on mountain farms. The sheep are buried many feet deep in the snow; and though the shepherd, with such assistants as he can procure, armed with poles and spades, and aided by the sagacity of his dog, may dig out a few, yet the greater number perish. While the sheep remain in artificial shelters of any kind they must of course be fed; and the only convenient food in such cases is hay, straw, or dried spray (the latter seldom resorted to in this country), which should be put into baskets, or racks. (*fig.* 894.) The Ryeland breed of sheep in Herefordshire, and some of the flocks in the Highlands of Scotland, are put under cover nightly throughout the year: a practice which has probably originated in security, and been continued as matter of convenience and habit.

894



Sect. V. *Folding of Sheep.*

7208. *Cotting or folding* is a practice more or less extensively followed with particular breeds and in particular districts, but now generally on the decline.

7209. *It was formerly thought to be indispensably necessary* to the success of the farmer in different districts; but of late a different opinion has prevailed, except in particular cases, and it is considered as merely enriching one field at the expense of another. The practice may, however, be beneficial where there are downs, heaths, or commons. Folding has been chiefly confined to England, and a small part of Wales and Ireland. The object is to enrich the arable land; but as this is done at the expense of the pasture, it is truly, as Bakewell expressed it, "robbing Peter to pay Paul."

7210. *The sheep best adapted to the fold* are those of the more active, short-woolled varieties, such as the Norfolk, Wiltshire, and South Down breeds; the heavy long-woolled kinds being less hardy, and some of them, as the Leicesters, much too valuable for a mode of treatment that converts them into dung carriers. The following calculation by Marshal will show, that though, in open lands, the practice may be in some cases tolerated on the ground of conveniency or expediency, it can possess no recommendation as a profitable mode of management in other circumstances.

7211. *This morning* (September 22. 1780), measured a sheep-fold, set out for six hundred sheep, consisting of ewes, wedders, and grown lambs. It measures eight by five and a half rods, which is somewhat more than seven rods to one hundred, or two yards to a sheep.

7212. *August* 29. 1781. Last autumn made an accurate experiment, on a large scale, with different manures for wheat, on a sandy loam, summer fallowed. Part of an eighteen acre piece was manured with fifteen or sixteen loads of tolerably good farm-yard dung an acre; part with three chaldrons of lime an acre; the rest folded upon with sheep twice; the first time at the rate of six hundred sheep to a quarter of an acre (as in first minute), the second time thinner. In winter and spring, the dung kept the lead; and now, at harvest, it has produced the greatest burden of straw. The sheep-fold kept a steady pace from seed-time to harvest, and is now evidently the best corned, and the cleanest crop. The lime, in winter and spring, made a poor appearance, but after some showers in summer it flourished much, and is now a tolerable crop, not less, I apprehend, than three quarters of an acre.

7213. *From these data* the value of a sheep-fold, in this case, may be calculated. It appears from the first minute, that one hundred sheep manured seven square rods daily. But the second folding was thinner; suppose nine rods, this is, on a par of the two foldings, eight rods a day each folding. The dung could not be worth less than half a crown a load, and the carriage and spreading ten shillings an acre; together fifty shillings an acre; which quantity of land the hundred sheep teathed twice in forty days. Supposing them to be folded the year round, they would, at this rate, fold nine acres annually; which, at fifty shillings an acre, is twenty-two pounds ten shillings a hundred, or four shillings and sixpence a head. In some parts of the island, the same quantity of dung would be worth five pounds an acre, which would raise the value of the teathe to nine shillings a head; which, at two-pence a head a week, is more than the whole year's keep of the sheep. It does not follow, however, that all lands would have received equal benefit with the piece in consideration; which, perhaps, had not been folded upon for many years, perhaps never before; and sheep folds, like other manures, may become less efficacious the longer it is used on a given piece of land. (*Marshal's Rural Economy of Norfolk*, vol. ii. p. 29.)

7214. *To fold on land in tillage all the year* is nearly impracticable; and where it could be done, the manure would be greatly diminished in value from rain and snow, to say nothing of the injury to the sheep themselves. So that the estimate of four shillings and sixpence, or nine shillings a head, is evidently in the extreme.

7215. *According to Arthur Young* (*Farmer's Calendar*), the same land will maintain one fourth more stock when the animals are allowed to depasture at liberty, than when confined during the night in folds. The injury to the stock themselves, though it is not easy to mention its precise amount with any degree of accuracy, cannot well be doubted, at least in the case of the larger and less active breeds, when it is considered that they are driven, twice a day, sometimes for a distance of two, or even three miles, and that their hours of feeding and rest are, in a great measure, controlled by the shepherd and his boy. When they are kept in numerous parcels, it is not only driving to and from the fold that affects them, but they are in fact driving about in a sort of march all day long, when the strongest have too great an advantage, and the flock divides into the head and tail of it, by which means one part of them must trample the food to be eaten by another. All this points the very reverse of their remaining perfectly quiet in small parcels.

7216. *The result of Parkinson's experience* is, "that were the pasture sheep of Lincolnshire to be got into a fold once a week, and only caught one by one, and put out again immediately, it would prevent their becoming fat." (*Parkinson on Live Stock*, vol. i. p. 367.) The only sort of folding ever adopted to any extent by the best breeders is on turnips, clovers, tares, and other rich food, where the sheep feed at their ease, and manure the land at the same time.

7217. *Folding in littered yards* is described by Dickson (*Complete Farmer*, art. *Sheep*) as combining all the advantages of folding on arable lands without any of its disadvantages. By this practice the sheep are confined at night in a yard well and regularly littered with straw, stubble, or fern; by which means the flock is said to be kept warm and healthy in bad seasons, and at the same time a surprising quantity of manure accumulated. A great improvement on this method, it is said, would be, giving the sheep all their food (except their pasture) in such yard, viz. hay and turnips: for which purpose they may be brought up not only at night, but also at noon, to be baited; but if their pasture be at a distance, they should then, instead of baiting at noon, come to the yard earlier in the evening, and go out later in the morning. This is a practice, he says, that cannot be too much recommended; for so warm a lodging is a great matter to young lambs, and will tend much to forward their growth: the sheep will also be kept in good health; and, what is a point of consequence to all farms, the quantity of dung raised will be very great. If this method is pursued through the months of December, January, February, March, and April, with plenty of litter, one hundred sheep will make a dunghill of at least sixty loads of excellent stuff, which will amply manure two acres of land; whereas one hundred sheep folded (supposing the grass dry enough) will not, in that time, equally manure an acre.

7218. *Our opinion of this sort of folding*, so warmly recommended by Sir J. Sinclair and A. Young, in the husbandry of Scotland, coincides with that of a very superior judge, who says, " that such a method may be advantageous in particular cases, it would be rash to deny; but generally it is not advisable, either on account of the sheep, or any alleged advantage from the manure they make. As to the sheep, this driving and confinement, especially in summer, would be just as hurtful as folding them in the common way, and it has been found that their wool was much injured by the broken litter mixing with the fleece in a manner not to be easily separated; besides, now that it is the great object of every skilful breeder to accelerate the maturity of his sheep, as well as other live stock; among other means, by leaving them to feed at their ease, and if circumstances permit, in small parcels; such a practice as this can never be admissible in their management; and with regard to manure, there can be no difficulty in converting into it any quantity of straw, stubble, and fern, by cattle fed in fold-yards, on green herbage in summer, and turnips, or other succulent food, in winter; while the soil, especially if it be of a light porous quality, is greatly benefited both by the dung and treading of sheep, allowed to consume the remainder of both sorts of food on the ground. It is true, that the dung of sheep has been generally supposed to be more valuable than that of cattle, but accurate experiments have not been made to determine the difference in this respect, among these and other polygastric animals. The greater improvement of pastures by sheep is probably owing as much to their mode of feeding, as to the richer quality of their dung." (*Sup. E. Brit.* art. *Agr.*)

Sect. VI. *Of Fatting Sheep and Lambs.*

7219. *The subject of fatting sheep* may be considered in regard to the age at which fatting is commenced, the kind of food, and the manner of supplying it.

7220. *The age* at which sheep are fatted depends upon the breed, some breeds, such as the Leicester, maturing at an earlier age than others, under the same circumstances; and also in the abundance and quality of the food on which they are reared; a disposition to early obesity, as well as a gradual tendency towards that form which indicates a propensity to fatten, being materially promoted by rich food, while the young animals are yet in a growing state. On good land, the Leicester wethers are very generally brought to a profitable state of fatness before they are eighteen months old, and are seldom kept for fatting beyond the age of two years: the Highland breeds, on the other hand, though prepared, by means of turnips, a year at least sooner than they could be in former times, usually go to the shambles when from three to four years old. The ewes of the first description are commonly fatted after having brought lambs for three seasons, that is, after they have completed their fourth year, and those of the small breeds, at from five to seven years of age, according to circumstances. (*Sup. E. Brit.* art. *Agr.*)

7221. *The kinds of food* on which sheep are fatted are good pastures, permanent or temporary; herbage crops, as clovers, tares, &c.; turnips and other roots; and linseed cake, grains, or other edible refuse of the oil manufactory, brewery, and distillery.

7222. *The mode of feeding* on rich pastures, herbage, and turnips has already been described when treating of these crops; and it remains only to notice the modes of using grains and oil cake. These, and also bran, oats, peas, and other grains and meals, whether given in winter or summer, should always be accompanied with pasture or dry food of some sort, especially hay. All food of this sort should be given in moveable troughs, divided in the middle, so that the sheep may feed on each side, with a sloping roof over them, so as to cover the sheep's heads and necks while feeding, as wet is not only prejudicial to the sheep but spoils the food. A rack for hay, fixed over the trough, might probably be made to answer in this intention, while it would be very convenient for holding that material and preventing waste. The whole should be fixed on wheels and made to stand steady, and a sufficient number for the quantity of sheep be always in readiness. In the fattening of wethers the use of barley meal, with grass or some other sort of green food, has likewise been found highly beneficial; and, when it can be procured at a reasonable rate, should not be neglected, as it is quick in rendering them fat, and the mutton is excellent. A pound of oil-cake or of meal per day, with hay or turnips, for each crone or wether, is reckoned a fair allowance in Lincolnshire. In the report of that county several instances of oil-cake feeding are given, by which it appears that that sort of food fattens in a shorter time than any other, is the most suitable food for fattening old sheep, and a rapid promoter of the growth of the wool.

7223. *In fattening sheep* as well as other animals, it should be made a rule never to allow them to lose flesh, from the earliest age till they are sent to the butcher. It is found of much advantage, with a view to speedy fattening as well as to the economy of food, to separate a flock into divisions, corresponding with its different ages, and the purpose of the owner as to the time of carrying them to market; and the change from the food of store to fatting stock, from that which is barely capable of supporting the condition which they have already attained to that which is adapted to their speedy improvement in fatting, ought to be gradual and progressive. Thus very lean sheep are never, in good management, put to full turnips in winter, nor to rich pastures in summer: they are prepared for turnips in good grass land; often on the after-grass of mown grounds and kept on second year's leys, and afterwards a moderate allowance of turnips if they are fatted on pastures. It is a common practice, in the instance of the Leicesters, to keep all that are not meant for breeding always in a state of fatness, and after full feeding on turnips through winter and spring, to finish them on the first year's clover early in summer, when the prices of meat are usually the highest.

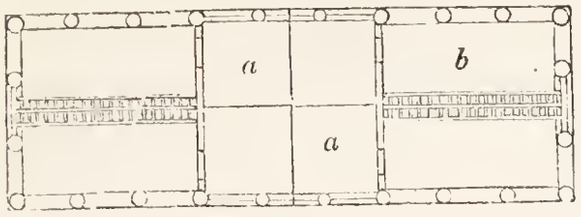
7224. *The fattening of lambs* during summer requires nothing more than keeping their mothers and them on the richest and best pasturage, and supplying such artificial food as the situation, season, or other circumstances may require: but the fatting of lambs during winter and spring requires attention to three things; the breed, or if any breed be used indifferently, the period of dropping, the lamb-house, and the feeding.

7225. *With respect to the breed*, as the sheep will take the ram at any season, any variety may be so managed as to drop their lambs at any period of the year; but it is found by experience, that the Dorsetshire sheep is easiest made to yean, and therefore this is the sort generally employed in Middlesex for rearing what is called house-lamb for the metropolis. The selection of the rams for breeding the lambs to be house-fed is, according to Middleton, founded on the following circumstances: — The sucklers, salesmen, and butchers of London are aware that such lambs as have sharp barbs on the inside of their lips are certainly of a deep colour after being butchered, and that all those whose barbs are naturally blunt do as certainly produce fair meat. This knowledge has been the occasion of many lambs of the latter kind being kept for rams, and sent into Dorsetshire expressly for the purpose of improving the colour of the flesh of house-lambs: the issue of such rams can generally be warranted fair, and such meat always sells at a higher price; hence arose the mistaken notion that Middlesex rams were necessary to procure house-lambs.

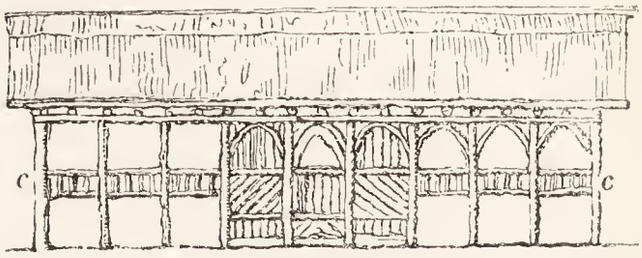
7226. *A lamb-house* may be any close shed, cow-house, or other spare house, or, even on a small scale, a roomy pigsty. But they are built on purpose by the extensive dealers in this article; and one to suckle from one hundred and sixty to one hundred and eighty lambs at a time should be seventy feet long and eighteen feet broad, with three coops of different sizes at each end, so constructed as to divide the lambs

according to their ages. A plan of a sheep-house, combining also a lamb-house, is given by Kraft in his *Rustic Designs*. It is wholly built of unbarked spars or young fir-trees. The plan (*fig.* 895.) contains four close apartments with doors for the lambs (*a*), and four others with racks for the sheep (*b*). The elevation

895

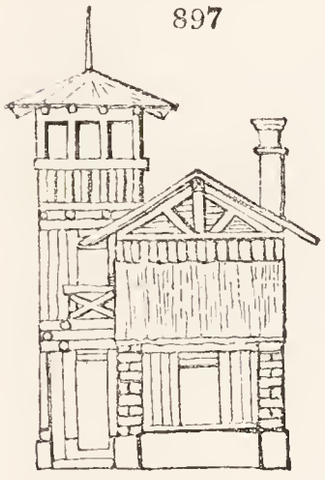


896



(*fig.* 896.) shows a gallery (*c*), which surrounds the building, and is used as a passage for viewing the sheep, handling them with the crook, and at night for the perambulations of a watch-dog. The roof being twenty feet from the floor, the interior is abundantly airy, which for sheep is an important object. Another design in the same work (*fig.* 897.) is accompanied by an elegant Indian watch-tower, with apartments therein for the shepherd.

897



7227. *The economy of the suckling-house* is as follows: — The sheep which begin to lamb about Michaelmas are kept in the close during the day, and in the house during the night, until they have produced twenty or thirty lambs. These lambs are then put into a lamb-house, which is kept constantly well littered with clean wheat straw; and chalk, both in lump and in powder, is provided for them to lick, in order to prevent looseness, and thereby preserve the lambs in health. As a prevention against gnawing the boards or eating each other's wool, a little wheat straw is placed, with the ears downwards, in a rack within their reach, with which they amuse themselves, and of which they eat a small quantity. In this house they are kept, with great care and attention, until fit for the butcher.

7228. *The mothers of the lambs* are turned, every night at eight o'clock, into the lamb-house to their offspring. At six o'clock in the morning these mothers are separated from their lambs, and turned into the pastures; and at eight o'clock such ewes as have lost their own lambs, and those ewes whose lambs are sold, are brought in and held by the head till the lambs by turns suck them clean: they are then turned into the pasture, and at twelve o'clock the mothers of the lambs are driven from the pasture into the lamb-house for an hour, in the course of which time each lamb is suckled by its mother. At four o'clock all the ewes that have not lambs of their own are again brought to the lamb-house and held for the lambs to suck; and at eight the mothers of the lambs are brought to them for the night.

7229. *This method of suckling* is continued all the year. The breeders select such of the lambs as become fat enough, and of proper age (about eight weeks old), for slaughter, and send them to markets during December and three or four succeeding months, at prices which vary from one guinea to four, and the rest of the year at about two guineas each. This is severe work for the ewes, and some of them die under excess of exhaustion. However, care is taken that they have plenty of food; for when green food (viz. turnips, cole, rye, tares, clover, &c.) begins to fail, brewer's grains are given them in troughs, and second-crop hay in racks, as well to support the ewes as to supply the lambs with plenty of milk; for if that should not be abundant, the lambs would become stunted, in which case no food could fatten them. (*Middlesex Report*, p. 355.)

Sect. VII. *Probable Improvement to be derived from Crosses of the Merino Breed of Sheep.*

7230. *The Merino*, or Spanish variety of the *Ovis Aries*, is supposed by Rozier and other French writers to have been originally imported from Africa to Spain. It is, however, at least as probable that they are indigenous to that country, or, if originally imported, that they have become modified to what they are by the soil and climate.

7231. *Merinos first attracted attention in this country* in 1764, in consequence of the reports of travellers, and a letter by Don John Bowley to Peter Collinson, published in the *Gentleman's Magazine* for that year. A few were imported in 1788, and more in 1791, and placed on the king's farm at Windsor, under the care of Sir Joseph Banks, who was then constituted his Majesty's shepherd. The first sale of stock was made in 1800; and from these, a flock imported from Spain in 1801 by Lord Somerville, and some other importations by different persons subsequently, have sprung all the Merinos and Merino rams in the empire. Since that period, a number of eminent breeders and scientific agriculturists have cultivated this breed both alone and by crossing, but especially Dr. Parry and Lord Somerville; and though the utility which its introduction may ultimately prove to the country can by no means be estimated at present, that it has already done much good by directing the public attention to the subject there can be no doubt; and many are of opinion, that by it the fleeces of our short-woolled sheep may be so improved as to render them fit substitutes for imported Spanish wool.

7232. *Dr. Parry's experiments* with the Merino breed were begun nearly at the same time with the king's. His farm was elevated, exposed, and unfit for any other purpose than breeding; and he fixed on the Ryeland breed, as one of the finest woolled varieties of British sheep, for crossing with Merino rams. His only object was the improvement of the fleece.

7233. *The effect of the fourth cross of the Merino ram*, according to the opinion of sheep cultivators on the Continent, on any breed of ewes, however coarse and long in the fleece, will be to give progeny with short wool equal to the Spanish. Of the truth of this proposition, however, Dr. Parry justly expresses some doubts, derived from his own experience and that of others. But it is certain, he adds, that one cross more will, in most cases, effect the desired purpose. If we suppose, he says, the result of the admixture of the blood of the Merino ram to be always in an exact arithmetical proportion, and state the native blood in the ewe as 64; then the first cross would give $\frac{32}{64}$ of the Merino; the second $\frac{48}{64}$; the third $\frac{56}{64}$; the fourth $\frac{60}{64}$; the fifth $\frac{62}{64}$; the sixth $\frac{63}{64}$, and so on. In other words, the first cross would leave thirty-two parts in sixty-four, or half of the English quality; the second sixteen parts, or one fourth; the third eight parts, or one eighth; the fourth four parts, or one sixteenth; the fifth two parts, or one thirty-second; the sixth one part, or one sixty-fourth, and so on. Now, if the filaments of the Wiltshire, or any other coarse wool, be in diameter double that of the Ryeland, it is obvious, that, according to the above statement, it would require exactly one cross more to bring the hybrid wool of the former to the same fineness as that of the latter. This, he believes, very exactly corresponds with the fact. The dif-

ference between one eighth and one sixteenth is very considerable, and must certainly be easily perceived, both by a good microscope, and in the cloth which is manufactured from such wool. In the latter method, he adds, "it certainly has been perceived; but I have hitherto had no opportunity of trying the difference by the former. The fifth cross, as I have before observed, brings the Merino-Wilts wool to the same standard as the fourth of the Merino Ryeland." (*Com. to the Board of Agr.* vol. v. p. 438.)

7234. *In the lambing season*, the Ryeland breed are usually cotted, because the new-born lambs are very thinly covered with wool. As January was considered the best lambing season for the produce of the cross, Dr. Parry found cotting was doubly necessary. Every night the flock were well sheltered; and they were allowed, in addition to the pasture which they could pick up in the day-time, linseed jelly, ground oil-cake, or grains, cabbages, rouen, winter and spring vetches, and tares. Salt, he says, I never gave to my flock but once, and that in the following way: — A small field of latter-math, cut in September, had been so often wetted, that I despaired of its ever being eaten. While it was putting into the rick, I strewed some salt between the layers; the consequence was, that cows and sheep greedily devoured it, scarcely leaving a single blade. (*Com. to the Board of Agr.* vol. v. p. 505.)

7235. *The shearing* of the sheep was performed in the second week of June, and of the lambs at the end of July. The finer fleeced lambs need not be shorn till the second season. Washing previously to shearing Dr. Parry disapproves of; because the fleece is so thick, that when thoroughly soaked with water, it is very long in drying; and if the weather prove wet and cold, the sheep are evidently much incommoded; he therefore recommends cleansing the wool, after being shorn, as in Spain.

7236. *The produce of wool*, considered as the result of Dr. Parry's well conducted experiments, was found to be 14 lbs. 14 oz. per acre, which at 3*s.* per lb. in the yolk throughout the fleece gives 2*l.* 4*s.* 7½*d.* per acre on land certainly not worth on an average 26*s.* (*See Comm. to the B. of Agriculture*, vol. v.)

7237. *Lord Somerville's experiments* may be considered as of equal, if not more importance than these of Dr. Parry. His Lordship tried crosses with several short-woolled breeds, but was most successful with the South Downs and Ryelands. Morris Birkbeck, a professional farmer of the first order, found that the fleeces of the first cross between Merinos and South Downs, washed, are to the parent South Downs as six to five in weight, and as three to two in value per pound, and believes that the improvement of the wool may go on, without detriment to the carcass, until we shall obtain a breed of sheep with Spanish fleeces and English constitutions; but this must be the result of careful and judicious selection.

7238. *Merino flocks are now established in most districts* of the empire, and but few years can elapse before their value to the farmer and the country be practically ascertained and evinced. (See *Sir J. Banks in Annals of Agriculture, Com. to B. of Agr. Bath Society's Papers, Dublin Society's Transactions, The Farmer's Magazine, Farmer's Journal. Lord Somerville's and Dr. Parry's Tracts on Wool and Merinos, and various other works.*)

Sect. VIII. *Anatomy and Physiology of Sheep.*

7239. *The general structure of the sheep* resembles that of the ox very intimately. Sheep however, like the ox, experience considerable variations in size, form, and qualities; resulting from the physical and moral agencies which they become exposed to, under various climates: and also, as whether fostered by cultivation, or left to the natural operations of nature around them. These circumstances have operated on even the bony base of the machine, as we see in the formations of the three-horned breed (*O*vis polycérata *Lin.*), natives of the north; in the spiral-horned (*O. S*trepsíceros *Lin.*), which inhabit Wallachia; and the long-horned (*C*àpra A'mmon *Lin.*), which are found in the countries bordering the Mediterranean: and which have been thought to be the parents of the present cultivated British sheep.

7240. *Cultivation weakens the otherwise inherent aptitude* to retain the original stamp of nature; and we find, therefore, that by these means, the original form of the sheep has submitted to vast alterations. We see some of them wholly without horns; we also find that the bony structure is otherwise subjected to our command, by becoming much more slender, though more compact. Accidents are also laid hold on by man to produce particular forms: thus a breed has been cultivated in America, called the ancon or otter breed, remarkable for crooked and deformed legs; which, by continued breeding from specimens that presented this originally accidental deformity, is become now a fixed and permanent breed, valuable for their incapacity to wander or climb. (*Dwight.*) The dunky, or wry-faced breed, is another instance of accidental deformity cultivated into a permanent variety: as the monstrous rump of the Tartarian sheep, and the over-grown tails of some breeds in Turkey, and the Cape of Good Hope, are similar instances in the softer parts of the body.

7241. *The skeleton of the sheep* presents an assemblage of bones, which bears a general resemblance to that of the ox in number and direction. Like him, the head naturally is surmounted by horns springing from the frontal bones. Like him, his frontal sinuses are large and open, and thus liable to the entrance of insects. The skull bones are wide and extended; his orbits are more lateral than central; and his facial angle is about thirty degrees. His vertebral column is the same as the ox, and his ribs also. The extremities descend on the same construction, ending in a divided hoof.

7242. *The visceral and soft parts* are but little dissimilar likewise. His brain is as one two-hundredth to the whole body; and his cerebéllum to the brain generally, as one to five. The pigment of the eye is of a pale yellowish green, varying occasionally to a blue. The víscera of the chest correspond with the ox; and those of the belly also, the stomachs being the same, and the economy of rumination not differing. The liver, páncreas, and spleen are similar. The pènis is taper, vesículæ seminàles wanting, and prostrates two.

7243. *The wool of the sheep* is but a crisped hair; and indeed in some foreign varieties, the outer covering is of long hair like that of oxen; while in others, the hair and wool are mixed.

Sect. IX. *Diseases of Sheep.*

7244. *The diseases of sheep* are numerous; for these animals are now so highly cultivated that they may be regarded in some respects as artificial machines: and thus, as a natural consequence, they are subjected to a variety of artificial defects or maladies.

7245. *The rot is a popular term* among shepherds, and includes within its range diseases widely different. We shall not, therefore, follow the custom of treating the different rots of sheep together; but we shall allow them to fall in their natural order, according to the plan pursued with the diseases of oxen.

7246. *The inflammatory and putrid fever*, popularly known by the names *higham striking*, or *blood striking*, does not differ materially from the same disease in oxen and cows; and is in sheep also sometimes epidemic; appearing by panting, dulness, watery mucus from the nose and eyes; and great redness of all such parts as are usually white.

7247. *The red water.* The inflammatory fever sometimes resolves itself into an universal secretion of serum throughout all the cavities; in which case, after a few days, the lymph tinged with blood will come

away from the nose and mouth in large quantities. Sometimes after death the bloody serum is found suffused throughout the skin as in the blood striking of skins.

7248. *The claveau or sheep pox* is also another variety of this disease, in which it takes on a pustular form. About the third day small variolæ appear: sometimes they are rather blotches than pustules. The weakness is usually extreme, and the putridity great. This form of the disease is seldom seen with us; but is still known on the Continent, where the pastures are very poor and low, and the general keep meagre.

7249. *The treatment* of all these in nowise differs from that directed under the inflammatory putrid fever of the ox; the doses of medicine being about a third of what is directed for them.

7250. *Malignant epidemic or murrain.* Sometimes an epidemic prevails, which greatly resembles the murrain of oxen: in appearances, termination, and treatment, it resembles the malignant epidemic of oxen. (6943.)

7251. *Peripneumònia or inflamed lungs, rising of the lights, glanderous rot, hose, &c.* These terms are all modifications of an inflamed state of the viscera of the chest, caught by undue exposure, bad pasturage, and often from over-driving. The cough, the tremblings, the redness of the eyes and nostrils, and the distillation of a fluid from them, with the heavings and hot breath, are all similar to those which characterise the pneumònia or rising of the lights in oxen. We remember to have seen the disease strongly marked in the February of 1808, on a farm in the neighbourhood of Streatham; where eleven sheep were attacked almost together, after a very stormy night. They were first affected with a loss of appetite; next with a fixed stedfast look, which was common to every one. After this, they reeled about, fell backwards, and became convulsed. When seen, five were already dead, whose internal appearances fully confirmed the nature of the disease. The rest recovered by bleeding and drenching, with drenches composed of nitre and tartar emetic. Sometimes the symptoms of pneumònia do not kill immediately, but degenerate into an ulceration of the lungs; which is then called the *glanderous rot.* This stage is always fatal: the others may, by early attention, be combated by judicious treatment, as detailed under the same disease in oxen.

7252. *A chronic cough* in sheep, when not symptomatic of rot, is always cured by a change of pasturage, particularly into a salt marsh.

7253. *Inflammation of the stomach* occurs from various causes. A common one arises from eating noxious vegetables; and produces the affections termed *tremblings.* It also produces the *grass ill* in lambs; which latter is always accompanied with black, fetid fæces, and is readily removed by an ounce of castor oil; while the former usually yields to half an ounce of oil of turpentine, beaten up with the yolk of an egg. Some herbs (as A'tropa *Belladónna*) when eaten produce spasmodic affections, which are called by shepherds the *leaping ill:* in such cases, the watery solution of aloes (*Vet. Pharm.* 6585.) in doses of two or three ounces is useful. Daffy's elixir we have also known to be given with good effect.

7254. *The hove, blast, or wind colic.* Sheep are as liable to be distended with an enormous collection within the maw as oxen. An instrument, similar to that invented by Dr. Monro, is also made for them; and when not relieved by these means, the same remedies are applicable as are directed for oxen. (6953.)

7255. *A wind colic* will also sometimes affect sheep more from the quality than the quantity of what they eat; it is best relieved by an ounce of castor or salad oil with an ounce of gin.

7256. *Inflamed liver, blood rot, or hot yellows*, are liver affections, arising from fever settling in that organ; or from obstructed bile irritating it. Sometimes there are great marks of fever; and at others more of putridity; according to which, treat as may be gathered from ox pathology.

7257. *Jaundice* also now and then occurs, when refer to that disease in oxen. (6962.)

7258. *Dysentery, gall scour, braxy*, are all affections brought on by sudden changes of temperature, or of undue moisture acting with cold pasturage. It is often seen in sultry autumns; and, by a judicious observer, has been said to be peculiarly frequent in hogs or sheep of one year. Like other dysenteries it is frequent in sultry autumns. The above authority recommends, when its origin may be supposed to arise from a previous costive state, to remove the affected (as is practised by the store-masters of Scotland) into turnips. The general medical treatment does not differ from ox braxy. (6961.)

7259. *Scouring* is the diarrhœa of sheep, and in very hot weather soon carries them off. It should be early attended to, by abstracting the affected, and housing them. The *treatment* is seen under diarrhœa of oxen (6960.), which it closely resembles.

7260. *Pinning, tag-belt, break-share.* The two former are only the adhesion of the tail to the wool, and the excoriation brought on by diarrhœa; the latter is the diarrhœa itself, known to some by this term.

7261. *The rot in sheep* is also called *great rot*, and *hydropic rot*, &c.; but it is more popularly known by the single term of *rot.* Many causes have been assigned for it, as the Fascìola hepática, or fluke worm; some particular plants eaten as food; ground eating; snails, and other ingesta; but, as most of the supposed deleterious herbs have been tried by way of experiment, and have failed to produce the disease, so it is attributable to some other cause. Neither is there satisfactory reason to suppose that the fluke worm is the original cause of it, but a consequence, since we know that the biliary vessels of other animals, as horses, asses, rats, &c., often have them: and above all, because that they are not always present in the rotted subject. From long experience, and the almost invariable effect produced by a humid state of atmosphere, soil, and product, we are warranted in concluding these are the actual and immediate agents: perhaps the saturated food itself is sufficient to do it. The morning dew has been supposed equal to it. Bakewell, when his sheep were past service, used to rot them purposely, that they might not pass into other hands. This he always readily did by overflowing his pastures. But great differences of opinion exist as to the quantity, form, and varieties of moisture, productive of this fatal disease. It is said that land on which water flows, but does not stagnate, will not rot, however moist: but this is contradicted by the experience of Bakewell, who used merely to flood his lands a few times only to rot his sheep. It is also said that they are safe from rot on Irish bogs, salt marshes, and spring-flooded meadows, which experience seems to verify. It is also said that the very hay made from unsound land will rot; but this wants confirmation. When salt marshes are found injurious, it is only in years when the rain has saturated or rather super-saturated such marshes. That putrid exhalations unaccompanied with moisture can occasion rot wants confirmation also; for these commonly go together, and it is difficult to separate their effects. It is not, perhaps, the actual quantity of water immediately received by land, but the capacity of that land to retain the moisture, which makes it particularly of a rotting quality.

7262. *The signs of rottenness* are sufficiently familiar to persons about sheep. They first lose flesh, and what remains is flabby and pale; they also lose their vivacity. The naked parts, as the lips, tongue, &c., look livid, and are alternately hot and cold in the advanced stages. The eyes look sad and glassy, the breath is fetid, the urine small in quantity and high-coloured; and the bowels are at one time costive, and at another affected with a black purging. The pelt will come off on the slightest pull in almost all cases. The disease has different degrees of rapidity, but is always fatal at last. This difference in degree occasions some rotted sheep to thrive well under its progress to a certain stage, when they suddenly fall off, and the disease pursues the same course with the rest. Some graziers know this crisis of declension, as it has been called, and kill their sheep for market in the immediate nick of time with no loss. In these cases, no signs of the disease are to be traced by ordinary inspectors, but the existence of the flukes, and still more, a certain state of liver and of its secretions, are characteristic marks to the wary and experienced.

7263. *The treatment of rot* is seldom successful unless when it is early commenced, or when of a mild nature; a total change of food is the first indication, and of that to a dry wholesome kind: all the farina are good, as the meals of wheat, barley, oats, peas, beans, &c. Carrots have done good mixed with these:

broom, burnet, elder, and melilot, as diuretics, have also been recommended; but it is necessary to observe, that there is seldom any ventral effusion but in the latter stages of the complaint. As long as the liver is not wholly disorganised, the cure may be hoped by a simple removal of the cause, which has been shown to be a variable temperature, with excessive moisture of pasturage, which may also be aided by such remedies as assist the action of the biliary system; salt acts in this way, and thus salt mashes are good; salt may also be given in the water. Salt appears the principal ingredient in Flesh's patent restorative for sheep; for it states it to be composed of turpentine, sal ammoniac, turmeric, quicksilver, brimstone, *salt*, opium, alkanet root, bark, antimony, camphor, and distilled water; but of this medley none of the articles can be in sufficient quantity to prove useful but the salt. In the more advanced stages of the disease, when the liver has become materially affected, it is prudent to rub the belly of each sheep with half a drachm of mercurial ointment every other day for a week: give also the following, every morning: — Watery tincture of aloes, half an ounce; decoction of willow bark, four ounces; nitric acid, twenty-five drops.

7264. *The pelt rot, hunger rot, or naked disease*, is a variety of the former, but with this difference, that whereas the liver in the hydropic rot is principally affected; in this the whole of the chylopoietic viscera are injured; the mesenteric glands are always swollen and obstructed, and from thence arises the emaciation and unhealthy state of all the secretions, by which the wool becomes incapable of receiving nutriment, and falls off, leaving the body bare, and in the last stages the teeth and horns also loosen. Indifferent, unhealthy keep is a very common cause of this malady, and a contrary course of feeding is the best remedy when the disease has not gone on too long.

7265. *The scab, shab, ray, or rubbers*, are sometimes erysipelatous eruptions, and sometimes they are psoric or mangy ones. In the former instance they are universal and very red, occasioning a great heat and itching, and are thence called the *rubbers:* in such cases, nitre administered quickly relieves, with change of food. The eruptive scab is seldom cured without an external application; either of those directed for mange, lowered to half the strength, will relieve it at once. (See *Vet. Pharm.*)

7266. *Foot rot.* Sheep have a secretory outlet between the claws peculiar to them, which is liable to become obstructed; for which soaking in warm water and afterwards wrapping up the foot, having first dressed it with tar, is sufficient. The feet of sheep are also sometimes injured by long travelling, when the same treatment is proper. The most serious foot rot is that which is, in some instances, simply produced by a long-continued series of humid weather, which predisposes the feet to this injury. In others it appears to be both epidemic and endemial, and has been thought contagious. When the season has been unfavourable, house and soil under cover. The medical treatment consists in removing all diseased portions, and then dressing with the thrush paste, or foot-rot application (*Vet. Pharm.* 6554), and afterwards wrapping up from external exposure. Professor Stonig extols the following application: — Take two parts of tar, and one of oil of turpentine; which having mixed, one part of muriatic acid, known as spirit of salt, is to be added slowly, to which afterwards add four parts of blue vitriol, with which dress the affected feet. (*Journ. de Med. Vet. et Comp.*)

7267. *Staggers, gid, turnsick, goggles, worm under the horn, sturdy, watery head, and pendro*, are all popular terms for hydatids, or an animal now known as the Tænias glóbulus, which, by some unaccountable means, finds its way to the brain, and settles itself there, either in some of its ventricles, or more frequently on its substance. Their size varies from the smallest speck to that of a pigeon's egg, and the sheep it attacks are usually under two years old. These animals are likewise occasionally found in all the natural cavities of the body.

7268. *The appearances of cerebral hydatids* are, stupidity, a disposition to sit on the rump, to turn to one side, and to incline the head to the same while at rest. The eyes glare, and from oval the pupils become round. An accurate examination will now usually discover some softness at a particular part of the skull, generally on the contrary side to that on which the animal hangs the head: when no softness of the skull is discernible, the hydatid usually exists in some of the ventricles, and the destruction of the sheep is certain and quick, from the greater disturbance to the functions of the brain; but when it is situated on the surface, it sometimes requires many months to destroy; an absorption of the bone taking place as the hydatid increases, which produces the thinness in the skull opposite to the affected part.

7269. *This disease is not incurable*, as has been supposed, but it is only relieved by a manual operation. In France it has been successfully treated by the application of the actual cautery: a pointed iron, heated red-hot, is forced through the skin and skull, to the surface of the brain; the principal nicety of which is in penetrating the hydatid with the hot iron without wounding the brain itself. In England, some shepherds are very dexterous in *wiring*, which they do by thrusting a wire up the nostrils till it rests against the skull. In the passage of the wire the hydatid is usually ruptured; others elevate the skull (by means of a trephine, or even a knife) opposite to the softened portion, and extract the hydatid, if possible, whole, which a little care will effect, by drawing it away with a blunt pincer, gently moving it from side to side. Tapping is merely letting out the fluid contents of the hydatid by an awl, which is practised by some shepherds with success; and if the instrument be not thrust to far, the sheep is not injured: to avoid which, it is passed obliquely. A well hardened gimlet is a very proper instrument, with which the skull is easily penetrated, and an opening by the twisting of the instrument is made, sufficiently large in the hydatid itself, to discharge its contents, which is all that is sufficient to ensure its destruction, and which, if no other exists, is followed by immediate recovery. A French author states, that when he fed his sheep on cinquefoil he had less staggers than at any other time.

7270. *Frontal worms.* Sheep are observed to gather together, with their noses thrust inwards to avoid the attack of the Œstrus ovis, or fly, that lays its eggs on the inner margin of the nose, which having become hatched, the larva creep up into the frontal and maxillary sinuses, to the torment of the sheep, and sometimes to their speedy destruction. The Continental shepherds trepan an opening into these cavities, and effect their removal; but our shepherds have not succeeded in the operation.

7271. *Fluke worms* are a parasitic animal, found in the biliary sinuses, not only of the sheep, but of the horse, ass, goat, deer, &c., and whose existence is rather a consequence than a cause of morbidity.

7272. *Pining*, the *Vinquish* in Galloway (languishing), is a disease described by Mr. Hogg, the Ettrick shepherd, in a recent number of the *Quarterly Journal of Agriculture*, xi. p. 697. He says, " It is most fatal in a season of drought; and June and September are the most deadly months. If ever a farmer perceives a flock on such a farm having a flushed appearance of more than ordinarily rapid thriving, he is gone. By that day eight days, when he goes out to look at them again, he will find them lying, hanging their ears, running at the eyes, and looking at him like so many condemned criminals. As the disease proceeds the hair on the animal's face becomes dry, the wool assumes a bluish cast; and if the shepherd have not the means of changing the pasture, all those affected will fall in the course of a month." (*Quar. Jour. Ag. Highl. Soc.* vol. ii. No. XI.)

7273. *The diseases of lambs* are principally indigestion, producing sometimes colic, which is relieved as in sheep, and sometimes diarrhœa, to be likewise cured by the means detailed for them. Sheep are also liable to an eruptive disease which begins on the rump, gradually extending along the chine, and when it becomes more universal, it usually destroys. The cure consists in giving daily drinks of half a drachm of cream of tartar, and one drachm of sulphur, in four ounces of chamomile decoction. Anoint also with mild mercurial ointment and Turner's cerate in equal quantities. Lambs dropped in cold weather, or in wet situations, become paralytic: bathe in warm water, hand-rub and house, giving milk and bean meal.

Chap. VII.

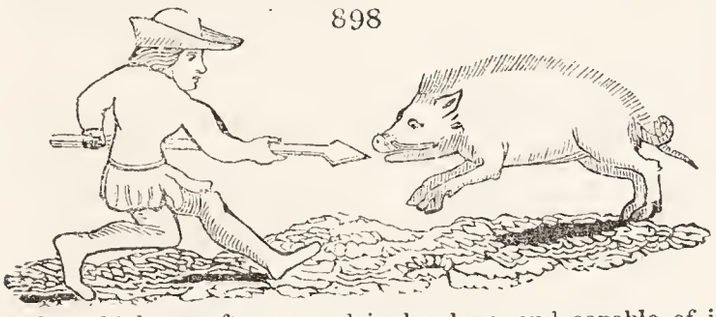
The Swine. — *Sús Scròfa* L. *Cochon*, Fr.; *Schwein*, Ger.; *Puerco*, Span.; and *Porco*, Ital.

7274. *Of swine* there are several species, but none in general domestication, or much used as food when taken wild, excepting the common sort, which includes the wild hog or wild boar, the original stock of our domestic breed, the European hog, and the Chinese hog.

7275. *The common hog* is found either in a wild or domestic state, in almost all the temperate parts of Europe and Asia; but it is not met with in the most northern parts of these continents. It is found in many parts of Africa. Mr. Pennant asserts, that the wild boar was formerly a native of this country, and hunted from the middle of November to the beginning of December; and it is asserted by Fitz-Stephens, that the vast forest which in his time grew on the north side of London, was the retreat of stags, wild boars, and bulls.

7276. *The wild boar* is still found in the forests of Germany, and in other parts of the Continent; and although now extinct in Britain, appears from ancient paintings (*fig.* 898.) to have been hunted by our ancestors. It feeds upon roots, acorns, and other vegetables: it is generally as large as the domestic hog, and is either dark grey or blackish, when full grown, and pale red or rusty brown when young. Between the bristles, next the skin, is a finer or softer hair of a woolly or curling nature. The snout is somewhat longer in proportion than that of the domestic animal; but the principal difference is in the superior length and size of the tusks, which are often several inches long, and capable of inflicting the most severe and fatal wounds. The hunting of the wild boar forms one of the principal amusements of the great in some parts of Germany, Poland, &c. and is a chase of some difficulty and danger, not on account of the swiftness, but the ferocity of the animal. Wild boars, according to Buffon, which have not passed the third year, are called by the hunters beasts of company, because previous to that age they do not separate, but follow their common parent. They never wander alone till they have acquired sufficient strength to resist the attacks of the wolf. These animals, when they have young, form themselves into flocks, and it is upon this alone that their safety depends. When attacked, the largest and strongest front the enemy, and by pressing all round against the weaker, force them into the centre.

898



7277. *Of the tame hog*, white is the most general colour; but other colours are often intermixed in various proportions. In some respects, the hog seems to form an intermediate link between the whole and the cloven-footed animals: in others he seems to occupy the same rank between the cloven-footed and digitated. Destitute of horns; furnished with teeth in both jaws; with only one stomach; incapable of ruminating; and producing at one birth a numerous progeny: the union of these faculties confers on the hog a remarkable peculiarity of character. He does not, like other animals, shed his fore teeth and put forth a second set, but retains his first set through life.

7278. *Hogs seem to enjoy none of the powers of sensation in eminent perfection.* They are said to hear distant sounds; and the wild boar distinguishes the scent of the hunter and his dogs, long before they can approach him. But so imperfect is their feeling, that they suffer mice to burrow in the fat of their backs without discovering any uneasiness, or appearing even to notice it. In their taste they show a singular degree of caprice. In the choice of herbs they are more delicate than any other herbiferous animal, yet devour the most nauseous and putrid carrion with more voracity than any beast of prey. At times they do not scruple to eat their own young; they will even mangle infants out of desperate voracity.

7279. *Hogs are remarkable for the smallness of their eyes:* hence a person whose eyes are very diminutive, and deep sunk in his head, is said to be pig-eyed. The form of the hog is inelegant, and his carriage is equally mean as his manners. His unwieldy shape renders him no less incapable of swiftness and sprightliness, than he is of gracefulness of motion. His appearance is always drowsy and stupid. He delights to bask in the sun, and to wallow in the mire. An approaching storm seems to affect his feelings in a very singular manner. On such an occasion, he runs about in a frantic state, and utters loud shrieks of horror. Hogs are infested with lice, and are subject to many disorders, such as the scurvy, scab, and scrofula. The sow brings forth in the beginning of the fifth month after conception, and she has often two litters in a year. She generally produces a numerous progeny at a birth; but her first litter is less numerous than those that follow. Hogs, when suffered to see the natural term of life, live from fifteen to thirty years. Their size and strength continue to improve till they are five or six years old.

7280. *Tame hogs are often very troublesome* in cultivated grounds, ploughing them up with their snouts, and thus entirely frustrating the labours of the agriculturist. Worms, the wild carrot, and other roots, are the objects of their search. The wild boar having a longer and stronger snout than the domestic variety, digs deeper, and continues his furrow nearly in a straight line. The inhabitants of America find the hog very beneficial in clearing their lands of rattlesnakes and other serpents, upon which he constantly preys, without apparently suffering any injury.

7281. *The hog is, in a very considerable degree, beneficial to mankind.* His flesh is pleasant, substantial, and nutritious. It affords numberless materials for the table of the epicure; among these is brawn, which seems peculiar to England. Pork takes salt better than the flesh of any animal, and is, in consequence, preserved longer, and always makes an important article in naval stores. The lard of the hog is essential to the cook and confectioner; it is used in various medical preparations, and is compounded by the perfumer into pomatums. The bristles are made into brushes, and are, moreover, of great use to the shoemaker. The skin is worked into coverings for pocket-books, and other articles.

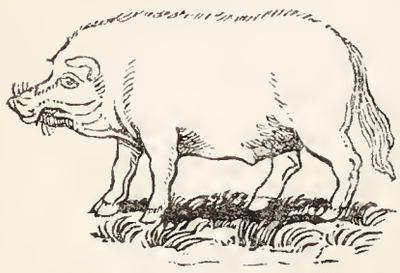
7282. *The hog in British farming* is in general viewed as a subordinate species of live stock, and chiefly valuable as consuming what would otherwise be lost. There are, however, swine husbandmen who keep large herds to advantage, especially millers, brewers, distillers, and dairymen, to whom they are an object of importance; and return, for the offal they consume, a greater weight of meat, according to some double the weight, than could be obtained from cattle. In those parts where potatoes are raised as a fallow crop, much beyond the demand for them as human food, — as is the case in particular in Ireland, and the west of Scotland, — the rearing and feeding of swine, the most of them sent to a distance in the state of bacon and pickled pork, is a branch of management on which great dependence is placed for the payment of their rents and other charges. The prolific nature of this animal, however, rendering it so easy to increase the supply beyond the demand, the price of swine flesh varies more than that of any other sort of butcher's

meat, and their culture can never be so much depended on by the general farmer as that of cattle or sheep. A writer in the *Farmer's Magazine* observes, that the swine are the only variety of granivorous animals that can be fed upon the offal of grain, or such articles as would otherwise go to waste about a farmsteading. Since the erection of threshing machines, a much greater quantity of light grain is beat from the straw, than was gained when the flail was employed. To use this extra quantity to advantage becomes an important concern to the occupiers of land; and this writer thinks that the using of it in raising and supporting swine is by far the most profitable mode of consuming an article, which, in other respects, is comparatively of little value.

Sect. I. *Varieties of the Common Hog.*

7283. *The domesticated European variety* of the common hog (*fig.* 899.) is too well known to require any description.

899



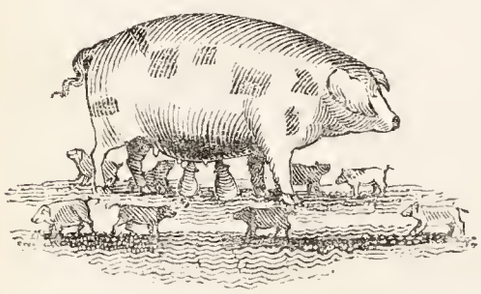
900

7284. *The Chinese hog* (*fig.* 900.) is distinguished fron the common, by having the upper part of its body almost bare, its belly hanging nearly to the ground; its legs are very short, and its tail still more disproportionately short. The flesh of this variety is whiter and more delicate. The colour is commonly a dark grey. It abounds in China, and is diffused through New Guinea, and many islands in the South Sea. The New Hebrides, the Marquesas, the Friendly and the Society Islands, possess this animal, and cultivate it with great care, as it is almost the only domestic animal of which they can boast. The varieties of hog cultivated in Britain, are partly the result of climate and keep in the European variety, and partly the effects of crossing with the Chinese. At the same time, it is only in particular districts that so much attention has been paid to this animal, as to give rise to any accurate distinction of breeds; and nowhere has it received any considerable portion of that care in breeding, which has been so advantageously employed on the other animals of which we have treated. Yet, among none of the varieties of those is there so great a difference as among the breeds of this species, in regard to the meat they return for the consumption of a given quantity of food. Some races can with difficulty be made fat, even at an advanced age, though fed from the trough with abundance of such food as would fatten any other animal; while others contrive to raise a valuable carcass out of materials on which no other creature could subsist.

7285. *The Chinese race*, according to Culley, has been subdivided into seven varieties or more; and it would be easy to point out twice the number of as prominent distinctions among the sorts in the third class. But such an affectation of accuracy is as useless as it would be tedious. One general form, approaching to that of other animals kept for their carcass, ought certainly to be preferred; and the size, which is the other distinguishing characteristic, must be chosen with a view to the food provided for their maintenance, and not because it is possible to raise the individuals to a great, and probably, unprofitable weight. The fineness of the bone, and the broad, though also deep, form of the chest, denote in this, as in the other species, a disposition to make fat with a moderate consumption of food; and while it may be advisable to prefer the larger breeds in those places where bacon and flitches are in most demand, the smaller breeds are most esteemed for pickling, and are, beyond all doubt, most profitable to those farmers who allow them little else than the range of the farm-yard and the offals of the kitchen.

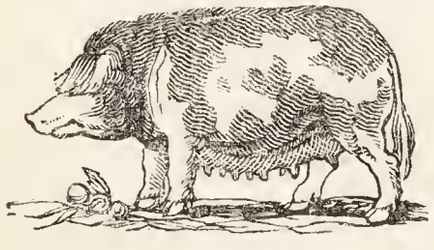
7286. *The Berkshire breed* (*fig.* 901.) is distinguished by being in general of a tawny, white, or reddish colour; spotted with black; large ears hanging over the eyes; thick, close, and well made in the body; legs short; small in the bone; having a disposition to fatten quickly; and when well fed, the flesh is fine. Berkshire has been long famous for its breed of swine, which, as it now stands, is, in the third class, in point of size, excellent in all respects, but particularly as a cross for heavy, slow-feeding sorts. It has extended itself from the district from which it takes its name over most parts of the island; is the sort mostly fattened at the distilleries; feeds to a great weight; is good for either pork or bacon; and is supposed by many as the most hardy, both in respect to their nature and the food on which they are fed.

901



7287. *The Hampshire breed* (*fig.* 902.) are large, longer in the body and neck, but not of so compact a form as the Berkshire; they are mostly of a white colour, or spotted, and are well disposed to fatten, coming up to a great weight when properly managed in respect to food. Lawrence says they are generally dark spotted, some black, of a longer and flatter make than those of Berks, ears more pointed, head long and sharp, resembling the Essex.

902

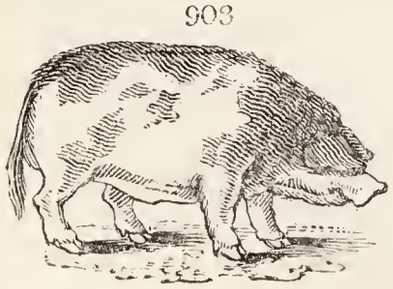


7288. *The Shropshire breed* is another large breed of hogs, which are found valuable where the keep is in sufficient abundance for their support. They are not so well formed as those of the Berkshire kind, or equal to them in their disposition to fatten, or to be supported on such cheap food. The standard colour of this breed is white, or brindled: Shropshire has long bred stores for the supply of the London feeders, and of the Essex farmers, who thus turn their clovers to the most profitable account.

7289. *The Gloucestershire breed* is likewise a larger breed, but inferior to either of the above, being tall and long in shape, and by no means so well formed. The colour is in general white. It has two wattles hanging from the throat.

7290. *The Herefordshire breed* (*fig.* 903.) is also a large useful breed, but perhaps without possessing any advantage over those that have been described above.

903



7291. *The Rudgwick breed* is a large kind of swine, which the author of the *Survey of Middlesex* says is the largest in the island, met with at the village of that name, on the borders of Sussex and Surrey. They feed to an extraordinary size, and weigh, at two years old, nearly double or triple the usual weight of other sorts of hogs of that age. As large breeds pay the farmers best in many cases, such a breed deserves to be attended to in the system of hog management.

7292. *The large spotted Woburn breed* is a breed introduced by the late Duke of Bedford, being large in size and of various colours. It is a hard, well formed, prolific sort, rising quickly to a large weight.

7293. *The Wiltshire breed* is a long-bodied, low hog, hollow about the shoulder, and high on the rump, middling large pointed ears, round bone, light in colour.

7294. *Yorkshire breed.* This, in the old breed, was probably the worst large variety we had; extremely long-legged and weak-loined, their constitution not of the soundest, and bad sty-pigs in the winter season; they were yet quicker feeders than some of the superior breeds. They have been improving some years from the Berkshire cross, but are still inferior to the north-western stock, rendering a less price at market.

7295. *The Northamptonshire breed* was formerly a handsome, light-eared, white, deep-sided pig, with middling bone, and quick of proof: the breeders have since tried the new Leicester.

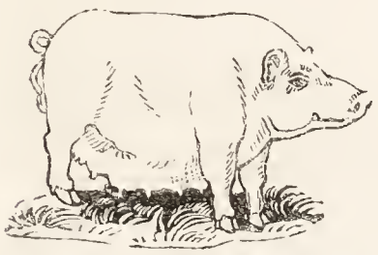
7296. *The Leicestershire breed* is, in the original stock, large, deep, and flat-sided, light-spotted, with rather handsome head and ears. The Bakewell variety has much merit.

7297. *The Lincolnshire breed* was formerly light-coloured and white, like those of Northamptonshire, many of them having curled and wooly coats. They are middle-sized, quick-proving pigs.

7298. *The Norfolk breed* is a small, short, up-eared porking sort, various in colour, white, bluish, striated, generally an inferior kind, which it would be to the interest of that great corn county to improve; they are, however, of a thin-skinned, quick-proving kind. But in the vicinity of Lynn, and generally on the Lincoln side of the county, there is a larger spotted variety of very good form and quality, which should be encouraged.

7299. *Suffolk breed.* (*fig.* 904.) This is a small, delicate, white pig, which has for many years had great reputation; and at this time there is not only a strong prejudice in their favour in their own county, but they have many advocates out of it. They are shorter and more pug-formed than the Norfolks, and by their dish-face, and pendent belly, it may be supposed that the variety proceeded originally from the white Chinese. Some of the Suffolks are very handsome, and very regularly shaped.

904



7300. *The Essex breed* are up-eared, with long sharp heads, roach-backed, carcasses flat, long, and generally high upon the leg, bone not large, colour white, or black and white, bare of hair, quick feeders, but great consumers, and of an unquiet disposition.

7301. *The small, white, English breed* is met with in many districts; it is of a white colour, thick, compact, and well made in the body; short in the leg; the head and neck well formed, and the ears slouching a little downwards. It is well disposed to fatten, and perfectly hardy. It prevails much in the northern districts.

7302. *Swing-tailed breed.* This is a useful sort of the smaller kind of hogs, hardy in its nature, and of considerable weight in proportion to its size.

7303. *There are many other varieties* and subvarieties in England which it is unnecessary to notice here. Donaldson remarks, that the Berkshire and Hampshire hogs are the largest; but that it is most probably from the Berkshire stock that the greatest number of the varieties of the country have sprung.

7304. *Of the Highland breeds*, that of the Hebrides, supposed by Dr. Walker to be the original, is of the smallest size, neither white nor yellow, but of a uniform grey colour, and shaggy, with long hair and bristles; they graze on the hills like sheep; their sole food is herbage and roots, and on these they live the whole year round, without shelter, and without receiving any other sustenance. In autumn, when they are in the best order, their meat is excellent, and without any artificial feeding; but when driven to the low country, they fatten readily, and rise to a considerable bulk. (*Walker's Hebrides*, vol. ii. p. 17.) In the Orkney islands they are commonly of a dark red or nearly black colour, and have long bristles, with a sort of coarse wool beneath them.

7305. *The old Irish breed* are a long-legged, thin-sided, lank, haggard, unprofitable sort of swine; but where they have been crossed with the Berkshire, they are considerably improved.

Sect. II. *Breeding and Rearing of Swine.*

7306. *In the breeding* of swine, whatever be the variety, the most perfect and best formed boar and sow should be chosen, and a due regard paid to their age, time of copulation, period of gestation, farrowing, castrating or spaying, and weaning.

7307. *In choosing the boar and sow*, regard must be had to their size, as well as perfection of form. Where food is abundant, or the object of the progeny is the production of bacon and flitches, the larger breeds, as already observed, are to be preferred: but where food is scarce or uncertain, as in the case of the cottager's stock, or rearing for suckled pork, fresh pork, or pickled pork, the smaller breeds, as the Berkshire, are to be preferred. A breeding sow ought to have a large capacious belly, and not to be too much inclined to obesity. To check this tendency, some allow them to breed five times in two years.

7308. *The age of the boar* should not be less than a year, as he will then be at his full growth; nor that of the female less than ten months. They may be used in breeding for three or five years, and then fed off for the shambles.

7309. *The period of gestation* in swine is about four months, so that two litters may be easily produced in a year, five in two years, or ten in four years.

7310. *The best times for copulation* are November and May; because then the progeny are brought forth in mild weather, and when green food is to be had. They should not be allowed to farrow in winter, as young pigs are exceedingly tender, and can with difficulty be preserved in very cold weather; nor at a time when food is scarce, as is generally the case upon corn farms in summer, if the stock of them is large. When the object is suckled pigs for the shambles, copulation should be so contrived as to produce parturition at all seasons.

7311. *The usual produce* is from about eight to ten or twelve pigs in the large but more in the smaller breeds, which in general bring the greatest number, and the most early. Twenty swine are estimated to bring at an average seven pigs and a half each for their first litter; but the number varies much, and many young pigs are lost soon after their birth by the unkindness of their dam, and by casualties, to which they are more exposed than most other young animals.

7312. *The pregnant swine* should be separated from the herd some time before she is expected to farrow, carefully watched, and littered with a small quantity of dry short straw. Too much straw is improper, both at the time of farrowing, and for a week or two afterwards, as the pigs are apt to nestle beneath it unperceived by the sow, and are thus in danger of being smothered when she lies down. A breeding sow should be well fed, particularly when nursing; and it is advantageous early to accustom the pigs to feed from a low trough on milk or other liquid food, mixed with meal or bran. Such of the pigs of both sexes as are not to be kept for breeding are usually *castrated* or *spayed* when about a month old, and the whole may be *weaned* at the end of six or seven weeks.

7313. *The food allowed to growing swine* depends in almost every case upon the circumstances of their owners; for, as already observed, it is a doubtful point whether swine will pay when all their food both in rearing and fatting is to be purchased. The cottager's pig must be contented with the scanty offals of his kitchen and of his dairy, the produce generally of a single cow; towards the end of autumn a few potatoes are added for the purpose of preparing it for the slaughter, and perhaps a little meal is mixed with boiled potatoes for a week or two before. Such pigs, however, often thrive amazingly, make themselves moderately fat, and form a most valuable addition to the winter stores of their owners. In the south-eastern

counties of Scotland, the hinds or married ploughmen are commonly allowed to keep a pig each, which they feed in this manner, and from which their families derive much benefit at very little expense. Near woods, acorns, mast, and other seeds, as well as some roots and vermin, afford excellent nourishment. On many corn farms, the chief, and not unfrequently the only, dependence of swine is on the straw-yards. The sweepings of the barn floor, corn left upon the straw, and oats found among the dung of horses, with a share of the turnips given to the cattle in winter, and of the clover in summer, afford ample subsistence to swine, in the proportion, perhaps, of one to every five or six acres under corn, clover, and turnips. The kitchen and dairy give some assistance to pigs newly weaned, and also to such as are soon to be slaughtered. A great many are killed when about a year old, that have never been fed at any expense that can be estimated. A few pigs, if of a good breed, will always be moderately fat at that age with the run of the straw-yard, and their flesh is of an excellent quality.

7314. *To prevent swine from digging* in the soil, the best method is to cut the two strong tendons of their snouts with a sharp knife, about an inch and a half from the nose. This may be done with little pain, and no prejudice, to the animal when about two or three months old. The common practice of restraining them by rings fixed in the snout is painful and troublesome; they must be replaced as often as they give way, and that happens so frequently that rings afford but little security against this nuisance.

Sect. III. *Fattening of Swine.*

7315. *The following system of rearing and fattening swine on an arable farm* is recommended by a writer in the *Farmer's Magazine.*

7316. *Upon a tillage farm* consisting of three hundred acres, whereof two hundred are kept under the plough, he is of opinion that a considerable sum may be annually gained from keeping swine, were the management arranged in a systematic manner. One main advantage of such a branch of rural economy arises from little or no capital being required to carry it on, while the trouble and outlay attending it scarcely deserve notice. With the addition of one acre of broad clover, and one acre of tares, for the summer and autumn months, and the like extent of ground for turnips and yams during the winter and spring months, this stock of swine may be amply supported.

7317. *Were two breeding sows* kept on a farm of the size mentioned, and their produce reared by the farmer, it may be calculated that forty swine, weighing seven or eight stone each, would be annually fed off, in the month of January and February each year, the time when pork is most in demand. That such a number of swine can be supported and fed upon the offals of a three-hundred-acre farm, and the other auxiliary articles specified, may be pronounced a certain fact.

7318. *The breeds* he recommends are the hardy smaller sized varieties; because he has found that such breeds will thrive and grow fat where larger and finer breeds would starve.

7319. *The mode of management* is, that a boar and two good sows of a proper age should constantly be kept, and that one young sow shall annually be reared, in order to supply the others when they pass maturity. He would cast off the oldest sows, *i. e.* feed them when they arrive at three years of age, which, of course, would cause four sows to be in hand at one time. These annually would produce more than the forty pigs which are to be held on; but the remainder might be sold as they are weaned, there being a regular and steady demand in most parts of the country for young pigs. He has for a number of years kept a stock of swine in the way recommended. They go at large in the court or yard belonging to the farm, and receive a feeding of offal grain in the morning, and of yams or turnips in the evening; and the meat fed in this way has constantly drawn the highest price. They get also the dish-washings of the house, any milk or whey that remains unconsumed, and have the dunghill to roam upon, where perhaps more food is to be gathered, especially if the horses are fed upon unbroken grain, than is commonly imagined. It will readily be concluded that, under this mode of management, the latter end of summer and the harvest months is the critical period for carrying on a stock of swine. During these months little threshing goes forward, and horses seldom receive any corn for aliment; hence all that can be consistently attempted is to keep the animals in a growing state, and prepare them for fattening cleverly, when food of a more nutritious quality can be procured. Clover and tares will do this effectually, the last particularly so when in a podded state. Turnips can also be got by the end of September; and it must be recollected, that through the summer months a considerable quantity of milk and whey can be given, upon which swine will be found to thrive heartily. He does not know a more beneficial stock upon a farm than swine, so long as the quantity kept is in proportion to the extent of offals about the premises. The other articles recommended are merely meant to render the consumption of offals more beneficial, to carry on the stock at periods when such offals are scarce. The charge of attendance is very small; indeed, the benefit gained by the dunghill will more than compensate the expenses incurred. To make as much profit from cattle or sheep requires a great advance of money; but in the article of swine hardly any is necessary, while the most part of the articles consumed cannot, in any other way, be converted to such beneficial purposes.

7320. *In fattening for bacon and flitches*, the larger breeds are chosen; and in breweries, distilleries, oileries, and dairies, fed on grains, oil-cake, and milk; but where arable farmers keep swine of this description, as is the practice in some of the western counties, the method is to rear chiefly on raw potatoes and Swedish turnips, and to fatten on these roots, boiled or prepared by steam, with a mixture of oat, barley, or bean and pea meal. Their troughs should be often replenished with a small quantity of food at a time, and kept always clean; and their food changed occasionally, and seasoned with salt. If proper care be taken, says a late writer, a feeding pig should not consume more than six Winchester bushels of oats made into meal. It ought to be shelled before it is ground, the same as for family use, but need not be sifted. (*Henderson's Treatise on Swine*, p. 26.)

7321. *In fatting sucking pigs*, all that is requisite is to keep the mother well lodged and nourished. Weaned pigs when to be fatted are kept constantly on whey, or skim-milk or buttermilk, with frequently an addition of peas or beans, or barley-meal. Such good keeping not only makes them increase rapidly in size, but renders them fit for the butcher at an early age. Swine are sold to the butcher at different ages, and under different names; as pigs when a few weeks old; as porkers at the age of five or six months; and as full grown hogs at from eighteen months to two years old. The young pigs are commonly roasted whole; the porkers are used as fresh or pickled pork; and the full grown hogs are for the most part converted into ham and bacon. The demand for porkers, which for London in particular is very great, and which continues almost throughout the year, is chiefly supplied from the dairies within reach of that metropolis.

Sect. IV. *Curing of Pork and Bacon.*

7322. *The curing or pickling of pork* is carried on to a considerable extent at many of our sea-ports.

7323. *The carcass is cut in pieces*, and packed in cases or kits made for the purpose, containing from one to two hundred weight. Salt is dissolved in water till the mixture be strong enough to swim an egg; it is then boiled, and, when cold, poured upon the pork; when the end of the cask is fixed in, the article is ready for being sent to market. Henderson, a late writer, has given particular directions for the curing of bacon, founded upon a long course of experience, which, therefore, deserves to be more generally known.

7324. *The curing of bacon* is thus described by Henderson, after much experience: —

7325. *After the carcass* has hung all night, lay it upon a strong table, or bench, upon its back; cut off the head close by the ears, and cut the hinder feet so far below the hough as will not disfigure the hams, and leave plenty of room to hang them by; then take a cleaving knife, and if necessary, a hand mallet, and divide the carcass up the middle of the back-bone, laying it in two equal halves: then cut the ham from the side by the second joint of the back-bone, which will appear on dividing the carcass; then dress the ham, by paring a little off the flank or skinny part, so as to shape it with a half round point, clearing off any top fat that may appear; the curer will next take off the sharp edge along the back-bone with his knife and mallet, and slice off the first rib next the shoulder, where he will perceive a bloody vein, which he must take out; for if it is left in, that part is apt to spoil. The corners must be squared off where the ham was cut out.

7326. *In killing a number of swine*, what sides you may have dressed the first day lay upon some flags or boards, piling them up across each other, and giving each pitch a powdering of saltpetre, and then covering it with salt: proceed in the same manner with the hams, by themselves, and do not omit giving them a little saltpetre, as it opens the pores of the flesh to receive the salt, and besides, gives the ham a pleasant flavour, and makes it more juicy. Let them lie in this state about a week, then turn those on the top undermost, giving them a fresh salting: after lying two or three weeks longer, they may be hung up to dry in some chimney, or smoke-house; or, if the curer chooses, he may turn them over again without giving them any more salt, in which state they may lie for a month or two without catching any harm, until he has convenience for drying them. Henderson practised for many years the custom of carting his flitches and hams through the country to farm-houses, and used to hang them in their chimneys and other parts of the house to dry, some seasons, to the amount of five hundred carcasses: this plan he soon found was attended with a number of inconveniences, and therefore he invented a smoking-house.

7327. *Henderson's smoking-house* is about twelve feet square, and the walls about seven feet high: one of these huts requires six joists across, one close to each wall, the other four laid asunder, at proper distances. To receive five rows of flitches, they must be laid in the top of the wall; a piece of wood strong enough to bear the weight of one flitch of bacon must be fixed across the belly end of the flitch, by two strings, as the neck end must hang downwards: the piece of wood must be longer than the flitch is wide, so that each end may rest upon a beam; they may be put so near to each other as not to touch; the width of it will hold twenty-four flitches in a row, and there will be five rows, which will contain one hundred and twenty flitches; as many hams may be hung at the same time above the flitches contrived in the best manner we can. The lower end of the flitches will be within two and a half or three feet of the floor, which must be covered five or six inches thick with sawdust, and must be kindled at two different sides; it will burn, but not cause any flame to injure the bacon. The door must be kept close, and the hut must have a small hole in the roof, so that part of the smoke may ascend. That lot of bacon and hams will be ready to pack up in a hogshead, to send off in eight or ten days, or a little longer, if required, with very little loss of weight. After the bacon is salted, it may lie in the salt-house as described, until an order is received, then immediately hang it up to dry. Henderson found this smoke-house to be a great saving, not only in the expense and trouble of employing men to cart and hang it through the country, but it did not lose nearly so much weight by this process.

7328. *In the disposal of bacon*, whatever is shipped for the London market, or any other, both bacon and hams, must be packed into a sugar hogshead, or something similar, to hold about ten hundred weight. Bacon can only be cured from the middle of September until the middle of April. (*Henderson's Treatise on Swine*, p. 39.)

Sect. V. *Diseases of Swine.*

7329. *Swine are subject to various diseases*, but according to Lawrence they are not easily doctored.

7330. *They are subject*, he says, to pox or measles, blood striking, staggers, quincy, indigestion, catarrh, peripneumònia, and inflammation of the lungs called heavings. When sick, pigs will eat, and they will take medicine in their wash; when they will not eat, there is no help for them. As aperients, cleansers, and alteratives, sulphur, antimony, and madder are our grand specifics, and they are truly useful. As cordials and tonics, treacle and strong beer, in warm wash, and good peas and pollard. In the measles, sulphur, &c. and, if the patient require it, give cordials now and then; in staggers, bleeding, fresh air, and perhaps nitre; in catarrh, a warm bed, and warm cordial wash; and the same in quincy, or inflammation of the glands in the throat. If external suppuration appear likely, discharge the matter when ripe, and dress with tar and brandy, or balsam. The heavings or unsoundness of the lungs in pigs, like the unsoundness of the liver in lambs, is sometimes found to be hereditary; there is no remedy. This disease in pigs is often the consequence of colds from wet lodging, or of hasty feeding in a poor state; in a certain stage it is highly inflammatory, and without remedy. Unction with train oil, and the internal use of it, have been sometimes thought beneficial.

Chap. VIII.

Of the Goat, Rabbit, Hare, Dormouse, Deer, and various other Animals, that are or may be subjected to British Agriculture.

7331. *The goat* (*Càpra Æ'gagrus L., fig.* 905.) is a native of many mountainous parts of Europe, Africa, Persia, and India: he is domesticated throughout Europe, feeds on branches of shrubs, on lichens, hemlock, &c.; is seldom destitute of horns, of active habits like the deer, treacherous, petulant, roaming, and lascivious; gravid four months and a half, brings from one to two at a birth, and lives ten or twelve years. The female will allow itself to be sucked by the young of various other animals; and a foal which has lost its mother has been seen thus nourished by a goat, which, in order to facilitate the process, was placed on a barrel. The attachment between the nurse and foal appeared strong and natural: in its internal structure, it ex-

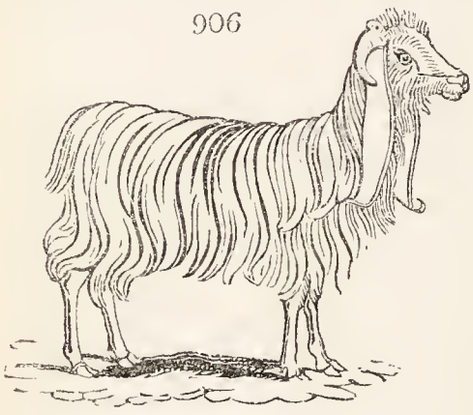
905

tremely resembles sheep, but is far superior to them in alertness, sentiment, and intelligence. The goat approaches man without difficulty, is won by kindness, and capable of attachment. The extremely unpleasant odour attending these animals is supposed to be beneficial, and horses appear so much refreshed by it, that a goat is, on this account, often kept in the stables of the great. It is a singular local peculiarity, that in Angora only, the animals of the *Capra*, *Ovis*, and *Lepus* tribe, have long soft silky hair.

7332. *The Angora goat*, a native of Turkey, is chiefly valued for its exquisitely fine hair down, which grows under its coarse hair, and of which the Cashmere shawls are manufactured. The down is obtained by gently combing them. A considerable number of this breed were imported into France from Persia, in 1819, and stationed at St. Omers, with a view to their increase, and the establishment of the shawl manufacture. The kids of this flock are said to be abundantly covered with down and hair, and superior in strength and appearance to indigenous French kids of the same age. It is a common opinion, that the down of this goat degenerates when the animals are removed from the pasturage of Angora; but this is likely in part to arise from the neglect of cleaning and washing them, which at Angora is so assiduously attended to. By a late Report of M. Terneaux to the Paris Agricultural Society, the French Angoras have increased in number, and prosper equally with the native variety.

7333. *The Syrian goat* (*fig.* 906.) is remarkable for its pendulous ears, and is common throughout the East, in Egypt, and on the coast of Africa. It has likewise been introduced into Sicily, but can only be kept in health in very warm situations.

906



7334. *The Chamois goat*, a native of Switzerland, is a species of antelope, and will be afterwards noticed.

7335. *The goats of Wales* are generally white, and are both stronger and larger than those of other hilly countries. Their flesh is much used by the inhabitants, and often dried and salted, and substituted for bacon. The skins of the kids are much valued for gloves, and were formerly employed in furniture, when painted with rich colours, of which they are particularly capable, and embellished with ornamental flowers, and works of silver and gold. The goat may be of some advantage in rocky barren countries, where nothing else can get a support for life. They will climb the steepest rocks, and there browse upon briers, heath, and shrubs of various kinds, which other creatures will not taste of. They will feed on grass in pastures; but, as they love browsing on trees much better, great care should be taken to keep them from valuable plantations.

7336. *The produce of the goat*, from which advantage is chiefly obtained, is the milk, which it yields in large quantities, and which is accounted the best milk of all animals. They mix this and cows' milk together in some parts of the kingdom, and a very valuable cheese is made from it. Besides this, the kids or young goats are very fine food, and the best kinds bring forth two or three at a time, and that twice a year.

7337. *Goat's hair* is also valuable; it may be sheared as the wool from sheep, and is excellent for making ropes that are to be used in the water, as they will last a great while longer than those made in the common way. A sort of stuff is also made of it in some places.

7338. *The suet of the goat* is also in great esteem, and many of the inhabitants of Caernarvonshire kill them merely for the sake of their fat, which makes candles of a superior quality to the common. Of their horns excellent handles are made for tucks and penknives. The skin is peculiarly well adapted for the glove manufactory, especially that of the kid, as it takes a dye better than any other skin. The old skin is also of great use, being preferred to that of the sheep, and the flesh affords a cheap and plentiful provision in the winter months, particularly when the kids are brought to market. The haunches of the goat are frequently salted and dried, and supply all the uses of bacon: this by the Welsh is called *coch yr wden*, or hung venison.

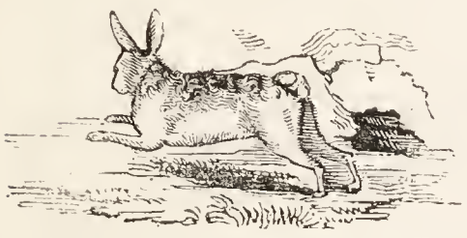
7339. *The kind of goats for keeping to advantage* should be chosen in this manner: — The male should have a large body, his hair should be long, and his legs straight and stiff; the neck should be plain and short, the head small and slender, the horns large, the eyes prominent, and the beard long. The female should have a large udder, with large teats, and no horns, or very small ones. Goats should be kept in flocks, that they may not straggle; and they should have good shelter both in summer and in winter, the heat and cold being both prejudicial to them, and coupled in December. They should have no litter in winter, but only a paved floor kept clean. The kids are to be brought up for the table in the same manner as our lambs are.

7340. *The Cashmere shawl goat* has been successfully introduced into England, by C. T. Tower, Esq. of Weald Hall, Essex; and as that gentleman by this time must have some of his flock to dispose of, we think their introduction among cottagers for their wool, and also, as suggested (*Gard. Mag.* vol. v. p. 532.), for their milk, a fair subject for some of our female readers to speculate on. This variety of the common goat, or probably it may be a distinct species, is a fine-looking animal, and would be very ornamental in a park, on a ruin, on the roof of a cottage, or in a churchyard. It would also be very pleasant to have a home-made Cashmere shawl. We shall therefore give all the information we can on the subject from Mr. Tower's account, as published in the last volume (xlvi.) of the Transactions of the Society of Arts. The Cashmere goat was brought from Persia to France during the time of Napoleon, and under his patronage, by the celebrated M. Terneaux, in 1823. Mr. Tower, happening at that time to be in Paris, purchased four of them, two males and two females, and succeeded in conveying them safely to his residence in Essex. The soil of the park at Weald Hall, where they have been kept ever since, is moist, and the situation is much exposed. The animals have, nevertheless, continued in health and multiplied rapidly; so that his present flock consists of twenty-seven, including the four original ones. Of these latter a polled female, which was old when purchased by him, has every year produced at least one kid, and has twice had twins. Those individuals of which the horns cross are in Persia esteemed the best; and one of Mr. Tower's last year's kids has this peculiarity. They show no impatience of cold, and are very healthy, requiring only the occasional shelter of a shed, in very rough weather. In spring, summer, and autumn, they graze like sheep; and during winter have been fed with hay, and refuse vegetables from the garden; but their favourite food is gorse (*Ulex europæa*), which they devour eagerly, without being annoyed by its prickles. They damage young plantations, but not more than other goats or deer will do. They breed very early; three of Mr. Tower's goats this year produced kids before they were themselves a twelvemonth old. A few produce brown wool; but that of far the greater proportion of the goats is white, and this latter is more valuable than the other. The coat is a mixture of long coarse hair, and of short fine wool: this latter begins to be loose early in April; and is collected easily and expeditiously by combing the animals two or three times, with such a comb as is used for horses' manes. A good deal of the long hair comes off at the same time, but the manufacturer has found no difficulty in separating it. The produce of a male is about four ounces, and of a female about two ounces. Two pounds of wool as it comes off the goat's back may be estimated to make one shawl, fifty four inches square. It will therefore require ten goats, male and female, to furnish materials for one shawl. Mr. Tower has this year had three shawls made of his wool,

one of which was examined by the committee of manufacturers. The yarn was spun by Messrs. Pease, of Darlington, and was woven by Messrs. Miller and Sons, of Paisley. Mr. Tower's shawl was compared with one made in Scotland, of French shawl-goat wool, to which it was evidently far superior. It was also compared with a shawl of M. Terneau's own make; and was considered by very competent judges to be superior to this also. (*Trans. Soc. Arts*, vol. xlvi. as quoted in *Gard. Mag.* vol. vii.)

7341. *The rabbit* (*Lèpus Cunículus L., fig.* 907.) is indigenous in most temperate climates, but not so far to the north as the hare.

907



7342. *In a wild state* it forms long winding burrows; keeps its hole by day; feeds morning, evening, and night on vegetables and grain; is the prey of hawks, badgers, polecats, and caught by ferrets; gravid thirty days, brings from four to eight young, five, and sometimes as many as seven times a year. The varieties common in Britain are the white, black, variegated, and silvery grey. The hare and rabbit are distinguished from each other externally, chiefly by the proportional length of the hind legs to that of the back, and in the ears of the hare being longer, and those of the rabbit shorter than the head. The haunts of rabbits are called warrens; which are most numerous in the sandy soils of Norfolk and Cambridgeshire. They sometimes extend to 2000 or 3000 acres, and many have been hitherto considered to pay better in that state than in any other. Arthur Young, however, has shown in his *Survey of Lincolnshire*, that though a rabbit warren may afford a high interest on the capital of the occupier, yet the rent it affords to the owner of the soil is less than would ultimately be obtained by planting or breaking up, and laying down with chiccory or some other suitable herbage plant. In the mean time, as they continue to exist, and are subjected to a kind of management, we shall submit a short outline of it under the heads of extent, soil and situation, fencing, stocking, breeding, rearing, and produce. Afterwards we shall take a view of the mode of managing rabbits in hutches.

7343. *The extent of warrens* varies from 100 to 3000 acres, but a convenient size is considered to be 1500 or 2000 acres. The soil and situation should be dry, sandy, warm, and poor; rich grass or herbage being found to produce a scouring, which sometimes carries off the greater part of the stock. Warrens are generally enclosed with walls either of stone or turf, an essential addition to the latter being a coping of furze, reeds, or stiff straw. Paling is used in some places, but a brook is found insufficient, as the rabbits have been found to swim across.

7344. *Warrens are often stocked* by nature, and all that art has to do in that case is to protect the produce; but in some cases they are formed on ground where rabbits do not exist naturally, or where they exist it is considered desirable to change the breed.

7345. *In stocking a warren*, whether the surface be flat or hilly, artificial burrows are sometimes made, to reconcile the rabbits to the ground, and to preserve them from vermin, until they have time to make their own burrows. These are bored with an auger of a diameter large enough to make a burrow of a sufficient width. In a level warren, these augers may, from time to time, be found useful in forming such holes. They, however, in most cases, are capable of making burrows for themselves. Some warren lands are stocked in the proportion of three couple to an acre; while in others it is in a considerably larger proportion. In Lincolnshire, one buck or male rabbit is said to be sufficient for one hundred does, or females; but this is certainly a much larger proportion than in most other districts. On the wold warrens of Yorkshire, according to Marshal, one male is considered sufficient for only six or seven females, and the nearer they can be brought to that proportion the greater the stock of young ones that may be expected, it being the nature or economy of the males to destroy their young, especially when the proportional number is too great.

7346. *The varieties employed as stock for warrens* are the common grey and silver grey breeds: the former of which is found to be considerably more hardy and much better for the purposes of food; but the latter has greatly the advantage in the value of the skin. Till lately, the common grey rabbit, probably the native wild rabbit of the island, was the only species. At present, the silver-haired rabbit is sought after, and has, within the last few years, been introduced into most warrens. The skin of the grey rabbit is cut; that is, the wool is pared off the pelt, as a material for hats: whereas, that of the silver-haired rabbit is dressed as fur; which, it is said, goes principally to the East Indies. The colour is a black ground, thickly interspersed with single white hairs. The skins of this variety sell for about four shillings a dozen more than those of the common sort; a sufficient inducement for propagating it in preference to the grey breed.

7347. *The rabbit begins to breed at an early age*, as at eight, ten, or twelve months, going only about thirty days with young, the young being little more than three weeks old before they appear from the burrows, during which time they are suckled twice in the day by the mother. It is, therefore, evident that they may breed seven times in the course of the year under good keep, as the does take the buck almost immediately after producing their young. In warrens that are enclosed it is, however, said that they seldom breed more than two or three times in the year.

7348. *The management of a rabbit warren* is a very simple business. Birds and beasts of prey are to be kept off by taking them in traps; dogs and cats kept off, and rats, moles, mice, and other vermin destroyed if abundant or troublesome. Man himself is to be guarded against in some situations. Additional food is to be supplied in the winter season, when the weather is severe, such as fine green hay, saintfoin, clover, turnips, and others of the same sort, which must be distributed over the warrens. It is supposed that turnips answer the best in deep snows, as the rabbits can discover them by the scent. This sort of food is given in the quantity of two or three large cartfuls to a thousand couple per day, and one load of hay in the same time during a storm. It is likewise sometimes the practice to distribute billets of new cut ash boughs, gorse or whins, and other similar woods in the warrens, the bark and other parts of which is eaten, by which the proportion of hay is lessened in a considerable degree. In great snows it is necessary to clear it away from the ditches or fences to prevent the rabbits from getting over them.

7349. *This sort of stock is mostly taken by nets or traps*, set in the form of a fold between the places where they run and those where they feed, the rabbits being hunted into them as they return from feeding. Sometimes they are taken by ferrets and terriers. The wold warreners, Marshal says, have three ways of catching their rabbits; with fold nets, with spring nets, and with types, a species of trap. The fold nets are set about midnight, between the burrows and the feeding grounds, the rabbits being driven in with dogs, and kept enclosed in the fold until morning. But the spring net when used is, he believes, generally laid round a haystack or other place where rabbits collect in numbers. It is added, that the trap is a more modern invention. It consists of a large pit or cistern, formed within the ground and covered with a floor, or with one large falling door, having a small trap-door towards its centre, into which the rabbits are led by a narrow mouth. This trap, on its first introduction, was set mostly by a haystack, hay being at that time the chief winter food of rabbits, or on the outside of the warren wall, where rabbits were observed to scratch much, in order to make their escape. Since the cultivation of turnips as a winter food for this species of stock has become a practice, the situation of the trap has, he says, been changed. Turnips being cultivated in an enclosure within the warren, a trap is placed within the wall of this enclosure. For a night or two the mouth is left open and the trap kept covered (with a board or triangular rail), in order to give the rabbits leave to retreat.

7350. *The annual produce* per acre is mostly estimated at from three or four to eight or ten couple, yielding a profit of from eight to ten, or even fifteen shillings, where they are conducted under a good

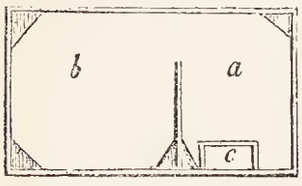
system of management. The produce is the largest on new lands; however, much of the profit must always depend on situation, so as to be near good markets. These animals are in what is termed season from the end of October to the beginning of January, in which period the best skins are produced: of course a large proportion of them is killed in this short time. The farmer often sustains great loss in what by the purchasers are called half skins, quarter skins, and racks, sixteen of which are only considered as a whole skin. The rabbits are disposed of by the hundred, six score couple being considered as an hundred.

7351. *The breeding and rearing of tame rabbits* is carried on in hutches or stores of boxes placed in sheds or apartments of any kind secure from vermin. We shall give a view of the practice as to rabbitry and furniture, varieties, breeding, feeding, and produce.

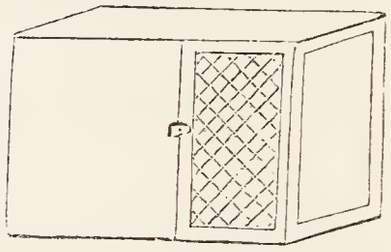
7352. *The rabbit-house* should be particularly dry and well ventilated, as these quadrupeds are very subject to the rot and to liver complaints like sheep.

7353. *The huts or hutches* (*fig.* 908.) are boxes or chests, eighteen inches or more high, and from two and a half to three feet wide, generally divided in two (*a* and *b*), and the rooms thus formed communicating by a sliding door, the use of which is to confine the rabbits in the inner division (*a*), whilst the outer, which has a wire door (*fig.* 909.), is cleaning. Generally these hutches are placed in rows above each other against one side of the rabbit-house, and sometimes they are placed in the open air against a wall, within a wired or netted enclosure. Sometimes they are ranged along the floor; but the neatest mode is to place them on brackets round the room, or on stands about three feet high on the floor. In both these cases it is to be understood that they are not allowed to run about the rabbit-room, the use of which is solely to enclose and protect them in an atmosphere of moderate temperature, and to contain a bin with corn, a truss of clover hay, and any such food as sheep will live and thrive upon. The utensil for feeding rabbits so hutched is simply a trough (*c*), which may be formed of pewter, very hard wood, earthenware, or cast iron, as rabbits are very apt to gnaw them; and it should be divided on the surface crossways every four or six inches, to prevent them from scratching and throwing out their corn. Some add a small rack for their clover, but that will not be lost if given on the floor in small quantities.

908



909



7354. *The rabbits of the Angora breed* yield in Normandy a wool which serves as a primary material in several considerable manufactures. It is used alone, and also mixed up with sheep's wool and cotton. The rabbits are found to delight more than any thing in the leaves of the Robínia pseùd-Acàcia; and as this plant grows on common sandy soils, it has been proposed to cultivate it for the sake of these rabbits. (*Com. to Board of Ag.* vol. i. p. 259.)

7355. *There are numerous varieties of tame rabbits;* but the broad-chested and short-legged are the most hardy, and fatten most expeditiously. There is a large variety of the hare colour, which has high-coloured and high-flavoured flesh, more savoury than that of the common rabbit; they make a good dish cooked like the hare, which at six or eight months old they nearly equal in size. The large white and yellow and white species have whiter and more delicate flesh, and cooked in the same way will rival the turkey. The Turkish or French rabbit is esteemed by some, but differs little from the common variety. All these and other varieties are to be had from the London dealers and poultrymen.

7356. *Breeding.* The doe will breed at the age of six months; and her period of gestation is thirty or thirty-one days. It should be premised, that the buck and doe are by no means to be left together; but their union having been successful, the buck must be immediately withdrawn, and the doe tried again in three days: in fact, with rabbits this business is conducted on the same principle as in the stud. Like chickens, the best breeding rabbits are those kindled in March. Some days before parturition or kindling, hay is to be given to the doe, to assist in making her bed with the flue which nature has instructed her to tear from her body for that purpose. She will be at this period seen sitting upon her haunches and tearing off the flue, and the hay being presented to her, she will with her teeth reduce and shatter it to her purpose. Biting down of the litter or bed is the first sign of pregnancy. The number produced, generally between five and ten; and it is most advantageous always to destroy the weak or sickly ones as soon as their defects can be perceived; because five healthy and well grown rabbits are worth more than double the number of an opposite description, and the doe will be far less exhausted. She will admit the buck again with profit at the end of six weeks, when the young may be separated from her and weaned: or the young may be suckled two months, the doe taken back at the end of five weeks, so that the former litter will leave her about a week before her next parturition. A notion was formerly prevalent of the necessity for giving the buck immediately after the doe had brought forth, lest she should pine, and that no time should be lost; and if it were intended that no time might be lost in destroying the doe, such indeed would be the most successful method. Great care should be taken that the doe, during her gestation, be not approached by the buck, or indeed by any other rabbit; as, from being harassed about, she will almost certainly cast her young. One doe in a thousand may devour her young; the sign that she ought to be otherwise disposed of. Some does admit the buck with difficulty, although often apparently in season: such should be immediately fattened off; since it can never be worth while to keep any individual for breeding of a stock to be produced in such multitudes against which there lies an objection. Should the doe be weak on her bringing forth, from cold, cough, or other causes, she will drink beer-caudle as well as any other lady; or warm fresh grains will comfort her, a salt mash, scalded fine pollard, or barley-meal, in which may be mixed a small quantity of cordial horse-ball. With due attention to keeping them warm and comfortable, and guarding against every sudden impression from cold, and more particularly moist air, and with the aid of the best and most nourishing food, rabbits may be bred throughout the winter, with nearly equal success as in the summer season; but in truth their produce is so multitudinous, that one might well be satisfied with four or five litters during the best part of the year, giving the doe a winter fallow.

7357. *Feeding.* According to Mowbray, it is better to feed three times than twice a day. The art of feeding rabbits with safety and advantage is, always to give the upper hand to dry and substantial food. Their nature is congenial with that of sheep, and the same kind of food, with little variation, agrees with both. All weeds and the refuse of vegetation should be banished from rabbit feeding. Such articles are too washy and diuretic, and can never be worth attention whilst the more solid and nutritious productions of the field may be obtained in such plenty, and will return so much greater profit. Rabbits may indeed be kept, and even fattened, upon roots, good green meat, and hay; but they will pay for corn, and this may be taken as a general rule: — Rabbits which have as much corn as they will eat can never take any harm from being indulged with almost an equal portion of good substantial vegetables. However, the test of health is that their dung be not too moist. Many or most of the town feeders never allow any greens at all; the reason, I suppose, because they feed almost entirely on grains. The corn proper for rabbits is oats, peas, wheat, pollard, and some give buck-wheat: the greens and roots the same as our cattle crops; namely, carrots, Jerusalem artichokes, and if potatoes, baked or steamed; lucerne, cabbage leaves, clover, tares, furze. Mowbray has had them hoven from eating rape; and not improbably field-beet might have a similar effect. The best dried herbage is clover and meadow hay, and pea and bean straw.

7358. *Rabbits are generally sold from the teat,* but there is also a demand for those of larger size, which may be fattened upon corn and hay, with an allowance of the best vegetables. The better the food, the

greater weight, better quality, and more profit, which is generally the case in the feeding of all animals. Some fatten with grains and pollard. Mowbray tried wheat and potato oats comparatively, but could find no differenee in the goodness of their flesh. The rabbit's flesh being dry, the allowance of succulent greens may tend to render it more juicy; and probably the old complaint of the dryness of the flesh in Devon beef, entirely fed with hay, might be remedied in the same way. Rabbits are in perfeetion for feeding at the fourth or sixth month; beyond whieh period their flesh becomes more dry and somewhat hard. It requires three months, or nearly so, to make a rabbit thoroughly fat and ripe; half the time will make them eatable, but by no means equal in the quality of the flesh: they may yet be over fattened, as appears by specimens exhibited a few years since at Lord Somerville's show, which were loaded with fat, without and within, like the best-feeding sheep.

7359. *The flesh of the rabbit* is esteemed equally digestible as that of fowls, and equally proper for the table of the invalid.

7360. *Castrated rabbits* might be fattened, no doubt, to the weight of upwards of ten pounds, at six or seven months old. It is said to be successfully practised in Sussex, near Chichester, where on the average not one in three hundred is lost by the operation, whieh is performed at five or six weeks old. With respect to the quantity of corn eonsumed in fattening, a young buck which weighed three pounds, fit for the spit, was put up in good case in August, and was only one month in feeding, consuming not quite four quarts of oats, with hay, eabbage, lucerne, and ehicory; the skin, silver and black, worth fourpence.

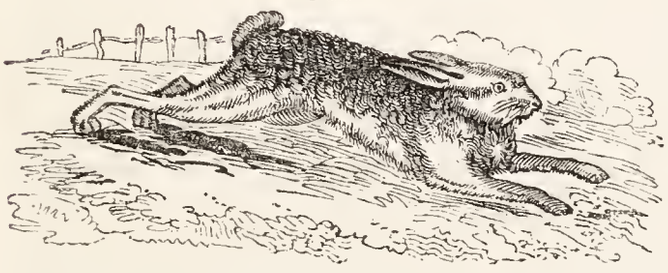
7361. *In slaughtering full-grown rabbits*, after the usual stroke upon the neck, the throat should be perforated upwards towards the jaws with a small-pointed knife, in order that the blood may be evacuated, which would otherwise settle in the head and neck. It is an abomination to kill poultry by the slow and torturing method of bleeding to death, hung up by the heels, the veins of the mouth being cut; but still more so the rabbit, which in that situation utters horrible sereams. The entrails of the rabbit, whilst fresh, are said to be good food for fish, being thrown into ponds.

7362. *The rabbit is a caressing animal*, and equally fond with the cat of the head being stroked; at the same time it is not destitute of courage. A whimsical lady admitted a buek rabbit into her house, when he became her companion for upwards of a twelvemonth. He soon intimidated the largest eats so much, by chasing them round the room and darting upon them, and tearing off their hair by mouthfuls, that they very seldom dared to approach. He slept in the lap by ehoice, or upon a chair or the hearth-rug, and was as full of mischief and trieks as a monkey. He destroyed all the rush-bottomed chairs within his reach, and would refuse nothing to eat or drink which was eaten or drank by any other member of the family.

7363. *Diseases.* No live stock is less liable to disease than the rabbit, with regular and careful attention, such as has been pointed out; so that any sudden and accidental disorder is best and most cheaply remedied by a stroke behind the ears. But want of care must be remedied, if at all, by an opposite conduct, and improper food exehanged for its contrary. Thus, if rabbits become pot-bellied, in the common phrase, from being fed on loose vegetable trash, they must be cured by good hard hay and corn, ground malt or peas, or any substantial or absorbent food. Their common liver complaints are incurable, and when such are put up to fatten, there is a certain criterion to be observed. They will not bear to be pushed beyond a moderate degree of fatness, and should be taken in time, as they are liable to drop off suddenly. The dropsy and rot must be prevented, as they are generally incurable; nor is a rabbit worth the time and pains of a probable cure.

7364. *The hare* (*Lèpus tímidus L.*, *fig.* 910.), if taken young, may be tamed and domesticated, and has occasionally been nursed by a cat. Sonnini the naturalist, and Cowper the poet, had hares in a complete state of domestication. As the fur of this animal is of greater value for hat-making than that of the rabbit, it would be a very desirable circumstance if it could be substituted for that animal in warrens. Its flesh would certainly be deemed preferable, and in general it is a large animal. It lives on the same sort of food as the rabbit, produces generally three young ones at a time, and breeds at least three times in a year. It is not improbable that in some situations, where the soil is dry and poor, a hare warren or pack might be found to answer; the price in the metropolis being never less than ten times that of rabbits.

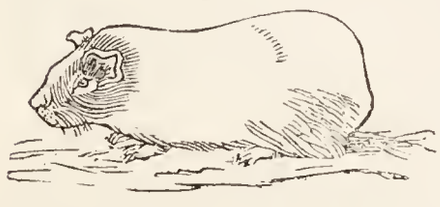
910



7365. *There is a hare warren* near Banstead Downs: it contains about three acres of ground: 200 brace are usually kept in it: they are fed in the summer on clover, rape, &c.; and in the winter, on hay. The warren is surrounded by a brick wall about ten feet high, with openings at regular distances, within which are wire gratings on hinges: these give way to the hares, when they enter the warren; and they are so constructed, that they immediately close after them, and so prevent their escape.

7366. *The Guinea pig*, or restless Cavy (*Càvia Cobàya* L., *fig.* 911.), is a native of Brazil, but domesticated in Europe, and treated and used like the tame rabbit. In Italy, the flesh is considered a delicacy, and the skins are nearly as valuable as those of rabbits.

911



7367. *The Guinea pig is one of the most prolific* of animals, and Buffon calculates that in twelve months only 1000 might be produced from a single pair, as the female has been known to bring forth young when two months old only: the time of gestation is only three weeks; and she will produce at least every two months. The young are six or seven months before they arrive at their maturity of growth, but within the short period of twelve hours from their birth are nearly as alert and active as those fully grown, and therefore require parental assiduity only for a little time. Vegetables form their food, and on a great variety of these they will flourish and fatten. They drink but little, appear after eating to ruminate, and are extremely apt to be affeeted by eold. They are uncommonly clean in their habitations, and are often to be seen smoothing and cleansing their fur with partieular attention and perseverance.

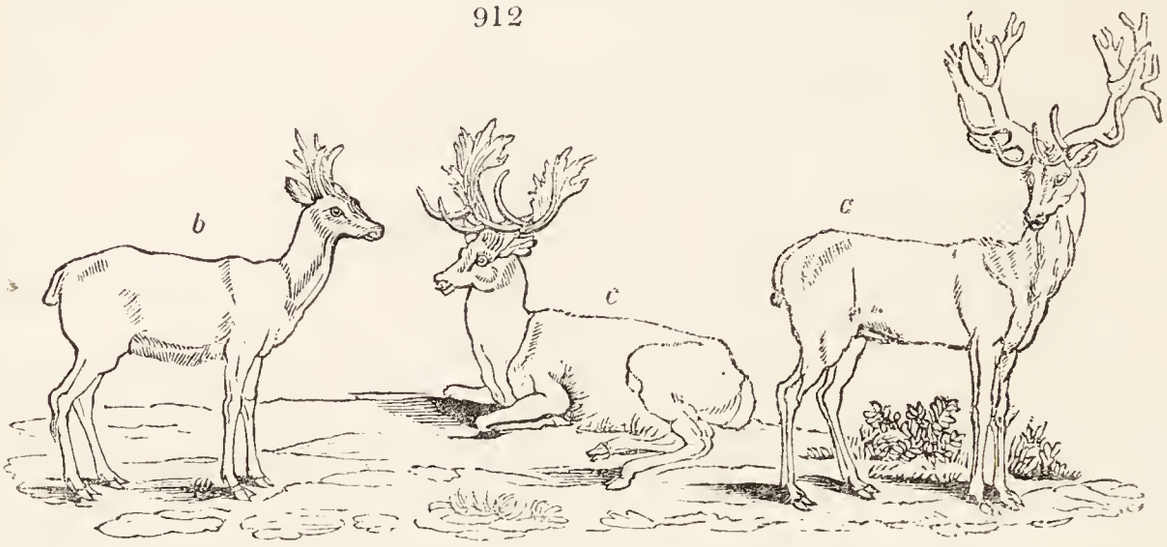
7368. *The fat dormouse* (*Myóxus Glís L.*) is a native of the woods of Germany and Russia; and has a good deal of the habits of the squirrel. It feeds on fruits, lays up a winter store, forms its nest in hollow trees, sleeps by day, and grows very fat in autumn.

It was cultivated by the Romans, and highly prized by them as food. The body is six inches long.

7369. *Of the deer* (*Cérvus L.*) there are three species in cultivation in this country: the stag, roe, and fallow deer. The latter are now almost exclusively cultivated in parks, as articles of luxury, and, it is conceived, might answer to a small extent in farming.

7370. *The stag* (*C. Elephas L., fig.* 912. *a*) is found in nearly all the temperate climates of Europe and

912



Asia. It is also found in North America, but attains its largest size in Siberia. From the branchiness of its antlers, the elegance of its form and movements, and the strength of its limbs, it deservedly attracts particular admiration, and may be regarded as a principal embellishment of the forest. The stag is remarkable for a fine eye, and an acute sense of smelling. His ear also is exquisitely sensible, and musical sounds appear to possess over him the power of exciting complacency, if not rapture. His enemies not unfrequently employ the shepherd's pipe to decoy him to his destruction; and Playford, in his *Introduction to Music*, states that he once met a herd of twenty stags near Royston, which readily followed the tones of a violin and bagpipe, played by their conductors, but stopped whenever the music was suspended. Their whole progress from Yorkshire to Hampton Court was attended, and it was supposed extremely facilitated, by these sounds. The stag is simple and unsuspicious, and employs no arts to avoid detection or pursuit, until after having received considerable molestation. His food consists in winter of moss and bark; in spring, of the catkins of willow and hazel, and the flowers and buds of cornel; in summer, of the grain of rye, and the tender shoots of the alder; in autumn, of the leaves of brambles, and the flowers of heath and broom. He eats with slowness, and ruminates with some considerable effort, in consequence of the distance between the first stomach and the mouth. In March, generally, he sheds his antlers, which are not completely renewed till August. He will live to between thirty and forty years of age, and was formerly, amidst the other vulgar errors of antiquity, supposed capable of attaining most extraordinary duration. The stag is supposed to have been introduced from France into England, where he has latterly been made to give way to the fallow deer, an animal more gentle in its manners, and more valuable as food. In some parts of Scotland he is yet to be found in his original wild state. A stag of five years old is, in hunting, termed a hart; the female, hinds; and the young, fawns.

7371. *The roe* (*C. Caprèolus L., fig.* 912. *b*) is the smallest of the deer tribes which are natives of Europe; it is generally of a reddish brown colour; graceful, sprightly, and courageous, particularly cleanly, and delighting in dry and mountainous situations: it leaves a strong scent behind it, but possesses such arts of defence, that by various doublings and intermixtures of past with present emanations from its body it frequently baffles the most experienced dogs, and remains in a state of security, while the full pack passes almost close by its retreat, distinguishing it neither by sight nor smell. It differs from the stag in the constancy of its attachment, and the parents and their young constitute a family, never associating with strangers: two fawns are generally produced by the female at a birth, one of each sex, which, living together, form a mutual and invincible attachment. When a new family is to be nursed, the former is driven off to provide for itself, but returns again after a certain interval to the mother, whose former affection is restored: a final separation speedily takes place, however, soon after this return, between the fawns of the season preceding the last and their dam; and the former remove to a distance, constituting a distinct establishment, and rearing an offspring of their own. When the female is about to bring forth, she secludes herself in some remote recess of the forest, from which she returns at the end of about ten days with her fawns, just able slowly and weakly to follow her steps: in cases of danger she hides them in a place deemed by her most secure from the enemy, and attracts the attention of the latter from them to herself; happy, by her own perils or even destruction, to effect the security of her offspring. In winter, these animals feed on brambles, broom, heath, and catkins; and in spring they eat the young wood and leaves of almost every species of tree, and are said to be so affected, as it were with intoxication, by the fermentation of this food in their stomachs, that they will approach men and other enemies (whom they generally shun with great care) without apprehension or suspicion. The flesh of these animals is excellent, though after two years of age that of the males is ill-flavoured and tough. The roe exists now in no part of Ireland, and, in Great Britain, only in a few districts of the Highlands.

7372. *The fallow deer* (*C. Dàma L., fig.* 912. *c*) is in general much smaller than the stag; but in Spain is nearly equally large. In France and Germany it is rarely to be found, and it has never been known to have existed in America. It has the elegance of the stag, connected with a much more tractable disposition. It sheds its antlers, which, as in the stag species, are peculiar to the male, every year; is stated to live to the age of twenty years, and arrives at its maturity in three; it is by no means fastidious in its food.

7373. *Deer husbandry.* The author of the *Agricultural Survey of the County of Hertford* observes, that, "the Earl of Clarendon, justly considering that there is no more impropriety in converting one animal to profit than another, makes deer an object of husbandry. As soon as the rutting season is over, or usually about the 10th of November, his lordship selects from the herd the weak ones, some of which would probably die in the winter, and keeps them in a small yard that has a shed on one side, and a net over the whole against pigeons, &c.; the spot very warm, and well sheltered. Their antlers are immediately sawn off, the place is well littered, and they are fed at a very small expense on pea-straw, hay, &c. warmth making up for the want of better food. At times, during the winter, they have clover-hay cut into chaff, and if they do not eat it well, a little salt is added. They have always plenty of water, and are

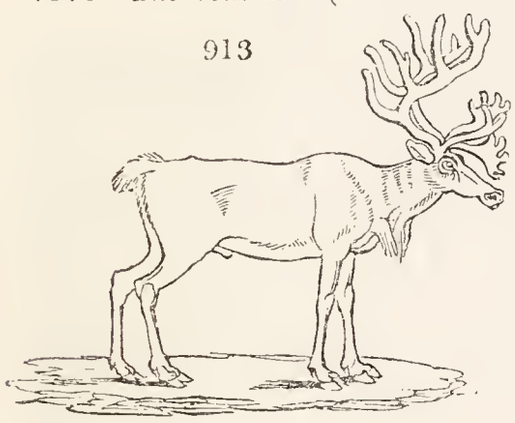
kept perfectly clean : much attention should, he says, be paid by the keeper to make himself familiar with them, that he may enter the place without disturbing them. The first week in March he gives them oil-cake, about half a cake each a day, with chaff, which fattens them so quickly that all are gone in May. Before killing they have some green meat given, to take away any ill flavour from the cake, supposing such to be the effect of the food; for it is certain that the venison is exceedingly good. As to weight, a haunch usually weighs about 24 pounds; a brace is sold for 15 guineas: the skin, worth 2*l.* 2*s.*, is the keeper's perquisite; so that the value of a brace amounts to 17*l.* 17*s.* exclusive of some trifling articles. The purchaser sends for them." It is added, that his lordship usually fattens nine brace: his whole winter stock rises to 350 head, in a park of 250 acres, but much of it is thickly covered with timber; thirty sheep and ten cows also feed on it. The park consumption of hay amounts to thirty-two loads, being reduced to that quantity by the use of much browse; all ash, elm, and Scotch pine being brought for that purpose before faggoting, which not only saves hay, but improves the flavour of the venison.

7374. *By castrating the males of deer* when newly dropped, which is not in the least dangerous, it affords the means of having good venison until Christmas, without any other sort of food than the common grass: they also fatten more quickly; the operation must, however, be performed while they are quite young. (*Devonshire Report.*)

7375. *The moose deer*, or elk (*Cérvus Alces L.*), is indigenous in Europe, America, and Asia, as far as Japan, and was formerly wild in this country, though now extinct. It is of the size of a horse; gentle, except when teazed by the gad-fly; feeds on twigs and branches of trees, and marsh plants; goes on its hoofs with a shambling gait at the rate of fifty miles a day; has a skin so hard as almost to resist a musket ball, but flesh tender and good. This animal might be introduced as an inhabitant of parks, where it would add to the variety of animated woody scenery and of venison.

7376. *The rein deer* (*Cérvus Tarándus* L., *fig.* 913.) is an inhabitant of the alpine mountains of America, Europe, and Asia, and is too remarkable an animal, and too well known, to require a particular description or account of his habits.

913



7377. *The tame variety* have been introduced more than once into this country by the Hon. Daines Barrington, Bullock, and others, but cannot be kept in parks on account of the want of their particular lichen. As this lichen abounds on several mountains in Yorkshire, and on many in Scotland and Ireland, some patriotic and curious noblemen might attempt its cultivation. The milk and cream, as Dr. Clarke states, are most excellent, and also the flesh; and even as an article of profit, the sale of the animals as breeding stock would pay for a time. Lichen hay might no doubt be imported at an easy rate from the gulf of Bothnia; and the animal by degrees in the course of a few generations might be habituated to grsas or the spray of trees.

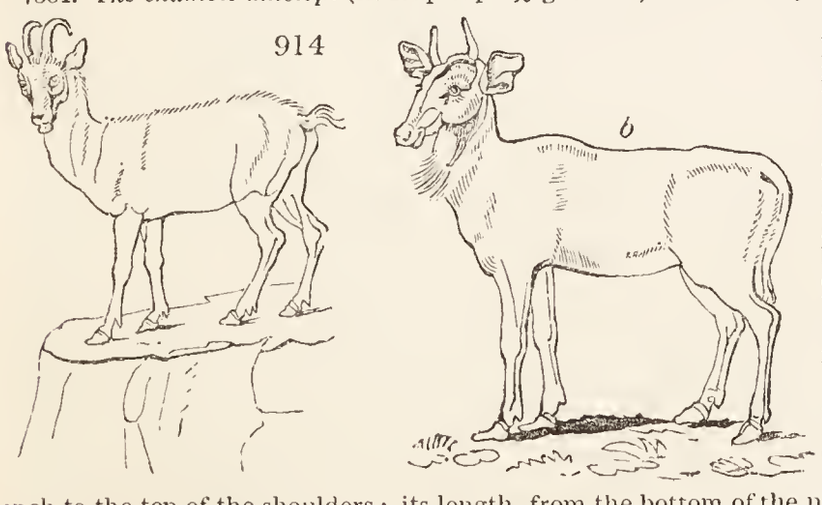
7378. *The antelope* (*Antelòpe L.*) is a beautiful and numerous genus of animals, partaking of the nature of the goat and deer. Two species, the *A. Saíga*, or scytheon, and the A. *Rupícapra* or chamois, are natives of Europe, but the rest of hot climates.

7379. *Antelopes*, Pennant observes, are animals generally of a most elegant and active make, of a restless and timid disposition, extremely watchful, of great vivacity, remarkably swift and agile, and most of their boundings so light and elastic as to strike the spectator with astonishment. What is very singular, they will stop in the midst of their course, gaze for a moment at their pursuers, and then resume their flight. As the chase of these animals is a favourite amusement with the Eastern nations, from that may be collected proofs of their rapid speed. One of the highest compliments that can be paid to female beauty in the Eastern regions is, *Aine el Czazel*, 'You have the eyes of an antelope.' Some species of antelopes form herds of two or three thousand, while others keep in troops of five or six. They generally reside in hilly countries, though some inhabit plains: they often browse like the goat, and feed on the tender shoots of trees, which gives their flesh an excellent flavour.

7380. *The common antelope* (*A. Cervícapra L.*) abounds in Barbary, and in all the northern parts of Africa. It is somewhat less than the fallow deer: its horns are about sixteen inches long, surrounded with prominent rings almost to the top, where they are twelve inches distant from point to point. The horns are remarkable for a beautiful double flexion, which gives them the appearance of the lyre of the ancients. The colour of the hair on the back is brown, mixed with red; the belly and inside of the thighs white; and the tail short.

7381. *The chamois antelope* (*A. Rupícapra, fig.* 914. *a*) was formerly considered as belonging to the genus *Cápra*, and is generally called the chamois goat. It is found on the mountains of Switzerland, where it is very shy, and hunted both for its flesh and skin. (342.)

914



7382. *The Scythian antelope* (*A. Saíga* L.) bears a good deal of resemblance to the common goat, and it is fully as easily tamed. They are found in immense flocks on the banks of Borysthenes and other parts of Russia, where they are valued both for the flesh and their skin, which is equal to that of the chamois for gloves.

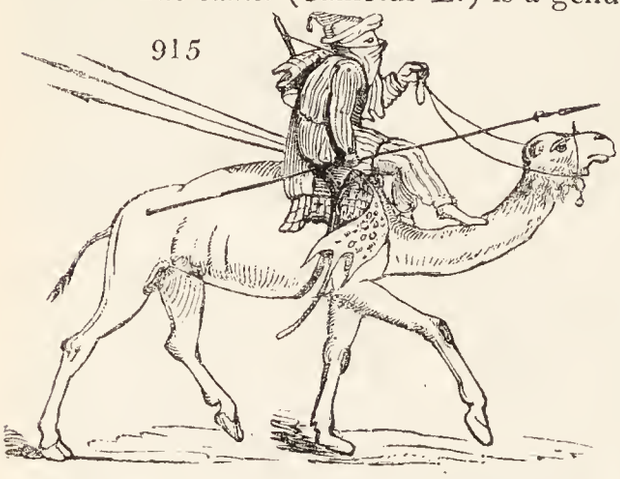
7383. *The nilgau*, or white-footed antelope (*A. pícta L. fig.* 914. *b*), is a large and beautiful species, known only within the space of a few years past. Its height is four feet one inch to the top of the shoulders; its length, from the bottom of the neck to the base of the tail, four feet; and the colour a fine dark grey. The nilgau has of late years been often imported into Europe, and has bred in England. In confinement, it is generally pretty gentle, but is sometimes seized by fits of sudden caprice, when it will attack with great violence the object of its displeasure. The nilgau is said to go

with young about nine months, and to produce sometimes two at a birth: the young is of the colour of a fawn.

7384. The above and various other species of antelopes might probably be acclimated and introduced in parks as objects of luxury. The cultivator who first succeeded in breeding them would find an ample demand at his own price if they happened to come in vogue.

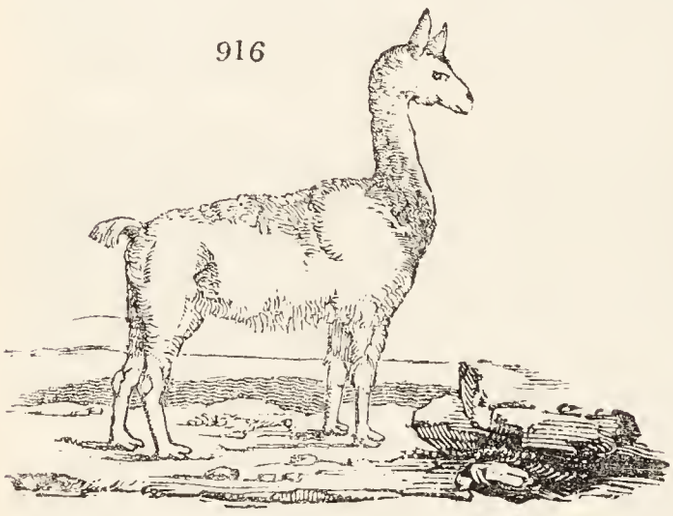
7385. *The camel* (*C*amèlus *L.*) is a genus of which there are several species, three of which, the dromedary, or Arabian camel (*fig.* 915.), the Bactrian camel, and the lama or Peruvian sheep, might certainly be partially acclimated in England, as the first is in Italy. (297.) They live upon a very little of the coarsest herbage; might have a warm house well littered to retire to in winter, or in cold nights, and would form a singular ornament to park scenery. Besides their hair and skin are valuable, and they might be sold perhaps to romantic travellers or cavalier quacks.

915



7386. *The lama* (*C*amèlus *Glama L.*, *fig.* 916.) is the camel of South America; and appears to hold a middle place between the sheep, deer, and camel.

916



7387. *Before the entrance of the Spaniards*, lamas were the only beasts of burden known to the South Americans. Like camels, they travel slowly, but are persevering, tractable, and very sure-footed. Since the introduction of mules, they are much less cultivated; but before they were depended on to carry the ores dug out of the rich mines of Potosi. The lama is furnished as the camel with ability to abstain from water, by keeping a quantity in its second stomach. Like the camel, its feet also divide, and spread; but by no means equal to those of the camel. It is also furnished with a singular protuberance or spur behind, which enables it the better to lay hold on the ground. The tame are of various colours, and some of them are smooth and others rough. The height of the lama is about four feet, and its length from the neck to the tail about six feet. It has a capacity of throwing out the saliva to a considerable distance, but which is not possessed of any acrid quality.

7388. *The camelopard* (*C*amelopárdalis *Giráffa* L.), a most singular and noble animal, seventeen feet high, and as tame and gentle as the camel, might also be naturalised. It lives on the green spray of trees and grass, and frequents forests.

7389. *The elephant, rhinoceros, musk ox*, and a variety of other exotic domestics, might be so far acclimated as to live in Britain as they do in the *Jardin des Plantes* at Paris, viz., with an enclosure for each sort, and a lodge or house for protection in winter or during inclement weather. Were as much attention paid to acclimating foreign animals as there is directed to the same branch of culture in plants, we should soon possess a rich Fauna; and the public taste may in time take this direction.

7390. *In acclimating* the more tender animals, it might be desirable to rear a few generations, first in the south of Italy or in Spain, next in France, and afterwards in the south of England. But the camel, musk ox, zebra, quagga, and antelope might be had at once from the acclimated stock in Italy.

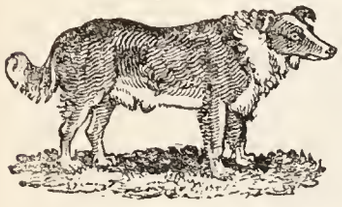
7391. *The dog* (*C*ànis familiàris) is an animal of universal utility and interest. From the earliest ages he has been the companion and assistant of the herdsman; and without his aid the flocks must have been confined to narrow limits, and consequently their propagation would have been greatly lessened. But hardy and bold, he watched by night, and toiled by day; securing his charge from the human thief, or the ravenous predatory beasts in the one, and collecting and organising their march during the other. Without the dog, sheep-farmers of the present day would be often at a loss to restrain the wanderings of their flocks; nor is he less useful in guarding the yard by nightly watchings.

7392. *The genus Cànis* includes other animals, as the wolf, the fox, the jackal, and the hyæna: and many naturalists have supposed our subject, the dog, to be only a mixed animal, originating from the union of some of these. Such is the opinion of Guldenstadt, Pallas, and Pennant; while the higher names of Blumenbach and Cuvier are ranged among those who assign him a distinct and specific origin. Blaine, who has long successfully advocated the cause of the dog, has bestowed much research on this point; and appears clearly to have traced the dog through his numerous varieties, to a specific origin; but whether originating from a specific or a spurious source, the dog has descended down into such innumerable varieties, that a detail of the forms and properties of them, as they appear among us only, would be utterly impossible. The wants as well as the luxuries of man have, however, laid hold on some of these varieties, and have fixed them into permanencies, by confining the sexual intercourse to their congeners alone; and of this number there are no less than forty. It would be unnecessary to draw the character of the dog as stated at length by Linnæus and others; the outlines are the same in all.

7393. *The shepherd's dog*, in an agricultural point of view, ranks foremost among the numerous varieties; indeed, the fanciful Buffon makes him the father of the whole race of dogs. But did no other difficulty arise, an insuperable one would be found in the opposite characters which different breeds of this dog possess. Few animals can be more unlike than the small sheep-dog of the Highlands of Scotland and the monstrous drover's dog of Smithfield.

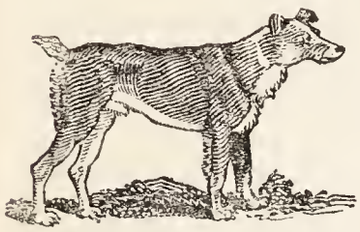
7394. *The English sheep-dog* (*fig.* 917.) is usually larger than the northern, is longer on the legs, and has been so long accustomed to have the tail taken off nearly close to the rump, that in some instances the custom has operated on nature; and these dogs are sometimes pupped tailless. The shepherd's dog is not, however, usually bred so large as the real cattle or drover's dog; but is yet sufficiently strong and fierce. Their colour is in general black and white, with half-pricked ears: they are extremely docile and intelligent, and seem almost to understand the looks of the shepherd. Some of them are smooth-coated; but by far the greater number are rough, and have their hair crisped, which enables them better to bear the effects of continued exposure. The dog very erroneously described by minor naturalists as the *cur dog* is nothing more than the shepherd's dog, confined principally to the operations of the farm; and often bred taller, and either smooth or rough, according to circumstances. The very term cur destroys all individuality of breed; it being applied to characterise any dog of spurious origin: neither in these farm-yard dogs is any characteristic difference whatever observed in forms, qualities, or uses. When the sheep-dog is generally employed in watching the farm-yard, he becomes more fierce and active; he accommodates his powers to the particular circumstances required of him; he knows every field, and every beast, and keeps the whole in subjection. His bite is keen, and principally directed at the heels of cattle, by which he keeps himself safe, and does not injure them.

917

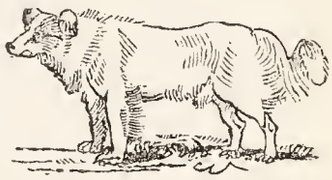


7395. *The sheep-dogs of Scotland* are varied in form and size (*figs.* 918. and 919.), but are all of them usually smaller than those in use in England: they are, nevertheless, without competitors in sagacity and excellence. Their general characters are, ears partially upright, head rather pointed, shaggy coat, and a remarkable villosity or fulness of tail beneath. Immense flocks of sheep may be seen ranging the wilds, without other control save the shepherd and his dog, which receives his commands, executes them, and then waits for further instructions: or he often acts with great judgment and promptitude from the impulses of his own sagacity, in which, perhaps, these dogs never shine more than in their readiness to distinguish the individuals of their own flocks, and their adroitness in keeping out intruders. In driving a number of sheep to any distance, a well trained dog never fails to confine the sheep to the road: he watches every avenues that leads from it, where he takes his stand, threatening every delinquent; and pursues the stragglers, forcing them into the ranks without doing them any injury. If the herdsman be at any time absent, he rests satisfied, knowing his dog will not abandon his charge, but will keep them together; and the moment he returns, the sagacious animal gives up his trust, or conducts them to his master, according to the word or signal given.

918

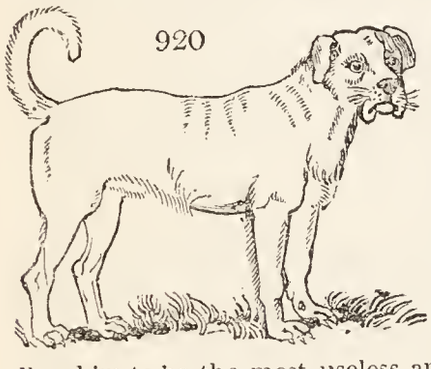


919



7396. *The mastiff* or *guard* (*fig.* 920.) is a noble animal, derived from the Dane; but by selection and cultivation is rendered thicker and heavier, though less tall than his original. The powers of this dog are immense; and as a guard he is unrivalled; having the ferocity of a tiger to a stranger, with the gentleness of a lamb towards those he knows. His sagacity in detecting the attempts of robbers, and his fidelity in resisting all their bribes, are such, that it is to be lamented his breed has given place to that of the Newfoundland dog, whose qualities as a guard are certainly not equal to his. The mastiff is characterised by small pendulous ears, smooth coat, colour various, often reddish or brindled. The lips are pendulous, jaws of immense strength, but seldom underhung; and his general form is symmetrical for strength.

920



7397. *The bull-dog* can no otherwise be considered as connected with agriculture, than as he is too often used in the disgraceful and inhuman sport of bull-baiting: and however we may admire his invincible fortitude, and his contempt of pain and danger, we must allow him to be the most useless among the dog species. In his attack on cattle he always aims at the front, and generally fastens on the upper lip, where he will hang in spite of every effort of the animal to disengage himself.

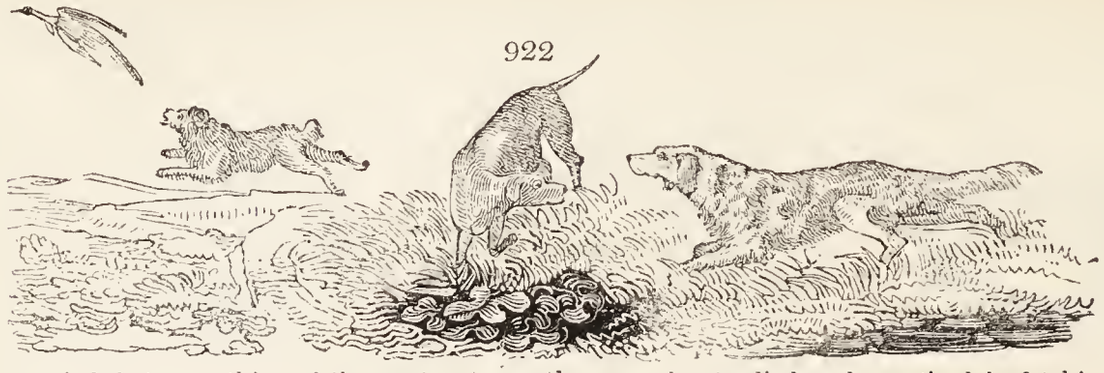
7398. *The terrier* (*fig.* 921.) is a dog of very great utility, and of very varied form and size. His qualities have gained him the greatest care in selection, training, and continuing the numerous distinct breeds we witness. The principal varieties may be reduced into the rough and the smooth breeds. The *rough breed* is originally derived from Scotland, where it is still preserved in a few families in its original purity. These specimens are seldom large, but are exceedingly rough and shaggy in their hair, which is much crisped and brindled. The rough breed in England has become larger, and is very often seen white. When mixed with the bull breed, this terrier becomes fierce, much inclined to combat, and forms an excellent guard. The *smooth breed* produces endless varieties; the principal of which is an elegant black animal with tan markings. A second variety is of varied colours, smaller, thicker, and longer; and is used for earthing foxes, badger-baiting, and vermin killing in general. For rabbit hunting, a wry-legged breed is in considerable request. Although particular varieties are often appropriated to particular purposes, yet all have a common property which renders them invaluable to the agriculturist; which is their determined hostility to those animals termed vermin, as foxes, otters, badgers, polecats; with rats and mice. To attack the former, they are bred strong, and have a portion of the bull breed in them: for the latter, their hardihood, activity, and keenness of gripe are particularly studied, in which the middle-sized breeds are frequently found to excel.

921

7399. *The pointer, setter, and spaniel* (*fig.* 922.) it might seem at the first view unnecessary to introduce to the notice of the agriculturist; but a little examination of the subject will show that they may be made an object of considerable importance to the farmer. Few dogs command such prices as sporting dogs; and few persons have such opportunities of rearing them so cheaply, or so well, as farmers. Many farmers shoot game; most of them do it more or less: and it would be very easy to make two brace of pointers or setters, with one or two brace of spaniels, pay a considerable part of the rent of the farm, without other expense than skim-milk and potatoes, or occasionally a little barley meal. We will suppose that a farm has on it three pointer bitches, and one pointer dog, all of acknowledged excellence, and two out of the three bitches may be expected to go to heat early, and to produce progeny between the seasons of shooting, when they are wanted: from these, four brace of puppies may be saved, and by continually following the servants and their master, they will become so handy, that their breaking may be effected

daily, and without any other trouble than what occurs in restraining them when a little wild. If their breed is very good, their stopping and backing will commence towards the end of the first season, and dur-

922



ing the periods between this and the next autumn they may be steadied and practised in fetching their game, &c., as directed in good sporting works. At the commencement of the following season, if they have been well attended to, although only fifteen months old, the whole may be sold to the London or country dealers, to average six or seven guineas each: or if sold privately, they will fetch from eight to twelve and fifteen guineas each, out of which, perhaps, not more than half a guinea can fairly be deducted for keep, &c. The trouble occasioned to the master will be trifling, because connected with a pleasing employ to him as a sportsman, and who will thus have his own sporters for nothing.

7400. *Setters*, as more valuable, will fetch a higher price; but they do not always command so ready a sale, and are more troublesome to break.

7401. *Spaniels* are commonly thought, but most erroneously, almost to break themselves. A really well broke spaniel, however, is so rare, that instead of being worth two or three guineas, which is the usual price, it will fetch from five to ten pounds. It would be even less difficult to the farmer to rear spaniels than pointers; and by following him continually about the grounds they might be taught perfect obedience, and close rangings, which are the grand requisites, without trouble or expense. In this way, four or five brace might be easily brought every season to market, and would always command a ready sale, and a price according to the perfection of their breaking.

7402. *In the breeding and rearing* of dogs for the above purposes, it is necessary to observe the greatest care in their original selection; that the breed be of the very best, and one which as it were breaks itself, for this shows the purity of the breed. It is likewise no less necessary that the breed be carefully preserved so; to do which, the moment the dogs begin to smell at a bitch, shut her and the intended male closely up, in a confinement inaccessible to other dogs, and there let them remain a fortnight. It is likewise almost equally necessary, that the dogs peculiarly appropriated to agriculturists, particularly the shepherd's dog, should be bred as pure; for no animal is more liable to sport into varieties. No crossing can on any account be permitted; but choice may be made among families of the same variety. In the rearing of this dog, his education should be early and carefully attended to, to make him hardy and familiar with all the signs of the shepherd, who ought himself to be equal to the regular education of his own dog.

7403. *The diseases of dogs* are very numerous. The following are described by Blaine as the most prevalent, with their methods of cure.

7404. *The canine asthma* is hardly ever observed to attack any but either old dogs, or those who, by confinement, too full living, and want of exercise, may be supposed to have become diseased by these deviations from a state of nature. It is hardly possible to keep a dog very fat for any great length of time, without bringing it on. This cough is frequently confounded with the cough that precedes and accompanies distemper; but it may be readily distinguished from this by an attention to circumstances, as the age of the animal, its not affecting the general health, nor producing immediate emaciation, and its less readily giving way to medicine.

7405. *The cure* is often very difficult, because the disease has in general been long neglected before it is sufficiently noticed by the owners. As it is usually brought on by confinement, too much warmth, and over-feeding; so it is evident the cure must be begun by a steady persevering alteration in these particulars. The medicines most useful are alteratives, and of these occasional emetics are the best. One grain of tartarised antimony (*i. e.* tartar emetic), with two, three, or four grains of calomel, is a very useful and valuable emetic. This dose is sufficient for a small dog, and may be repeated twice a week with great success, — always with palliation.

7406. *Of diseases of the eyes*, dogs are subject to almost as great a variety as ourselves, many of which end in blindness. No treatment yet discovered will remove or prevent this complaint.

7407. *Sore eyes*, though not in general ending in blindness, is very common among dogs. It is an affection of the eyelids, is not unlike the scrofulous affection of the human eyelids, and is equally benefited by the same treatment: an unguent made of equal parts of nitrated quicksilver ointment, prepared tutty and lard, very lightly applied. Dropsy of the eyeball is likewise sometimes met with, but is incurable.

7408 *Cancer*. The virulent dreadful ulcer, that is so fatal in the human subject and is called cancer, is unknown in dogs; yet there is very commonly a large scirrhous swelling of the teats in bitches, and of the testicles (though less frequent) in dogs, that as it sometimes becomes ulcerated, so it may be characterised by this name. In the early state of the disease discutients prove useful, as vinegar with salt, and camphor and Spanish flies, with mercurial ointment, have sometimes succeeded; taking care to avoid irritating the part so much as to produce blister. But when the swelling is detached from the belly, and hangs pendulous in the skin, it had better be removed, and as a future preventive suffer the bitch to breed. Scirrhous testicles are likewise sometimes met with; for these no treatment yet discovered succeeds but the removal of the part, and that before the spermatic chord becomes much affected, or it will be useless.

7409. *Colic*. Dogs are subject to two kinds of colic; one arising from constipation of the bowels, the other is of a kind peculiar to dogs, apparently partaking of the nature of rheumatism, and also of spasm. From a sudden or violent exposure to cold, dogs become sometimes suddenly paralytic, particularly in the hinder parts; having great tenderness and pain, and every appearance of lumbago. In every instance of this kind, there is considerable affection of the bowels, generally costiveness, always great pain. A warm bath, external stimulants, but more particularly active aperients, remove the colic. Colic arising from costiveness is not in general violently acute from the pain it produces; sometimes, however, it appears accompanied with more spasm than is immediately dependent on the confinement of the bowels. In the former give active aperients, as calomel with pil. cochiæ, *i. e.* aloetic pill and glysters; in the latter castor oil with laudanum and ether.

7410. *Cough*. Two kinds of cough are common among dogs, one accompanying distemper, the other in an asthmatic affection of the chest. (See 7404. 7411.)

7411. *Distemper*. This is by far the most common and most fatal among the diseases of dogs; hardly any young dog escaping it; and of the few who do escape it in their youth, three fourths are attacked with it at some period afterwards: it being a mistake that young dogs only have it. It, however, generally

attacks before the animal arrives at eighteen months old. When it comes on very early, the chances of recovery are very small. It is peculiarly fatal to greyhounds, much more so than to any other kind of dog, generally carrying them off by excessive scouring. It is very contagious, but it is by no means necessary that there should be contagion present to produce it; on the contrary, the constitutional liability to it is such, that any cold taken may bring it on: and hence it is very common to date its commencement from dogs being thrown into water, or shut out on a rainy day, &c. There is no disease which presents such varieties as this, either in its mode of attack, or during its continuance. In some cases it commences by purging, in others by fits. Some have cough only, some waste, and others have moisture from the eyes and nose, without any other active symptom. Moist eyes, dulness, wasting, with slight cough and sickness, are the common symptoms that betoken its approach. Then purging comes on, and the moisture from the eyes and nose from mere mucus becomes pus, or matter. There is also frequently sneezing, with a weakness in the loins. When the disease in this latter case is not speedily removed, universal palsy comes on. During the progress of the complaint, some dogs have fits. When one fit succeeds another quickly, the recovery is extremely doubtful. Many dogs are carried off rapidly by the fits, or by purging; others waste gradually from the running from the nose and eyes, and these cases are always accompanied with great marks of putridity.

7412. *The cure.* In the early stages of the complaint give emetics; they are peculiarly useful. A large spoonful of common salt, dissolved in three spoonfuls of warm water, has been recommended; the quantity of salt being increased according to the size of the dog, and the difficulty of making him vomit: while a dog remains strong, one every third day is not too much. The bowels should be kept open, but active purging should be avoided. In case the complaint should be accompanied with excessive looseness, it should be immediately stopped by balls made of equal parts of gum arabic, prepared chalk, and conserve of roses, with rice milk as food. Two or three grains of James's powder may be advantageously given at night, in cases where the bowels are not affected; and in the cases where the matter from the nose and eyes betokens much putridity, we have witnessed great benefits from balls made of what is termed Friar's balsam, gum guaiacum, and chamomile flowers in powder: but the most popular remedy is a powder prepared and vended under the name of distemper powder, with instructions for the use of it. Dogs, in every stage of the disease, should be particularly well fed. A seton we have not found so useful as is generally supposed: where the nose is much stopped, rubbing tar on the upper part is beneficial; and when there is much stupidity, and the head seems much affected, a blister on the top is often serviceable.

7413. *Fits.* Dogs are peculiarly subject to fits. These are of various kinds, and arise from various causes. In distemper, dogs are frequently attacked with convulsive fits, which begin with a champing of the mouth and shaking of the head, gradually extending over the whole body. Sometimes an active emetic will stop their progress, but more generally they prove fatal. *Worms* are often the cause of fits in dogs. These deprive the animal wholly of sense; he runs wild till he becomes exhausted, when he gradually recovers, and perhaps does not have one again for some weeks. Confinement produces fits and likewise costiveness. Cold water thrown over a dog will generally remove the present attack of a fit; and for the prevention of their future recurrence, it is evident that the foregoing account of causes must be attended to.

7414. *Inflamed bowels.* Dogs are very subject to inflammation of their bowels, from costiveness, from cold, or from poison. When inflammation arises from costiveness it is in general very slow in its progress, and is not attended with very acute pain, but it is characterised by the want of evacuation and the vomiting of the food taken, though it may be eaten with apparent appetite. In these cases the principal means to be made use of are, the removal of the constipation by active purging, clysters, and the warm bath. Calomel with aloes forms the best purge. But when the inflammation may be supposed to arise from cold, then the removing of any costiveness that may be present is but a secondary consideration. This active kind of inflammation is characterised by violent panting, total rejection of food, and constant sickness. There is great heat in the belly, and great pain; it is also accompanied with great weakness, and the eyes are very red. The bowels should be gently opened with clysters, but no aloes or calomel should be made use of. The belly should be blistered, having first used the warm bath. When the inflammation arises from poison, there is then constant sickness; the nose, paws, and ears are cold; and there is a frequent evacuation of brown or bloody stools. Castor oil should be given, and clysters of mutton broth thrown up; but it is seldom any treatment succeeds.

7415. *Inflamed lungs.* Pleurisy is not an uncommon disease among dogs. It is sometimes epidemic, carrying off great numbers. Its attack is rapid, and it generally terminates in death on the third day, by a great effusion of water in the chest. It is seldom that it is taken in time; when it is, bleeding is useful, and blisters may be applied to the chest.

7416. *Madness.* The symptoms of madness are concisely summed up by Daniel, in the following words:— "At first the dog looks dull, shows an aversion to his food and company, does not bark as usual, but seems to murmur; is peevish and apt to bite strangers; his ears and tail droop more than usual, and he appears drowsy: afterwards he begins to loll out his tongue and froth at the mouth, his eyes seeming heavy and watery. If not confined he soon goes off, runs panting along with a dejected air, and endeavours to bite any one he meets. If the mad dog escapes being killed, he seldom runs above two or three days, when he dies exhausted with heat, hunger, and disease." As this is a subject of no slight importance, we shall stand excused for introducing the criteria as described by Blaine, whose account of the disease, founded on long experience and attentive observation, is calculated to remove many unfounded and dangerous prejudices relative to it. He describes it as commencing sometimes by dulness, stupidity, and retreat from observation; but more frequently, particularly in those dogs which are immediately domesticated around us, by some alteration in their natural habits; as a disposition to pick up and swallow every minute object on the ground; or to lick the parts of another dog incessantly; or to lap his own urine, &c. About the second or third day the disease usually resolves itself into one of two types. The one is called raging, and the other dumb madness. These distinctions are not, however, always clear; and to which is owing so much discrepancy in the accounts given by different persons of the disease.

7417. *The raging madness*, by its term, has led to an erroneous conclusion, that it is accompanied with violence and fury; which, however, is seldom the case: such dogs are irritable and snappish, and will commonly fly at a stick held to them, and are impatient of restraint: but they are seldom violent except when irritated or worried. On the contrary, till the last moment they will often acknowledge the voice of their master and yield some obedience to it. Neither will they usually turn out of their way to bite human beings; but they have an instinctive disposition to do it to dogs; and in a minor degree to other animals also: but, as before observed, they seldom attack mankind without provocation.

7418. *Dumb madness* is so called because there is seldom any barking heard, but more particularly because the jaw drops paralytic, and the tongue lolls out of the mouth, black, and apparently strangulated. A strong general character of the disease is, the disposition to scratch their bed towards their belly; and equally so is the general tendency to eat trash, as hay, straw, wood, coals, dirt, &c.: and it should be remembered, that this is so very common and so invariable, that the finding these matters in the stomach after death, should always render a suspicion formed of the existence of the disease confirmed into certainty. Blaine is also at great pains to disprove the notion generally entertained, that rabid dogs are averse from water; and neither drink nor come near it. This error he contends has led to most dangerous results; and is so far from true, that mad dogs from their heat and fever are solicitous for water, and lap it eagerly. When the dumb kind exists in its full force, dogs cannot swallow what they attempt to lap; but still they will plunge their heads in it, and appear to feel relief by it: but in no instance out of many hundreds did he ever discover the smallest aversion from it. He lays very great stress on the noise made by

rabid dogs, which he says is neither a bark nor a howl, but a tone compounded of both. It has been said by some that this disorder is occasioned by heat or bad food, and by others that it never arises from any other cause but the bite. Accordingly this malady is rare in the northern parts of Turkey, more rare in the southern provinces of that empire, and totally unknown under the burning sky of Egypt. At Aleppo, where these animals perish in great numbers, for want of water and food, and by the heat of the climate, this disorder was never known. In other parts of Africa, and in the hottest zone of America, dogs are never attacked with madness. Blaine knows of no instance of the complaint being cured, although he has tried, to their fullest extent, the popular remedies of profuse bleedings, strong mercurial and arsenical doses, vinegar, partial drowning, nightshade, water plantain, &c.; he therefore recommends the attention to be principally directed towards the prevention of the malady.

7419. *The preventive treatment of rabies or madness* is, according to Blaine, always an easy process in the human subject, from the immediate part bitten being easily detected; in which case the removal of the part by excision or cautery is an effectual remedy. But, unfortunately for the agriculturist, it is not easy to detect the bitten parts in cattle, nor in dogs; and it would be therefore most desirable if a certain internal preventive were generally known. Dr. Mead's powder, the Ormskirk powder, sea-bathing, and many other nostrums are deservedly in disrepute; while a few country medicines, but little known beyond their immediate precincts, have maintained some character. Conceiving that these must all possess some ingredient in common, he was at pains to discover it; and which he appears to have realised by obtaining among others the composition of Webb's Watford drink. In this mixture, which is detailed below, he considers the active ingredient to be the *Búxus* or box, which has been known as a prophylactic as long as the times of Hippocrates and Celsus, who both mention it. The recipe detailed below has been administered to nearly three hundred animals of different kinds, as horses, cows, sheep, swine, and dogs; and appears to have succeeded in a very great majority of the cases, where it was fairly taken and kept on the stomach. It appears also to have strong prophylactic powers in the human subject; but as it would be most imprudent to trust to it alone, where excision can be practised, so it will be long before the extent of such power can be ascertained in man. The box preventive is thus directed to be prepared: —

Take of the fresh leaves of the tree-box 2 ounces,
of the fresh leaves of rue - - 2 ounces,
of sage - - - - - ½ ounce.

Chop these fine, and boil in a pint of water to half a pint; strain carefully, and press out the liquor very firmly; put back the ingredients into a pint of milk, and boil again to half a pint; strain as before; mix both liquors, which forms three doses for a human subject. Double this quantity is proper for a horse or cow. Two thirds of the quantity is sufficient for a large dog; half for a middling-sized, and one third for a small dog. Three doses are sufficient, given one on each of three subsequent mornings fasting; the quantity directed being that which forms these three doses. As it sometimes produces strong effects on dogs, it may be proper to begin with a small dose; but in the case of dogs we hold it always prudent to increase the dose till effects are evident, by the sickness, panting, and uneasiness of the dog. In the human subject, where this remedy appears equally efficacious, we have never witnessed any unpleasant or active effects; neither are such observed in cattle of any kind. About forty human beings have taken this remedy, and in every instance it has succeeded equally as with animals: but candour obliges us to notice, that in the major part of these, other means were used, as the actual or potential cautery; but in most of the animals other means were purposely omitted. That this remedy, therefore, has a preventive quality, is unquestionable, and now perfectly established; for there was not the smallest doubt of the animals mentioned either having been bitten, or of the dog being mad that bit them, as great pains were in every instance taken to ascertain these points.

7420. *To prevent canine madness* Pliny recommends worming of dogs; and from his time to the present it has had, most deservedly says Daniel, its advocates. He tells us that he has had various opportunities of proving the usefulness of this practice, and recommends its general introduction. Blaine, on the contrary, asserts, that the practice of worming is wholly useless and founded in error; that the existence of any thing like a worm under the tongue is incontestably proved to be false; and that what has been taken for it is merely a deep ligature of the skin, placed there to restrain the tongue in its motions. He also observes, that the pendulous state of the tongue in what is termed dumb madness, with the existence of a partial paralysis of the under jaw by which they could not bite, having happened to dogs previously wormed, has made the inability to be attributed to this source, but which is wholly an accidental circumstance, and happens equally to the wormed and unwormed dog.

7421. *Mange.* This is a very frequent disease in dogs, and is an affection of the skin, either caught by contagion or generated by the animal. The scabby mange breaks out in blotches along the back and neck, and is common to Newfoundland dogs, terriers, pointers, and spaniels, and is the most contagious. The cure should be begun by removing the first exciting cause, if removable; such as filth or poverty, or, as more general the contrary (for both will equally produce it), too full living: then an application should be made to the parts, consisting of sulphur and sal ammoniac; tar-lime-water will also assist. When there is much heat and itching, bleed and purge. Mercurials sometimes assist, but they should be used with caution; dogs do not bear them well.

7422. *Worms.* Dogs suffer very much from worms, which, as in most animals so in them, are of several kinds; but the effects produced are nearly similar. In dogs having the worms the coat generally stares; the appetite is ravenous, though the animal frequently does not thrive; the breath smells; and the stools are singular, sometimes loose and flimsy, at others hard and dry: but the most evil they produce is occasional fits, or sometimes a continued state of convulsion, in which the animal lingers some time, and then dies: the fits they produce are sometimes of the violent kind; at others they exhibit a more stupid character, the dog being senseless and going round continually. The cure consists, while in this state, in active purgatives, joined with opium and the warm bath; any rough substance given internally acts as a vermifuge to prevent the recurrence.

7423. *The worming* of whelps is performed with a lancet, to slit the thin skin which immediately covers what is called the worm; a small awl is then to be introduced under the centre of the worm to raise it up; the farther end of the worm will, with very little force, make its appearance, and with a cloth taking hold of that end, the other will be drawn out easily. The advocates for worming direct that care should be taken that the whole of the worm comes away without breaking; and it rarely breaks, unless cut into by the lancet or wounded by the awl.

7424. *The cat* (*Fèlis Càtus L.*) is distinguished from the lion, tiger, leopard, and others of the genus *Fèlis*, by its annulate tail.

7425. *Its habits* are thus given by Linnæus: — "Inhabits woods of Europe and Asia; domesticated every where; when tranquil purrs, moving the tail; when irritated is very active, climbs, spits, emits a fetid odour; eyes shine at night, the pupil by the day a perpendicular line, by night large, round; walks with its claws drawn in; drinks sparingly; urine of the male corrosive; breath fetid; buries its excrements; makes a horrid mewling in its amours; mews after and plays with its kittens; wags its tail when looking after prey; the lion of mice, birds, and the smaller quadrupeds; peaceful among its tribe; eats flesh and fish; refuses hot or salted things and vegetables; washes behind its ears before a storm; back electric in the dark; when thrown up, falls on its feet; is not infested with fleas; gravid sixty-three days; brings three to nine young, blind nine days; delights in marum, cat-mint, and valerian."

7426. *The cat is of great use in the farmery* in catching mice, rats, and even birds. It is most desirable to keep males, as where females are kept the noisy gallantry of the adjoining tom-cats is exceedingly annoying.

7427. *The Genet cat* (*Vivérra Genétta*) is a species of weasel, with an annulate tail and spotted blackish fawny body. It is a native of Asia, Spain, and France; is mild and easily tamed; and answers all the purposes of a cat at Constantinople and other places.

7428. *The ferret* (*Mustèla Fùro* L., *fig.* 923.) is an animal of the weasel and polecat kind, distinguished by its red fiery eyes.

923

7429. *It is a native of Africa*, but is tamed in Europe for the purpose of catching rabbits. It procreates twice a year, is gravid six weeks, and brings from six to eight young; smells very fetid. The ferret is very susceptible of cold, and must be kept in a box provided with wool or other warm materials, and may be fed with bread and milk. Its sleep is long and profound, and it awakes with a voracious appetite, which is most highly gratified by the blood of small and young animals. Its enmity to rats and rabbits is unspeakable, and when either are, though for the first time, presented to it, it seizes and bites them with the most frenzied madness. When employed to expel the rabbit from its burrows it must be muzzled, as otherwise it will suck the blood of its victim and instantly fall into a profound sleep, from which it will awake only to the work of destruction, committing in the warren, where it was introduced only for its services, the most dreadful waste and havoc. It is possessed of high irritability, and when particularly excited is attended with an odour extremely offensive.

Chap. IX.

Animals of the Bird kind employed in Agriculture.

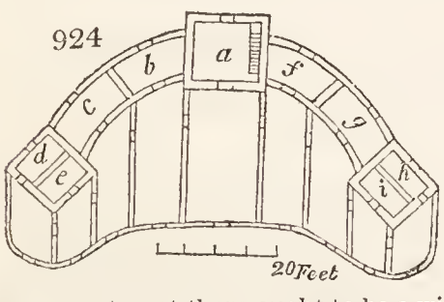
7430. *Though poultry* form a very insignificant part of the live stock of a farm, yet they ought not to be altogether despised. In the largest farm a few domestic fowls pick up what might escape the pigs and be lost; and on small farms and among cottagers, the breeding and rearing of early chickens and ducks, and in some situations the rearing of turkeys and the keeping of geese, are found profitable. There are few who do not relish a new egg or a pancake, not to say the flesh of fowls; and there are some of these comforts which happily can be had in as great perfection in the cottage as in the palace. The various kinds of domestic fowls and birds which are used in agriculture may be classed as gallinaceous, or with cleft feet; anserine, or web-footed; and birds of fancy or luxury. Before proceeding to the first division we shall offer some remarks on poultry hovels.

Sect. I. *Poultry Houses and their Furniture and Utensils.*

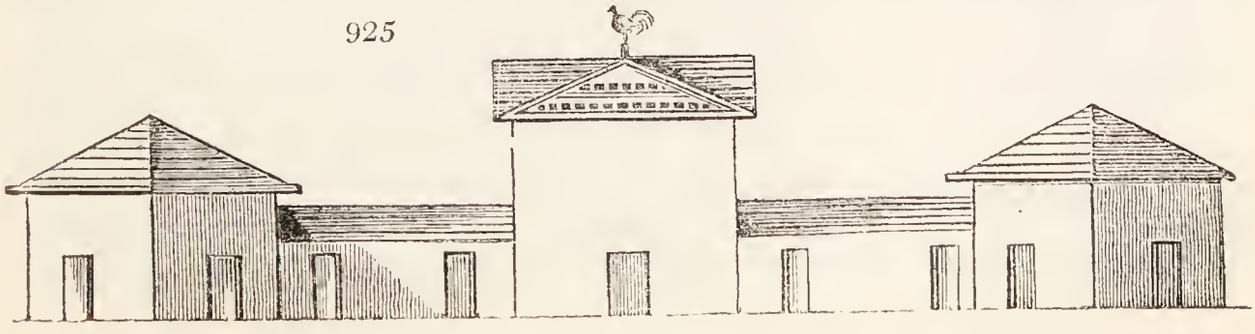
7431. *The situation of the poultry house* should be dry, and exposed either to the east or south-east, so as to enjoy the sun's rays in winter as soon as he appears above the horizon. Though in many cases all the commoner sorts of poultry are lodged in the same apartment; yet to be able to bestow on each species its proper treatment, they ought to be separated by divisions, and enter by separate doors. Apartments for aquatic fowls may be made in part under those of the gallinaceous tribe, and the peacock often prefers roosting on a tree, or on the roof of high buildings, when it forms an excellent watch bird to the poultry-yard or farmery.

7432. *Where a complete set of poultry houses* are intended, then a situation should be fixed on near or close to the farmery, and with ample space around for the fowls to disperse over in the day-time, and one or more ponds for the aquatic sorts. A space thirty feet by fifty feet may be made choice of for the buildings and yard (*fig.* 924); the building may be ranged along the north side, and the three other sides enclosed with a trellis or wire fence from six to eight feet in height, and subdivided with similar fences according to the number of apartments. The hen-house (*a*) and turkey-house (*b*) may have their roosts (*c c*) in part over the low houses for ducks (*d*) and geese (*e*), and besides these there may be other apartments (*f*, *g*, *h*) for hatching or newly hatched broods, for fattening, to serve as an hospital, or for retaining, boiling, or otherwise preparing food, killing poultry, and other purposes. A flue may pass through the whole in moist or very severe weather; the walls should be built hollow in the manner already described (7002.), which will at the same time be a saving of material; and the windows ought to have outside shutters, both for excluding excessive heats and excessive colds. In every apartment there ought to be a window opposite the door, in order to create a thorough draught when both are opened, and also a valve in the roof to admit the escape of the hottest and lightest air. Every door ought to have a small opening at bottom, for the admission of the fowls when the door is shut. The elevation (*fig.* 925.) should be in a simple style, and there may be a pigeonry over the central building.

924



925



7433. *In ordinary cases*, where poultry are kept on a farm merely to consume what would otherwise be lost, one or two compartments of the low range of buildings on the south side of the yard are usually devoted to them, or any dry convenient place, according to the general plan of the farmery.

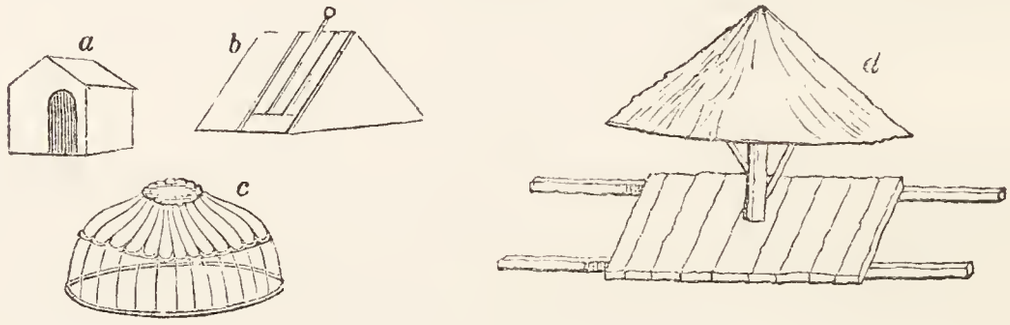
7434. *The furniture or fixtures* of the poultry houses are very few; the roost is sometimes a mere floor or loft, to which the birds fly up or ascend by a ladder; at other times it is nothing more than the coupling timbers of the roof, or a series of cross battens: but the most approved mode is a series of rough polygonal or angular battens or rods rising in gradation from the floor to the roof, as already explained (2840. and 2842.); the battens placed at such a distance horizontally, as that the birds when roosting may not incommode each other by their droppings. For this purpose they should be a foot apart for hens, and eighteen inches apart for turkeys. The slope of the roost may be about 45°, and the lower part should lift up by hinges in order to admit a person beneath to remove the dung. No flying is requisite in the case of such a roost, as the birds ascend and descend by steps.

7435. *Nests* are sometimes fixtures, in which case they are nitches built against the wall, not unlike wine bins; where there is more than one tier on the ground floor, each superincumbent range must have a projecting balcony in front of about a foot in width, with stairs of ascent at convenient distances.

7436. *A small boiler* for preparing food may sometimes be requisite, though on a small scale this may be done in the kitchen. Watering troughs are generally fixed in the yards. In confined situations there should be a large cistern of sand, in which the fowls may nestle and roll about in order to free themselves from vermin; there should also be a spot composed of gravel, sand, and soft earth, for nearly the same purpose, but more especially for exercising the young chickens. A roof for shelter and protection from the sun may very appropriately be placed over this last compartment, or a part of it.

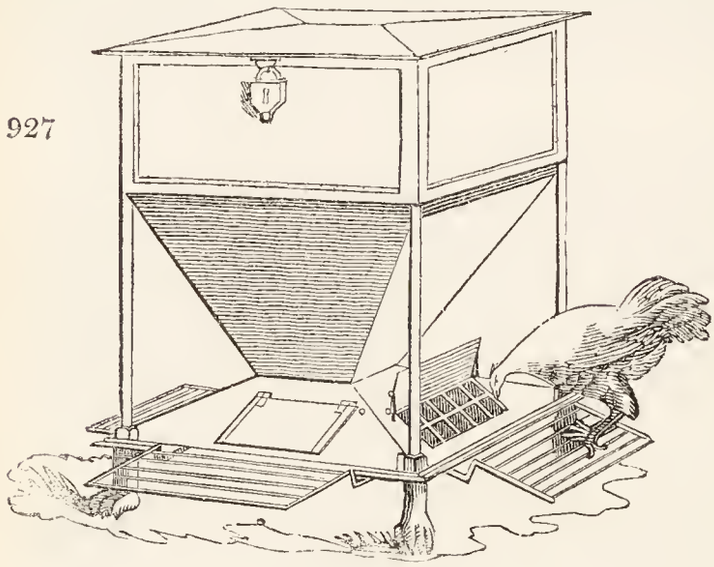
7437. *The utensils* are the portable nest, (*fig.* 926. *a*), coops (*b c*), portable shelter (*d*); feeding dishes,

926



corn bin for retaining a store of food, egg basket, and feather bags. We avoid enumerating the utensils used in cramming, considering that unwholesome and disgusting practice as unfit for the present age.

927



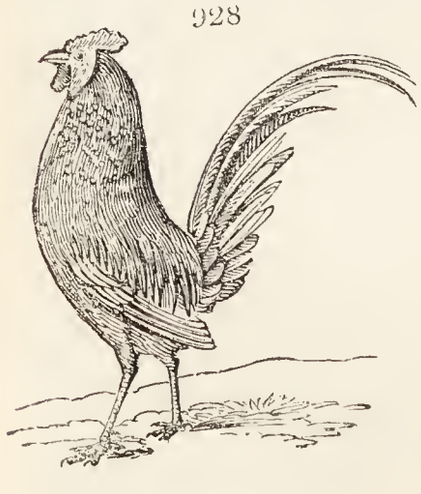
An improved poultry feeder (*fig.* 927.) has lately been published in the *Transactions of the Highland Society*. It is made to hold half a quarter of grain, not one particle of which can be lost. When once filled, it requires no more trouble, as the grain falls down into the receiver below, as the fowls pick it away; and the covers on that, which are opened by perches, and the iron cover above, which is secured by a padlock, completely keep the grain from the rain, so that the fowls get it always quite dry; and as nothing less than the weight of a hen on a perch can lift a cover on the lower receiver, sparrows, and other small birds, are completely excluded, whilst the small cross bars through which the fowls pick prevent cattle and other large animals from getting at the grain. It is astonishing with what facility the fowls learn to leap upon the perch, and so open the cover of the receiver which covers the grain.

Sect. II. *Gallinaceous Fowls, their Kinds, Breeding, Rearing, and Management.*

7438. *Under the order* Gallíneæ are included the common hen, turkey, Guinea, and peacock; and we shall here treat of each of these birds in succession.

7439. *The different species of fowls*, that is, of cocks and hens, inhabit in their native state the continent and islands of Asiatic India. Naturalists have not agreed whether these numerous varieties of this most useful bird, seen in a domesticated state, have originated from one or from two species. M. Temminck considers the Bankiva cock (Gállus Bankìva) as the origin of our domestic poultry; while others think they may have sprang from the Jungle cock (*fig.* 928. *G.* Sonneràt*ii*), still found in the greatest plenty in the forests of India. The term chicken is applied to the female young of gallinaceous animals till they are four months old; afterwards they are called pullets, till they begin to lay, when they become hens. The male is a chicken till he is three months old, then he is a cock bird till the age of twelve months, when he becomes a cock; unless, indeed, he has been artificially deprived of the faculty of procreation, when he becomes a capon; and when the ovarium is taken from a pullet or hen, she is called a hen capon.

928



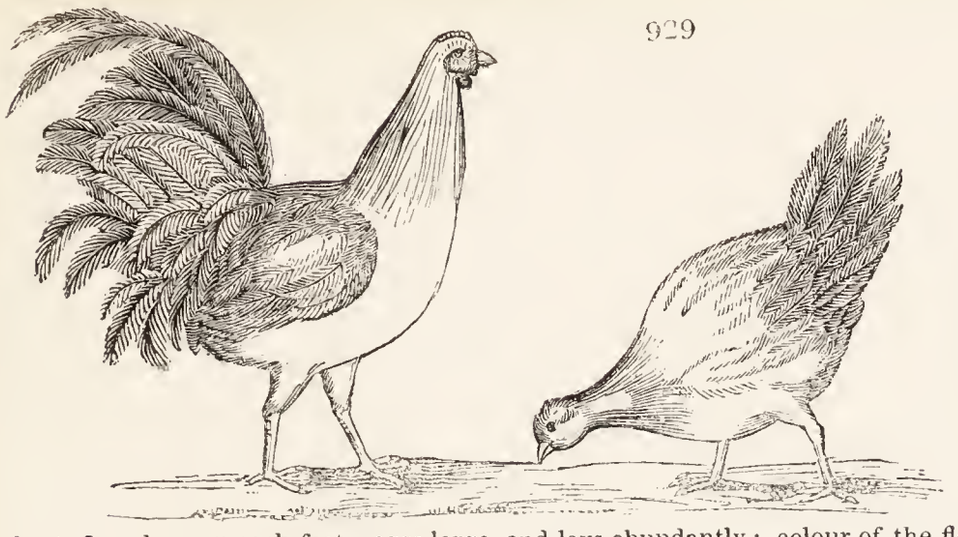
7440. *The varieties* of a bird so long under culture may naturally be expected to be numerous; those most esteemed in Britain, at the present time, are the following: —

7441. *The common dunghill cock and hen*, middle size, of every colour, and hardy.

7442. *The game cock and hen* (*fig.* 929.), rather small in size, delicate in limb, colour generally red or brown; flesh white, and su-

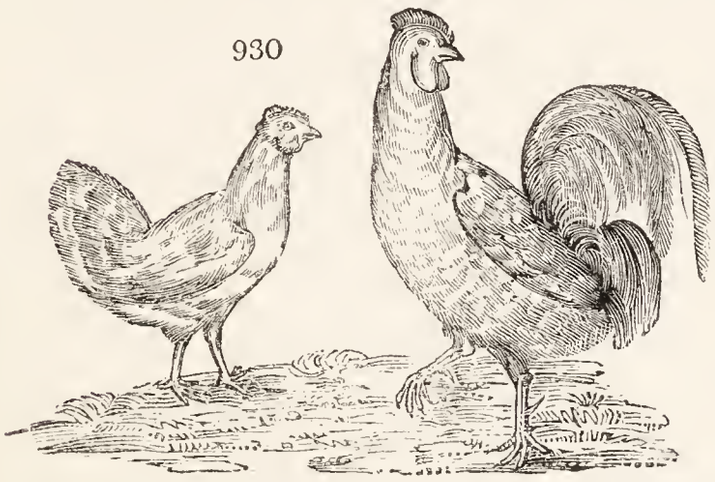
perior to that of any other variety for richness and delicacy of flavour; eggs small, fine shaped, and extremely delicate: the chickens are difficult to rear from their pugnacity of disposition. The game cock has long been a bird both of cruel and curious sport in this as well as other countries; but the taste for these amusements, like that for others suited to times of comparative leisure and ignorance, is now happily on the decline in Britain.

929



7443. *The Dorking cock and hen* (*fig.* 930.), so called from the town in Surrey of that name, is the largest variety; shape handsome; body long and capacious; legs short, five claws on each foot; eggs large, and lays abundantly; colour of the flesh inclining to yellowish or ivory. Both hens and cocks often made into capons.

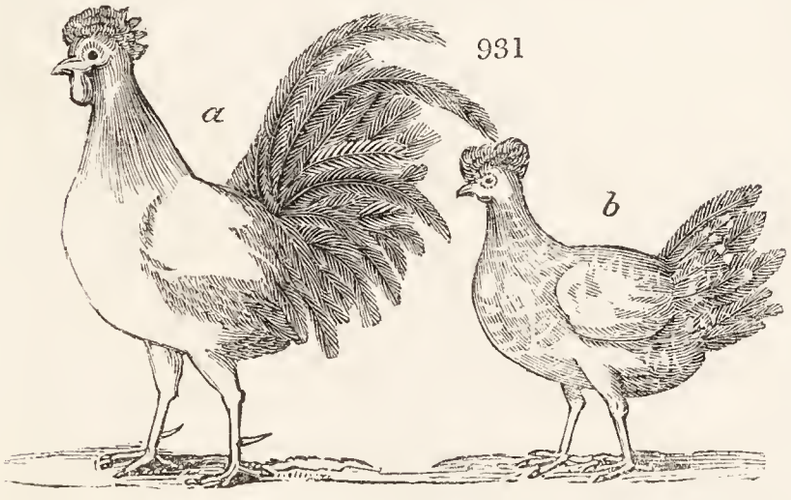
930



7444. *The Poland cock and hen* (*fig.* 931. *a*) were originally imported from Holland. The colour shining black, with white tops on the head of both cock and hen; head flat, surmounted by a fleshy protuberance, out of which spring the crown feathers, or top, white or black, with the fleshy king David's crown (the *celestial* in heraldry), consisting of four or five spikes; their form plump and deep; legs short, feet with five claws; lay abundantly; are less inclined to set than any other breed; they fatten quickly, and are more juicy and rich than the Dorking. On the whole, this is one of the most useful varieties. There is an ornamental subvariety known as the golden Poland (*b*), with yellow and black plumage.

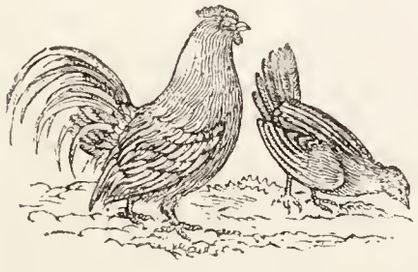
7445. *The every-day cock and hen* is a subvariety of the above, of Dutch origin; they are of smaller size, and said to be everlasting layers. Their tops are large, and should be periodically clipped near the eyes; otherwise, according to Mowbray (*Treatise on Domestic Fowls*, 24. and 115.), they will grow into the eyes of the fowls and render them very subject to alarm.

931

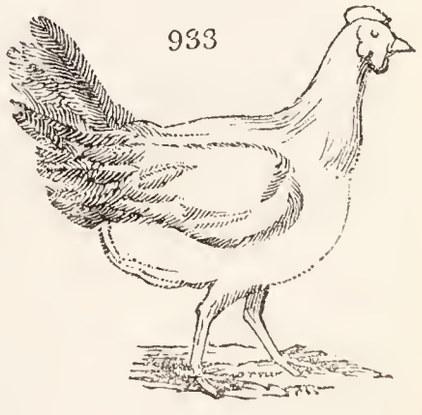


7446. *The bantam cock and hen* (*fig.* 932) is a small Indian breed, valued chiefly for its grotesque figure and delicate flesh. Mowbray mentions a subvariety, extremely small, and as smooth-legged as a game fowl. From their size and delicacy they are very convenient, as they may always be used as substitutes for chickens, when small ones are not otherwise to be had. They are also particularly useful for sitting upon the eggs of partridges and pheasants, being good nurses as well as good layers. There are two varieties of this breed, of which the more common is remarkable for having the legs and feet furnished with feathers. The other, and more scarce, variety is even smaller; and is most elegantly formed, as well as most delicately limbed. There is a society of fanciers of this breed, who rear them for prizes, among which Sir John Sebright stands pre-eminent.

932



933



7447. *The Chittagong or Malay hen* (*fig.* 933.) is an Indian breed, and the largest variety of the species. They are in colour striated, yellow, and dark brown; long necked, serpent-headed, and high upon the leg; their flesh dark, coarse, and chiefly adapted to soup. They are good layers; and being well fed produce large, substantial, and nutritive eggs: but these birds are too long-legged to be steady sitters.

7448. *The Shack-bag, or Duke of Leeds' breed*, was formerly in great repute, but is now nearly lost. It is sometimes to be met with at Wokingham (Oakingham), in Berkshire, and is so large, and the flesh so white, firm, and fine, as to afford a convenient substitute for the turkey.

7449. *The improved Spanish cock and hen* is a cross between the Dorking and Spanish breed, also to be found in and around Wokingham. It is a large bird with black plumage, white and delicate flesh, the largest eggs of any British variety, and well adapted for capons.

7450. *Breeding.* The common variety is easily procurable; but the others must either be procured from those parts of the country where they are usually bred, or from the poulterers and bird fanciers in large towns, and especially in London. It should be a general rule to breed from young stock; a two-year-old cock, or stag, and pullets in their second year. Pullets in their first year, if early birds, will, indeed, probably lay as many eggs as ever after; but the eggs are small, and such young hens are unsteady sitters. Hens are in their prime at three years of age, and decline after five, whence, generally, it is not advantageous to keep them beyond that period, with the exception of those of capital qualifications. Hens with a large comb, or which crow like the cock, are generally deemed inferior; but I have had hens with large rose combs, and also crowers, which were upon an equality with the rest of the stock. Yellow-legged fowls are often of a tender constitution, and always inferior in the quality of their flesh, which is of a loose flabby texture, and ordinary flavour.

7451. *The health of fowls* is observable in the fresh and florid colour of the comb, and the brightness and dryness of the eyes; the nostrils being free from any discharge, and the healthy gloss of the plumage. The most useful cock is generally a bold, active, and savage bird, sometimes cruel and destructive in his fits of passion, if not well watched, to his hens, and even to his offspring. Hens above the common size of their respective varieties are by no means preferable either as layers or setters. The indications of old age are paleness of the comb and gills, dulness of colour, and a sort of downy stiffness in the feathers, and length and size of talons, the scales upon the legs becoming large and prominent.

7452. *The number of hens to one cock* should be from four to six, the latter being the extreme number, with a view of making the utmost advantage. Ten and even twelve hens have been formerly allowed to one cock, but the produce of eggs and chickens under such an arrangement will seldom equal that to be obtained from the smaller number of hens. Every one is aware that the spring is the best season to commence breeding with poultry, and in truth it scarcely matters how early, presupposing the best food, accommodation, and attendance, under which hens may be suffered to sit in January.

7453. *The conduct of the cock towards his hens* is generally of the kindest description, and sometimes, as in the Polish breed, so remarkably so, as to be quite incredible to those who have not witnessed it. It is not an uncommon occurrence, however, for the cock to take an antipathy to some individual hen; when it continues for any length of time it is best to remove her, and supply her place by another, taking care that the stranger be not worried by the hens. Spare coops or houses will be found useful on such occasions.

7454. *The change of a cock*, from death or accident, is always attended with interruption and delay, as it may be some considerable time before the hens will associate kindly with their new partner; and further, a new cock may prove dull and inactive from the change, however good in nature. This frequently happens with cocks of the superior breeds, purchased from the London dealers, in whose coops they have been kept in such a high state of temperature, that they are unable to endure the open air of the country, unless in the summer season. Such being removed in autumn, winter, or early in spring, if immediately turned abroad with hens, are liable to become aguish, torpid, and totally useless; perhaps, in the end, turning roupy or glandered. The only method of safety in this case is to keep such a cock in the house, upon the best and most nourishing food, turning the hens to him several times in the day, and permitting him to be abroad an hour or so, the weather being fine, until, in a few weeks, he shall be accustomed to the air.

7455. *In making the nests*, short and soft straw is to be preferred; because, the straw being long, the hen, on leaving her nest, will be liable to draw it out with her claws, and with it the eggs. The hen, it is ascertained, will breed and lay eggs without the company of a cock; of course, such eggs are barren.

7456. *Eggs for setting* should never exceed the age of a month, the newer to be preferred, as nearly of a size as possible, and of the full middle size; void of the circular flaw, which indicates the double yolk, generally unproductive, nor should there be any roughness or cracks in the shells. The number of eggs, according to the size of the hen, from nine to fifteen, an odd number being preferable, on the supposition of their lying more close. The eggs to be marked with a pen and ink, and examined when the hen leaves her nest, in order to detect any fresh ones which she may have laid, and which should be immediately taken from her, as they, if at all, would be hatched too late for the brood. It is taken for granted the box and nest have been made perfectly clean for the reception of the hen, and that a new nest has not been sluggishly or sluttishly thrown upon an old one, from the filth of which vermin are propagated, to the great annoyance of the hen, and prevention of her steady sitting. Eggs broken in the nest should be cleared away the instant of discovery, and the remaining washed with warm water, and quickly replaced, lest they adhere to the hen, and be drawn out of the nest; if necessary, the hen's feathers may also be washed, but always with warm water.

7457. *With respect to the capriciousness of some hens*, in the article of sitting, it is a risk which must be left to the judgment of the attendant, who has to determine whether the hen which appears desirous of sitting may be safely trusted with eggs. Leaving a number of eggs in the nest is an enticement. Very frequently a hen will cluck, and appear hot for incubation, yet after sitting over her eggs a sufficient number of hours to addle them, will then desert them; and, probably, in the course of a few days will be taken with another fit of incubation. Much useless cruelty is too often exercised to prevent the hen from sitting, when eggs, rather than chickens, are in request. A late author recommends to thrust a feather through the hen's nostrils, in order to prevent her from sitting; and to give her half a glass of gin, then swing her round until seemingly dead, and confine her in a pot during a day or two, leaving her only a small breathing hole, to force her to sit! It is full time that those and a hundred other such utterly useless and barbarous follies of former days, practised upon various animals, should be dismissed with the contempt they merit. The pamphlet alluded to is the *Epicure*, by Thomas Young, a publication replete with good things on the interesting subjects of eating, wines, spirits, beer, cider, &c. It is written with *haut gout.* (*Mowbray.*)

7458. *Moulting.* Every succeeding year after the third, the hen continues to moult later in the season, and laying fewer or no eggs during the moulting period, which is sometimes protracted to two or three months. It should seem that old hens are seldom to be depended upon for eggs in the winter, such being scarcely full of feather until Christmas; and then, probably, may not begin to lay till April, producing at last not more than twenty or thirty eggs. In general, it is most profitable to dispose of hens whilst they are yet eatable or saleable for that purpose, which is in the spring of the third year. Nor do delicate white hens lay so many eggs in the cold season as the more hardy-coloured varieties, requiring warmth and shelter, particularly by night. Moulting, or the casting and renewal of feathers, lasts with its effects from one to three months, according to the age and strength of the bird. Whilst under this natural course, poultry are unfit for the table, as well as for breeding. It is the same with respect to young poultry, whilst shedding their feathers in the spring. The regular moulting of full-grown fowls begins in the autumn.

7459. *In some hens the desire of incubation* is so powerful, that they will repeat it five or six times in the year; in others it is so slight, that they will probably not sit more than once or twice in the season. A skilful breeder will take advantage of these qualities, and provide abundance of eggs from the one variety, and of chickens by means of the other. Hens, when sitting, drink more than usual: and it is an advisable practice to place water constantly before them when in this state, and food (say corn) at least twice a day. The time of incubation is twenty-one days.

7460. *Hatching.* The chicken, hitherto rolled up like a ball, with its bill under the right wing, like a bird asleep, begins generally on the morning of the twenty-second day to break its way through the shell; neither the hen, nor can the art of man, with safety render them aid in this very interesting and wonderful operation. The parental affection of the hen, as Mowbray and Parmentier have observed, is always

intensely increased, when she first hears the voice of the chicks through the shells, and the strokes of their little bills against them. The signs of a need of assistance, the former author observes, are, the egg being partly pecked, and the efforts of the chicken discontinued for five or six hours. The shell may then be broken cautiously, and the body of the chicken carefully separated from the viscous fluid which lines it. Réaumur gives it as his opinion, that no aid ought to be given to any chickens but those which have been near twenty-four hours employed without getting forward in their work.

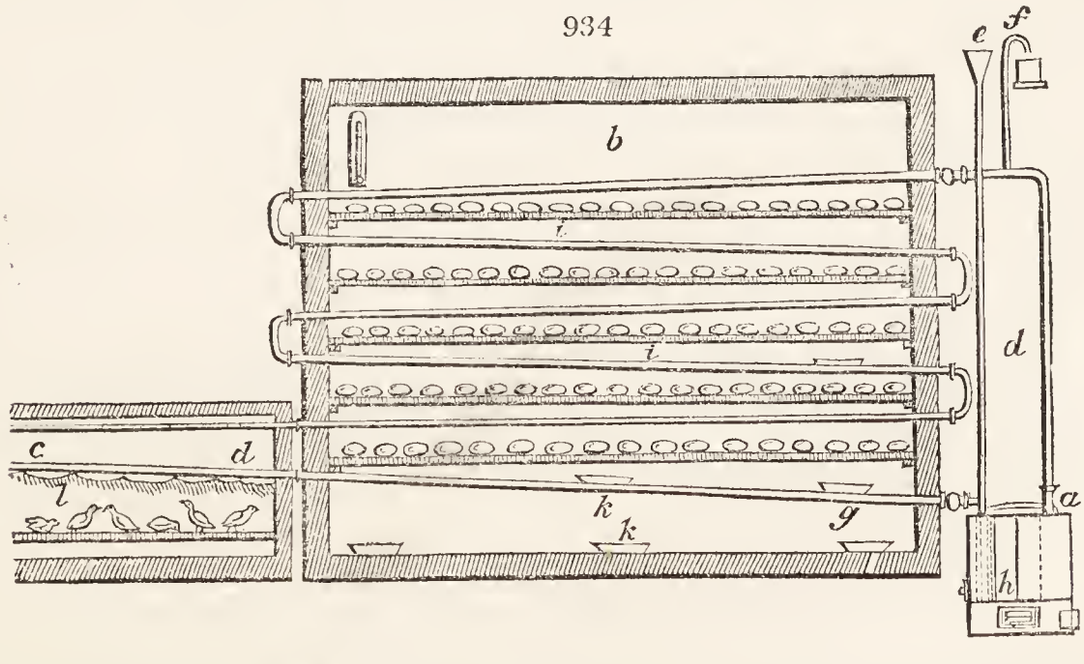
7461. *The chickens first hatched* should be taken from the hen, lest she be tempted to leave her task unfinished. Those removed may be secured in a basket of wool or soft hay, and kept in a moderate heat, if the weather be cold, near the fire. They will require no food for many hours, even four-and-twenty, should it be necessary to keep them so long from the hen. The whole brood being hatched, the hen is to be placed under a coop abroad, upon a dry spot, and, if possible, not within reach of another hen, since the chickens will mix, and the hens are apt to maim or destroy those which do not belong to them. Nor should they be placed near numbers of young fowls, which are likely to crush young chicks under their feet, being always eager for the chickens' meat. The first food should be split grits, afterwards tail wheat; all watery food, soaked bread, or potatoes, is improper. Eggs boiled hard, or curd chopped small, are much approved as first food. Their water should be pure and often renewed; and there are convenient pans made, in such forms that the chickens may drink without getting into the water, which often, by wetting their feet and feathers, numbs and injures them. A bason whelmed in the middle of a pan of water will answer the end, the water running round it generally; and, independently of situation, and the disposition of the hen, there is no necessity for cooping the brood beyond two or three days; but they may be confined as occasion requires, or suffered to range, as they are much benefited by the scratching and foraging of the hen. They must not be let out too early in the morning, or whilst the dew remains upon the ground, far less be suffered to range over the wet grass, one common and fatal cause of disease. Another caution is of the utmost consequence, to guard them watchfully against sudden unfavourable changes of the weather, more particularly if attended with rain. Nearly all the disorders of gallinaceous fowls arise from cold moisture.

7462. *For the period of the chickens quitting the hen*, there is no general rule: the most certain is, when the hen begins to roost, leaving them; if sufficiently forward, they will follow her; if otherwise, they should be secured in a proper place, the time having arrived when they are to associate with the young poultry, as nearly of their own age and size as possible, since the larger are apt to overrun and drive from their food the younger brood.

7463. *Hatching by artificial heat* is an Egyptian practice, mentioned by Diodorus and Aristotle, and was brought into notice about the middle of the eighteenth century, by Réaumur in his "*Art de faire éclore, &c. des Oiseaux domestiques.*" The requisite degree of heat is 90 degrees, which is supplied by fire, steam, hot water, or fermentible substances; after hatching, the birds are placed in a cage, in which is placed a lamb-skin suspended from the roof of a box, and enclosed by a curtain of green baize; or, according to Parmentier, they may be placed under a capon, which, after being prepared for receiving pleasure from feeling the chickens under its belly, by depriving it of the greater part of the feathers and excoriation, is to be confined with them in the same coop, and after being fed together for a day or two, it is said the capon will become an excellent nursing mother. Excepting as matter of curiosity, however, it is not at present worth while either to hatch or rear chickens artificially in this country. Whether Réaumur's mode of hatching be adopted, or Mrs. D'Oyley's of depriving hens of their chickens as soon as hatched, and thus causing one hen to hatch five or six broods in succession, the human attention required, and the risk of failure are so great, that the surest modes, under all the present circumstances, are such as are natural. Where it is tried for experiment or curiosity, the heat of tan or dung is more likely to prove steady than that from smoke, air, or steam, probably even than that of hot water, successfully tried, however, and, we believe, still practised in the neighbourhood of Paris. An enclosure in the middle of a broad vinery or hothouse might serve at once to hatch and rear early chickens; and such a mode of rearing, at least in the winter season, certainly deserves the attention of those who are curious in having this luxury in February and March. In 1822 or 1823 some interesting experiments were exhibited by Mr. Barlow at the Egyptian Hall, London, relative to an improved method which he had invented, of hatching eggs by artificial heat. The method, and the machine necessary to practise it, seem to have come very little into use.

7464. *The incubation of chickens by hot water* is the invention of M. Bonnemain, physician, of Paris, in 1777; and still alive when we were in that capital in 1828. Chickens hatched in this way at St. Germain's, under M. B.'s direction, it is said, supplied the table of Louis XIV. The boiler of the apparatus is called a *calorifère*, (*calor*, heat, and *fero*, to bear,) and consists of a small boiler (*fig.* 934. *a*), a box or

934



building (*b*) for hatching the eggs, a cage or coop (*c*) for rearing the chickens, tubes (*d*) for circulating the hot water, a supply tube and funnel (*e*), and a safety tube (*f*). Supposing the water heated in the boiler, it will rise by its specific levity through the tube (*a*, *d*), move progressively through all the tubes, and return again to the boiler by the tube (*g*), which is inserted in the lid like the other, but passes down to its lower part (*h*). This circulatory movement, once commenced, continues so long as the water is heated in the boiler, because the temperature is never equal throughout all parts of the apparatus. We may readily conceive that a perfect equality of temperature can never exist, on account of the continual loss of heat, which escapes from the exteriors of all the tubes. Meanwhile, the temperature of the air en-

closed in the box differs but little from that of the numerous tubes which traverse it; and as the bends of the tubes on the outside of the box afford but little surface to be cooled by the surrounding air, so the force of the circulation, which is always in the ratio of the difference between the temperature of the waters passing out of the calorifère and re-entering it, does not become greatly diminished, even after having expended a large portion of its heat on the outside of the box, in maintaining a gentle heat in the cage (*c*) adjoining to it. We see, therefore, that the more the water is cooled which passes through the last circumvolutions of the tubes, the more active is the circulation in all parts; and, consequently, the more equal is the temperature of all the tubes which heat the box, and of the air within it: indeed, to prevent the loss of heat as much as possible, the boiler, and all those parts of the tubes which are placed on the exterior of the box, are enveloped in lists of woollen cloth. M. Bonnemain having thus applied these principles with so much skill, is always enabled to maintain in these boxes an equal temperature, varying scarcely so much as half a degree of Réaumur's thermometer; but, as if it was not sufficient to have thus far resolved the problem, he contrived that this degree of temperature in all parts of the stove should be maintained at that point which was found most favourable for promoting incubation. It was by means of an apparatus for regulating the fire that he attained this desirable object. The action of this regulator is founded on the unequal dilatation of different metals by heat. A movement is communicated near to the axis of a balanced lever, which lever transmits it by an iron wire to a register in the ash-pit door of the furnace. Combustion is by these means abated or increased. The details of this piece of machinery are fully described and delineated in *Gill's Technological Register* (Feb. 1828, p. 70.).

7465. *When we would hatch chickens by hot water*, we light the fire and raise the temperature till we obtain that degree of heat in the box which is fitted for incubation; we then place the eggs near to each other, upon the shelves, with borders to them (*i*, *i*), which are fixed under each row of tubes. It is convenient not to cover, on the first day, more than a twentieth part of the superficies of the shelves, and to add every day, for twenty days, an equal quantity of eggs; so that, on the twenty-first day, the quantity of eggs first placed will be, for the greatest part, hatched: so that we may obtain every day nearly the same number of chickens; but which may, nevertheless, be occasionally regulated by the particular season of the year.

7466. *During the first days of incubation*, whether natural or artificial, the small portion of water contained within the substance of the egg evaporates through the pores in its shell: this is replaced by a small quantity of air, which is necessary to support the respiration of the chick; but as the atmospheric air which surrounds the eggs in the box at that degree of temperature is either completely dry, or but little humid, so the chick would greatly suffer, or finally perish, from this kind of desiccation. The aqueous vapour which exhales from the breathing of the old fowls while hatching, in some degree prevents this ill effect; but, nevertheless, in dry seasons, the vapour is hardly sufficient: and thus, in order that the eggs may be better hatched in the dry seasons, the hens cover them with the earth of the floor of the granary. In artificial incubation, to keep the air in the stove constantly humid, they place in it flat vessels, such as plates (*k*, *k*), filled with water. When the chickens are hatched, they are removed from the stove, and carried to the cage (*c*), where they are fed with millet, and nestle under a sheep's skin with wool on it (*l*), suspended over them. They also separate, by means of partitions in the cage, the chickens as they are hatched each day, in order to modify their nourishment agreeably to their age. Artificial incubation is exceedingly useful in furnishing young fowls at those seasons when the hens will not sit, and, in some situations, to produce, or, as we may say indeed, to manufacture a great number of fowls in a small space. (*Gill's Technological Repository*, No. viii. p. 73. as quoted in *Gard. Mag.* vol. iv. p. 307.)

7467. *The products of the cock and hen* are eggs, feathers, and the carcass.

7468. *Eggs* become desiccated, and, in consequence, lose great part of their substance and nutritive quality, by keeping; and every body knows the value of a fresh-laid egg. They will retain their moisture and goodness, however, three or four months, or more, if the pores of the shell be closed and rendered impervious to the air, by some unctuous application. We generally anoint them with mutton suet melted, and set them on end, wedged close together, in bran, *stratum super stratum*, the containing box being closely covered. Laid upon the side, the yolk will adhere to the shell. They thus come into use, at the end of a considerable period of time, in a state almost equal to new-laid eggs, for consumption; but ought not to be trusted for incubation, excepting in the case of the imported eggs of rare birds.

7469. *The largest eggs* will weigh two ounces and a half, those of the Chittagong hen perhaps three ounces. To promote fecundity and great laying in the hen, nothing more is necessary than the best corn and fair water; malted or sprouted barley has occasionally a good effect, whilst the hens are kept on solid corn; but if continued too long they are apt to scour. Cordial horse-ball is good to promote laying in the cold season, and also toast and ale, as every housewife well knows. It must be noted, that nothing is more necessary towards success in the particular of obtaining plenty of eggs, than a good attendance of cocks, especially in the cold season; and it is also especially to be observed, that a cock whilst moulting is generally useless. Buffon says, a hen well fed and attended will produce upwards of one hundred and fifty eggs in a year, besides two broods of chickens. Mowbray observed, that a hen generally cackled three or four days previously to laying; and that some half-bred game hens began to lay as soon as their chickens were three weeks old; the consequence of high keep and good attendance of the cocks.

7470. *Feathers or down* intended for use should be plucked as soon as possible after the bird is dead, and before it is cold, otherwise they are defective in that elasticity which is their most valuable property, and are liable to decay. The bird should, besides, be in good health, and not moulting, for the feathers to be in perfection; and being plucked, and a sufficient number collected, the sooner they are dried upon the oven the better, since they are else apt to heat and stick together.

7471. *The feathers of birds* are applied to various purposes of utility and ornament. "The plumassier collects and prepares the delicate feathers of birds, and gives them the most brilliant colours, in order to vend them to the embroiderer, and the manufacturer of artificial flowers, who introduces them into their embroideries, and forms them into bouquets and garlands, to add to the elegancies of dress and furniture, according to the tastes indicated by fashion. The plumassier only employs the feathers of the ostrich, the heron, the peacock, the swan, the goose, and the cock; these he prepares and disposes in a fit manner to adorn our hats, robes, &c.; he also makes *aigrettes*, and an infinity of other objects. The workman who forms the feathers for these uses is termed a *plumassier*. All the kinds of feathers which possess great brilliancy, extent, and fineness, are also employed in a great variety of circumstances, although those are preferred which we have above mentioned." (*Gill's Tech. Rep.* vol. vi. See p. 248.)

7472. *Where hens are kept more than a year* they are sometimes plucked towards the end of the spring season for the sake of their feathers. This operation, where it takes place, ought to be performed in the most tender and careful manner, and the birds housed afterwards for a time sufficient to enable them to endure the air: but the practice is cruel, and we trust it is not likely to come into general use.

7473. *Feeding and fattening the carcass.* Fowls will become fat on the common run of the farm-yard, where they thrive upon the offals of the stable, and other refuse, with perhaps some small regular daily feeds; but at threshing time they become particularly fat, and are thence styled barn-door fowls, probably the most delicate and high flavoured of all others, both from their full allowance of the finest corn, and the constant health in which they are kept, by living in a natural state, and having the full enjoyment of air and exercise. They are also confined during a certain number of weeks, in coops, those fowls which are soonest ready being drawn as wanted. It is a common practice with some housewives, to coop their barn-door fowls for a week or two, under the notion of improving them for the table, and increasing their fat; a practice which, however, seldom succeeds, since the fowls generally pine for their loss of liberty,

and slighting their food, lose instead of gaining additional flesh. Such a period, in fact, is too short for them to become accustomed to confinement.

7474. *Feeding-houses* should be warm and airy, with earth floors well raised, and capacious enough to accommodate twenty or thirty fowls; the floor slightly littered down, and the litter often changed. Sandy gravel and a little lime rubbish should be placed in different places, and often changed. A sufficient number of troughs, for both water and food, should be placed around, that the stock may feed with as little interruption as possible from each other, and perches in the same proportion should be furnished for those birds which are inclined to perch, which few of them will desire after they have begun to fatten, but which helps to keep them easy and contented until that period. In this mode fowls may be battened to the highest pitch, and yet preserved in a healthy state, their flesh being equal in quality to that of the barn-door fowl. To suffer fattening fowls to perch is contrary to the general practice, since it is supposed to bend and deform the breast-bone; but as soon as they become heavy and indolent from feeding, they will rather incline to rest in the straw; and the liberty of perching in the commencement of their cooping has a tendency to accelerate that period, when they are more inclined to rest on the floor. Fowls, moreover, of considerable growth will have many of them become already crooked breasted from perching whilst at large, although much depends upon form in this case, since we find aged cocks and hens of the best shape which have perched all their lives with the breast bone perfectly straight.

7475. *The privation of light*, by inclining fowls to a constant state of repose, excepting when moved by the appetite for food, promotes and accelerates obesity; but a state of obesity obtained in this way cannot be a state of health, nor can the flesh of animals so fed equal in flavour, nutriment, and salubrity, that of the same species fed in a more natural way. Economy and market interest may perhaps be best answered by the plan of darkness and close confinement; but a feeder for his own table, of delicate taste, and ambitious of furnishing his board with the choicest and most salubrious viands, will declare for the natural mode of feeding; and in that view, a feeding-yard, gravelled and turfed, the room being open all day, for the fowls to retire at pleasure, will have a decided preference, as the nearest approach to the barn-door system.

7476. *Insects and animal food* form a part of the natural diet of poultry, are medicinal to them in a weakly state, and the want of such food may sometimes impede their thriving.

7477. *For fattening the younger chickens*, the above feeding-room and yard is well calculated. These may be put up as soon as the hen shall have quitted her charge, and before they have run off the sucking flesh; for generally, when well kept and in health, they will be in fine condition and full of flesh at that period, which flesh is afterwards expended in the exercise of foraging for food, and in the increase of stature, and it may be a work of some time afterwards to recover it, more especially in young cocks, and all those which stand high upon the leg. In fact, all those which appear to have long legs should be fattened from the hen, to make the best of them; it being extremely difficult, and often impossible, to fatten long-legged fowls in coops, which, however, are brought to a good weight at the barn-door.

7478. *In the choice of full-sized fowls for feeding*, the short-legged and early hatched always deserve a preference. The green linnet is an excellent model of form for the domestic fowl, and the true Dorking breed approaches the nearest to such model. Of course the smaller breeds and the game are the most delicate and soonest ripe. The London chicken butchers as they are termed, or poulterers, are said to be of all others the most dexterous feeders, putting up a coop of fowls and making them thoroughly fat within the space of a fortnight; using so much grease, and that perhaps not of the most delicate kind, in the food. In the common way this business is often badly managed, fowls being huddled together in a small coop, tearing each other to pieces, instead of enjoying that repose which alone can ensure the wished-for object; irregularly fed and cleaned, until they are so stenched and poisoned in their own excrement, that their flesh actually smells and tastes of it when smoking upon the table. Where a steady and regular profit is required from poultry, the best method, whether for domestic use or sale, is constant high keep from the beginning; whence they will not only be always ready for the table, with very little extra attention, but their flesh will be superior in juiciness and rich flavour to those which are fattened from a low or emaciated state. Fed in this mode, the spring pullets are particularly fine, and at the same time most nourishing and restorative food. The pullets which have been hatched in March, if high fed from the nest, will lay plentifully through the following autumn; and not being intended for breeding stock, the advantage of their eggs may be taken, and themselves disposed of thoroughly fat for the table in February, about which period their laying will be finished. Instead of giving ordinary and tail corn to fattening and breeding poultry, it will be found most advantageous to allow the heaviest and best, putting the confined fowls upon a level with those fed at the barn-door, where they have their share of the weightiest and finest corn. This high feeding shows itself not only in the size and flesh of the fowls, but in the size, weight, and substantial goodness of their eggs, which in those valuable particulars will prove far superior to the eggs of fowls fed upon ordinary corn or washy potatoes; two eggs of the former going further in domestic use than three of the latter. The water also given to fattening fowls should be often renewed, fresh and clean; indeed, those which have been well kept will turn with disgust from ordinary food and foul water.

7479. *Barley and wheat are the great dependence for chicken poultry*; oats will do for full-grown hens and cocks, but are not so good as barley; both, when they have their fill of corn, will eat occasionally cabbage or beet leaves. Steamed potatoes and oatmeal mixed together make an excellent mess, but must not be given in great quantities, otherwise it renders the flesh soft and flabby.

7480. *Cramming.* Barley and wheat meal are generally the basis or chief ingredient in all fattening mixtures for chickens and fowls; but in Sussex ground oats are used, and there oats are in higher repute for fattening than elsewhere, many large hogs being fattened with them. In the report of that county, the Rev. Arthur Young says, "North Chappel and Kinsford are famous for their poultry: they are fattened there to a size and perfection unknown elsewhere. The food given them is ground oats made into gruel, mixed with hog's grease, sugar, pot-liquor, and milk; or ground oats, treacle, and suet, sheep's plucks, &c. The fowls are kept very warm, and crammed morning and night. The pot-liquor is mixed with a few handfuls of oatmeal and boiled, with which the meal is kneaded into crams or rolls of a proper size. The fowls are put into the coop two or three days before they are crammed, which is continued for a fortnight; and they are then sold to the higglers. These fowls, full grown, weigh seven pounds each, the average weight five pounds; but there are instances of individuals double the weight. They were sold at the time of the survey (1809) at four to five shillings each. Turner, of North Chappel, a tenant of Lord Egremont, crams two hundred fowls per annum. Great art and attention is requisite to cut the capons, and numbers are destroyed in the operation."

7481. *Oakingham in Berks is particularly famous for fatted fowls*, by which many persons in that town and vicinity gain a livelihood. The fowls are sold to the London dealers, and the sum of 150*l.* has been returned in one market-day by this traffic. Twenty dozen of these fowls were purchased for one gala at Windsor, after the rate of half a guinea the couple. At some seasons, fifteen shillings have been paid for a couple. Fowls constitute the principal commerce of the town. Romford, in Essex, is also a great market for poultry, but generally of the store or barn-door kind, and not artificially fed.

7482. *The Oakingham method of feeding* is to confine the fowls in a dark place, and cram them with paste made of barley-meal, mutton-suet, treacle, or coarse sugar, and milk; and they are found completely ripe in a fortnight. If kept longer, the fever that is induced by this continued state of repletion, renders them red and unsaleable, and frequently kills them. Geese are likewise fed in the same neighbourhood, in great numbers, and sold about midsummer to itinerant dealers; the price at the time the survey was made (1808), two shillings to two and three-pence each. It appears utterly contrary to reason, that fowls fed upon such greasy and impure mixtures can possibly produce flesh or fat so firm, delicate, high flavoured,

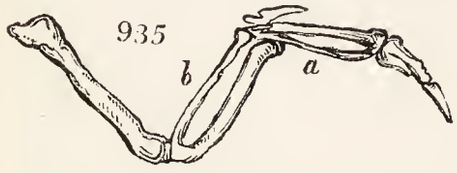
or nourishing, as those fattened upon more simple and substantial food; as, for example, meal and milk, without the addition of either treacle or sugar. With respect to grease of any kind, its chief effect must be to render the flesh loose and of indelicate flavour. Nor is any advantage gained, excluding the commercial one.

7483. *The methods of cramming by confining in a box* the size of the body of the fowl, and allowing its head and vent to project for intromission and ejection; of blinding the bird for this purpose; or of nailing it to the board; and also the mode of forcing down liquid food by a particular kind of pump, worked by the foot of the feeder; all these and other cruel practices we wish we could abolish in practice, and obliterate from the printed page.

7484. *Castration* is performed on cocks and hens only in some districts, and chiefly in Berkshire and Sussex. The usual time is when they have left the hen, or when the cocks begin to crow, but the earlier the better. It is a barbarous practice and better omitted. Capons are shunned both by hens and cocks, which, it is said, will not roost on the same perch with them. The Chinese mode of making capons is fully described and illustrated with cuts in the *Farmer's Magazine*, vol. vi. p. 46.

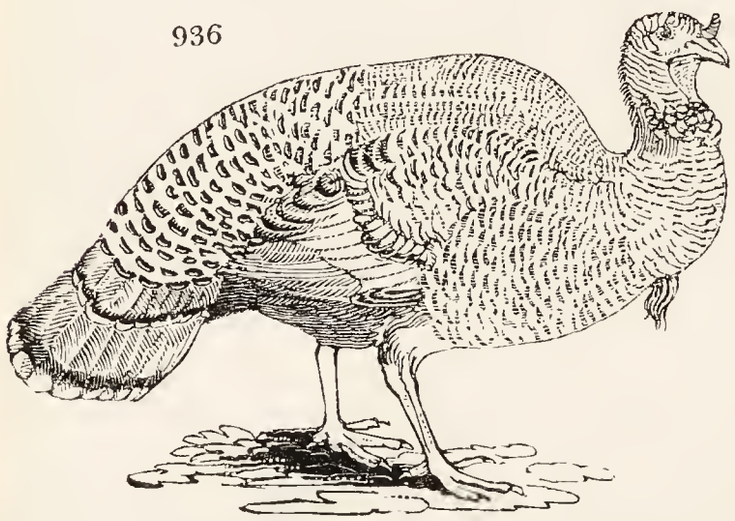
7485. *Pinioning of fowls* is often practised to restrain them from roosting too high, or from flying over fences, &c.; and is much more convenient than the cutting their wing feathers only. But in the ordinary methods of merely excising the pinion, it is frequently fatal; and almost always so to full-grown birds or fowls, by their bleeding to death. To prevent this in the long-winged tribes, as ducks, geese, &c., pass a threaded needle through their wing, close by the inside of the smaller bone (*fig.* 935. *a*), and making a ligature with the thread across the larger bone, and returning it on the outside of all, the principal blood-vessels are secured, which could not be accomplished by a ligature confined to the surface only. After the blood-vessels have been thus secured, cut off the portion of wing beyond the ligature with scissars or shears. In the Gallinàcea or short-winged tribes, as cocks, hens, &c., the operation is rendered safer by being performed on the beginning of the next joint (*b*), making the ligature embrace all the vessels between these two bones by passing it twice through, and securing each bone individually, and passing the ligature around the whole of that part of the wing generally. In this way also birds which have been accidentally winged in shooting may be preserved.

935



7486. *The turkey* (*M*elèagris Gallipàvo *L.*, *fig.* 936.) is a native of America, and was introduced into this country from Spain soon after the discovery of the former country. The colour in the wild state is black, but domestication has produced great variety.

936



7487. *In a state of nature* they are said to parade in flocks of five hundred, feeding, in general, where abundance of nettles are to be found, the seed of which and of a small red acorn is their common food in the American woods. They get fat in a wild state, and are soon run down by horses and dogs. They roost on the highest trees, and since the clearing of extensive tracts in America, have become rare in many places: their antipathy to any thing of a red colour is well known. In this country they are supposed to be of a tender constitution, which only applies to them when young; for when grown up they will live in the woods with occasional supplies of food, as is actually the case to a great extent in the demesne lands of the Marquis of Bute, in Bute.

7488. *The varieties* are few, and chiefly the copper and white, said to be imported from Holland, the former too tender for general culture; the black Norfolk is esteemed superior to all others.

7489. *Breeding.* One turkey cock is sufficient for six hens or more, and a hen will cover according to her size from nine to fifteen eggs. The hen is apt to form her nest abroad in a hedge, or under a bush, or in some secure place; she lays from eighteen to twenty-five eggs or upwards, and her term of incubation is thirty days. She is a steady sitter, even to starvation, and therefore requires to be regularly supplied with food and water. Buffon says she is a most affectionate mother; but Mowbray observes, that from her natural heedlessness and stupidity, she is the most careless of mothers; and being a great traveller herself, will drag her brood over field, heath, or bog, never casting a regard behind her to call in her straggling chicks, nor stopping while she has one left to follow her. The turkey differs from the common hen in never scratching for her chicks, leaving them entirely to their own instinct and industry; neither will they fight for their brood, though vigilant in the discovery of birds of prey, when they will call their chickens together by a particular cry, and run with considerable speed. Hence, when not confined within certain limits, they require the attendance of a keeper.

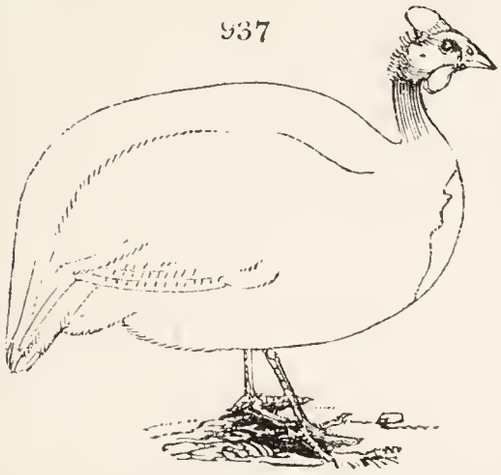
7490 *Turkey chicks* should be withdrawn from the nest as soon as hatched, and kept very warm by wrapping them in flannel, or putting them under an artificial mother in a warm room or other warm place. Various nostrums are recommended to be given and done at this season, as a peppercorn and a tea-spoonful of milk, immersion in cold water, &c. Mowbray wisely rejected all these unnatural practices, and succeeded by giving curd and hard eggs, or curd and barley meal kneaded with milk, and renewed with clear water rather than milk, as he found the last often scoured them. A sort of vermicelli, or artificial worms, made from pulling boiled meat into strings, he found beneficial for every species of gallinaceous chicken. Two great objects are, to avoid superfluous moisture, and to maintain the utmost cleanliness, for which purposes as little slop food is given as possible. A fresh tuft of short sweet grass should be daily given as green food, but not snails or worms as scouring, and no oats; nettle seed, clover, rue, or wormwood gathered, as recommended by the elder housewives. Water is generally preferable to milk. When the weather is favourable, the hen is cooped abroad in the forenoon. During the rest of the day and night, for the first six weeks, she is kept within doors. After this the hen may be cooped a whole day externally for another fortnight, to harden the chickens; and afterwards they may be left to range within certain limits, or tended by an old man or woman, being fed at going out in the morning and returning in the evening. Their ordinary food may be that of the common cocks and hens. They will prefer roosting abroad upon high trees in the summer season, but that cannot generally be permitted with a view to their safe keeping.

7491. *Fattening.* Sodden barley, or barley and wheat-meal mixed, is the most approved food; and the general mode of management is the same as that of the common cock and hen. They are generally fed so as to come in at Christmas, but they may be fattened early or late. Sometimes though, but rarely, they are caponised. Buffon says, the wild turkey of America has been known to attain the weight of sixteen pounds; the Norfolk turkeys are said sometimes to weigh twenty and thirty pounds; but Mowbray says,

he never made any higher than fifteen pounds ready for the spit. The living and dead weight of a turkey are as 21 to 14.

7492. *Feathers.* Turkeys are sometimes plucked alive, a barbarous practice which ought to be laid aside. Parmentier proposed to multiply the breed of white turkeys in France, and to employ the feathers found on the lateral part of the thighs instead of the plumes of the ostrich.

937



7493. *The Guinea hen* (Numídia *Melèagris L.*, *fig.* 937.) is found in a wild state only in Africa, from whence it has been diffused over every part of Europe, the West Indies, and America. In a state of nature these birds associate in flocks of two or three hundred. They delight in marshy places, but always perch during the night in trees, or high situations. It is bigger than a large cock, and is active, restless, and courageous; and will even attack the turkey, though so much above its size.

7494. *The properties of the pheasant and the turkey* have been said to be united in this bird; its flesh is more like that of the pheasant than that of the common cock and hen both in colour and taste, and is reckoned a very good substitute for the former bird. It is also very prolific, and its eggs are nourishing and good. It assimilates perfectly with common fowls in its artificial habits and kinds of food; but it has this peculiarity — that the cocks and hens are so nearly alike, that it is difficult to distinguish them, and it has a peculiar gait, and cry, and chuckle.

7495. *The peacock* (*Pàvo* cristàtus *L.*) is a native of India, and found in a wild state in Java and Ceylon, where they perch on trees like the turkey in America. The age of the peacock extends to twenty years, and at three the tail of the cock is full and complete. The cock requires from three to four hens; and where the country agrees with them, they are very prolific, a great ornament to the poultry yard and lawns, and useful for the destruction of all kinds of reptiles. Unfortunately, they are not easily kept within moderate bounds, and are very destructive in gardens. They live on the same food as other domestic fowls, and prefer barley. They are in season from February till June; but though a peacock forms a very showy dish, the flesh is ill-coloured and coarse, and they are therefore kept more as birds of ornament than of use.

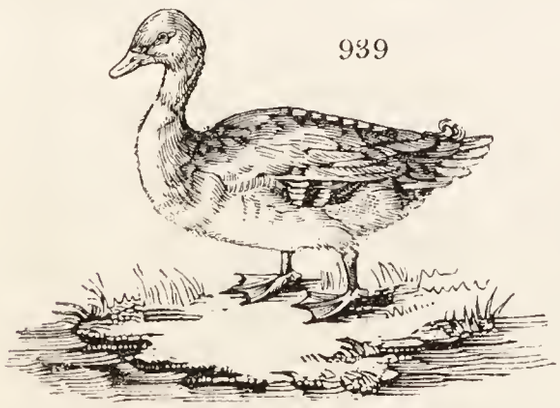
938

7496. *The crested curassow* (*Crax Alector L. fig.* 938.) is a beautiful and majestic bird, nearly the size of a turkey; it is common in some parts of tropical America, and is mentioned as being abundant in Paraguay. In those countries it is tamed, and readily associates with the other domestic poultry. Like most gallinaceous birds, it lives in flocks of about a dozen, feeds upon Indian corn, rice, and other grain during the day, and roosts on high trees at night. Its size, disposition, and the delicacy of its flesh, all recommend our attempting to domesticate it in this country.

Sect. III. *Anserine or Aquatic Fowls.*

7497. *The order anseres* comprehends the duck, goose, swan, and buzzard. Under a regular system, Mowbray observes, it would be preferable to separate entirely the aquatic from the other poultry; the former to have their houses ranged along the banks of a piece of water, with a fence, and sufficiently capacious walks in front; access to the water by doors, to be closed at will. Should the water be of considerable extent, a small boat would be necessary, and might be also conducive to the pleasure of angling.

939



7498. *The duck* (*Anas Bóschas L., fig.* 939.) is a native of Britain, and found frequenting the edges and banks of lakes in most parts of Europe. The flesh of this and various other species of the duck is savory and stimulant, and said to afford preferable nourishment to that of the goose, being less gross, and more easily digested. The flesh of the wild duck, though more savoury than that of the tame, is reckoned still more easy of digestion. The ancients went even beyond our greatest modern epicures in their high esteem for the flesh of the duck; and Plutarch asserts, that Cato preserved his whole household in health by dieting them on duck's flesh.

7499. *Varieties and species.* There are the *Rhone*, the *Aylesbury*, the *canvass-backed*, and the *Muscovy*.

7500. *The Rhone duck* is originally from France, and generally of a dark-coloured plumage, large size, and supposed to improve our breed. They are of darker flesh, and more savoury, than the English duck; but somewhat coarse. Rhone ducks have been so constantly imported for a great number of years, that they are very generally mixed with our native breed. The English duck, particularly the white variety, especially when they chance to have light-coloured flesh, are never of so

high and savoury flavour as the darker colours. Muscovy, and other foreign species of the duck, are kept rather out of curiosity than for the table.

7501. *The white Aylesbury* are a beautiful and ornamental stock, matching well in colour with the Embden geese. They are said to be early breeders.

7502. *The canvass-backed*, bred only on the Potowmac and Susquehanna rivers, are of very recent introduction from America, and are only to be found in a few places near Liverpool; they are said to be the best in the world, and if so will soon become better known.

7503. *The Muscovy duck* (*A.* moschàta *L.*) is a native of Brazil, but domesticated in Europe. It is a curious dark-coloured bird, distinguished by its naked face, kept more out of curiosity than use; to be retained in any place, they must be reared there from the egg, otherwise they will fly away.

7504. *Breeding.* One drake is generally put to five ducks; the duck will cover from eleven to fifteen eggs, and her term of incubation is thirty days. They begin to lay in February, are very prolific, and are apt, like the Turkey, to lay abroad, and conceal their eggs, by covering them with leaves or straws. The duck generally lays by night, or early in the morning: white and light-coloured ducks produce similar eggs; and the brown and dark-coloured ducks, those of a greenish blue colour, and of the largest size. In setting ducks, it is considered safest to put light-coloured eggs under light ducks, and the contrary; as there are instances of the duck turning out with her bill those eggs which were not of her natural colour.

7505. *During incubation*, the duck requires a secret and safe place, rather than any attendance, and will, at nature's call, cover her eggs, and seek her food, and the refreshment of the waters. On hatching, there is not often a necessity for taking away any of the brood, barring accidents; and having hatched, let the duck retain her young upon the nest her own time. On moving her with her brood, prepare a coop upon the short grass, if the weather be fine, or under a shelter, if otherwise: a wide and flat dish of water, often to be renewed, standing at hand; barley, or any meal, the first food. In rainy weather particularly, it is useful to clip the tails of the ducklings, and the surrounding down beneath, since they are else apt to draggle and weaken themselves. The duck should be cooped at a distance from any other. The period of her confinement to the coop depends on the weather and the strength of the ducklings. A fortnight seems the longest time necessary; and they may be sometimes permitted to enjoy the pond at the end of a week, but not for too great a length at once, least of all in cold wet weather, which will affect, and cause them to scour, and appear rough and draggled. In such case they must be kept within a while, and have an allowance of bean or pea meal mixed with their ordinary food. The meal of buck-wheat and the former is then proper. The straw beneath the duck should be often renewed, that the brood may have a dry and comfortable bed; and the mother herself be well fed with solid corn, without an ample allowance of which ducks are not to be reared or kept in perfection, although they gather so much abroad.

7506. *Duck eggs are often hatched by hens*, when ducks are more in request than chickens; also as ducks, in unfavourable situations, are the more easy to rear, as more hardy; and the plan has no objection in a confined place, and with a small stock, without the advantage of a pond; but the hen is much distressed, as is sufficiently visible, and, in fact, injured, by the anxiety she suffers in witnessing the supposed perils of her children venturing upon the water.

7507. *Ducks are fattened*, either in confinement, with plenty of food and water, or full as well restricted to a pond, with access to as much solid food as they will eat; which last method is preferable. They fatten speedily, in this mode, mixing their hard meat with such a variety abroad as is natural to them, more particularly, if already in good case; and there is no check or impediment to thrift from pining, but every mouthful tells and weighs its due weight. A dish of mixed food is preferable to white corn, and may remain on the bank, or rather in a shed, for the ducks. Barley, in any form, should never be used to fatten ducks or geese, since it renders their flesh loose, woolly, and insipid, and deprives it of that high savory flavour of brown meat, which is its valuable distinction; in a word, rendering it chickeny, not unlike in flavour the flesh of ordinary and yellow-legged fowls. Oats, whole or bruised, are the standard fattening material for ducks and geese, to which may be added pea-meal, as it may be required. The house-wash is profitable to mix up their food under confinement; but it is obvious, whilst they have the benefit of what the pond affords, they can be in no want of loose food. Acorns in season are much affected by ducks which have a range; and they will thrive so much on that provision, that the quantity of fat will be inconvenient, both in cooking and upon the table. Ducks so fed are certainly inferior in delicacy, but the flesh eats high, and is far from disagreeable. Fed on butcher's offal, the flesh resembles wild fowl in flavour, with, however, considerable inferiority. Offal-fed duck's flesh does not emit the abominable stench which issues from offal-fed pork. When live ducks are plucked, only a small quantity of down and feathers should be taken from each wing.

7508. *Decoys for wild ducks.* Wild ducks, and other aquatic birds, are frequently taken by the device termed a decoy, which, in the low parts of Essex, and some other marshy districts, may be considered as connected with husbandry. A decoy is a canal or ditch, provincially pipe of water (*fig.* 940.), with a grassy

940

sloping margin (1) at its junction with a river or larger piece of water (8), to invite aquatic fowls to sit on and dress their plumage; but in other parts, covered with rushes and aquatic plants for concealment. Along the canal of the decoy are placed reed fences (2, 2), to conceal the decoy-man and his dogs from the sight of the ducks. There is an opening in this fence (3), where the decoy-man first shows himself to the birds to force them to take the water; and having taken it, the dog drives them up the canal, the man

looking through the fenee at different places (4, 5, 6) to frighten them forward. At the end of the canal is a tunnel net (7), where the birds are finally taken. In operating with this trap, as the wild duck is a very shy bird, and delights in retirement, the first step is to endeavour to make the given water a peaceful asylum, by suffering the dueks to rest on it undisturbed. The same love of coneealment leads them to be partial to waters whose margins abound with underwood and aquatie plants; hence, if the given water is not already furnished with these appendages, they must be provided; for it is not retirement alone which leads them into these reeesses, but a seareh after food also. At eertain times of the day, when wild fowl are off their feed, they are equally delighted with a smooth grassy margin, to adjust and oil their plumage upon. On the close-pastured margins of large waters, frequented by wild fowl, hundreds may be seen amusing themselves in this way; and perhaps nothing draws them sooner to a water than a eonvenieney of this kind: hence it becomes essentially neccssary to sueeess, to provide a grassy, shelving, smooth-shaven bank (1) at the mouth of the deeoy, in order to draw the fowl, not only to the water at large, but to the desired part of it. Having, by these means, allured them to the mouth of the deeoy; the diffieulties that remain are, those of getting them off the bank into the water, without taking wing, and of leading them up the eanal to the snare whieh is set for them in the most easy manner.

7509. *In order to get them off the bank into the water*, a dog is neeessary (the more like a fox the better), whieh should steal from behind the skreen of reeds, (2, 2,) which is placed by the side of the eanal to hide the deeoy-man as well as his dog, until the signal be given. On seeing the dog, the ducks rush into the water; where the wild fowl eonsider themselves as safe from the enemy whieh had assailed them, and of eourse do not take wing. Among the wild fowl, a pareel (perhaps eight or ten) of decoy-ducks should be mixed, which will probably be instrumental in bringing them, with greater confidenee, to the bank. As soon as these are in the water, they make for the decoy, at the head of which they have been eonstantly fed, and in whieh they have always found an asylum from the dog. The wild ducks follow; while the dog keeps driving behind; and, by that means, takes off their attention from the trap they are entering. When, as soon as the deeoy-man, who is all the while observing the operation through peep-holes in the reed skreen, sees the entire shoal under a eanopy net whieh covers and eneloses the upper part of the canal, he shows himself, when the wild fowl instantly take wing, but their wings meeting with an impervious net, instead of a natural eanopy, formed of reeds and bulrushes, they fall again into the water, and, being afraid to reeede, the man being elose behind them, they push forward into the tail of the tunnel net, which terminates the deeoy. In this way, nine dozen have been eaught at a time.

7510. *The form of the pipe or canal* ought to resemble the outlet of a natural brook, or a natural inlet or ereek of the prineipal water. The mouth ought to be spaeious, and free from confinement, that the wild fowl, on their first rushing into the water, and while they have yet the power of recolleetion, may be indueed to begin to follow the tame ducks; and for the same purpose it ought to be erooked, that its inward narrowness, and the nets, may not, in the first instance, be perceived. The lower part of a French horn is considered as the best form of the eanal of a decoy that ean be had. A material eireumstanee remains yet to be explained. It is the invariable nature of wild fowl to take wing with their heads towards the wind; and it is always imprudent to attempt to take them in a decoy, unless the wind blow down the pipe; for, while their enemy is to leeward of them, they have less sernple to go up the pipe, making sure of an eseape by their wings. But, what is of still more eonsequence, if the wind set up the pipe when they take wing under the eanopy net, some of them would probably eseape (a eircumstanee always to be dreaded), and those which fell again into the water would fall, of eourse, with their heads towards the wind, and would with greater difficulty be driven into the tunnel. This point is so well known by deeoy-men in general, that every deeoy is, when eireumstances will admit of it, furnished with three or four different canals, pointing to distinct quarters of the horizon, that no opportunity may be lost on aceount of the wind being in any particular point.

7511. *The goose* (*A*nas *A*nser *L.*, *fig.* 941.) is a native of Britain, and most parts of the north of Europe, but less common than the duck.

941

7512. *The flesh* of the common and various species of geese is highly stimulant, strong in flavour, viseous, and of a putrescent tendeney. The flesh of the tame goose is more tender than that of the wild, which tastes of fish; but either kind is only adapted for good stomaehs, and powerful digestion, and should be sparingly used by the sedentary and weak, or persons subjeet to cutaneous diseases. The fat of the goose is reekoned peeuliarly subtle, penetrating, and resolvent, and is generally earefully preserved for domestie applieations. The goose attains to a great age, well authenticated instanees being on record to the extent of seventy and eighty years. The best geese in England are probably to be found on the borders of Suffolk and Norfolk, and in Berkshire; but the greatest numbers are in Lincolnshire, whence they are sent in droves to London to be fed by the poulterers, some of whom fatten in the vicinity of the metropolis above five thousand in a season.

7513. *Of varieties and species* there are several, the former differing in colour, as blaek, white, and grey, and also in size. There is also the Spanish white goose, and large white Embden goose, the latter in most esteem. When one has seen a wild goose, says Pennant, a deseription of its plumage will, to a feather, exactly eorrespond with any other: but in the tame kinds, no two of any speeies are exaetly alike; different in their size, their eolours, and frequently in their general form, they seem the mere ereatures of art; and having been so long dependent upon man for support, they seem to assume forms entirely suited to his neeessities.

7514. *There is a Chinese species* (*A. cygnöïdes*), and an Ameriean goose (*A.* eanadénsis). The Chinese species is a domestie bird, but as yet little known in this eountry. It is longer and narrower in the body than the eommon goose, and stands higher on the legs. The Canadian goose is domesticated in several plaees, and is not considered uneommon in England. It is the most ornamental of the goose kind on water in pleasure-grounds, and is abundant in the Duke of Devonshire's park at Chiswick.

7515. *Breeding.* One gander is generally put to five geese: the goose lays from eleven to fifteen eggs; and the period of incubation is from twenty-seven to thirty days. A nest should be prepared as soon as the female begins to carry straw in her bill, and by other tokens deelares her readiness to lay. This is generally in March, and sometimes two broods are produced within the season; an advantage obtainable by high feeding through the winter with sound eorn, and on the commencement of the breeding season allowing them boiled barley, malt, fresh grains, and fine pollard mixed up with ale or other stimulants. A good gander sits near his geese whilst they are sitting, and vigilantly protects them. Feeding upon the nest is seldom required; and it is unnecessary to take any of the goslings from the mother as hatched; but pen the goose and her brood at once upon dry grass well sheltered, putting them out late in the morning, or not at all in severe weather, and ever taking them in early in the evening. The first food may be similar to that recommended for the duck, sueh as barley meal, bruised oats, or fine pollard, with some cooling green vegetables, as cabbage or beet leaves intermixed.

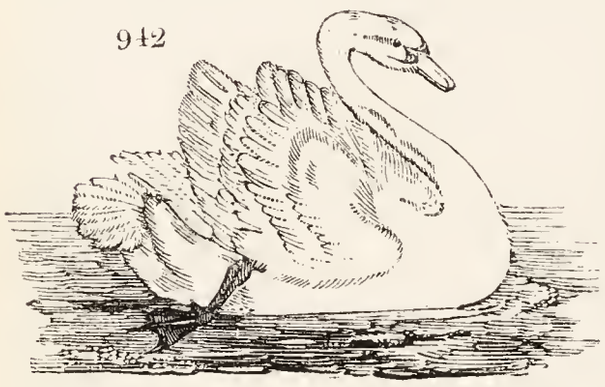
7516. *Rearing.* At first setting at liberty the pasturage of the goose should be limited; otherwise, if allowed to range over an extensive common, the gulls or goslings will become tired and cramped, and some of them will fall behind and be lost. Mowbray advises to destroy all the hemlock and nightshade in

their range; and he says he has known them killed by swallowing sprigs of yew. As the young become pretty well feathered, they become also too large to be brooded beneath the mother's wing, and as they will then sleep in groups by her side, they must be well supplied with straw beds, which they will convert into excellent dung. Being able, says Mowbray, to frequent the pond and range the common at large, the young geese will obtain their living, and few people, favourably situated, allow them any thing more, excepting the vegetable produce of the garden. But it has been his constant practice always to dispense a moderate quantity of any solid corn or pulse at hand to the flocks of store geese, both morning and evening, on their going out and their return, together, in the evening more especially, with such greens as chanced to be at command: cabbage, mangel-wurzel leaves, lucerne, tares, and occasionally sliced carrots. By such full keeping his geese were ever in a fleshy state, and attained a large size; the young ones were also forward and valuable breeding stock. Geese managed on the above mode will be speedily fattened green, that is, at a month or six weeks old, or after the run of the corn stubbles. Two or three weeks after the latter must be sufficient to make them thoroughly fat. A goose fattened entirely on the stubbles is to be preferred to any other; since an over-fattened goose is too much in the oil-cake and greese-tub style, to admit even the ideas of delicacy, tender firmness, or true flavour; but when needful to fatten them, the feeding-houses already recommended for hens (7474.) are most convenient. With clean and renewed beds of straw, plenty of clean water, oats, crushed or otherwise, pea or bean meal (the latter, however, coarse and ordinary food), or pollard mixed up with skim-milk, geese will fatten pleasantly and speedily.

7517. *Feathers.* Pennant, in describing the methods used in Lincolnshire in managing geese, says, "They are plucked five times in the year; first at Lady-day for the feathers and quills, and four times for the feathers only, between that and Michaelmas." He says, he saw the operation performed on goslings of six weeks old, from which the feathers of the tails were plucked, and that numbers die of the operation, if the weather immediately afterwards proves cold. This seems a cruel practice, and surely would be better left off. Lean geese furnish the greatest quantity of down and feathers, and of the best quality.

7518. *The mute or tame swan* (*Cygnus mansuètus L., fig.* 942.) has long been known in England, but is only found wild in Russia and Siberia. It has been preserved by the severity of the laws, which have long accounted it felony to steal their eggs. Formerly they were fattened at Norwich for the city feast, and commanded a guinea each. The foot of the swan possesses nearly the same property as that of the goose; and the skin was formerly held to contain medical properties. At present swans are chiefly to be considered as ornamental in pleasure-grounds, clearing water from weeds, and occasionally affording cygnet and some swan down feathers and quills. It is a curious circumstance that the ancients considered the swan as a high delicacy, and abstained from the flesh of the goose as impure and indigestible.

942



7519. *Other species* are, first, the swan goose (*A. cygnoïdes L.*). This is of an intermediate size between the tame swan and the common goose, with the last of which they will breed; and although they vary considerably in their colours, the species is always known by a knob on the bill. The two others which have been domesticated with us are the Canadian and the Egyptian species. The first is equally valuable with the common goose, and is very ornamental in ponds; the latter is now become very rare. The black swan, once considered a prodigy, is abundant in various parts of New Holland or Australia.

7520. *Rearing.* The swan feeds like the goose, and has the same familiarity with its keepers, kindly and eagerly receiving bread which is offered, although it is a bird of courage equal to its apparent pride, and both the cock and hen are extremely dangerous to approach during incubation, or whilst their brood is young, as they have sufficient muscular force to break a man's arm with a stroke of their wing. They both labour hard in forming a nest of water plants, long grass, and sticks, generally in some retired part or inlet of the bank of the stream or piece of water on which they are kept. The hen begins to lay in February, producing an egg every other day until she has deposited seven or eight, on which she sits six weeks, although Buffon says it is nearly two months before the young are excluded. Swans' eggs are much larger than those of a goose, white, and with a hard and sometimes tuberous shell. The cygnets are ash-coloured when they first quit the shell, and for some months after; indeed they do not change their colour, nor begin to moult their plumage, until twelve months old, nor assume their perfect glossy whiteness until advanced in their second year.

7521. *Feathers and down.* Where the living swan is plucked, only the ripe down should be taken from each wing, and four or five feathers. This may be repeated to the extent of three times in the course of a summer.

7522. *The bustard* (*Otis tárda L., fig.* 942.) is a native of England, the largest indigenous land bird in Europe, the cock generally weighing from twenty-five to twenty-seven pounds. The neck a foot long; the legs a foot and a half. It flies with some little difficulty. The head and neck of the cock ash-coloured; the back barred transversely with black and bright rust colour. The greater quill feathers black, the belly white; the tail, consisting of twenty feathers, marked with broad black bars: it has three thick toes before, and none behind.

943

7523. *Three species* of bustard are found in England; that called the little bustard (*O. tètrax*) differs chiefly in size, not being larger than a pheasant. Bustards were known to the ancients in Africa, and in Greece and Syria; are supposed to live about fifteen years; are gregarious, and pair in spring, laying only two eggs, nearly of the size of a goose egg, of a pale olive brown, marked with spots of a darker hue. They sit about five weeks, and the young ones run, like partridges, as soon as delivered from the shell. The cocks will fight until one is killed or falls. Their flesh has ever been held most delicious: they are

fed upon the same food as the turkey. There were formerly great flocks of bustards in this country upon the wastes and in the wolds, particularly in Norfolk, Cambridgeshire, and Dorset, and in various parts of Scotland, where they were hunted with greyhounds, and were easily taken. Buffon was mistaken in his supposition that these birds are incapable of being propagated in the domestic state, chiefly on account of the difficulty of providing them with proper food, which, in their wild state, he describes to be heath-berries and large earth-worms. Probably the haw or whitethorn berry might succeed equally well. To those who aim at variety and novelty in this line, the bustard appears peculiarly an object for propagation and increase, since the flesh is of unrivalled excellence; and it is probable this fowl will render great weight of flesh for the food consumed.

Sect. IV. *Diseases of Poultry.*

7524. *The diseases of poultry* are generally the result of improper nourishment and lodging, and the best mode of cure is by the immediate adoption of such as is proper. When that will not succeed, very little help can be derived from medical assistance; at least as that art stands at present with respect to poultry. In fact, as Mowbray observes, the far greater part of that grave and plausible account of diseases to be found in our common cattle and poultry books is a farrago of absurdity, the chief ground of which is random and ignorant guess-work.

7525. *Common fowls* are attacked by the pip, roup or catarrh, the flux, constipation, and vermin. The pip is an outside skin or scale, growing on the tip of the tongue, and is cured by tearing off the skin with the nail and rubbing the tongue with salt. Imposthume on the rump is called the roup, which term is also applied to catarrh, to which gallinaceous fowls are very subject. The imposthume is to be opened, the core thrust out, and the part washed with salt and water. Generous food and warmth is the only cure in the catarrh. The flux is to be cured with good solid food; and its opposite, constipation, with scalded bran mixed with skim-milk or pot liquor, adding a small quantity of sulphur. Vermin appear in consequence of low keep and want of cleanliness; the simplest remedy is to allow plenty of sand and ashes for the birds to roll in, and to keep their houses and roosts sweet and clean, white-washing them two or three times a year.

7526. *The roup* is a very common, and one of the most fatal, complaints to which chickens are subject. Those attacked by the disease are constantly coughing and gasping for breath. Upon dissection the windpipe is found almost closed up by great numbers of small red worms, which, in a certain stage of their growth, congregate into bundles large enough to stop respiration, and which, if the sufferer cannot discharge at the mouth, soon produces suffocation. Decoctions of the common yellow Linària vulgàris (*Hort. Brit.* 15845.) is given as drink, which, being nauseously bitter, is supposed offensive to the worms; but perhaps some mercurial preparation, taken inwardly or applied outwardly, would answer the purpose, and, if effectual, would save thousands of chickens every year. This suggestion has never been tried.

7527. *But the catarrh* is the chief disease to which chickens and fowls are liable; and when the malady becomes confirmed with running at the nostrils, swollen eyes, &c. they are termed roupy, and the disease is infectious. They should now be separated, and kept in a warm apartment and well fed. Roupy hens seldom lay, and their eggs are unwholesome. In chickens this disease is called the chip: they are seen shivering, pining, and dying in corners, apparently from cold, though they are in fact in a fever. Abundant warmth and rich food are the only remedies.

7528. *Broken legs, wings, or toes* may be set and spliced, and will recover: the head being raw and the eyes blinded from fighting, wash the eyes with milk and water, and the head alternately with brandy in which is a few drops of laudanum, and with fresh butter. A cock's spurs being too long, impeding his walk and wounding his legs, they should be cut carefully with a sharp pen-knife, but not too near the quick, every three months.

7529. *Geese* are subject to the gargle, or stoppage in the head, the consequence of cold. House the patient, and give garlic beat up with fresh butter; or toast and ale, with a little confinement, will succeed equally well.

7530. *All poultry*, when young, are apt to be carried off by rats and other vermin, which must either be vigilantly guarded against or destroyed.

Sect. V. *Birds of Luxury which are or may be cultivated by Farmers.*

7531. *Birds of luxury* include the pigeon, pheasant, partridge, quail, grouse, singing birds, and birds kept as curious objects.

7532. *Of the pigeon* (*Colúmba L.*) there are three species and many varieties in cultivation. The species are the common, ring, and turtle doves, all natives of Britain. The varieties of the common pigeon enumerated by Linnæus amount to twenty-one; but those of the pigeon-fanciers to more than double that number. The ring-dove (*C. Palúmbus L.*) and the turtle-dove (*C. Túrtur*), with the greater number of the varieties, are cultivated only by a few persons, known as pigeon-fanciers; but the common pigeon of different colours is cultivated for the table.

7533. *The flesh* of the young pigeon is very savoury and stimulating, and highly valued for pies; that of the full-aged pigeon is more substantial, harder of digestion, and in a considerable degree heating. Black or dark feathered pigeons are dark fleshed and of high flavour, inclining to the game bitter of the wild pigeon. Light-coloured feathers denote light and delicate flesh. The dung of pigeons is used for tanning upper leathers for shoes; it is also an excellent manure. Pigeons are now much less cultivated than formerly, being found injurious to corn fields, and especially to fields of peas; they are, however, very ornamental. A few may be kept by most farmers, and fed with the common poultry; and some who breed domestic fowls on a large scale may, perhaps, find it worth while to add the pigeon to their number.

7534. *The variety of pigeon* most suitable for the common pigeon-house is the grey pigeon (*fig.* 944.), inclining to ash-colour and black, which generally shows fruitfulness by the redness of the eyes and feet, and by the ring of gold colour which is about the neck.

944

7535. *The varieties* of the fancy breeders are numerous, and distinguished by a variety of different names, as carriers (*fig.* 945. *a*), croppers, powters, horsemen, runts, jacobines, turbits, helmets, nuns, tumblers (*b*), barbs, petits, owls, spots, trumpeters, shakers, turners, finikins, &c. From these, when differently paired, are bred bastard pigeons; thus from the cropper or powter and the carrier is bred the powting horsemen (*c*); from the tumbler and the horsemen dragoons, &c.

7536. *The stocking of pigeon-houses* is best performed in May or August, as the birds are then in the best condition. Young birds called squeakers should be chosen, as the old are apt to fly away.

945

7537. *In breeding*, the pigeon lays two white eggs, which produce young ones of different sexes. When the eggs are laid, the female sits fifteen days, not including the three days she is employed in laying, and is relieved at intervals by the male. The turns are generally pretty regular. The female usually sits from about five in the evening till nine the next morning; at which time the male supplies her place, while she is seeking refreshment abroad. Thus they sit alternately till the young are hatched. If the female does not return at the expected time, the male seeks her, and drives her to the nest; and should he in his turn be neglectful, she retaliates with equal severity. When the young ones are hatched, they only require warmth for the first three days; a task which the female takes entirely upon herself, and never leaves them except for a few minutes to take a little food. After this they are fed about ten days, with what the old ones have picked up in the fields, and kept treasured in their crops, from whence they satisfy the craving appetite of their young ones, who receive it very greedily. This way of supplying the young with food from the crop, in birds of the pigeon-kind, differs from all others. The pigeon has the largest crop of any bird, for its size; which is also quite peculiar to the kind. In two that were dissected by an eminent anatomist, it was found that, upon blowing the air into the windpipe, it distended the crop or gullet to an enormous size. Pigeons live entirely upon grain and water; these being mixed together in the crop are digested in proportion as the bird lays in its provision. Young pigeons are very ravenous, which necessitates the old ones to lay in a more plentiful supply than ordinary, and to give it a sort of half maceration in the crop, to make it fit for their tender stomachs. The numerous glands, assisted by air and the heat of the bird's body, are the necessary apparatus for secreting a sort of pap, or milky fluid (commonly called pigeon's milk); but as the food macerates, it also swells, and the crop is considerably dilated. If the crop were filled with solid substances, the bird could not contract it; but it is obvious the bird has the power to compress its crop at pleasure, and, by discharging the air, can drive the food out also, which is forced up the gullet with great ease. The young usually receive this tribute of affection from the crop three times a day. The male for the most part feeds the young female, and the old female performs the same service for the young male. While the young are weak, the old ones supply them with food macerated suitable to their tender frame; but, as they gain strength, the parents give it less preparation, and at last drive them out, when a craving appetite obliges them to shift for themselves; for when pigeons have plenty of food, they do not wait for the total dismission of their young; it being a common thing to see young ones fledged, and eggs hatching at the same time and in the same nest.

7538. *The terms applied to pigeons* of different ages are, the youngest, when fed by the cock and hen, squabs, at which age they are most in demand for pies. Under six months of age, they are termed squeakers; at that age they begin to breed, and then, or earlier, they are in the fittest state for removal to a strange situation.

7539. *In respect to food*, pigeons are entirely granivorous, and very delicate and cleanly in their diet; they will sometimes eat green aromatic vegetables, but are fondest of seeds; and tares, and the smallest kind of horse-beans, is the most suitable food both in point of economy and fattening qualities. Peas, wheat, buck-wheat, and even barley, oats, &c., are also eaten by pigeons, but old tares may be reckoned their very best food; new tares, peas, or beans, are reckoned scouring. Wherever pigeons are kept, the best way to keep them chiefly at home, and thereby both prevent their being lost, and their doing injury to corn-crops, is to feed them well: this is also the only way in which, in modern times, they will afford abundance of fat and delicate squabs for the table, which, well fed, they will do every month in the year, and thus afford a constant supply of delicate stimulating food. Pigeons are generally fed in the open air adjoining their cote or house; but in inclement weather, or to attach new pigeons to their home, both food and water should be given internally. That this may be done without waste, and without frequently disturbing the birds, two contrivances are in use: the first is the meat-box, or hopper, from whence grain or pulse descends from the hopper as eaten out of a small shallow box; the next is the *water-bottle*, an ovate, long, naked bottle, reversed in a small basin to which it serves as a reservoir. Any bottle will do, but the pigeons are apt to alight on and dirty such as when reversed present a flat top.

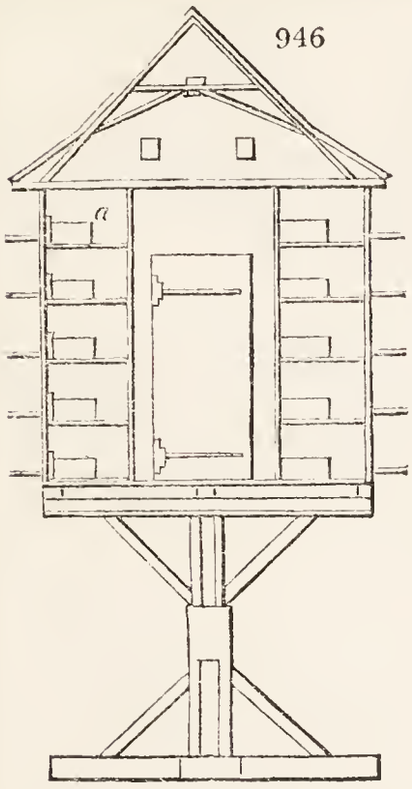
7540. *Pigeons being fond of salt*, what is called a *pigeon cat* is placed in the midst of the pigeon-house, or in the open air near it. It seems these birds are fond of salt and hot substances, and constantly swallow small stones to promote digestion. The *salt-cat* is thus composed. Gravel or drift-sand, unctuous loam, the rubbish of an old wall, or lime, a gallon of each (should lime be substituted for rubbish, a less quantity of the former will suffice); one pound of cummin-seed, one handful of bay-salt; mix with stale urine. Inclose this in jars, corked or stopped, holes being punched in the sides, to admit the beaks of the pigeons. These may be placed abroad. They are very fond of this mixture, and it prevents them from pecking the mortar from the roofs of their houses, which they are otherwise very apt to do.

7541. *Cleanliness* is one of the first and most important considerations: the want of it in a dove-cote will soon render the place a nuisance not to be approached; and the birds, both young and old, will be so covered with vermin, and besmeared with their own excrement, that they can enjoy no health or comfort, and mortality is often so induced. Mowbray's were cleaned daily, thoroughly once a week, a tub standing at hand for the reception of the dung, the floor covered with sifted gravel, often renewed.

7542. *Pigeon-houses* are of three kinds, small boarded cases fixed on posts, trees, or against the ends of houses; lofts fitted up with holes or nests; and detached buildings. The first are generally too small to contain a sufficient brood, and are also too subject to variations of temperature; and the last, on the other hand, are now-a-days too large, and therefore the most suitable for the farmer is a loft or tower rising from a building in which no noisy operation is carried on. The lofts of any of the farm-buildings at a distance from the threshing machine are suitable, or a loft or tower over any detached building will answer well; but the best situation of all is a tower raised from the range of poultry-buildings, where there is such a range, as the pigeons can thus be more conveniently treated, and will feed very readily with domestic poultry. For a tower of this sort, the round form should be preferred to the square; because the rats cannot so easily come at them in the former as in the latter. It is also much more commodious; as, by means of a ladder turning round upon an axis, it is possible to visit all the nests in the house, without the least difficulty; which cannot be so easily done in a house of the square form. And in order to hinder rats from climbing up the outside of it, the wall should be covered with tin-plates to a

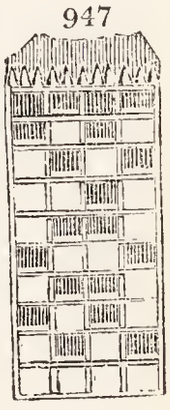
certain height, as about a foot and a half; which should project out three or four inches at the top, to prevent their getting up more effectually. A common mode in France is to raise a boarded room on a strong post powerfully braced (*fig.* 946.), the interior sides of which are lined with boxes for the birds (*a*), and the exterior east and west sides with balconies, or sills for them to alight on and enter their boxes (*b*). The north and south sides are lined with boxes inside, but without openings, as being too cold on the one front, and too warm on the other.

946

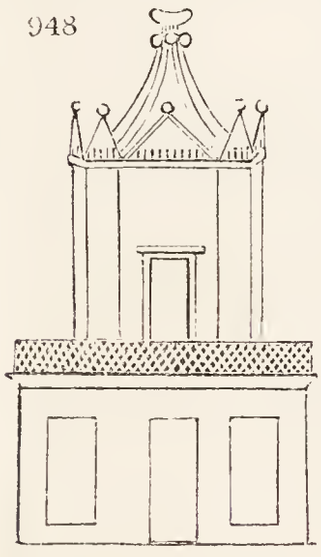


7543. *The interior of the pigeon-house* must be lined with nests or holes; subdivided either by stone, as in the ancient mural pigeon-houses; by boards; or each nest composed of a vase or vessel of earthenware fixed on its side. Horizontal shelves (*fig.* 947.), divided vertically at three feet distance, are generally esteemed preferable to every other mode; the width of the shelf may be twenty inches, the height between shelf and shelf eighteen inches; and a slip of board three or four inches high is carried along the front of the partitions to keep in the nests. Sometimes, also, a partition of similar height is fixed in the middle of each three-feet division, which thus divides it into two nests. This Mowbray and Girton concur in recommending, as likely to prevent the young from running to the hen when sitting over fresh eggs, and perhaps occasioning her to cool and addle them; for when the young are about a fortnight or three weeks old, a good hen will leave them to the care of the cock, and lay again. Some prefer breeding-holes with no board in front, for the greater convenience of cleaning the nests; but as the squabs are apt to fall out by this practice, a good way would be to contrive the board in front to slip up and down in a groove, by which each nest might be cleaned at pleasure. As tame pigeons seldom take the trouble of making a nest, it is better to give them one of hay, to prevent the eggs from rolling. There are also straw buckets made in the form of nests, and also nests or pans of earthenware. Where pans are used, it is common to place a brick between them (two being placed in a breeding hole), for the cock and hen to alight on; but on the whole straw nests are best. The pigeon-house has two entrances, one a common-sized door for man, either on the ground level, or to be ascended to by a ladder, as used formerly to be the case; and the other on a rising above the roof, and consisting of small holes three or four by twelve or fourteen inches, for the entrance of the pigeons. A series of ranges of these are generally placed over each other, in a boarded front looking to the south, with a shelf to each range, and surrounded by a row of iron spikes to protect them from cats. The elevation of pigeon-houses (*fig.* 948.), as already described, are of endless variety.

947



948



7544. *The breeding holes* constitute the fixtures of the pigeon-house; its *utensils* are the hopper and bottle already described (7539.), a barrel or box for food, a step ladder to reach the nests, and some other articles not peculiar to this department of rural economy. The pigeon-trap, for enticing and entrapping the pigeons of others, we do not describe.

7545. *Pigeons in new lodgings are apt sometimes to forsake their habitations.* Many nostrums have been recommended to prevent them from doing so; but if squabs be selected, cleanliness and security attended to, and a salt cot placed in or near the house, there will be little danger of this taking place. Fumigation with highly odoriferous drugs, or even assafœtida, is also said to attract pigeons to a neglected dovecote, or attach them to a new one

7546. *Diseases of pigeons.* Fancy pigeons, being many of them monstrous productions, are very subject to diseases. Girton enumerates upwards of a dozen, with their cures, including the corruption of the egg in the uterus from over high feeding; a gorged crop from voracious feeding; insects from filthiness in the pigeon-house, and the canker from cocks fighting with each other. Little can be done in the way of curing any of these diseases otherwise than by recurrence to the proper regimen: if this does not speedily take effect, it is better to put the bird *hors de peine*, both for humanity's sake and to prevent infection. Fortunately, the common pigeon reared for the table is little liable to diseases.

7547. *Laws respecting pigeons.* By the 1st of James, c. xxvii., shooting, or destroying pigeons by other means, on the evidence of two witnesses, is punishable by a fine of 20*s.* for every bird killed or taken; and by the 2d of Geo. III. c. xxix. the same offence may be proved by one witness, and the fine is 20*s.* to the prosecutor. Any lord of the manor or freeholder may build a pigeon-house upon his own land, but a tenant cannot do it without the lord's licence. Shooting or killing within a certain distance of the pigeon-house, renders the person liable to pay a forfeiture.

7548. *The common pheasant* (*Phasiànus cólchicus L.*) is a native of the old continent, but not of America, and has long been naturalised in the warmer and most woody counties of England. It is very common in France, and before the Revolution used to be a great nuisance to the farmers, even to the gates of Paris. The pheasant runs fast, but flies low and heavily; it crows not unlike the common cock, being of the same genus, and is supposed to live six or eight years.

7549. *Pheasants are both granivorous and carnivorous;* they feed upon all sorts of insects and vermin like the peacock, and are said to be greedy of toads, when not too large to swallow; whereas, according to report, they will not touch the frog, of which ducks are so fond. They are prized in park scenery for their beautiful plumage and showy figure, and as game for the delicacy of their flesh, which is of a high flavour and alkalescent quality. It is in season in autumn, and most esteemed when under a year old, and very fat. Every gentleman who has a well wooded, well enclosed park, and in whose woods are abundance of such evergreens as the spruce fir, holly, box, broom, &c., may stock it with pheasants; and he may preserve his stock if he will continue to supply them with abundance of food, and deter thieves, polecats, &c. The more common the pheasant becomes, the less will it be subjected to the attacks of those enemies.

7550. *Varieties.* Besides that which may be considered common or wild in this country, and which is generally of a brown colour, there is the *gold* and *silver*, natives of China, and very hardy in this country, and good breeders. The ring-necks, natives of Tatary, bred in China, very scarce; their plumage very beautiful. The white and pied; both sorts will intermix readily with our common breed, as will the Bohemia, one of the most beautiful of its kind, and equally scarce. The golden variety is generally of the highest price, and the common most hardy, and of the largest size.

7551. *Breeding.* In a wild state the hen pheasant lays from eighteen to twenty eggs in a season, but seldom more than ten in a state of confinement. As this bird has not hitherto been domesticated, and as the flesh of those brought up in the house is much inferior to that of the wild pheasant, they are chiefly bred for show, for replenishing a park, or for turning out in well enclosed recluse scenes, which they will not readily leave if well fed, and not much disturbed. Hence every proprietor may naturalise them at least on a part of his grounds; say, for example, a wood with glades of pasture enclosed by a close paling or high wall. The natural nest of the pheasant is made on the ground, and composed of dry grass and leaves, which being provided for her in confinement, she will always arrange properly. They will breed freely with the common fowl; but as neither flesh nor form are improved by the cross, this is seldom resorted to.

7552. *In stocking a pheasantry*, the general mode is to procure eggs from some establishment of this sort or otherwise; and the following are the directions of Castang, as given in Mowbray's *Treatise on Poultry:* — Eggs being provided, put them under a hen that has kept the nest three or four days; and if you set two or three hens on the same day, you will have the advantage of shifting the good eggs. At the end of ten or twelve days, throw away those that are bad, and set the same hen or hens again, if setting-hens should not be plenty. The hens having set their full time, such of the young pheasants as are already hatched put into a basket, with a piece of flannel, till the hen has done hatching. The brood now come, put under a frame with a net over it, and a place for the hen, that she cannot get to the young pheasants, but that they may go to her; and feed them with boiled egg cut small, boiled milk and bread, alum curd, ants' eggs, a little of each sort, and often. After two or three days they will be acquainted with the call of the hen that hatched them, may have their liberty to run on the grassplat, or elsewhere, observing to shift them with the sun, and out of the cold winds; they need not have their liberty in the morning till the sun is up; and they must be shut in with the hen in good time in the evening. Every thing now going on properly, you must be very careful (in order to guard against the distemper to which they are liable) in your choice of a situation for breeding the birds up; and be less afraid of foxes, dogs, polecats, and all sorts of vermin, than the distemper. Castang had rather encounter all the former than the latter; for those with care may be prevented, but the distemper once got in is like the plague, and destroys all your hopes. What he means by a good situation is nothing more than a place where no poultry, pheasants, or turkeys, &c. have ever been kept; such as the warm side of a field, orchard, pleasure-ground, or garden, or even on a common, or a good green lane under circumstances of this kind, or by a wood side; but then it is proper for a man to keep with them, under a temporary hovel, and to have two or three dogs chained at a proper distance, with a lamp or two at night. He has known a great number of pheasants bred up in this manner in the most exposed situations. It is proper for the man always to have a gun, that he may keep off the hawks, owls, jays, magpies, &c. The dogs and lamps shy the foxes more than any thing; and the dogs will give tongue for the man to be on his guard if smaller vermin are near, or when strollers make their appearance. The birds going on as before mentioned, should so continue till September, or (if very early bred) the middle of August. Before they begin to shift their long feathers in the tail, they are to be shut up in the basket with the hen regularly every night; and when they begin to shift their tail the birds are large, and begin to lie out; that is, they are not willing to come to be shut up in the basket: those that are intended to be turned out wild should be taught to perch (a situation they have never been used to); this is done by tying a string to the hen's leg, and obliging her to sit in a tree all night: be sure you put her in the tree before sunset; and if she falls down, you must persevere in putting her up again till she is contented with her situation; then the young birds will follow the hen, and perch with her. This being done, and the country now covered with corn, fruits, and shrubs, &c. they will shift for themselves. For such young pheasants as you make choice of for your breeding-stock at home, and likewise to turn out in spring following, provide a new piece of ground, large and roomy for two pens, where no pheasants, &c. have been kept, and there put your young birds in as they begin to shift their tails. Such of them as you intend to turn out at a future time, or in another place, put into one pen netted over, and leave their wings as they are; and those you wish to keep for breeding put into the other pen, cutting one wing of each bird. The gold and silver pheasants you must pen earlier, or they will be off. Cut the wing often; and when first penned feed all your young birds with barley-meal, dough, corn, and plenty of green turnips.

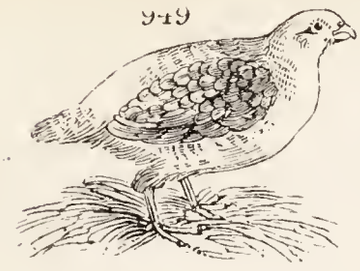
7553. *A receipt to make alum curd.* Take new milk, as much as your young birds require, and boil it with a lump of alum, so as not to make the curd hard and tough, but custard-like. Give a little of this curd twice a day, and ants' eggs after every time they have had a sufficient quantity of the other food. If they do not eat heartily, give them some ants' eggs to create an appetite, but by no means in such abundance as to be considered their food. The distemper alluded to above is not improbably of the same nature as the roup in chickens, contagious, and dependent on the state of the weather, and for prevention requiring similar precautions. When a pheasantry is connected with a piece of ground covered with bushes or shrubbery, the birds may be bred in houses or pens, and afterwards put out into small enclosures, say one hundred feet square, with fences twelve feet high, each containing abundance of low evergreens, especially the spruce fir, and an artificial or natural supply of water. Under such an arrangement the hen pheasant will hatch her own eggs, and the following directions are given as to attendance by the same experienced person: — Not more than four hens to be allowed in the pens to one cock. And in the out covers, three hens to one cock may be sufficient, with the view of allowing for accidents, such as the loss of a cock or hen. Never put more eggs under a hen than she can well and closely cover, the eggs fresh and carefully preserved. Short broods to be joined and shifted to one hen. Common hen pheasants in close pens, and with plenty of cover, will sometimes make their nests and hatch their own eggs: but they seldom succeed in rearing their brood, being so naturally shy; whence, should this method be desired, they must be left entirely to themselves, as they feel alarm even in being looked at. Eggs for setting are generally ready in April. Period of incubation, the same in the pheasant as in the common hen. Pheasants, like the pea-fowl, will clear grounds of insects and reptiles, but will spoil all wall-trees within their reach, by picking off every bud and leaf.

7554. *Feeding.* Strict cleanliness to be observed, the meat not to be tainted with dung, and the water to be pure and often renewed. Ants' eggs being scarce, hog-lice, ear-wigs, or any insect may be given; or artificial ants' eggs substituted, composed of flour beaten up with an egg and shell together, the pellets rubbed between the fingers to the proper size. After the first three weeks, in a scarcity of ants' eggs, Castang gives a few gentles, procured from a good liver tied up, the gentles when ready dropping into a pan or box of bran; to be given sparingly, and not considered as common food. Food for grown pheasants, barley or wheat; generally the same as for other poultry. In a cold spring hempseed, or other warming seeds are comfortable, and will forward the breeding stock.

7555. *In keeping fancy pheasants*, as the gold, silver, or other breeds, the best mode is to enclose a few poles of ground containing trees and bushes with a well painted copper netting, and in some concealed part to have a house or lodge for supplying water and food. This forms by far the most elegant aviary, and is the only one that at all times appears clean. They will thrive very well, however, in an aviary on the common construction.

7556. *The partridge* (*T*étrao *P*érdrix, *fig.* 949.) is a native of all the temperate regions of Europe, but unable to sustain rigorous cold or intense heat.

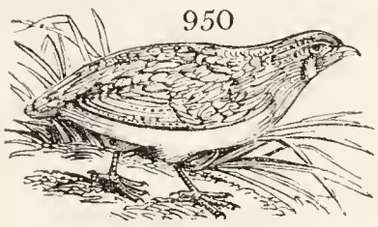
949



7557. *Partridges are highly valued as food* on most parts of the Continent, and as a table luxury in England. In the Ukraine both partridges and pheasants are more abundant than any where else in Europe: they were formerly so common in France, that Rozier informs us that the cultivators were obliged to sow three or four times the corn that was necessary to raise a crop, and that even this had often to be done three or four times in a season. The bird feeds like the pheasant on insects and seeds, and is particularly fond of those of the wild mustard. It has not been domesticated, but may be hatched and reared in the same manner as the pheasant.

7558. *The quail* (*T*étrao *C*otúrnix, *fig.* 950.) is a native of the East, and abounds in Egypt, as appears from the supplies the Israelites obtained while in the wilderness, and also in the islands of the Archipelago, and in Italy. They migrate from warmer to colder regions. They are naturalised and breed in England, changing their residence within it on the approach of winter, from the more exposed to the more temperate districts. They are very abundant in France, and are caught in snares and nets (described by Rozier), and sent both to the Paris and London markets. The bird was proverbial among the Romans as captious and quarrelsome, and is employed among the Chinese for the same amusement as game cocks are in England. Here it is not domesticated, but may be reared and preserved in the same manner as the pheasant and partridge, and its food is nearly the same as that of the latter bird.

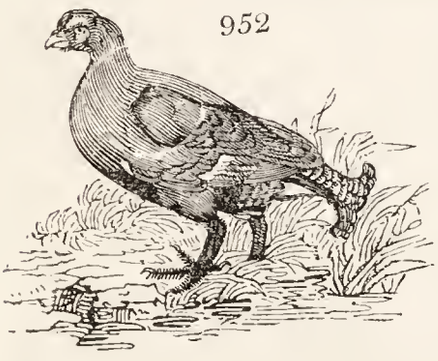
950



951

7559. *The red grouse,* or moor cock, (*T*étrao scóticus, *fig.* 951.) is an esteemed variety of *G*allinàcea, pursued with avidity by sportsmen in the mountainous districts of England, Wales, and Scotland, in which latter it abounds, there feeding in plenty among the heather, its favourite food. Its beautiful plumage, and its exquisite flavour, render it an object of considerable interest.

952



7560. *The black grouse,* or black cock (*T*étrao *T*ètrix, *fig.* 952.), is less common than the red grouse, and is therefore more highly prized. It is also larger, weighing nearly four pounds. Its plumage is a rich mixture of black with blue, relieved by marking of white. Its legs are also covered with very fine minute feathers; and it draws a peculiar characteristic from the curvilinear form of the tail, which branches out at the end into two crooked expansions. In wet seasons a great mortality is frequently observed among the grouse from intestinal worms.

7561. *The wood grouse,* or cock of the wood (*T*ètrao Urogállus, *fig.* 953.), is, after the bustard, the largest bird among those we call game; it being little less than a turkey. It was originally common in the mountainous parts of Britain; but is now nearly if not wholly extinct with us; though still common in the northern parts of Europe, where it lives in pine forests, on the cones of which it is supposed to subsist, and which at some seasons gives its flesh a terebinthinated taste: at other times it is delicious eating, and is often sent to England frozen. Like the other grouse, he has the scarlet patch on his head, his legs are defended in the same manner by a feathered covering, and his whole markings are equally varied and beautiful. From the richness of the plumage in all the varieties of the *T*ètrao, and from the extreme delicacy of their flesh as an article of food, it is to be lamented that attempts are not made to domesticate them in addition to our other poultry. It is thought by observant sportsmen and scientific naturalists, that this might be attended with less difficulty than the domesticating the partridge and pheasant; and the attempt is recommended to the patriotic amateur.

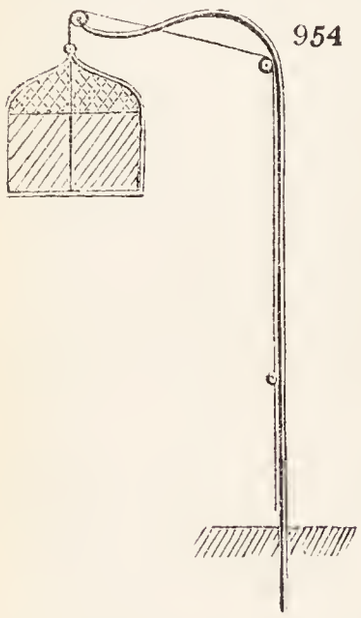
953

7562. *The lark* (*A*laúda arvénsis *L.*) and other birds were reared and fatted by the Romans for the table. The lark is caught by nets and other means in some of the open districts of England, as about Dunstable, Cambridge, &c., and brought to market for the table, as are various other birds by a particular class of men known as bird-catchers. It is an idle uncertain kind of life not to be recommended.

7563. *Of singing birds*, a great variety are domesticated; and their breeding and rearing forms a very peculiar and curious branch of rural economy. Not only all the birds which please by the natural song are domesticated and kept in cages, as the canary, nightingale, lark, linnet, finch, thrush, &c.; but even some which do not sing in a wild state, as the sparrow, hammer, &c., are by art taught the notes of other birds.

7564. *Wild singing birds* are caught by various deviees, according to the speeies of bird and season of the year. The pairing season in spring, generally March and April, is on the whole the best season, and the common means are a net called a clap-trap; a bird of the speeies to be caught, called a call-bird, to attract the wild one; and another, a female, called a brace-bird. Bird-lime is also very generally used; and for nightingales, a small hole dug in the ground covered with a perforated board, or a small round spring trap, called a nightingale trap, is resorted to. Glasses called larkers are used to call larks, and hawks are used to frighten some species, to render them more readily taken As it is only the male birds which sing, or at least are of any value for their song, it is a very material part of the bird-fancier's art to know the male from the female when they are both young; in general he is larger and longer.

7565. *In breeding and rearing tame birds* the chief art consists in teaching them to sing. This is frequently done by the human voice alone, but more commonly by the aid of the flageolet or a small barrel organ. The organ is used in Germany in teaching the nightingale-notes to the canary; and in teaching regular tunes, as marches, waltzes, &c. to the bulfinch, which after being so taught are called piping bulfinches, and cost from 5*l.* to 7 or 8 guineas each in London. In Italy the canary is taught various notes and tunes by the flageolet. In France, and also in this country, one bird is taught by another being placed in a cage near it. When not taught at all, and not within the hearing of other birds, each bird utters its natural notes but very imperfectly. In general they are more ready to imitate the note of any bird they hear, even of a hen or duck, than to utter those which are natural to the species. This certainly appears singular, but it is a well known fact.



954

955

7566. *The aviary*, or place for breeding and keeping singing birds, may be a long narrow apartment fronting the south; the front to be covered with wire netting, and within this glass sashes which may be removed in summer. There should also be a flue in the floor or back wall to supply heat in cold weather. In such a building various birds may be kept in cages, or a few sorts in compartments. Thus a considerable space may be allotted to the breeding of the canary, for which there is the greatest demand; the next largest to the linnet and nightingale; and any others may be kept in cages. Indeed, singing birds are invariably found to sing best when kept in separate cages, and apart from each other. In gardens or pleasure-grounds these cages may be suspended from trees, or supported by light iron props (*figs.* 954, 955.); and those who would wish to pursue this branch, either as one of amusement or profit, will find ample instructions in *Thomson's Bird Fancier*, and other similar works.

7567. *Foreign aquatic birds* may be kept in the artificial waters of pleasure-grounds by shortening the feathers of one wing, and without any other care than a duck-house or shelter during night.

7568. *The training of hawks and other birds for hunting*, of decoy birds of different sorts, as ducks, singing birds, pigeons, &c., belongs more to sportmanship than agriculture, and may be learned in Daniel's *Rural Sports*, and various old books, such as *The Country Gentleman's Recreation*, &c.

Chap. X.

Fish and Amphibious Animals subjected to Cultivation.

7569. *The cultivation of fish* is carried on to a very limited extent in Britain, owing to the great superiority of the sorts obtained by fishing in rivers or the sea, and to the decline of the catholic religion, which no longer renders fish an article of importance on certain days and seasons. However, in a few places fish are bred and reared for the market, and in gentlemen's grounds in the interior of the country some attention is generally paid to stocking the ornamental pieces of water with appropriate fish. Bakewell, in his instructive *Travels in the Tarantaise*, suggests the idea of introducing exotic fish and naturalising them in our lakes and rivers, and he mentions some Swiss species that he thinks would be particularly valuable. In the *Edinburgh Review* for 1822, is a curious paper on the possibility of rearing sea-fish in our fresh water lakes. See also *Brande's Quarterly Journal*, Nos. xxxiii. and xxxiv. It appears that the flounder and the mullet have been naturalised to fresh water; and that it is probable the whole of the fishes of analogous habits, and particularly those of the genus Pleuronéctes, might be habituated to inland lakes.

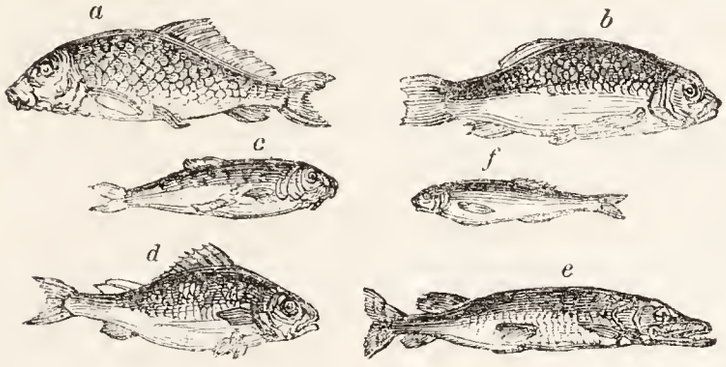
7570. *The mode of constructing ponds* for retaining water for general purposes has been already described. (4467.) Ponds, expressly for the purpose of breeding and rearing fish, are formed at least expense in deep valleys, and slight depressions between hills, where there are rivers or waters; and

different ones may often be made on the same line, the head of one constituting the bottom of that above it. The extent of them must be regulated by the nature of the situation, and the supplies of water that can be procured. In situations of this nature, the principal expense consists in constructing the banks or heads across the valleys, for keeping up the waters, and providing them with suitable sluices, which, where the land is of the loamy or clay kind, may be cheaply effected in the manner that earth works are usually performed. The foundations being laid sufficiently deep, and the earthy materials well applied by proper puddling and ramming, in the way of making embankments. The heights and strength of the dams or heads being regulated by the nature of the situations, and the quantity of water that is to be dammed up. The slopes should be the greatest which are next the waters. There must also be diverting channels for taking off the superabundant waters in the time of floods, which may be formed along the sides; the sluices being placed in the lowest parts, and being well made of seasoned oak, and tightly rammed in with the earthy materials. Detailed instructions on this subject will be found in the *Quarterly Journal of Agriculture*, vol. i. p. 297.

7571. *Sea water fish-ponds* are unknown on the Continent, and not common in England. In Scotland, however, there are several, which are stocked chiefly with turbot, cod, haddock, whiting, thornback, coal-fish, and salmon. One of the largest and best of these fish ponds is that of Macdonnel of Laggan, in Wigtonshire, which has been in existence for upwards of thirty years. (*Macdiarmid's Sketches from Nature*, and *Highland Soc. Trans.* vol. vii. p. 297.)

7572. *The kinds of fish* adapted for ponds are chiefly the carp, tench, perch, gudgeon, eel, and pike.

7573. *The carp* (*Cyprinus Carpio L. fig* 956. *a*) is by far the best fish for artificial management, and especially that variety known in England as the Prussian carp. Carp inhabits the slow and stagnant waters of Europe and Persia, and was introduced into Britain in the year 1514; about four feet long; grows fast and is very long-lived; feeds on herbs, fat earth worms, and aquatic insects, and any soft substance; is extremely fertile, and the prey of larger fish, aquatic birds, and frogs; body above blue-green, the upper part of the sides greenish-yellow and blackish, beneath whitish; tail yellow; scales large, longitudinally striate; of the gall is made a green paint, and of the sounds or air-bladder a fish-glue.



7574. *In raising carp*, it is often the practice to have three ponds: — One for the purpose of spawning the fish in, and in which they should be left during the rest of the summer and the following winter, as they mostly spawn from the beginning of May to the latter end of July; another for the convenience of nursing up the young fry, into which they should be put about the latter end of March or the beginning of April, choosing a calm but not sunny day for the business; after which they should be carefully prevented from coming to the sides and being destroyed: in this pond they may remain two years, and become four, five, or six inches in length, and good for use. The third or main pond is destined for the reception of the grown fish, as those that measure a foot or more, including the heads and tails. The proportions in which these different ponds are advised to be stocked are these: — For each acre of the first sort, "three or four male carps, and six or eight female ones;" the most suitable sort for this use being "those of five, six, or seven years old, in good health, with full scale, fine full eyes, and a long body, without any blemish or wound." The ponds should be previously cleared of all sorts of voracious fishes and other animals, as "perch, pike, eel, and trout; the water-beetle, and also the newts or lizards." Such ponds as are warm and have an open exposure, with soft water, are the most proper for this use; all kinds of water fowl being kept from them. For the nursing ponds, a thousand or twelve hundred may not be more than sufficient for an acre; and for the main ponds, one to every square of fifteen feet is the proportion advised, as their growth depends greatly on the room and quantity of food that is allowed. The best seasons for performing the business in this case are those of the spring and autumn. Some advise, in these cases, the stocking with carp or tench in the proportion of three to a square perch. In first stocking large ponds or waters, as where they are to the extent of three or four acres, carp, in the proportion of three hundred to the acre, are recommended; and where they do not extend to such sizes, not so great a portion. And in stocking, after two or three years, four hundred to the acre.

7575. *The tench* (*Cyprinus Tinca L., b*) inhabits almost every where in stagnant waters; grows quickly, and reaches from four to eight pounds weight; is very fertile and tenacious of life, and will live all the winter under the ice; feeds on worms and water plants; is very foolish, and may be easily caught; body covered with a thick mucus, and small scales which adhere firmly to the skin; above dark-green, the sides above the line green, beneath yellow, belly white; varies in its colours by age, sex, or the waters it inhabits; flesh white, soft, and well tasted.

7576. *In stocking with tench* the number per acre may be more than of carp. In Berkshire, where there are many ponds for the preserving of fish, they usually stock with tench or carp in the proportion of one hundred to the acre, the fish remaining four years in them: but in the management of Sir Harry Featherstone, in Sussex, in a pond of twenty acres reduced to sixteen by the deposition of mud, the stock is generally in the proportion of twelve hundred carp and an equal number of tench; or at the rate of seventy-five brace to the acre. And in this proportion they are said to succeed well.

7577. *The gudgeon* (*Cyprinus Gobio L., c*) is a very inferior fish to the carp or tench; but being of easy culture and rapid increase, is kept in many places as food for pike and perch. It inhabits gentle streams and lakes of Northern Europe; is tenacious of life, and very fertile; about eight inches long; feeds on herbs, worms, insects, the fry of other fish, and parts of carcasses: body narrow, spotted, above livid, the sides above the line blue, beneath whitish yellow, but it varies its colours by age, the different waters it inhabits, and its food; flesh white, and very grateful.

7578. *The perch* (*Perca fluviatilis L., d*) is an excellent fish, and though naturally found in streams in Europe and Siberia, yet will live in large ponds or lakes, provided the water be clear. It grows to two feet long; back and part of the sides deep green, with five broad black bars, which are sometimes dark green or blue, and very rarely wanting; belly white, tinged with red; swims with great swiftness and at a certain height in the water; is tenacious of life, but eagerly takes a bait; feeds on aquatic insects and smaller fish; spawns in May and June, and is very prolific; it has no real air-bladder; and from its integuments may be obtained a kind of glue; flesh very delicate.

7579. *In stocking with perch*, as they are great breeders, six hundred to the acre may be sufficient.

7580. *The pike* (*Esox Lucius L., e*) inhabits most lakes of Europe, Lapland, Northern Persia, and North America, and is found even in the Caspian Sea; swims, and grows very rapidly, one to eight feet long; is extremely voracious and long-lived; feeds on almost any thing which comes in its way, even its own tribe; spawns from February to April; body above black, the sides cineraceous spotted with yellow, beneath white dotted with black; rarely orange spotted with black or green; scales small, oblong, hard. The pike is best reared in deep ponds by itself in which some gudgeons may be put to breed

for its food. It will thrive in waters partaking of the chalybeate quality, in which few other fish would live.

7581. *The gold fish* (*Cýprinus auràtus L.*) is an inhabitant of the rivers of China and Japan, and is naturalised almost every where on account of its elegance and vivacity; the colours vary greatly, but are naturally and mostly of a most splendid golden hue; scales large. It is bred in small ponds in gardens near London and Paris for sale, as an ornamental inhabitant of crystal vases, or garden basins of water.

7582. *The minnow* (*Cýprinus Phóxinus L., f*), the *dace* (*C.* lentíscus *L.*), and the *roach* (*C.* rùtilus *L.*), are very small fish, which abound, the first in gravelly streams, and the others in still waters; both are useful as affording food to other fish, and may therefore be put into fish ponds. They are also very good to eat.

7583. *Of the trout and salmon family* there are several species, as the lake trout, gilt and red charr, which inhabit Alpine lakes in northern countries, and might probably be introduced with advantage into the lakes of Cumberland, Westmoreland, and the Highlands of Scotland. The red charr is caught in Keswick lake. The salmon and salmon-trout (*Sálmo Sàlar*, and *S.* Trútta,) require salt water and a river; and the fresh water trout (*S. Fàrio*) requires too rapid a stream for art to imitate; they succeed, however, to a certain extent, in very slow-running waters which are clear.

7584. *The salmon* is a very prolific fish; both male and female are frequently fit for propagation during the first year of their age. The roe of the female is found, on an average, to contain from 17,000 to 20,000 ova or eggs. During the months of August, September, and October, the reproductive organs, both of the male and female salmon, have more or less completely reached maturity, at which period the instinct of propagation impels them eagerly to seek rivers, and to ascend nearly to their sources, in order to find a place suitable for the deposition of their spawn. They no longer, as in the winter and spring months, roam over the coast and shores, and return backwards and forwards with the flowing and ebbing of the tide; but pursue the most direct route by the mid-channel up the rivers, and make the greatest efforts to overcome every obstacle, either natural or artificial, that may impede their progress. The spawning is accomplished in the months of November, December, and January. When the parent fishes have reached the spawning ground, they proceed to the shallow water, generally in the morning, or at twilight in the evening, when they play round the ground two of them together. After a turn, they begin to make a furrow, by working up the gravel with their noses rather against the stream; as the salmon cannot work with his head down the stream, for the water then going into his gills the wrong way, drowns him. When the furrow is made, the male and female return to a little distance, one to the one, and the other to the other, side of the furrow. They then throw themselves upon their sides, again come together, and rubbing against each other, both shed their spawn into the furrow at the same time. This process is not completed at once; as the eggs of the roe must be excluded individually, from eight to twelve days are required for completing the operation. When the process is over, they betake themselves to the pools to recruit themselves. The spawn thus deposited is afterwards covered with loose gravel; and in this state the ova remain for weeks, or sometimes much longer, apparently inert. like seeds buried in the soil. In an early spring the fry come forth early, and later when the spring is late. Generally, they begin to rise from the bed about the beginning of March, and their first movement is generally completed by the middle of April. The appearance which they present is that of a thick braird of grain rushing up in vast numbers. The tail first comes up, and the young animals often leave the bed with a portion of the investing membrane of the ovum about their heads. From experiments that were made upon the roe, it appears that they can only be hatched in fresh water; for when a portion of the roe was put into salt water, none of the ova ever came into life; and when a young fish that had been hatched in fresh water was put into salt water, it showed symptoms of uneasiness, and died in a few hours. When the evolution from the ova is completed, the young fry keep at first in the eddy pools, till they gain strength, and then prepare to go down the river, remaining near its sides, and proceeding on their way till they meet the salt water, when they disappear. The descent begins in the month of March, continues through April and a part of May, and sometimes even till June. The reason why the fry thus descend by the margin in rivers, and the mid-channel in estuaries, is apparently, according to Dr. Fleming, because the margin of the river is the easy water, and consequently best suited to their young and weak state: but when they reach the estuary or tide-way, then the margin of the water being the most disturbed, the fry avoid it, and betake themselves to the deepest part of the channel, disappearing alike from observation and capture, and so go out to sea. After remaining some weeks at sea, the smelts or samlets, as the fry are called, return again to the coasts and rivers, having obtained a pound or a pound and a half of weight; by the middle of June they weigh from two to three pounds, and are said to increase half a pound in weight every week. They are now known in Scotland by the name of grilses, and by the end of the fishing season they have obtained the size of seven or eight pounds. In the first five months of its existence, that is, from April to August, both inclusive, it may be stated that the salmon reaches, in favourable circumstances, eight pounds weight, and afterwards increases, though more slowly, yet so as to have acquired the weight of thirty-five pounds in thirty-three months. After the process of spawning is completed in the river, the parent fishes retire to the adjoining pools to recruit. In two or three weeks from that time, the male begins to seek his way down the river; the female remains longer about the spawning ground, sometimes till April or May. The fishes which have thus spawned are denominated kelts. In their progress to the sea, when they reach the estuary, they pursue a course precisely similar to the fry, not roaming about the banks like clean fish, but keeping in the mid-channel. They are at this time comparatively weak; and in thus betaking themselves to the deepest part of the channel, they are better able to resist the deranging effects of the flood-tide, and to take advantage of the ebb tide in accelerating their migration to the sea. It appears that some which descend as *kelts* in spring return again in autumn in breeding condition, a recovery which is no less remarkable than the early growth of these animals. The sea seems to be the element in which the salmon feeds and grows. When caught in fresh water, not only is their condition comparatively poor, but scarcely any thing is ever found in their stomachs. In estuaries and on coasts, on the other hand, they feed abundantly, and their stomachs are often found full of sand-eels. (*Edin. New Phil. Jour.* Jan.—April, 1828.)

7585. *The eel* (*Muræ`na Anguílla L.*) inhabits almost every where in fresh waters; grows sometimes to the length of six feet, and weighs twenty pounds; in its appearance and habits something resembles the serpent tribe; during the night quits its element, and wanders along meadows in search of snails and worms; beds itself deep in the mud in winter, and continues in a state of rest; is very impatient of cold, and tenacious of life: the flesh of such as frequent running water is very good; is viviparous, and has 116 vertebræ. One advantage of the eel is, that it will thrive in muddy ponds of very small size, where no other fish would live.

7586. *On the subject of cultivating fishes* it may be observed, that the waters of some ponds are better adapted for raising some sorts of fish than others. Thus, those where the water is rich and white are more adapted for carp; while such as have a thicker appearance, and where there is a greater deposition of muddy matter, are better suited to tench. Perch are capable of being raised in almost any sort of ponds. Eels succeed best where the ponds are not very large; but where fed by a spring, and there is a large portion of rich sediment. Pike should never be kept in ponds with carp or tench; but in separate breeding-ponds, where the supplies of small fry are considerable and not wanted for stores. Carp, tench, and perch are the sorts principally cultivated with a view to profit, with a few eels occasionally. But perch and eels should not be admitted where the ponds are but thinly stocked, as they are great devourers of the young fish. Carp and tench answer best together where the extent of the ponds are pretty large; as, in other cases, the former, from being a much more powerful fish, beats and deprives the latter of his

food. Carp seldom afford much profit in ponds of less extent than half an acre; but tench thrive well in those of almost every size, being often found good in ponds of only a few perches square. Carp, perch, and eels succeed well together; and also tench and eels. Carp more frequently injure themselves by breeding than tench, though it sometimes happens with the latter. It is not improbable, but that in small ponds it may be the best practice to keep the carp and tench separate. The produce or profit afforded by fish-ponds has not yet, perhaps, been sufficiently attended to in different situations to afford correct conclusions; nor is it well ascertained what is the annual increase in weight in fish of different kinds, in different periods of their growth, and under different circumstances of soil and water. Loveden (*Annals of Agriculture*) states, that in Berkshire a pond of three acres and a half, drawn after being stocked three years with stores of one year old, produced of carp 195 lb. weight, of tench 230 ditto; together 425 lb., which sold for 20*l.* 10*s.* or nearly 2*l.* 6*s.* per acre per annum.

7587. *The taking of cultivated fish* is generally done with nets, and sometimes by emptying the pond of water. Whatever way is adopted, only those fit to be used are taken, and the rest returned to grow larger. No fish is taken, or fit to be used, for a month before and after the spawning season, which with most fresh water fish is in April, May, or June. The Marquis de Chabanes proposes to catch fish, both in fresh and salt water, by immersing a burning lamp in an air box with mirrors, and round which he has traps into which the animals are to be entangled, while approaching the light and the multiplied images of their own species. For this contrivance he has taken out a patent. Salmon are sometimes caught by torch-light.

7588. *The castration of fish* has been successfully practised both in this and other countries, and both with the male and female. Castrated fish attain to a larger size, and are in season at any period of the year. The mode of performing the operation is described in Rees's *Cyclopædia*, art. *Fish, Castration of;* and in the *Philosophical Transactions*, vol. 48. part ii. p. 106.

7589. *Of the amphibia* which are or may be cultivated for food or ornament, the principal are the frog and tortoise.

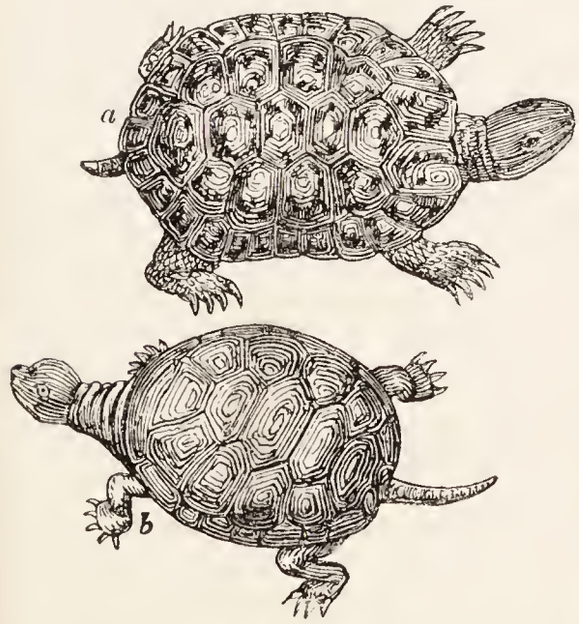
7590. *The esculent frog* (*R*ana esculénta *L.*, *fig.* 957. *a*), though generally despised in this country, is yet an excellent article to those who are accustomed to it; and there are few Englishmen who have eaten a *fricassée* of the thighs of this animal in France or Italy, but what would wish to do so again. The body of this frog is green, with three yellow lines, the middle ones extending from the mouth to the anus, with the angles of the mouth distended in a globular form; the male makes a continual croaking in an evening, especially before rain; when irritated will pursue and destroy a pike. It is rare in England, but very common on the Continent, where it is in season for the table in June.

957

7591. *The tree frog* (*R*ana arbòrea *L.*, *b*), is green above, and whitish beneath, with a yellow curved line on the side. In elegance and activity it is superior to every other European species. In summer it resides in the woods, and haunts the trees in quest of insects, which it approaches on its belly in the same manner as a cat to a mouse, and at length seizes with an elastic and instantaneous spring. It is particularly noisy on the approach of rain. In winter it takes up its abode in the bottom of the waters, remaining till the spring in a state of torpor. The noise of this frog is by many considered musical, and it is often kept in houses in Germany both as a curiosity and as a weather guide. It certainly deserves introduction to this country. We brought one from Carlsruhe, in 1828, which has remained in a glass jar covered with gauze at the top, living on flies, till the present day, Nov. 2. 1830.

7592. *There are two species of tortoise* which might be cultivated; the common, and the mud tortoise. The common tortoise (*T*estùdo græ'ca. *L. fig.* 958. *a*) weighs three pounds, and the length of its shell is about seven inches. It abounds in the countries surrounding the Mediterranean, and particularly in Greece, where the inhabitants not only eat its flesh and eggs, but frequently swallow its warm blood. In September or October it conceals itself, remaining torpid till February, when it re-appears. In June it lays its eggs, in holes exposed to the full beams of the sun, by which they are matured. Tortoises attain most extraordinary longevity, and one was ascertained to have lived in the gardens of Lambeth to the age of nearly one hundred and twenty years. It will answer the purpose of a barometer, and uniformly indicates the fall of rain before night, when it takes its food with great rapidity, and walks with a sort of mincing and elate step. It appears to dislike rain with extreme aversion, and is discomfited and driven back only by a few and scarcely perceivable drops.

958



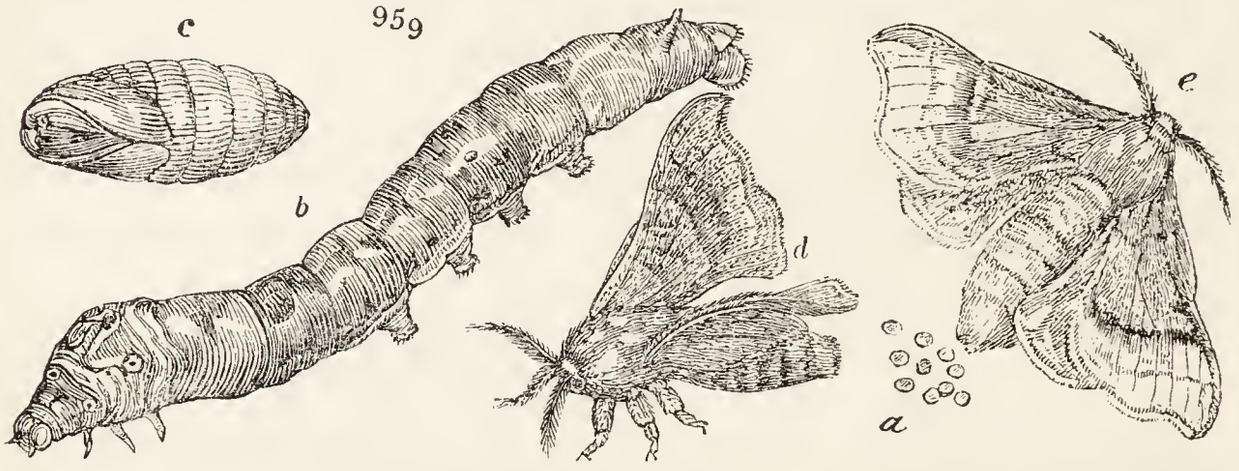
7593. *The mud tortoise* (*T.* lutària, *b*) is common both in Europe and Asia, and particularly in France, where it is much used for food. It is seven inches long; lays its eggs on the ground, though an aquatic animal; walks quicker than the land tortoise; and is often kept in gardens, to clear them from snails and various wingless insect. In fish ponds it is very destructive, biting the fishes, and, when they are exhausted by the loss of blood, dragging them to the bottom and devouring them. The tortoise may be fed on any vegetable refuse, milk, worms, offal, or almost any thing. Linnæus says they are in all things extremely slow, and in copulation frequently adhere together a month, and live several days after the head is cut off. (*Shaw's Zoology.*)

Chap. XI.

Insects and Worms which are or may be subjected to Culture.

7594. *The silkworm and the honey-bee* are the two most valuable insects in Europe. The first, from its great importance, has recently engaged the attention of the legislature, no less than of private individuals, who have embarked large sums in the attempts now making to introduce its culture in this country on a large scale.

7595. *The silkworm* is the larva or caterpillar of a moth (*Bómbyx mòri F., fig.* 959.):



it is a native of China, and was introduced into Europe A. D. 160. When full grown the worm is nearly three inches long, of a yellowish grey colour, with a horn-like process on the last joint of the body.

7596. *In Italy and other silk countries* the eggs are carefully preserved in some place of cool and even temperature, where they remain until the new leaves of the white mulberry, which is its natural food, are produced. The object is to hatch the eggs precisely at this time, that the new-born worm may be fed on food suitable to its infant state. A grower of silk never hatches his whole stock of eggs at once, as a night's frost will frequently destroy the leaves. Lettuce answers well in *this* stage of the worm's existence; but if it is fed entirely upon this plant the silk is of a very inferior description, and is, indeed, perfectly useless. The pabulum of the white mulberry, in fact, is superior in nutritious matter to that of all others. The leaves in the autumn succeeding to those stripped in the spring, are commonly given to cattle and pigs, who fatten upon them exceedingly. There is an unfounded prejudice in many silk countries that the silk produced from the second leaf is inferior to the spring crop, and in France and Italy the vernal leaf only is used. In India the mulberry tree is grown in moist places, like the osier in England, and produces from three to six crops annually: the prejudice therefore of the Italian and French growers against the second crop is unfounded. The real fact seems to be, that the worms are more difficult to breed in autumn than in spring, from the great change of temperature, against which the growers in general make no artificial provision. Another reason may probably be, that the silk is reeled with greater economy and advantage in the height of summer, when the length of the days, and the heat of the weather, is then sufficient to dry the thead in this operation. The native reelers of these countries are entirely unaccustomed to use artificial methods for creating a regulated temperature in houses or manufactories.

7597. *The ventilation and cleanliness of the nursery or feeding apartments*, and the preservation of a regular heat within them, are highly important to the health of the worm. These points are much neglected on the Continent, where the nurseries are usually situated in the midst of the mulberry plantations, exposed to the external air, and seldom cleaned. It was satisfactorily ascertained by M. Guyton de Morveau a few years ago, that a ruinous and unexpected mortality, which then raged among the worms, arose chiefly from want of ventilation and cleanliness. It has likewise been proved, by experiments lately made on a sufficiently large scale in Devonshire, that less mortality prevails among the worms in England than either in France or Italy.

7598. *In about six weeks the worm reaches its full size*, previously casting its skin four times, and abstaining from food for some time before each change; at these periods the worms are very sickly, and a great mortality generally takes place. When full grown and about to spin, they exhibit symptoms of restlessness and uneasiness; small twigs of birch, or of other slender trees, are set up in the boxes or shelves; upon these the worms climb, each fixing upon its own berth. As it sometimes happens that two worms spin together, forming what is called a double cocoon, this must be carefully prevented by separating them; such a cocoon not only being difficult to run off when reeled, but two fibres are produced injurious to the size of the thread: the double cocoons are therefore always wound off by themselves. In preparing its case or cocoon, the worm first forms a loose envelopement of silken fibres, and then proceeds to enwrap itself in a ball or case of an oval form, and finally changes into the pupa or chrysalis; and after being thus enclosed for about fifteen days, becomes a moth. This, however, is always prevented when the animal is not kept for breeding, otherwise the hole formed by the moth in effecting its escape would destroy the continuity of the silk, and prevent its reeling. The chrysalides are killed by two processes, by baking in an oven, or by letting steam into a tight chest enclosing the cocoons. The latter method is preferable, as the heat can be better regulated.

7599. *The cocoon*, after the chrysalis is killed, is either reeled off at once, or sold to others who make this a distinct trade. The silk, as formed by the animal, is so very fine, that if each cocoon was reeled separately it would be totally unfit for use; the ends of four are therefore joined and reeled together out of warm water, which softening their natural gum, makes them stick together so as to form one strong smooth thread. When the filament of any single cocoon breaks, or is exhausted, its place is supplied by a new one, so that the united thread may be wound to any length; the single filaments of the newly added cocoons are simply joined by being laid on the thread, to which they adhere by their gum. The old apparatus for reeling merely consists of a large metal basin of water, under which is a fire to keep it hot, and a reel of a poor and even rude construction: some important improvements, however, have been recently made in this machine. In reeling it is desirable that a round thread of equal thickness and smoothness should be produced, having the filaments of which it is composed as equal and as firmly united as possible. When the skein is quite dry, it is taken off the reel, and a tie is made with refuse silk at its two ends; it is then doubled into a hank, and is ready for sale. In this state it arrives in England, and is called raw

silk: the principal part is afterwards sent to a mill to be thrown, that is, to be twisted singly, or to have two or more ends of it doubled and twisted together to form singles, tram, or organzine, in order to fit it for the loom. There are, however, purposes for which a single untwisted thread is applied. We have before stated that a single thread is generally composed of the filaments from four cocoons, and four of these threads compose the organzine, or that used as the warp of fabrics; each thread is first spun or twisted, and then the four are thrown together into one. The weft or tram generally consists of four raw threads simply twisted together. The reason of drawing so fine a silk on the reel as that composed of four cocoons, is, that the *fileuse*, or attendant at the basin, cannot perfectly see more cocoons in one set, so as to replace the ends when the cocoons are exhausted. If a thread of sixteen cocoons were to be reeled, the *fileuse* could not ensure regularity. Sometimes she would have only eight or ten running, and at the next moment possibly twenty; consequently a most uneven silk would thus be produced: to prevent this evil, four cocoons are only run at once, and combined as before described. The important invention of Mr. Heathcoat, which we shall hereafter notice, applies to the object of drawing off sixteen or more cocoons at once on the reel, so as to form a thread as even as that produced by four cocoons, and thus abridge the expense of the subsequent processes of throwing. We understand this invention is fully appreciated by the reelers abroad, and by the manufacturers at home, and that it produces an astonishing improvement in the quality of the silk, and a great reduction in its price. Mr. H. has obtained patents in the silk countries no less than in England for this invention, which there is every reason to think will be generally adopted.

7600. *Culture of the silkworm in England.* It is well known to those who have considered the subject, that the silkworm will breed and thrive very well in England, where the range and extremes of temperature are within narrower limits than in France or Italy. The white mulberry flourishes equally well with us as in those countries. It remains, however, to be proved whether the weight of leaves produced on a given space of ground is equal to the average crop in warmer climates. This is evidently an important consideration in the question, of whether England can compete with foreign countries in the production of raw silk. The high value of land in a country so densely peopled as England, and the fact that the mulberry tree not only requires great space for its perfect growth, but also a clear ground beneath, renders the prospect of profit from this branch of agriculture very questionable. A joint stock company, in the management of which all the cabinet ministers were more or less concerned, was established in 1825, by the name of "The British, Irish, and Colonial Silk Company." They possessed a very large capital, and had formed extensive plantations of trees in several parts of England and Ireland, particularly near Windsor and Cork. Mr. John Heathcoat of Tiverton, in Devonshire, has also applied himself to the investigation of this important subject with great ardour; and, previously to the formation of the company above alluded to, had made considerable progress in the cultivation of the tree and the management of the worm. With the true liberality of a man of science, he presented to the company several thousand Italian plants destined for his own plantations, that they might commence their establishments without delay. It ought to be generally known, that to this gentleman we are indebted for the cheap production of that beautiful article called bobbin-net lace, which has become so important a branch of manufacture in England. It was in the attempt to render silk sufficiently even for his use in lace, that he made the discovery in reeling which we have before mentioned; and it is from the result of his investigations that the attention of government has so lately been directed to the subject. Admitting, as we have done, that no natural impediments exist against the successful culture of silk in England, it will naturally be asked why all attempts hitherto made have been unsuccessful? This question embraces a variety of considerations, into which our limits will not permit us to enter at large. We may, however, observe, that neither the mulberry tree nor the silkworm are indigenous to Britain. Centuries elapsed before even the south of Europe began their culture, which, commencing in the east of Asia, was propagated slowly and at distant periods westward. It obtained firm root in France during the reign of Henry IV., after great resistance on the part of the people, whose prejudices against the application of land to this purpose excited frequent rebellions. The unsuccessful attempt of James I. to establish it in England is not accounted for; but the times which succeeded were unfavourable to the introduction of new arts and inventions. The manufacture of silk goods was introduced into this country in the fifteenth century, and received a great stimulus by the revocation of the edict of Nantes in 1685. By this intolerant and disgraceful measure Louis XIV. drove thousands of his most industrious subjects to seek an asylum in foreign countries; of whom it is supposed not less than 50,000 emigrated to England. From this period the manufacture of silk goods became an important branch of trade in England. The common and even still existing prejudice, that our climate is unfitted for the growth of the tree, and the production of the worm, would probably be still more inveterate in former times. The acknowledged fact that England is much colder than the south of France or Italy, would naturally induce the idea that it was unsuitable both to the tree and the worms. Individuals among our countrymen have, however, constantly asserted the contrary, and numerous insulated experiments have been brought forward in support of their opinion. Miss Croft of York, in 1792, sent to the Society of Arts a specimen of silk produced by worms fed entirely upon lettuce leaves. We are not told, however, whether proper trials were made by subsequent experiments to prove its quality; and we have already observed that such silk, for purposes of manufacture, is perfectly useless, even in Italy. Yet we know it to be the opinion of men now perfectly conversant with the subject, that the various experiments and trials that have been hitherto made would long ago have succeeded, had we been fully informed on *all* the requisite points connected with the management of the tree, the worm, and its produce the cocoon. Our experimentalists have all laboured under one difficulty,—they were ignorant of the reeling process; and this probably arose from their experiments having been conducted on too small a scale to render it necessary to import or require the skill of winding the silk from the cocoon. This difficulty has at length been overcome by the exertions of Mr. Heathcoat, at whose establishment in Devonshire the improved method of reeling is now carried on with complete success.

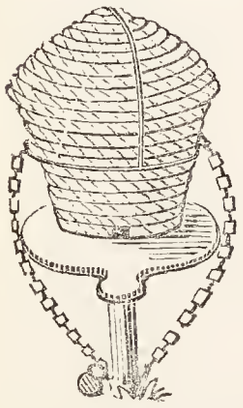
7601. *The recent attempt to establish the culture of the silkworm in Britain* appears to have completely failed for the present. After collecting a great quantity of mulberry trees, and establishing considerable plantations in Devonshire and near Windsor in England, and in the vicinity of Cork in Ireland, the company in 1828 gave up the whole, without, in our opinion, having given the attempt a fair trial. As the mulberry will produce abundance of leaves as far north as Stockholm, and as the worms have to be hatched and brought forth in artificial heat even in France, there cannot be a doubt as to the success of this branch of culture in any part of the British islands. Whether it would pay is a different thing; we by no means think it would, even in Ireland.

7602. *This common honey bee* (*Apis mellífica L.*) inhabits Europe in hollow trees, but is chiefly kept in hives, being domesticated every where. Perhaps more has been written on the economy of this insect than on any other animal employed in agriculture, and certainly to very little purpose. After all that has been done in England, France, and Italy, the bee is still more successfully cultivated, and finer honey produced, in Poland, by persons who never saw a book on the subject, or heard of the mode of depriving bees of their honey without taking their lives. Much as has been written in France and England on this last part of the subject, it is still found the best mode to destroy the hive in taking the honey. Unanswerable reasons for this practice are given by La Grenée, a French apiarian, which are elsewhere quoted by us at length (*Encyc. of Gard.* art. *Bees*), and

allowed to be conclusive as to profit even by Huish. The honey produced by any hive or apiary depends much more on the season, and the quantity and kind of flowers with which the neighbourhood abounds, than on the form of the hive or artificial management. Viewing the subject in this light, we shall avoid noticing the mode of operating with glass, storying, cellular, or other curious hives of recent invention, and treat only of the simplest methods. The author we shall follow is Howison.

7603. *The apiary*, or place where the bee-hives are placed, should in very warm situations be made to face the east, and in colder districts the south-east. It should be well protected from high winds, which not only prevent the bees from leaving the hive in quest of honey, but they also surprise them in the fields, and often kill them by dashing them against the trees and rocks or into rivers. The hives in an apiary should always be placed in a right line; but should the number of the hives be great, and the situation not capacious enough to admit of their being placed longitudinally, it is more advisable to place them over one another on shelves (*fig.* 417.) than in double rows on the ground. A bee, on leaving the hive, generally forms an angle of about forty-five with the horizon; the elevation of the hive should therefore be about two feet from the ground, in order to protect it from humidity. The greater the elevation of the hive, the longer is the flight of the swarm; and when they are at a certain point of elevation, the swarms are lost for ever to the proprietor. If the hives are to be placed in a double row, the hinder ones should alternate with, and be placed at such a distance from, the front ones, that when the bees take their flight no obstruction is offered to their ascent. Huish recommends placing every hive upon a single pedestal, and at two or three feet distance from each other. By this means, when any thing happens to one hive, the others are less likely to be disturbed than when placed on a shelf in a bee-house; and the hive may be chained down and locked. (*fig.* 960.) It is usual to have three or four legs or supports to the bee-boards; but those who have tried one will never resort to more, as one is a much better protection from vermin and insects. The space in front of the apiary should be kept clear of high plants for two or three yards.

960



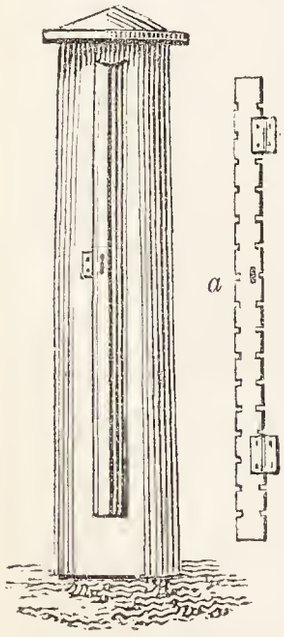
7604. *The variety of bees* employed is a matter of some consequence. To the common observer all working bees, as to external appearance, are nearly the same; but to those who examine them with attention, the difference in size is very distinguishable; and they are, in their vicious and gentle, indolent and active natures, essentially different. Of the stock which Howison had in 1810, it required 250 to weigh an ounce; but they were so vicious and lazy that he changed it for a smaller variety, which possesses much better dispositions, and of which it requires 296, on an average, to weigh an ounce. Whether size and disposition are invariably connected, he has not yet had sufficient experience to determine.

7605. *The best material and form* for hives is a straw thimble or flower-pot placed in an inverted position. Hives made of straw, as now in use, have a great advantage over those made of wood and other materials, from the effectual defence they afford against the extremes of heat in summer and cold in winter.

7606. *The size of hives* should correspond as nearly as possible with that of the swarms. This has not had that attention paid to it which the subject demands, as much of the success in the management of the bees depends on that circumstance. From blind instinct bees endeavour to fill with combs whatever hive they are put into, before they begin to gather honey. Owing to this, when the hive is too large for its inhabitants, the time for collecting their winter store is spent in unprofitable labour; and starvation is the consequence. This evil also extends to occasioning late swarming the next summer; it being long before the hive becomes so filled with young bees as to produce a necessity for emigration, from which cause the season is too far advanced for the young colonies to procure a winter stock. A full-sized straw hive will hold three pecks; a small-sized from one and a half to two pecks.

7607. *The Polish hive* (Pasieka *Pol.*, *fig.* 961.) appears to us to be the second in merits to that described, and perhaps it may deserve the preference, if the mode of using it were generally known. It is simply the trunk of a tree, of a foot or fourteen inches in diameter, and about nine feet long. It is scooped out (boring in this country would be better) for about six feet from one end, so as to form a hollow cylinder of that length, and of six or eight inches diameter within. Part of the circumference of this cylinder is cut out during the greater part of its length, about four inches wide, and a slip of wood is made to fit the opening. On the sides of this slip or segment (*a*) notches are made every two or three inches, of sufficient size to allow a single bee to pass. This slip may be furnished with hinges, and with a lock and key; but in Poland it is merely fastened in by a wedge. All that is wanting to complete the hive is a cover at top to throw off the rain; and then it requires only to be placed upright like a strong post in the garden, so as the bottom of the hollow cylinder may be not nearer the ground than two feet, and the opening slip look to the south. When a swarm is to be put in, the tree, with the door or slip opened, is placed obliquely over it; when the bees enter the door is closed, and the holes stopped with clay till the hive is planted or placed upright. When honey is wanted, the door is opened during the finest part of a warm day, when most of the bees are out; its entire state is seen from top to bottom, and the operator, with a segar in his mouth, or with a lighted rag, to keep off the bees from his hands, cuts out with a crooked knife as much comb as he thinks fit. In this way fresh honey is obtained during the summer, the bees are never cramped for room, nor does it become necessary to kill them. The old comb, however, is annually cut out, to prevent or lessen the tendency to swarming, which, notwithstanding this and the size of their dwelling, they generally do once a year; for the laws of nature are not to be changed. Though it be a fact that a small swarm of bees will not do well in a large hive; yet, if the hive extend in length and not in breadth, it is admitted both by Huber and Huish that they will thrive in it. "If too great a diameter," says Huber, "be not given to the abode of the bee, it may without danger be increased in the elevation; their success in the hollow trees, their natural domicile, incontestably proves the truth of this assertion."

961



7608. *The feeding of bees* is generally deferred till winter or spring; but this is a most erroneous practice. Hives should be examined in the course of the month of September, or about the time of killing the drones; and if a large hive does not weigh thirty pounds, it will be necessary to allow it half a pound of honey, or the same quantity of soft sugar made into syrup, for every pound that is deficient of that weight; and in like proportion to smaller hives. This work must not be delayed, that time may be given for the bees to make the deposit in their empty cells before they are rendered torpid by the cold. Sugar simply dissolved in water (which is a common practice), and sugar boiled with water into a syrup, form compounds very differently suited for the winter store of bees. When the former is wanted for their immediate nourishment, as in spring, it will answer equally as a syrup; but if to be laid up as store, the heat of the hive quickly evaporating the water, leaves the sugar in dry crystals, not to be acted upon by the trunks

of the bees. Hives may be killed with hunger while some pounds' weight of sugar remain in this state in their cells. The boiling of sugar into syrup forms a closer combination with the water, by which it is prevented from flying off, and a consistence resembling that of honey retained. Howison has had frequent experience of hives, not containing a pound of honey, preserved in perfect health through the winter with sugar so prepared, when given in proper time and in sufficient quantity.

7609. *To protect hives from the cold*, they are covered with straw or rushes, about the end of September, or later, according to the climate and season. This is an essential business, as well covered hives always prosper better the following season than such as have not been covered. In October, the aperture at which the bees enter should generally be narrowed, so as only one bee may pass at a time. Indeed, as a very small portion of air is necessary for bees in their torpid state, it were better, during severe frosts, to be entirely shut up, as numbers of them are often lost from being enticed to quit the hive by the sunshine of a winter day. It will, however, be proper at times to remove, by a crooked wire, or similar instrument, the dead bees and other filth, which the living at this season are unable to perform of themselves. To hives, whose stock of honey was sufficient for their maintenance, or those to which a proper quantity of sugar had been given for that purpose, no further attention will be necessary until the breeding season arrives. This, in warm situations, generally takes place about the beginning of May; and in cold, about a month after. The young bees, for a short time previous to their leaving their cells, and some after, require being fed with the same regularity that young birds are by their parents; and if the store in the hive be exhausted, and the weather such as not to admit of the working bees going abroad to collect food in sufficient quantity for themselves and their brood, the powerful principle of affection for their young compels them to part with what is not enough for their support, at the expense of their own lives. To prevent such accidents, it is advisable, if during the breeding season it rain for two successive days, to feed all the bees indiscriminately, as it would be difficult to ascertain those only who require it.

7610. *The swarming of bees* generally commences in June, in some seasons earlier, and in cold climates or seasons later. The first swarming is so long preceded by the appearance of drones, and hanging out of working bees, that if the time of their leaving the hive is not observed, it must be owing to want of care. The signs of the second are, however, more equivocal, the most certain being that of the queen, a day or two before swarming, at intervals of a few minutes, giving out a sound a good deal resembling that of a cricket. It frequently happens that the swarm will leave the old hive, and return again several times, which is always owing to the queen not having accompanied them, or from having dropped on the ground, being too young to fly to a distance. Gooseberry, currant, or other low bushes, should be planted at a short distance from the hives, for the bees to swarm upon, otherwise they are apt to fly away; by attending to this, Howison has not lost a swarm by straying for several years. When a hive yields more than two swarms, these should uniformly be joined to others that are weak, as from the lateness of the season, and deficiency in number, they will otherwise perish. This junction is easily formed, by inverting at night the hive in which they are, and placing over it the one you intend them to enter. They soon ascend, and apparently with no opposition from the former possessors. Should the weather, for some days after swarming, be unfavourable for the bees going out, they must be fed with care until it clears up, otherwise the young swarm will run a great risk of dying.

7611. *The honey may be taken* from hives of the common construction by three modes, partial deprivation, total deprivation, and suffocation.

7612. *Partial deprivation* is performed about the beginning of September. Having ascertained the weight of the hive, and consequently the quantity of honeycomb which is to be extracted, begin the operation as soon as evening sets in, by inverting the full hive, and placing an empty one over it; particular care must be taken that the two hives are of the same diameter, for if they differ in their dimensions it will not be possible to effect the driving of the bees. The hives being placed on each other, a sheet or large table-cloth must be tied round them at their point of junction, in order to prevent the bees from molesting the operator. The hives being thus arranged, beat the sides gently with a stick or the hand, but particular caution must be used to beat it on those parts to which the combs are attached, and which will be found parallel with the entrance of the hive. The ascent of the bees into the upper hive will be known by a loud humming noise, indicative of the pleasure in finding an asylum from their enemy; in a few minutes the whole community will have ascended, and the hive with the bees in it may be placed upon the pedestal from which the full hive was removed. The hive from which the bees have been driven must then be taken into the house, and the operation of cutting out the honeycomb commenced. Having extracted the requisite quantity of comb, this opportunity must be embraced of inspecting the hive, and of cleaning it from any noxious matter. In cutting the combs, however, particular attention should be paid not to cut into two or three combs at once, but having commenced the cutting of one, to pursue it to the top of the hive; and this caution is necessary for two reasons. If you begin the cutting of two or three combs at one time, were you to extract the whole of them, you would perhaps take too much; and secondly, to stop in the middle of a comb would be attended with very pernicious consequences, as the honey would drop from the cells which have been cut in two, and then the bees, on being returned to their native hive, might be drowned in their own sweets. The bees also, in their return to their natural domicile, being still under the impression of fear, would not give so much attention to the honey which flows from the divided cells; and as it would fall on the board, and from that on the ground, the bees belonging to the other hives would immediately scent the wasted treasure, and a general attack on the deprivated hive might be dreaded. The deprivation of the honeycomb being effected, the hive may be returned to its former position, and reversing the hive which contains the bees, and placing the deprivated hive over it, they may be left in that situation till the morning, when the bees will be found to have taken possession of their native hive, and, if the season proves fine, may replenish what they have lost. (*Huish's Treatise on Bees.*)

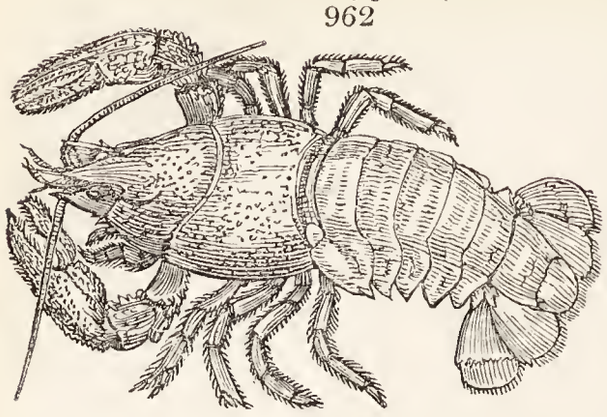
7613. *Total deprivation* is effected in the same manner, but earlier in the season, immediately after the first swarm; and the bees, instead of being returned to a remnant of honey in their old hive, remain in the new empty one: which they will sometimes, though rarely, fill with comb. By this mode, it is to be observed, very little honey is obtained, the bees in June and July being occupied chiefly in breeding, and one, if not two, swarms are lost.

7614. *Suffocation* is performed when the season of flowers begins to decline, and generally in October. The smoke of paper, or linen rag soaked or smeared with melted sulphur, is introduced to the hive by placing it in a hole in the ground, where a few shreds of these articles are undergoing a smothering combustion; or the full hive may be placed on an empty one, inverted as in partial deprivation, and the sulphureous smoke introduced by a fumigating bellows, &c. The bees will fall from the upper to the lower hive in a few minutes, when they may be removed and buried, to prevent resuscitation. Such a death seems one of the easiest, both to the insects themselves, and to human feelings. Indeed, the mere deprivation of life to animals, not endowed with sentiment or reflection, is reduced to the precise pain of the moment, without reference to the past or the future; and as each pulsation of this pain increases in effect on the one hand, so, on the other, the susceptibility of feeling it diminishes. Civilised man is the only animal to whom death has terrors, and hence the origin of that false humanity, which condemns the killing of bees in order to obtain their honey; but which might, with as much justice, be applied to the destruction of almost any other animal used in domestic economy, as fowls, game, fish, cattle, &c.

7615. *On the produce and profit* of bees much has been said by the patriotic apiarians. Both, however are extremely uncertain; and as to the profit, it can never be great, while there is the competition of all Europe to contend with as to honey and wax, and no great demand for swarms. Bees, however, are interesting creatures; are supported at almost no expense; and a hive or two is therefore very desirable in the garden of every farmer and cottager.

7616. *The craw or cray fish* (*C*ancer *A*stacus *L.*, *fig.* 962.), called sometimes the fresh water lobster, inhabits still rivers, and forms holes in the banks.

962



7617. *They are said to be nutritious* and of an excellent flavour, and are prepared in cooking like lobsters or shrimps. In former times they were celebrated for sundry medicinal virtues, but these seem to be now forgotten. The flavour of these animals, nevertheless, depends entirely on the nature of their food. Like all others of their tribe, they feed principally upon flesh. They might be advantageously cultivated in ponds and marshes, but should not be put into fish ponds, as they are detrimental to the fry. A breeding stock may frequently be purchased in Covent Garden market, or procured from any of the small rivers near London; they are also said to be plentiful near Alnwick in Northumberland.

7618. *The edible snail* (Hèlix pomàtia *L.*, fig. 71. *a*), although a native of the Continent, has been long naturalised in some parts of England.

7619. *It is the largest species found in Europe.* The animal being fleshy, and not of an unpleasant flavour, has been used as food from early times. It owes its introduction into England to certain medicinal virtues, no less than to its repute on the Continent as an article of food; but the first of these properties has long since been forgotten, and no progress has yet been made in introducing it on our tables. It is not so abundant in Italy as the common garden snail (H. horténsis *L.*), which may be seen, exposed in cages, in the markets of Genoa and other cities. We have no certain information which of these species was held in repute among the Romans, who had their cochleària or stews, where snails were bred, and fattened upon bran and sodden lees of wine. The H. pomàtia is preserved near Vienna in large pits, covered with boards, and fed with cabbage leaves and other vegetables.

620. *The medicinal leech* (*H*irùdo medicinàlis *L.*) grows to the length of two or three inches. The body is of a blackish-brown colour, marked on the back with six yellow spots, and edged with a yellow line on each side; but both the spots and the lines grow faint, and almost disappear at some seasons. The head is smaller than the tail, which fixes itself very firmly on any thing the creature pleases. It is viviparous, and produces but one young at a time, which is in the month of July. It is an inhabitant of clear running water; but in winter the leech resorts to deep water, and in severe weather retires to a great depth in the ground, leaving a small aperture to its subterranean habitation. It begins to make its appearance in March or April. Water alone is not the natural element of leeches, as it is supposed, but conjointly with ground or mud.

7621. *The usual food of the medicinal and trout leech* is derived from the suction of the spawn of fish; and leeches will not unfrequently be found adhering to the fish themselves: but frogs form the most considerable portion of their food; hence, the best leeches are found in waters much inhabited by these animals. The medicinal and trout leech do not, like the horse leech, take any *solid* food; nor have they the like propensity to destroy their own or any other species of the genus; but these the horse-leech will not hesitate to devour. (*Newton's Journal*, vol. iv. p. 313.) If put into shallow clear ponds it will breed freely, and this is practised by some herbalists and apothecaries in the neighbourhood of London.

7622. *The use of leeches* for the purpose of local bleeding is very considerable. There are four principal importers of leeches in London alone, whose average imports are said to be 150,000 per month each; making a total of 600,000, or *seven millions two hundred thousand in one year.* On the Continent, where they are obtained at a much cheaper rate, the numbers employed are enormous. (*Ibid.*) The London market is partly supplied from the lakes of Cumberland, where the leeches are caught by women, who go into the water bare-legged, and after a few have fastened, they walk out and pick them off. A good many are also brought from Holland.

Chap. XII.

Animals noxious to Agriculture.

7623. *Almost every animal may be injurious to the agriculturist in some way or other.* All the cultivated live stock will, if not excluded by fences, or prevented by herding, eat or tread down corn crops or other plants in culture. Those animals, as the dog and ferret, which assist him in deterring or in catching noxious animals which would prey on others, will themselves become depredators if not attended to; and even man, the only rational, and therefore the most valuable of agricultural servants, will prove, under certain circumstances, the greatest of all enemies to the agriculturist. We shall glance at the different animals more especially noxious in the order of their usual classification.

Sect. I. *Noxious Mammàlia.*

7624. *Of noxious Mammàlia* man, in a demoralised state, is the most injurious. The remedy is furnished by the law; — the preventive is good education, and civil and kind treatment by the master.

7625. *The fox* (*C*anis *V*úlpes) commits great ravages among lambs, poultry, geese, &c. To destroy it, the farmer must take a sheep's paunch and fasten it to a long stick; then rub his shoes well upon the paunch, that the fox may not scent his feet. He should then draw his paunch after him as a trail, a mile

or upwards, till he gets near some large tree; then leave the paunch and ascend into the tree with a gun; and as the night comes on, he may see the fox come after the scent of the trail, when he may shoot him. The trail should be drawn to the windward of the tree, if he can conveniently contrive so to do. — Or, set a steel-trap in the plain part of a large field, distant from paths and hedges; then open the trap, place it on the ground, cut out the exact shape thereof in a turf, and take out just so much earth to make room for it to stand, and then cover it again very neatly with the turf you cut out. As the joint of the turf will not close exactly, procure some mould of a mole-hill newly thrown up, and stick some grass on it, as if it grew there. Scatter some mould of the mole-hill very thin three different ways, at the distance of ten or twelve yards from the trap; let this mould be thrown on spots fifteen or sixteen inches square; and where the trap is placed, lay three or four small pieces of cheese; and then, with a sheep's paunch, draw a trail a mile or two long to each of these three places, and from thence to the trap, that the fox may approach one of the places first; for then he will advance to the trap more boldly; and thus you will be almost always sure of catching him. You must take care that your trap be left loose, that he may draw it to some hedge or covert, or he will otherwise bite off his leg, and so make his escape. — Or near the spot where the fox uses much to resort, fix a stick or pole, much in the same manner as for a woodcock. To explain this more exactly: tie a string to some pole set fast in the ground, and to this string fasten a small short stick, made thin on the upper side, with a notch at the lower end of it; then set another stick fast in the ground, with a nick under it; bend down the pole, and let the nicks or notches join in the slightest degree: then open the noose or string, and place it in the path or walk of the fox. By strewing flesh-meat, pieces of cheese, &c., as you pass along, you may entice the fox to take the same road.

7626. *To shoot a fox*, anoint the soles of the shoes with swine's fat, a little broiled; then go towards the wood, and, in returning, drop here and there a bit of swine's liver, roasted and dipped in honey, drawing after you a dead cat; and by these means he will be allured to follow you.

7627. *The fox is sometimes taken with a hook*, made of large wire, and turning on a swivel like the collar of a greyhound; it is usually hung so high from the ground, that he is compelled to leap to catch at it; and baited with fresh liver, cheese, &c., and if a trail be run with a sheep's paunch, as before directed, he will be drawn to the bait with the greatest ease.

7628. *The pole-cat* (*Félis Putórius L.*) may be caught and destroyed by a dead-fall, constructed in the following manner: — Take a square piece of wood, weighing forty or fifty pounds: bore a hole in the middle of the upper side, and set a crooked hook fast in it; then set four forked stakes fast in the ground, and lay two sticks across, on which sticks lay a long staff, to hold the dead-fall up to the crook; and under this crook put a short stick, and fasten a line to it: this line must reach down to the bridge below; and this bridge you must make about five or six inches broad. On both sides of this dead-fall place boards or pales, or edge it with close rods, and make it ten or twelve inches high. Let the entrance be no wider than the breadth of the dead-fall. — A pigeon house, surrounded with a wet ditch, will tend to preserve the pigeons; for beasts of prey naturally avoid water.

7629. *The weasel, or Foumart* (*Félis vulgáris L.*), though in some respects beneficial, in as much as when domesticated it destroys rats, mice, moles, and other noxious vermin, is nevertheless, in a wild state, a formidable foe to poultry and rabbits. Weasels may be destroyed by putting in their haunts small pieces of paste, consisting of pulverised sal ammoniac, mixed up with the white of an egg, wheaten flour, and honey. The strewing of rue round the place where hens nestle, is also said to drive away these depredators; as also will the smell of a burnt cat; as all animals are terrified at the burning of one of their own, or of a similar species.

7630. *The badger* (*Ursus Mèles L.*) destroys great numbers of young pigs, lambs, and poultry, every year. Some use a steel-trap, or a spring, such as foxes are taken in, to catch them. Others sink a pit-fall, five feet in depth and four in length, forming it narrow at top and bottom, and wider in the middle; they then cover it with small sticks and leaves, so that the badger may fall in when he comes on it. Foxes are sometimes taken in this manner. Others, again, pursue a badger to his hole, and dig him out: this is done by moonlight.

7631. *The mole* (*Tálpa europæ'a*) is injurious by the subterraneous roads and hills of earth which it forms in grass lands. With regard to the removal of mole-hills various practices are in use; but the most effectual is that derived from the experience of a successful mole-catcher, and communicated to the public by Dr. Darwin, in his *Phytologia*. This man commenced his operations before sun-rising, when he carefully watched their situation; and frequently observing the motion of the earth above their walks, he struck a spade into the ground behind them, cut off their retreat, and then dug them up. As moles usually place their nests at a greater depth in the ground than their common habitation lies, and thus form an elevation or mole-hill, the next step is to destroy these nests by the spade; after which the frequented paths are to be distinguished from the bye-roads, for the purpose of setting subterraneous traps. This object may be effected by marking every new mole-hill with a slight pressure of the foot, and observing the next day whether a mole has passed over it, and destroyed such mark; and this operation should be repeated two or three mornings successively, but without making the pressure so deep as to alarm the animal, and occasion another passage to be opened. Now, the traps are to be set in frequented paths, and should be made of a hollow wooden semi-cylinder (*fig.* 292.), each end of which should be furnished with grooved rings, containing two nooses of horse-hair, that are loosely fastened in the centre by means of a peg, and are stretched above the surface of the ground by a bent stick or strong hoop. As soon as the mole passes half way through one of these nooses, and removes the central peg in its course, the hoop, or bent stick, rises in consequence of its elasticity, and of course strangles the mole. The simplicity of this mode of destroying mole-hills and moles recommends itself to general adoption, as those whose grounds are thus infested may easily extirpate them, by teaching this practice to their labourers.

7632. *The domestic or Norway rat* (*Mús Rattus L.*, *fig.* 963.) is now generally diffused throughout this country, where it has almost extirpated the indigenous black rat. It is the most noxious quadruped we have, as it is destructive both to the live and dead stock of the farmer. The following methods for destroying it are preferable to all others, and are given in *Willich's Domestic Economy*, vol. iii.: — Fry a piece of sponge with salt butter in a pan; then compress it between two plates, and cut it into small pieces, and scatter them about the holes frequented by rats and mice. This preparation is devoured with avidity; it excites thirst in the animals, which should be gratified by exposing shallow vessels containing water. On drinking this fluid, after having swallowed the burnt sponge, it distends their stomach, and proves a fatal repast. — Or, a capacious cask of moderate height must be procured, and put in the vicinity of places infested with rats. During the first week this vessel is only employed to allure the rats to visit the solid top of the cask, by means of boards or planks arranged in a sloping direction to the floor, which are every day strewed with oatmeal, or any other food equally grateful to their palate; and the principal part of which is exposed on the surface. After having thus been lulled into security, and accustomed to find a regular supply for their meals, a skin of parchment is substituted for the wooden top of the cask, and the former is cut for several inches, with transverse incisions through the centre, so as to yield on the smallest pressure. At the same time, a few gallons of water, to the depth of five or six inches, are poured into the empty cask. In the middle of this element a brick or stone is placed, so as to project one or two inches above the fluid; and that one rat may find on the former a place of refuge. These preparatory measures being taken, the boards as well as the top of the cask should now be furnished with proper bait, in order to induce them to repeat their visits. No sooner does one of these marauders plunge

963

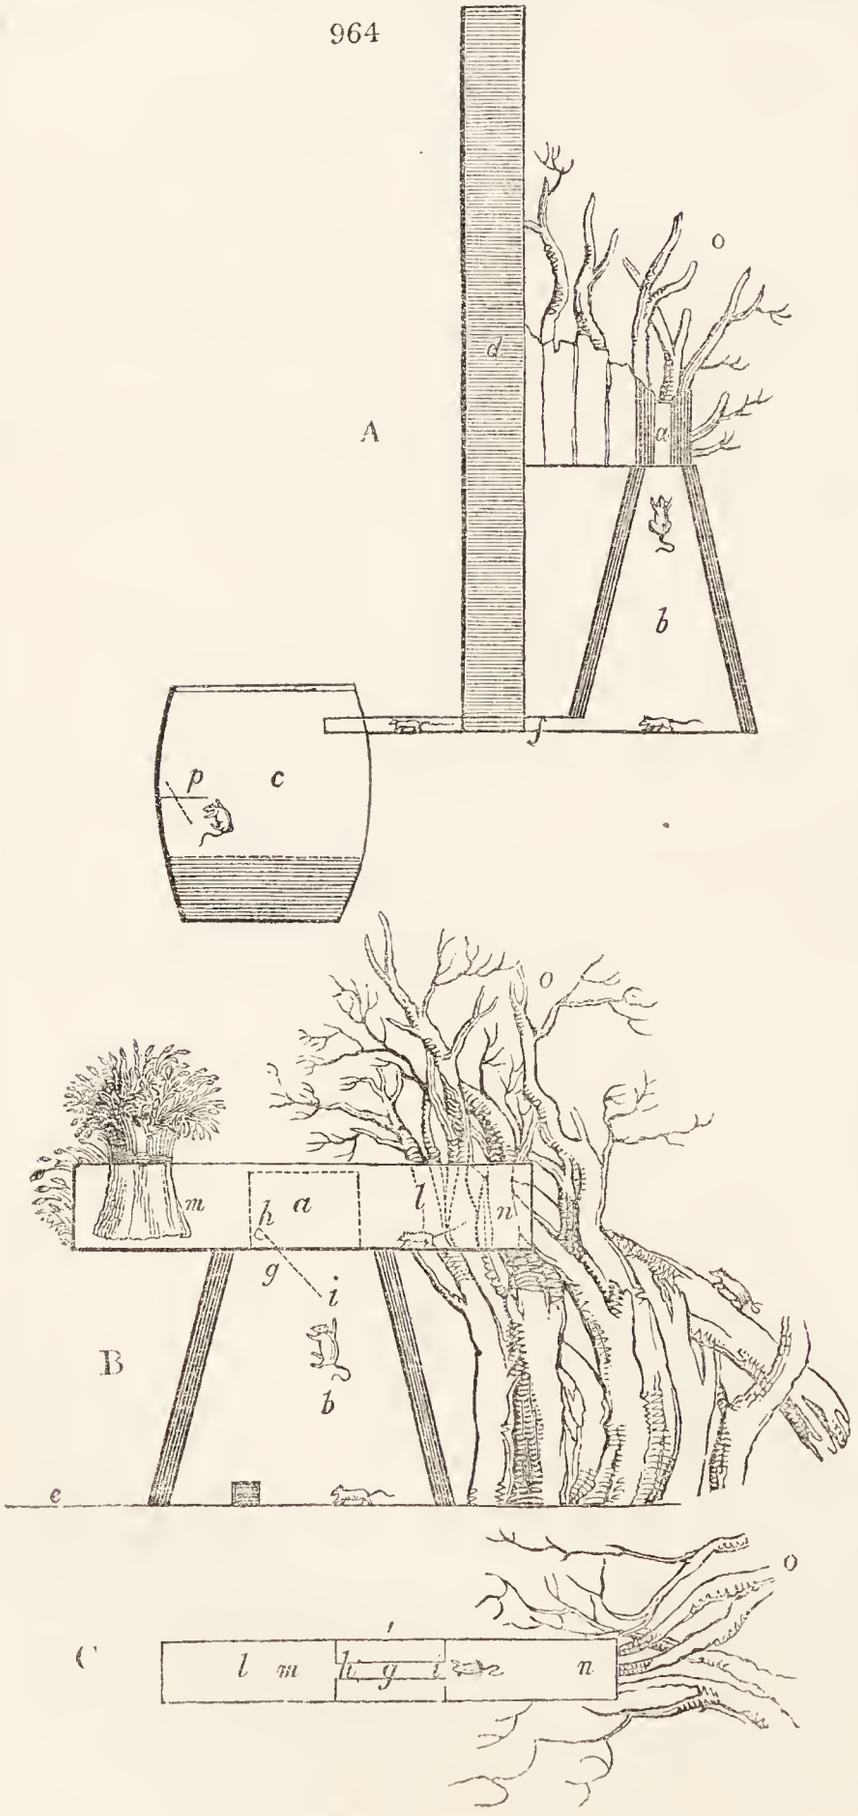
through the section of the parchment into the vessel, than it retreats to the brick or stone, and commences its lamentations for relief. Nor are its whining notes uttered in vain; others soon follow, and share the same fate; when a dreadful conflict begins among them, to decide the possession of the dry asylum. Battles follow in rapid succession, attended with such loud and noisy shrieks, that all the rats in the neighbourhood hasten to the fatal spot, where they experience similar disasters. Thus hundreds may be caught by a stratagem, which might be greatly facilitated by exposing a living rat taken in a trap, or purchased from a professional rat-catcher.

7633. *A successful mode of enticing rats* has been lately practised by Broad, a farmer at Thruxton in Herefordshire. He uses a bore trap, two feet long, eight inches wide, and nine inches deep, and little different in construction from the common one. His secret consists in scenting light-coloured malt, and also some wheat straws, with oil of caraways, and not setting the traps for a day or two till the rats have been accustomed to eat the malt without fear. (*F. Mag.* xiv. p. 431.)

7634. *Paul of Starston's rattery* is thus described by S. Taylor, Esq. in the *Gardener's Magazine*: —

7635. *This rattery* was invented by Mr. R. Paul of Starston, in Norfolk. He bestowed much labour and time to bring it to perfection; and, though living in a situation peculiarly favourable for encouraging the breed of rats, used to boast that he had completely subdued them. In fact, I have heard him say that he offered a reward to any one who would bring rats on his premises; and that having marked and turned off one particular pair, he betted a wager that he should soon catch them both; which, in the course of a very few days, he did. He selected, as the site of his rattery, some outhouse where rats were known to frequent, and which he could lock up, and keep sacred to his own devices and operations. Here he fixed his trap, the construction of which will be best understood by referring to the accompanying sketches (*figs.* 964, 965.). This

964



The same letters refer to each of the figures.

A, End view of the trap, with the tub (section).

B, Longitudinal section of trap.

C, Birdseye view of longitudinal section of trap.

a, Doubting Castle.

b, Forlorn Hope.

c, Slough of Despond.

d, Partition wall.

e, Ground level.

f, Pipe of brick or tile.

g, Falling floor, or bottom of trap.

h, The weighted end of the fall, to bring it back into its place.

i, The end of the fall, that gives way under the rats.

l, Trough, or thoroughfare, in which the trap (*a*) is placed.

m, The feeding end of the trough.

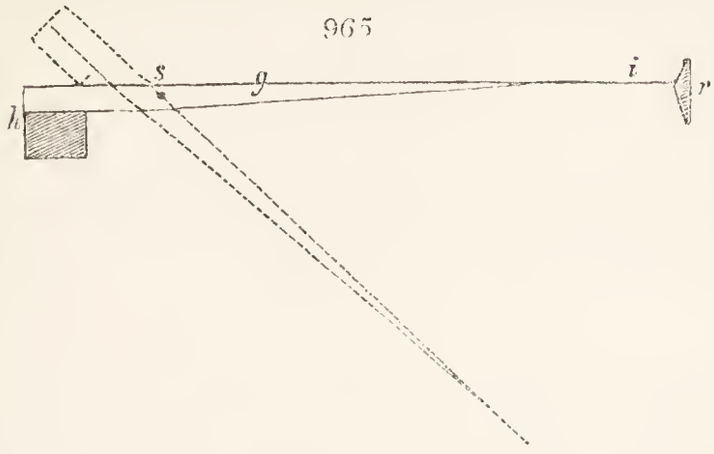
n, The end at which the rats enter.

o, Loose wood, to serve both as a cover and a road into the trap.

p, A slip of wood, to which the rats spring from the pipe *f*, and which gives way under them, and lets them into the water below.

spot he endeavoured to make as inviting and comfortable to the animals as possible; for which purpose he placed faggots, loose wood, and even straw, with an occasional wheat sheaf, on and about the trap. His plan was, to render the trough (*l*) a complete thoroughfare; for which purpose the trap or falling bottom (*g*) was, for several days, secured by a pin, and the end (*m*) used as a feeding place. After the rats had got accustomed to the spot, and passed the bridge with confidence, he took out the pin which secured it, and every rat that attempted to pass thereafter was taken prisoner. I should here observe, that great care is necessary in the construction of this part of the trap. It is not enough that the floor give way under the rat, and be merely brought back into its place again by the balance weight at the end of the bridge (*h*). One rat might be accidentally so caught, but you would not catch a second. They are, as is well known, remarkably cunning and suspicious in their dispositions; and are in the habit of trying the bridge with their fore-feet, in order to ascertain its soundness, previously to adventuring the weight of their bodies thereon. It is obvious, therefore, that unless the bridge is sufficiently fastened to enable the rat to make this trial, the trap will be no trap to them; and yet the catch or fastening should not be so stiff but that it will suffer the bridge to give way under their weight when once upon it. I cannot show this catch in my sketches; they are so small, but (enlarging the scale) it is, when the bridge is viewed sideways, something like the annexed sketch (*fig.* 965.). *g* is the bridge or fall of wood tipped with thin sheet iron at the end (*i*), which works into the catch (*r*). This catch should be sufficiently rank to bear the trial already spoken of; and yet not so rank but that it suffer the bridge to fall when wanted (as shown by the dotted lines *n*). It is brought back by the weight (*h*), and moves on pivots at *s*.

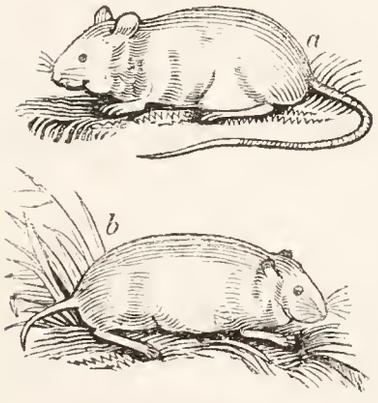
965



7636. *The beauty of Paul of Starston's trap* is, that, when once set, and the catch (*r*) regulated to its proper pitch, it requires no further trouble. One is sufficient for the whole premises. The great object is, to give them time enough to get acquainted with it; for which purpose every thing should be done to attract them to the spot, and to make them feel themselves at home. A little pale malt, slightly tinctured with oil of caraway, will prove to be the most inviting dish you can set before them; and it will be well to bear in mind, that no part of the trap, not even the straw or the wood by which it is surrounded, ought to be touched by the naked hand without first rubbing the skin with a portion of the oil of caraway. Do not scatter the malt *upon* the bridge (*g*), but spread it carelessly, as it were, about the feeding end of the trough (*m*). It will thus be in sight from the other end (*n*); and, to get it, the rats must pass the bridge (*g*); for it will be seen at *fig.* 964. B, that the entrance to the trap is now (by means of the wood piled up) at the end of the trough (*n*), although at first it had an entrance at each end, and was, as I have stated, a complete thoroughfare. Indeed, some have them on this plan still; having no particular feeding place, and trusting entirely to time and chance for what they may catch; having first taken pains to make the trap a *run*, and the place itself a harbour for rats. I do not know that it is requisite for me to add many more words. The drawings sufficiently explain the principle; and as to dimensions, those can be determined by the projector, and must, in some degree, depend on the size and convenience of the building to which the rattery is attached. The trap itself should not be above three or four inches wide, and twelve or fifteen inches long; in order to allow plenty of room for the fall of a large rat. "The forlorn hope" into which he dropped from "doubting castle,"—for, you will observe, my friend had the *Pilgrim's Progress* in his eye when he was thus labouring to entrap sinners,—"the forlorn hope," I say, should be sufficiently deep to prevent the rat from making any attempt to reach the bottom of the trap (*g*); for which purpose it should be of a conical form, and perfectly smooth inside. Once in "the forlorn hope," therefore, he has no means of egress but by the pipe or drain (*f*), the length of which is immaterial, and which conducts to a tub or cistern of water called, not inaptly, "the slough of despond." Against the side of this tub is fixed a flap (*p*), upon which, as the only chance of escape, the rat jumps from the mouth of the pipe (*f*). It gives way under him, as shown by the dotted line, and he soon ends his career in "the slough of despond." It will be observed, that the operation of this trap is so silent, and yet so effectual, that hundreds may be caught in quick succession without any alarm being given to the remainder; for it appears that they continue but a very short time in "the forlorn hope," leaving it almost immediately for "the slough of despond;' their immersion in which (it being at such a distance from the trap) is unattended with any noise; whereas, had the water been immediately under the fall (*g*), each rat would have occasioned more or less disturbance, and thus have intimidated many. Besides, the mere examination of the cistern, and taking out the captured, would have been a constant source of annoyance; whereas, in its present situation, it may be examined every day without in the least interfering with the trap. My friend had a mouse-trap on the same principle, only on a smaller scale, and of lighter materials, which answered extremely well. The mice dropped through the trap into a little cistern of water beneath. (*Gard. Mag.* vol. vi. p. 585.)

7637. *The long-tailed field mouse* (*Mús* sylváticus *L.*, *fig.* 966. *a*), and the short-tailed field mouse (*b*), are both rather larger than the common mouse. Of late years they have appeared in vast numbers in some parts of England, and caused incalculable damage to the agriculturist. In 1814, and the following year, the extensive plantations in Dean and New forests were nearly destroyed, over an extent of five hundred acres: the devastation was caused by these vermin attacking the five-year-old oak and chestnut plants, which they barked round at the bottom, and consequently destroyed. Ash, larch, fir, and holly plants were served in the same way; and, in many instances, the roots were gnawed through two or three inches below the surface. Lord Glenbervie observes, that this alarming havoc first became apparent in 1811, and increased to such a degree in the three following years, that the greatest alarm was felt by government for the safety of the growing timber on these extensive forests. Seven or eight different sorts of traps were set, a great variety of poisons tried, cats were brought in numbers and turned loose in those enclosures most infected, and crows, magpies, and owls were impressed into the service; but the number of these animals was so prodigious that no sensible diminution was perceived. At length a vast number of pits were dug; and as this method produced the most beneficial results, we shall describe it. The pits were made from eighteen to twenty inches deep at the bottom, about two feet in length, and one foot and a half in width, and, at the top, only eighteen inches long and nine wide, or, indeed, as small as the earth could be got out of a hole of that depth; for the wider they are below, and the narrower above, the better they answer their purpose. They were made twenty yards asunder, or about twelve on an acre; or, where the mice were less numerous, thirty yards apart. By this method thirty thousand mice were caught in a short time, but a far greater number had been taken out of the holes, either alive or dead, by stoats, weasels, crows, and especially hawks. It was for a long time supposed that this damage had been caused by rabbits; and it is very probable that similar injuries are frequently attributed erroneously to these animals. Some years ago an extraordinary quantity of mice created similar devastation in Lord Bagot's extensive woods in Staffordshire, and in those of Lord Downes in Yorkshire (*Zool. Journal*, No. 4. p. 433.).

966



7638. *The field mouse, in the forest of Dean*, had become so destructive in 1813, that after trying traps, baits with poison, dogs, cats, &c. with little success, at last the plan of catching them by holes was hit upon. These holes were made from eighteen inches to two feet long, sixteen or eighteen inches deep, about the width of a spade at the top, fourteen or fifteen inches wide at the bottom, and three or four inches longer at the bottom than at the top. The object was to get the bottom of the hole three or four inches wider every way than the top, and the sides firm; otherwise the mice would run up the sides and get out again. The holes were made at twenty yards apart each way, over a surface of about 3200 acres: 30,000 mice were very soon caught, and the ground was freed from them for two or three years. As many as fifteen have been found in a hole in one night; when not taken out soon, they fell on and ate each other. These mice, we are informed, used not only to eat the acorns when newly planted, but to eat through the stems of trees seven and eight feet high, and one inch and a half in diameter; the part eaten through was the collar, or seat of life. (*Billington's Facts on Oaks and Trees, &c* p. 43.)

Sect. II. *Birds injurious to Agriculture.*

7639. *Of birds,* the most decidedly injurious to man are the different hawks and kites, as most of the species attack and devour young poultry.

7640. *Various methods* have been proposed for remedying this evil, but they evince little acquaintance with the habits of these birds. Mr. Swainson recommends that the prevalent custom, of nailing such as have been killed against barn-doors or outhouses, be exchanged for the following: — In such parts of the country as are frequented by these birds, let two or three poles, ten or twelve feet high, be placed in the farmer's poultry yard, each pole being furnished with an iron spike six or eight inches long; pass this spike through the body of a dead hawk in the direction of the back-bone: it will thus be firmly secured, and give the bird an erect position; the wings being free will be moved by every breeze, and their unnatural motion will prove the best scarecrow either for ravenous or granivorous birds, more particularly the latter. Destruction by the gun is of course the most effectual.

7641. *Whether granivorous birds are more injurious* than beneficial to the farmer, is very questionable.

7642. *The crow, rook, raven, sparrow, magpie, and starling* are commonly called granivorous; yet this is an error, for they are all omnivorous, that is, feeding both upon animal and vegetable substances, and more particularly upon insects. We are annually told of large crops being either wholly or partially destroyed by insects of some sort or other; but we never hear that these injuries have been occasioned by birds. These complaints have certainly been more numerous of late years than formerly, and this is attributed by Mr. Swainson to the destruction of small birds (as waste lands are brought into cultivation); to the great diminution of rookeries; and to the foolish prejudice which the generality of farmers have taken up against these latter birds, which they destroy without mercy. In this instance we have been less wise than our ancestors, who protected and cultivated them, and by whom they were justly considered of the greatest benefit to mankind. Nature seems, indeed, to have pointed this out to us, for she has distributed the crow in all parts of the habitable world. Yet the farmer will enquire, "What good can these birds do me, when they come on my newly sown land, and root up the seed?" The answer is very short. The crows and rooks do not come for the express purpose of eating or destroying the seed, but for devouring the insects, snails, and grubs turned up by the plough or harrow; these are their favourite food, and while so occupied, the small quantity of seed they may eat or displace is returned to the farmer ten-fold by that saved from the insects. Wallis, in speaking of the destruction caused by the hedgechaffer or cockchaffer, says, that "whole meadows and corn-fields were destroyed by them;" and judiciously concludes by observing, "that the many rookeries with us is the reason why we have so few of these destructive insects." (*Hist. of Northumberland.*)

Sect. III. *Insects injurious to Agriculture.*

7643. *Insects, above all other animals,* are by far the most injurious to the agriculturist; not only from their numbers, but from their attacking the produce of the earth in all its stages of growth and maturity. We have already pointed out the advantage, not to say the necessity, of a certain knowledge being acquired respecting insects, by all persons engaged in agricultural pursuits. We shall now explain, in popular language, the different tribes or orders into which they are divided; the changes they undergo; and the injuries they produce to man, and the animals and vegetables which he cultivates. Numerous insects, much more destructive than those we shall enumerate, are found in other climates, but from which the British agriculturist has, happily, nothing to fear, and therefore need not be acquainted with. The reader will, however, find much valuable information respecting them concentrated in Kirby and Spence's *Introduction to Entomology,* vol. i.

Subsect. 1. *Physiology of Insects.*

7644. *Insects are distinguished from worms* (*Vermes L.*) by always having feet in their perfect state, as the beetle, butterfly, &c. Worms crawl upon their bellies and have no feet, as the earth-worm, slug, snail, &c. The generality of insects have only six feet; but some few, generally called by this name, have a great many, as the wood-louse, centipede, &c.

7645. *Nearly all insects are oviparous;* that is, produced from an egg. These eggs are seldom found singly; they are small in size, and do not grow. The eggs of some species are hatched in a few days, while those of others remain during the winter, and the young do not come forth until the season at which the leaves of the plants upon which they feed begin to expand.

7646. *The second state of the insect is called the eruca,* or larva in systematic language, and is known to the vulgar by various names. Caterpillars are those larvæ which are exposed, and feed upon leaves and plants, as the caterpillar of the common cabbage butterfly (*fig.* 971. *a*). The larvæ of beetles usually live in the earth, in the trunks of trees, or in the substance upon which they feed; they are generally of a whitish colour, thick and clumsy in form, and are called grubs. The larva of the common cockchafer (*fig.* 970. *b*), and of the nut-beetles (*fig.* 970. *c*), are of this description; while the name of maggots is usually given to the larvæ of flies, bees, ants, &c., all of which live in the same confined state as those of beetles. It is in this stage of existence that insects are most voracious, and consequently most destructive to plants.

7647. *When the larva has attained to its full size,* it changes into the pupa or chrysalis state. This is done in different situations, according to the tribes to which they belong. The chrysalis of butterflies (*fig.* 971. *b*, *c*) are naked, and are either suspended or attached to trees, branches, walls, &c. Those of moths are either concealed in a case like the cocoon of the silkworm, or the caterpillar undergoes its change in the earth. The period in which insects remain in this state varies according to the species; but in most cases they are inactive and torpid.

7648. *The imago, or perfect insect,* is produced from the chrysalis, and is the only state in which all its parts and members are fully developed. The appearance and economy of perfect insects, in general, is totally different from those of the larvæ and pupæ, and it is only in its final stage of existence that the species can be ascertained. With the exception of such insects as form the A'ptera of Linnæus, all others are furnished with wings, either four or two in number. Some few exceptions, however, occur to this rule; the female of the glow-worm and of some few moths are apterous, while many beetles (although furnished with hard winged cases) are destitute of real wings.

7649. *The duration of insects* is extremely variable: the greatest proportion appear to be annual, emerging from the egg and passing through the three stages of their existence within the space of a year. But there are a great number of species, particularly among the beetles, which pass three, and even four, years in the caterpillar state; and instances are on record of beetles remaining in timber from ten to fifteen years. The greatest proportion of moths are biennial, passing the winter in the chrysalis state and closing their existence in the succeeding summer. The transitory life of the *Ephémera* is proverbial; the perfect insect indeed exists but for a day, and seems born only to continue its species; yet in the larva state it enjoys a life of one, two, or even three years.

Subsect. 2. *Arrangement or Classification of Insects.*

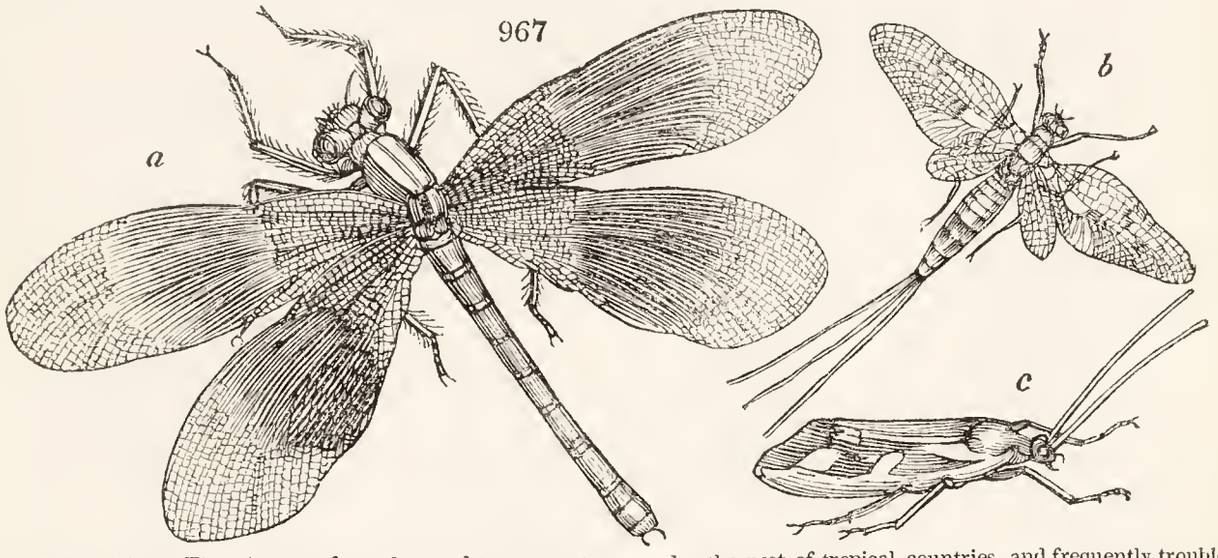
7650. *All insects*, as Macleay observes, may be divided into two groups: 1. *Apterous insects*, having either no metamorphosis, or only that kind of it the tendency of which is confined to the increase of the number of feet: these, as their name implies, are destitute of wings. 2. *True insects*, or those whose metamorphosis has a tendency to give wings to the perfect or image state, but never more than six feet.

7651. *True insects* are again divisible into two primary groups; the first of these are organised for mastication in their perfect state, and the second are organised for suction alone. Each of these divisions, according to the system of Macleay, contains five separate orders, the principal characters of which we shall endeavour to make intelligible in common language.

7652. *The Mandibulàta, or masticating insects*, are furnished with jaws of a horny or membranaceous substance, infinitely diversified in their form and structure. They are divided into the following orders: —

1. *Trichóptera.* The wings are four, soft, and generally transparent; the upper pair slightly hairy, and the lower folded when at rest. The insects of this order are comparatively few. The caddy, or cadis worm, is the larva of the spring fly (Phrygànea), and lives in the water, concealed within a tube of its own construction. There are many species in this country, well known, in their perfect state, to all lovers of angling. Phrygànea rhómbica (*fig.* 967. *c*) may serve as an example of this order.

967



2. *Hymenóptera.* The wings are four, clear and transparent. The tarsus (or outer division of the foot) is composed of five joints, and the body is armed with a sting. The bee, the ant, and the wasp, are familiar examples.

3. *Coleóptera.* This well defined and most extensive order comprehends all insects known by the name of beetles. They have two wings, concealed beneath a pair of hard wing-cases, which meet close together in a straight line down the back. There are many tribes of these insects, which, both in their larva and perfect state, are extensively injurious to man.

4. *Orthóptera.* The true wings are but two, very large when expanded, and folded lengthways when at rest. They are covered, either partially or wholly, by two wing-cases of a thin, tough, and rather opaque substance, somewhat resembling parchment, and reticulated with small nerves. The leading characters of this order are exemplified in the *Blátta*, or cockroach; the pest of tropical countries, and frequently troublesome in our kitchens and larders.

5. *Neuróptera.* The wings, with very few exceptions, are four in number, clear, transparent, and reticulated with numerous areolets, or irregularly square divisions; the tail of the female is not armed with a sting. Few, if any, of these insects may be considered as injurious: some are, indeed, beneficial; as, from their predatory habits, they attack and devour a vast number of smaller insects. This is more particularly the habit of the green dragon-fly (A'grion vírgo, *fig.* 967. *a*), which every one may see, during summer, hovering over ponds, and flying about like a hawk in search of its prey. The *Ephémera*, or day-fly (*E.* vulgàta, *fig.* 967. *b*), likewise belongs to this order; and, although not very numerous in this country, is so abundant on the Continent, that they are collected annually in barrows, and afford to the agriculturist a rich and valuable manure.

7653. *The Haustellàta*, or suctorial insects, likewise contain five orders. Although apparently destitute of jaws, there is every reason to believe, from the observations of the celebrated Savigny, that the rudiments of the mastieating organs exist in these insects, but that they are so slightly developed as to be totally useless, and only discoverable under a very strong magnifier. The suctorial insects in their larva state are mostly furnished with strong and well defined jaws, and feed voraciously upon animal and vegetable bodies; yet, from the perfect insect being supported by suction alone, it is obvious that in this state they can do no injury to the agriculturist. The orders into which they have been divided are these: —

1. *Lepidóptera.* The wings are four, thin, membranaceous, and covered with a fine powdery substance, which, by the magnifying glass, is shown to consist of minute scales, lying one upon another, like those on fishes. The butterfly and moth tribes are familiar to every one, as well known examples of these insects, the larva of which are called caterpillars. The *Papílio* urticæ, or small tortoise-shell butterfly (*fig.* 968.), will serve as a good example of the egg (*a a*), larva (*b*), and pupa state (*c*) of most day-flying lepidopterous insects.

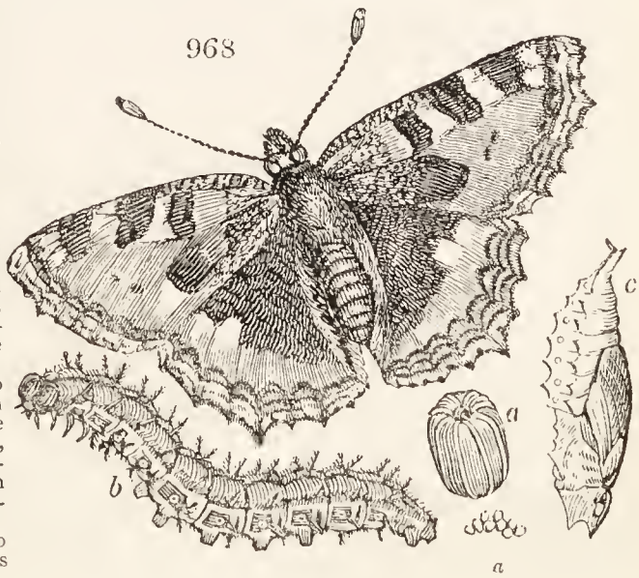
2. *Díptera.* The wings are two, clear and transparent, like those of the common house-fly. This order is very numerous, and contains many insects which are injurious to vegetables as larvæ, and troublesome to man in a winged state; as the gnat (*Cùlex*), whane-fly (*Tabànus*), crane-fly (*Típula*), &c.

3. *A'ptera.* Entomologists of the last century arranged all insects without wings under this order; but it is now restricted, by Latreille and Macleay, to such only as have a bivalve articulated sheath to their mouth or rostrum, and no wings, as in the case of the common flea.

4. *Heméptera.* Insects of this order are furnished with two folded wings, covered by wing-cases, also crossing over each other, of a semi-corneous substance, and which are likewise useful as organs of flight. The tarsi are composed of three, two, or sometimes only of one joint, and the body is much flattened. The various insects commonly called field-bugs, which emit a strong and disagreeable smell when handled, are all arranged under this order.

5. *Homóptera.* These insects have a great resemblance to the last; but the body, instead of being depressed and flat, is

968



a

convex and thick; the wings also, instead of being folded over each other, are deflexed, and embrace the sides of the body. There are, comparatively, few homopterous insects in England; but the frog-hopper (Cicàda spumària *L.*) is a good example when in its perfect or winged state. The larva resides in a drop of froth of its own making, and is then commonly known as the cuckoo-spit insect; by feeding upon the sap it causes the leaves to curl up, and the growth of young plants is thus materially checked.

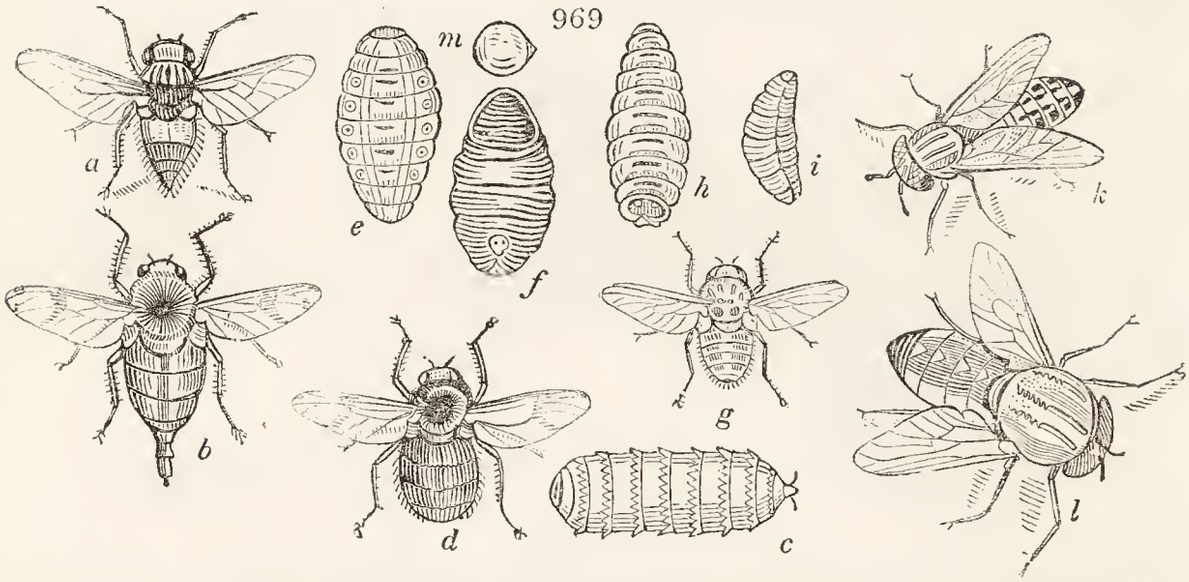
7654. *The different orders of insects* we have now enumerated are connected by others of an inferior extent, and which are called osculent orders. But as a description of these is not essential to our present purpose, and as they do not contain any decidedly injurious insects, we shall merely refer the reader to the Hòræ Entomológicæ of Macleay, and the Entomology of Messrs. Kirby and Spence.

Subsect. 3. *Insects injurious to live Stock.*

7655. *All organised beings, whether animal or vegetable,* are subject to be attacked and destroyed by insects. Even man himself is not exempt from the dominion of these small but formidable creatures. For some wise but unknown purpose, there are peculiar species appropriated to receive their nourishment from man alone, and which cannot exist in any other situation. The remedies for these must be prescribed by the physician; but it is the business of the intelligent agriculturist to make himself acquainted with such as are injurious or hurtful to the animals and plants, upon which, the success of his operations mainly depends: for there are as yet no agricultural physicians, to whom the farmer can apply for advice or information when his labours are counteracted by insect devastators. We shall therefore briefly notice the domesticated animals and cultivated plants most subject to these injuries, pointing out the most efficient modes by which they may be checked.

7656. *The horse.* The principal foes to this noble animal are the horse-bee (*Œ*strus èqui) and gad-fly (*Œ.* hæmorrhoidàlis). The first deposits its eggs on such parts of the body as are liable to be licked by the tongue; and the animal, unconscious of what it is doing, thus conveys its enemy into its stomach; the young larvæ are there nourished, and become whitish rough maggots (*fig.* 969. *c*), which are known by

969



the name of bots. They attain their full size about the latter end of May, and are voided by the anus from that time until the end of June. On dropping to the ground, they find out some convenient retreat, where they change into a chrysalis; and in six or seven weeks the fly appears. The female (*b*) is distinguished from the male (*a*) by the lengthened shape of her body. The inside of the knee is chiefly selected for depositing her eggs, which will frequently amount to four or five hundred on one horse. The other species (*Œ.* hæmorrhoidàlis *L.*) is still more troublesome; it deposits its eggs upon the lips, and causes excessive and distressing uneasiness to the animal. Mr. Bracy Clark, who has investigated the history of these insects with great ability, observes that in ordinary cases it is not improbable that they are beneficial to our cattle, by acting as perpetual stimuli or blisters; yet, when they exceed certain limits, they produce disease, and sometimes death. (Clark in *Linn. Trans.* vol. iii.) The prevention of bots belongs to the farmer, the cure to the veterinary surgeon. The first may be effected by watching the animal at the season when the female deposits her eggs (usually in August and September), and should the horse appear much agitated in its pasture, there will be good reason to suspect it has been attacked by the fly; the eggs may then be removed by the brush and currycomb, or by a pair of scissors. When the disease is certain, one of the best methods to destroy the insect is to fasten a bag net on the horse, for the purpose of catching the excrement, as well as the full-fed larvæ. By throwing the dung every morning into a deep pit, any larvæ that may be enclosed in it will thus be prevented from working their way to the surface when their last transformation is about to take place, and their death will cut off a numerous progeny. There are other dipterous insects which feed upon the blood both of horses and cattle; the most formidable of these are the horse-flies (*T*abàni, *k*, *l*); others, much smaller (Stomóxys cálcitrans), assail him in every situation during summer, and dart their long probosces into his legs and belly. But none are more trying to him than the forest fly (Hippobósca equìna *L.*), which runs sideways or backwards like a crab, and shelters itself in those parts least covered by hair: it may, however, be caught by the hand, when the animal is in his stall; but its substance is so hard, that it can only be destroyed by rolling it between the finger and thumb.

7657. *Horned cattle* are likewise subject to the attacks of a peculiar species of gad-fly (*Œ.* bòvis, *d*, *e*, *f*), which causes them great terror and distress. The larva (*e*) is smooth and fat: and the chrysalis (*f*) opens by a lid (*m*) when the insect (*d*) emerges from it. The herdsman may know when this insect appears among his flocks, by the agitation they exhibit; the whole herd, with their tails erect, or carried in some grotesque attitude, gallop about and utter loud lowings. When oxen are employed in agriculture, the attack of this fly is often attended with danger, as they become quite unmanageable, and, whether in harness or yoked to the plough, will run directly forward. Their harness at this season should therefore be so constructed as to be easily loosened. The eggs are deposited *within* the skin of the animal, and in a wound made by a tube resembling an auger, with which the female is provided. These flies only attack young and healthy subjects; but, independently of the terror they create, do not appear to occasion any material injury. The cattle of Hungary and the neighbouring countries, as also those of Abyssinia, are subject to more deadly enemies, which fortunately are unknown in England.

7658. *Sheep* are also infested by another species of gad-fly (*Œ.* òvis *L.*, *g*, *h*, *i*), which deposits its eggs in the inner margin of their nostrils. The moment the fly touches this part of the sheep, they shake their heads, and strike the ground violently with their fore feet; at the same time, holding their noses close to the earth, they run away looking about them on every side, to see if the fly pursues: they will sometimes crowd together in a rut or dusty road with their noses close to the ground. The larvæ (*i*) are white, flat on one side and convex on the other; they inhabit the cavities of the maxillary sinuses, and crawl, when the animal is dead, into those of the horns and frontal sinuses; when full grown, they

fall threugh the nostrils, and change to the chrysalis (*h*), which produces the fly (*g*) in about two months. Swine, pigeons, and all kinds of poultry are subject to fleas, and lice of various kinds, but never to such a degree as to occasion death.

7659. *Fish*, in their young or fry state, are the food of the larvæ of water beetles (Dytísci). These insects are frequently seen in great numbers in ponds: they may be caught by a hand net (made of very small meshes), inserted beneath the insect, as he reposes (with his head downwards) on the surface, and then suddenly drawn upwards.

Subsect. 4. *Insects injurious to Vegetables.*

7660. *The ravages of insects upon plants* commence from the time that the seed is committed to the ground, and continue until the produce is gathered into the barn. These various injuries, in one shape or other, are annually experienced; and many of them, beyond all doubt, will hereafter increase to an alarming extent, if the great body of agriculturists persevere in their mistaken prejudice against crows, rooks, and other useful birds, which Providence has kindly given us, to keep the insect tribes within due limits. We have already noticed the destructive insects which are in a great degree peculiar to certain plants, as wheat, barley, &c. in a general way (Part III. Book VI.): we shall now enumerate those that infest the grains, clover, pastures, cabbages, and fruits, plantations, as well as those universal destroyers of *all* vegetables, the wire-worm, the plant lice, and the different species of crane-fly.

7661. *Wheat*, in every state, is subject to many insect depredators. Mr. Marsham describes a small grub (by some mistaken for the wire-worm), which eats into the young plant about an inch below its surface, devours the central part, and thus causes its immediate death. Out of fifty acres sown with wheat in 1802, ten had been destroyed in this way so early as October. At a later period this grain is attacked by a fly nearly related (according to Mr. Kirby) to the Mosíllus arcuàtus of Latreille. It makes a lodgement in the heart of the principal stem just above the root, which stem it invariably destroys, giving the crop at first a most unpromising appearance; but it proved ultimately that the plant, instead of being injured, derived great benefit from this circumstance; for, the main stem perishing, the root (which was not hurt) threw out fresh shoots on every side, so as to yield a more abundant crop than in other fields where the insect had not been. When first observed in England, this insect caused great alarm among agriculturists, who thought it might prove the Hessian fly. When the wheat blossoms, it becomes exposed to the attack of a small orange-coloured gnat, which deposits its eggs in the centre of the flower; the larva or grub devours the pollen, and thus prevents the impregnation of the grain. The weevil, a small coleopterous insect (*Calándra* granària *F.*), is extremely destructive to wheat when in the granary, where it feeds both in the larva and perfect state: against the first, we are acquainted with no remedy, as it lives in the grain; but as this is larger than the perfect beetle, the latter may be in a great measure collected by means of a sieve, large enough for the insect (but not the grain) to pass through: it is often found in such numbers, that they have been collected and destroyed by bushels. The same insect, or one very near it, often infests sea biscuit; and can only be killed by baking or heating the biscuits over again in an oven.

7662. *Rye* is subject to the attacks of a small fly (*Músca* pumiliònis), which introduces its eggs into the heart of the shoots, and occasions a loss of from eight to fourteen plants in a square of two feet. No remedy has yet been proposed for this pest, which, if not extensive, may be checked by plucking the injured ears, and burning them.

7663. *Barley*, besides other insect foes, has one peculiar to itself, in the shape of a small moth (*Tínea* hórdei *K*). This fly deposits from twenty to thirty eggs on a single grain; when hatched, each of the larvæ disperses, and selecting a grain for itself, enters from without, and lies totally concealed: should these moths be observed in a granary, the injury may be stopped by carefully covering the grain, leaving a few handfuls exposed; upon these the moths will deposit their eggs, and by roasting or destroying this small quantity, the rest may be saved from infection.

7664. *Oats* are subject to few diseases; but, like all other grain, the plants are liable to be destroyed by that universal devastator the wire-worm, of which a more particular account will be found in treating of insects universally injurious to vegetables.

7665. *The diseases of peas* are mildew and blight, but these are only occasional; its insect enemies, however, are formidable. The principal of these is the plant louse (A'phis), one species of which is peculiar to this plant. In the year 1810, the crops of peas throughout the whole kingdom was so much destroyed by it, that the produce was not more than the quantity sown; and many farmers turned their swine into their pea-fields, not thinking them worth gathering. (*Kirby and Spence*, i. p. 177.) Beans are exposed to the same injury from another species of A'phis of a black colour, which begins at the top of the plant, and multiplies downwards. In both cases the most effectual remedy is to top the plants at an early period of the infection, and burn the parts so gathered; this plan is likewise advantageous, as it improves both the quality and quantity of the crop. The earlier peas are sown, the better chance they stand of escaping this pest; or if a small quantity of quick-lime is sprinkled upon them when they are a few inches high, experience has shown that the plants remain uninjured, while the A'phis is totally destroyed.

7666. *The diseases of beans* are the rust, honey-dew, and mildew. The insects which infest it, and their eradication, have already been noticed. (5256.)

7667. *Turnips* are subject to several peculiar diseases, and are the food of many noxious insects. On the first appearance of the cotyledon leaves, a whole host of little jumping beetles (Háltica némorum), called by farmers the fly and blackjack, attack and devour them, so that the land is often obliged to be resown. An eminent agriculturist has calculated, that from this cause alone the loss sustained in the turnip crops of Devonshire in 1786 was not less than 100,000*l*. (*Young's Annals*, vii. p. 102.) Nearly as much damage is sometimes caused by a little weevil (*C*urcùlio contráctus *Marsham*), which in the same manner pierces a hole in the cuticle; watering with lime water, &c. may serve to check both these evils.

7668. *The caterpillar* of a saw-fly (*T*enthrèdo *L.*), entirely of a black colour, appears on the plants so soon as they have produced three or four rough leaves: these have sometimes occasioned considerable mischief, particularly in 1783, when many thousand acres were, on this account, ploughed up. These caterpillars are sought after with so much avidity by crows, rooks, and magpies, that those farmers, whose good sense have led them not to destroy, but rather to encourage, these useful birds, need not fear any great damage from this insect. To destroy it in the most effectual way, watering or sprinkling with lime has been strongly recommended.

7669. *The caterpillar of the turnip butterfly* (Pieris nàpæ *F.*) is also sometimes found on the turnip in great numbers: nearly fifty of the grub, which so much resembles the wire-worm, and which we have before alluded to (766.), have been found just below the leaves of a single bulb. These may, in a great measure, be enticed and destroyed, like the true wire-worm, which also does extensive injury to turnips. The small knob or tubercle, often observed on the roots, is inhabited by another kind of grub, probably the larva either of Curcùlio contráctus *M.*, or Rynchæ'nus assímilis *F.*, two small weevils. These, however, do not seem to affect the growth of the plant.

7670. *The vegetable diseases of the turnip* are the mildew (by some considered the effect of insects), distortion of the root (known principally by the name of fingers and toes), the anbury, the canker, and gangrene, or wasting from water and frost. None of these injurious diseases, as far as is known, admit either of prevention or cure: under favourable circumstances of soil, culture, climate, and weather, they seldom occur; and therefore all that the cultivator can do is to prepare and manure his land properly, and in the sowing season supply water when the weather is dry.

7671. *The hop* is liable to many external and internal diseases: by the first term we must be understood as alluding to injuries caused by insects, while those which belong to the vegetable are certainly internal. When the plants first emerge above the ground, they are infested by a small beetle, vulgarly called the flea. In a more advanced state the tops and branches are devoured by the hop A'phis, known to some by the name of the green fly, while at the same period the roots are subject to the attack of the caterpillar

of a singular species of moth, named by collectors the ghost. The vegetable diseases incident to the hop are, the honey-dew, the mould, the blight, and the fire-blast, all of which take place at different times, though mostly when the plant is full grown.

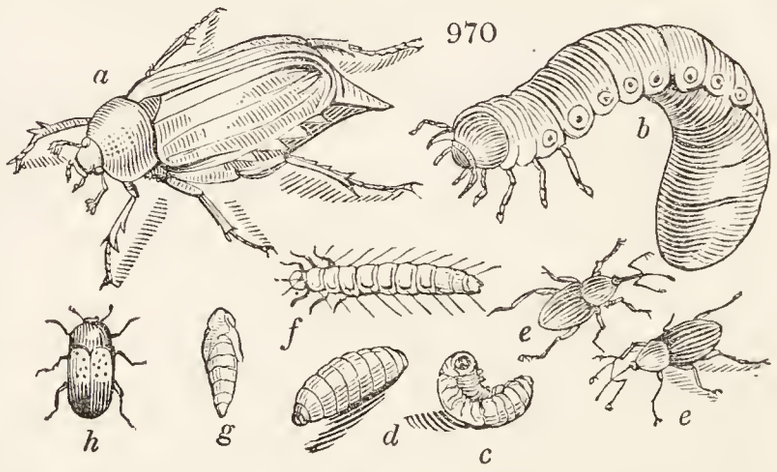
7672. *The hop insect, improperly called the flea*, has no other resemblance to that animal, than that it is small, and jumps. It is, on the contrary, a beetle (Háltica concínna), of a species closely allied to that which infects young turnips. In its perfect state it commits great havoc, by eating the tender shoots of the young plants. It has been said, that this insect abounds most in seasons when the nights are cold, and the days hot and dry. Others assert, that it is most frequent on plants in grounds that have been dunged the same year, on which account it has been recommended, that the manure used for covering the hills should be previously well mixed as before directed (6019.), and applied either over all the land, or only on the hills; but this and various other plans do not appear to have originated in a due knowledge of the subject. Nothing as yet appears known regarding the nature or habitation of this insect in its larva or grub state; and unless it is ascertained to live, during that period, in manure, the above plan will inevitably prove abortive. The deadly effects of lime upon insects, however small, has been extensively proved, and should be resorted to in all cases where the expected value of the crop will bear the expense of its application. Mr. Samuel Curtis has stated in the Horticultural Transactions (vol. 6. part 2. p. 124.) the very great advantages he has derived by applying pulverised quick-lime to fruit-trees; and there is no doubt that the same remedy would be equally successful if extended to the turnip and hop plants, so soon as the young leaves begin to appear, or on the first symptom of their being attacked by this insect.

7673. *The hop louse*, called by some the green or long-winged fly, is a species of A'phis peculiar to the plant; it makes its appearance towards the end of May, and during the two next months. These insects propagate so prodigiously, that whenever they have once made a settlement upon a hop plantation, they seem to have baffled every art of man, either to extirpate them, or even to check their increase. It is a vulgar error to suppose that they come or are carried away by any particular wind; or that mildly warm weather will affect their removal. It is true, that on such days the perfect insects are seen on the wing; but it is only to extend their destructive race to other plantations, and to establish new colonies. Sudden and violent showers of rain, or gusts of wind, causes the death of millions; and vast quantities are devoured by sparrows and other small birds; yet these are accidental and insufficient palliatives. It is, therefore, strongly recommended, that the process described by Curtis, of throwing pulverised lime by the instrument he used, be tried on hops infected by the A'phis; and we venture to predict that it would be attended with considerable success.

7674. *The ghost moth* (Hepìalus hùmuli *F.*) deposits its eggs near the roots of the hop plant, upon which the larva or caterpillar feeds, sometimes doing them considerable injury. The best preventive is to destroy the moth, and this may be done by attracting it at dusk to a candle and lantern, carried by a boy over the grounds, who could knock down very many with his hat. The moth is of a tolerable size; and one sex is entirely white, so that it may be seen, even at night, with ease. It hovers over a small spot of ground, so that a good catcher of insects might clear the plantation in a few evenings. In 1826 the ghost moth appeared in many parts of Warwickshire, in very considerable numbers.

7675. *Clover* is very subject to be injured by a very small weevil (A'pion flavifemoràtum *K.*), which at all seasons feeds upon the seed of the purple clover, while another species of the same tribe (A. flávipes) devours that of the white or Dutch clover; the injury, unfortunately, cannot be known while the plants are growing, as they have then every appearance of being perfectly healthy. The young shoots of the purple clover are often devoured by the same little jumping beetles (Háltica *F.*) which attack both turnips and hops.

7676. *Pastures in general* are often destroyed to a very great extent by the larva or grub of the cockchafer (970. *a*), known in different parts of England by the following provincial names: —Brown tree-beetle, blind beetle, chafer, Jack horner, Jeffry cock, May bug, brown-clock, dor, and miller.



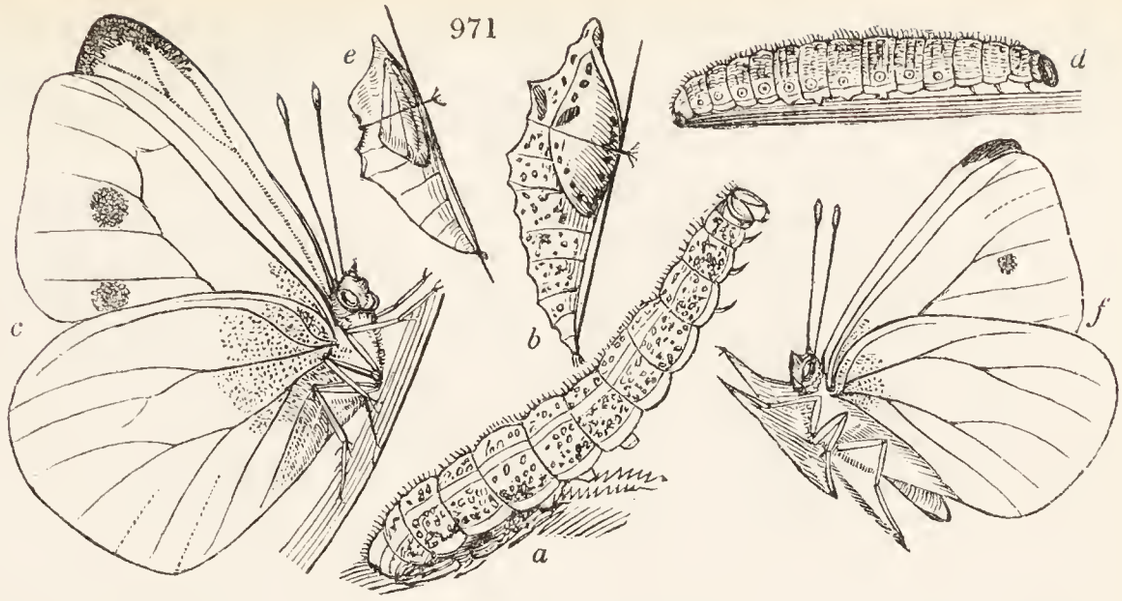
7677. *The ravages of the larvæ* are even exceeded by those of the perfect insect, which sometimes appears in this country in prodigious multitudes, and, like a flight of locusts, devour every green thing on the face of the earth. The eggs of this terrible devastator are white, and are deposited in the ground, where they soon change into a soft whitish grub with a red head, and about an inch and a half long (*b*). In this state it continues four years, during which time it commits most destructive ravages on the roots, not only of grass, but of all other plants and young trees. Whole acres of the richest pastures are thus rendered unproductive; all verdure is lost, and the turf will roll up almost with as much ease as if it had been cut with a spade. The whole of this injury being carried on under ground, admits neither of preventive nor palliative measures; but the destruction to be expected from the perfect insect may yet be prevented. If the dried and withered turf is now removed, the soil underneath will appear turned into a soft mould for about an inch in depth, like the bed of a garden; in this will be found the grubs, lying on their backs in a curved position, and vast quantities may be gathered and given to pigs and poultry. When full grown, the larvæ dig in the earth to the almost incredible depth of five or six feet, spin a smooth case, and then change into a chrysalis. In this inactive form they remain until the following spring.

7678. *The perfect insect or beetle* then comes from the ground, and commences an immediate attack upon the leaves of all trees. Their numbers are sometimes so immense, that, was not the following account fully authenticated, we should almost doubt its correctness:—In 1688, the cockchafers appeared on the hedges and trees in the county of Galway in clusters of thousands, clinging to each others' backs in the manner of bees when they swarm. During the day they remained quiet, but towards sunset the whole were in motion, and the humming noise of their wings sounded like distant drums. Their numbers were so prodigious, that for the space of three miles they darkened the air; and the noise they made in devouring the leaves was so loud, as to have been compared to the distant sawing of timber. In a very short time the leaves of all the trees for some miles were destroyed, leaving the whole country, in the middle of summer, as naked and desolate as it would have been in winter. Swine and poultry devoured them in vast quantities; they waited under the trees for the clusters dropping, and became fat upon this unusual food: even the lower orders of the people, from these insects having eaten up the produce of the earth, adopted a mode of dressing them, and used them also as food. Towards the end of summer they are said to have suddenly disappeared; and we have no account of their having been seen in any considerable numbers the following year. (*Phil. Trans.* xix. p. 743. &c.) These grubs did so much injury about seventy years ago to a poor farmer near Norwich, that the court of that city, out of compassion, allowed him 25*l.*; the man and his servant declaring that they had gathered eighty bushels of these beetles. The best, and indeed the only effectual remedy for the destruction of the perfect insect, is to shake the trees or bushes at noon, when they are either asleep, or in a state of stupor, and then to sweep or gather them up. One person in this way has been known to capture a thousand in a day, which, on a moderate calculation, prevented no less than one hundred thousand eggs from being laid. Some judicious farmers plough the ground when they have reason to think it is infested by the grub, and this is generally indicated by the rooks attempting to reach them. They are also greedily devoured by crows, magpies, and jays, whose sole employment, for nearly three months in the spring of the year, is to search for insects of this sort; and the destruction they cause among them is above all calculation.

7679. *Cabbages and other esculent vegetables* are well known to be greatly injured by the caterpillars of two different kinds of white butterflies (*fig.* 971.), one of these (Pìeris brássicæ, *c*) is much larger than the other: the caterpillar is pale yellow, with black spots (*a*): when full fed, it shelters itself on walls, pales, or trunks of trees, and changes into the chrysalis state (*b*), in which it still preserves the same cast of colouring: the perfect insect (*c*) appears early in spring, and continues until the end of summer. The other species of caterpillar is green (*d*); the chrysalis (*e*) is of the same colour; and the butterfly (*f*) is produced about the same time as the preceding. Various methods have been recommended to prevent the winged insect from depositing its eggs upon those plants which nature has given them the instinct to select; these are, however, ineffectual, and in many cases sufficiently ridiculous: handpicking the larva, and searching for the chrysalis, are the only plans we can recommend, either for these or the gooseberry and currant caterpillars.

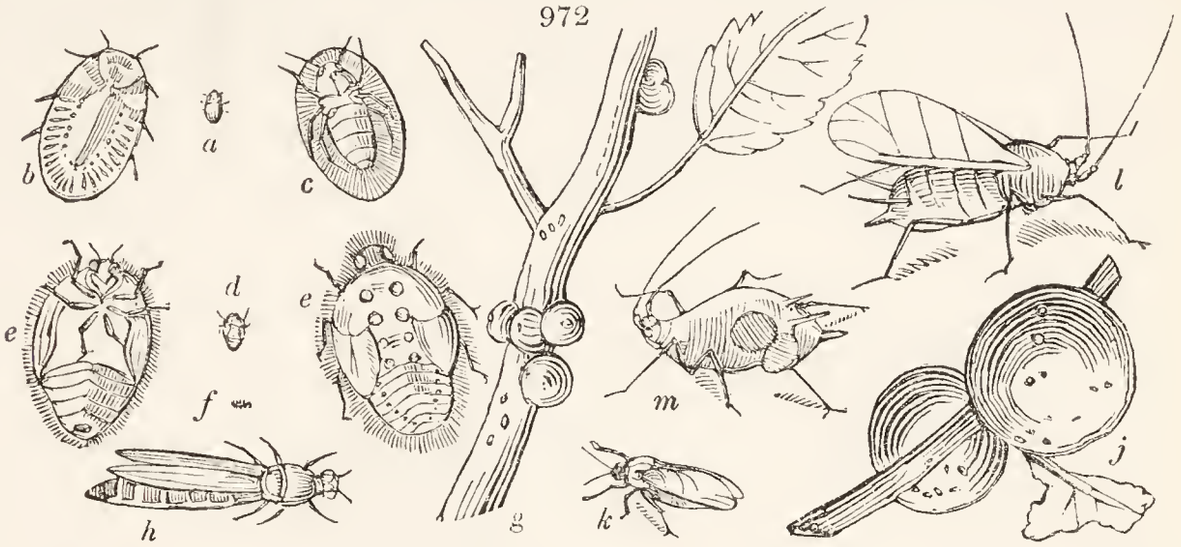
7680. *Fruit trees of all kinds*, and their produce, are attached and devoured by a great variety of insects, an enumeration of which will be found in our *Encyclopædia of Gardening*. We shall, however, advert to those curious minute insects (Thríps Phýsapus, *fig.* 972. *f*, *h*) so often seen in flowers and blossoms during the spring, and which, in their natural size (*f*), appear like short black lines. Nearly all fruit trees are liable to considerable injury from different species of Cóccus or cochineal insects. They are mostly so small

971



(*fig.* 972. *a*, *d*), that their form cannot be well distinguished without the aid of a magnifying glass; many of them resemble small scales or scabs fixed on the bark and shoots. One is entirely of a brown colour (Cóccus persicòrum *a*): when magnified (*b*) it somewhat resembles the tortoise beetle (Cássida *L.*), the legs and head being only discernible when the insect is turned on its back (*c*). Another (C. fòl. quércus,

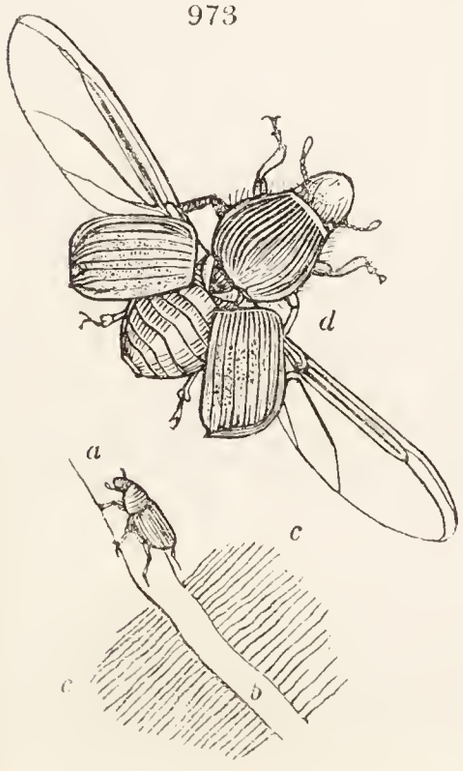
972



d, *e*, *e*) does much injury to the oak; while the C. fàgi attacks the twigs of the beech (*g*), and causes small round excrescences to appear; these are, however, very different from the gall apples of the oak (*j*), which are often found of a considerable size, and are produced by the Cỹnips quércus fòlii *L.* (*k*), or oak gall-fly, and always contain either the larva or imperfect insect. The weevils (Curculiónidæ) form an exceedingly numerous family, subsisting principally upon fruit, seed, and grain. One of the largest found in this country is the nut-weevil (*C.* nùcum, *fig.* 970.*e*, *e*), the larvæ of which (*c*, *d*) are the maggots so frequently found in this fruit.

7681. *The insects injurious to plantations* are less numerous in this country than on the Continent, yet we have two species whose devastations of late years have caused much alarm and extensive injury. The pine plantations in various parts of Britain have suffered from the great saw-fly (Urócerus gìgas *Lat.*), the larva of which, feeding upon the heart of the tree, and boring it in all directions, soon destroys it. Another small insect of the beetle kind (Scólytus destrúctor *F.*, *fig.* 973. *d* magnified) is equally deadly to the elm; and from being more common, and propagating very rapidly, is more to be dreaded. The sudden destruction of a large proportion of the elms in St. James's and Hyde Parks has recently called the attention of government to this beetle; and at the request of the noble rangers, Mr. Macleay undertook to investigate the evil: the result of his observations have been since published (*Edinb. Phil. Journal*, No. 21.). It appears that the female (*a*) may be found upon the trunk of the elm from March to September: she first penetrates through the bark, and then proceeds to form a passage between that and the wood, depositing her eggs during her progress on each side; when these are exhausted, the parent dies, and is often found dead at the extremity of the passage (*b*) thus formed. When the eggs are hatched, the young larvæ immediately begin to feed by working nearly at right angles (*c c*) from the path of the parent, each proceeding in a parallel direction and close to his neighbour: in this state they may be found in January. To stop this mischief as much as possible, Mr. Macleay recommends that the trees should be inspected twice a year: in summer, when the perfect insect is on the wing; and again in winter, when infected trees should be cut down and burned, or subjected by fumigation to such a degree of heat as may destroy the larvæ; or the bark may be covered with a mixture of tar and train oil, in March, to a certain height from the ground, applying this composition only to such trees as there are still hopes of preserving.

973



7682. *The A'phides or plant lice*, next to locusts, are the most universal devastators of the vegetable world: almost every plant has its peculiar species; their fecundity is so prodigious, that Reaumur has calculated that in five generations one A'phis may be the progenitor of 5,904,900,000 descendants; and it is supposed that in one year there may be twenty generations! Those which attack the different kinds of grain seldom multiply so fast as to be very injurious; but those peculiar to pulse increase rapidly, and take such possession, that the plants are greatly injured and frequently destroyed before the seeds are matured.

7683. *These insects are equally injurious* in their winged (*fig.* 972. *l* magnified) and in their larva or apterous state (*m* magnified); they are a favourite food of sparrows and other birds, who destroy numbers: they are likewise exposed to other deadly and cruel enemies; one of these is a small hymenopterous insect, which deposits its egg in the body; it is there hatched, and feeds upon the intestines; in a short time the A'phis swells, becomes hard, and, from being green, changes to a dark red colour. The artful destroyer within, when he finds his victim dying, eats a hole through its belly, and fastens the A'phis, by that part, to a leaf or twig. When the parasite has thus devoured the inside, and is ready to emerge as a perfect insect, he opens a passage for himself by cutting out a round hole in the side, leaving the piece, like a door on its hinges, adhering to the body (*m*). But the most inveterate and destructive foe to the plant-lice is the lady-bird or lady-cow (Coccinélla *L.*, *fig.* 974. *a*), which, in its larva state (*b*), feeds entirely upon these insects; and the havoc made among them may be conceived, from the myriads upon myriads of these pretty little creatures which are usually seen in years when the plant-louse abounds; every one, probably, destroying tens of thousands of A'phides before he becomes a beetle. On this account the lady-bird is the greatest friend to the gardener and farmer; and could there be any method devised of increasing these useful insects at will, our hot-houses, gardens, fields, and hop plantations, would soon be cleared from the ravages of plant-lice. The

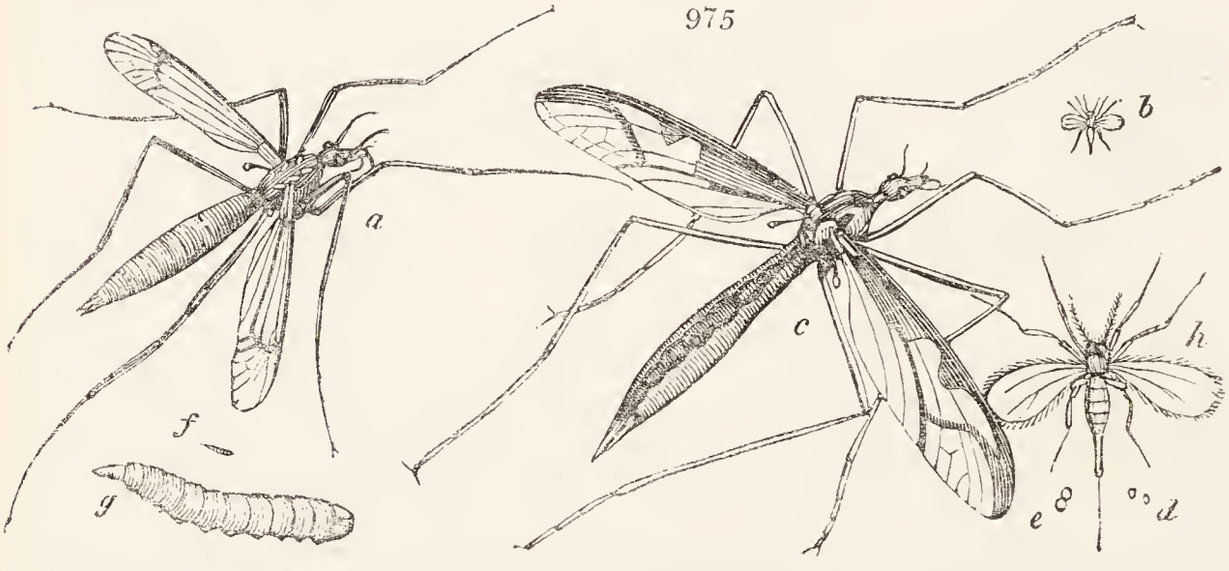
974

larvæ of several bee-like flies (Sýrphus *F.*, *c*) are no less useful in this respect. Their form very much resembles that of the leech, having no apparent head. Some species are green, with a white stripe down the middle; others brown, variegated with darker shades. They are always found upon those plants most infected by A'phides, upon which they solely depend for nourishment; hence they become most beneficial, and should on no account be destroyed. As palliative measures, the application of powdered quicklime may be resorted to; or the infected shoots may be topped off before the insects are greatly multiplied, repeating the same operation before the time that the winter stock of eggs are deposited. By the first pruning a very numerous present increase will be prevented; and by the second, the following year's breed may, in a great measure, be destroyed. (*Phil. Trans.* 41. p. 181.)

7684. *The wire-worm* is a name that has been given, without discrimination, to the larvæ or grubs of various insects, totally different from each other: hence it is, that much confusion and contradiction will be found respecting it in agricultural books. The true wire-worm is the grub of a small beetle (E'later ségetis *Marsham*), and it derives its name from its slender form and uncommon hardness. It lives in the larva state nearly five years; during which time it is supported by devouring the roots of wheat, rye, oats, and grass, which it attacks indiscriminately, and causes annually a large diminution of produce: it abounds chiefly in newly broken-up land, and is particularly destructive in gardens recently converted from pasture land. In the larva state it may be decoyed by offering it more tempting food; but no method has yet been devised for destroying the perfect insect.

7685. *The grub* is a general name for several larvæ of crane flies (*T*ipùladæ), called by the country people long-legs, or gaffer long-legs.

975



7686. *One of the most destructive* among these insects to the roots of grass and grain is the *T*ípula oleràcea. The larva is said, by some authors, merely to loosen the roots by burrowing among them; but others assert, that it likewise feeds upon the fibres. However this may be, the evil produced is evident; for in many parts of England it cuts off a large proportion of the wheat crops, especially if sown upon clover-lays. Reaumur informs us, that sometimes in France, particularly in marshy lands, the grass of whole districts has been so destroyed by it, as not to produce the food necessary for the sustenance of the cattle. No effectual remedy has yet been discovered for this evil; and Steckney observes, that the insect is not killed by lime, even when applied in much larger doses than usual.

7687. *There are several other species* of a large size, as the *T*ípula crocàta (*fig.* 975. *a*), and *T*ípula rivòsa (*c*), which, in a less degree, are also injurious to such lands as are moist and humid.

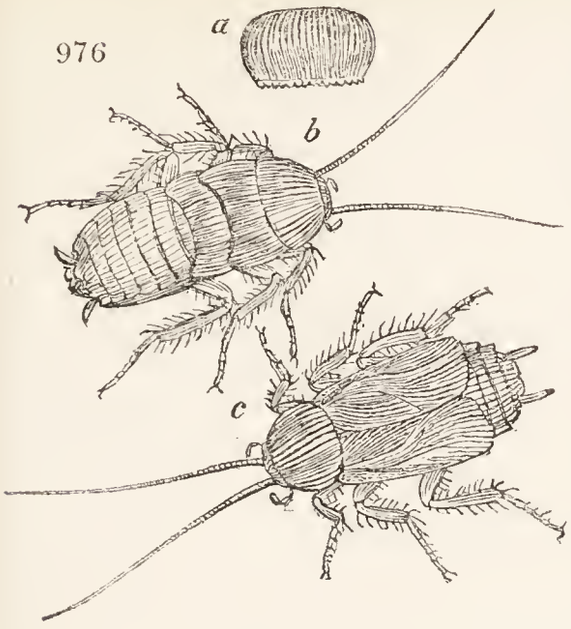
7688. *Another minute species* is particularly destructive to corn, and is generally known as the wheat-fly (*T*ípula trítici, *b*): its history and economy has been ably investigated by Mr. Marsham and Mr. Kirby. The injury first appears in the ear, several of which, on being opened, will be found to contain an orange-coloured powder; in this are concealed very minute larvæ (*f*), which, on being magnified (*g*), are seen to be thick at one end, extending and contracting themselves at pleasure, and frequently jumping half an inch at one spring; they take their station in the longitudinal furrow of the grain, and by sucking its milky juice causes it to shrink up, and become what the farmers call *pungled*: the last sown wheat always appears the most infected. In the beginning of June the perfect insect (*b*) may be seen in innumerable multitudes, flying in the evening in all directions over the corn-fields; but during the day not one is to be perceived. The female lays her eggs (*d e* magnified) by means of a retractile tube, which encloses a very long and acute sting resembling a hair; but this can only be distinctly seen when the insect is magnified (*h*). The wheat-fly would soon become a formidable enemy to mankind, were not its race exposed to an inveterate foe, scarcely larger than themselves; this is the *I*chneùmon *T*ípulæ, the female of which carefully searches out the grubs of the wheat-fly, and deposits in each one of her eggs: these are hatched, and ultimately the larva devours the body which gave it life. One *I*chneùmon will thus cause the death of many dozens, and prevent the future multiplication of thousands. The only palliative that has been recommended for stopping the progress of this insect has originated in Mr. Kirby; this consummate naturalist thinks much benefit would be derived by fumigating the corn with tobacco and sulphur, when the wind is in a favourable quarter: this must be done as soon as the ear begins to shoot from the leafy stalk. (*Linn. Trans.*)

Subsect. 5. *Insects injurious to Food, Clothing, &c.*

7689. *The manufactured produce of our fields and gardens*, whether as food or clothing, is still exposed to the ravages of other tribes of insects, which take up their residence in our dwellings, and on every thing about us. Fortunately, however, these domestic enemies are much less numerous and hurtful in this country than in the tropical regions of America, India, and Africa, where their devastation is almost incredible. Amongst the few that are indigenous, or that have been naturalised in Britain, the principal are the cock-roach, the house-cricket, and the bacon-grub.

7690. *The cock-roach*, called by some the black beetle (*Blátta orientàlis*, *fig.* 976. *c*), was originally imported from India, but is now naturalised in every temperate part of Europe. Like most of its tribe, it shuns the light, both natural and artificial. In the London houses, particularly in the rooms on the ground-floor, it is very abundant, and indiscriminately devours bread, meat, flour, and even clothes. As soon as light appears they all scamper off as fast as they can, and vanish in an instant. It is said to be killed by devouring red wafers. The young are contained in a singular horny case (*a*), which is divided into a number of transverse partitions or chambers; it is rather flattened, and quite smooth except one side, which is toothed. The larva and pupa (*b*) are both without wings, and generally larger than the perfect insect (*c*).

976



7691. *The house-cricket* (*Grýllus domésticus L.*) is sometimes as abundant in farm-houses as the cock-roach is in those of London and other large towns: both insects devour every kind of food, and are often found drowned in pans of water, milk, and other fluids; it is said they will even attack stockings, or linen hung out to dry. They require great warmth, and are therefore mostly found in kitchens and bakehouses. Another species is peculiar to pastures, which, in conjunction with the male cricket, feeds only upon roots: both these, however, are too local in this country to be very extensively injurious.

7692. *The bacon-grub* (*Derméstes lardàrius L.*) is a great pest to the winter provisions of the farmer, devouring hams, bacon, and all sorts of dried meats. This is principally done when the insect is in its larva or grub state (*fig.* 970. *f*). When full fed it becomes a chrysalis (*g*), which ultimately changes into a small beetle (*h*) about a third of an inch long, of a dusky brown colour, with the upper half of the wing-cases whitish or ash-coloured, marked with black specks. The grub, from lying concealed in the meat, cannot be effectually removed; but by watching the time when the perfect insects appear, they may then be destroyed, and a recurrence of the evil in a great measure prevented.

7693. *Woollen clothing of every description, furs, &c.* are liable to be devoured by the larvæ or caterpillars of no less than five distinct species of small moths. Most of these enclose themselves in little tubular cases of a silky texture, and are so well disguised externally by fragments of the stuff they feed upon as often to escape immediate observation. The receipts for preventing these ravages are numerous, but few of them can be depended upon. As a preventive, pieces of Russia leather, or tobacco leaves, may be laid between the folds of garments (in drawers) which are not often used. If there is reason to fear the moths are in the house, these garments should be frequently opened, and aired by exposing them to the sun. When furs of any kind are laid by for the summer, they may either be sprinkled with snuff or camphor, and Russia leather or tobacco leaves put in the drawer or box. Should the moth actually have got into furs, the only way of checking the evil is to put them into an oven moderately heated, and by keeping them in this situation a quarter of an hour every grub will be effectually killed; the degree of heat may be ascertained, in the first instance, by putting in some common feathers, which should come out uninjured.

7694. *The principal insects injurious to the agriculturist* have now been enumerated: there are many others which feed upon cultivated vegetables and domestic stores, but in a less extensive degree. Let us not suppose, however, that these little animals have been created for our punishment or annoyance. We have but taken a view of one side of the picture; the other would show us innumerable benefits, either immediate or remote, which we derive from this race of beings. The silkworm, the honey-bee, and the cochineal insect must not be forgotten; and myriads of others are created, whose sole occupation during life appears to be that of devouring and keeping within due limits those tribes that are injurious and hurtful to man.

Subsect. 6. *Operations for subduing Insects.*

695. *The operations for destroying insects*, or counteracting their injurious effects, are various, and in most cases must be regulated according to the species. These we have already pointed out in treating upon the insects themselves, or of the particular plants upon which they feed. It only remains to offer such general rules as are more or less applicable to all destructive insects; these are of three kinds, preventives, palliatives, and efficient processes.

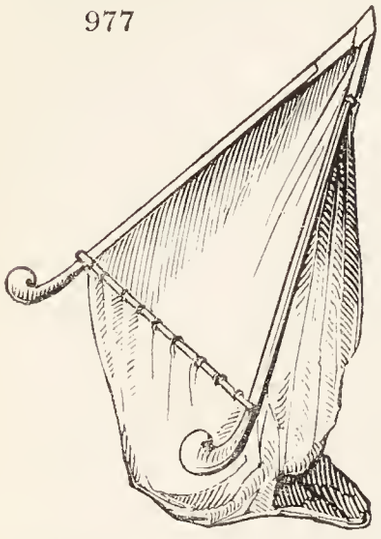
7696. *The preventive operations* are those of the best culture as relates to the choice of seed nor plant, soil, situation, treatment, and climate: the four first are under the control of man, and an attention to them will undoubtedly lessen the risk of injured crops; but as regards weather, neither his foresight nor care can avail any thing.

7697. *The palliative operations are numerous;* and such as are eminently successful may be considered as efficient; inasmuch as it rarely if ever happens that any insect can be exterminated, even from one district: its numbers may be diminished, but the species will still remain, although in such small numbers that its operations may escape notice. Most insects will be injured, and in part destroyed, by artificial bad weather, such as excessive waterings, stormy application of water with a syringe, and violent wind produced by shaking the tree or plant: many will thus be bruised, and others that are shaken to the ground can be destroyed. Insects may be further injured by watering the plants upon which they feed, either with tobacco or lime-water, or by scattering upon the leaves powdered quick-lime, soot, ashes, barley awns, &c. The smell of tar is particularly offensive to all insects, and the effects produced by the fumes of tobacco, sulphur, urine, &c. are well known. Hot water may be applied with much advantage. Water heated to 120 or 130 degrees will not injure plants whose leaves are fully expanded, and it may be increased to 200 for such as are without leaves.

7698. *Insects may be destroyed* in a much more effectual manner by enticement, or placing in their way other food as a trap. The late noble and generous Sir Joseph Banks has the merit of having recommended and made known this most efficient method. It simply consists in cutting slices of potatoes or turnips, sticking them upon skewers, and then burying them near the seeds sown: the vermin will collect upon them during night, and by examining them every morning, vast numbers may be destroyed; this plan has been very advantageously tried with the wire-worm, and no doubt would be equally beneficial in clearing all crops that are attacked by under-ground feeders. Mr. Kirby states, "that it was very successfully employed in 1813, by J. M. Rodwell, Esq. of Barham Hall, near Ipswich, one of the most skilful agriculturists in Suffolk, to preserve some of his wheat-fields from the ravages of a small grey slug, which threatened to demolish the plant. Having heard that turnips had been used with success to entice the slugs from wheat, he caused a sufficient quantity to dress eight acres to be got together; and then, the tops being divided and the apples sliced, he directed the pieces to be laid separately, dressing two stetches with them, and omitting two alternately, till the whole field of eight acres was gone over. On the fol-

lowing morning he employed two women to examine and free from the slugs (which they did into a measure) the tops and slices; and when cleared, they were laid upon those stetches that had been omitted the day before. It was observed invariably, that in the stetches dressed with the turnips, no slugs were to be found upon the wheat, or crawling upon the land, though they abounded upon the turnips; while, on the undressed stetches, they were to be seen in great numbers both on the wheat and on the land. The quantity of slugs thus collected was near a bushel. Mr. Rodwell is persuaded that by this plan, he saved his wheat from essential injury. (*Kirby and Spence, Int. to Entomology*, i. p. 182. note.)

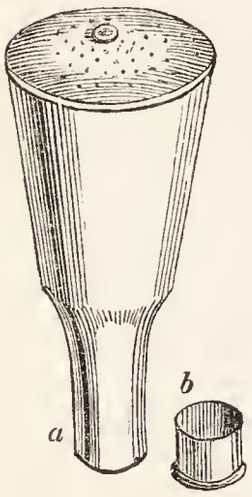
977



7699. *The turnip net* (*fig.* 977.) is an instrument invented by Mr. Paul of Starston in Norfolk. It is the most successful expedient that has yet been thought of for the capture and destruction of the little beetles called by farmers the black jack, and by hop-growers the flea. It consists of two pieces of stout wood, the ends of which, at one extremity, are fixed into a handle in a forked direction: the other ends are left thick and curved upwards, for the purpose of passing the instrument smoothly and easily over the surface of the ground: towards this end, the sticks are connected by a cross-bar formed by a thin iron rod, that may be taken on and off at pleasure; these three sides constitute the frame work for supporting a long and ample bag, made of strong glazed calico. The method of using it is by the operator shoving it before him on the ground, over the tops of the turnips or other plants; by this means the insects that are upon the leaves fall into the bag, which may be occasionally shaken during the process, so as to bring them to the bottom (which is made narrow) where they will remain. Vast quantities of insects, which from their smallness and agility defy hand-picking, will be thus captured. The turnip net may be made either large or small; perhaps two feet and a half for the side sticks is the best length; it being obvious that the wider they are apart, the greater space will be brushed at once,

7700. *The lime-duster* (*fig.* 978.) is a recent invention by Mr. Samuel Curtis of Glazenwood, near Coggeshall, Essex, and has been used by him with great success in throwing pulverised quick-lime over apple trees infected by caterpillars and other insects. His orchard, containing many thousand fruit trees, and occupying fifty acres, had been for many years completely divested of most of their foliage and young fruit in the spring months. Washing the stems and branches with lime and water (as might have been expected) was found ineffectual for the destruction of insects which fed only on the young buds and leaves. The instrument in question consists of a canister twelve inches long, seven inches wide at its broadest, and four inches on its narrowest part; the handle (*a*) is five inches and a half long. The top of the handle is fitted with a cap (*b*), which is put on when the lime is to be thrown on low trees; but when high trees are to be operated upon, the cap is removed, and a pole of sufficient length to reach the height required is inserted into the handle. Quicklime pulverised (and often sifted through a fine sieve) is put into the canister, and shaken over the young foliage just as it was expanding. The time for doing this is in the dew of the morning, or whenever the leaves are damp; and if there should be a gentle breeze, sufficient to carry the dust obliquely through the head of each tree, it is the more quickly performed. Under favourable circumstances of this nature, Mr. Curtis says, "I found that three men, provided with the powder in a large box on a light wheelbarrow, could dress from two to three thousand trees in a day: when the wind changed, I had the trees dressed on the other side. Although used ever so freely, no person need fear any injury, from the caustic quality of the lime, on the most delicate and fresh expanded foliage; it is only prejudicial to insects *of all kinds*, and to dead vegetable matter." (*Hort. Trans.* vol. vi. p. 2. page 124.) We know not whether the lime-duster has ever been tried upon hop plantations infected by the green fly or plant louse; but it appears to us equally well adapted to effect a great destruction among those insects.

978



7701. *Grain of all descriptions* that is infected by weevils, or by the grubs of other insects, should be spread in the sun, and frequently turned: the warmth will bring the animals out of the grain, and considerable numbers may be destroyed. It has been said that they may be kept away by strewing boughs of elder or branches of henbane among the grain, but this wants confirmation.

7702. *Hand-picking*, independent of the foregoing methods, is too tedious and too ineffectual for general adoption in large crops, but is probably the best that can be resorted to in gardens or small enclosures. In this way the different esculent vegetables, and the common and low kinds of fruit trees, as currants, gooseberries, &c. may be cleared of a vast number of caterpillars.

7703. *Catching the perfect insect* is undoubtedly the most certain plan for preventing a return of the same injury the following year, for the death of one female will cut off a generation of a hundred larvæ; but from the difficulty that attends an extensive adoption of this plan, it is not likely to be much attended to.

Sect. IV. *Worm-like Animals injurious to Agriculture.*

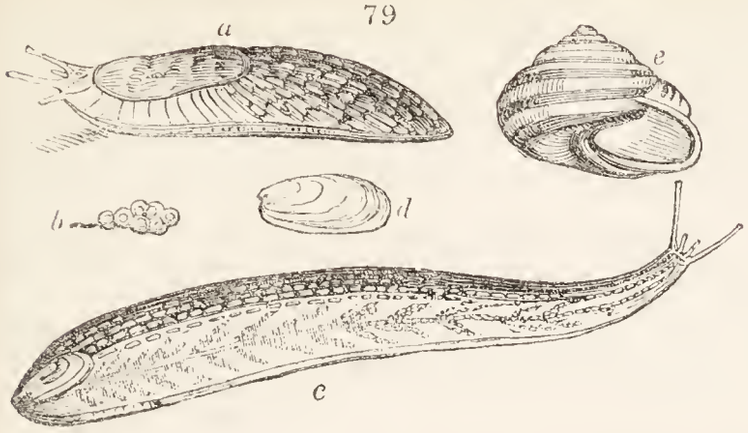
7704. *Of worms* (*Vérmes L.*) generally so called, there are but few which may be considered as injurious to agriculture. The principal of these are the various species of slug (*Arìon* F., *Limax L.*) and the large and small snails (*Hèlix* horténsis and nemoràlis *L.*), mostly found in garden plantations. The earth or dew worm (*Lumbrìcus* terréstris *L.*), unless existing in great numbers on a single spot, cannot be ranked among injurious animals, notwithstanding the prejudices of farmers and gardeners against them. Without worms the earth would soon become hard, cold, incapable of receiving moisture, or of giving nourishment to roots: they are, in fact, the great promoters of vegetation, by boring, perforating, and loosening the soil beneath, and by manuring it above with their excrement, which is thrown up into lumps called worm casts. The wire-worm does not belong to this tribe, but is the larva of a small beetle already noticed.

7705. *Worms of the slug kind* are without shells. There are several species inhabiting Britain, all of which subsist on leaves, roots, and vegetables. The most common is the *Limax* agréstis (*fig.* 979. *a*), of which there are several varieties injurious to the agriculturist and gardener; they devour the young shoots of turnips, wheat, and indeed all kinds of grain, frequently to a ruinous extent: their eggs (*b*) are small, round, of a semipellucid whiteness, and are deposited in the earth. The methods of destroying or eradicating the perfect animal have been already described.

7706. *The shell slug* (Testacéllus *móngi* F., *c*) is a native of Teneriffe, and has likewise been found in several parts of France and Spain; it has recently been discovered in some gardens near Bristol, by Mr. Miller, of that city. It is a highly curious animal, remarkable for feeding upon earth worms; and may, therefore, be beneficially introduced into such gardens as are overstocked by that otherwise

useful animal. It is readily distinguished from all other slugs in this country by having a thin oval shell (*d*) affixed to the hinder part of its body. Slugs in general are easily enticed by cabbage leaves, scattered near such garden vegetables as they appear to injure most.

79



7707. *Snails*, are slugs covered by a shell. The two species most prejudicial to cultivated vegetables, are the garden snail (Hèlix aspérsa *Gm.*), and the variegated snail (Hèlix nemoràlis, *c*): both these seek the same description of food, and are equally injurious, as slugs; and, like them, may be enticed by cabbage leaves and other juicy vegetable refuse.

PART IV.

STATISTICS OF BRITISH AGRICULTURE.

7708. After having considered agriculture as to its history, as to the scientific principles on which it is founded, and the application of these principles to the different branches of practice; it remains only to take *a statistical survey and estimate* of its present state and future progress in the British isles.

BOOK I.

OF THE PRESENT STATE OF AGRICULTURE IN THE BRITISH ISLES.

7709. *The present state of British Agriculture,* as to knowledge and the details of practice, has been the subject of the former parts of this work: but its importance in the general economy of society, can only be learned by a view of the manner in which it is actually carried on; the modifications to which it has given rise in the pursuits of those who have embraced the art as a source of livelihood; of the kinds of farms cultivated by different orders of agriculturists; of the principal practices of each of the different counties of Britain and Ireland as to agriculture; of the British authors who have written on the subject; and of the professional police and public laws relative to husbandmen and agriculture.

Chap. I.

Different Descriptions of Men engaged in the Practice or Pursuit of Agriculture.

7710. *Agriculturists* may be arranged as *operators,* or serving agriculturists; dealers, or *commercial agriculturists; counsellors;* professors, or artists; and *patrons.*

Sect. I. *Operators, or serving Agriculturists.*

7711. *The lowest grade in the scale of this class is farm labourers,* who may be either men, women, or children; and either local residents, periodical visitants for particular labours, as hay-making, reaping, &c., or itinerant workmen for taking jobs, as ditching, stocking, &c. None of this class of operators are supposed to have received any other professional instruction than what they have derived casually, or from observing others.

7712. *Apprentices* are little known in agriculture; but they occur sometimes, either as the children of other operators, whose parents bind them a certain number of years, during which they are to work for their food and clothes, and 5*l.* or 10*l.* to be received at the end of the term according to conduct; or sons of richer persons, who pay a premium for the instruction to be received, and for boarding with the master. The former class of apprentices generally look forward to being ploughmen, shepherds, head ploughmen, or inferior bailiffs; the latter to being first bailiffs, stewards of estates, or to farming on their own account. Parish boys are sometimes bound apprentices of the first class, and various noblemen's sons from almost every kingdom of Europe have been included in the second.

7713. *The term journeyman* is as little known in agriculture as apprentice. Those who answer to that term are the professional operators of a farm, such as ploughmen, cattle herds, shepherds, and hedgers. These rank decidedly above labourers of all-work. A ploughman may not unaptly be considered as of the rank of an apprentice till he can *fear* or set out ridges, and after he can do this as of the rank of journeyman till he can stack and sow. He may then be considered as a master of his art, entitled to work the best pair of horses, and if twenty-five or thirty years of age, to enter into the marriage state.

7714. *A hedger* is a professional operator, who may be considered as ranking with a master ploughman. His business is to plant, clean, prune, cut, lay, plash, and repair hedges; prune forest and orchard trees, and effect other operations with ligneous plants on the farm. In Berwickshire hedgers are generally very intelligent men, and keep the fences on the farms in the border counties in excellent order, and the hedge-row trees handsomely pruned.

7715. *A woodman* is an operator employed to prune trees and manage hedges, and is of the same rank and requires the same kind and degree of professional knowledge as the hedger. Generally he is more conversant with barking trees for the tanners, converting copsewood and measuring timber, than the other, being more engaged with woods than hedges.

7716. *A head ploughman*, on small farms, is to be considered as the bailiff in the absence of the master. He works the best pair of horses, and assists the master in stacking and sowing. On larger farms, where a regular bailiff is kept, there is also a head ploughman, who acts as substitute for the bailiff in his temporary absence, as far as operatives and overlooking operations; but not in money matters or contracts.

7717. *A farm bailiff* is, or should be, a person of tolerable education, who understands accounts, measuring of work, land, and timber, and can draw up agreements for hiring servants. He should have practised every part of farming himself, from tending poultry, swine, and sheep, to stacking and sowing. When employed by a gentleman, or one who has no skill in farming, he should not be under twenty-five years of age; but a farmer's bailiff need not exceed twenty-one years, is to be considered as a sort of apprentice, and will be directed in all leading matters by his master.

7718. *A bailiff and gardener*, or gardener and grieve, as they are called in some places, is a sort of hybrid upper servant, who seldom excels either as a farmer or a gardener, and is only fit for situations of limited extent, and an indifferent style of performance.

7719. *The forester* or head woodman is to the woods of an estate what the bailiff is to the farm lands in hand. He directs and superintends the woodmen and their labourers, in planting, rearing, and pruning plantations, and in the felling of timber or copse, barking, charcoal making, and in short every thing connected with timber, trees, copses, or hedges.

7720. *The land steward* (*Factor*, Scotch; *Facteur*, Fr.; *Factor*, Ger.; and *Fattore*, Ital.) is to a whole estate what a bailiff is to the demesne or a particular farm. His business is to control the managers of the lands in hand, as the forester, gardener, bailiff, &c.; to see that farmers fulfil the covenants of their leases; to attend to repairs, roads, public and parochial matters in behalf of the landlord; and generally to receive rents.

7721. *Under stewards*, or steward's bailiffs, as they are called, are assistants to the main steward, or have the care of detached estates, containing a few farms or woods.

7722. *Demesne stewards* are such as are kept chiefly for regulating the affairs of demesne lands; that is, lands surrounding the mansion in hand, or of an estate of small size, where all the lands are in hand, but where an extensive establishment of horses, servants, a large garden, &c. are kept up. Here the steward performs the duties of bailiff, forester, and in some degree of house-steward, by his connection with the stables and game-keeper, and other domestic rural matters.

7723. *Court farmer* (*Hoffmeyer*, Ger.; *Grangero de la corte*, Span.; *Agronome de la cour*, Fr.; and *Fattore della corte*, Ital.), may be considered the highest step, the *summum bonum* of agricultural servitude. The late Ramsay Robinson, Esq. was bailiff to Geo. III.; his sister, Miss Robinson, was royal dairy-woman; and Sir Joseph Banks, royal shepherd.

Sect. II. *Commercial Agriculturists.*

7724. *The lowest grade here is the jobbing farmer*, who keeps a team, a cart, plough, pair of harrows, and probably one or two hand implements. He hires himself by the day, week, or by the acre, to plough, sow, or labour, the small spots of ground of tradesmen who keep a cow but no labouring stock; or to assist farmers who are behind with their labours. The contractors for executing works devised by the agricultural engineer (7754.), though widely separated in point of wealth from the common jobber, yet belong to the same species; both agree in selling their labour and skill in a raw state, not when manufactured into produce like the other commercial agriculturists.

7725. *Itinerant agriculturists* are of two kinds: such as take grounds for the culture of one or two crops of particular sorts of plants, as woad, flax, &c. (5963.); and such as travel with a plough and pair, &c. to teach that operation to young farmers or their servants, a practice at one time carried on in Ireland under the patronage of the Dublin Society.

7726. *Cottage farmers* are such as possess a cottage and an acre or two of land, which they may either keep in aration or pasture; disposing of the corn, green crops, or dairy produce in various ways, according to local circumstances.

7727. *Poultry farmers*, such as devote themselves chiefly to the breeding, rearing, and fattening of poultry, and the growing of feathers and quills.

7728. *Garden farmers* are such as possess lands near large towns or sea-ports; and grow the commoner garden vegetables, as peas, onions, cabbages, &c. for the market, or herbs for the distillers and druggists.

7729. *Seed farmers*. Small farmers who devote themselves chiefly to the growing of garden seeds for the London seedsmen, and for the distillery. They are to be found only in a few counties in the central and southern districts of England, and chiefly in Kent and Essex. (See *Encyc. of Gard.* 2d edit. 7390.)

7730. *Orchard farmers* are such as farm grass or arable orchards, sometimes joined to hop lands and garden farms; often with a small dairy; with rearing of poultry, rabbits, &c., and sometimes with the breeding and training of dogs; the latter a very lucrative branch when well understood.

7731. *Hop farmers*, such as make hops a principal article of cultivation, to which are sometimes joined garden and orchard farming.

7732. *Milk or cow farmers*, such as keep cows for selling their milk in an unmanufactured state. These farmers are of course limited to populous neighbourhoods. Cow-keepers differ from cow-farmers, in having their establishments in towns, and in purchasing, not growing, their cow provender.

7733. *Dairy farmers*, such as keep cows and manufacture their milk into butter or cheese. These are most common in rich moist flat districts, as Cheshire, part of Gloucestershire, Leicestershire, &c.

7734. *Graziers*, farmers whose chief business consists in buying, feeding, and selling cattle and sheep. Their farms are chiefly in old pasture, and they are more commonly feeders than breeders. The most extensive in England are in Leicestershire and Lincolnshire.

7735. *Stock farmers*, such as devote themselves to breeding and rearing different kinds of live stock, especially horses and cattle. They are most common in Yorkshire.

7736. *Store farmers*, breeders who devote themselves chiefly to the sheep and cattle families. They are common in the border counties, in Wales, and in the Highlands.

7737. *Hay farmers* are confined to a small district round London; where they grow chiefly natural or meadow hay for the London coach and saddle horses, and for cow-keepers.

7738. *Corn-farmers*, as opposed to hay, dairy, grazing, and breeding farmers, is a term employed to such as occupy lands more adapted for the plough than for pasturage, as arable clays and loams.

7739. *Wood-farmers*, such as rent woodlands, to be periodically cut for fuel, bark, fence-wood, charcoal, or other purposes.

7740. *Quarry-farmers*, such as rent quarries of lime or other stone, gravel-pits, clay-fields, marl-pits, &c.

7741. *Mine-farmers*, or master miners or mine-holders, such as rent coal-mines, or mines of iron, lead, or other metals.

7742. *Salmon or river-farmers*, or fishery renters, such as rent rivers or ponds for the sake of their fish.

7743. *Commercial or professional farmers*, such as farm lands for profit. Those who farm an extent of good land under one hundred acres are considered small farmers; under three hundred acres, middling farmers; above and under five hundred acres, large farmers; and exceeding that quantity, extensive farmers: a very proper title, for few arable lands can be profitably cultivated to a greater extent in one farm or by one establishment than five hundred acres, and those which exceed that quantity are generally breeding or other stock farms, characterised by their extent.

7744. *Gentlemen farmers*, are professional farmers on a large scale, who do not associate with their minor and personally working brethren; but who affect in their style of living the habits and manners of independent men or gentlemen. It is a character extremely liable to ridicule by the vulgar yeoman and purse-proud farmer on the one hand, and those persons who are gentlemen by profession and men of family on the other.

7745. *Yeomen farmers*, small proprietors who farm their own lands, but yet aspire not to the manners and habits of gentlemen.

7746. *Farming landlords*, proprietors who farm their own lands on a large scale.

Sect. III. *Agricultural Counsellors, Artists, or Professors.*

7747. *The land-measurer* is the lowest grade of agricultural artists: he is very often the village school-master, and is called in to measure work done by the job; as mowing, reaping, hedging, trenching, &c.

7748. *The agricultural salesman* is a person who attends at fairs, markets, &c., and acts as agent to buyers and sellers of corn and cattle. There are also salesmen purposely for hay and straw, others for green food, turnips, potatoes, &c.

7749. *The appraiser*, or valuer of farming-stock, comes next in order. This professor values the live and dead stock, and crop, tillages, manures, &c., and sometimes also the remainders of leases between outgoing and incoming tenants, or betwixt tenants and their landlords. Occasionally the appraiser is employed to value lands, but this is generally the business of the land-valuer.

7750. *The land-surveyor* generally confines his avocations to the measuring and mapping of lands; or to their subdivision, or the arrangement of fences and other lines; but sometimes he joins the business of appraiser and valuer, and even timber-measurer.

7751. *The timber surveyor and valuer* confines himself in general to the measurement and valuation of fallen or standing timber; he also measures and estimates the value of bark, faggots, roots, charcoal, ashes, willows, hoops, and various other products of ligneous plants.

7752. *The land-valuer* not only values the rental, but the price or fee-simple of lands, buildings, woods, quarries, and waters. He does not often meddle with metallic or saline mines; but he sometimes values fisheries, stone and lime quarries, brick-earth, gravel, chalk, &c. This profession requires not only a general knowledge of agriculture in the most extensive sense of the word, but a very extensive acquaintance with the country in which the property lies, and great experience in business. There are local and general land-surveyors and land-valuers: the general professors live in the capital cities or in the metropolis, and generally unite the business of land-agent.

7753. *The land-agent* may or may not be a land-valuer, but at all events he should possess the knowledge of the valuer in an eminent degree. His business is to effect the transfer of property by purchase, sale, hiring, or letting; and also to collect rents, and often to re-let farms, and effect other business belonging to the land-valuer. Land-agents are very frequently attorneys, who know little of agriculture; but who save their employers the trouble of employing both a land-steward of superior abilities, and a lawyer to draw up agreements and leases. It is the opinion of the best informed agriculturists both of Britain and France, that the employment of attorneys as land-stewards and agents has been one of the chief causes of the retardation of agriculture throughout Europe. Chateauvieux has clearly shown how this cause has operated in France and Italy; and Dr. Henderson, Arthur Young, Marshal, and various others, have deprecated its influence in Britain. The love of precedent, which these men cannot abandon from habit; the love of litigation, to which they adhere from taste and interest; and the ignorance of agriculture, from the nature of their education; are the causes that have counteracted the tendency to change and amelioration.

7754. *Of agricultural engineers* there are considerable variety. The *drainer*, for laying out drains and water-works; the *irrigator*, for watering the surface of grass-lands; the *road engineer*, for laying out roads; the *mineral surveyor*, for searching for, measuring, mapping, and valuing mines and minerals; the *coal viewer*, for estimating the value of coal works; the *rural architect*, for designing and superintending the execution of agricultural buildings; and the *hydrographical and canal engineers*, for canals, harbours, mills, and the greater water-works.

7755. *The veterinary surgeon*, or agricultural doctor, is to be considered as a rural professor; and as subordinate grades, may be enumerated the farrier (*Ferrier*, Fr.; *Ferrajo*, Ital., a smith, from *ferrum*, Lat. iron), cowleech, and castrator or gelder.

7756. *The agricultural draftsman*, or artist by way of eminence, is employed in designing and painting live-stock, implements, plants, and cultivated scenery; the plans of farms are taken by the land-surveyor, designs of buildings made by the architect, and new inventions in machinery and implements are drawn by the inventors, whether millwrights or agricultural mechanists.

7757. *The agricultural author* may be considered as the most universal kind of agricultural counsellor, since his province includes every branch of the art, and comprehends times and practices past, present, and to come. The simplest variety of this species is the author of single papers in magazines, or the transactions of societies; the most extensive, he who embraces the whole of the subject; and the most valuable, he who communicates original information.

7758. *The professor of agricultural science* (*Professeur d'Agriculture ou d'Economie Rural*, Fr.; *Hochlehrer von Ackerbau*, or *H. von Landwirthschaft*, Ger.; *Professor d'Agricultura*, Span.; and *Professore d'Agricultura*, Ital.), when appointed by a permanent or national institution, may be reckoned the highest grade of agricultural counsellor: since he is not a self-constituted instructor, like the author; but constituted by competent judges as capable of instructing the public. The first public professor of agriculture appointed in Britain was Dr. Coventry of the University of Edinburgh, about 1790; and the next Sir Humphry Davy, Lecturer on Agricultural Chemistry to the Board of Agriculture, about 1807: both highly eminent as agricultural counsellors, independently of their other merits. There are agricultural professors in Dublin and Cork. In almost every University on the Continent there is an agricultural chair, and in some of the German and Russian Colleges there are chairs for gardening (Gärtnerey), forest-culture (Forstwissenschaft), and rural architecture (Landbaukunst).

Sect. IV. *Patrons of Agriculture.*

7759. *Every man being a consumer* of some description of agricultural produce, may be considered a promoter of the art by causing a demand for its productions. The more valuable consumers are such as

live on the best bread, butcher's meat, fowls, and dairy products; and the greatest of all patrons, both of agriculture and gardening, are such as fare sumptuously every day.

7760. *Amateur agriculturists*, lovers of agriculture, promote the art by the applause they bestow on its productions; of which, to a certain extent, they become purchasers, as of farming books, prints of cattle, implements, &c.

7761. *Connoisseurs*, critical or skilful lovers of agriculture, promote the art in the same way as the amateur, but much more powerfully, in proportion as approbation founded on knowledge is valued before that which arises chiefly from spontaneous affection. By the purchase of books, models, attendance at agricultural exhibitions, &c., connoisseurs encourage both counsellors and commercial agriculturists. Sometimes, also, by their writings, of which Sir John Sinclair is an eminent example.

7762. *Employers* of agriculturists, whether of the serving class, as bailiffs, stewards, &c., or of the order of professors or artists, are obvious encouragers of the art.

7763. *Amateur farmers* are patrons on the same principle as employers; and sometimes, also, they effect improvements, or communicate valuable information to the public. Cline, the late eminent surgeon, and the late physician, Dr. Parry, were eminent examples.

7764. *Noblemen and proprietor farmers* are conspicuous patrons. They render the art fashionable; and by the general attention so directed, and consequent occupation of many minds on the same subject, new ideas are elicited, and dormant talents called forth and employed. The names of Russel, Coke, Curwen, and Somerville stand preeminent among this species of patrons, and many others might be added.

7765. *Noblemen and gentlemen improvers*, whether by planting, building, road-making, establishing villages, canals, harbours, &c. are evidently greater patrons of agriculture than noblemen farmers, since their improvements affect society more extensively. As decidedly at the head of this species of patron may be mentioned the late Duke of Bridgewater and the present Marquess of Stafford, and to these names might be added a number of others.

Chap. II.

Different Kinds of Farms in Britain relatively to the different Classes of Society who are the Occupiers.

7766. *Cottage farms* form the first link in the chain of temporary terrestrial possessions. They consist of one or more acres appended to a cottage, for the purpose of enabling the occupier to keep a cow: if any part of this farm is in aration, the labour is either hired of some jobbing agriculturist, or done by spade; or two or more cottagers join together and form a team of their cows, with which, and implements borrowed from the village carpenter or smith, they accomplish their labour.

7767. *Farms of working mechanics.* These are larger than the former, and are rented by country blacksmiths, carpenters, &c., who often keep a horse or a pair of horses. Both this and the former sort are very often injurious to the occupiers, by drawing off their attention from their principal source of income; though it must be confessed at the same time, that the idea of occupying land, and raising one's own corn, clover, milk, butter, eggs, pulse, &c. is highly gratifying; gives a sort of sense of property, and has an air of independence and liberty, highly valued by men in general.

7768. *Farms of village tradesmen and shopkeepers.* Many of these men, such as bakers, butchers, grocers, &c. keep a horse at any rate; by renting a few acres they are able to keep another, and add a cow, and other minor species of live stock. The attention required from the master forms a healthful recreation, and agreeable variety of occupation; and if this recreation does not interfere with main pursuits, there is a gain of health and respectability.

7769. *Farms occupied with a view to profit by town and city tradesmen.* These are on a larger scale than the last, and held by stable-keepers, cow-keepers, butchers, corn-dealers, &c. They are often of considerable size, mostly under grass, and managed by bailiffs. Arable farms in such hands are rarely well managed, as every thing is made to depend on manure; but as less skill and vigilance is required in managing grass-lands, hay or pasture farms of this description are generally well manured, and consequently productive. They are seldom, however, profitable, and it is only because the renter reaps the double profit of grower and consumer, has some enjoyment in the idea of the thing, and some increase of health from the requisite visits to it, that he finds it suitable to continue his farming operations.

7770. *Farms occupied by city tradesmen for recreative enjoyment.* These are of various descriptions, and generally managed by bailiffs. They may be considered as affording recompense only by the amusement, exercise, and health which they afford, and the interest in country matters which they excite. Many a worthy man thus throws away, almost at random, on agriculture, what he has gained by trade with the greatest industry and frugality, often joined to skill and ingenuity. When the farm promises well, the tradesman is sometimes tempted to sell his trade and turn farmer for good (as it is called, *i. e.* for a principal occupation), and often ends in impoverishing, or even ruining himself.

7771. *Farms attached to the villas and country houses of wealthy citizens.* On these the wealthy citizen plays at agriculture, aided by a skilful manager or bailiff. Immense sums of money are thus expended in the neighbourhood of large towns; many ingenious practices are displayed; and though nothing in the way of profit is ever expected to be gained, yet on the whole an attention to agriculture is excited in the minds of wealthy commercialists, who buy books on the subject, procure bailiffs, approved implements and breeds of stock; and thus give encouragement to these and other productions connected with the subject. The history of farming for the last twenty years round Edinburgh, Liverpool, and London, affords some curious, singular, and extravagant examples of this description of farming, and some of a much more judicious description.

7772. *Demesne farms*, or such as are occupied by the landed proprietors of the country. These are of a great many different kinds; some regularly appended to the park; some comprising a part of the park separated by temporary fences; and others taken into occupation without regard to situation. Some proprietors take all the farms on their estate successively into their own hands, cultivate them for a few years, bring them into excellent order, and then let them to farmers. Much good is often done by proprietors occupying land themselves; new practices, and new kinds of vegetables and live stock, are exhibited and disseminated; and the landlord himself, being instructed by experience in the practice of farming, is better able to judge what his land should let for; and more likely to appreciate good tenants, and sympathise with the losses of his farmers in bad seasons. Add also, that a proprietor in this way procures better butcher-meat of every kind than he could generally purchase in the neighbouring markets; and, if he chooses, better legumes and roots, and even better cabbages and other culinary vegetables than he could grow in his kitchen garden. The bailiffs on such farms are, or ought to be, well educated men, brought up to farming in the best districts. They should be well paid, and have sub-bailiffs under them. The establishments of Bedford, Coke, Curwen, Albemarle, &c. are or were among the most complete in this kind of farming.

7773. *The farms of professional farmers.* It must be obvious, that this class includes more than nine tenths of all the farms in the country. They are of every description of soil, climate, situation, &c. which the country affords; of all manner of sizes, according to the demand created by such as follow farming as a business; and either devoted to the general purposes of corn and cattle, or more particularly for poultry,

milking, dairying, garden crops, hops, orchard crops, grazing, breeding, hay, corn, wood, minerals, as stone quarries, &c., or to fisheries. At the origin of what we now call farming, or when the hiring of land by cultivators succeeded to cultivating them for the landlords, or in partnership with the landlords, as is still the case in Italy and most other countries, farms would of course be small, and farmers' men of scarcely any capital or consideration in society. Just emancipated from a state of bondage and villanage, the new-created independent tenant could not easily throw off the chains which formerly shackled his mind and prevented his energies from being brought into action, and he could have little or no property when he had no means of acquiring it but by plunder, or preserving it but by concealment. Hence the first tenants were assisted by their landlords; and one remnant of this practice, that of allowing farmers to have a year's rent always in hand, or, in other words, not to demand the rent till half or a whole year after it is due, still exists in some parts of Scotland and Ireland. In process of time, however, and from various direct and indirect causes, farmers at length acquired some degree of capital and respectability; and as they naturally thought of employing the former, of course farms began to be enlarged to afford scope, and leases granted to afford security. This practice has been going on in Britain for more than two centuries past, and receives a fresh impulse whenever the prices of grain rise high, and continue so for some time. At no period have they been so high as about the commencement of the present century, and during no period have the riches and respectability of farmers so much increased. More recent political changes, however, have proved singularly disastrous to farmers; and till the corn laws are either obliterated, or regulated on some permanent and more moderate principle, agriculture and its practisers of every description will remain liable to the extremes of profitable occupation and ruin.

Chap. III.

Topographical Survey of the British Isles in respect to Agriculture.

7774. *The British isles*, as we have already observed (1280.), are, in their present state, naturally and politically more favourable to the practice of the agriculture of ale, butcher-meat, and wheat, than any other country in the world. They have their disadvantages both in climate, and in civil and political matters; but, notwithstanding, there is no country in the world where farmers or proprietors are so respectable a class of men, and where such excellent corn, herbage, roots, and hay, either raw, or in their manufactured state of bread, ale, and butcher-meat, are brought to market.

7775. *The following outline of the state of agriculture in each of the different counties of the United Kingdom* is taken from the *Surveys* published under the authority of the Board of Agriculture, or the Dublin Society; from Marshal's remarks on these surveys, and his other writings; and, in some cases, from our own observation, having at various periods, since the year 1805, been in almost every county in Britain, and in most of those in Ireland. Agricultural improvement is often of so variable and fleeting a nature, that, notwithstanding our utmost care, some things may be found here inserted as such that no longer exist; and from the period, varying from twelve to twenty years, which has elapsed since the surveys were published, many improvements may have been made deserving of insertion which are omitted. These are unavoidable defects attendant on this part of our work; but though we cannot render it perfect, yet we are of opinion we can bring together a sufficient number of facts, as to the natural and agricultural circumstances of each county, as to render it both interesting and useful to the reader. We regret much, that notwithstanding our most earnest invitation to the readers of the *Gardener's Magazine* to send us corrections and additions for this part of the work, yet we have received so few, that we are unavoidably obliged to send into the world the second edition of this chapter, in November, 1830, almost as imperfect as was the first, in November, 1825.

Sect. I. *Agricultural Survey of England.*

7776. *The surface of England* is estimated at from thirty-two to thirty-six millions of acres, with the exception of some mountains in Cumberland and Westmoreland, almost every where cultivated, and nowhere incapable of cultivation; in most places varied, gently and beautifully in some districts, and abruptly and on a grander scale in others. The most high and mountainous districts are those of the north, and the most level those of the east. The most humid climates are those of the north-western counties; as Cheshire and Lancashire; and the most dry those of the south-east, as Norfolk and Suffolk. The richest grass lands are in the vales of the great rivers, as the Severn, Trent, and Thames. The richest arable lands, in Worcestershire, Warwickshire, and in part of various other counties; and the best farming, in Northumberland, Durham, and Cumberland. The greatest variety of farming may be seen in the counties round London; and the greatest sameness, regularity, order, science, success, and the wealthiest farmers in Northumberland and the county of Durham. The geology and minerals of the kingdom are most ably indicated in *Smith's Geological Map of England, Wales, and part of Scotland*, 1815; *Smith's County Geological Maps*, 1819 to 1824; and *Smith's Geological Table of British Organised Fossils*, 1819. These works are of the greatest importance to landed proprietors.

7777. MIDDLESEX is part of the north side of a vale watered by the Thames, and contains 192,000 acres, exhibiting a great variety of agriculture. (*Middleton's Survey*, 1806. *Marshal's Review*, 1818. *Edin. Gaz.*, 1827.)

1. *Geographical State and Circumstances.*

Climate. Healthy; warmer near London, from the fires kept there, which consume 800,000 chaldrons of coals annually; stationary winds from the S. W. and N. E., those from the S. W. blow 6-12ths of the years, N. E. 8-12ths. Greatest falls of rain from a few points W. of S. and are of the longer continuance when the wind has passed through the east to the south. In spring, frost in the hollows, when none on the hills, thermometer has been as high as 83°, and as low as 6° below zero.

Soil. By long continued manuring, the surface soil almost every where looks like loam. Sand and gravel on Hampstead Hill. Loamy sand from Hounslow to Colnbrook. Sandy loam on west side of Hanwell and Hounslow. Strong loam about Ryslip, Pinner, Harrow, and South Mimms; loamy clay between Uxbridge Common and Harefield. Clay of the most adhesive and ungrateful kind about Hendon and Highwood Hill; peat from Rickmansworth to Staines, on a substratum of the gravel of flints. Marsh land or rich loam deposited from still water in the Isle of Dogs, and on the Lea and Coln.

Surface. Gently waving; highest towards the north. Hampstead 100 feet above the level of the sea. One mile from London on the Kingsland Road, the surface of upwards of 1000 acres is lowered at an average five feet from the brick earth dug out, which of ordinary quality has produced 4000*l.* per acre; and when marly, for malms or white bricks, 20,000*l.* per acre. Brick earth formerly 100*l.* per acre, now 500*l.* per acre. An acre at four feet deep yields four millions of bricks.

Mineral strata. 1. Cultivated surface. 2. Gravel of flints, 5 or 10 feet in thickness. 3. Lead or blue clay, 200 or 300 feet in depth. 4. Marine sediment, 3 or 4 feet in depth. 5. Loose sand, gravel, and water, the latter arising in such quantities as to prevent digging deeper.

Water. Abundant and excellent. The Thames, from Oxford to Maidenhead, falls about 24 feet in ten miles; from Maidenhead to Chertsey Bridge, 19 feet in ten miles; thence to Mortlake, 13 feet per ten miles; and to London, one foot per mile; from London the fall diminishes till it is lost in the sea. Tide flows twenty-three miles up the Thames. Spring water found at various depths, from 5 to 300 feet; the latter, the depth of Paddington.

Mineral waters at East Acton, Hampstead, and Bagnigge-wells; chalybeates little used.

Fish caught in the Thames. Sturgeon, salmon, tench, barbel, roach, dace, chub, bream, gudgeon, ruffe, bleak, eels, smelts, and flounders.

2. *State of Property.*

Estates and their management. Generally under the care of attorneys, and badly managed.

Tenures. Much freehold, considerable extent of copyhold, some church, college, and corporation land.

3. *Buildings.*

Houses of proprietors. Numerous, splendid, commodious.

Farm-houses, offices, repairs. Oldest built with timber lathed and plastered, roofs thatched; erected piecemeal; situated in villages, sides of lanes, and near large ponds. Those built within the present century, of brick, and covered with tiles. Farmery of Sutton Court, Chiswick, Wickgreen, and Isleworth, models of their kind. Very few buildings required on hay farms.

Cottages, brick and tiled, and generally in villages; formerly with right of common, now done away by enclosures.

4. *Mode of Occupation.*

Size of farms. Generally small compared with other counties; three cow-farms near town, from 500 to 600 acres each, rented at from 2000*l.* to 5000*l.* each. Many of 200*l.*; average of county 100*l.*

Character of the farmers. Four classes. 1. Cow-keepers, gardeners, and nurserymen. 2. Amateur farmers of fortune. 3. Amateur farmers, who have left other pursuits. 4. Commercial or professional farmers, equal in number to half the others.

Rural artificers. Bad; impossible to get any agricultural implement or machine made on a good principle by the country artificers; but able mechanics in London; Cottam and Hallen, Wykes and Phillips, Snowden, and especially Weir, a Northumberland man, and practically acquainted with agriculture.

Rent paid in money, sometimes a small part in butter and cream at fixed prices. Varies from 10*s.* to 10*l.* per acre, or higher for nurseries.

Tithes in many places taken in kind, in some compounded for annually, or for a fixed period.

Poor, and the rates for their relief, average 3*s.* 6*d.* per acre.

Leases, general. Often for fourteen and twenty-one years, drawn up by lawyers—"a composition of obsolete unintelligible covenants."

Expense and profit. Expenses on entering a farm, greater than in distant places: profits seldom more than a mere subsistence to the farmer. The increase of canals, and the prospect of steam carriages and locomotive steam-engines on railroads, is rapidly rendering distant and near farms and farmers' profits on a level.

5. *Implements.*

All bad; plough barbarous; threshing mills rare.

6. *Enclosing.*

Now mostly enclosed. Nineteen commons enclosed from 1800 to 1806, containing 20,000 acres and upwards. Old fences of a mixture of white and black thorn, maple, hazel, briar, crab, damson-plum, &c.; new of white thorn with ditch and bank; gates mostly five-barred, and of oak; enclosures too numerous.

7. *Arable Land.*

About 14,000 acres; wretchedly managed, ploughed with teams of three or four horses; rotation generally fallow, wheat, beans.

8. *Grass Lands.*

Meadows better managed; hay-making good.

9. *Gardens and Orchards.*

From Kensington through Hammersmith, Chiswick, Brentford, Isleworth, and Twickenham, seven miles of garden ground; may be denominated the great London fruit garden, north of the Thames. An upper and under crop taken at the same time; the upper the fruits on trees; the under strawberries and various herbaceous crops. To increase shelter and warmth in autumn, they raise banks of soil 3 feet high, facing the south, and sloped to an angle of 45°; on these they plant endive in September, and near the bottom, from October to Christmas, they drill a row of peas; the endive is preserved from rotting, and the peas come to maturity nearly as early as if under a wall. The springs here lie eight or ten feet under the surface, and the water is raised from the wells by a bucket and lever, balanced by a stone. (*fig.* 132.) Three thousand acres of garden ground here, employing five persons, a man, his wife, and three children, per acre, during the winter half-year, and during summer, five persons more, chiefly Welsh women. Estimated produce 100*l.* per acre.

Kitchen gardens. Much fresh littery dung required for growing mushrooms, early cucumbers, salads, potatoes, asparagus, &c. Consumption of the metropolis and its environs, for fruits and vegetables, estimated at upwards of a million sterling per annum. Several farming gardens pay 1000*l.* per annum.

Nursery grounds. About 1500 acres, producing 75,000*l.* a year.

10. *Woods and Plantations.*

Copses and woods decreasing for ages: still a few acres near Hampstead and Highgate.

Hedge-row timber much disfigured by being pollarded or pruned to may-poles.

Willows or osiers. Many islets on the Thames, rented by basket-makers, and planted with osiers; also, wet borders of the river so planted. Species *Salix vitellina, amygdalina*, or almond-leaved, and *viminalis*, or osier; willows when cut made up in bundles, or boults, forty-two inches round, at sixteen inches above the but-ends.

11. *Improvements.*

Draining, to carry off surface water. The mode of making surface gutters on meadows, by means of an addition to cart-wheels (3979.), invented by the reporter.

Manure produced in London by 30,000 horses, 8000 cows, and 700,000 human beings, equals 500,000 loads; of which, half is carried into the Thames by the sewers, including ninety-nine per cent of the night soil.

12. *Live Stock.*

Less live stock on the farms of this county than in any other: no breeding. Short horned cows of Holderness chiefly used by milkmen: number kept 8500; average produce nine quarts per day; fed on hay, turnips, brewer's grains, linseed cake and jelly, and grass: retail dealers adulterate the milk, preferring dirty water to clean; and adulterate the cream by adding molasses and a little salt. Very little butter made in the county. Brewer's drays supplied with horses from the Berkshire farmers, who buy them young from Northamptonshire, and work them two or three years before they sell them. Not more than one dove-house in the county; but many pigeons kept in empty wine pipes set upon posts, fifteen or twenty feet high, and many kept by journeymen tradesmen, pigeon fanciers in the poorer parts of London, and most other towns and villages of the county.

13. *Rural Economy.*

Half the manual labour done by the job; labourers ruined in morals and constitution, by the public houses. Gentlemen's servants a bad and contaminating set.

14. *Political Economy.*

Highways of the parishes good, turnpike roads generally managed on Macadam's principle, and good; several canals terminate in or near London; and New River for supplying water; fairs on the decline. Uxbridge the greatest corn market next to Mark Lane. Great cattle markets, Hounslow and Smithfield. Commerce great. Manufactures not many; considering agriculture as a manufacture, and the soil as the raw material, and worth 16*s.* per acre, at an average of England; it is increased in value to 5*l.* or 525*l.* per cent. Distilleries and breweries numerous.

15. *Obstacles to Improvement.*

Tithes, land-agents being attorneys, bad leases, bad rural artificers, bad and thieving servants.

16. *Miscellaneous Observations.*

Society of Arts, Veterinary College, excellent institutions. Fines called heriots should be removed; weights and measures lately regulated; much damage is done by game.

17. *Means of Improvement.*

Ample in the metropolis, and the progress rapid; in the country, want of intelligence the grand drawback.

7778. SURREY. A surface of 519,040 acres beautifully varied: poor and heathy in the west, chalky in the east, and clayey in the south. The field cultivation of clover and turnips appears to have first taken place in this country. (*Stevenson's Survey*, 1813. *Malcolm's Survey*, 1809. *Marshal's Review*, 1818. *Smith's Geological Map*, 1821. *Edin. Gaz.*, 1827.)

1. *Geographical State and Circumstances.*

Climate. Healthy winds S.W. and W.: seldom blows from any point between N.W. and N.E. for any time. East winds in spring, and then weather cold, raw, and drizzling. Most rain falls when the wind is S.S.W. or S.

Soils. Various and most irregularly distributed; a broad zone of tenacious clay bordering Sussex: patches of brick earth at Walworth, Sutton, and Stoke. Considerable extent of chalk hills from Croydon to Nuttfield, and thence narrowing to the western extremity of the county. A good deal of black rich land interspersed among all the soils.

Surface. St. Anne's Hill, Cooper's Hill, and Richmond Hill celebrated; Leith Hill the highest, commands a prospect of from thirty to forty miles on every side.

Minerals. Iron ore, fuller's earth, firestone, limestone, and chalk. Iron-works on the decline, on account of the dearness of fuel. Abundance of fuller's earth in the southern part of the county, which has been dug since the beginning of the eighteenth century. Excellent firestone: when first quarried soft; kept under cover a few months becomes compact, and able to endure the action of a common fire. Owing to this stone, Dawson, proprietor of the Vauxhall plate-glass works, can make plates of such a size as to surprise the French, from whom he discovered the art of plate-glass making in the disguise of a common labourer. Excellent limestone at Dorking, which hardens under water; contains a little flint. Chalk used chiefly as a manure. The sand about Ryegate the finest in the kingdom, and in considerable demand for egg and hour glasses, writing-sand boxes, &c. At Nonsuch, there is a bed of brick earth, from which fire bricks and crucibles are made.

Water. Scarce in many places, particularly on the chalk. Several supplies procured round London, by boring down from one hundred to five hundred feet to the chalk stratum, where the water is excellent, soft, and abundant. Artesian (from the county of Artois, where such wells were first brought into notice,) wells are now so numerous in the neighbourhood of London, that in places where the water formerly rose in the bore three or four feet above the surface, it will now scarcely reach the surface. (*Mag. Nat. Hist.* vol. ii. and iii.)

Fish ponds common on the heaths, at the western side of the county; have been used for upwards of two centuries, for breeding and rearing carp and other fish. One of the largest, containing one hundred and fifty acres, is near Hersham.

Mineral waters numerous. Epsom water is impregnated with sulphate of magnesia, and is purgative. Epsom salts originally made there, now chiefly from common salt water at Lymington in Warwickshire. The other springs are more or less impregnated with sulphate of magnesia, carbonate of lime, and iron.

2. *State of Property.*

No large estates: largest 10,000*l.* a year. Yeomanry not numerous; but some gentlemen round Guildford farm their own estates of from 200*l.* to 400*l.* per annum. Estates mostly managed by attorneys; so far proper as to law terms, but as absurd as to agricultural restrictions, as it would be to employ a farmer to draw up the covenants in technical language. Till the farmer becomes active, inquisitive, free from prejudice, and intelligent, no covenants, or care of attorneys and stewards, will prevent him from injuring himself and his landlord by bad husbandry. When he becomes active, &c. he will take care of the landlord's interest for the sake of his own; and the first step to forcing the farmer to become active and intelligent is to leave him to the exertions of his own mind. Tenures chiefly freehold.

3. *Buildings.*

Few counties that can vie with Surrey in the number and

elegance of its country seats. (*Encyc. of Garden, Surrey.*) Possesses a great advantage over the north and east of Middlesex and Essex, in this respect, as the prevalence of the S.W. winds drives away the smoke of London. Proprietors generally reside on their estates, and eagerly introduce improvements.

Farm houses and offices. Ruinous and mean in the weald, or clayey district bordering on Sussex; better in other places. Oldest of brick covered with slate, stone, or brick nogging and tiles; situations seldom central or convenient to the farm, in villages. Stables not divided into stalls. Cow-houses near London, good. Cottages often large, convenient, and picturesque; with a porch, a flower-plat, and vine in front.

Drinking ponds. Great attention paid to these on the Surrey hills; generally a first pond, where the water deposits its grossest dirt and mud before it enters the second.

4. *Occupation.*

Farms of all sizes, but mostly small, forty and fifty acres to three hundred. Largest farm between Guildford and Farnham is Wanborough; it contains 1,600 acres; formerly occupied by Morris Birkbeck, and now by his son. Average size one hundred and seventy acres. Tendency to large farms, by which the public is unquestionably benefited, certainly by the saving of labour, and, in all probability, by the superior cultivation and increased produce. The driven out farmer may generally support or enrich himself equally well though in a different line of life. "But in every country, in all situations and circumstances, and in our own country, particularly in the situation in which it is now placed, it is of the highest importance to consider, whether a mere increase of wealth may not be purchased too dearly; whether it be prudent or wise to diminish the number of those whose souls are knit to their native land, by stronger ties than are known to the mere manufacturer. To the patriot, it can be little satisfaction to see his country the richest in the world, if the measures and causes which make it rich diminish in the most trifling degree, its independence; either by raising any passion above the love of our country, or by diminishing the number of those who must be its most natural and powerful defenders. To the moralist it can afford little pleasure to be told, that by the saving of agricultural labour, the manufactures of his country will be extended or increased, if he perceive that by the change of employment the health and virtue of part of the community are sacrificed.' (*Stevenson.*)

Farmers. Old class about the clayey wealds, equal enemies to improvements in agriculture, and relaxations in morals: have no idea of educating their sons, and so little of the spirit of commerce, that they prefer selling their grain to an old customer at a lower price than taking a higher from a new one. Go to market in round frocks, the dress of their forefathers, and shy and jealous to strangers. Nearer town the farmers are more on a level with the age; but either unable or unwilling to communicate information; some exceptions of liberal, enlightened, and communicative men. Many tradesmen have turned farmers, and occupy lands near town.

Rent low. Tithe rigidly exacted, poor's rates and other outgoings high.

Leases general, for fourteen or twenty-one years, or on three lives.

5. *Implements.*

Great variety of ploughs, swing ploughs, the Scotch swing plough used only in two places; bad effect of so many different sorts of ploughs on the servants. The cultivator used by Birkbeck, and highly approved of: — with six horses, goes over eight acres in a day. Lester's friction threshing-machine introduced in a few places, and found to succeed: but it threshes very slowly, and has no advantages over Meikle's, but that of not breaking the straw of wheat. This advantage is too trifling ever to render it general. Very few winnowing machines. Sowing troughs in use, the advantage of which is, that the sower fills it himself instead of having a woman, toiling through rough ground. Smut machines also in use, in one or two instances. (2796.)

6. *Arable Land.*

Proportion considerable, tillage bad. Drilling, though introduced by Duket of Esher, and strongly recommended, is confined to a few adjoining parishes, where the soil is light. Fallowing on clays general, but most imperfectly executed. Rotations generally good.

Turnips, supposed to have been grown in Surrey as long or longer than in any county in England. Sir R. Weston, of Sutton, having described the Flanders culture in 1645, and as he addressed his book to his sons, it is thought they would attempt culture. Very badly cultivated at present, and seldom in raised drills. The Siberian turnip has been tried; it is a variety between the cabbage and turnip, but with a root inferior in point of size and flavour to the latter, and a branchy loose top: it does not seem adapted for field culture, though as a novelty it deserves trial and attention. Carrots answer well on the sandy soils. Potato tops sometimes given to cows, cut when in flower; a bad plan with a view to the tubers. Clover introduced by Sir R. Weston at the same time as turnips. Saintfoin succeeds well on calcareous soils, producing good crops for eight years. In forming a new road though a field of saintfoin, between Croydon and Godstone, the roots were found to have penetrated several yards below the surface. The culture of hops, brought from Suffolk to Farnham about A.D. 1600; prefer a calcareous sub-soil: occupy 800,900 acres. Farnham hops esteemed more than others, because picked earlier, and hence more delicate, and better sorted. Peppermint, lavender, wormwood, chamomile, liquorice, and poppy, grown near Mitcham; and more extensively than in any other county. One hundred acres of peppermint. Elecampane, rhubard, soapwort, coltsfoot, vervain, angelica, rosemary, the damask and red roses, hyssop, horehound, marsh mallow, pennyroyal, and several acres of daisies, wall-flowers, sweet-williams, primroses, violets, pinks, batchelors-buttons, and the like, are also grown for Covent Garden market, where they are carried, either as entire plants in flower with balls for planting in town, flower-pots or in pots, or the flowers are gathered and sold for nosegays. Weld is grown in a few places.

7. *Grass Land.*

But in small proportion to the rest; most pasture in the wolds. Paring and burning considered by Birkbeck as the best first step of breaking up old grass lands.

8. *Gardens and Orchards.*

Asparagus grown in great quantities at Mortlake, East Sheen, and Battersea. Radish and other seeds also grown extensively at Battersea. Onions for seed at Mortlake and Barnes: though chiefly at Deptford. Three thousand five hundred acres of Surrey employed in raising vegetables for the London market. Orchards attached to many of the farms, sufficient to supply from four to twelve hogsheads of cider. Generally in a very bad state of cultivation; trees covered with moss; many walnuts grown at Norbury, and at some other places; produce 20 to 50 bushels per tree.

9. *Woods and Plantations.*

The wold formerly a wood: some copse there still: shoots for hoops grown; charcoals for gunpowder made from hazel, dogwood, &c.; common charcoal, hop-poles and faggots. Box Hill, formerly called Whitehill, by tradition originally cultivated, till the Earl of Arundel, in the reign of Charles I., brought box trees from Kent, and planted there. Many with good reason think it not planted, but aboriginal. Soil of the hill, pale loam or chalk; timber now all cut; brought only five pounds per ton. Many fir trees on chalk hill: at Crowhurst, one fifty feet high and thirty-six in circumference. Brooms made from the ware or spray of birch to a great extent. Fine limes at Beckworth. Osier holts or grounds about Chertsey and Byfleet, brought the same rent one hundred and fifty years ago which they do now. Furze grown for the burning of bricks; sown both broadcast, and in drills; cut every three years, and bound like corn, then stacked.

10. *Heaths, Commons, and Common Fields.*

Extensive heaths on south-west; surface flat, soil back sand, and gravel. A number of commons, and great extent of common-field lands.

11. *Improvements.*

Draining, paring, and burning. Manuring with London manure of a great variety of kinds.

12. *Live Stock.*

Very inconsiderable; only six hundred and nineteen cows, kept for supplying London with milk.

Duket of Esher used to rear calves to a great extent; many cattle fed by the distillers and starch manufacturers. Adam of Mount Nod, one of the architects of that name, has constructed extensive buildings for cattle, and stall-feeds six hundred at a time. Sheep kept in considerable numbers on the chalk hills and wealds. Birbeck has been very successful in cross-breeding with merinos, that is, with the Ryeland merino of Dr. Parry, and the South Down. Immense number of pigs fed at the distilleries, and of geese kept on the wealds. Dorking hens are well known. (7443.) A hare warren near Banstead Downs, already described. (7365.)

13. *Rural Economy.*

Hands scarce; servants unsettled; prejudiced, like many of their masters, against all new practices.

14. *Political Economy.*

Bad roads, though flints and other good materials abound in many places. An iron railway between Wandsworth and Westham for general use; the first in the kingdom of that kind, the rest being confined to the carriage of goods belonging to individuals; this open to all who choose to employ the waggons; as a canal is open to all who choose to employ the boats. Though on a level, and admitting of carriage both ways, yet not found to pay. The first canal locks in England were erected on the Wey. Sir R. Weston, of Sutton, brought the contrivance from Holland; and, under his direction, the Wey was rendered navigable from Guildford to Weybridge, about 1690. Numerous fairs; several flour, paper, and oil mills. An extensive iron work at Garratlane, near Wandle; a mill for staves at Stoke; a delft manufactory at Mortlake. A horizontal air-mill of a new construction at Battersea bridge; several distillers, brewers, and starch manufacturers. Poor, numerous and degraded. Poor's rates enormous.

7779. SUSSEX. A maritime county of upwards of 900,000 acres; distinguished by chalk hills and extensive wealds, a rich soil, but little excellence or variety of agriculture: excels in South Down sheep. (*A. Young's Sussex*, 1809. *Marshal's Review*, 1818. *Smith's Geological Map*, 1819. *Edin. Gaz.*, 1827.)

1. *Geographical State and Circumstances.*

Climate. Warm in western parts, bleak on South Down hills; westerly gales violent, unroof stacks, hedges injured by the spray of the sea.

Soil. Chalk nearly the universal soil of the South Down hills; clay of the wealds, which constitutes more than half the surface of the county. Rich land about Chichester, and sand and gravel in a few places.

Surface hilly, most so where the soil is chalk. No high hills.

Minerals. Sussex or Petworth marble used by the statuaries, but not generally. Limestone, ironstone, sandstone, chalk, marl, and fuller's earth.

2. *State of Property.*

Largest estate 7500*l.* a year. Most proprietors hold land in their own occupation, and pay great attention to its culture, as E. of Egremont, D. of Richmond, E. of Chichester, Lord Sheffield.

3. *Buildings.*

Noblemen's seats splendid, of stone; farm-buildings generally of stone; on the South Downs built of flints: houses very generally faced with tiles, which keeps the walls dry. Corn generally stacked on circular stone piers, which prevents vermin. Sheep-yards, or permanent folds walled round, and furnished with sheds and hay-racks, have been built by Ellman and some other eminent sheep farmers on the Downs. Large wooden barns. Cottages of stone, and on the Downs of flints, and more comfortable than in many parts of England. Magnificent semicircular piggery, erected by E. of Egremont, at Petworth.

4. *Mode of Occupation.*

The most extensive farms on dry soils. Average of the

wealds 100 acres. Size on the Downs 1200 to 2000 acres. Tithe taken in kind in many places, in others compounded for. Poor's rates high.

5. Implements.

Plough with two wheels, large and singularly clumsy. The Rotherham plough introduced, and deemed a real improvement. Several excellent new implements introduced by the noblemen already mentioned.

6. Enclosing.

County enclosed from earliest antiquity; fields small; hedges very irregular and broad. White thorn fences at Goodwood, by the Duke of Richmond, trained in a masterly manner; being like walls, or rather hogged manes of verdure rising from the earth.

7. Arable land.

Tillage bad, three or four horses to a plough with a holder and driver; plough from one half to three quarters of an acre a day; fallowing general on the stiff soils. Rotation bad, barley often follows wheat. Wheat trod in on the sandy lands; threshed by flail, and generally cleaned with a shovel and broom; one or two threshing and winnowing machines. Oats a great deal cultivated on the wealds. Peas much cultivated on the South Downs. Hops much cultivated on the eastern part of the county; but not found profitable. Rhubarb, and the poppy for opium cultivated by E. of Egremont. The roots of the rhubarb, after growing seven or eight years, are taken up, washed, dried in the sun, and then cut in slices and dried on the hot-house flues. (6176.) Incisions are made in the poppy heads, and the exuded juice, when dry, scraped off into an earthen vessel, dried in the sun, and preserved for use. Incisions are made as long as milk flows. André, the domestic surgeon, uses the home-grown rhubarb and opium, and no other. Saintfoin does well on the chalky soils, and lucerne near Eastbourne and Brighton. Lord Egremont tried 100 acres of chiccory, and found it support much stock, though on a poor soil.

8. Grass Land.

Badly managed; overrun with rubbish. One person tried hay oiled when stacking; he oiled every layer, with a watering pan and rose, lightly with linseed oil; the hay came out moist and clammy; and it is said that beasts, and sheep were fond of it, but it was deemed too hot for horses. Salt sprinkled on hay when a little damaged found a great advantage; it is done in stacking.

9. Orchards.

Some considerable orchards, and cider made. One or two fig orchards at Tarring, near Worthing. (See *Encyc. of Gard. Sussex.*)

10. Woods and Plantations, 175,000 acres.

County celebrated from the remotest antiquity for the growth of its timber, especially oak. County at the conquest one continued forest, which extended from Hampshire to Kent. Underwoods cut at twelve years, for hoops and hop-poles. Ash the most profitable underwood. Finest oak timber at Petworth.

11. Wastes.

Of considerable extent to the north of the county. Some hundreds of acres improved by E. of Egremont answer well.

12. Improvements.

E. of Egremont sent for Elkington to find water to fill a lake. E. undertook to do so; but all his trials and predictions of the effect of certain borings and open cuts, which he caused to be made, proved abortive and false: no water was found. Failed in three remarkable instances at Petworth, but drained a meadow very well. Lord Egremont considers him as not a scientific drainer, but a very good common drainer, and nothing more.

13. Live Stock.

Cattle and sheep among the best in the kingdom; total amount of sheep kept is about 450,000; cattle red; little dairying; generally breeding and feeding. Oxen worked extensively by E. of Egremont and Lord Sheffield; broken to the yoke at two years and a half; yokes five feet long used and preferred by Lord Egremont. Lord Sheffield harnesses the same as for horses; twelve oxen and nine horses required to work 200 acres in tillage. For hoven cattle one quart of linseed oil given, which vomits them directly, and never fails in giving relief. South Down sheep celebrated. Ellman the first breeder both of cows and sheep; breeds from the same race. New Leicester and Spanish breeds introduced to the county by Lord Sheffield. Rabbits abound and flourish every where, and are the nuisance of the county. Fowls fattened to great perfection at North Chappel and Kinsford: food, oats ground, hog's grease, sugar, pot liquor, and milk, all mixed; or oats, treacle, and suet; also, sheep's plucks; they are kept very warm, and crammed morning and night; put into the coop two or three days before they begin to cram them, which is done for a fortnight, when they weigh 7 or 8 lbs. each, and are sold to the higglers; average weight 5 lbs., but some weigh double. One of Lord Egremont's tenants crams 200 fowls a year; many capons fed in this manner; great art requisite in castrating them, and numbers die in the operation. The Dorking or Darking fowls extensively raised in the wealds of Sussex; Horsham principal market for them.

The fish-ponds on the weald are innumerable: carp the chief stock; but tench, perch, eels, and pike, are raised. A stream should always flow through the pond, and a marly soil is best. Carp fed with peas in marl-pits have weighed 25 lbs. per brace. Carp kept five years before selling; then twelve to fifteen inches long; 100 stores, or one-year-old carp will stock an acre. At one year old, carp is three inches long; at two years old, seven; at three, eleven or twelve inches; at four, fourteen or fifteen; and then they breed. Lord Egremont has breeding and feeding ponds; fishes them every three years.

14. Rural Economy.

Labour high, as smuggling attracts away many young men.

15. Political Economy.

Roads bad on the clayey districts, good on the chalky. Rother river rendered navigable at Lord Egremont's expense. Fairs numerous. Manufactures of iron, charcoal, gunpowder, paper, bricks, and potash. Large court of poor-houses at Eastbourne, of which a plan and elevation is given in the "Report." In 1772, a society was established at Lewes for the encouragement of agriculture, manufacture, and industry, by John Baker Holroyd, Esq., now Lord Sheffield, and premiums offered; but, on the breaking out of the war in 1778, it was dropped. In 1797 Lord Egremont established a society at Lewes, and gave large premiums. This society still exists. The patriotic and charitable exertions of E. of Egremont are most extensive. He gives away to proper objects immense quantities of clothes; food twice a week; feasts all the labouring classes at Christmas; and keeps a surgeon, apothecary's shop, and midwife, entirely for their service: they are also inoculated, and instructed gratis, &c.

7780. KENT (*Cant* or *Angle*) forms the south-east corner of the kingdom, and extends over 900,600 acres. It is diversified by chalky eminences in some places, low marshy grounds on the Thames and part of the sea-coast, and an inland, flat, and woody tract bordering on Sussex, called the Weald, or wood (Saxon). It is one of the oldest cultivated counties in England; it was noted even by Julius Cæsar, as "the civilest place of all this isle, and full of riches." Viewed from the great road from Dover to London, it has, with the exception of the Downs near Dover, a more garden-like appearance than any county in Britain. Its agriculture is various; and it is celebrated for the culture of hops, fruits, barley, and various garden crops. (*Boy's Kent*, 1796. *Marshal's Review*, 1818. *Smith's Geological Map*, 1819. *Edin. Gaz.*, 1827.)

1. Geographical State and Circumstances.

Climate. Subject to cold winds; the prevailing are the N.E. and S.W.; former in winter, attended by severe frosts, twelve inches of ice, and the destruction of turnips. Milder in S.W. part of the county. In Sheppy and Thanet an early harvest, commences July 20. on the hills 1st August.

Soil. That of Thanet rich on rock chalk; of East Kent very various; chalk, loam, strong loam, hazel mould, stiff clay, flint, gravel, sand. Isle of Sheppy strong stiff clay; West Kent very various, but chalk and loam on chalk rock prevails; Weald chiefly clay, but mould, sand, and gravel in a few places. Romney Marsh sediment of the sea; a soft loam and clay.

Surface. Gently varied hills of chalk; Downs not so high as those of Sussex.

Minerals. Numerous chalybeate springs, at Tunbridge Wells the chief.

2. State of Property.

Much divided; number of yeomanry on the increase; 9000 freeholds, and a good deal of church and college lands; socage and gavelkind tenures prevalent.

3. Buildings.

Twenty or thirty noblemen's seats, and many seats of gentlemen and citizens, merchants, bankers, &c.; few modern-built farm-houses; old ones of oak or chestnut, and ill contrived; thatched; now improving considerably. Cottages are in general comfortable, built with bricks and tiles.

4. Mode of Occupation.

Size of farms greatest on poor lands; many farms from ten to fourteen acres each, few exceed 200 acres, some 600 to 1500 acres. Tithes in many parts collected in kind. Leases for fourteen years most common. Many church leases on three lives, some on twenty-one years, renewable.

5. Implements.

Kentish turnwrest plough almost the only one known in the county, drawn by four horses in heavy, and three in light, soils. Corn rakes in use after mown corn. Stubble rakes to drag stubble together; first threshing-machine erected at Betshanger by the reporter.

6. Enclosing.

No common-field lands but several commons; fences old and broad, belts of copse more frequent than thorn hedges. Water fences eight to fourteen feet wide, and from three to five feet deep in the marsh lands; post and rail fences prevalent in Romney Marsh. Neither fences, drains, nor water furrows wanted in Thanet, where corn is grown, and often, for years in succession, without manure.

7. Arable Lands.

Plough for all crops from five to seven inches deep. Fallows always made on poor lands. Rotations good. Peas of various kinds for podding are sown from the middle of February to the end of March. Leadman's dwarf and the early grey thought the most prolific. Canary seed and radish seed much cultivated in Thanet and East Kent for the London seedsmen. Radish seed sown in March, and crop seldom fit to reap before October, and is sometimes out on the fields at Christmas without receiving any injury from wet weather; requires much rain to rot the pods that it may thresh; will produce from eight to twenty-four bushels per acre. Spinach sown in March in Thanet; when in blossom the male plants (it being a dioecious plant) are pulled and given to pigs with advantage. Crop threshed on the field; produce, two to five quarters per acre. Kidney-beans much cultivated at Sandwich and in Thanet for the London seedsmen; plant from five to ten gallons per acre between the 8th and 20th of May; if earlier in danger of frosts; pulled up by roots from August to October, tied up in bunches and hung on poles to ripen; produce, ten to twenty bushels per acre. Cress and white mustard sown at the rate of two or three gallons per acre in March; reaped in July and threshed in the field; produce, eight to twenty bushels per acre. Weld sown among beans at the last hoeing in the beginning of July: ten or twelve lbs. of seed per acre; pulled when in bloom, which happens the second year, in July, and tied in single handfuls to dry; when dry bound in bundles, weighing thirty lbs.; sixty of these a load; produce, from one half to one and a half load per acre. Sometimes remains in stooks or barns for several years for want of a market; at other times 21*l.* per load; generally bought by speculating merchants, who supply the dyers with it as opportunity offers. Madder formerly much culti-

vated in the eastern part of the county, now given up; first cultivated on a large scale near Feversham.

8. *Grass.*

Hay chiefly produced in the marshes and the weald; pastures for dairying on every farm; but no dairy farms of any extent in the county; lands in Kent seldom changed from grass to arable, or the contrary. Hay-making badly conducted in most parts of the county, owing to the scarcity of hands. In Thanet and East Kent lean sheep and cattle brought in and put on the marshes and meadows till fit for the butcher.

9. *Gardens and Orchards.*

Near all the great towns a considerable portion of land devoted to the cultivation of vegetables; at Deptford and Gravesend are whole fields of asparagus, onions, cauliflowers, &c.; at Maidstone, many fields of from one to ten acres of fruit trees; apples, cherries, and filberts, raised among hops, the culture of which causes the former to grow with great luxuriance; common practice to plant 800 hop hills, 200 filberts, and forty apple and cherry trees per acre; the hops stand twelve years, filberts thirty, and the apples and cherries an unknown length of time. Sometimes apples and cherries in alternate rows with two rows of filberts between; filberts also raised among hops without any other trees; trees planted in holes two feet square, and two spits deep; pieces of rock taken out; trees stalked and their stems brushed over with lime and night soil, which is said to make them grow exceedingly. The golden rennet apple and black heart cherries, when a few years planted, found to gum and die; yet many old trees in full vigour: cherries do best with land laid down to grass; filberts answer on few soils; best cider maker Stone of Maidstone, mixes all sorts of apples; golden pippin makes good cider alone; no occasion to watch the fermentation of cider in order to rack it off at any particular time, as alleged in Herefordshire; eating apples sent to London by the hoys, and to the north of England by the coal vessels. Fruit orchards considered the most valuable estates. Tithe on fruit 2*s.* per pound on sales. Cherries require a deep soil, and bear well for thirty years; filberts a stony, shattery, sandy loam, rather inferior; they will not bear in rich soil; principal hop grounds about Canterbury and Maidstone, on deep rich loam with a subsoil of loamy brick earth; produce two to fourteen or fifteen cwt. per acre; average seven cwt.

10. *Woods and Plantations.*

Principal produce hop poles, fuel, husbandry wood, and some little for the dock yards; few artificial plantations.

11. *Improvements.*

Open drains made between flat ridges by deepening the furrows; turf and brushwood drains in use; chalk will answer when below the reach of frost; sea beach and refuse bricks also used. Several windmills which drive pumps to drain the water from marsh lands. Some bogs drained under the direction of Elkington, and now good meadows. Sea-weed used as manure; several thousand loads are sometimes thrown ashore by one tide, and washed away by the next; generally mixed with some yard dung, which it helps to rot; sand spread on stiff soils without being of any use; powdered kelp sown at the rate of twenty cwt. per acre on pasture, saintfoin, and clover, without any perceptible benefit; weeding a general practice; county long noted for its clean crops of corn. Thistles in grass lands mown while in bloom never come up again. Some land in Thanet recently embanked from the sea; bank thirty-six feet at base, nine feet high, and three feet wide at top; base of outside angle twenty-two, of inner eleven feet. Borders of the Medway below Rochester offer great scope for embanking, and perhaps warping.

12. *Live Stock.*

Neither a dairying nor grazing county: little attention paid to the breed of cattle. Romney Marsh breed of sheep remarkable for fatting early. Fine teams of heavy horses kept at a great expense. A few rabbit warrens; the rabbits within these few years affected with the rot. Formerly many pigeons, now few; few poultry but for home consumption; few bees.

13. *Rural Economy.*

Labour generally done by job; servants, scarce, dear, and saucy.

14. *Political Economy.*

Roads generally good, formed of chalk and flints; or limestone and gravel; roads in the weald very bad for want of materials. As clay is there abundant, if duty taken off bricks they might be burned on the spot and the roads paved; 340,000 will pave a road one mile long and nine feet wide. No canals, but one near Gravesend; fairs and weekly markets very numerous. Agricultural commerce of county consists chiefly in exporting corn to London markets. Manufactures trifling. At Down and Maidstone paper mills; at the Isle of Grain salt works; in the Weald iron works; and at Whitstable and Deptford copper works. Gunpowder made at Deptford and Feversham; calicoes printed, and linens whitened, at Crayford. Poor well taken care of; earn from forty to sixty pounds per annum, by hop picking and other rural employments for their wives and children.

15. *Miscellaneous Observations.*

Kent Agricultural Society, established at Canterbury in 1793, by Sir E. Knatchbull and F. Honeyman, Esq. Some potatoes dried on an oat kiln were found to retain their properties during long voyages, as attested by letters from the victualling office.

7781. ESSEX, 942,720 square acres, the greater part marshy grass lands near the Thames, and the rest arable lands of a mixed culture, chiefly of corn and herbage. It is an old cultivated county; contains many small gardens and seed-farms near the towns, and is one of the few districts in the south-east of England where the plough is drawn by only two horses. (*Young's Survey*, 1810. *Marshal's Review*, 1818. *Smith's Geological Map*, 1820. *Edin. Gaz.* 1827.)

1. *Geographical State and Circumstances.*

Climate mild; north and east the prevailing winds, which bring blights to plants, and cold and hoarseness to animals; ague general both in the high and low lands.

Soil almost every where a loam, and more generally heavy than light. Generally well adapted for grass or corn.

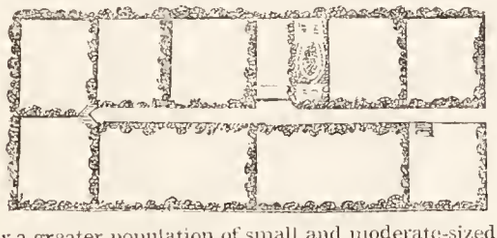
Surface beautiful about Havering (Have a ring) from Romford to Lord St. Vincent's and Lord Petre's, both fine seats on the Stour; also very fine from Sharbury to Harwich.

Water abundant, in rivers, creeks, and springs.

2. *State of Property.*

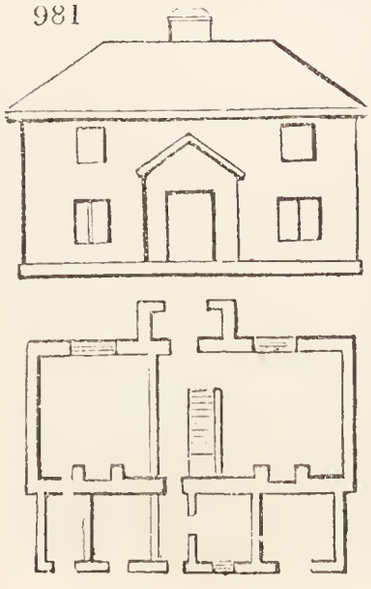
Estates vary much in size from 5*l.* to 20,000*l.* a year: in no

980



county a greater population of small and moderate-sized farms occupied by their owners. Managers of large estates sometimes attorneys, capital farmers, or private gentlemen. Farmers of all sorts; land held by farmers on short leases, often at will, sometimes on eight, ten, or twenty-one years' leases. Some of the seed or garden farms neatly laid out (*fig.* 980.).

981



3. *Buildings.*

Wanstead one of the largest houses in the kingdom; in 1823 pulled down. Audley-end well known. Misty Hall a most striking place. Gossfield and Thorndon, the latter finely wooded by the scientific Lord Petre. Many others: but some districts of the county with very few seats. Farm houses good, outbuildings numerous and convenient; expensive rick covers and barns. Cottages not very good; some built on a better plan (*fig.* 981.) by the Duke of Buckingham, with a garden of one fourth of an acre to each. Joseph French, at East Horndon, finding labour dear, and servants difficult to be got, took the plan of fixing them by building them cottages and attaching gardens.

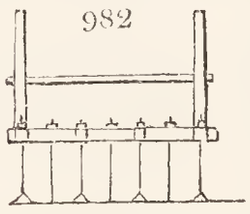
4. *Occupation.*

Some of the largest farms in the kingdom; so early as 1767 Arthur Young found some at 1500*l.* and 200*l.* a year. Lord Braybrook farms 1100 acres, Lord Petre 1468. Many farmers men of information, ingenuity, and exertion. Tithes average 4*s.* 9*d.* to 6*s.* per acre when compounded for. Many farms held on running leases, terminable or renewable every seven years. The refusal of leases increasing.

5. *Implements.*

Essex plough, a large unwieldy implement, with two wheels. A great variety of swing ploughs, all bad compared with the Rotheram kind or Northumberland plough. An iron road cleaning plough by Western; a concave roller and scraper attached, delineated in the report, but no reason given for the shape. Many cultivators, scufflers (*fig.* 982.), &c. delineated, and a donkey hoe. Some of Pasmore of Doncaster's threshing-mills, and winnowing machines, in use. The Scotch cart, plough, and other improved implements introduced by Western. Flemish scythe tried, but found not to answer; did not understand its use. Pattison of Maldon has made an ingenious improvement of the common sowing basket; he has made the bottom a wire sieve for sifting out the seeds of weeds in the motion of sowing, and attached a cloth bag beneath for catching them. An ant-hill machine. Good specimens there of amateur improvements on implements.

982



6. *Enclosing.*

Essex for ages an enclosed county; still some waste to enclose. Hedges broad and mixed plants, and with pollard trees.

7. *Arable Lands.*

Cultivated better than nine in ten of the other counties: plough with two horses or three horses abreast without a driver; fallows universal; rotations good; potatoes cultivated to a great extent for the London market. Carrots in various places planted for seed three feet apart; produce five or six cwt. per acre, sometimes ten or twelve; rye-grass disliked generally; wire-worm comes after it, and is sure to destroy wheat. Rape, ribwort for seed; hops in a few parishes. Saintfoin succeeds well on poor calcareous soils; some lucerne. Wire-worm often injurious to young wheat, after clover leys; rolling and treading lessens its effects; on strong soils slugs very troublesome. Famed for the excellence of its wheat, which always obtains a high price in the London market.

8. *Grass Lands.*

Extensive marshes and salt-ings (or salt-islets).

9. *Gardens and Orchards.*

Some cherry orchards at Burnham; many cottages without gardens.

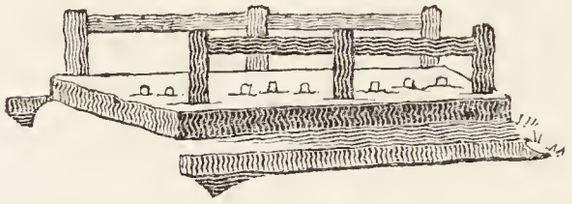
10. *Woods and Plantations.*
Fifty thousand acres, chiefly natural and ornamental scenery. Some fine old elms at Gossford. At Saint Osyth the three original Lombardy poplars which Lord Rochford brought from Italy about 1758, and from which the greater part of those in the kingdom have been raised; they are seventy feet high and seven feet three inches in circumference, five feet from the ground; a Portugal laurel more than fifty-two yards in circumference, and a very large *Arbutus*. The largest abele trees in England at Bellhouse, Aveley; large elms; Lord Petre has sold thirteen oaks for 600*l*. at 13*l*. a load including top and bark. Oaks at Hatfield worth 100 guineas each. Hatfield broad oak celebrated, but now in ruins. An oak at Wimbish increased in girth four and a half inches in thirteen years; a larch, two feet nine inches in the same time; the larch, however, was younger.

11. *Wastes.*
Fifteen thousand acres; said that in James the First's time almost the whole county was waste.

12. *Improvements.*
A good deal of draining; a machine in use like the Flemish mouldebaert (*fig.* 59.) for lowering the surface of ploughed lands at those places where they intend making cross-furrows to carry off the water from the regular furrows. The draining wheel (3978.) in use, inventor not mentioned. Chalk much used as a manure.

13. *Live Stock.*
Essex never famous for this branch. The largest dairy farms at or near Epping, famous for its butter and cream; no particular sort of cows kept; Derby and Leicestershire breeds preferred, but any taken; fed on natural and artificial grasses in summer, and hay and grains in winter: dairies built on the north sides of the farm-houses; milk kept in troughs lined with lead, which hold nine to ten gallons of milk, five to six inches in depth. This in winter is skimmed four, and in summer two or three times, and the cream, after being kept three or four days, churned; milk given to hogs. A few cows kept for milk; in other places for suckling calves, and feeding on the marshes. Western has the finest swine in the county; feeds them in what he calls a hog case; a cage which effectually prevents the animal from taking exercise. A hog half fat put into a case gains fifteen pounds a week, if well fed with barley meal and water. A miller, near Maldon, has made a treble case on wheels, to keep moving about on grass land, for its improvement. A portable bridge, carried on a pair of wheels, for passing sheep over marsh ditches, in use by Wakefield of Bournham. (*fig.* 983.) A decoy for ducks and other aquatic birds in Mersea island, the largest in the county. Every person that approaches a decoy takes a piece of lighted turf stuck

983



on a table fork in his hand, to prevent the ducks from smelling man. Without this caution they will quit the pond. A decoy at Goldhanger, at which one waggon load and two cart loads of dun birds were taken at one haul of the nets; but the disturbance so frightened such as escaped, that no more were taken that season. Seven fish ponds at Spaines Hill for carp, tench, and eels. A chain of ponds at Leigh's Priory, belonging to Guy's Hospital, near a mile in length, and occupying about thirty acres, once completely sluiced and carefully cultivated, now dry and neglected.

14. *Rural Economy.*
Labour done generally by the piece.

15. *Political Economy.*
Roads mostly good; few canals; various fairs; and some cattle markets. In the creeks of Crouch, Blackwater, and other rivers and estuaries, considerable quantities of oysters are deposited for breeding. The produce is afterwards dredged and deposited at Wivenhoe and other places for feeding. What are called Colchester oysters are fed there, and sent to Hamburgh, Flanders, and France, in time of peace, as well as to London. Oysters are also dredged on the Hampshire coast, and fed in the Coln, or Colchester beds. No distinct account of the oyster economy, however, is given in the report. There are salt-water ponds for various sorts of sea fish in Foulness island; the fish are caught in weirs on the extensive sandy coasts, and deposited, when plentiful, in these ponds, whence they are dragged for with small nets, as wanted.

Manufactures of woollen have existed from time immemorial in the county; also of sacks, hop bags, calicoes, baize, lime, bricks. Much baize made at Colchester, Coggeshall, and other places, for Spain. A society of agriculture at Chelmsford.

7782. HERTFORDSHIRE. A surface of upwards of 400,000 acres, the north part forming a chalky ridge, which extends across the kingdom in this direction; the general features are rich, woody, and the agriculture various, chiefly tillage; the corn produced equal in quality to any in the kingdom. Ellis, a well known agricultural author, farmed in this county. (*Walker's Report*, 1795. *Arthur Young's Survey*, 107. *Marshal's Review*, 1818.)

1. *Geographical State and Circumstances.*
Climate, dry and healthy.
Soil, chiefly loam and clayey loam, next chalk, and a small part bordering on Middlesex gravel; vales, rich sandy loams, chiefly under pasture, and woods very beautiful. Naturally barren, but rendered fertile by careful cultivation.

2. *Property.*
Much divided, the county being a favourite one for wealthy persons building villas and other retreats. 7000*l*. a year the largest estate; great part copyhold, which sells here at six years' purchase less than freehold.

3. *Buildings.*
Hatfield, Cashiobury, Ashridge (partly also in Bucks), Gorhambury, Brocket, the Hoo, the Grove, Gilstone, Ware Park, &c. noble mansions. Brown's farm-yard, at North Mims, one of the best in the county. Immense barns at North Mims and Bedfordbury. Gutters to the eaves of farm buildings at Alkenham; wide fattening stalls, with conveniences for giving hay, water, and oil-cake. Cottages seldom with land attached. A moveable sheep-house at Hillhouse, a cumbrous expensive affair, of which plans, sections, &c. are given in the report.

4. *Occupation.*
Farms small, largest 500 acres; many of the very small farmers who rent 30*l*. a year worse off than day labourers. Sir John Sebright, of Beachwood, a scientific breeder, farms 700 acres, 300 of which are in arable and well cultivated. The Earl of Bridgewater, at Ashridge, farms 500 acres, besides the park of 1080 acres. The Marchioness of Salisbury farms 290 acres, besides the park of 1050 acres, and has made many curious experiments; a prejudice against leases.

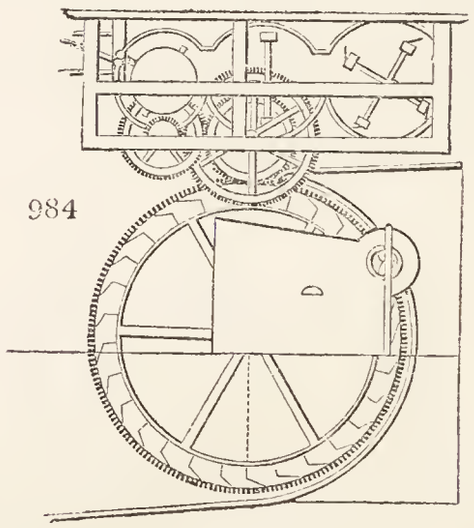
5. *Implements.*
Plough large and unwieldy, with two large wheels, the same as figured in old farming books 150 years ago. One or two threshing machines of Meikle's kind. (*fig.* 984.)

6. *Enclosures.*
Various, but still some commons and open fields; old fences of mixed species; new ones of thorn; planting well understood, but the cut with the bill made in a direction downwards instead of upwards, as in Berwickshire, by which the stem throws out a brush of small twigs at the wound, instead of a few strong healthy shoots.

7. *Arable Land.*
By far the greater part of the county in tillage: crops chiefly wheat, barley, and oats; turnips and clover supposed to have been introduced in the time of Oliver Cromwell: depth of ploughing generally four or five inches. Greg, who has written a tract on managing clay lands without naked fallows, ploughs as deep as the staple will admit. Rotations various, generally with a naked fallow, once in three, five, or seven years, or oftener. Combing or ribbing in use in some places instead of drilling. Turnips cultivated broad-cast, and very poor crops produced; the introduction of turnips in this county attributed to Cromwell, who is said to have settled 100*l*. a year on the farmer who first grew them. Cabbages grown to a large size by the Marchioness of Salisbury, for cows; large red sort preferred. Carrots, parsneps, beets, &c. cultivated by the Marchioness on her experimental farm. Good saintfoin on the chalks. Drilling corn crops with Cooke's drill practised in various places. Watercress for the London market, cultivated in the streams at Rickmansworth. Sixty acres of furze for faggots at Ashridge.

8. *Grass.*
Quantity small, and chiefly a narrow margin near Barnet,

984



on which hay is grown for the London market; some good meadows on the Stort.

9. *Orchards.*
Apples and cherries abound in the S.W. corner of the county on farms of from twenty to fifty acres. In ten years after planting, cherry trees begin to bear; produce till the twentieth year, six dozen pounds; when full grown, fifty dozen pounds; price, ten-pence to three shillings a dozen. Caroon, and small black, the favourite sorts. Kentish will not thrive here. None of the apples for cider: orchards kept in grass, but not mowed.

10. *Woods.*
The copse kind abound in the northern and in many parts of the county; produce faggot wood and hurdles; cut at twelve years; black willow, ash, and hazel, best for hurdles; alders bought by turners and patten-makers. Fine woods, natural and artificial, at the Earl of Clarendon's, the Grove, near Watford. A superb oak at Panshanger, Earl Cowper's; seventeen feet round at five feet from the ground; called the great oak in 1709: on a soil gravelly above, but, doubtless, clay below. The timber in Moor Park of great antiquity, and in a state of decay; many immense pollards; and, on the whole, one of the most forest-like parks near London. Vast oaks and beeches at Ashridge and Beechwood. Beech excels there; also cedars and the oak, ash, larch, spruce, and common pine excellent. Beech sold to turners, chair-makers, and for barrel staves.

11. *Improvements.*
Underdraining clay by numerous parallel cuts filled with straw, wood, or stones general: manuring well understood; much brought from London of every sort; bones, soot, sheep trotters, night soil, oil-cake dust, rags, leather clippings, furriers' clippings, horn-shavings, malt-dust, hair, sticklebacks, &c. Top dressings more frequent than in any other county. Chalk a very common manure on clayey soils; laid on unburned, and left on the surface to be pulverised by heat and rains, or frosts and thaws; then harrowed with a bush harrow, to spread it, and ploughed in. Some irrigated meadows at Rickmansworth and other places; but the frequency of mills is against the process.

12. *Live Stock.*
All the spare clover, hay, and straw carried to London, and manure brought out in return. Sir J. Sebright prefers Suffolk cows and horses, and uses the Wiltshire sheep. A good many house lambs suckled about Rickmansworth, fed with grains and malt-dust in winter. Folding sheep generally approved of. Soiling with clover and tares common. Grey works Suffolk oxen in harness, four to a team. Hon. G. Villiers prefers the Glamorganshire oxen for work; and thinks stall-fed oxen can hardly be kept too warm; prefers oil-cake for finishing to every thing else; Lady Salisbury has the wild breed of pigs, which fatten to forty-eight stone; feeds on lettuces, which is found to answer well. Stevenson, the bailiff, bred a gardener, which renders him a superior cultivator of green crops. Lord Clarendon feeds deer (7373.) and sells them. Poultry at the Grove kept in wheeled coops about twelve feet long and two and a half wide, boarded on one side and open on the other; these are wheeled up and down the park, and a boy attends them to keep away hawks. In the poultry-yard distinct houses for all sorts of fowls; the roosts so contrived that they may not dung on one another.

13. *Rural Economy.*
Ploughmen generally hired by the year.

14. *Political Economy.*
Good roads; few manufactures excepting plaiting straw, which is very general in the county, especially about Dunstable, St. Albans, Redburn, &c. Weak wheat straw from chalky and white land, and such as grows under trees or near hedges preferred. The plaiters give from two-pence to four-pence a pound for it, and sort it themselves. Much malt made about Ware and Hertford for the London market.

7783. BUCKINGHAMSHIRE. 478,720 square acres of hilly surface, and chiefly of clayey or loamy soil; a considerable part chalky, and the agriculture nearly equally divided between tillage and grass. (*Survey by St. John Priest, Secretary to the Norfolk Agricultural Society*, 1810. *Malcolm's Survey*, 1794. *Marshal's Review*, 1818. *Smith's Geological Map*, 1820. *Edin. Gaz.* 1827.)

1. *Geographical State and Circumstances.*
Climate, cold and windy on the Chiltern Hills.
Soil, chiefly clay and chalk, with some gravelly loam; Chilterns wholly chalk; vales generally clay.
Minerals. Some ochre, used in painting; a quarry of good marble at Newport, but too deep to be profitably worked; a freestone quarry near Olney.
Water. Numerous rivers and canals for sending produce to market; but often filled with weeds, bushes, and other obstructions, which, after heavy rains, occasion frequent floods: a "commission of waters" proposed by the reporter as a remedy.

2. *Property.*
Some large estates, as those of the Dukes of Bedford, Buckingham, &c.: tenures very various: a description of lands here called yard lands (*virgata terræ*), which entitle the holders to certain rights of common.

3. *Buildings.*
Stowe, and Ashridge (the latter partly in Herts), the first of Grecian, the other of Gothic architecture, the two noblest mansions in the county. Tyringham, Wycombe Abbey, &c. also very good houses, and many others: some good farm-houses, and the dairies very clean and neat; churning often performed by horse machinery: the churns of the barrel kind. Lord Carrington has built some good farmeries, and the Duke of Buckingham some very complete cow-houses. Drake has a good circular pigeon-house, with brick cells or lockers in rows, with shelves before for the pigeons to light upon; frequently white-washed, to keep them free from bugs. A foot bridge at Fawley Court, moveable upon two pivots at its ends, and being heavier on one side than the other, always hangs perpendicularly, excepting when any one walks upon its light side, when the weight of the person keeps it flat: hence it admits the passage of men, but not stock: cottages good, and mostly with gardens attached: some at Brickhill worse than piggeries. Sir J. D. King gives premiums for the best cultivated gardens; also gives clothing and other rewards for good conduct in servitude.

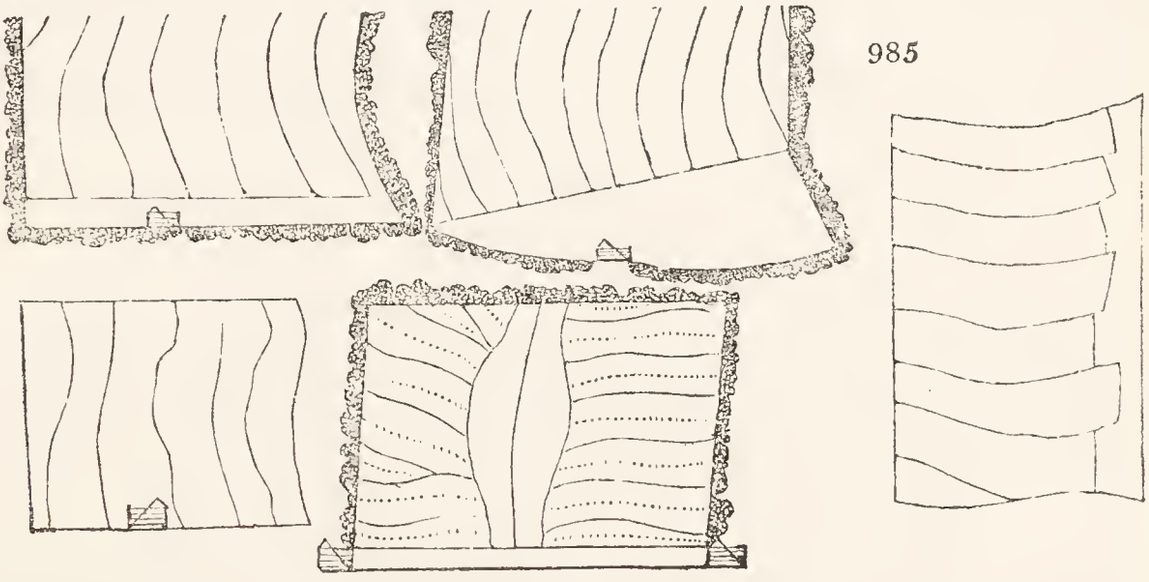
4. *Occupation.*
Size of farms moderate: number in the county 2039; one of 1000 acres, one of 900, four or five between 600 and 700 acres, ten between 500 and 600, twenty-four between 400 and 500, and the rest from 400 down to ten acres; average, 179 acres. Westcar, of Kreslow, a celebrated grazier, occupies 900 acres, of which only between sixty and seventy are arable. Very few leases, and those given with very objectionable covenants. Lord Carrington and other more enlightened proprietors grant leases.

5. *Implements.*
Swing ploughs and four horses in a line common.

6. *Enclosing.*
Has gone on rapidly; old hedges mixed, and with many ash and oak pollards.

7. *Arable Land.*
Ridges high, crooked, with waste spaces between, around, or at the ends (*fig.* 985). Fallow in general every third year,

985



most common rotation fallow, wheat, beans: chief grains, wheat and barley; beans drilled and hand-hoed: some turnips on the light lands.

8. *Grass.*
Pastures a prominent feature; those in the vale of Aylesbury, especially thence to Bicester, very rich; generally fed, but occasionally mown. Removing ant-hills called banking, a piece of management to which the renters of grass lands are generally bound in their leases. They are removed by skinning, gelding, or gutting, and kept down by rolling; thistles are spudded; size of grass fields from 20 to 300 acres.

9. *Gardens and Orchards.*
Few of either worth notice: cherries are grown at Hackwell Heath, for the London and Aylesbury market.

10. *Woods and Plantations.*
Willow pollards planted round the margins of fields, on soils suitable for hurdle wood. Birch, the most common timber, very abundant; chiefly used for manufacturing chairs: woods constantly full of young plants from the mast, which grow up and succeed those which are felled; thus the same timber on the same soil and surface for ages. At Shardeloes, a beech seventy-five feet from the ground, to the first bough: oak and beech trees in Ashridge Park, containing from three to six loads of timber: very fine beeches at Missenden; mast given to pigs.

11. *Improvements.*
Draining much wanted; well performed on some hogs on the Duke of Buckingham's estates by digging a well and boring in the bottom till the spring was tapped, and then leading it off in an underdrain; paring and burning in general use for bringing grass land to tillage: chalk much used as a manure, sixty or seventy loads per acre, once in twenty-one years, or forty once in twelve years; allowed to lie on the surface for one winter at least before being ploughed in. Only one instance of irrigation worth notice, which is at Cheynies, by a tenant of the Duke of Bedford.

10. *Live stock.*
Cattle kept chiefly for beef and butter, seldom for cheese or work; Hereford oxen preferred, and next the Devon; Holderness cows for the dairy; some prefer the long horned Lancaster, and others the Suffolk; many of the Holderness cows, after being kept a few years, are sold to the London cow-keepers; men are generally the milkers; only one instance found of women performing that operation. Earl of Bridgewater keeps eight teams of Welsh, one of Sussex, and one of Durham oxen, all yoked as horses; five used in the cart, and four in a plough; a few other gentlemen have ox teams; cattle generally fed off in summer; cows kept during winter fed on straw, hay, and oil-cake; little herbage or roots in use; milk

generally kept in flat vessels of lead; some wooden trays, tinned, in use; skimmed every twelve hours; in some few places three times a day; cream from first two skimmings kept by itself; the third skimming makes what is called after-butter; skimming dish, if tin, circular, a foot in diameter, with holes in it, and a handle upon the top of it; butter made twice a week, in churns of the barrel kind, usually turned by a horse; time allowed for the butter to come, an hour and a half; butter made up in lumps of two pounds each, and sent to London in square flat baskets, eleven inches deep, holding from thirty-six to 120 pounds. They have each on three of their sides three marks, the number of pounds the basket holds; a letter, denoting the farmer's name from whom it is received, and the name and residence of the carrier. The baskets and butter cloths are the property of the carrier; all that the farmer has to do is, to carry his butter to the nearest point where the carrier passes, and to make his agreement with his butter-factor in London, and receive monthly, or otherwise, the payment. Quantity of butter made, six pounds per cow per week, at an average, when in good keep, and not nearly dry. Calves generally sold to sucklers; a few suckled in the county, and a few brought up as stock.

Sheep. Culture directed to the fattening of lambs, and the breeds preferred are the Dorset, and next the Gloucester and Berkshire.

Horses generally soiled; five or six put to a plough in many places, and never less than three. A team of asses kept by the Duke of Buckingham for the use of his garden; many used at the potteries at Amersham.

Hogs, an important article on account of the milk from the dairies; breed the Berkshire, and next, the Chinese and Suffolk.

Ducks, a material article at Aylesbury and places adjacent; breed white, and of an early nature. They are bred and brought up by poor people, and sent to London by the weekly carriers. One poor man had before his door a small pit of water, about three yards long and one yard broad: at two corners of this pit are places of shelter for the ducks, thatched with straw; at night the ducks are taken into a house. In one room belonging to this man (the only room he had to live in) were on the 14th of January, 1808, ducks of three growths, fattening for the London market; at one corner, about seventeen or eighteen, four weeks old; at another corner, a brood a fortnight old; and at a third corner a brood a week old. Ducks six weeks old sold at that time for twelve shillings a couple. Besides the above, there are other persons who breed many more ducks than the person now mentioned, and, as far as it was possible to discover, this person sends 400 ducks in a year to London. Allowing, then, forty persons to send only as many, at an average of five shillings per duck, the return of ducks from Aylesbury alone will amount to 4000*l.* per annum. This return has been magnified into 20,000*l.* per annum.

13. *Political Economy.*

Bye-roads extremely bad and dangerous; difficult to be discovered from mere drift ways; turnpike-roads, not to be commended; canals various and useful; grain sent to London at two shillings per quarter. Box clubs generally established for the poor; no agricultural society in Bucks. Principal manufactures paper and lace.

14. *Miscellaneous.*

In calculating the number of acres, Priest the Reporter tried the mode, first shown by the Bishop of Llandaff, of weighing the portion of paper containing the map; he next took an exact copy of Cary's map upon paper, by tracing its outline, after the map was strained upon a canvass blind at a window. This copy was cut out with great exactness by a sharp pointed knife, and then divided into pieces, which were so neatly laid together, as to form a right-angled parallelogram: another piece of paper was cut into the form of an assumed parallelogram longer than necessary, upon which the pieces of the copy were laid, and cemented by gum-water, so as to fill all parts of a right-angled parallelogram shorter than that assumed; the difference between the assumed parallelogram and that formed by the pieces of the copy of the map, was accurately measured and subtracted from the assumed parallelogram, and the remainder gave 391,040 acres, the measure of the number of acres in Bucks. Thus then we have the number of acres taken from Cary's map, by weight 396,013, by measure, 391,040. From which, if we take an average, we shall probably state it as accurately as it can be found to be, 393,526 statute acres; which, for the sake of round numbers, we will call 393,600 statute acres.

7784. BEDFORDSHIRE. An irregular parallelogram of 290,000 acres, not much varied in surface, and for the most part of a clayey soil. The agriculture chiefly directed to the raising of wheat, barley, and beans, but of an inferior description in many respects. Little pasturage; scarcely any market orchards, but good vegetable gardens established at Sandy, on the east of the county, from time immemorial. Great exertions made in every department of culture by the late and present Duke of Bedford, by whom were employed many valuable men in conducting improvements, as Farey, Smith, Salmon, and Pontey. A valuable set of experiments on grasses, conducted by Sinclair under the direction of the present Duke. (*Stone's Bedfordshire*, 1794. *Batchelor's Bedfordshire*, 1808. *Marshal's Review*, 1818. *Smith's Geological Map*, 1820.)

1. *Geographical State and Circumstances.*

Climate, mild, genial, and favourable to the growth of vegetables; rather later than Hertfordshire; prevalent winds S.W.; coldest winds N.E.

Soil, chiefly clay, next sand, and lastly in the southern extremity embracing Herts, chalk. Some of the sands grey silts, and producing nothing but heath, others more loamy, as about Sandy, which is supposed to contain the best garden-ground in the county.

Minerals, some ironstone; limestone abounding with cornua ammonis and other shells, petrified wood, gryphites belemnites; freestone, chiefly lime, at Tatternhoe.

Water. Principal river the Ouse; several mineral springs.

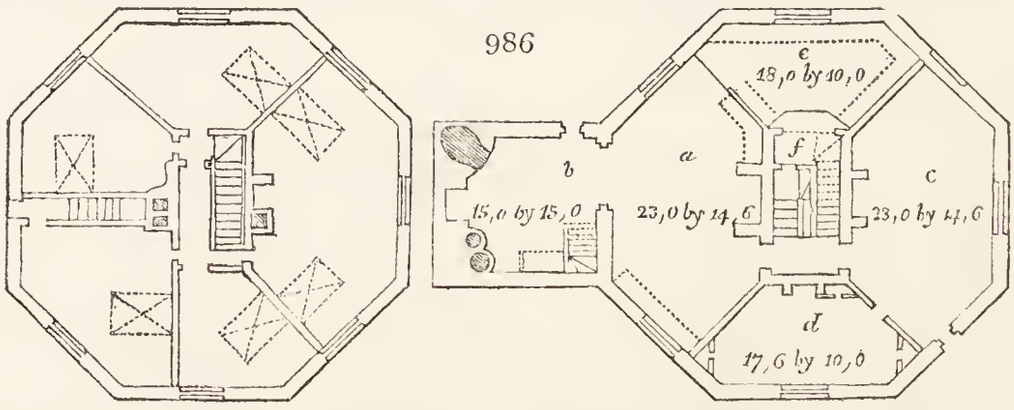
2. *State of Property.*

Duke of Bedford's estates the largest, next Lord St. John's and Whitbread's: united rental estimated at 40,000*l.* a year, Estate managers attorneys and considerable farmers.

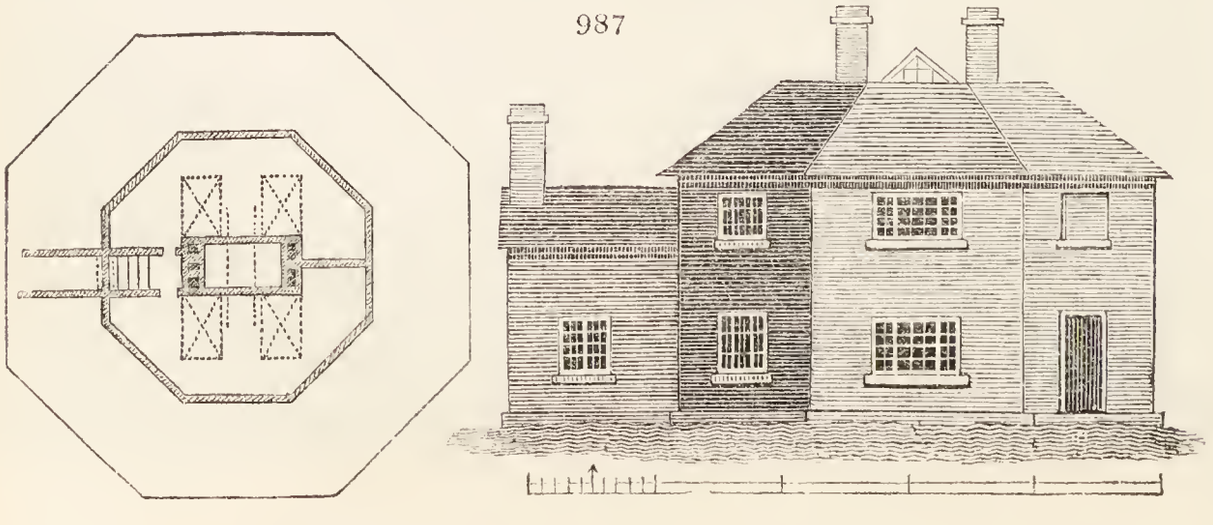
3. *Buildings.*

Several farm-houses were formerly the seats of gentlemen who farmed their own estates. Farm-houses in general badly situated, seldom at the centre of the farms to which they belong, and generally consist of piecemeal erections. Francis, Duke of Bedford, erected an octagonal farm house, on a most commodious plan. (*fig.* 986.) On the ground floor it contained a large kitchen (*a*), bake and brewhouse, and washhouse (*b*), a hall or master's room, with a cellar under (*c*), a good parlour (*d*), a dairy (*e*), besides a pantry (*f*), closets, and beer and ale cellar under. On the first floor were five, and on the second (*fig.* 987.) two good bed-rooms. The expense of this house on the octagonal plan was 671*l.*; had it been built in the

986



987



square form it would have cost 733*l*. It is built of brick, slated, and was designed by Mr. R. Salmon, a well known mechanist, resident at Woburn. The same accommodations on a square plan forms a house more convenient for placing furniture (*fig.* 988.) Wattle and dab; that is, clay plastered on hedge-work of splinters, or on wood frame-work, and also the *Pisé* manner of clay-working, in use in some places, both for farm-houses and cottages. *Pisé* walls found warmer and cheaper than any other, and when whitewashed said to make good cottage walls.

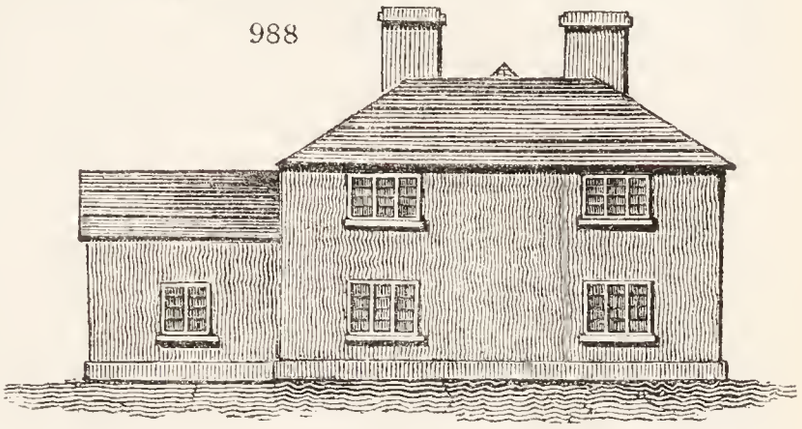
4. *Occupation.*

Many farms of from 200 to 500 acres; average 150 acres; Duke of Bedford's farms generally of the average size. Farmers much improved by the example of Woburn and the annual meetings. The experiments made by Francis Duke of Bedford were to ascertain the quantities of hay consumed by working oxen; comparison between large and small cattle as to food; comparative value of different foods, &c. Tithes mostly in lay hands; farms held generally from year to year, some on leases of fourteen or twenty-one years.

5. *Implements.*

Plough of the swing kind, with a wooden board and a wedge nailed on as a mould board, one fixed handle, and a loose one called a plough staff; the whole singularly rude, though in general use throughout the county. Improved forms of all machines introduced by the Duke of Bedford's Northumbrian manager, Mr. Wilson, and other enlightened men. A good straw cutter winnowing machine, a hay tedder, and also an excellent weighing machine, invented by the late Mr. Salmon, an engineer of genius, resident on the Duke's estate, and employed by him as an agent.

988



6. *Enclosing.*

Formerly three fourths of the county unenclosed, now chiefly enclosed.

7. *Arable Land* wretchedly ploughed.

Fallows, which occur on the clays generally once in three years, badly worked. Usual crops are fallow, wheat, beans, or fallow, barley, beans; turnips common on the sands and chalks, sown broad-cast, and hand-hoed. Chiccory was tried by the Duke of Bedford, who found it yield ample produce; had twelve acres which, in 1797, kept six sheep per acre from the second week in April till Michaelmas; four and a half kept ten sheep an acre from the second week in April till 22d July, and then seven per acre to end of October. Sheep thrive well and free from diseases.

8. *Grass Land.*

Of very limited extent, and in many places covered with sedge (Carex), and ant-hills.

9. *Gardens and Orchards.*

Gardens of Sandy and Girtford long celebrated for the excellence and abundance of their culinary vegetables. Soil a deep sand, of a yellowish brown colour; products peas, beans, cucumbers, potatoes, parsneps, and carrots, radishes, cabbage plants, and turnips, sent to market in all directions to the distance of sixty miles. Cucumber chiefly to London, and sold at ten and twenty shillings a bushel for pickling. Orchards small. Potatoes, gooseberries, and other small fruits grown in cottage gardens.

10. *Woods and Plantations.*

About 7000 acres, situated on the slopes of hills on cold marly clays. Various new plantations formed by the principal proprietors, especially the Duke of Bedford. Furze grown on some of the sandy hills, for burning lime. Some fine trees of the silver fir, and others of the genus *Pinus* at Woburn, planted under the direction of the celebrated Miller; a fine beech, figured by Pontey in his *Forest Pruner*.

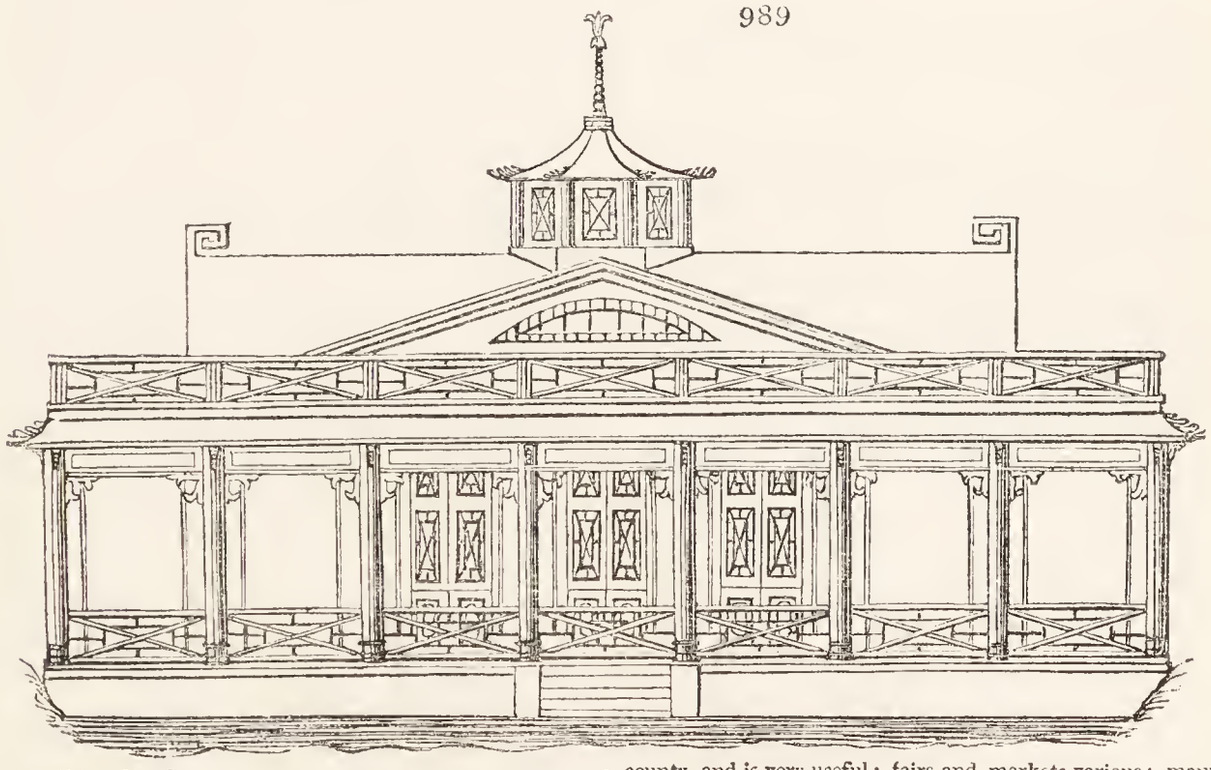
11. *Wastes.*

Four thousand acres of chalky down at Dunstable, not much any where else.

12. *Improvements.*

A good deal drained, especially bogs. Elkington's mode said to have been tried with very partial success. Bush and straw-draining attempted on the clayey soils, and the mole plough a good deal used in the furrows. Irrigation introduced by the Duke of Bedford, and various examples are to be found in different parishes on his Grace's estates. Peat is used as fuel, and also burned for the ashes as a manure; ample experiments made on manures, by Dr. Cartwright, at Woburn; but no agricultural experiments on a small scale can be depended on. The dairy at Woburn (*fig.* 989.) is a fanciful structure in the Chinese style; but the plan and arrangement is not well calculated for keeping milk and butter cool and sweet.

989



13. *Live Stock.*

Cattle a mixed breed of long and short horned Alderney, &c. Some dairying conducted as in Buckinghamshire. Some sheep, but of no particular breed; folding generally practised and approved of; horses a heavy breed from Huntingdonshire; rabbit warrens destroyed as much as possible; geese kept by many from an idea that they preserve the health of the pasturing animals where they feed. Turkeys and pigeons kept before the enclosure in various places, but now much on the decline. Bees kept by a few cottagers and small farmers.

14. *Rural Economy.*

Husbandry business generally performed by day labourers; though on most large farms a horsekeeper, cowkeeper, shepherd, and kitchen maid hired by the year.

15. *Political Economy.*

Almost all the cross roads, and many of the main roads, very bad. Grand Junction Canal passes through a part of the county, and is very useful; fairs and markets various; manufactures chiefly plaiting of straw and lace; children of ten or twelve years of age acquire the art of plaiting, while their mothers sort and bleach the straw. Lace-making a more sedentary employment, and the women and children generally appear sickly. There are school-mistresses for teaching both straw plaiting and lace-making. Begin to learn to make lace at six or seven years of age; do little good for two years, at ten years earn two shillings a week, at sixteen as much as can be made by the business, or nearly six shillings a week; work in summer from six o'clock in the morning till sunset, and in winter from nine till eleven at night; maid servants scarce in consequence, but poor rates kept down. Some rush mats made near the Ouse to the west of Bedford.

Bedford House of Industry.—"The poor in the house are employed in the following manner: A manufacture of coarse baize furnishes employment for all the boys five years of age, and some of the men; the remaining part of the men cultivate

an acre and a half of garden-ground, and weed and keep in order twenty-five acres of sward land attached to the house. The old women spin flax to make linen for the use of the family; the other women (exclusive of those engaged in domestic concerns), and girls above six years old, make thread lace. One-sixth of the earnings of the poor is paid weekly to those who work, by way of gratuity. The Governor of the House of Industry adds, that the above employments have answered the most sanguine expectations of the directors of the establishment."

Many useful benefit clubs.

16. *Obstacles to Improvement.*

Want of knowledge and leases. Mice generally destroyed by professional rat catchers; some farmers keep ferrets for the rats. Larks destroy a great deal of new sown wheat. They, with other birds, are very abundant in Bedfordshire, especially about Dunstable, where they are caught in traps, in quantities for the London market. Wire-worms supposed to be increased by artificial grasses.

17. *Miscellaneous.*

An agricultural society founded by the Duke of Bedford in 1801; various premiums offered and paid, to the extent of 100*l.* a year in some years. Cheap publications on agriculture, it is thought, would be a considerable means of improvement.

7785. HUNTINGDONSHIRE. A dull flat surface of above 200,000 acres; till Edward the First's time one continued forest. The name of the county is said to be derived from the facility it afforded for hunting. The soil is almost uniformly good, but injured by water; it is chiefly under tillage, but remarkable for no excellence in agriculture. Rape-seed and mustard are more cultivated than in most other counties, and timber more rare. (*Stow's Huntingdonshire*, 1793. *Maxwell*, 1793. *Parkinson*, 1811. *Marshal's Review*, 1813. *Smith's Geological Map*, 1821. *Edin. Gaz.* 1827.)

1. *Geographical State and Circumstances.*

Climate, tolerably healthy, considering that the east part is skirted by fens, and but a small part supplied by water from springs.

Soil. Loam prevalent, but the county every where spotted with roundish patches of clay, sand, marl, fen, moor, or lakes, which, in the map of soils annexed to Parkinson's Report, assumes a very singular appearance.

Water chiefly supplied from ponds; Ouse and Nene the only rivers; the meres are natural ponds, surrounded by reeds and other aquatic plants, and a considerable zone of marsh or bog, according as the soil may be loam or sand. Whittlesea Mere contains 1570 acres, but is not above two feet deep. It abounds with fish and wild fowl.

2. *State of Property.*

Old enclosed lands in the hands of a few proprietors; half the county freehold, the remainder almost all copyhold.

3. *Buildings.*

Farm-houses very inconveniently situated, partly owing to the want of high and dry sites on central parts of farms; some good cottages lately erected as the only means of retaining farm servants for any length of time with the same master.

4. *Occupation.*

Many large farms, though small ones predominate; leases frequent; tithe in kind.

5. *Implements.*

Plough, with one handle, originally from Holland; one wheel, a circular plate of iron which is kept sharp, acts as a coulter.

6. *Tillage.*

Plough, with a pair of horses, or three abreast; two crops and a fallow the common rotation; chief crops, wheat, oats, and beans; rape sown on the fens; lands either once ploughed out of grass, or pared and burned; also on uplands; manured and treated as turnips; seed threshed in the field; straw generally burned, or used for yard fences; wheat succeeds well after rape; hemp sown in a few places; mustard cultivated with great success: sometimes pays 40*l.* an acre on land worth not more than 50*l.*, but very uncertain. Parkinson thinks hemp, flax, rape-seed, and mustard, should be encouraged, as they enrich the farmer, and are all good preparatives for wheat. The only way, he says, to enrich the soil, is to enrich the farmer first.

7. *Grass.*

Some good meadows on the Ouse and Nene; the pastures lie remote from the farm buildings, but are in general rich, though neglected; require to be pared and burned, and brought under aration.

8. *Woods and Plantations.*

A good many pollard willows in the fens, and some osier plantations.

9. *Improvements.*

Great want of a general county drainage, such as that of the Bedford level, in the adjoining counties of Lincoln, Cambridge, and Northampton. The advantages of such a drainage is ably pointed out by Parkinson. Embarkments very extensive, and the soil being in general a loose porous sand, puddle walls are generally made in the middle of the mound.

10. *Live Stock.*

Stilton cheese, now chiefly made at Little Dalby, in Leicestershire; is no longer made at Stilton, though it is supposed to have been originally made there about 1720; or, according to some, by a Mrs. Orton, in 1730. A good many horses bred, and a mixture of Lincoln and Leicester; folding sheep much practised. No fewer than 271 pigeon-houses in this county, and a few bees; one gentleman cultivates rabbits.

11. *Political Economy.*

Bad roads; a lace manufactory at Kimbolton; a paper mill at St. Neots; two sacking manufactories at Standground; an agricultural society at Kimbolton.

7786. CAMBRIDGESHIRE. A flat or little varied surface of 437,040 acres, generally of good soil, and having about one third under tillage; remarkable only for the extent of its fen lands, and their embankment and drainage, both very imperfect. The valley watered by the Cam is called the Dairies, being almost entirely appropriated to dairy farms. Horses are a good deal bred in the county, and also pigeons. (*Vancouver's Cambridgeshire*, 1795. *Gooche's Cambridgeshire*, 1807. *Marshal's Review*, 1813. *Edin. Gaz.* 1827.)

1. *Geographical State and Circumstances.*

Climate. On the uplands dry and healthy, but in the fens the contrary; there the inhabitants suffer most when the fens are driest. Agues have somewhat diminished since the fens began to be better drained.

Soils are very irregularly distributed; loam, clay, and rich black earth extend themselves in irregular masses, and nearly of the same extent. The soil of the fens, is rich, black and deep, and may occupy a third of the whole surface. The rich marshes in the vicinity of Wisbeach consist of a mixture of sand and clay, or silt, a sea-sand, finely pulverised by the action of the waves; and the uplands consist of chalk, gravel, loam, and tender clay. There are no minerals.

Rivers. The Ouse, the Granta or Cam. The Ouse and Nene also cross part of the county, and the old and new Bedford rivers. All these are navigable for barges, and are kept open in frosty weather by ice boats, drawn down the stream by eight horses, four on each side.

2. *Estates.*

Vary much in size. Those of Lord Hardwicke, Duke of Bedford, Duke of Rutland, Sir H. Peyton, and Thorpe, are the largest; greatest part of the county in estates of from 200*l.* to 500*l.* and 1000*l.* per annum; many from 20*l.* to 50*l.* and even 400*l.* a year, occupied by their owners; tenures of all sorts, and a variety of college-land tenures.

3. *Buildings.*

Farm-houses and premises in general bad and inconvenient; lath and plaster, or clay and wattle, the common materials, and clunch or clay walls in general use. Jenyns, of Bottisham, has adopted Arthur Young's plan of building stacks on frames, which run on an iron railway, and are pulled into the barn, where they are forked on to the platform of the threshing machine. Cottages "wretchedly bad," except a few built by Lord Hardwicke, and some other gentlemen.

4. *Occupation.*

Farms from 20 to 100 acres; many from 100 to 1000, but few exceed the latter number; tithes taken in kind in many places.

5. *Implements.*

Ploughs, with a sharp iron wheel, or running coulter, as in Huntingdonshire. Shepherd, of Chippenham, has invented a variety of implements. Some threshing machines, and the best Lothian implements, at Lord Hardwicke's. The *Ely bear roller* is an iron roller, with a number of pieces of iron like small spades fixed into it. It is used in the fenny districts for cutting up the weeds, which choke up the slow running rivers. The horses walk along the bank, and draw it several times up and down the river. The weeds are thus rooted up, and carried down the stream by the first flood.

6. *Arable Land.*

Ploughed and cultivated in general as in Huntingdonshire; hemp is cultivated more extensively; flax is grown, and mustard, near Wisbeach and Outwell; a few lentils, as in Huntingdonshire, but are considered of less value than tares. The reporter says, a second crop of mustard is obtained by what shells from the first, and that mustard springs up in land where it has not been cultivated for upwards of a century. Woad is in cultivation, and for every forty acres a woad mill, it is said, is required. No crop pays equal to the reed, which requires no culture but cutting and bunching; owing to the improvement of the fens, they are now becoming scarce. Whiteseed (*Poa aquática*), or fen hay, is produced on many parts of the fen lands, and even on such parts as have been dug for peat. The land is inundated till the crop appears above the water, and then, wherever it can be effected, it is let off; in other cases the grass grows to a great height in the water, is mown twice in the season, and often produces two tons per acre each time. The hay is esteemed valuable for cows; causing them to produce much milk, and, it is said, giving the particular flavour to Cottenham cheese.

7. *Grass Lands.*

Extensive; some under no management, and of little value; others very productive, both as hay and feeding lands. In the district called the Wash, they will carry from one to two bullocks, and from five to twelve sheep per acre fed the greater part of the year.

8. *Gardens and Orchards.*

Good market and fruit gardens at Ely, Soham, Wisbeach, &c. which supply Lynn and various places, by water carriage, with apples, cherries, and vegetables.

9. *Woods and Plantations.*

Some young plantations. The Rev. G. Jenyns, of Bottisham, "does not cut off the tap roots of oaks in the usual manner, and finds they thrive faster." (That he is mistaken, see 3927.) Osiers are grown in various places for the basket makers, and found to pay as well as any crop.

10. *Wastes and unimproved Fen.*

In 1794, 158,500 acres.

11. *Improvements.*

In no part of the island draining and embanking so much wanted as in the fens of this county.

The former state of the fen lands, and their degradation to their present state, is given at length in the report, chiefly from a pamphlet by Lord Hardwicke. It was the opinion of Atkins (a commissioner of sewers in the reign of James I., 1604) that

these fens (a space of upwards of 280,000 acres) were once "of the nature of land-meadows, fruitful, healthy, and very gainful to the inhabitants, and yielded much relief to the highland counties in time of great droughts." Sir W. Dugdale (who was born 1605, and died 1686) was of the same opinion, adding as a proof, "that great numbers of timber trees (oaks, firs, &c.) formerly grew there, as is plain from many being found in digging canals and drains, some of them severed from their roots, the roots standing as they grew, in firm earth, below the moor."

On deepening the channel of Wisheach river, in 1635, the workmen, at eight feet below the then bottom, discovered a second bottom, which was stony, with seven boats lying in it, covered with silt. And at Whittlesea, on digging through the moor at eight feet deep, a perfect soil was found with swards of grass lying on it, as they were at first mown. Henry of Huntingdon (who lived in the reign of Stephen, 1135,) described this fenny country "as pleasant and agreeable to the eye; watered by many rivers which run through it, diversified by many large and small lakes, and adorned by many woods and islands." And William of Malmsbury (who lived in the first year of Henry II., 1154) has painted the state of the land round Thorney in the most glowing colours: he says, "it is a very paradise, in pleasure and delight it resembles heaven itself; the very marshes abounding in trees, whose length without knots do emulate the stars." "The plain there is as level as the sea, which, with the flourishing of the grass, allureth the eye; in some parts there are apple-trees, in others vines." It appears then, on the authority of the authors quoted, that the fens were formerly wood and pasture. The engineers were of opinion that the country in question, formerly meadow and wood, now fen, became so from partial embankments preventing the waters from the uplands going to the sea by their natural outfalls; want of proper and sufficient drains to convey those waters into the Ouse; neglect of such drains as were made for that purpose; and that these evils increased from the not embanking the river Ouse, and the erection of sluices across it preventing the flux and reflux of the sea; the not widening and deepening, where wanted, the river Ouse; and from not removing the gravels, weeds, &c. which have from time to time accumulated in it.

The first attempt at draining any part of the fens appears to have been made in the time of Edward I. (1272, &c.); many others with various success followed. The famous John of Gaunt (or Ghent, who died in 1393), and Margaret, Countess of Richmond, were amongst the draining adventurers; but Gough, in his addition to Camden, says "the reign of Elizabeth may be properly fixed on as the period when the level began to become immediately a public case. Many plans were proposed and abandoned between that time and 1634, when King Charles I. granted a charter of incorporation to Francis Earl of Bedford, and thirteen gentlemen adventurers with him, who jointly undertook to drain the level, on condition that they should have granted to them, as a recompense, 95,000 acres (about one third of the level). In 1649, this charter was confirmed to William Earl of Bedford, and his associates, by the Convention Parliament; and in 1653, the level being declared completely drained, the 95,000 acres were conveyed to the adventurers, who had expended 400,000*l.*, which is almost 4*l.* 4*s.* per acre on the 95,000 acres, and about 1*l.* 8*s.* on the whole breadth, if the whole level contain 285,000 acres, and it is generally supposed to contain 300,000 acres. In 1664, the corporation called "Conservators of the great level of the fens" was established. This body was empowered to levy taxes on the 95,000 acres, to defray whatever expenses might arise in their preservation; but only 83,000 acres were vested in the corporation, in trust for the Earl of Bedford and his associates; the remaining 12,000 were allotted, 10,000 to the King, and 2000 to the Earl of Portland. At first the levy was an equal acre tax; but upon its being deemed unjust, a gradual one was adopted, which is now acted upon. In the year 1697, the Bedford level was divided into three districts, north, middle, and south; having one surveyor for each of the former, and two for the latter. In 1753, the north level was separated by act of parliament from the rest. In addition to the public acts obtained for draining the fens, several private ones have been granted, for draining separate districts with their limits, notwithstanding which, and the vast sums expended, much remains to be done; a great part of the fens is now (1806) in danger of inundation: this calamity has visited them many times, producing effects distressing and extensive beyond conception, indeed many hundred acres of valuable land now drowned, the misfortune aggravated by the proprietors being obliged to continue to pay a heavy tax, notwithstanding the loss of their land."

The interior drainage of the fens is performed in most places by windmills, which are very uncertain in their effects. Steam has been tried, and there can be no doubt would be incomparably preferable, as working in all weathers.

Embanking may be considered a necessary accompaniment of draining on the fen-lands. The fens are divided into three large levels, and each of these levels are subdivided into numerous districts by banks; but as these banks are made of fen-moor, and other light materials, whenever the rivers are swelled with waters, or any one district is deluged, either by rain, a breach of banks, or any other cause, the waters speedily pass through these bright, moory, porous banks, and drown all the circumjacent districts. The fens have sometimes sustained 20,000*l.* or 30,000*l.* damage by a breach of banks; but these accidents seldom happen in the same district twice in twenty years; the water, however, soaks through all fen banks every year in every district; and when the water mills have lifted the waters up out of the fens into the rivers in a windy day, a great part of the water soaks back through the porous banks in the night upon the same land again. This water that soaks through the bank, drowns the wheat in the winter, washes the manure into the dykes, destroys the best natural and artificial grasses, and prevents the fens from being sown till too late in the season. This stagnant water, lying on the surface, causes also fen agues, &c.; thus the waters that have soaked through the porous fen banks have done the fertile fens more real injury, than all the other floods that have ever come upon them. The remedy for the soaking through of the water is obviously that of forming a puddle wall in the middle, which appears to have been first thought of among the fen bank-makers by Smith of Chatteris, a professed embanker, who thus describes his mode of putting a vertical stratum of puddle in old mounds: "I first cut a gutter, eighteen inches wide, through the old bank down to the clay (the fen substratum being generally clay); the gutter is made near the centre, but a little on the land side of the centre of the old bank. The gutter is afterwards filled up in a very solid manner with tempered clay; and to make the clay resist the water, a man in boots always treads the clay as the gutter is filled up. This plan was tried last summer (1794), on a convenient farm, and a hundred acres of wheat were sown on the land. The wheat and grass lands on this farm are now all dry, whilst the fens around are covered with water. This practice answers so well on this farm, that all the farmers in the parish are improving their banks in the same manner, and some have begun in adjacent parishes."

With respect to *embanking from the sea*, Vancouver is of opinion, that the ground ought to be covered by nature with samphire or other plants, or with grass, before an attempt is made to embank it; there is particular danger in being too greedy. "If the sea has not raised the salt marsh to its fruitful level, all expectation of benefit is vain, the soil being immature, and not ripened for enclosure; and if, again, with a view of grasping a great extent of salt marsh, the banks or sea wall be pushed further outwards than where there is a firm and secure foundation for it to stand upon, the bank will blow up, and in both cases great losses and disappointments will ensue."

Paring and burning is every where approved of, and considered the *sine qua non* of the fen district, in breaking up turf. Without it corn crops are destroyed by the grub and wire-worm.

Irrigation. Col. Adeane, of Barhraham, has 300 acres of meadows which have been irrigated from the time of Queen Elizabeth. "Pallavicino, who was collector of Peter's pence in England, at the death of Queen Mary, having 30,000*l.* or 40,000*l.* in his hands, had the art to turn Protestant on the accession of Queen Elizabeth, and appropriated the money to his own use; he bought with it an estate at Barbraham, and other lands near Bournbridge; and procuring a grant from the crown of the river which passes through them, was enabled legally to build a sluice across it, and throw as much of the water as was necessary into a new canal of irrigation, which he dug to receive it in the method so well known, and commonly practised in Italy long before that period. The canals and the sluices are all well designed, and are the work of a man evidently well acquainted with the practice; but in taking the waters from them, for spreading it by small channels over the meadows, there does not seem to be the least intelligence, or knowledge of the husbandry of watering. No other art is exerted but that merely of opening in the bank of the river small cuts for letting the water flow on to the meadows always laterally, and never longitudinally, so necessary in works of this kind. The water then finds its own distribution, and so irregularly, that many parts receive too much, and others none at all. From the traces left of small channels in different parts of the meadows, it would appear that the ancient distribution formed under Pallavicino is lost, and that we see nothing at present but the miserable patch-work of workmen ignorant of the business. Irrigation has not spread from this example, but might be extensively practised on the banks of all the rivers."

12. *Live Stock.*

Cattle a breed peculiar to the county; but some of all sorts. Butchers give more for a Cambridge calf than a Suffolk one, fancying the former whiter veal. The Cottenham cheese ascribed to the excellence of the grass, in great part *Poa aquatica*.

The *cow system* consists chiefly in suckling of calves and making of butter; there is not much cheese made, except the noted ones of Soham and Cottenham. The suckling season is from Michaelmas to Lady-day. It requires, on an average, two cows to fatten a calf. The cows, when at a distance from home, are milked in the pasture, and the milk brought home by a horse or ass, in tubs, slung across: women could not do this work, the travelling being, after the least rain, very bad, even when there is no water to go through. The butter is sold rolled up in pieces of a yard long, and about two inches in circumference; this is done for the conveniency of colleges, where it is cut into pieces, called "parts," and so sent to table; its quality is nowhere excelled.

Bullocks of various kinds fattened on grass, and when not ready in autumn, put up and finished on corn or oil-cake. Col. Adeane buys in London at a falling market, and keeps till a rising one before he sells.

Sheep chiefly as in Huntingdonshire; some Norfolks and South Downs; folding on the uplands.

Horses of the cart kind much bred, and considered an article in which the county excels; they are very large and bony; black; with long hair from the knee to the fetlock trailing on the ground. A cart stallion has cost 255 guineas, and his colts have sold for sixty guineas. Horses kept in the stable throughout the year, at a great expense, because on dry food; herbage plants, artificial grasses, and roots being neglected, and no soiling practised.

The *deer* in Wimpole Park attacked by a singular disease, a sort of madness; the diseased animal begins by pursuing the herd, then sequesters himself, breaks his antlers against the trees, and gnaws large pieces of flesh from his sides, &c. becomes convulsed, and soon expires.

Pigeon-houses on almost every farm; kept in a great measure because if any one were to give them up, he would be obliged to keep the pigeons of others; destroy thatched roofs, and oblige every farmer to sow more seed than he otherwise would; produce sent to London and other parts; often 100 dozen per annum from one pigeonry; dung highly prized.

13. *Rural Economy.*

Peat, sedge, or thin turf, and dried cow-dung used as fuel. The cow-dung is spread on grass, about an inch and a half thick, and cut into pieces, eight or twelve inches square; there it lies till dry.

14. *Political Economy.*

Roads miserably bad; canals or navigable cuts in the fens in all directions; a few fairs; a pottery at Ely for coarse ware; excellent white bricks made there, and at Chatteris and Cambridge; lime burned at various places.

7787. SUFFOLK. A crescent-like flat surface of 800,000 acres, the soil chiefly in patches of clay, poor sandy soil, and rich loam, and the agriculture directed to the growing of corn. The county is, however, famous for its breed of cows, horses, and hogs, and it is one of those in which carrots are a good deal grown. One of the largest sheep fairs in the kingdom is held at Ipswich, where it is said as many as 150,000 or 200,000 sheep and lambs have been exposed for sale. The celebrated Arthur Young was a native yeoman of the county, and farmed his own estate near Bury. (*Young's Suffolk*, 1810. *Smith's Geological Map*, 1819.)

1. *Geographical State and Circumstances.*

Climate. One of the driest in the kingdom; the frosts severe; and the N. E. winds in spring, sharp and prevalent.

Soil. The predominating a strong loam on a clay-marl bottom in the centre of the county; chalk also occurs extensively as a substratum; a zone of sand stretches along the coast; and some sand and fen land in the north-west angle; no minerals.

2. *Property.*

Chiefly in the hands of rich yeomanry, who cultivate their own estates of from 100*l.* to 400*l.* a year; one estate of 1500*l.* a year; and two or three of 10,000*l.*

3. *Buildings.*

Great erections have been made for the convenience of men of large fortunes; but not so many for those of smaller incomes; farm-houses improved, but still inferior to what they might be; often of lath and plaster, and wanting requisite repairs; barns uselessly large; cottages in general bad habitations; the door generally opens from the external air into the living room; reparation bad, and the deficiency of gardens general.

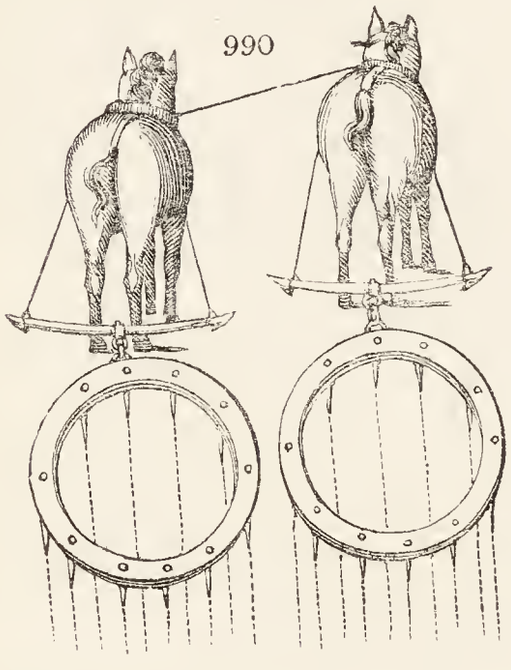
4. *Occupation.*

Farms generally large; some from 20*l.* to 100*l.* a year; generally from 150*l.* to 900*l.*; the largest on the sandy districts. Leases for seven, fourteen, and twenty-one years; but little land held at will.

5. *Implements.*

The Suffolk swing plough, though known as one of the best of the old English swing ploughs, is now giving way to improved forms; various threshing machines, and other improved implements introduced; circular harrows (*fig.* 990.) were used on the farm of the late celebrated Arthur Young.

990



6. *Enclosures.*

Suffolk one of the earliest enclosed counties in England; a few recent enclosures.

7. *Arable Land.*

Plough, with two horses, one acre a day on stiff soils, and one and a quarter to one and a half on sands; ploughmen skilful, and subscribe prizes among themselves for such as draw the straightest furrow, &c. Besides all the common crops, a larger proportion of peas grown than is usual in most counties. Hops, cabbages, carrots, lucerne, chiccory, and hemp, are grown in a few places. The culture of carrots is, of course, confined to the sandy districts, and that of rape for seed, and of hemp, to the fenny angle of the county. A. Young seems to have been the chief cultivator of chiccory, having had "ninety acres of it for sheep." Hemp is grown both by cottagers and farmers, and for the seed as well as fibre, but never on a large scale; five acres is the greatest breadth to be met with.

8. *Grass.*

Pastures coarse and not extensive; both these and meadows badly managed, overrun with mole and ant hills, bushes, tufts of bad grasses, weeds, &c. Hay-making badly performed.

9. *Gardens and Orchards.*

Garden walls built of the width of a brick, by making them wavy. (*Encyclopædia of Gardening*, 1567.)

10. *Woods and Plantations.*

Few, and pay badly; but large oak timber formerly produced in the clay districts.

11. *Improvements.*

Wheat substituted for rye. Draining much practised on the clays; bushes, straw, or stubble used for filling them; claying and marling the sands practised, but sand laid on clay found of no use, or marl on clay, according to the old adage —

Marle clay, throw all away;
Marle sand, and buy land.

Some workmen procured from Gloucestershire to execute irrigations in the manner of that county.

12. *Live Stock.*

In cows, horses, and hogs, Suffolk excels. The Suffolk breed of cows spread over the whole county. To keep the breed polled, horned calves are never reared, but sold to the sucklers. Cows in prime give eight gallons of milk per day, and great part of the season six gallons; best milkers red brindle, or yellowish cream coloured; not always the best feeders. Often fed in winter with cabbages. A point of bad management is, that the bulls, when three years old or thereabouts, are either sold or castrated for fatting, by which means, when a good stock-getter is thought to be discovered, when searched for he is no more; thus no improvement can be made in the breed, but by accident. Cows are allowed to range over turnip fields and eat where they please, and often the same as to cabbages. In some cases they are tied to posts in the open field, littered, and the vegetables brought to them: both barbarous modes of management. Dairy management not particularly good; women in general the milkers; milk generally seven or eight cows an hour; one for a wager milked thirty in three hours. Quality of milk depends not only on the food, but on the condition of the cows as to health and fatness. Chafing dishes of charcoal kept in the dairies during frost, but the cream does not rise so well. Butter generally salted in firkins.

The *sheep* used are of various breeds, and the practice of folding is universal.

Horses of the best variety found on the sandy soils, as about Lowestoff, Woodbridge, Orford. About the middle of last century, a considerable spirit of breeding, and teams drawing against teams for large sums, existed. The old breed were ugly, with slouching ears, ill shaped head, and low in the fore end; a great carcass, short legs and short back; they could only walk and draw, and no more trot than a cow; of late, by aiming at coach horses, the breed has become handsomer, and one of the best for draught in England. In the east district, horses are turned out of the stable in winter at night, about eight o'clock, into a yard well littered with straw, with plenty of oaten and barley straw to eat, but no hay; so treated, they are found to keep free from diseases, and work several years longer than if kept constantly in stables.

The *hogs* fatten early and at little expense, but are not great breeders.

Rabbits. Many warrens in the sand district; one at Brandon returns 40,000 rabbits in a year; twenty rabbits per acre usual produce; carcass defrays rent and taxes, and the skin profit; so that no mode of farming can be more profitable to the occupier.

Poultry. Turkeys generally cultivated, but chiefly for home use.

Pigeons abound on the borders of Cambridgeshire.

13. *Political Economy.*

Roads very good; made with flints and gravel; some canals. Ipswich and Bury excellent markets; a good deal of fishing on the coast; spinning and combing wool, and spinning and weaving hemp, among the cottagers. Says and silk manufactures at Sudbury. Various hundreds in this county incorporated by charter for erecting houses of industry for the poor; they manufacture netting for the fishers, spin, &c., and cultivate a few acres of land; they are admirably kept and managed, and the poor live like the pensioners in Chelsea college; but these houses of industry have little effect in lowering the poor rates. The best managed are of very expensive tendency, and of equivocal effect as to comfort and morality. Those badly managed are nurseries of idleness and vice, attended with great discomfort and expense. Marshal considers them as the grave of morality and independent policy, and as we are informed, by a gentleman who has been a director of one of them for many years, with perfect truth.

14. *Obstacles to Improvement.*

The great abundance of game in the county is such, that instances are given of corn having been injured to the extent of half and three fourths of its value by hares and pheasants, which are common every where, and on the sand district more especially.

An agricultural society, called the Milford society, meets alternately at Milford and Bury.

7788. NORFOLK. A flat surface of 1,288,000 acres, chiefly of a loamy and sandy soil, and devoted to the growth of corn, and the fattening of cattle and sheep. This county has acquired celebrity for its general culture, and especially for that of turnips and clover. It displays a great variety of practices, and abounds in wealthy farmers. It is also noted for the estate of Coke, a true and consistent patriot for upwards of half a century, the most munificent of landlords, and the greatest friend to farmers. Norfolk, in short, was formerly reckoned the finest county in England for agriculture, as Northumberland is at present. Mackie's nursery at Norwich, the property and under the direction of a lady, is one of the most extensive and best managed of provincial nurseries. (*Kent's Norfolk*, 1795. *Young's Norfolk*, 1801. *Marshal's Review*, 1813. *Dr. Rigby's Holkham, its Agriculture, &c.* 1819. *Smith's Geological Map*, 1819. *Edin. Gaz.* 1827.)

1. *Geographical State and Circumstances.*

Climate colder and more backward than Suffolk; N. E. winds severely felt in spring; salubrity of the air affected by the fens of Lincolnshire and Cambridgeshire to the extent of 5 or 600,000 acres, which lie on the west side of the county.

Soil. A sandy loam or sand; Kent says, similar and equal in value to that of the Austrian Netherlands. There is a small patch of silt or warp clay on the borders of Lincolnshire, and of rather stiffer clay on the borders of Cambridgeshire.

Water. The sea and rivers for navigation; watering ponds for cattle made at Holkham, each to serve four enclosures, forty-two feet square at bottom, twelve and seven feet deep, bottom and sides well covered with sand; within a yard of the top, the clay two feet thick, and paved with bricks set on edge. These ponds made by men from Gloucestershire, at two and sixpence per superficial yard. To divide the ponds for four fields, a large stone with a hole wrought in it to receive a post is necessary at the centre, and the post has mortices to receive rails from the sides.

2. *Property.*

Estates of all sizes; one of 25,000*l.* a year; one of 14,000*l.*; one of 13,000*l*; two of 10,000*l.*; many of 5000*l.* Land sells currently at thirty years' purchase. Tenure by freehold three fifths, church, collegiate, and corporate estates one fifth, and copyhold under lay lords one fifth.

3. *Buildings.*

Some noble seats of proprietors. Kent says farm buildings are on too large a scale; "they are always crying out for barn-room, though wheat is preserved cheaper and better on staddles;" barns on a farm of 100*l.* a year that have cost 300*l.* Coke has expended above 100,000*l.* on farm-houses; barns at Holkham 120 feet long by 30 broad and 30 high, surrounded with sheds for sixty head of cattle; walls of fine white brick, and roof of blue slate. At Lyderstone an immense barn of Coke's, containing the crop of 140 acres. Seven men necessary on the goff or mow, at the unloading of every waggon, and dare not venture to tread the corn for fear of bursting the barn; farmers fond of immense barns. In building, Coke has substituted milled lead for ridge tiles to the roofs; copper wards to all locks; front edges of mangers are rollers covered with tin; mangers themselves plated with iron; bottoms of the stall fences of Penryn slate. In building walls not to be roofed, they are drawn in to a brick's length at top. Lime-wash used as a preservative to boards, walls, &c.: it is composed of lime fresh from the kiln, and clean sharp sand, mixed with hot water, and laid on hot; stirring it up so as always to lay on sand with the lime. An excellent plan. At Holkham a brick manufactory, where bricks of all forms are made, and common bricks are cut, five parts in six, through in various directions, so as to give half and quarter bricks, angles, &c., without breaking and waste. This is one of the most complete manufactories in the kingdom. At Belwy a capital farmery, labourers' cottages, and gardens. Sharp clean sand dashed on new paint found to answer the end of imitating stone, &c. A. Young did not see a good farm-yard in the county.

Cotlages much wanted; some built of flint-work.

4. *Occupation.*

Farms large on the dry soils, and smaller on the wet ones; 2000 acres arable, the largest measuring from 400 to 600. Farmers famous for their improvements, excellency of their management, and the hospitable manner in which they live, and receive their friends and strangers. The farming-mind of the county has undergone two revolutions, one between 1730 and 1760, when great improvements were made; and the next about 1790, when drilling began to be introduced. Coke began to promote farming; and the South Down sheep were introduced about that time. The great improvements for seventy years past effected in consequence of twenty-one years' leases. The advantages of leases ably advocated by Kent. Coke adheres steadily to this term, while some others are reducing it to seven and nine years.

5. *Implements.*

For more than half a century these remained stationary; now improvements making; Norfolk plough has a high-pitched beam, wheels near to the share, and is reckoned lighter than most wheeled ploughs.

6. *Enclosures.*

Many since middle of eighteenth century. In planting hedges on a loamy soil, the plants being laid in, and the bank over them raised to the usual height, the face of it, and also of the ditch, for one foot or more below the original surface is plastered over with clayey stuff taken out of the bottom of the ditch, to the thickness of two or three inches, or more about the sets. The advantage of this plan is, that this loamy puddle, from the bottom of the ditch, is without the seeds of weeds itself, and by its compactness excluding the air from these in the mould below, it prevents them from germinating; the consequence is, hedges planted in this manner require little or no weeding for several years.

7. *Arable Land.*

Plough with two or four horses very shallow; carefully preserve the hard basis formed by the sole of the plough, which is called the *pan* of the land; breaking this up is said to let down the riches into the hungry subsoil, &c. Culture of turnips erroneously stated by Kent to have been introduced from Hanover by Townsend, in the reign of George I.; — doubtless has increased since that period. Clover very general, and wheat on the clover ley; turnips all broadcast, or if drilled, never on ridgelets, but on the flat surface; rotations good, such as turnips, barley, clover, wheat, &c. Turnips fed off with sheep, or given to cattle in stalls, or the open yard; sometimes carted on the sown wheats in February, and eaten off them by sheep or bullocks, the soil being very dry and loose; clover eaten off, or mown for soiling or hay;—most generally eaten off by ewes and lambs. Wheat dibbled in some places, a practice which originated in this county, and has scarcely been adopted in any other. Carrots not so much cultivated as in Suffolk; a good deal of mustard from March to Wisbeach; on the rich black lands, four crops of mustard taken in succession, and then wheat; produce three to four quarters per acre. Hemp and flax cultivated in the spots of ground belonging to houses of industry, and in some other cases, but to no extent. Saintfoin not much cultivated; Coke had 400 acres. Lucerne at a few places; mangold wurzel introduced by Sir Mordaunt Martin, who continues to cultivate it. Drilling and dibbling of wheat and peas generally practised on the sandy soils. Coke drills all his corn. Arable culture, in every department, greatly improved since 1790. — A paper, by Kent, entitled *Fallowing exploded*, has been justly condemned by Marshal, and other men of more general experience in culture: his notions of shallow ploughing, and continual tillage and cropping without rest, most erroneous, and contrary to experience.

8. *Grass.*

Very little of natural turf in the county; transplanting turf recently introduced. (5715.)

9. *Gardens and Orchards.*

Orchards to most of the farm-houses; some public ones near the large towns. Norfolk beefin an excellent apple, and much used for baking dry in ovens, a very particular operation known only to a few bakers. They are repeatedly taken out of the oven, and pressed flat with the hand, and then put in again.

10. *Woods and Plantations.*

Much planting has taken place on the poorer sands; Marsham of Stratton, the chief planter, and next Berney of Bracon, Coke, and Windham. From 1781 to 1801, Coke planted 718 acres, with upwards of two millions of trees and shrubs, of more than fifty kinds. Bevan, of Riddlesworth, 966,000 trees. Marquess Townshend feeds cattle, sheep, and deer, with the trimmings of plantations. Sheep are fond of the bark of the Scotch fir and ash.

11. *Improvements.*

A good deal of draining done of late years; very little irrigation; among the manures are reckoned marl, lime, gypsum, oyster shells, sea ouse, sea weeds, pond weeds, burnt earth, sticklebacks, oil cake, rape cake, ashes, soot, malt dust, ploughing in growing buck-wheat, yard dung, leaves, burning stubbles, river mud, and town manure. Marling, or claying as it is called, has been much used for an unknown length of time, and is found of great use on the sands; laid on at all seasons, but chiefly on the clover leys in autumn, and spread in spring, before ploughing for peas or oats; quantity, twenty to eighty loads an acre; duration, twenty to fifty years. Sea ouse, a calcareous mud, forty loads per acre. The sea mud is chiefly part of a stratum of rotten timber on the sea-shore, and which is washed out by the tides; it is perfectly black and rotten, and ten loads manures an acre. Burnt earth is the burnt ant-hills of moory meadows; ashes of cottagers who burn turf, &c. Leaves raked, stubbles burned, &c. by some. Some judicious and successful embankments made on the Ouse, near Lynn, by the late Count Bentick, and continued by his son, the present Governor Bentick.

12. *Live Stock.*

Predominant cattle Scotch, bought in every year from the drovers, for feeding. Norfolk black-legged sheep gradually giving way to South Downs; folding on the decline. Poultry good, especially the turkey, owing to the dryness of the soil, and great range of pasture. Decoys, and pigeon houses, formerly numerous, but now on the decline. Rabbits, hares, pheasants, partridges, and rooks abundant.

13. *Political Economy.*

Charles II. observed, that Norfolk should be cut into roads for all the rest of England; few canals.

7789. OXFORDSHIRE. An irregular, inland, elevated surface, of 450,000 acres, chiefly in aration, and in a very backward state as to agriculture. There are rich grass lands, subjected to the same dairy management as in Buckinghamshire, and some natural wood lands. The principal agriculturist and patriot of the county is Fane, of Wormsley. (*Davis's Report*, 1794. *Arthur Young's Oxfordshire*, 1809. *Marshal's Review*, 1813. *Smith's Geological Map*, 1823.)

1. *Geographical State and Circumstances.*

Climate cold and bleak. On the Chiltern hills, cold, moist, and foggy.

Soil in three great divisions, red land, stonebrash, and chiltern, or chalky hills; the basis of all these soils is calcareous; there is also a considerable portion of loamy soil.

2. *Property.*

Few large estates; church tenures very common; one estate of 20,000*l.* a year, one of 12,000*l.*, one of 7000*l.*, one of 5000*l.*, and so on.

3. *Buildings.*

Blenheim, the noblest in England; Maylands' house at Broadeaton, recorded by Young as a model for houses, which cost about 20,000*l.* building. In farm buildings the best thing is the coped stone rick and granary stands; farm buildings generally of stone, covered with stone slate; wretchedly contrived, and badly executed, in most parts of the county. Gardens to most of the cottages. Bishop of Durham has built some very comfortable ones at Mungewell.

4. *Occupation.*

Farms generally smaller than in most other counties; few above 500 acres. Leases of fourteen and twenty-one years not uncommon; many of seven years. Farmers in general very ignorant, and much prejudiced against new practices.

5. *Implements.*

The prevailing plough a swing wooden-boarded implement, drawn by from three to six horses, and incapable of making good work under the guidance of the best ploughman.

6. *Arable Land.*

Very badly managed in general; on heavy lands two crops and a fallow, but the fallow kept unploughed for the sake of affording couch-grass leaves for the sheep. Davis of Bloxham, an extensive farmer and land-surveyor, "never saw any land upon which a naked fallow is necessary; not even on the stiffest soils;" has been in many counties, and employed on twenty-six commissions of enclosure at the same time! Wheat sown early, and either ploughed in or folded; often both. A scantlet of lentils cultivated. Turnips in most parts seldom bigger than

apples. A good deal of saintfoin on the Chiltern, and other calcareous soils, also on the stonebrash, which is chiefly lime.

7. *Grass.*

Some good meadows near Oxford, on the Thames and Isis; very rich grass land at Thame.

8. *Woods and Plantations.*

Of considerable extent. A great part of the forest of Whichwood belongs to the government. Great attention paid by Fane of Wormsley to pruning; many beech woods on the Chiltern hills; young wood at Blenheim neglected. The natural forests of Whichwood and Stoken Church chiefly of beech, but some oak, ash, birch, and aspen.

9. *Improvements.*

Fane, Prat, Davis, and others are of opinion, that the agriculture is much superior to what it was thirty years ago, chiefly from the introduction of a better breed of stock, the use of roots and herbage plants, and the enclosure of commons and common fields.

Scotch Farming. In 1809 an attempt was made to improve the estate of Great Tew, by letting it to Scotch farmers. As this originated in consequence of a pamphlet which the compiler of the present work published in 1808, it might be deemed a defect in this sketch if the circumstance were passed over without particular notice. It will, no doubt, long be recollected in the county as at least a ruinous project of wild adventurers; this being the very mildest term applied to failures in similar cases. At this distance of time, looking back on the matter, as far as the result affected ourselves, with our natural *sang froid*, we shall state our opinion as to the causes of failure. This resulted principally from too great anxiety, both in the landlord and tenants, to reap a large benefit; and secondly, from the general fall of prices, both of land and produce, which succeeded to the published report of the Bullion Committee in 1807. Anxiety to increase the rent-roll induced the landlord to let the whole of his estate of nearly 4000 acres, then under nearly a score of tenants, to two cultivators, instead of trying first the effect of one or two moderate-sized farms under the new mode. The same anxiety induced the tenants to offer too high rents, and to attempt a profit by subletting. Before the estate had been eight months let, it was sold on the new rental for nearly four times the sum at which it was offered for sale only a year before; but the title not proving satisfactory to the purchaser, the purchase was never completed. The landlord became involved in difficulties, owing to the expenses of new buildings, roads, drainages, the purchasing up of certain outgoing tenants, and other causes: he found, that though one person had been willing to buy the estate held on twenty-one years' leases, yet that it would sell much better if held by tenants at will; and was thence induced to buy up from the Scotch tenants the leases granted them two years before, and was still unsuccessful in endeavouring to sell the estate. At last the proprietor found himself with the greater part of his lands in hand; and one farm, it is proper to observe, was put under the management of an Irishman, who rendered himself notorious by some parts of his conduct, and finally left the country clandestinely; and whose actions have unfortunately often been confounded with those of the Scotch farmers, after all the latter had completely left that part of the country. When peace was concluded in 1814, land fell still lower; and finally this estate was sold for less than half what it had been sold for in 1809: but still (which may be considered as remarkable) for about double what was asked for it in 1807. It was in 1823 probably not worth a third part of what was given for it by the purchaser, from the change in the times; so that even had the original scheme and sale worked well, it is probable that by that time both landlord and tenants would have been ruined; for more money might have been raised by mortgage on such an estate in 1810 than it would have sold for in 1820. The depreciation of the estate has been attributed to the breaking up of old turf; a most unfounded error, as there were not 1000 acres to break up, and of them only 250 were ploughed, and, as would have been proved had the convertible system been continued a few years, greatly to the benefit of the whole. We regret that the landlord, a most amiable and patriotic man, should have suffered in this business; but he entered into it aware that he was incurring an extraordinary chance of loss for an extraordinary chance of benefit, and of course he takes the result as every man ought to do. Besides he has still a very handsome fortune.

As a trait of the spirit of the Board of Agriculture at this time, we may mention that Arthur Young examined the estate a few weeks after it was sold at so high a rate, and drew up a remarkable report (a MS. copy of which, from his office, is in our possession) in favour of Scotch farming, which was published in the first edition of Sir John Sinclair's *Husbandry of Scotland.* In that report a disingenuous attempt is made to attribute to the Board the merit of the introduction of Scotch farming into this and other counties; whereas it was and is perfectly well known, that the Farmer's Magazine, the Scotch farmer Gourlay, late of Wiltshire, and our pamphlet, were the true causes. By the time a second edition of the *Husbandry of Scotland* was called for, Scotch farming had become unpopular, and the Report mentioned, and all the compliments to the Board of Agriculture for having introduced it, were withdrawn. A general account of all the operations on Tew estate by Scotch farmers will be found in *Designs for Farms and Farm Buildings in the Scotch Style, adapted to England, &c.* 4to. 1812.

10. *Live Stock.*

There is a good deal of dairying in the county; the permanent grass lands being chiefly occupied in this way. The practices are almost entirely the same as in Buckinghamshire. The butter is taken to London by waggons from all the principal towns. Much good dairying at Atterbury. A. Young asked John Wilson, of that neighbourhood, if he ever fed on straw? Answer, "*No; straw be a good thing to lay on.*"

Sheep, the Berkshire, Gloucester, Wiltshire, Leicester, and other hardy breeds. Fane has tried crossing the Ryelands and South Downs with Merinos. Several other proprietors of farms have also tried Down Merinos and other crosses; and some the pure breed.

11. *Political Economy.*

Forty years ago roads "formidable to the bones of all who travelled on wheels;" now they are much changed for the better. Birmingham canal and the Thames of immense importance to Oxfordshire. A good deal of wool, formerly woven into blankets at Witney; now very little. About the beginning of the last century the manufacture of polished steel was introduced at Woodstock, and flourished for half a century; at present nearly extinct. Steel chains have been made here weighing only two ounces, and sold for 170*l.* Scissors from five shillings to three guineas. The steel is wholly made from old nails of horse-shoes. Leather breeches-making and glove-making have succeeded to the steel manufacture, and the latter thrives well: from 360 to 400 dozen of gloves are manufactured weekly.

12. *Miscellaneous.*

Dr. Sibthorpe, the late professor of botany at Oxford, left 200*l.* a year to endow a professor of agriculture and rural economy, to be established as soon as the *Flora Græca* is completed. This will not be for some years.

7790. BERKSHIRE. One of the most beautiful counties of England; occupies a surface of 474,000 acres, of which about 200,000 are enclosed, or in parks or plantations; 190,000 in common fields and downs; 40,000 in forests, wastes, and commons; and 8977 in roads. Its productions are almost equally corn and stock; it produces a good deal of butter and cheese, and the breed of swine is noted for its excellence. The celebrated Jethro Tull was a yeoman in this county. George III. and E. L. Loveden, Esq. were among its most noted farmers. On the whole it is a county much more indebted to nature than to art. (*Pearce's Berkshire*, 1794. *Mavor's Report*, 1808. *Marshal's Review*, 1813. *Smith's Geological Map*, 1821.)

1. *Geographical State and Circumstances.*

Climate diversified, but in every part the air pure and salubrious; in elevated situations pure, piercing, and braces by its sharpness; in the vales relieves the weak organs of respiration by its soft and balsamic qualities; no storms known in the county. About Reading vegetation nearly a fortnight earlier than in some parts of the county.

Soil calcareous in general, but in some places gravel, and in a few clay; vale of the White Horse entirely chalk.

Minerals. None excepting chalk, Sarsden stones, a sort of large siliceous pebble, in lumps scattered over the Wiltshire and Berkshire Downs, and frequently blasted and used for paving. In the vale of Kennet is a considerable stratum of peat, formed from prostrate trees and other vegetable bodies, and used for fuel, and also burned for the ashes as a manure. The ashes abound in sulphate of lime.

Water. Some artificial lakes for breeding fish. Loveden has one of thirty acres, and a "fish-house" or cottage, with an apartment in which are three stews with covers, which lock, so as to prevent even the cottager from stealing the fish. Many gentlemen have ponds, which are let to tenants, and produce a crop, if it may be so termed, every third or fourth year, of carp and tench. The occupier stocks with yearlings about two inches long, obtained chiefly from Yately, on the neighbouring confines of Hampshire. The breeders are about eight or nine pounds weight; but in the Berkshire ponds they are never suffered to breed, but are sold off to the inns at Henley and other places, when the ponds are drawn, which is generally once in four years, and weigh at that age about three or four pounds each. The value of land thus applied cannot average less than about twenty shillings per acre. The ponds are regularly laid empty, and the fish with which they are stocked, which are uniformly carp and tench, are taken out every third or fourth year. The pond is afterwards allowed to lie fallow for the remainder of the summer season, and is again stocked early in the ensuing year with yearling fry of the same species. The ponds in one parish are all subject to an abundance of coarse, hony, insipid fish, denominated Prussian or German carp. As this species is carefully destroyed, it is wonderful they should increase with the rapidity and universality which they appear to do. Every acre of pond, properly stocked and well situated, must produce an annual increase of from eighty to one hundred pounds weight. If artificially fed, the increase would be greater; or less, if the pond is not so situated as to receive manure from the circumjacent lands. By retail, the fish here are generally sold at a shilling per pound; but under particular circumstances they may sometimes be had as low as tenpence.

2. *State of Property.*

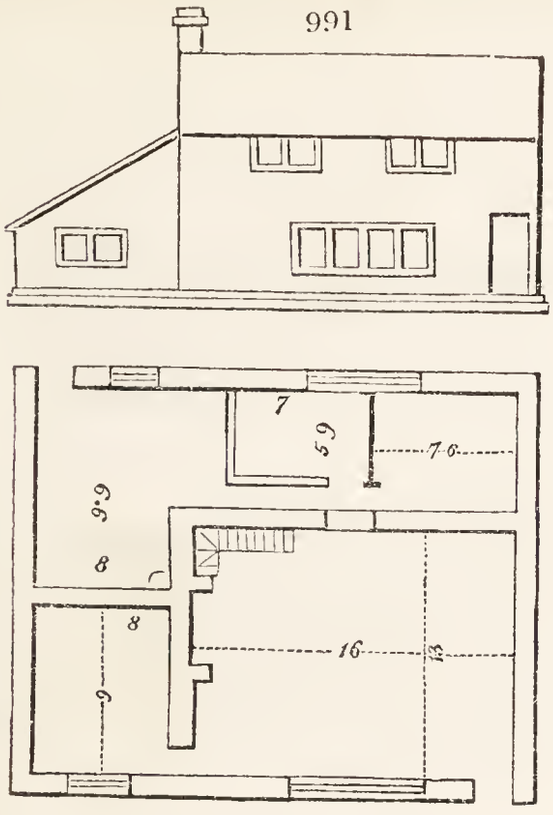
Largest estate 8000*l.* a year; a few of 5, 6, or 7000*l.*: Earl Craven and E. L. Loveden, Esq. the largest proprietors; several handsome seats with land not exceeding 100 acres, and many small freeholders and yeomanry. Some curious customs; at Enborne and Caddleworth manors, belonging to Earl Craven and R. W. Nelson, Esq., the widow of a copyholder, guilty of incontinency or marrying again, lost her freebench or life interest, unless she submitted to the ceremony of riding into the court on a black ram, and of repeating some well-known confessional lines. (See *Addison's Spectator.*) In the manor of Great Farringdon the customary tenant's daughter, on being convicted of incontinency, was to forfeit the sum of forty pence to the lord, or to appear in court, carrying a black sheep on her back, and making confession of her offence in these words: "*Ecce porto pudorem posteioris mei.*" Many other curious customs.

3. *Buildings.*

Windsor Castle and many fine seats; houses of the yeomanry genteel and elegant: farm-houses generally comfortable. Loveden's ample but ill arranged; cottages of the poor generally in a bad state, some present erections better. (*fig.* 991.) Farmeries on collegiate or corporate lands generally in bad repair, because the fines for renewal of the leases take all the spare money, &c.

Chelsey Farm, near Wallingford, in 1800, the property of Lord Kensington, and formerly reputed to be the largest and most compact farm in England. Rent 1000*l.* per annum. Before the dissolution of monasteries it belonged to the Abbot of Reading, who had a seat here. The great barn in which his

tithes were deposited is yet standing, and measures 101 yards in length and eighteen in breadth. The side walls are only



eight feet high, but the roof rises to a great height, and is supported by seventeen stone pillars, each four yards in circumference. This construction is obviously judicious; high side walls, unless tied together by cross beams, would have been in danger of being thrust outwards when the barn was filling with corn. This, as we have seen (7788.), is the case with the handsome high-walled barns of Coke.

4. *Occupation.*

One third of the county occupied by proprietors. Farms of all sizes under 1000 or 1200 acres, but few exceeding 500 acres or under 50*l.* a year. Character of the Berkshire farmer stands high. "A hospitable style of living, liberality of sentiment, and independence of principle, are characteristic of the Berkshire farmer; to which he unites persevering industry and integrity in his dealings, which render him worthy of the comforts he enjoys." (*Dr. Mavor.*)

5. *Implements.*

The Berkshire waggon, one of the lightest and best implements of the waggon kind. The sort of draught chain described and recommended by Gray (2755), is in use on one estate; "the object is to prevent the draught of the trace horse from pulling down the thiller." The county plough, a clumsy implement with wheels; a pressing plough (2714.) recently invented: it has three wheels with the tires wedge-shaped, and is intended "to press in the grips or channels made by the common ploughs, that no hollow places may remain for the seed to be buried too deep," &c. This sort of improvement is usual among amateur agriculturists, who have one implement invented to correct the faults of another, both of course bad. A number of other inventions, including a curious hand threshing machine, ingenious enough, but quite unnecessary, are figured and described. The Duke of Gloucester has, at Bagshot Park, one of the most complete threshing machines in the empire, which has been arranged under the direction and agreeably to the plan of his present farm manager, Mr. Burnes. Having received a plan of it too late for introduction here, we intend giving it in an appendix, for the benefit of agriculturists in countries where manual labour is dear, and where running water abounds.

6. *Arable land.*

Plough generally with four or five horses at a snail's pace. George III. had two farms, one of 800 acres, cultivated in the Norfolk manner, and another of 450 acres, managed in the Flemish manner; 450 of the former, and 150 of the latter, were arable. The whole delegated to the care of N. Kent, of Craig's Court, land-agent, and author of "*Hints to Gentlemen of Landed Property*," 1790. Rye cultivated on the Royal farms near Windsor, and on the Downs. Some hops, woad, flax, and other plants not usually cultivated; seventy acres of lavender at Park Place, on the side of a chalky hill, originally planted by General Conway, who distilled it himself at his coke manufactory. As the plants die they are replaced by others from a small nursery plantation. It begins to flower about the end of July, when nearly one hundred women and children are employed in cutting off the flower spikes, which they tie up in bundles, and send to the still-house in baskets, carried by two men. The lower part of the stalks are then cut off, and the heads are put into the still, and distilled. The chemical oil, being separated, is poured into copper jars for sale.

7 *Grass.*

About one fifth of the county under permanent grass, exclusive of the Downs and wastes. A tract of excellent meadow on the Thames, from the windings of the river, 105 miles in length, little irrigated, but a good deal flooded after heavy rains. Excellent meadows at Reading; those on the Kennet, over the stratum of peat, of rather a coarse quality. Manuring meadows not general, though they are for the most part mown once a year; upland pastures manured when mown. Herbage, plants, and artificial grasses, a good deal sown. Meadows chiefly fed by oxen after being once mown. The dairy farmers occupy the poorer upland grassy districts, and the breeders of sheep the Downs.

8. *Gardens and Orchards.*

About forty acres of market garden and orchard at Reading, where onions are raised in great quantities; asparagus for the London and Bath markets, and cabbage seeds for the London seedsmen; good apples there and at other places; some cider made, and a good many cherries grown for market. Near Abingdon an orchard of twenty-one acres, containing 541 trees.

9. *Woods and Plantations.*

Extent of Windsor Forest, belonging to the crown, 5454 acres, including wood and water; private property, called Forest Lands, 29,000 acres; encroachments 600 acres. The forest is under the government and superintendence of a lord warden, who appoints his deputy lieutenant, the rangers or head keepers of the several walks, and the under keepers. Great part of the timber on the forest sold, as well as that retained, is truly venerable and picturesque in appearance, but rotten or mildewed to the heart in such a way as to be fit only for fuel. This rot, or mildew as it is called, seems to be the natural process of decay, and is particularly fatal to beech trees, which are by no means so long lived as the oak, ash, and others. Various young plantations on different estates, especially those of Loveden, Fishe Palmer, Wheeble, &c. Osier beds on the moist parts of the Thames meadows. Extensive plantations have lately been made on the Duke of Gloucester's demesne at Bagshot, under the direction of his very intelligent managers, Christie, Barnes, and Toward. (See *Gard. Mag.* vol. vii.)

10. *Improvements.*

An account of the culture of George III.'s farms, by Kent, dated 1798, is given as of the greatest national consequence, &c. Oxen are used both in farm and road-work, and the ploughs are the Norfolk wheel plough and the Suffolk iron plough. At a later period the Rotherham plough, and with which two oxen, yoked in collars, will plough, on the light soil of the forest, an acre a day. Draining in the Essex manner a good deal practised; the drains filled with straw, rubbish from brick kilns, wood, cinders, or gravel.

Peat ashes is a manure almost peculiar to Berkshire, though they might be obtained by the same process wherever peat of similar quality abounds, and are so obtained in Holland, and the ashes extensively used there, and sometimes shipped to this country. In the year 1745 peat was first burnt in Newbury, by a Thomas Rudd, who at the same time spread the ashes on clovers, for which they have ever since been famous. An acre of peat land at that period sold for 30*l.*: it has since sold, according to its quality, for 300*l.* and 400*l.*, and, in one instance, reached about 800*l.* per acre. Over the stratum of peat, which is about five or six feet deep, is a good meadow soil, and under the peat is gravel. The peat varies in colour, but the blackest is reckoned the best, and is used for firing, the ashes of which are most esteemed, and have the reddest colour. What is burnt for sale, is mixed with turf and other substances, which gives it a pale whitish hue. It is usually dug with a long-handled spade, from the middle of May to the end of June, and is conveyed from the spot in little wheelbarrows, to a short distance, where it is spread on the ground, and after lying about a week, the pieces are turned. This being three or four times repeated, a heap is made in the middle of the place where the peat is spread, and in the centre of this heap some very dry peat is put, which being lighted, the fire communicates slowly to the rest of the heap. When it is completely lighted, an additional quantity of peat is put upon the heap, and this operation is continued till the whole is consumed, which generally takes a month or six weeks, as quick burning is not approved of. Rain seldom penetrates deep enough to extinguish the fire. The heap is commonly of a circular form, and rather flat at top. At first it is very small; but at last it is sometimes two or three yards deep, and six or seven yards in diameter. The ashes being riddled, are conveyed away in uncovered carts, to a distance sometimes of twenty miles, and put into a house, or under a shed, to keep them from the wet, till they are wanted to be put on the ground.

The usual time of applying peat ashes is March and April. They are generally taken in carts, and sown on the ground before or after the seed is sown on the land. The quantity is usually from twelve to fifteen Winchester bushels per acre, according to the soil and crop. It is supposed that too large a quantity would be injurious. For barley, wheat, and peas, they are not in much estimation; but for all sorts of artificial grass, more especially, they are preferred to all other manures. In turnips they assist to prevent the ravages of the fly; and in grass seeds the farmers reckon on an acre, manured with ashes, producing nearly a ton of hay beyond what it would have yielded without them. The effect is supposed to be of no longer duration than two years. On meadow land, from fifteen to twenty bushels may advantageously be put; they much improve the grass.

11. *Live Stock.*

No particular breed of cattle; long horned most common. A dairying tract in the west of the vale of White Horse; much butter made, and some cheese of the single Gloucester kind. Calves a good deal suckled in some places. Buscot parish famous for cheeses, in the shape of pine apples; they are of most excellent flavour, and sell higher than other cheeses. The curds are well worked with the hands, then pressed into a wooden mould in the shape of a flower pot, and afterwards suspended from beams, rafters, or pegs, in an airy apartment, in a net, whose meshes indent their surface like a pine apple. Salt is then rubbed over them, or they are steeped in brine; weight, 5lbs. The milk is conveyed from the field to the dairies in what is called a tankard, drawn by a horse or ass. (*fig.* 993.)

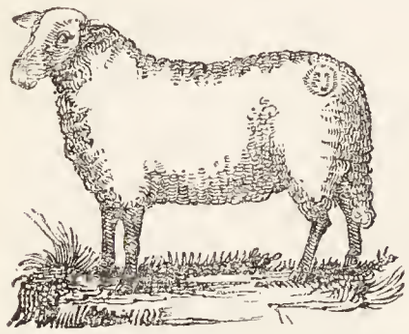
Sheep, a native breed known as the Berkshire polled, or notts (*fig.* 992.); strongly marked, but in much less repute than formerly; it is now difficult to be met with pure; they are considered as very hardy, and particularly adapted for the low strong lands, and for folding.

Horses of the common heavy black race. Pearce calculated in 1794, that 12,000 horses were kept in Berkshire for the purposes of agriculture, and that one third of the number might be saved by the use of improved implements: most of the horses are bought from the Northamptonshire breeders; many, after being kept a year or two at work, are sold for the London drays.

Hogs, the native breed one of the best in Britain; a cross

with the Chinese, now more common than the pure native breed. Wherever there is a dairy, hogs are kept, but they are not counted a profitable stock to be fed with what would fatten cattle or sheep. Carcass chiefly made into bacon; cured in the usual way, and dried in rooms heated with wood or coal. Loveden has a bacon house, heated by a stove and flues. In farm-houses, much is smoke-dried in the chimneys with wood fires, which is supposed to have the best flavour.

992



Poultry. Near Oakingham, many are crammed for the market: they are put up in a dark place, and crammed with a paste made of barley-meal, mutton suet, and some treacle, or coarse sugar, mixed with milk, and are found to be completely ripe in a fortnight. If kept longer, the fever that is induced by this continued state of repletion renders them red and unsaleable, and frequently kills them. In the eastern part of the county, many geese reared on the common.

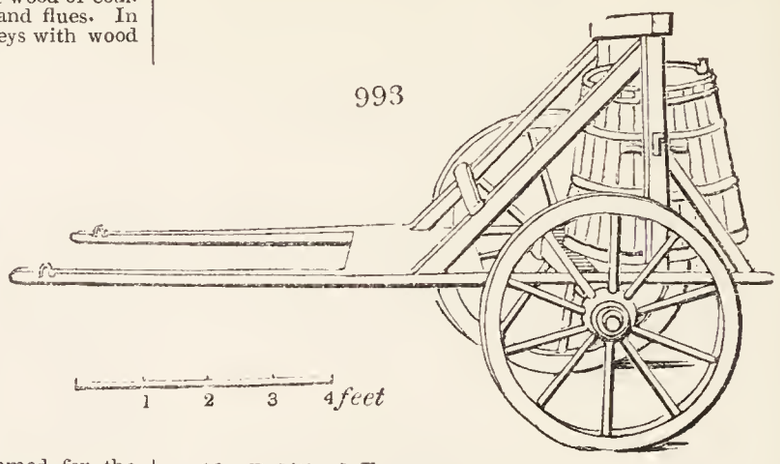
Pigeons in considerable numbers.

Bees, not very common. Sir William East, of Hullplace, a celebrated apiarist. In the forest district, bees are most common. One gentleman removes his hives to a heath at the flowering season.

Deer kept in several parks; 2500 fallow, and 300 red deer, in Windsor Great Park.

Rabbits kept in warrens, in one or two places; and one gentleman rears tame rabbits of a pure white, the skins of which sell high for trimmings.

993



12. *Political Economy.*

Roads for the most part good, especially since a part has been put under the care of M'Adam. Gravel, flint, or chalk, abounds in most places. Canals and navigable rivers so interspersed, that no part of the county is further than twelve miles from water carriage. Cloth for sacking and hammocks, manufactured at Abingdon and Maidenhead, also some sailcloth, and rush, and twine matting. Cotton mills at Taplow. Paper, and formerly blankets and other woollens, at Newbury. A parchment manufacture at Oakingham. At Reading, a pin manufactory, and the weaving of galoon, satin, ribands, and other light fabrics; a floor cloth manufactory; twine and rope making; sail making, sacking, &c.

The Berkshire Agricultural Society, established in 1794.

7791. GLOUCESTERSHIRE. A surface of nearly 800,000 acres, in three natural divisions; the Cotswold hills, the vale of the Severn, and the Forest Lands. Great part of the county is under meadows, pastures, and orchards; and cheese and cider are its known agricultural productions. It is also a manufacturing county, and its fine broad-cloths are celebrated, as well as its iron, tin-plates, and pins. There is no very eminent gentleman agriculturist, nor any agricultural society in the county, but Dr. Tennant farmed a small estate on the Chilterns. (*Turner's Report*, 1794. *Rudge's Report*, 1807. *Marshal's Review*, 1818. *Smith's Geological Map*, 1821.)

1. *Geographical State and Circumstances.*

Climate, cold and bleak on the Cotswold hills; mild in the vale, which lies open to the south winds; on the sandy soils of the forest district, the harvest is sometimes cut a fortnight earlier than in the vale.

Soil of the Cotswold is all calcareous loam or stonebrash; in the vale, a fine black loam, or fertile red loam, and in some places a strong clay and peat earth; the finest soil is generally sandy loam, sand, or peaty earth.

Minerals. None in the Cotswolds, but iron and coal in the Forest of Dean, both worked. Lead found in the limestone rocks of the lower part of the vale; not worked. Though iron ore be abundant in the Forest of Dean, only a small quantity is raised, it being found more profitable to bring the richer ore of Lancashire, which is burnt with the coke of the forest coal for cast-iron, and plates for tinning. Coal pits numerous, and worked at a shallow depth, for want of proper machinery to exhaust the water; three sorts delivered, kitchen coal, smith's coal, and lime coal. Claystone and freestone found in various parts of the forest; paving stones, grindstones, yellow and grey stone tiles raised in different parts of the Cotswolds; gypsum is raised for stuccoing, and sent to Bath from Hanbury; it is also used as alabaster for chimney pieces, &c.

Water. Produce of the Severn is roach, dace, bleak, flounders, eels, elvers, chub, carp, trout, and perch. The sea-fish taken within the limits of the county, in the Severn, are salmon, lampreys, lamperns, chad, soles, shrimps, cod, plaice, conger-eel, porpoise, and sturgeon. Salmon formerly caught in great abundance, but now comparatively scarce. Great mischief done by the use of small meshed nets, which take the samlets or fry.

Ponds for water made on the Cotswold hills, as already described (4467), in the vale in the common manner. The waters, which rise through beds of blue clay, are often strongly saline, as at Cheltenham, &c.

2. *Property.*

Largest estate 8000*l.* a year among the nobility, and 3000*l.* among the gentry; tenures chiefly freehold, some copyhold, and about one fortieth corporate or ecclesiastical. Estates under the see of Gloucester, leased out on lives; those of the corporation of the city the same; usual fine for renewal of a life, one year and a half of the improved annual value.

3. *Buildings.*

Many handsome seats; farm-houses and cottages on the Cotswolds built of freestone, and covered with stone tiles; often as many on an estate of 100*l.* a year as are required for a farm of 500*l.* a year, under the correction of modern improvement; barns, however, of a moderate size; wheat stacked on stone staddles. Cottages, as in most counties, neglected, and uncomfortable; some judicious remarks on the subject by Rudge.

4. *Occupation.*

Farms differ much in size; few exceed 1000*l.* or fall short of 50*l.* a year. Some grazing farms in the vale of 500 acres, but 200 and 300 more common. Leases of three years most common, next of seven years, not many of fourteen, and those of twenty-one on corporate property.

5. *Implements.*

A narrow-wheeled waggon in general use among farmers. Various ploughs; a short-beamed one-wheel plough in use on the Cotswolds; in the vale a clumsy swing plough. Lumbert's draining-plough much in use with the improved draught apparatus, and in the old way. Various improved ploughs and other implements, as well as threshing and winnowing machines, introduced. A thistle drawer (*fig.* 221.) in use for extracting the corn thistle (*Serrátula arvénsis*) from cornfields; cradle-scythe used for cutting beans.

6. *Enclosing.*

The first enclosures during Queen Anne's reign; eleven during the reign of Geo. II.; and upwards of seventy during the reign of George III. Hedges of white thorn, on which the reporter observes medlars might be grafted, and raised in great plenty. Black thorn (*Prùnus spinòsa*) hedges, he says, never suffer from the blight; a most erroneous idea.

7. *Arable Land.*

300,000 acres; much ploughing on the Cotswolds lightens the staple of the weak soils: seven horses often used in the vale teams; ridges in the vale so high that a person six feet high may stand in the furrows, and not be able to see the crown of the second ridge from him; to reduce them a small ridge often begun between them. Fallowing practised on the clays, then wheat and beans, or oats. Rotation on the Cotswolds — 1 turnips, 2 barley, 3 and 4 clover mown the first year, 5 wheat, 6 oats, tares, or peas; if oats, frequently laid down with saintfoin. On crumbly soils wheat is sown and ploughed in during rather wet weather, otherwise the seedling plants are apt to be thrown out with the first frosts; the same thing attended to in Oxfordshire and various other counties; this is called seven-field husbandry. Beans either drilled or dibbled; a broad bean, the mazagan, used when the land is in good heart, and ticks when less so. The Burbage pea, an early grey variety, most in use. "Some lands have the peculiar quality of raising *siddow peas*, or such as boil freely;" on them the Charlton is grown, and sold for splitting: clay lands never have this property. Tares common, and among these a sort called dill, supposed by Marshal to be the *E'rvum hirsùtum L.*, but erroneously termed *Anèthum* by Rudge. Turnips on the Cotswolds always broad-cast, and sometimes after wheat or tares, and then called stubble turnips; consumed by sheep in hurdle folds; sometimes given to horses, and found to induce them to eat barn chaff with a better appetite. Some flax raised; teasels a good deal cultivated formerly, now not 100 acres of them in the whole county.

8. *Grass.*

Very rich meadows on the Severn, overflown during winter and spring, on which the farmers depends for a crop. When the salt water overflows, the meadows are termed marshes, and grazed by horses and cattle that require rest and spring physic. In general meadows are mown and pastured alternately, excepting near Gloucester, where abundance of manure is obtained. Herbage, plants, and rye grass sown on the Cotswolds, but little in the vale; saintfoin much cultivated on the stonebrash soils. Grass lands fed in general from May to the end of September, and then the cattle, unfinished, are taken in and completed with hay, oil-cake, and other artificial food, but seldom with roots. The *Orchis máscula* so common in the meadows, that it has been gathered, Rudge informs us, and made into sago. (6184.)

9. *Gardens and Orchards.*

Most of the cottages, such as they are, have gardens, and almost every farm its orchard; but large ones, so as to admit of

making cider for sale, are found only on the sides of the hills and in the vale and forest district. The stocks are planted in the orchard when six or seven feet high, ten or twelve yards asunder on pasture, and sixteen or seventeen on arable lands. A year after planting they are grafted. Sometimes fruit trees are planted in the hedge rows; hedges are often composed of apple seedlings, raised from the kernels in the cider mast; and here and there the farmer often leaves a stem to rise above the general height of the hedge, and grafts it; frequently also wildings are allowed here and there to rise into trees, and their fruit is used with that from grafted trees, in crushing for cider. Grafts are inserted in the cleft manner, at seven feet from the ground, two in each stock: if both succeed, one is removed the following spring, and the stock sloped to the remaining graft, to prevent the lodging of water, and clayed afresh, to facilitate the growth of bark over the wound. After grafting, "braids," that is, inverted wicker baskets, rising about two feet high, are fitted to the stock, which serve at once to guard the grafts, and direct their shoots to a proper form. The stock is next protected from cattle or the plough harness, by four posts placed round it, with six tier of rails; by three posts and six tier of rails; by two broad posts and rails; by a bundle of thorn branches; by planting a thorn or briar along with the stock; or by twisting a shoot of the creeping rose (*Rosa arvensis*) round the stock. The mode of planting a creeping rose with the stock, and twisting it round the stem, is said to be found the cheapest and best; but it must evidently impoverish the soil. Pruning is not attended to on young grafted trees, or any others, as it ought to be, nor the removal of moss and misletoe. Grafting the branches of old trees often practised with great success; a young stock grafted will probably not produce a bushel of apples in twenty years, but a branch grafted bears the second year. Dr. Cheston, of Gloucester, practises root grafting, but which is quite unsuitable for field orchards. Grafted trees bear little till twenty years of age; their produce increases till fifty years, and is then ten or fifteen bushels; an apple will bear 100 or more years from this period, and often much longer. A pear tree at Minsterworth 300 years old at least.

Cider-making. Best orchardists shake off the fruit, and never beat the tree, which destroys the blossom-buds; limb by limb is shaken by a person in the tree, and those which adhere allowed to remain some time longer to ripen: the horse-mill used by large, and the hand-mill by small farmers; the cylinders of the hand-mill of wood, and fluted; sometimes there are two pair of cylinders, one finer fluted under the first pair, and in other cases the cylinders are set wide the first time the apples are passed through, and closer the second; the other processes as usual. Of the various apples grown, the white-styre of the Forest district makes the strongest and richest cider; it is often valued equally with foreign wine, and sold at extravagant prices. Ciders from the Hagloe crab, golden pippin, and Longney russet, are next in esteem. The white-must, woodcock, and half a dozen others, are fine old fruits, but now going off.

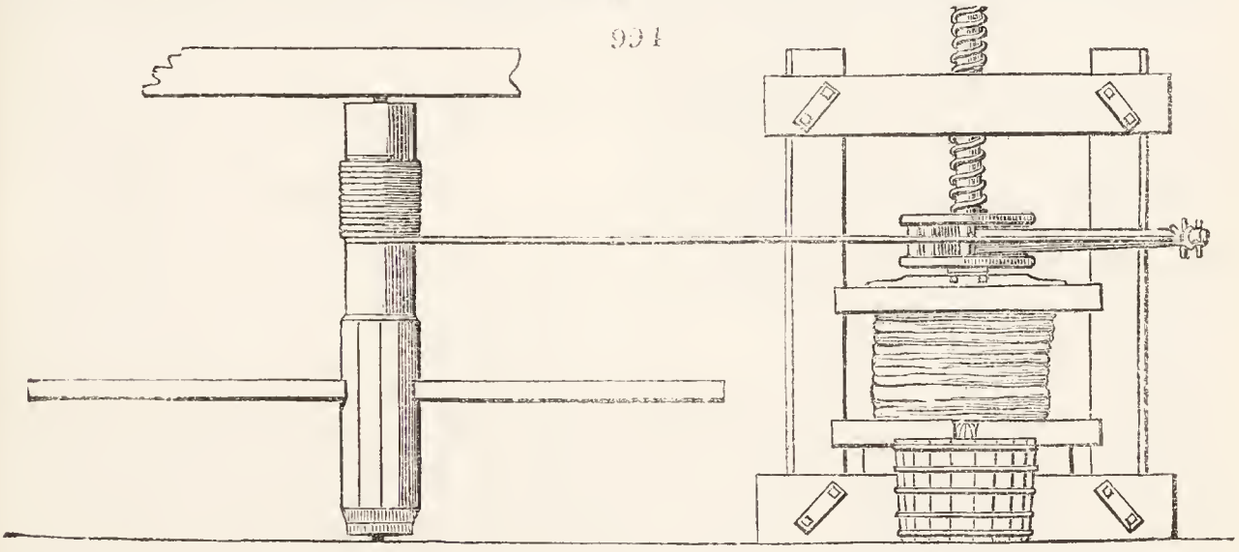
Perry from the squash pear is esteemed the best; and next from the Huffcap and sack.

Table fruits, where farmers live near canals, pay much better than those of the cider kind; especially those of the keeping varieties, such as the golden and Moreland pippin, Longney russet, &c.

10. *Woods and Plantations.*

Most extensive on the Cotswolds; the sorts there beech and ash; timber sold to dealers, who convert it on the spot to scantling for gun-stocks, saddle-trees, bedsteads, chairs, and other cabinet work, and staves for sugar hogsheads. Some fine old specimens of chestnut, elm, oak, and ash in the vale. Tortworth chestnut, 500 years old, in the time of King John. In the Forest of Dean a considerable quantity of good timber belonging to government, and nearly 3000 acres lately planted with acorns. The method of planting is, first, to mark out the ground; then taking off about a foot square of turf, to set two or three acorns with a setting-pin; afterwards to invert the turf upon them, and, by way of raising a fence against hares and rabbits, to plant two or three strong white thorn sets round. They are seldom thinned till they have attained the size of hop poles, and then are left at twelve feet distance from each other, with the view of again thinning them, by taking out every other one, when they are thirty years old, and have attained the size of five or six inches diameter. By growing thick, no side-shoots are thrown out, which supersedes the necessity of pruning; the young trees which are drawn at the first thinning are transplanted, and, as it is thought, grow equally well with those that have not been removed, and produce timber as full at the heart, compact, strong, and durable, as "that which is raised immediately from the acorn." The "whitten," or small-leaved lime (*Tilia cordata L.*), is found in several coppices on the Welsh side of the Severn; and, what is singular, ropes for halters, plough traces, cider presses (*fig.* 994.), draw wells, and fishery boats, &c. are made from it as

994



in Russia. These ropes are found to contract and expand less from moisture or drought than hempen ropes. The bark is stripped off about Midsummer, dried like hay in the sun, and manufactured on the spot or elsewhere. Many walnut trees in the parish of Arlingham; the fruit shipped to distant places, and the timber sent to Birmingham for gun-stocks.

Artificial plantations, to a great extent, made round gentlemen's seats on the Cotswold hills. The osier in beds on the Severn.

11. *Improvements.*

On the lands adjoining the Severn inundations were frequent; but a commission of sewers have erected banks and flood-gates, which protect upwards of 12,000 acres. At other places private banks or floodgates on the rivers or banked ditches are placed, and operate by the alternate influence of the tides and accumulated inland waters.

Draining much practised; both in the turf, stone, wood, straw, and with Lumbert's plough; the plough drawn by twelve horses, or worked by a long lever and axle (2645.), by which one horse gains the power of thirty. Before the mole draining plough is used, it is a good practice to turn off the sward with the common plough; then to make the incision for the drain in the centre of this; the sward being afterwards turned back to its place, completely covers the aperture, and protects it from the effects of a subsequent dry season. The long-continued drought of the summer of 1806 opened many drains which were cut by Lumbert's plough, so much that the bottom was clearly seen; while many that have been done by hand have formed still wider chasms, and will probably not answer the purpose intended at all. In both instances there is reason to think, that this would not have happened if the operation had been performed in autumn, and the surface turf first turned back, as recommended.

The accumulated water of underground drains raised from low meadows in one parish by a wheel driven by the water of surface ditches.

Paring and burning practised on the Cotswolds; weeding corn general.

Irrigation chiefly pursued in the valleys of the Cotswolds, adjoining rivulets, and especially the Coln and Churn. Carried to greatest perfection in the parish of South Cerney; first began here under the Rev. W. Wright, who wrote several tracts on the subject. When the first great rains in November bring the waters down in a muddy state, it is let into the meadows. In December and January the land is kept sheltered by the waters from the severity of frosty nights; but every ten days, or thereabouts, the water is let entirely off, to give air and prevent the roots from rotting. In February great care is required. If the water now remains long on the meadows, a white scum will generate, which is found to be very injurious to the grass. On the other hand, if it be taken off, and the land exposed to a severe frosty night, without being previously dried for a whole day, much of the tender grass will be cut off. Towards the middle of this month less water is used than before, keeping the land rather wet than watered. At the beginning of March there is generally in such meadows plenty of pasturage for all kinds of stock; the water, however, should be taken off nearly a week before cattle are turned on, and a little hay at night during the first week is very proper. It is the custom with some to spring-feed with ewes and lambs folded, with a little hay. The meadows, however, must be entirely clear of stock by the latter end of April. If May be at all intruded on, the hay crop will be much injured, and the grass become soft and woolly, like lattermath. After spring-feeding the water is let in again for a few days. It is remarked, that autumnal, winter, and spring watering will not occasion rot in sheep; but if the water be used for a few days in any of the summer months, the pasturage becomes unsafe for such stock. This is conformable to the general idea of rot; viz. that it is occasioned by summer moisture, and is seldom known to any considerable extent without a long continuance of warmth and rain. A wet summer, therefore, is always productive of this disease in the vale. The general advantages of watering are, that the land and herbage are continually improving, without manure; and the crop is not only full and certain, but also early.

Warping might be practised to a considerable extent on the banks of the Severn, if the commissioners were to direct their attention to the subject.

12. *Live Stock.*

The dairy the principal object with most of the vale farmers. Good milkers preferred, without much regard to perfection of shape. Gloucestershire breed resembles the Glamorganshire excepting in colour, which is red or brown, bones fine, horns of middling length, white with a black tip at the ends, udder thin in flesh and large. In the higher vale the improved long

horned cows of Bakewell and Fowler in most repute. Devons, Herefords, and various others in use. The best land does not always produce the most marketable cheese; oftentimes the reverse; if it has either been much manured with dung, or sheep feeding, the quantity of milk will be increased, but the quality materially altered. This is probably owing to the introduction of plants, which did not grow there before, or to the destruction of some that did. The cause does not originate with the cow, but the herbage on which she feeds. The same cow, on two pastures, separated only by a hedge, will give milk of different qualities: from one shall be made fine, rich, and close cheese; while from the other shall be made rank, "heaving," hollow, unpleasant to the palate, and unfit for the market. In the parish of Haresfield, two grounds adjoining each other were alternately used for the pasture of cows: while they were on one, excellent cheese was made; but on the other, it was difficult to make any tolerably good. The latter had been lately well dressed with manure, which produced plants unfavourable to the dairy; and the dairy woman herself remarked, that if the farmer continued to enrich the herbage with dung, she must give up making cheese. It is proper, therefore, that milking-cows should not be removed from one pasture to another indiscriminately, but that certain grounds, in proportion to the stock, should be assigned to their use; and this is the practice on many farms where cow pastures have for time immemorial been appropriated exclusively to the use of the dairy. The dung of the cow, indeed, being of a cooling nature, is the best manure for cow-pastures. Other animals, such as colts and sheep, may occasionally be let in to eat the refuse grass, but not more than one sheep should be allowed to an acre. Among the plants which are useless, or unfavourable to the making of good cheese, are white clover (*Trifolium repens*), the different kinds of crow-foot (*Ranunculus*), and garlic (*Allium*). White clover is brought forward by manure and sheep stock, and is a proof of good land, at least of land in a state of high cultivation; hence it has a tendency to raise the quality of the milk, and make the cheese heave.

Cheese-making. Best cheese not attempted while the cows are on hay; generally commences about May, when the cows are turned into the pastures. Cows milked twice a day, at four in the morning, and at the same hour in the afternoon; the cheese-factor discovers the "hoved" cheese by treading on them.

Sheep. Principal breed the Cotswolds; now very much mixed by crosses with the Leicester and South Downs. The liver rot common in the vale, and therefore few bred there. Wiltshires are bought in and fed off.

Horses, no particular breed.

Pigeons, formerly numerous, now on the decrease.

13. *Political Economy.*

On the hilly districts, where stone abounds, the roads greatly improved of late; those under M'Adam excellent; but the vale roads in many places very bad. Manufacture of woollen broad-cloths, chiefly superfine from Spanish wool, extensively carried on in the district called the Bottoms. Carpet weaving and thin stuffs at Cirencester; stocking frame knitting at Tewkesbury; wire, cards, rugs, blankets, iron and brass wire, tin plate, pins, writing paper, felt hats, manufactured at different places. Spinning of flax the winter work of women in the vale of Evesham. Extensive iron works in the forest; the best iron in the kingdom made at Huxley; nails made at Littledean. Articles of agricultural commerce, cheese, bacon, cider, perry, grain, and salmon, to the extent of 4000*l.* per annum; in manufacturing commerce, broad-cloths and pins are of the greatest importance.

7792. WORCESTERSHIRE. A surface of 431,360 acres, according to the official estimates laid before parliament, though some of the calculations which have been published make it amount to 599,040 acres, distinguished by the two extensive vales of Worcester and Evesham. In the fertility of its soil, and the amenity of its situation, surface, and natural embellishments, very few districts of similar extent are equal to it — scarcely one excels it. And its agricultural products are not only more abundant, but more various, than those of other counties; not corn, cattle, and dairy produce only, but fruits, liquors, and hops, rank among its productions. (*Pomeroy's Worcestershire*, 1794. *Pitt's Report*, 1807. *Marshal's Review*, 1818. *Edin. Gaz.* 1827.)

1. *Geographical State and Circumstances.*

Climate of the middle, south, and west of the county, remarkably mild, soft, and salubrious; the vales of the Severn, Avon, and Teme, with the contiguous uplands, rising to 150 feet above their level, ripen their products from a fortnight to a month earlier than what takes place in elevated counties, even with a similar soil and surface; sixty yards perpendicular = one degree more to the north; conformably to this idea, early at Worcester, and late at Birmingham. Apparently much less rains falls here, than in counties more elevated and more inward.

Soil. Ten thousand acres of deep rich sediment deposited by the Severn, and a good deal on the Avon, Teme, and Stour; half the rest of the county, rich clay and loam: some light sandy soils about Kidderminster, and springy gravel about Bromsgrove.

Minerals. Brick-clay, gravel, sand, marl, freestone, coal, at Mamble; quartzern, a siliceous stone, forms the basis of the Malvern hills. Extensive lime quarries and coal mines at Dudley; excellent common salt at Droitwich.

Water. Rivers, but no lake, pool, or pond formed by nature. Malvern well, a good chalybeate; it is limpid, without smell or taste.

Fish in the Severn, salmon, shad, lamprey, and lampern; the lamprey grows to twenty-six inches long, and is often three or four pounds in weight; it leaves the sea in the spring, and is esteemed a great delicacy, but unwholesome when eaten too freely. The lampern goes to the sea at certain seasons; is ten or twelve inches long, about the size of a man's finger, and common in Worcester, potted or preserved; vast quantities sold for baits to the cod fishery.

2. *Property.*

Variously divided among all classes; many resident families of considerable opulence and fortune.

3. *Buildings.*

Some magnificent residences; farm-houses erected at different times, and no way remarkable, unless for being badly situated and arranged; great want of sheds for cattle. Cottages have nothing to recommend them; often built of timber and plaster, and covered with thatch. Some good stone bridges over the Severn, and an iron one of one arch, 150 feet span and fifty feet rise, at Stourport.

4. *Occupation.*

Farms small from 40*l.* to 400*l.* a year, but some larger; seldom held on lease; but when a tenant takes a farm on strong lands, where the course is fallow and three crops, he holds it by custom for four years. Knight, of Lea Castle, farms 330 acres in a masterly style; large farmers have a turn for improvement; small ones have seldom an opportunity; many inventions proposed and introduced, but the sensible farmer unfortunately finds few of them that will answer.

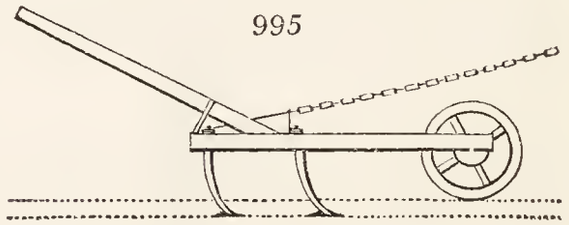
Picturesque farming by Knight. About 200 acres around Lea Castle, formerly in irregular uncouth divisions, with wide slovenly hedges, are now laid, or laying together, the roads better disposed both for convenience and appearance, and the hedges stocked up; but the trees, which are in abundance, carefully preserved, to give a park-like appearance; this is divided into lots by temporary hurdles.

Military farming. The same gentleman, when the volunteer cavalry were raised, sold his heavy farm horses, and bought light ones, chiefly Clevelands, on which he mounted ten of his own servants for military service. The horses doing all the farm work, and occasionally serving for saddle horses, or to draw his carriage.

5. *Implements.*

Plough two-wheeled, and drawn by three horses in a line, walking in the furrow; in the vale of Evesham, a heavy swing plough; these ploughs are seen nowhere else; they are all wood, excepting the share and coulter; very long in the tail, throat, and sideboard; a load for a team; the four-wheeled trolley is a low waggon, used for harvest work. Knight uses improved implements, and ploughs with two horses abreast. Various drills for sowing wheat, and stirring the soil between the rows (*fig.* 995.), manufactured at Evesham, and used in the neighbourhood.

995



6. *Arable Land.*

Fallows ploughed four times, which is rather rare in England; rotations generally a fallow and two corn crops, with an intervening leguminous herbage, or turnip crop. Drilling in use for wheat, in the vale of Evesham and other places; beans commonly dibbled. Turnips cultivated broad-cast; and Carpenter, author of *A Treatise on Practical and Experimental Agriculture*, has discovered since he published his book, that the fly is to be prevented or destroyed by steeping the seed in sulphur before sown, and harrowing as soon as the fly is discovered; "then sow eight bushels per acre of dry lime, or fine ashes, when the dew is on the leaves, so as it may adhere to them." Carrots sown by Knight and others in the neighbourhood, where a good deal of seed is raised for the London seedsmen.

Hops grown to great perfection, and fruit trees generally planted among them, at the rate of forty-eight to an acre; 1000 stools of hops are considered an acre, whatever ground they may stand on, and labour is paid for accordingly. Golding-vine, mathon-white, red, nonpareil, and Kentish grape, local names for varieties distinguished by very slender shades. Land stirred between the plants with the plough; only two poles to a stool; picking chiefly by Welsh women. When tithe of hops is taken in kind, the parson may either take every tenth basket when green, or every tenth sack when dried; in the latter case, allowing 25*s.* per cwt. for drying, sacking, and duty. The culture of hops having been carried too far, the trade here, as elsewhere, is on the decline; corn, on the average of years, is found to pay better.

Asparagus, cucumbers, and onions, grown in the fields of Evesham, and sent to Birmingham market, though thirty miles distant; also, poppy-heads for the London druggists. Clover for seed in various parts of the county.

7. *Grass.*

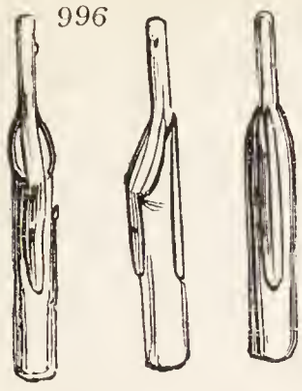
The banks of the rivers chiefly under meadow of the very richest kind; employed chiefly in fatting cattle and sheep; clovers and rye grass cultivated.

8. *Gardens and Orchards.*

Market gardens near most of the principal towns; produce, besides local consumption, is sent to Bath, Bristol, and Birmingham. Orchards, long and successfully cultivated in the middle, south, and western parts of the county; round towns, villages, and farm-houses; and all the hedge-rows of a farm often planted with fruit trees, and very productive. In a plentiful year, or what is called a "hit of fruit," it will not pay for carriage to market from remote places; no casks can be got for all the juice. In 1784, cisterns were formed in the ground to receive the liquor, but they ran out; in Pershore, it is said currents of perry ran into the common sewers. Large quantities of apples rot, or are devoured by hogs; cider in such a year sold for 21*s.* a hogshead, in Worcester market: two or three tons of cherries often sold in Worcester market in the morning before five o'clock; six tons have been sold there in one morning; 2000*l.* has been paid for the tonnage of fruit on the Trent and Severn canal in one year: canal forty-six miles long, tonnage 1½*d.* per ton per mile; 7000 tons must

therefore have passed. The stocks are not grafted here till three years after planting out, and saddle grafting of a peculiar kind (*fig.* 996.) is preferred to the cleft manner used in Gloucestershire. Sometimes the boughs of the stock are each grafted in the whip manner. When cleft-grafting is performed, the cleft is made with a saw, and afterwards smoothed with a knife; little care paid to the trees afterwards; they bear at five years, are at perfection at thirty, and continue in full bearing for at least thirty years more. Sheep should be excluded from the orchards, and coarse grass or straw burned in them on the first appearance of a blight; this fumigation destroys myriads of insects. Fruit is gathered as it falls from the tree; no force used till the leaves are mostly fallen, and then only shaking or striking with a light pole. Cider made as in Gloucestershire, but with no great attention to the mixture of fruit, or its previous sweet and clean state. Pomeroy proposes to separate the core and kernels from the pulp, by forcing a cutting cylinder through each apple, and then grinding the core and pulp apart, as much of the flavour of cider depends on bruising the seeds.

996



9. *Woods and Plantations.*

Abundance of oak and elm. Croome, Hagley, &c. well-wooded. Forest of Wire, near Bewdley, supplies oak poles, rails, hurdles, laths, hoops, &c.

10. *Improvements.*

Earl of Coventry drains his park by open cuts wide, and their sides turfed to the bottom; all the attention they require is preventing the establishment of large weeds or coarse tufts of grass, which would interrupt the water; some embankments on the Severn, and some meadows irrigated, but mostly by floods.

11. *Live Stock.*

No particular breeds; land too good for breeding; feeding chiefly attended to, and some dairying; some soiling, and a good deal of oil-cake used for finishing autumn-fed oxen. Mules used in agriculture in some parts of the county, especially near Bewdly; rise to fifteen hands or more; Skey's carriage mules bred from grey or white mares and a white spotted foreign ass. The great age to which they attain is one of their chief advantages; at perfection at thirty, and work till seventy or upwards. Asses employed by Carpenter, of Bromsgrove, farmer and author.

12. *Political Economy.*

Principal roads good; cross-roads very bad. A subterranean canal near Dudley A road club, established in the vale of Evesham in 1792, the members of which bind themselves to become road surveyors, gratis, in their turns, and strictly to enforce all laws, and to take all the means in their power for procuring and keeping good roads. Several canals, fairs, and markets. Manufactures of gloves in Worcester, and also of porcelain and cabinet furniture: of woollen cloth and glass at Stourbridge; of glass and nails at Dudley; leather-making from sheep-skins at the same place; nails, needles, linen, wool-combing and spinning at Bromsgrove and Redditch; tanning in most places; carpets at Kidderminster; various iron works on the Stour; stocking frames at Tewkesbury and Bredon.

Droitwich salt works on record from 816. The strata over the salt are, mould five feet, marl thirty-five feet, talc, a gypsum or alabaster, forty feet, then a reservoir of brine twenty-two inches, then talc seventy-five feet, then a rock of salt, into which the workmen bored five feet. The brine is inexhaustible; on boring through the talc, it immediately rises and fills the pit. Salt made here and sold in one year, from April 5. 1771, to April 5. 1772, 604,579 bushels; of which exported abroad, 110,120 bushels. Duty paid into the salt-office, London, 61,457*l.*, which was then nearly one third of the whole revenue from salt in England. The process of making salt at Droitwich is as follows: — A little common water is first put into the pan, to keep the brine from burning to the bottom; the pan is then filled with brine, and a small piece of resin thrown in to make it granulate fine; when the brine is boiling, the salt first incrusts at the top, and then subsides to the bottom; when subsided, the persons employed ladle it out with an iron skimmer, and put it into wicker barrows, each containing about half a bushel, in the shape of a sugar loaf, and let them stand at the side of the pan for some minutes to drain; they then drop the salt out of the barrow, and place it in the stove to harden. In 1775, Baker, a druggist, from London, spent 12,000*l.* in a project for conveying the Droitwich brine in pipes to the Severn, without success. Dr. Nash, from experiment, believes Droitwich salt to be neither manure in itself, nor capable of exciting any vegetative principle on the earth, as animal or vegetable salts or lime may do; it produces bad effects on ploughed lands, by increasing their dryness in hot weather, and by making them greasy, and what the farmers call raw, in damp weather. He has found it serviceable to scatter foul salt upon large heaps of manure, to kill weeds and destroy their seeds, but not to enrich; care must be taken that it be not laid near the roots of the trees, as it will certainly destroy them. If laid at the bottom of pools, it enables them to hold water; it is wholesome to granivorous and graminivorous animals, but prejudicial to carnivorous ones.

13. *Means of Improvement.*

The establishment of village and parish libraries recommended; and a paper on the subject copied, which appeared in the Worcester newspaper. From the books recommended, as well as other evidence, the writer of this paper is Sir Richard Phillips. The plan is excellent, and would probably, in the course of a generation, effect a complete change in the lower classes of society. Le Couteur's treatise on apple trees and cider, as applicable to the Isle of Jersey, appended to the survey.

7793. MONMOUTHSHIRE. A surface of 316,800 acres varied by hills, some of which are of considerable height; more distinguished by its woods and its mineral products than its agriculture. A part of the coal basin of South Wales a fund of wealth of immense consequence to Britain, extends into Monmouthshire, and, with the iron works, forms an important source of industry and wealth. (*Hassal's Report*, 1811.)

1. *Geographical State and Circumstances.*

Climate. Mild in the vales and cold on the confines of Breconshire, where the snows sometimes remain on the ground till a late period in spring; atmosphere humid, as in most western counties; highly favourable to the growth of grass.

Soil. Clay, loam, and grey soil on rock or marble, and beds of limestone. Caldicot and Wentlog levels on the Severn; under the court of sewers is a rich silty loam. Soil of the hills a reddish loam. No poor soil in the county.

Minerals. Coal, iron, and lime. Upwards of twenty iron works in the coal district; coal not brought into general use till 1792, when the canals and rail-roads were completed. Principal proprietors of the mineral district, Sir Chas. Morgan, C. Leigh, Esq., B. Hall, Esq., and the Earl of Abergavenny. A particular description of the mineral basin of South Wales given by Martin (*Phil. Trans.* 1806).

2. *Property.*

Duke of Beaufort and Sir Chas. Morgan the chief proprietors; next class, 1000*l.* to 3000*l.* a year; a third class, 500*l.* to 1000*l.* a year. Many proprietors occupy a part of their estates, and cultivate them well; some very small proprietors of orchards and grass lands.

3. *Buildings.*

Some fine old seats; farm-houses of the oldest date, timber thatched; new ones covered with tile stone; seldom any farmyards; but cattle-houses and barns scattered about at random; cottages on the most frugal plan, generally with a garden.

4. *Occupation.*

Size of farms, 60 to 300 acres; 140 acres about the average; leases not very general.

5. *Implements.*

The proprietors of iron works have introduced many improved forms from the north; very neat iron gates and posts. (*fig.* 997.)

6. *Arable Land.*

Less than the pasture; tillage chiefly by oxen. "Many farmers are so circumstanced, as to be ever on the watch, lest the avarice of their landlords should interfere with their industry, by taking advantage of any improvement they make in the soil, and unexpectedly raise the rent. That such unfair dealing is become too frequent, is much to be lamented, and can only be guarded against by leases."

7. *Grass Land.*

"Some farmers insist on it that rushes shelter and protect grass, and will not allow them to be removed by draining or otherwise."

8. *Gardens and Orchards.*

The latter very general on a small scale; apples for eating much in demand at the iron mills; best orchards and hop-grounds in the hundred of Ragland.

9. *Woods and Plantations.*

County long famous for the size of its oaks; stock now much diminished.

10. *Live Stock.*

Mixed cattle; some dairying, but feeding more general; Hereford horses a good deal bred; asses and mules in use about the iron works: the mules found better than horses for carrying charcoal from the woods to the iron works.

11. *Political Economy.*

Valentine Morris, Esq., of Piercefield, being examined as to the roads of the county, before Parliament, was asked, —

Q. What sort of roads have you in Monmouthshire?

A. None.

Q. How do you travel then?

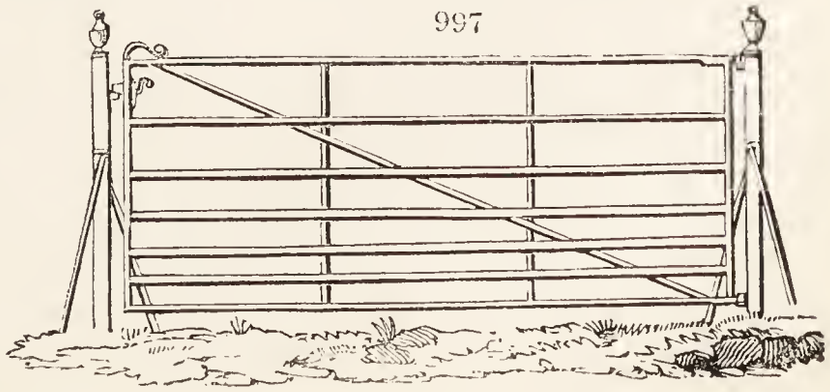
A. In ditches.

This was thirty years ago (1800); they are now (1830) improved, but still bad; various railways and canals.

12. *Means of Improvement.*

Leases; embanking the river meadows; drainage; knowledge.

997



7794. HEREFORDSHIRE. A surface of 600,000 acres, studded with hills, hillocks, and minor swells of various heights and dimensions; almost every where of a rich soil, devoted exclusively to agriculture, and highly productive in corn, cattle, fruit, cider, hops, and timber. The most distinguished cultivator in the county is T. A. Knight, Esq., known in agriculture by his Treatise on the Apple and Pear, many valuable papers in the Transactions of the Royal Society, and communications to the Board of Agriculture; and in gardening by numerous essays and improvements, and his honourable office of President of the Horticultural Society. (*Clark's Herefordshire*, 1794. *Duncombe's Report*, 1808. *Marshal's Review*, 1818.)

1. *Geographical State and Circumstances.*

Climate, remarkably healthy; west winds the coldest; warmest and earliest part about Ross.

Soil. A marly clay of great fertility extends over most of the county. The heaviest crops of wheat produced on a clayey tract between Hereford and Ledbury; the lightest lands in the south-east about Wormelow, and known as the "Rye lands," from the prevailing produce there in former times.

Minerals. Iron ore in the sandy district, but none manufactured at present. Red and yellow ochres, pipe-clay, and fullers' earth, but only the latter worked for.

Water abounds; salmon caught in the Wye, but, owing to the weirs and illegal practices, not so abundantly as formerly.

2. *Property.*

Guy's Hospital, Duke of Norfolk, Earl of Oxford, Earl of Essex, Sir G. Cornwall, &c. the largest proprietors. Their estates divided into farms of from 200 to 400 acres. A number of estates from 400*l.* to 1000*l.* per annum constantly resided on by their owners, and cultivated and managed in good style, with a view to the introduction of the best agricultural practices. The tenures of gavelkind and borough-english exist in a few places, but are generally nullified by will.

3. *Buildings.*

Some fine seats of proprietors, as Hom Lacy, Hampton Court, Downton Castle, &c. Old farm-houses of wood, ill designed, and placed: some good new ones on the Guy's Hospital and other estates. Cottages very humble, and of an inferior construction. Strawberries lately cultivated by some cottagers, for the Hereford market, with success and profit.

4. *Occupation.*

Small farms on the decline; few opportunities now by which an industrious couple can devote 50*l.* or 100*l.*, acquired by personal labour, to stock a few acres, and bring up their family, and pass their latter years in comparative independence. Hence matrimony on the decline, and licentiousness on the increase. Hence Duncombe humanely recommends proprietors to forego the temporary advantages of throwing the whole of their estates into large farms, and advises some of all sizes, from 5 to 500 acres, as ultimately best for the country. "The old-fashioned farmer of Herefordshire receives any new experiment in agriculture with great hesitation, if not reluctance. When its utility is confirmed by repeated trials, he slowly and gradually falls into the practice; but he wisely leaves the experiment and the risk to those who recommend or suggest it; and happily the county is at this moment well provided with agriculturists, who possess the means and the spirit to undertake the patriotic task." Leases of twenty-one years most commonly in three periods of seven years, determinable at the end of each period by either landlord or tenant.

5. *Implements.*

Plough called the light lamnias, without a wheel, and drawn by three or four oxen generally in a line, abreast; but often the yoke is the usual mode of harnessing. Various improved implements by the amateurs, but none in general use.

6. *Arable Land.*

Wheat principal grain cultivated, and generally sown on a fallow. Change of seed procured from the chalk hills of Oxfordshire; steeped in brine and lime, to guard against vermin and smut. Knight, late of Eaton, now of Downton Castle, steeps in water and then envelopes in lime, and his wheat was as free from smut and other diseases as that of his neighbours from changed seed. Hops a good deal cultivated, and chiefly disposed of to Bristol dealers.

7. *Grass.*

Fertile meadows on the Wye, Frome, and Lug; mown and fed. Not a dairy county for home consumption, seldom for exterior markets, or Smithfield. Butter supplied from Wales, and cheese from Shropshire and Gloucestershire. "The general soil of Herefordshire appears to be unfavourable to the making of cheese. T. A. Knight, with that accuracy and skill which he is known to possess on all subjects connected with agriculture and natural history, has proved by experiment, that equal quantities of milk in Herefordshire and Cheshire will produce unequal quantities of curd, highly to the advantage of Cheshire: and farther, that better cheese has been produced in that county, from milk, half of which has been previously skimmed, than is produced in this from milk altogether unskimmed. The want, therefore, of complete success in this valuable branch of rural economy is not solely to be attributed to the want of skill in our dairy-maids; and the cause of failure is rendered more difficult of discovery, and consequently more difficult to he remedied, from an observation that the plants were nearly the same in the Herefordshire and Cheshire pastures, on which the above experiments were made: white clover abounded in each, with the crested dog-tail grass and rye-grass mixed with others in small quantities. Of such plants the pastures of Herefordshire are generally composed

A mode of managing sound meadows and pastures has lately been tried, and attended with a great increase of produce. The grass is mown as soon as it is in blossom, and consequently previously to the formation of seed. The after-grass is not grazed until it begins to contract a yellow appearance, in the latter end of October or beginning of November. In this case the ground remains covered during the winter with a portion of dead herbage, through which the young grass springs with the greatest vigour at an early period of the succeeding spring.

8. *Gardens and Orchards.*

Fruit trees first extensively planted in Herefordshire in the time of Charles I., by Lord Scudamore, of Home Lacy. Orchards and hedge-row trees of the apple and pear kind are found on every aspect, soil, and under every culture. The soil best adapted to most kinds of apples, is a deep rich loam when under the culture of the plough; the Styre and golden pippin, in particular, form exceptions, and flourish most in a hot and shallow soil, on a lime or sandstone. The best sorts of pear trees also prefer the rich loam, but inferior kinds will even flourish where the soil will scarcely produce herbage. The apples are divided into old and new sorts; each class comprises some called kernel fruits, namely, the fruit growing on its native roots, as a distinction from those produced by the operation of grafting. The old sorts of apples are those which have been long introduced, such as the Styre, golden pippin, hagloe-crab; several varieties of the Harvey; the brandy apple, red-streak, woodcock, moyle, gennet, red, white, and yellow musks; fox whelp, loan, and old pearmains; dymock red, ten commandments, and others. Some of these names are descriptive of the fruit, and others are derived from the places where they have been first found, or found in most abundance. The old pears held in most estimation are, the squash, so called from the tenderness of its pulp; the oldfield, from having grown as a seedling in a field of that name; the huffcap, from the quantity of fixed air contained in its liquor; the barland, from fields in the parish of Rosbury, called the Barlands; the sack-pear, from its richness; and the red pear, from its colour. Of more common sorts, the long-land is the most valuable, and for the general use of the farmer perhaps the best of any.

9. *Woods and Plantations.*

Oak very abundant, and more rapid in its growth in this county and Monmouthshire than in most parts of England, Lord Oxford's estates and Croft Castle contain the finest old trees in the county; fine woods at Foxley, U. Price, Esq.; most luxuriant oak timber and coppices at Moccas Court and Stoke Park; a curious weeping oak at Moccas. Most productive ash coppices at Hampton Court and Ledbury; cut every thirteen years for crate ware, hurdles, &c. and bring from 18*l.* to 35*l.* per wood acre, which is to the statute acre as 8 to 5. Elm trees are interspersed in the hedge-rows with fruit trees.

10. *Improvements.*

Draining much wanted, but practised chiefly by proprietors; watering little practised, though introduced in 1610 by R. Vaughan, Esq. of New Court, whose tract on the subject has been already mentioned. (4376.) One of the greatest experiments in this way which have been attempted of late years in Herefordshire, has been attended with complete success on the estate of T. A. Knight. By making a weir on the river Teme, with proper courses for the water, that gentleman is now enabled to irrigate two hundred acres of land, which were never watered before, with the assistance of the least flood; and one half of that quantity even in the driest season.

11. *Live Stock.*

Hereford cattle esteemed superior to most, if not to all, other breeds; those of Devon and Sussex nearest them in appearance. Large size, an athletic form, and unusual neatness, characterise the true sort; the prevailing colour is a reddish brown, with white faces. The rearing of oxen for agricultural purposes universally prevails; nearly half the ploughing is performed by them, and they take an equal share in the labours of the harvest. They are shod with iron in situations which frequently require their exertions on hard roads. The show of oxen in thriving condition at the Michaelmas fair in Hereford, cannot be exceeded by any similar annual collection in England; on this occasion they are generally sold to the principal graziers in the counties near the metropolis, and there perfected for the London markets.

Herefordshire *not being a dairying county*, breeders direct their attention to producing that form of animal best adapted for feeding rather than milking. "The whole attention of the Leicestershire breeder has been directed to the improvement of his cow; and for the use of the grazier, he has made her an excellent animal. The Herefordshire breeder, on the contrary, has sacrificed the qualities of the cow to those of the ox; he does not value his cow according to the price which the grazier would give for it, but in proportion as it possesses that form and character which experience has taught him to be conducive to the excellence of the future ox. Hence the cow of Herefordshire is comparatively small, extremely delicate, and very feminine in its characters. It is light-fleshed when in common condition, but capable of extending itself universally in a short space of time, when fattening. Experience seems fully to have proved, that these qualities in the cow are necessary to perfection in the ox; and that when the cow is large and masculine in its character, and heavily loaded with flesh, the ox will be coarse and brawny, and, consequently, unkind and tedious in the process of fattening. It may here be remarked, that there is an extraordinary difference between the weight of a Herefordshire cow and the ox bred from her; perhaps other sorts, eminent for producing fine oxen, are similarly distinguished; but it is a fact, that a Herefordshire cow will not unfrequently be the mother of an ox of nearly three times her own weight. T. A. Knight, who made this observation, recollects no instance of this great disproportion in the weight of the males and females of the long-horned cattle. That gentleman farther observes, that he is unable to discover what advantage the public have derived, or are likely to derive, from a breed of cattle which are neither calculated for the dairy nor for breeding oxen. The difference in the dairy between a good and an indifferent milking cow, on the pasture which is adequate to the keep of the latter, will seldom exceed five pounds, and if the animal be good, a very poor pasture will be sufficient; but the difference between a good and bad ox will often exceed twenty pounds, where both have consumed in fattening equal quantities of food: individuals and the public are, therefore, equally and evidently interested in the improvement of the labouring ox. Persons of little experience, Knight adds, in the breeding of cattle, may perhaps think that a sort is obtainable which will unite the two objects; but experience will convince them, that in endeavouring to

approach two opposite points at the same time, they will never be able to reach either. Where the soil is well calculated for the dairy, every attention should be paid to obtain and improve the best sorts of milking cows; and where the ox is kept to a proper age as a beast of draught, nothing conducing to his excellence ought to be neglected. A cow must, however, give milk enough to keep its calf fat, or it is disqualified for breeding a good ox; because the calf would be spoiled before it had acquired the proper age to be weaned.

Sheep. The provincial breed, the Ryeland, named from the sandy district in the neighbourhood of Ross. They lamb in February and March; but during winter, and particularly in time of lambing, the store flocks are generally confined by night in a covered building, provincially termed a cot, in which they are sometimes fed with hay and barley straw, but much more frequently with peas-haulm. Some breeders accustom them to the cot only in very severe weather, and in lambing time. The practice was derived from the Flemings, and introduced into England about the year 1660. A cross has been made between the Ryelands and the new Leicester sorts, to the advantage, perhaps, of the breeder who is situated on good land, but certainly to the detriment of the wool. A cross between the Ryeland and real Spanish seems the most probable mode of adding to its fineness and value. Dr. Parry's experiments have been already related. (7232.)

12. *Rural Economy.*

"If a certain proportion between the price of labour and the average price of wheat could be fixed by law, so as to render the applications for parochial aid necessary only in cases of a very large family, of unusual illness, of scanty seasons, or any other real emergency; the measure, it is presumed, would be honourable to the country, would stimulate industry and fidelity, would check dishonesty, and endear to a numerous class their native soil."

13. *Political Economy.*

Roads formerly bad; now improving; materials, coarse limestone. Gloves, to a small extent, manufactured in Hereford. An agricultural society established in 1797, which has given many premiums, and done much good.

7795. SHROPSHIRE. A surface of 890,000 acres; in general flat, but with hills of considerable height on some of its margins. The soil is chiefly clay, but in part light turnip land; both are devoted to the raising of corn-crops. Breeding and dairying is also practised to a moderate extent. The greatest improver in the county is the Marquis of Stafford, whose extensive and important operations on the estate of Lilleshall are described at length by Loch, in his *Improvements on the Marquis of Stafford's Estates*, 1819. (*Bishton's Shropshire*, 1794. *Plymley's Shropshire*, 1801. *Marshal's Review*, 1819.)

1. *Geographical State and Circumstances.*

Climate. Considerable difference according to the soil and surface; more warm on the eastern side than in the middle of the county. E. winds prevail in spring, and W. in autumn.

Soil. Nearly an equal quantity of wheat and turnip land, the former rather predominant. S.W. side of the county variable; thin soil upon clay or rock; extensive tracts of hills and waste; and most sorts of soils except chalk and flint.

Minerals. Lead in granulated quartz very productive. Copper ore found but not worked. Coal of excellent quality on the eastern side of the county; lime, building-stone, chalybeate and spa waters, at different places. At Kingly Wick a spring of salt water, used for making soda at a work established at Wormbridge. Extensive iron works at Colebrook Dale, where the first cast-iron bridge was erected by Mr. Telford about 1780.

Waters. Twenty-two sorts of fish found in the Severn in Shropshire. Salmon in season from Michaelmas to May.

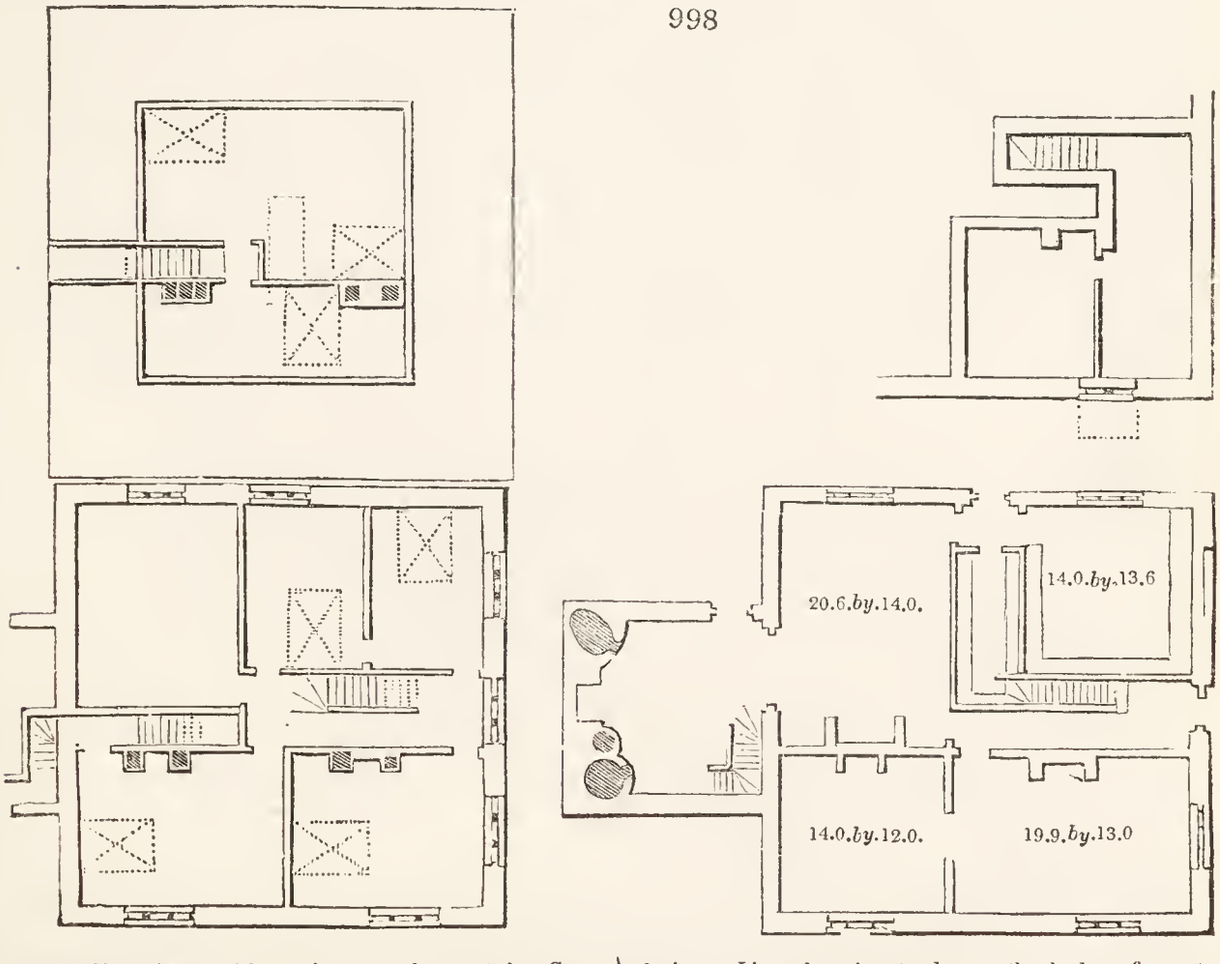
2. *Property.*

Estates of from 10 to 25,000 acres, and an infinite number of freeholders: yeomanry estates of all inferior sizes: much copyhold, but the lords upon some customary manors have enfranchised the copyholders upon receiving an equivalent in money.

3. *Buildings.*

Some good new mansions; above eighty of these named in old maps become farm-houses. Farm-houses generally in villages. Excellent new ones on the Marquis of Stafford's estates. (*fig.* 998.)

998



Comfortable cottages with gardens much wanted. Some judicious observations by Plymley; prescribes no particular forms, but suggests the impropriety of making them, or indeed any other object, bear an outward appearance, intended to contradict their inward use; all castellated or gothicised cottages, all churchlike barns, or fortlike pigsties, he conceives to be objectionable. They are intended to deceive, and they tell you that they are intended to deceive. It is not pleasant to encourage any thing like deceit, but in these instances imposition effected is rarely gained; it amounts only to imposition attempted; or, could the deceit succeed, it would only present a prospect with fewer proprieties about it than there really are. Almost every species of country building has a good effect, if properly placed and neatly executed; and what are the least ornamental, or indeed the most disgusting, of their appendages, cease to shock when supported by the relative situation they stand in, showing their necessity and their use. A dunghill in a farm-yard creates no disagreeable idea; but connected with a Gothic gateway or embattled tower, it is bad. Cattle protected by the side of a barn form a picturesque group; but sheltering under a Grecian portico, the impropriety is glaring. Linen hanging to dry on the hedge of a cottage garden may be passed without displeasure; but the clothes of men, women, and children surrounding the cell of an anchorite, or the oratory of a monk, have their natural unseemliness increased by the contrast. On the other hand, a fine-dressed lawn with miserable cottages may be compared to the laced clothes and dirty linen some foreigners were formerly accused of wearing. The whole of a gentleman's estate should be his pleasure-ground: the village should be one object in the scene; not shut out from it. There may be a little more polish about the mansion, but it should not be an unnatural contrast to the surrounding objects. The face of no country is bad but as it is disfigured by artificial means; and the cheapest and best improvement is merely to remove what offends, and to take care that the buildings or fences that are wanted are neat and appropriate, exhibiting distinctly their real intention. Plymley is a friend to single cottages, because two families under one roof may have more causes of contention arise between them. On the other hand, in illness poor people have frequently the merit of forgetting their differences; and then the assistance they are inclined to give each other is made more easy by near-

ness of situation. It is possible, however, where two, or even three houses are joined together, to contrive the gardens in such a manner that there may be little interference; and sometimes three neighbouring families may do better together than two.

4. *Occupation.*

On the borders of Wales the farms are small, many not exceeding twenty acres; on the east side of the county from one to 500 acres: farmers in general very industrious; work along with their servants; wives brew, bake, dairy, and at spare hours spin, and get up a piece of linen cloth for sale every year. Leases for lives formerly very common. Bishton of Kilsall has taken great pains to prepare printed leases, which answer very well. The term he recommends is seven, fourteen, or twenty-one years. By being printed the farmer can read them at his leisure.

5. *Implements.*

Plough with two wheels, drawn by four or five horses, or six or eight oxen, in the strong lands, and two horses with a boy to drive in the turnip soils. Various improved implements and threshing-machines: some excellent mills on Lord Stafford's estates, driven by steam.

6. *Enclosing.*

Much practised, and still going on. Plashing hedges is usually very ill done in Shropshire; it is a business which requires great nicety and judgment, and has the most ignorant operators to perform it in general; who in the first place cut downwards, through mere idleness, instead of upwards, and so expose the heart of the plant to the weather. Many miles of hedges lately planted on the Stafford estates.

7. *Arable Land.*

Fallowing very badly done on the strong lands. Common crops of the county wheat, barley, oats, peas, and turnips. Peas found not to boil well unless grown on a sharp gravel or sand; those grown on clay given to pigs and horses. Some hemp and hops cultivated.

8. *Grass.*

Some natural meadows on the Severn and other rivers; not much attention paid to them. Artificial herbage and grasses grown on the turnip soils.

9. *Gardens and Orchards.*

Many farmers have small orchards, from whence they make a little cider for home consumption; and on the confines of Herefordshire and Worcestershire the orchards are larger, and cider is made for sale.

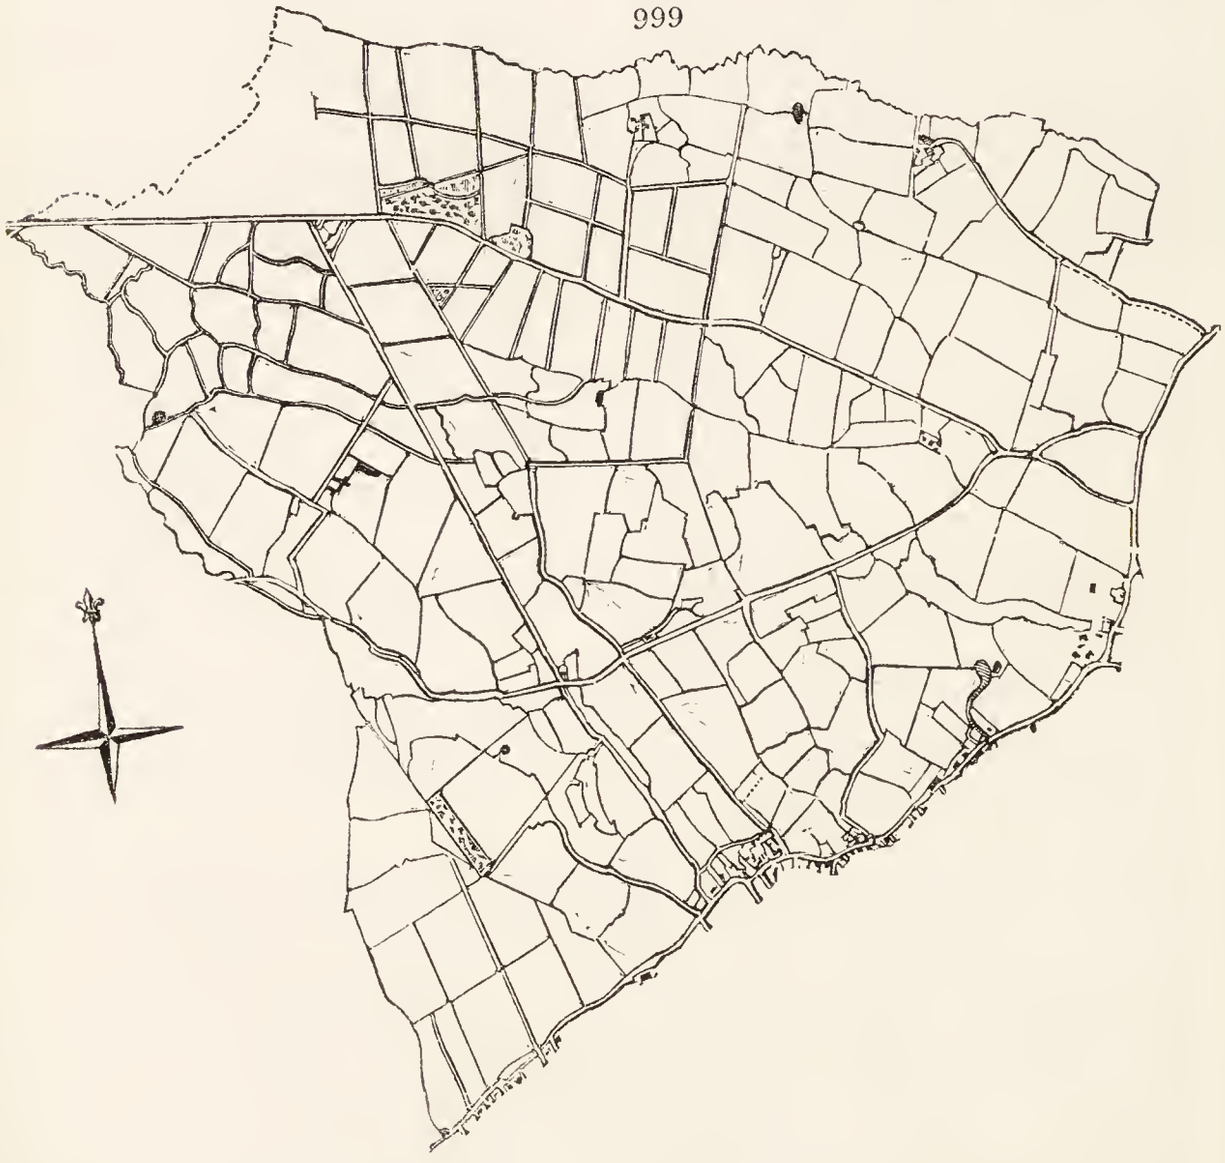
10. *Woods and Plantations.*

A good deal of hedge-row timber, and some fine oak woods; also numerous young plantations. Narrow-leaved elm reckoned an excellent hedge-row tree, but the broad-leaved better timber, and less difficult as to soil and situation. In this county few persons will bury their relations in any but the best oak timber, which contributes much to its scarcity.

11. *Improvements.*

Marl used, and some irrigation. A good deal of draining done with brick, stone, and faggot wood. Some bogs drained in Elkington's manner. On the Lilleshall estate of Lord Stafford (*fig.* 999.), in 1816 and 1817 there has been executed about 17,000 yards of embankment; 27,000 yards of water course deepened and scoured; 46,000 yards of main ditches made or

999



deepened; 315,000 yards of fence-ditches deepened, scoured, and straightened: 49,000 yards of old fences stocked; 30,000 yards of new quick fences made; 21,000 yards of turf draining; and 462,000 yards of under-ground draining, laid with tiles and filled with stones; besides the erection of many new farmeries of the most commodious plans and substantial execution. But to have an adequate idea of these and other improvements effected by this munificent and patriotic nobleman, it is necessary to peruse the very interesting work of Loch already referred to.

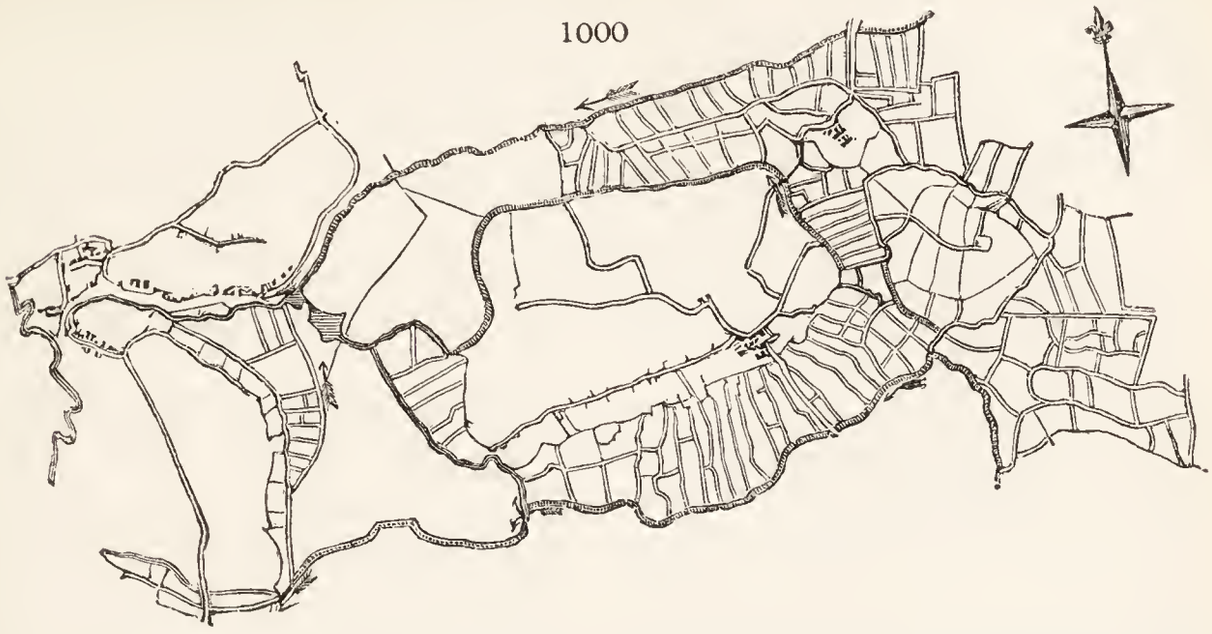
On the Wildmoor estate of Lord Stafford (*fig.* 1000.) excellent roads have been formed; so that several parts, before inaccessible in winter and during wet weather, may now be approached at all times with ease. The effect, as Loch observes, has thus been to add so many acres to the estate. But the most considerable work executed upon these estates is the drainage of the extensive district alluded to, called the Wildmoors. The extent and nature of this improvement is such as to deserve a particular and detailed description. Some adjoining properties have benefited by this work, and contributed to the expense of it, which was done under the authority of an act of parliament; but as almost the whole of the land belongs to the Marquis of Stafford, and the expense having been chiefly borne by him, the direction of its progress, and its preservation hereafter, is entirely vested in a surveyor chosen by his lordship.

These moors consisted of an extensive tract, amounting, with the land similarly circumstanced, to near twelve hundred acres. The soil is composed of a fine black peat, incumbent on a bed of red sand, full of water. They are bounded chiefly by the upland part of these estates, and surround the parish of Kynnersley, which also belongs to it, and which is composed of some of the finest turnip and barley soil in the kingdom. They had evidently formed the bottom of an extensive lake. The different brooks from the surrounding country held their course through them. These brooks are known in the country by the name of *Strines*, being distinguished from each other by the name of the places from which, or past which, they flow. Their course to the Tearn (which river drains the whole of this country into the Severn) was devious and crooked in the extreme, injuring to a great extent the land through which they ran.

A great proportion of these moors was occupied by the tenants of the adjoining farms, who turned their stock in upon them for a portion of the summer season only. During the rest of the year it was impossible to use them. They afforded but a small quantity of food, and were in most places so wet that it

was at all times difficult to walk over them, it being necessary to select the hardest places to step on. They were covered with water after almost every severe rain, owing to which the inhabitants of the neighbourhood were subject to frequent attacks of ague. The adjoining lands besides, to an extent exceeding six hundred acres, were kept in nearly a state of

1000

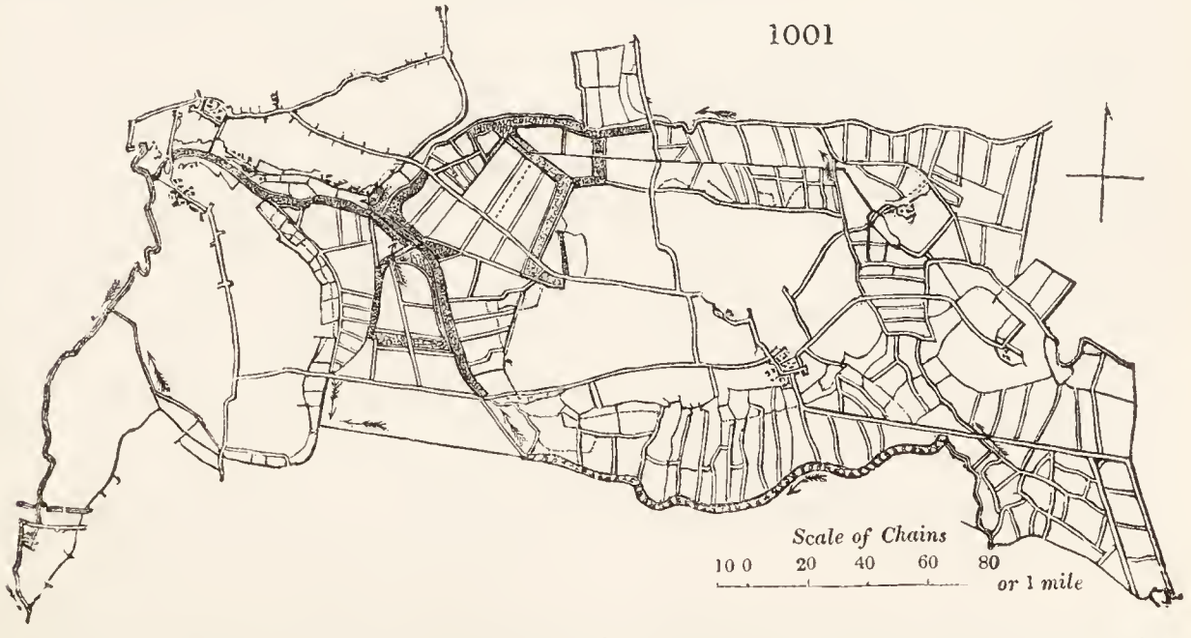


nature, owing to there being no level by which they could be drained while this extensive district continued subject to such inundations.

The difficulty which occurred in draining this tract of land arose from the want of level, and from the river Tearn being pounded so high by the mill-pools as to throw the water back to a great distance upon the land. The plan for draining this extensive district was extremely well conceived and judiciously laid out, in the double view of securing this object and of interfering as little as possible with private property and the existing establishments situated on the Tearn. It was suggested by John Bishton, Esq., the first commissioner under the Act. The great object was to gain as much additional level as would create a run throughout the whole extent of the moorlands. This was to be obtained by beginning the cut which was to carry off the water a considerable way lower down the Tearn than the water had hitherto been discharged into that river; and a good deal below the mill-pool at Long, which occasioned this poundage. The original courses of the strines were straightened and widened, but they were still made to convey the water from the uplands, and to discharge them into the Tearn in their original direction. To prevent them overflowing the adjoining lands, and to cut off the effects of the back poundage of the Tearn on the upper moors, these brooks were embanked for the whole length of their course through the Wildmoors. These are technically called argue banks. At the back of these banks deep ditches were carried, but in a more direct line than the course of the strines. Into these ditches the drainage of the moorlands is emptied. The level which was thus brought from the river Tearn, from below Long Mill, was carried in a tunnel under the Shrewsbury canal, and was conducted below the several strines in siphon culverts, and thus communicated with the ditches described as having been made behind the banks which confined the waters of these brooks.

In some instances it has been necessary to construct one set of culverts over another, in order that the waters coming from the uplands may be kept in the several brooks through which they had constantly flowed, and that this water flowing from the uplands might not fall into the back drains; it being again explained, that the water flowing from the higher grounds is still confined to the original strines or brooks on an upper level; the drainage water alone of the moorlands being thrown into the back drains. Thus has a great additional level been obtained, and the whole of this district is now entirely relieved of water, and such a thing as a flood has not been known for years. This district is in some instances so flat, that the old course of the Preston strine, which formerly conducted the water of that brook in one direction, has with little difficulty been made a part of the drainage, and to carry the drainage water in exactly the contrary direction, a new channel having been cut for the strine. Taking advantage of this drainage, main ditches upon a regular system have been carried into all the neighbouring parts of the estate, thereby enabling the landlord and the tenant to execute various other improvements.

1001



This district has been subsequently divided into *regular enclosures*, by great ditches, which fall into the main drains; and wherever it has been possible, these ditches have been made to serve this purpose, as well as that of a fence to the new roads which have been constructed across these moors. In one instance, one of these roads has been carried in a straight line for about two miles. On each side of this road trees have been planted, at regular distances, which will soon form one of the finest avenues in England. These moors have besides been all regularly under-drained by turf drains, which stand remarkably well. In the different ditches are placed flood-gates, to pound back the water during the summer, preserving the meadows in a state of perpetual verdure. The water is let off at least once in every fourteen days, and being drawn off with as much velocity as possible, it scours and keeps clear both the ditches and the underground drains; — the mouths of these latter are all defended with tiles. The moorlands have been greatly improved by very heavy and repeated rollings and top-dressings; and their value as let to a farmer, in many instances, is fully doubled. This improvement has cost a very large sum of money; which was increased beyond what was necessary, owing to the inefficiency of the late surveyor belonging to the commission, which is not yet closed. The drainage, however, has lately been put under a surveyor (Lewis), approved of by Lord Stafford in terms of the Act, and the expense is diminished, and the whole put in better order.

A very rapid improvement has taken place on these lands. In place of being the very worst part of the estate, they are rapidly becoming equal to the best and finest meadows on it. In order to shelter them from the blasts which come round the Wrekin, from the Welsh mountains, they have been intersected with various plantations. A plan of the Wildmoors previous to (*fig.* 1000.), and another subsequent to, this improvement (*fig.*1001.), will serve to give an accurate notion of what has been done; the whole being well worthy the examination and inspection of an intelligent agriculturist and improver. (*Loch*, p. 226.)

12. *Live Stock.*

Cattle of mixed breeds: some dairying, chiefly for butter to the manufacturing towns; some cheese, but not very good. Calves raised as stock, and sometimes suckled for veal. Sheep in breeding flocks of various kinds. Stock in general neglected as to improvement; all sorts of crosses permitted, so that the original breeds of sheep and hogs are now lost. Pork and bacon are much used among the poorer people, when they can procure them; therefore the sort which is to be fed with the least trouble is to be preferred. A mixture of the Shropshire and Chinese has, in this respect, been found to answer for bacon, and a cross of the wild breed for pork.

Geese, reared on the commons, and sold to farmers, who fatten them on their stubbles.

Turkeys, reared in large quantities by some farmers, and sold to higlers, who drive them to Birmingham and other large towns. Markets in general well supplied with fowls. It is to be lamented that they are generally carried alive to market. Death is no misfortune to an animal that has no previous apprehension of it. But poultry, carried in bags or baskets to market, have several hours of previous suffering, and the burden and trouble of carrying them thither seem much increased thereby.

13. *Political Economy.*

Roads generally bad; various canals; trade of Shrewsbury, flannel, and Welsh webs, used for clothing for the slaves in the West Indies and South America. Manufactures in the county numerous; iron, pottery, porcelain, glass, dyeing cloth, woollens, flannels, linen, gloves, &c. An agricultural society at Drayton.

7796. STAFFORDSHIRE. 765,000 acres of hill and dale, some parts rugged and others smooth, but on the whole more a mining and manufacturing than an agricultural county. The Marquis of Stafford, Lord Anson, and the Marquis of Anglesea, are the chief improvers. Excellent markets for produce within the county in consequence of the numerous manufacturing towns and villages. (*Pitt's Report*, 1808. *Marshal's Review*, 1813. *Loch's Improvements*, 1819. *Edin. Gaz.* 1827.)

1. *Geographical State and Circumstances.*

Climate. Air sharp and cold, and inclining to wet; annual rains thirty-six inches; those of London twenty or twenty-one inches; of Upminster, in Essex, nineteen inches and a quarter; Lancashire forty-two; of Ireland forty-two to fifty. Annual rain on the west side of the kingdom double that on the east side.

Surface. In the north side of the county hills arise, forming the commencement of a ridge, rising gradually higher and higher into Scotland, under different names: here called Moorlands, then Peak, then Blackstone Edge, then Craven, then Stanmore; and then, parting into two horns, called Cheviots.

Soil. Very various; about one third of the county strong loam or clay; one third mixed soils of almost all sorts, and the remainder light, calcareous or alluvial; no chalk.

Minerals. Valuable and extensive; 50,000 acres or upwards of coal. Iron ore and lime of unknown extent.

2. *Property.*

Largest estates 10,000*l.* a year, and many of all sizes, from that amount down to 40*s.* a year. Attorneys generally the managers, but some excellent examples of gentlemen of from 500*l.* to 5000*l.* a year managing their estates themselves; residing on them, and cultivating a part, and giving every encouragement to their tenants.

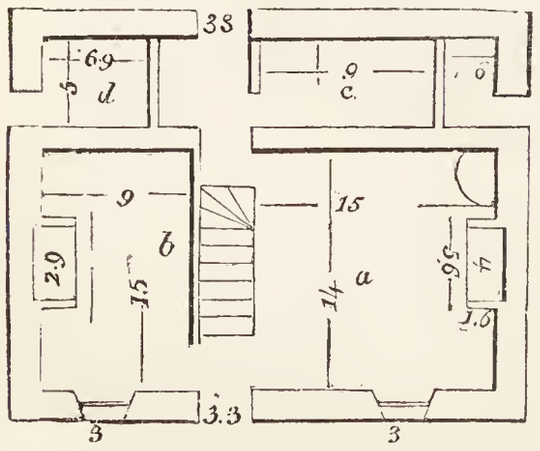
3. *Buildings.*

Some noble mansions, as Trentham, Beaudesart, Ingestree, &c. Excellent farm-houses constructed on some estates, as Trentham, Lord Stafford's; but the majority, as in other counties, bad, and badly situated. A farm-yard has been constructed at the family seat of the Ansons, for a demesne farm of 2000 acres. It was built by S. Wyatt, of London, and consists of the farming steward's house at one end; a range of building along one side contains a brewhouse upon a large scale, a water corn-mill for the family and farm use, and in which corn is ground for the neighbouring poor gratis, and a malt-house: the opposite side and end are occupied by stalls for feeding cattle, store-rooms, stables, and other appendages; and in the middle of the yard is a very complete hoggery, built of large stones set edgeways, and covered with slate, with a boiler for heating hog-food, a cold bath supplied by the mill stream, for giving an occasional swill to the young pigs. In this building a number of hogs are fatted on dairy refuse, boiled roots or vegetables, pulse, ground barley or bran, supplied by the mill near at hand. At some distance above is the stack-yard and barns, where a powerful threshing-machine is worked by the same stream that afterwards supplies the garden, and turns the corn mill in the farm-yard.

4. *Occupation.*

Farms of all sizes, from twenty-five to 500 acres; many consolidated since 1795. Some very good cottages with gardens, and containing comfortable and commodious accommodation for agricultural or manufacturing operatives. A specimen of one is given (*fig.* 1002.), which contains a living-room (*a*), working or lodging room (*b*), pantry, dairy, cellar, &c. (*c*), cow-house (*d*), with a water closet, and three bedrooms over. Leases generally granted for twenty-one years. Little made by farming unless

1002



with a combination of all, or most of the following circumstances:—First, an easy rent; second, a pretty good and extensive farm; third, economy and industry; and fourth, length of time. In the present system of farming, at a moderate rent, the writer of this knows from experience, that it requires not only the most diligent industry, but also the most prudential economy, to keep the balance on the right side. To which Marshal adds, "I have rarely found a farmer making a fortune by his profession alone, unless on fresh land, on virgin marsh, old grazing-ground, ancient sheep-walk, or well soiled common; a fortune, I mean, any way resembling that which, with the same ability and industry, and with a small share of the outset capital, he would have been making by trade, manufacture, or commerce."

5. *Implements.*

Very various; double furrow-ploughs drawn by four horses, a good deal in use in the light lands. Excellent threshing-machine, and various new implements introducing by proprietors, and especially by the Marquis of Stafford.

5. *Arable Land.*

Most annual field-crops cultivated, including hemp and flax.

7. *Grass.*

Meadow on the rivers and brooks, and artificial grasses sown; feeding in general preferred to dairying.

8. *Gardens and Orchards.*

Common to many farm-houses; but few or no sale orchards, and scarcely any fruit crushed for liquor.

9. *Timber and Woodlands.*

Best-timbered estate Blithfield Park, Lord Bagot; the park contains many hundred trees of extraordinary bulk, containing from 200 to 400 feet of timber each; much of it is mentioned by Dr. Plott as full grown in 1686. Chillington and Beaudesart also remarkably well timbered. The remains of Needwood forest, chiefly remarkable for its beautiful hollies. On the whole the country abundantly wooded. Sneid's coppices cut once in six years to make crates and large hampers for the potteries.

10. *Improvements.*

Irrigation and draining practised, the former only to a moderate extent. Jessop, the engineer, suggests that nine parts in ten of the waters of the kingdom at present run away in waste, a great part of which might be usefully employed; nay, further (putting expense out of the question), that every stream in the kingdom may be made to run equally through the whole year. This position, however extraordinary, is easily demonstrable; for if, upon any given stream, one or more reservoirs be made, capable of containing its flood water, and through the dam or dams be laid a pipe or pipes, whose apertures will just discharge the average produce, the business is done: and though there may be no probability of this business being ever brought to so great a nicety, yet from hence some idea may be formed of the prodigious extent to which improvements by water may be carried.

Great and radical improvements have been effected on the Trentham estates. The first object was the laying the lands together, in farms of considerable extent, varying in size according to the nature of the soil, and other circumstances. In effecting these necessary changes, wherever the old tenant was removed, which was done as seldom as possible, he was, unless he took a farm elsewhere, accommodated with his house and his best grass crofts for his life, at a low and inadequate rent; and in every case where it was possible to treat with the person beneficially interested in the lease, and whose continuance in the farm was incompatible with the new arrangement of the land, his interest was purchased either for an annuity or a sum of money, to enable him to look out for, and to stock a new farm. The size of the farm being thus enlarged, it was necessary to enlarge the size of the inclosures, and to lay several closes into one, and, where possible, to give them a more regular and uniform shape. This arrangement enabled the landlord to get rid of the long useless lanes, by which a considerable addition to the number of arable acres was acquired.

In order to give each tenant every advantage in draining his farm, the great lines of ditches were executed by the landlord; and wherever it was possible, these were made the boundaries of the farms. Thus the whole drains on the estate were conducted according to one uniform plan, by which the system of drainage was rendered much more complete, and the interests of the whole, and not that of any individual tenant, were consulted, nor was any one allowed to interfere with the interests of his neighbour. Such a perfect system will have the effect of rendering the condition of these estates more complete in this respect than that of any other in England. Attention has also been paid, in the execution of these works, to make the water available for the construction of water-meadows, and for impelling the threshing-machines of the respective farms.

In consequence of the complete state of ruin in which *the farm buildings* on these estates were found, it was necessary to incur a serious expense in constructing new ones. In this way it has been necessary to erect thirty-seven new, and to repair throughout eight other, extensive sets of farm offices, besides the smaller repairs which such estates necessarily require. They have been executed in the most substantial manner. They are built of the best possible brickwork, covered with tiles or slates; and their cost, including the expense of those thoroughly repaired, may, on an average, be stated at from 1500*l.* to 1600*l.* each.

We have already given examples of these buildings (2955. and 2957.), which are remarkably complete in design, and substantial in execution; and several of them are furnished with

threshing-machines, driven by water or steam, a thing rare in England, excepting in Northumberland. It is believed, Loch observes, that they unite as many advantages with as few faults as any buildings of the sort, and that they will supply useful hints to others.

It had been at one period the custom to permit *huts* to be erected in all parts of the estate. These huts amounted in number to many hundreds; they were inhabited by the poorest, and, in many instances, by a profligate population. They were not regularly entered in the rental book, but had a nominal payment fixed upon them, which they paid annually at the court leet. These cottages were built on the sides of the roads, and upon the lord's waste, which was gradually absorbed by the encroachments which the occupiers of these huts made from time to time, by enclosing that which lay next to them. They gradually fell into the hands of a body of middlemen, who underlet them at an extravagant rent to the actual occupiers. In this manner the poor people were oppressed, and the landlord was in danger of losing his property.

To remedy the evils arising out of this system, the cottagers were made immediate tenants to the landlord, and their rents made payable at the half-yearly audits; an arrangement perfectly satisfactory to them, as they were no longer exposed to the vexations of an intermediate possessor, and, in many instances, their rents to their landlord were less than they had been accustomed to pay to those from whom they had hitherto held their houses. Since they have been placed in this situation, greater attention has been necessarily paid to their conduct and character, as well as to their wants. As they know that their good conduct will now be noticed by, and meet with the approbation of, their landlord, a considerable improvement in their habits has taken place. There can be no doubt but that these important and necessary arrangements were far from being agreeable to those who suffered from them. In altering such a system, not only was the direct interest of the existing middlemen affected, but also the expectant interests and influence of many who contemplated the chance of one day benefiting from their favour. These were not few, and it did not always happen that the person who expressed his dissatisfaction loudest, was the one most likely to succeed in his wishes; and in proportion as this object was near its completion, was the vexation and discontent of those who were disappointed. To the larger farms some of these cottages have been added, to enable the occupier to put into them married farm-servants, who have thus a great inducement to behave honestly and industriously, and to attend with good will and zeal to the interest and the business of their master. It is by giving such inducements as this, and by making them feel an interest in acting right, that this most invaluable class of labourers can alone be maintained and supported.

What has been done by the proprietor, has been well seconded by the exertions of his tenants. A more respectable and enterprising body of men do not exist; and, while they are in a better situation of life than a great body of this class, they have not allowed themselves to forget, that it is by a constant attention to their business, by their keeping in the line of life to which they belong, and never attempting to commit the management of their affairs to bailiffs, that they have gone on steadily improving and bettering their condition. In the knowledge of stock, in their capacity as excellent market-men, in the management of their grass land, and in the cultivation of and in cleaning their lighter soils, they are surpassed by no farmers in the kingdom. The rotation they follow is the Norfolk husbandry; and in the cleanness of their crops, and the excellence of their drill turnips, they cannot be surpassed. The breadth of turnip annually sown is very great, and the rapidity with which they have adopted the drill system of husbandry is as creditable to them as it is satisfactory in the result.

Except ploughing with too many horses, and not being sufficiently active in getting in their harvest, they have fewer practices to abandon, and there are fewer things which they have to adopt from any other of the well cultivated districts of the island, than is generally the case. Every means has been used to explain to them the advantages of ploughing with fewer horses; and there is every reason to expect that their good sense will soon see the propriety of these suggestions, as many of them have already adopted this system. The fact is, that the difficulty consists in being able to persuade the ploughmen to adopt it as the labour of holding the plough is more severe: it is impossible for one or two individuals to contend successfully against the feelings of a country; but when undertaken by so numerous and wealthy a tenantry, supported by the influence of the landlord, these feelings must speedily give way.

This mode of ploughing has made rapid progress at Trentham. The reason of which is, that it is more generally admitted, that this system is calculated to suit the stiff better than the lighter soils, inasmuch as two ploughs, drawn by two horses abreast, do much more work than a double plough, drawn by four horses, can do in such soil: the superiority of the work, also, is very conspicuous. On the other hand it is argued, and with some apparent force, that on light soils the double plough, drawn by four horses, and guided by *one* man, can do as much work as two ploughs drawn by two horses each, and guided by *two* men. In this way the labour of one man is saved. It must be admitted that the argument would be in favour of the double plough, were it not that the work it performs is neither so neat, so perfect, nor can it plough so deep as is done by the two-horse system. It is remarkable that this mode of ploughing with two horses should be confined to the eastern parts of England, from which it was adopted, at no very distant period, in Scotland, where the ploughing with a number of horses yoked along with oxen existed to an extent never practised in any part of this country.

In order to encourage these men to make this change, *an annual ploughing-match has been instituted*, at which prizes are distributed to the best ploughmen. The effect this has already had is very considerable; and at the exhibition in October 1814, no fewer than fifty ploughs started for the premiums. The progress of such a system must be also slow; as it cannot be expected that the tenants should at once lay aside all their old implements, and purchase new. The difficulty of procuring good ploughs operated much against the adoption of this mode of ploughing. In removing this inconvenience, there has been established, both in Shropshire and in Staffordshire, a manufactory for the construction of the more improved implements of modern husbandry: and it is strongly recommended to the persons who have been thus established, that they should take their apprentices entirely from the lads of the country.

It is *in the management of their stiff lands that tenants are most defective.* Of late, however, they have made so great exertions in draining their lands, that it is hoped they are beginning to adopt a better system. The defect of their management consists in their ploughing very shallow; the effect of which is, that the depth of soil is not sufficient to protect the roots of the plant from being chilled with the cold and wet (which is upheld by the impervious nature of the subsoil), when the ground is wet, and exposes it to the too rapid action of the drought when the weather is dry. To plough deeper is, therefore, the first, the most simple, and the most important improvement which can be adopted in these soils.

They also, until lately, *hurt these cold lands by making use of a large quantity of a bad sort of red clay marl*, which they dug out of every field. The effect produced was, to increase the tenacity of the soil, and to render it still less fit for the purposes of agriculture. Of this fact, all the intelligent part of the tenants are themselves convinced, though some of those who are still wedded to their old customs, lament the regulation which prohibits them from using this article. On those farms where the inclosures have been entirely renewed, and where, in consequence, a portion of several of the ancient inclosures have been thrown into one close, the bad effects of this system of marling is perceived in a remarkable degree, and a distinct line in the appearance of the crop, points out with precision the land which had been formerly so treated, from that which had not. The consequence of this prohibition has been, that the tenants have applied themselves much more to the use of lime as a stimulant, which has repaid them, as might have been expected. It has also put a stop to the rapid deterioration of property, which was occasioned by the digging of the pits, which every where disfigure and destroy a considerable portion of the farms of this district.

To level down these marl-pits, and to render them again fit for the purposes of husbandry, has been an object of great attention. In this way there was applied the labour of a great proportion of the parishioners, to whom, from time to time, employment had been afforded, in those years when the circumstances of the country rendered such an exertion of the landlord's bounty necessary. This was more particularly the case in 1817; in which year a vast body of men was employed on each of the Marquess's estates.

In another particular, *the management of the stiff soils might be considerably amended*; which is, in the mode of working the fallows, which are left too generally to grow full of weeds, in place of being cleaned as they ought to be. The muck, also, is laid on at an improper season of the year, by which its good effects rather go to encourage the growth of weeds, than to improve the crop. At Trentham, the strong soils are of a far superior quality, fit in every respect for the most improved system of wheat and bean husbandry. But the lands were so much subdivided, and the capital of a large proportion of the tenants, until lately, was so inadequate to the right cultivation of their land, that no improvement could take place or be expected, and this estate remained stationary, amidst the general progress which was so conspicuous in the other parts of the county. These defects have been remedied in both instances; and the introduction of some skilful farmers from Shropshire and Cheshire, at Trentham, has given rise to that spirit of enterprise which at present characterises the tenants of these estates, and which must prove so beneficial to the country, by the additional surplus produce which will be brought to market.

The *rotation which they followed*, on both estates of the stiff soils, was, fallow, wheat, oats, clover. That is now altered, by clover being substituted after the wheat; and an attempt has been made to induce them to try a six-shift course of husbandry, by introducing beans into their rotation. Little progress, however, has as yet been made in this experiment. To this they have considerable objection, which arises from the defective mode of cultivating their bean-crop. In the first place, they are unwilling to sow them in drills. They are, besides, longer in planting them, and allow them to stand later in the year than they ought to do. The consequence is, that their crop is often damaged, and the nutritious matter of the bean-straw is entirely lost. They cannot be persuaded, therefore, that it forms an excellent and nourishing food for horses and cattle; and the complaint that they make of its being an exhausting crop is quite correct, in consequence of their permitting it to stand so long upon the ground.

One improvement the tenants have paid much attention to, and a more valuable one they could not adopt, which is *the construction of water-meadows.* They have lost no opportunity in making use of whatever water they could obtain for this purpose. They were allowed the rough materials to construct the flood-gates, and the example was shown them as to what could be done in this respect to a very great extent at Trentham. The value of this improvement is well known to every experienced agriculturist in England, and no opportunity should be lost in taking advantage of every circumstance to promote its adoption. There has been lately finished a new water-meadow on the home farm at Trentham, at the expense of about twenty pounds an acre, which will now let for near four pounds an acre, besides the advantage derived to the adjoining upland. This meadow was not worth ten shillings an acre previous to such an improvement. It consists of a small deep dingle, with steep banks, in which a copious spring rises near the top: the upper part being formed into a fish-pool. From this head the water is conducted on the different levels on each side, with the proper catch-water drains carrying the water round the various knolls. The whole being adorned by some fine trees, it forms for its extent a very perfect union of useful and ornamental farming. It shows how much may be made of such a piece of land, incapable of any other sort of useful occupation.

Much money, however, in this neighbourhood has been thrown away by watering land which has not been previously thoroughly drained; this latter improvement is the foundation of all others. Another mistake has also been fallen into, by attempting to convert into water-meadows peat soils, without first bringing them to a proper state of consistency by means of repeated heavy rollings and top-dressings. A proportion of ten acres of water-meadow to every hundred acres of pasture or arable land, adds at least two shillings and sixpence an acre

to the value of every acre of such a farm, in addition to a fair rent being put upon the meadow.

The attention and influence of Lord Stafford has been used in whatever way it could be employed beneficially in extending the comfort or advancing the good behaviour of his cottagers; a conduct so characteristic of the great and wealthy proprietors of these kingdoms, that it must ever distinguish them in the history of human benevolence.

Schools, wherever they have been necessary, have been encouraged, either aiding them by subscription, or by granting the accommodation of school-houses. Two Banks for Savings, one at Lilleshall and another at Trentham, of which Lord Stafford is the treasurer, have been established, and the whole details are conducted by his managers, assisted by the parochial clergymen and the principal tenantry, and their success among the agricultural labourers has been very gratifying.

The *charities of this family* are worthy of an English nobleman; and during the residence of the Marquess and Marchioness at Trentham, there is distributed daily to every poor object, who is travelling along the road, and who applies for the same, a portion of good wholesome bread, in quantity about fourteen ounces to each full-grown man, and less in proportion to women and children, with a pint of good table-beer. The number of people who received this donation in 1819, amounted to 9504 men, 2376 women, and 1789 children, consuming 1590 loaves, and 1703 gallons of beer. From this charity are excepted all soldiers and sailors receiving the King's pay, all persons residing within the parish of Trentham, or in its immediate vicinity. Other distributions take place on particular occasions; for example, to those who reside in the parish, annually on St. Thomas's day, there is a distribution of a certain quantity of beef to the poor. During 1819, there were 12,785 quarts of rich soup, and above 8500 quarts of milk, distributed within the parish, besides 14,134 quarts of milk given away under the head of allowances. Such facts are strongly illustrative of the beneficial effects derived to the poor from the residence of the great families of England on their respective estates.

The foregoing statement would have been given with some hesitation, had not the facts been of a nature rather to exhibit and illustrate the character and extent of *the charities distributed by the great families of England in general*, than as being at all peculiar to the instance to which the details belong; and these facts may help to explain to foreigners the nature of the connection which exists between the richer and poorer classes in this country.

The *town of Lane End*, one of those which compose the Staffordshire potteries, is partly situated on, and is partly contiguous to the east end of the Trentham estate. The inhabitants being ill supplied with water, carried in barrels, they petitioned to be provided with this necessary article, which request has been complied with; and this town, after a very considerable outlay, now enjoys a regular supply of water, conveyed in iron pipes.

The *character of the numerous cottagers upon the estates* is also an object of great solicitude, and without any interference with the manner in which a man may choose to occupy himself, their regular and decent behaviour is made the subject of care and attention; and the steward has strict directions to watch carefully over them, and where possible to promote their improvement. Wherever a potato garden can with advantage be added to their cottage, that accommodation is afforded them. In the vicinity of Trentham the cottages are of the best sort, and with their gardens kept in the nicest order. To almost every one of them is attached land for the maintenance of one or two cows. It is a circumstance worthy of remark, that of all the labourers who possess a cow, none receive relief from the poor's rate, except one widow at Trentham, who has a large family, and even in this instance, the relief she receives is in a less ratio than any person labouring under similar difficulties. (*Loch in* 1819.)

11. *Live Stock.*

Cattle generally of the long-horned breed. The Staffordshire cow is generally considered a tolerable milker, as well as feeder.

Sheep. Three sorts considered native breeds: the grey-faced hornless, or Cannock heath sheep, with fine wool; the black-faced horned, with fine wool; and the white-faced hornless, with long wool.

Swine. A cross between the slouched-eared and dwarf breeds; require little attention or feeding, and easily get fat on the refuse of the dairy or barn. Pitt, the reporter, had a very fine sow, which littered ten at the first litter.

Rabbits. Wild in the sandy lands. A good many bees kept; Thorley's plan tried, but bees are found to succeed best in straw hives thatched in autumn. "Those which have not raised a sufficiency of food for winter, it is doubtless humanity to destroy, as sudden suffocation is better than a prolonged but certain starvation."

12. *Political Economy.*

Roads now generally good; numerous canals; several private rail-roads. Manufactures, iron, hardware, nails, glass, toys, japanned goods, potters' ware, cotton cloth, silk fabrics, leather, woollen, linen, and many others. Manufactures sometimes carried on in the country in straggling groups of houses, but for the most part in towns. Many thousands both of men and women employed in making nails. An agricultural society at Newcastle, and another at Litchfield.

Experimental Farming. "It would be a wholesome plan for the Board to commence farming upon their own ideas, particularly in counties where the modes of agriculture seem improper; for instance, Lancashire, Westmoreland, Cumberland, Northumberland, &c.; by which ocular demonstration their plan might be imitated; for hearing or reading of any particular practice will not do for farmers in general." Such is the reporter's opinion, in ours a most erroneous one.

7797. WARWICKSHIRE. A surface of nearly 639,760 acres, mostly flat, but generally rich in soil and beautiful in appearance. It is chiefly a corn county, and produces excellent wheat; but also many fat cattle, and formerly much cheese. There are no distinguished agriculturists in the county; but it has produced more good to agriculture than many others, by giving birth to Elkington, who gave rise to much discussion on draining. (*Wedge's Report*, 1794. *Murray's Report*, 1808. *Marshal's Review*, 1813. *Edin. Gaz.* 1827.)

1. *Geographical State and Circumstances.*

Climate, mild and healthy. S. W. the prevailing winds: effects of an easterly variation felt till the middle of May, and vegetation checked; not, however, by excess of damp or frost.

Soil, chiefly clay or sand, marl, and limestone. The portion of sandy or moorish soil very small. The tract of land called the county of Coventry is a rich, red, sandy loam, chiefly in grass. The land near Birmingham is generally either sand or stiff clay.

Minerals, coal, limestone, freestone, iron, blue flagstone, marl, blue clay, and soapy clay, which the late Earl of Warwick attempted to prepare for sale as a soap.

2. *Property.*

Largest estate Stoneleigh, Chandos Leigh, Esq., 25,000 acres; but a great variety of extent, and some curious and absurd tenures.

3. *Buildings.*

Warwick Castle and Ragley first-rate edifices. Old farm-houses built of mud and timber, and frequently at the extremity of the farms. The Duke of Buccleugh, at Dunchurch, has constructed some good farmeries.

4. *Occupation.*

Farms from 80 to 500 acres; 150 the average size; on the increase. Farmers in general exceedingly shy and jealous; one, considered as at the head of his profession, told Murray "he did not see any advantage the county of Warwick would derive from such a survey; that it must do a great deal of hurt instead of good; and that such being his opinion, he declined giving any information on the different heads of queries put to him." Lands generally held at will, but very low rental. Cheap farms, in general, are a drawback on industry and improvements: farmers that have cheap farms may farm well; but those that have dear farms must farm well, or their career will soon terminate.

5. *Implements.*

Ploughs the double and single Rotherham with wheels, the double drawn by five or six horses in a line, the single plough by three and four, or five horses in a line, and in both cases with a driver. Small's plough, with two horses abreast, and no driver, the reporter remarks, would make better work, and do more of it. Some winnowing and threshing machines in use by proprietors.

6. *Tillage.*

Large crooked ridges gathered very high with a small one between; go only one yoking per day throughout the year. Fallowing general, and then two white crops.

7. *Grass.*

235,000 acres in meadows and pastures, and 60,000 in artificial herbage. Formerly dairying common, and Warwickshire cheeses produced in abundance; but now breeding is fast assuming its place. Old pastures overrun with ant-hills and rubbish. Murray very prophetically observes, that if peace were to take place, grass lands would be safer for the farmer than corn lands. Dairying and feeding both in practice.

8. *Gardens and Orchards.*

The gardens of the Marquis of Hertford, at Ragley, noted for their pine apples; few sale orchards of any extent.

9. *Woods and Plantations.*

Oak and elm every where abounds; the Leigh estate the best wooded, but every where abundance of timber

10. *Improvements.*

Much draining done in the northern part of the county; but it is rather singular that the names of Fazeley, Elkington, or their farms, are not once mentioned in Murray's report. Joseph Elkington lived at Princethorp, in Stretton on Dunsmoor, six miles S. W. of Coventry, and afterwards in Birmingham. He died in 1806. He was a mere empiric practitioner, and knew nothing of geology, the only foundation for draining on scientific principles; less even than some of his contemporaries, as Farey has ably shown in the Derbyshire report.

Irrigation practised in a few places on a small scale.

11. *Live Stock.*

No particular breed of cattle; but as feeding is the prevailing practice, farmers buy in whatever breed they think will pay them best.

Sheep a good deal attended to; the large-polled sheep, or ancient Warwickshire, now generally mixed with other breeds. The first cross of a Leicestershire ram and Warwickshire ewe produces the best sheep for the butcher.

Horses, the heavy black Leicestershire breed; a good many bred, of cart, coach, riding, and hunting horses.

Poultry abounds, owing to the prevalence of small farms; great quantities sent to Birmingham and London.

Game, as pheasants, partridges, and hares, more than commonly abundant.

12. *Political Economy.*

Roads tolerably good; several canals; innumerable manufactures, especially at Birmingham, for iron, and others of the metal kind, and Coventry for ribands.

13. *Means of Improvement.*

Leases; a more economical mode of labouring; draining; drilled root, and herbage crops, and better rotations.

7798. LEICESTERSHIRE. 522,240 acres of gently varied surface and fertile soil; distinguished for its pastures, and for the progress that has been made in the improvement of cattle and sheep. It is the county of Bakewell, whose name will ever stand at the head of breeding farmers. (*Monk's Report*, 1794. *Pitt's Report*, 1809. *Marshal's Review*, 1813. *Smith's Geological Map*, 1821.)

1. *Geographical State and Circumstances.*

Climate mild and temperate; no mountains or bogs to produce a cold or moist atmosphere.

Soil; no stiff clay or sand, no chalk; the peat bogs which existed have been long since drained, and become meadow soil; clayey loam, sandy loam, and meadow, compose the soil of the county. Dishley farm, so well known, consists of a mild friable loam, of a good depth, on a clay or marl bottom.

Minerals; coal, lime, lead, iron, slate, and freestone; all worked. A mineral spring at Burton Lazars.

2. *Property.*

Estates generally large; that of the Duke of Rutland has been much improved, and always managed in the most liberal and benevolent manner.

3. *Buildings.*

Many very magnificent, as Belvoir Castle, Donnington Priory, &c. Farm-houses not built since the commencement of this century are of very inferior construction; timber and plaster covered with thatch. In general, the modern enclosed parishes have the worst farm-houses, they being almost always cooped up in the villages; in the more ancient inclosures, farm-houses have been erected in the midst of the occupations, and built with better materials. Dishley farm-house is of ancient construction, and has probably been built at different times, whence it wants regularity and compactness; it has, however, taken altogether, a style of pastoral simplicity, united with neatness, and exhibits a specimen of that judgment and taste which joins convenience with economy, so far as it can be attained without regular design; the out-buildings too seem to have been put up at separate times, as wanted; the yards and pavements are remarkable for neat cleanliness, and the whole farm business for being conducted with good order and system. The houses of other principal breeders are comfortable and substantial, and of course fitted up in a style suitable to the taste and situation in life of the occupier.

Cottages generally in villages, and formed of mud walls and thatch; a few good new ones of brick and native slate.

4. *Occupation.*

Farms of all sizes: a great many from 80 to 100 acres, on which the farmers work with their own hands; near market-towns, many under 100 acres, occupied by tradesmen and manufacturers; general size, 100 to 200 acres; and those of the principal breeders, from 200 to 500 acres. Land chiefly in pasture for sheep, the dairy feeding cattle, breeding horses, and hay for winter use: dairy farms have also sufficient arable land to produce straw and turnips for their own use; the most inferior soils in aration. The Duke of Rutland has 2000 acres in hand, including the park, woods, gardens, &c. At Donnington, Lord Moira had 370 acres, under a Northumbrian bailiff, besides the park of 450 acres. Dishley Farm, near Loughborough, in the occupation of the family of the Bakewells for three generations, and now of Robert Honeybourne, nephew to the last Robert Bakewell, who died a bachelor, contains between 400 and 500 acres.

Irrigation is judiciously practised, and the culture of the arable uplands has been long conducted on so correct a system that few weeds now come up; the most troublesome is chickweed. Heifers of three or four years old draw in the cart or plough; three of them form a team, and work nine hours a day. Farmers in general intelligent. Leases not universal.

5. *Implements.*

Plough with two wheels, and drawn by three, four, or five horses, or cattle in a line walking in the furrow. Thirty years ago, wheels were first applied to the fore end of the beam, and it was found that by pitching the ploughs a little deeper, and setting the wheels so as to prevent its drawing in too deep, the wheels were a sufficient guide, and the plough required no one to hold it, except in places of difficulty; one person attending was therefore sufficient to drive on the team, turn the plough in and out at the ends, or guide it in particular hard or soft places. Soon after another furrow was added, by slipping an additional beam to the off side of the former one, somewhat lengthened, with foot-share and shelboard; the same number of wheels, viz. one on each side, guiding the two furrows. Among the uncommon implements may be included, a rack and manger for four colts on wheels, to be drawn from one pasture to another. It is square in the plan, and therefore each colt has a side to itself, and cannot kick or bite at the others; a break for shoeing oxen; a fastening for ewes, to lessen the fatigue of the ram during copulation; and also several ploughs, rakes, &c. the invention of Hanford and Co. at Hathern, near Leicester.

6. *Arable Land.*

Many farms have none. Drilling corn crops principally introduced; but not for turnips, even at Dishley; thought to lose ground; cabbages and rape a good deal cultivated on the soils too strong for turnips.

7. *Grass.*

Excellent meadows on the rivers and rills; fertilised by inundations; upland pastures sometimes manured. Stilton cheese made in most villages about Melton Mowbray. On the Trent, considerable patches of reed, which pay as well as the best meadow land.

8. *Gardens and Orchards.*

Gardens much wanted to cottages; orchards rather neglected, though the soil is in many places well adapted for them.

9. *Woods and Plantations.*

Few, excepting about gentlemen's seats, and in the hedgerows. Willows, as pollards, grown on Dishley and other farms, to supply stuff for hurdles, rails, and gates.

10. *Improvements.*

Elkington was a good deal employed by the proprietors. Irrigation more extensively practised in this county than in most others.

11. *Live Stock.*

Cattle, the long-horned breed. What was the particular breed of cattle in Leicestershire before the middle of the last century, about which time Bakewell began his exertions, it is difficult to determine; perhaps there was not any distinct breed, with particular specific characters, whereby they might be distinguished; although there were always great numbers bred, yet the produce was never equal to the supply of the county: there always was, and still is, an influx from Ireland, Wales, Scotland, Shropshire, Staffordshire, Herefordshire, Northumberland, and Lancashire; the latter of which were most probably the stock from which Bakewell began his breed. His first best cows, it is believed, were artfully obtained from Webster of Canley, in Warwickshire; and his famous bull, Twopenny, was bred from one of these cows, or from one procured from Phillips of Garrington, and a bull from Northumberland. From these beginnings, with great judgment and attention, in a short time he reared some beautiful cattle; they were long and fine in the horn, had small heads, clean throats, straight backs, wide quarters, and were light in their bellies and offals; they were gentle and quiet in their tempers; they grew fat with a small proportion of food, but gave less milk than some other breeds. Some years ago, Bakewell put three new-milched cows in three separate stalls, a Holderness, a Scotch, and one of his own breed; the Holderness ate most food, and gave much the greatest quantity of milk; the Scotch ate less food, and gave less milk, but produced most butter; his own cow ate least food, gave the least milk, and made the least butter, but laid on the most flesh: hence it will follow that the Dishley cattle are most adapted for the grazier, and the produce of beef. No man, perhaps, ever made more comparisons between the different breeds of cattle than Bakewell, and no one that was able to tell so much has told us so little about them. Many capital herds of cattle in the county, and a number of dairies, from which great quantities of cheese is sent to market.

Sheep. The present stock consists of three varieties, the old and new Leicester, and the forest sheep. The old breed, which is spread over Northamptonshire, Warwick, and Lincolnshire, are an improvement on the ancient stock of the common fields. The new breed Bakewell produced by breeding from selected sheep from his neighbours' flocks, or those of the Gibbers. A ram society was formed by Bakewell and others, and still exists, the object of which was a monopoly of ram-letting. The late Bakewell bound himself, and his successor, Honeybourne, binds himself, not to engage nor show his rams to any person till the members of the society have seen them and are supplied, and not to let a ram to any person within fifty miles of Leicester, for a less sum than fifty guineas, for which, and other privileges, the society pay a large annual sum; and Honeybourne, and the other members of the society, confine themselves not to sell, nor to let, their ewes at any price, nor to show their rams at any public fair, nor at any other place than their own houses, and that only at stated times, from the 8th of June to the 8th of July, and again from the 8th of September till the end of the season; with several other regulations of a similar tendency.

Ram-letting alone has produced to Bakewell 3000*l.* in one year. The greatest prices were paid about 1789; since that time they have declined; still, about 1807, from sixty to one hundred guineas have been given for the use of a ram for one season. Much curious information on this subject will be found in the report.

Folding is not practised.

Fatting is practised as usual with grass, and in winter and spring with artificial food. Bakewell frequently fattened sheep in stalls; in three days they were reconciled to their confinement, and began to feed. "Further than this," the reporter's informant, Bakewell's successor, "knows not, or is not inclined to communicate."

The *forest sheep* are confined to Charrwood: they are grey-faced, and partially horned, but now almost extinct.

Horses have been bred in Leicestershire from time immemorial, and the breed considered superior. Bakewell went through Holland and Flanders and purchased some Friesland mares, which excelled in those points wherein he thought his own horses defective, from which, with great labour, expense, and judgment, he produced some capital horses, and in particular, his famous horse Gee, the noblest, and most complete and beautiful, creature of the kind that had been seen in Europe. How far his elegant points were adapted for the labour that horses of this sort are principally designed to perform, is a question, perhaps, undetermined; be this as it may, beyond all controversy he was strong and handsome, and commanded the admiration of all who saw him; for a time he was the first subject of conversation, and almost the wonder of the day; he was taken to Tattersall's, and shown there to the nobility and gentry, with great approbation; and Bakewell had the honour of showing him personally to Geo. III.; he is said to have been very quiet and docile, and Bakewell, in describing his points, invited his majesty to touch him, which was declined. He was killed by lightning, in his pasture. The present horse-system at Dishley is this:—Three or four very capital black stallions are constantly kept; these are occasionally worked, and are always rendered docile enough for that purpose, if wanted; those kept at home cover at two guineas the mare, and those let out never at less than one guinea. Eight or ten brood mares, of the same stout black breed, are also kept, but no geldings; these do all the farming work of between 400 and 500 acres, with occasional assistance from the stallions, as well as from bullocks and heifers; of the mares, all that are fit are put to the horse, of which three are reckoned upon the average to rear two foals, allowing one in three for casualties.

Asses used in many parts of the county for carrying burdens, and lately introduced as farmer's stock; especially for clearing green crops from clayey soils, in wet weather, their step being light. The turnip panniers open at bottom, to let out the load. Lord Moira had Spanish stallion asses, fourteen hands high, which he let out to cover at two guineas a mare.

Mules have long been in use for the saddle, road-work, and the plough.

Hogs greatly improved by various breeds. Honeybourne's seem to have a cross of the wild boar. Astley's is between the Chinese and Berkshire. At Donnington is a German boar, the bacon from whose progeny is of extraordinary sweetness and good flavour.

Bees attended to, but not so much as they deserve.

12. *Political Economy.*

The roads in the north-west of the county, in the neighbourhood of Loughborough and Ashby, are many of them laid out upon the concave system.

Bakewell and others were advocates for this system; but it does not appear that they are considered to be attended with

any advantages by those who live beside them, and constantly use them. Various railways and canals. Manufactures, wool-combing, woollen yarn, worsted, and especially worsted stockings; also cotton-works, hats, patent net-lace for veils, &c. The Leicestershire and Rutlandshire agricultural society established 1794.

7799. DERBYSHIRE. A mountainous and hilly surface of 622,080 acres of great variety of soils, but more remarkable for its mining and manufacturing productions than its agriculture. It is, however, at the same time both a corn and pasture county, and noted for its cheese; it is every where full of ingenuity and interest; and the Report by Farey, in three volumes, is one of the most interesting and valuable of the county reports: it is an example of extraordinary industry, research, and excellent general views, and will be read with great profit by every class of readers. Farey, indeed, was a philosopher ahead of the age in which he lived. (*Brown's Derbyshire*, 1794. *Farey's Agricultural and Mineral Survey*, 3 vols. 1811 to 1815. *Marshal's Rev.* 1812.)

1. *Geographical State and Circumstances.*

Climate. Cold on the hills, but mild in the plains; in the vales hoar frosts often injurious; no prevailing winds; rain about twenty-eight inches per annum.

Soil very various, chiefly calcareous.

Minerals. Lead and iron those chiefly worked; also some zinc, calamine, black jack, manganese, sulphur, &c.; coal, lime, alabaster, slate, freestone, paving stone, rolling, grinding, scythe, and cutlers' stones, and a variety of others, both for use and ornament, as spar, &c. Clay in some districts, as at Overmoor, is burned by spadefuls, dried, and mixed with small coals in heaps, for the roads. E. M. Munday, Esq. of Shipley, formed his private roads of a sort of bricks, made without the corners to avoid the duty.

Water. When scarce, drinking ponds made by puddling and paving in the Gloucestershire manner. An artificial pond discovered in 1808, concealed under peat, the head of which was puddled in the centre; a proof that puddling is no new art. Stone cisterns, placed in the lines of neatly cut thorn hedges, serve to supply two fields: the water brought to them in thin zinc pipes, as being cheaper, and perhaps more durable than lead.

2. *Estates.*

Of various sizes as in other counties; managed by attorneys, at a low salary, who make it up by law business, and otherwise.

3. *Buildings.*

Chatsworth, Keddlestone, and some other noble stone mansions in this county; some good houses, covered with cement (known in London as Atkinson's), made from clay stones found on Lord Mulgrave's estates in Yorkshire, and which Farey considers as superior to that made from the clay balls of the London clay stratum. Grottos frequent, fitted up with the spar of the county. At Ashover a frize of a chimney-piece, representing a section of the strata taken across the parish. At Chatsworth, and various places, the spits in the kitchens turned by water-wheels, of the overshot kind, supplied by small lead pipes. Hair lines, in covered boxes, placed on drying parts, and the lines wound and unwound by a handle, for drying clothes. At several houses foot lath-wheels, turning spindles, on which were other wheels, dressed with emery for cleaning knives; also brush spindles for boots and shoes, as at the Angel Inn, Oxford; boot-rack, in which boots are reversed on upright pins and taken off by a stick, which prevents dust settling inside the boot.

Farm-houses as in other counties; a few good ones recently erected. One of the most complete farmeries is that of the Earl of Chesterfield, at Bretby Park; it is of hewn stone, slated, and combines a general farm-yard, dairy court, and two poultry courts, including pheasantries. Buildings in general roofed with grey stone or other slate; water, in some cases, conducted down from gutters by a light wooden rod, down which the water runs as well as if it were in a spout or tube, and not blown about by the winds, as it would if no rod were there. Fire-proof floors made by arching them with hollow bricks; in the cottages, cast-iron ovens by the sides of the fires very common, and also iron cisterns for hot water; both these were originally brought into notice by the Griffin foundry, about 1778.

Cottages better than in most other counties; some good ones erected by the principal manufacturers and noblemen. Virgin's bower, or other beautiful flowering creepers, and shrubs, and plants, are not uncommon at the cottage doors in this county, among other indications of their attention to neatness and of their comforts, compared with the inhabitants of the miserable huts in many other districts.

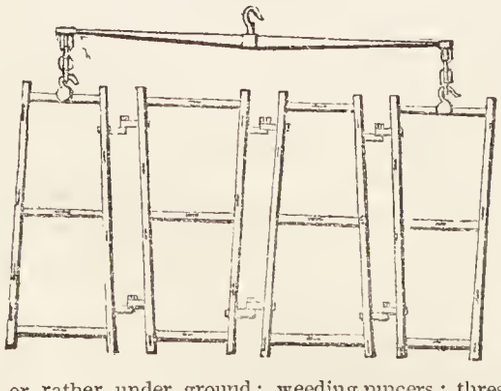
4. *Occupation.*

Farms generally of small size; farmers rank higher in intelligence than those of most southern counties; nothing but leases and larger occupations wanting to render this one of the most improved counties of England. Best farmers also at same time manufacturers or miners.

5. *Implements.*

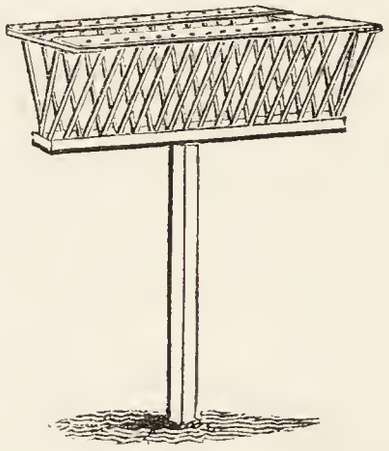
Swing ploughs and pair; one-horse carts; good harrows (*fig.*1003.); weeding scissars, for clipping off weeds among corn

1003



close, or rather under ground; weeding pincers; threshing-machines; cast-iron rick stands; cattle cribs mounted on posts, which turn round on a pin, so that when the cattle have well trodden the litter on the two opposite sides, in standing to eat from the crib, it is turned half round for them to tread and dung, &c. in the opposite direction. (*fig.* 1004.) Turnip-slicers, chaff-cutters, bruisers, slate cisterns as milk vessels, &c.

1004



6. *Enclosures.*

In setting out fences, less attention paid to separating the different kinds of soils than is requisite; walls frequent; and holes often made in them for passing sheep; to be closed when not wanted by a flat stone; slacked lime plastered on the face of a newly planted hedge (as clay is in Norfolk), to prevent the weeds from rising. Young thorn hedges, with a northern aspect, do best, as the morning sun in spring injures the bud of those facing the south when previously covered with frost. Roots of thorns, sometimes planted as sets with success; old thorn-hedges effectually renewed by cutting off the shoots below the surface of the ground; the roots then throw up vigorous shoots. Neatly clipt hedges at Ashbourne. Magnesian, limestone, and marly soils found to suit the holly better than any other.

7. *Arable Land.*

Only one fifth of the county in aration; formerly six horses were generally employed in ploughing, now only two; turnips drilled in the Northumberland manner in various places; some wheat dibbled; oats a good deal cultivated, and oat-cakes or Haver (*Ger.*) cake made, by pouring sour dough on a hot stone: a sprinkling of parsley sown with clover to prevent cattle hoving; sides of oat ricks tucked in with a spade, to leave no loose straws for sparrows to rest on.

Chamomile "is cultivated to a very considerable extent on the limestone and coal strata near Ashover;" the flowers are picked by children, dried first in the shade and then on a malt-kiln, afterwards packed tight into bags, and sent to the London druggists; the crop stands three years, and then gets weedy and declines."

Woad cultivated on a small scale.

Widow-wort (*Genista tinctoria*) infests old pastures, and is pulled when in flower, and dried and sold to the dyers.

Yarrow (*Achillea Millefolium*) is in some places also taken up, tied in bunches, and dried for the dyers.

Valerian (*Valeriana* officinalis) is grown at Ashover, and also elecampane (*Inula Helenium*), lavender, peppermint, and rhubarb, on a small scale, in one or two places.

Truffles (*Tuber cibarium*) collected in various places, especially under the shade of the beech trees, and on dry hedge banks. Roses formerly cultivated for the flowers, but not at present.

8. *Grass.*

Three fifths of the county under permanent grasses (though it appears by the marks of ridges to have been formerly every where arable), and the application chiefly cheese-making. Droppings of cattle and horses on pastures spread by rakes, which injure the grass less than any other implement. Fern and other weeds collected from wastes, and dried and burned, and their ashes made into balls, and laid aside, to be used as ley for washing. This practice declines with the frequency of enclosures. When worms are engaged forming worm-casts in fields, scatter barley chaff, fresh and dry from the winnowing machine, which, sticking to the worms when they come out, prick them, and prevent their return to their holes, till rooks, &c. devour them.

9. *Gardens and Orchards.*

Good market-gardens at all the principal towns, and few of the farm-houses and cottages without gardens. "Samuel Oldknow, Esq. of Mellor keeps a professed gardener, on three acres of rich sheltered land, by the river Goyte, on the Cheshire side of it, who cultivates, gathers, prepares, and delivers all the useful vegetables and common garden fruits in season to his cotton mill work-people and tenants, and renders an account once a fortnight to the mill-agent, who deducts what they have purchased from the garden from their several wages; the perfection and utility of his arrangement for these purposes cannot but prove highly gratifying to those who wish to see the labouring classes well and comfortably provided for from the fruits of their industry. Proper rooms, for drying, cleaning, and preserving garden-seeds and fruits, and his wool-chamber and other like offices, are attached to the gardener's house, and

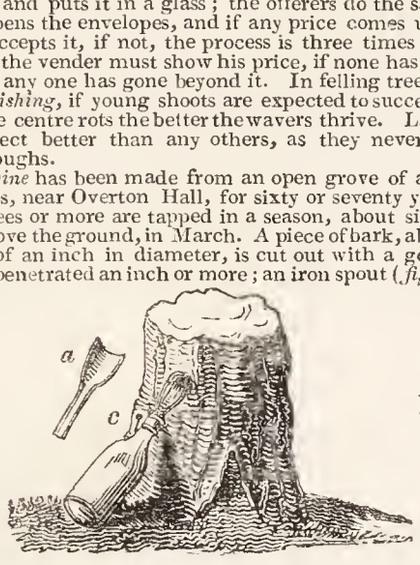
placed under his care." A most productive garden at Belper, on a very poor soil, but irrigated in winter from a cesspool, in which centres the liquid manure of fifty cottages, belonging to Messrs. Strutt's cotton mills.

Orchards seldom planted, though the soil is well adapted for them in many places.

10. *Woods and Plantations*

A good many coppices, the produce of which is much in demand both for mining and agricultural purposes. Sir Joseph Banks, at Ashover, has planted some exposed sites in a new manner: first planting narrow slips of Scotch fir at the distance of 100 yards, then intersecting them by others, so as to leave the surface checkered; after the Scotch firs are grown a few years, it is the intention to fill the intervening patches with larches, at such a distance as that they will never require any thinning. This plan, as Farey justly hints, is more ingenious or fanciful than likely to be useful; the mixture of the larch and Scotch firs, with a proper attention to thinning, would be a more effectual, speedy, and economical mode of producing timber. Some judicious observations on pruning trees, and the propriety of Pontey's mode, pointed out by various examples. Hedge row trees, sparingly introduced and well trained, are nearly all that fertile agricultural land ought to contribute to the national stock of timber. Key-bearing ash trees, or any forest tree much given to bearing seeds, no longer increases much in timber, and therefore ought to be cut down; hence male ashes preferable to females, or such as have both male and female flowers on the same tree. The use of the spray and buds of the oak as bark recommended, as practised in Cheshire and South Wales; when collected, they should be immediately sent to a mill and crushed. A most complete seasoning kiln for timber at Belper. Timber often sold by ticket sale, — thus described: the vender meets the proposed purchasers, writes his price in an envelope, and puts it in a glass; the offerers do the same; the vender opens the envelopes, and if any price comes up to his, then he accepts it, if not, the process is three times repeated, and then the vender must show his price, if none has come up, but not if any one has gone beyond it. In felling trees with an axe, cut *dishing*, if young shoots are expected to succeed, as the sooner the centre rots the better the wavers thrive. Larch trees bear neglect better than any others, as they never produce timber boughs.

Birch wine has been made from an open grove of about 100 birch trees, near Overton Hall, for sixty or seventy years past. Thirty trees or more are tapped in a season, about six or eight inches above the ground, in March. A piece of bark, about three quarters of an inch in diameter, is cut out with a gouge, and the wood penetrated an inch or more; an iron spout (*fig.* 1005.*a*).



1005

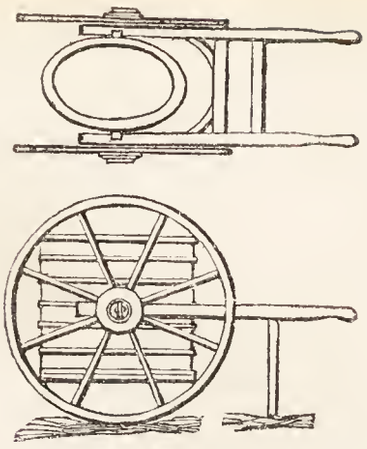
is then driven into the bark below the hole, which conducts the sap bottle (*c*). In warm weather the holes soon grow up, and will cease to run in four or five days; but in windy weather they will run for a month. Some trees will run twenty-four gallons in twenty-four hours, others not half a pint. The water is sold at sixpence a gallon, to those who make small wine as a substitute for small beer. If the water is scalded (not boiled), it may be kept a month before it is made into wine; if not, it will not keep above a day or two. For making the wine, two pounds of coarse sugar, and a quarter of a pound of Malaga raisins, are added to every gallon of birch water, when cold: it is then boiled about an hour, until it is observed to grow clearer, when it is set to cool; and when about at the same heat that beer is set to work, a toast of bread, spread with yeast, is put into it, and for four days suffered to work freely, when it is barrelled, and the same quantity of raisins as before, and about an ounce of isinglass to every twenty gallons is added. It seldom works out of the barrel, and in two or three weeks is ready for close bunging down, to remain for three months, when it should be bottled off, and in two or three weeks after it is fit for drinking, but is the better for keeping longer.

11. *Improvement.*

Magnesian or hot lime very thinly spread has its inimical properties; and it would seem such limes may be used where a stimulant rather than an addition of calcareous earth is required. Lime over-burned melts and runs together, will not slack, and becomes useless; the consequence of too strong a fire being applied to magnesian limes more especially. Might not the dried mud of limestone roads be used instead of lime? Many bone mills in use: they are composed of ratchet-like iron wheels and rollers, between which the backbones of horses, with their adhering ribs, pass with facility, and are crushed into small pieces; the bones collected in London, from the churchyards and other sources; seven quarters dress an acre. Coal ashes almost entirely neglected, though a valuable manure. Importance in draining of bearing in mind the difference between surface and spring draining, and bog and upland draining.

12. *Live Stock.*

Cow stock for the dairy the prevalent stock in Derbyshire; no particular breed; noticed nine breeds and nine crosses of these. Many consider that rather poor land makes the best cheese, and old sward more and better than artificial grasses. In some cases some slacked and powdered lime strewed on the willow trees within the reach of cows, to prevent their eating them, and tasting the butter. Milk set to raise its cream in yellow dishes, with lips; in some places in slate troughs; carried home in suspended tubs. (*fig.* 1006.)



1006

Sheep. Ten different breeds, and seven crosses of these and others; wool chambers generally form a part of the accommodations of the farmeries.

Horses. Those of Derbyshire ranked next to those of Leicestershire, for being stout, bony, and clean-legged.

Asses in considerable number used by the smaller manufacturers, and in the coal-works, potteries, &c.; also on the iron railways.

Swine. The Earl of Chesterfield supplies his table with delicious sucking pigs, of a fortnight old, from his Otaheite sow; plan of shaving off the gristly or horny projection of the snout, to prevent digging, recommended. Tethering by the neck also suggested for eating down sturdy herbage crops. A pin and screw to be used like those for fixing down Salmon's harmless man-trap. (*Trans. Soc. Arts*, vol. xxvii. p. 183.)

Poultry. The Earl of Chesterfield's poultry yards at Bretby, perhaps as complete as any in the kingdom. The roosting-house is well contrived, with covered places for the ducks and geese under the fowls, and the whole is constantly kept strewed with fresh saw-dust. The sitting-house, and which serves also for laying, is furnished with flues, to preserve an equal temperature in frosts. In the feeding-houses, the fronts, partitions, and floors of the pens, are all of lattice-work, which readily take out in order to wash them thoroughly; shallow drawers with fresh sawdust pass under each pen to catch the dung. The fatting poultry are fed twice a day, and after each the food is taken away, and the daylight excluded, for them to rest and sleep.

A breed of *brown American turkeys* at Brailsford; they roost upon trees or the high parts of buildings; cocks weigh twenty pounds when fat, but the hens much smaller.

Geese when let out have a stick about two feet long slung before the breasts of the old ones, which is found to prevent them creeping through hedges, &c.; feed on *Festuca* fluitans, &c. When waters are much impregnated with lime, the eggs of geese and ducks that frequent them are so much thickened that hatching becomes difficult.

Hens. At Plesby a fine breed of black fowls; round Wingerworth many game fowls kept for cocking. In Tansley the cockpit converted into a methodist meeting-house. Eggs preserved hung in nets, and turned into a fresh position each day; this being the main essential in preserving eggs, whose yolks subside slowly when left unmoved, and come at length to touch the shells on the lower side, when rottenness almost immediately commences.

Bees kept in various places.

Fish. Certain ponds in Sir Thomas Windsor Hunlocke's Park, in Wingerworth, are appropriated to the feeding of castrated male carp and tench, which are found very superior in size and flavour to other fish; the late Sir Windsor Hunlocke saw this practised in Italy, many years ago, and had one of his servants, who was with him, instructed in performing the operation; which is less difficult or dangerous than might be supposed, and in consequence of which, not more than one in fourteen or fifteen of the fish die.

Angling permitted at Combs-brook reservoir of forty-five acres, the angler paying sixpence per pound for the fish taken. Salmon pass and trap on the Derwent, at Belper bridge.

31. *Rural Economy.*

Rewards are offered by the Agricultural Society at Derby, as by most others in the kingdom, for long and meritorious hired or day service, but seldom for having performed the greatest quantities of job-work, or earned the most money by such at fair prices. At the beginning of the present century, it was calculated, taking the labourer's wages at two shillings and sixpence per day, that he must work four and a half times as many days to earn the same quantity of food, as from three to five centuries back he could, when his daily wages was from fourpence to twopence per day! Part of this was doubtless occasioned by the many idle saints' days which the church of Rome imposed on the people at the earlier periods.

14. *Political Economy.*

Various concave roads formerly, made through the influence of Joseph Wilks, Esq. of Measham; these in a very indifferent state, and illustrate the absurdity of the principles on which they are constructed. To level across a road a string level used. It consisted of a piece of boxwood eleven inches long, one and a half broad, and one and a quarter deep, into the top of which a spirit-level tube was deeply sunk, and to the top, at each end of this level, several yards of strong whipcord was fastened. In using this instrument, a labourer was placed on each side of the road, having the cord in his hand, which they pulled very tightly, and steadily against each other, and thereby made the bubble assume the middle of the tube or either end, according as the two ends of the string were held level or one higher than the other.

Some remains of wavy roads (3551.), but nothing to justify any deviation from the general form of slightly convex roads, with straight or even surfaces as to length. The road between Ripley and Little Eaton, where washing or irrigation has been adopted as a mode of clearing (*Com. B. Ag.* vol. i.) was "miserably deep, loose, and bad."

In *Manufactures* Derbyshire ranks next to Lancashire, Staffordshire, and Warwickshire.

1. *Trades, &c. depending on the Animal Products of the county.*

Blanket-weaving, and scouring.

Bone-crushing mills.

Butter.
Button-moulds, of horn and bone.
Candle making, of tallow.
Carpet-weaving.
Cheese.
Curriers or leather-dressers.
Fellmongers.
Fulling mills.
Glue-makers.
Leather mills, for oiled and chamois leather.
Meat, beef, lamb, mutton, pork, veal.
Shoe factory.
Skinners, or leather-dressers, chamois, &c.
Soap-makers.
Stockings, of worsted.
Tanyards.
Woollen-cloth factories, yarn spinning, weaving, and cloth dressing.
Worsted spinning, for the hosiers, by hand and jennies.

2. *Trades, &c. depending on Animal Substances, imported.*
Hat-making and unsplit straw hats.
Silk-spinning mills.
Silk-stocking weaving.

3. *Trades, &c. depending on Vegetable Productions of the county.*
Basket and wicket making.
Besom or broom do.
Boat or barge building, for the canals
Breweries.
Chamomile flowers.
Charcoal burning and grinding.
Charcoal mills, for grinding it.
Corn, barley, beans, oats, peas, wheat.
Hoops for casks, of wood.
Malt-makers.
Mattresses, chair-bottoms, &c. of straw.
Millers, flour or meal makers.
Sieves, or riddles for corn.
Shelling, or oat-meal mills.
Timber.
Turning mills, for wood, bobbins, bowls, cheese-vats, dishes, tool-handles.

4. *Trades, &c. depending on Vegetable Substances, imported.*
Bleaching-houses, and grounds.
Calico-printing.
Calico-weaving.
Cambric-weaving.
Candle-wick, bump or bomp spinning-mills
Cotton-spinning mills.
Dye-houses.
Flax-spinning mills, linen-yarn mills.
Fustian-weaving, thicksets.
Hop-bag spinning and weaving, wool-bags, &c.
Lace-weaving, or warp frame-lace making.
Lace-working, or needle-working of frame-lace.
Linen-weaving, sheeting, checks, &c.
Muslin-weaving.
Nightcaps, of cotton frame knitting.
Packthread spinning, string, twine.
Paper-making.
Rope-making, cords, halters.
Sacking weaving, corn-bags.
Sail-cloth weaving.
Stocking-weaving; principally of cotton, some of worsted frame-knit.
Tape-weaving mills.
Thread-spinning.
Whipcord-spinning.

5. *Trades, &c. depending on Mineral Products of the county.*
Bakestone making.
Boiler-making, of wrought iron, for steam-engines.
Brick-making, building, draining, fire, paving.
Building-stone, or free-stone, ashler, caping, eaves-slates, gable-stones, paving, ridging, grey slates, or tilestones and stack-posts.
Cannon-balls, or shot and shells.
Cannon-casting and boring.
Chain-making, iron and cast-iron.
China-stone, or white potter's chest-pits.
Cisterns and troughs of stone, to hold water.
Clay-pits, brick, china, fire, pipe, pottery, and tile.
Coal-pits.
Coke-burning.
Copperas-stone, brasses or pyrites pits.
Fryingpans of iron.
Grind-mills, blade-mills, grindstone mills.
Grindstones.
Gypsum, alabaster, plaster.
Hammer mills, forge, tilt, planishing mills.
Hoops for casks, of iron.
Iron forges and furnaces.
Ironstone pits, argillaceous ore.
Lead-mines, or veins of lead ore.
Lead-smelting cupolas, and slag-mills.
Lime-kilns.
Limestone quarries.
Malt-kiln plates, of perforated cast-iron.
Marble quarries.
Marble sawing and polishing mills.
Marl pits, for manuring.
Mill-stone quarries.
Nail-making, of cast-iron.
——— clasp (or carpenter's), and spikes, &c.
——— horse-shoe.
——— shoe-makers.
Ore dressing washing, buddling.
Patten rings, or clog irons.
Pipe-making, tobacco pipes.
Pipes, of earthenware, hollow bricks, for conveying water.
— of lead, drawn.
— of zinc.
Plaster of Paris works, gypsum.
Potteries, earthenware, stoneware.
Pot-stones, pye or lump stones for the iron forges.
Puncheons, stauncheons or props, for the coal pits.
Red-lead works, minium.
Rivets, of iron, softened, for coopers, boiler-making.
Rolling and slitting mills, for iron bars, plate iron, nail rods.
Rotten-stone, or polishing earth.
Sand-pits, casting or founders', house-floor, mason's mortar, scouring, and scythe-stick sand.
Saw mills, for stone and wood, also with circular saws.
Screws, carpenters', for wood.
Scythe-sticks and stones for sharpening scythes, hay-knives.
Sheet-lead, milled lead, rolled lead. Common sheet-lead is cast by most of the plumbers and glaziers of the county.
Shot, leaden.
Slitting mills.
Spar-workers, petrifaction workers, gypsum, calcspar, fluor.
Sulphur-works, annexed to the principal smelting houses.
Tenter hooks, of cast-iron, softened.
Tile-kilns, draining, gutter, hip, pan, plane and ridge.
Tire for carriage wheels.
Whetstones, rubbers, hones.
White-lead works.
Wire-drawing, steel.
Wire-working, safes, sieves, screens.
Zinc mines, blend and calamine.
— work, malleable plates, wire pipes, &c.

6. *Trades, &c. depending principally on Mineral Substances, imported.*
Axes, hatchets, bills, adzes.
Brass foundry.
Bridle-bits and buckles.
China factories.
Chisels, gouges, plane-irons, and other edge tools.
Clock and watch making.
Colour-grinding mills, paint.
Cotton machinery makers, for the cotton-spinning mills.
Cutlery, knives, forks, &c.
File-making, rasps.
Flint-grinding mills, for pottery glazing.
Frame-smiths, stocking-loom makers.
Glass-making.
Gunpowder-making.
Hoes (garden, turnip), paring shovels, trowels, &c.
Implement makers, agricultural tools.
Malt mills, steel mills.
Mangles, for linen clothes.
Mechanists, machine, tool and engine makers.
Millwrights.
Needle-making.
Reaping-hooks, smooth-edged.
Scissars, of cast-iron, cemented to steel.
Scythe-smiths.
Sickles, toothed reaping tools.
Snuffers.
Soda water makers.
Spades, shovels.
Spurs, of steel.
Stirrup-irons of cast-iron, cemented.
Tin-plate workers, tin-men.
Washing machines for clothes.
Worsted machinery maker, for the worsted spinning-mills.

Notwithstanding that many of the manufactures and productions above mentioned are separately of small importance and may contribute little or nothing towards an export trade from the county, yet, taken in the aggregate, they must be admitted to present a most flattering picture of the varied and great manufacturing industry of the county; showing it to contribute far beyond most other counties towards the supply of all its own wants, and contributing at the same time, in no small degree, towards the supply and general trade of the kingdom at large.

Education,

Among the labouring classes, the reporter observes, is better attended to than in most of the adjoining counties. He approves of the great attention paid to bringing up children in habits of frugality and industry; and contemplates, as "the great and desirable end, their complete emancipation from the moral slavery of poor-law dependence, and its attended vices and misery." There are some persons, no doubt, who may not approve of all that Mr. Farey has advanced on this subject; for where is the writer that can please every reader? but there are none, we hope, who would not be gratified with his sincere and ardent desire for the more general and universal happiness of the British poor. Though we are of opinion that very little amelioration of that division of society which constitutes the agricultural or labouring class can be effected without an alteration in the laws; yet we are equally convinced, that no great alteration of what are called the poor laws would be advisable, till the poor are prepared for it, by having imbibed such a degree of knowledge as would enable them to meet the consequences with advantage, or at least without an increase of misery.

We agree with the reporter, that the case is somewhat different with the operative manufacturers, and mechanics congregated together in towns; for the wages of their labour depends, in most cases, as the wages of all labour ought to do, on the demand and the supply; whereas the weekly wages of the agricultural labourer depends but too often on the decision of the parochial vestry. The consequences of this state of things are ruinous to the rustic labourer, and call loudly for legislative interference and general sympathy. The extraordinary exertions at present making by the different classes of mechanics, to enlighten and ameliorate themselves, cannot fail in a short time to awaken the dormant powers of the country labourer.

15. *Means of Improvement.*

There are reading societies in most of the principal towns: to be regretted that the funds of the board of agriculture do not permit it to circulate cheap agricultural books; agricultural books have as large a sale in Derbyshire as in most other counties; some take the "Farmer's Magazine," and a great number the "Farmer's Journal;" which, if the stamp duty were taken off, would greatly increase in circulation, and be an incalculable source of improvement. An agricultural society at Derby, since 1794; a society for fat wether sheep at Repton: at Hayfield, a society of mountain sheep keepers, since 1790. A list given by Farey of ninety-three agricultural societies in England and Wales. The late Earl of Chesterfield's premiums annually to his tenants, as recorded in the Farmer's Journal, 27th December 1813, and 15th January 1816.

7800. NOTTINGHAMSHIRE. 495,000 acres of uneven or hilly surface, in great part a sandy soil, and more a corn than a pasture county. It contains the Forest of Sherwood, the only one belonging to the Crown north of the Trent. This forest was once celebrated as being the scene of the adventures of the famous Robin Hood. Very little wood, however, now remains. The report is one of the most defective and least interesting which the board have published, and is, besides, above a fourth of a century old. (*Lowe's Report*, 1798. *Marshal's Review*, 1812. *Smith's Geological Map*, 1821. *Edin. Gaz.* 1827.)

1. *Geographical State and Circumstances.*

Climate, remarkably dry.

Soil, chiefly sandy, great part clayey, and the remainder a lime and coal district.

Minerals. Stone, lime, coal, gypsum, and marl.

2. *Property.*

Estates from 12,000*l.* a year, downwards.

3. *Buildings.*

Few countries contain more gentlemen's seats in proportion to its size. Alston Grove, a noble residence; the gardens formerly in the ancient style, but lately modernised. Clumber Park contains four thousand acres. Newstead Abbey, celebrated as having been the residence of the Byron family; but now sold and divided. Thoresby park, thirteen miles round. Welbeck Abbey, the scene of the horticultural improvements of Mr. Speechly. Woolaston Hall, a singular mansion of the date of Queen Elizabeth, by Thorpe, the same architect who built Holland House, near London. Farm-houses "not very spacious," of brick and tile, sometimes thatched; now and then of stud and mud. Good farmeries, and centrical on the new enclosures.

4. *Occupation.*

Few farms exceed 300*l.* per annum: generally from 100*l.* to 200*l.* Few leases.

5. *Implements.*

Rotheram plough general; waggons have wide frames moveable for harvest use.

6. *Various.*

Enclosing going on rapidly; in arable culture, rotations good, but no remarkable practice mentioned; various hop-grounds and orchards, many woods and plantations; extensive woods raised from seed on the Welbeck and Clumber estates; the ground is first cleared of surface incumbrances, then cropped with corn two years, and turnips one year; the fourth year acorns, at the rate of four or six bushels, ash keys four, hawthorn berries one, and Spanish chestnuts one bushel, are sown broadcast on an acre, and ploughed in. The stocking and lace trade, cotton and silk manufacture, pottery, and various others carried on at Nottingham and other towns.

7801. LINCOLNSHIRE. 1,848,320 acres of uplands, vale and water formed lands. The soil in most places rich, and chiefly devoted to grazing; yielding on an average more beef and mutton per acre than any county in the island. Examples of embanking, draining, and warping, are numerous along the sea-coast and the Humber. (*Stone's Report*, 1799. *Arthur Young's*, 1794. *Marshal's Review*, 1812.)

1. *Geographical State and Circumstances.*

Climate, formerly unhealthy in the low parts, now the ague much less frequent. N. E. winds prevail in spring; much of the rain in summer from the northern and eastern quarters.

Surface, a great extent of low land, once marsh, and fen along the coast, now rich land in consequence of the embankments and drainage, which have been going on for nearly two centuries. Adjoining the lowlands are the wolds or calcareous hills, and the mainland part of the country is in general flat and uninteresting. Some parts of the county, however, as about Dalby, Spilsby, Stainton, &c. are varied and wooded, and command fine views of the low country.

Soil. There are large districts of clay, sand, loam, chalk, peat, and considerable extent of mixed soils.

2. *Property.*

Very much divided in the isle of Axholm; inhabitants collected in hamlets and villages, and almost every one is proprietor and farmer of from one to forty acres, as in France; and, as in that country, every farm cultivated by the hands of the family, and the family poor as to money, but happy as to their mode of existence. "The poorer farmers and other families work like negroes, and do not live half so well as the inhabitants of a poor-house; but all is made amends by possessing land." Lord Carrington, Sir John Sheffield, and — Goulton, Esq. great proprietors in the county; largest estate 25,000*l.* a year, others of 14, 11, 10, 8, 7, &c. and six of 2000*l.* a year. Lacely, a pretty village, "where each man lives on his own."

In the *management of a great estate*, "I remarked a circumstance at Reevesby, the use of which I experienced in a multitude of instances. The liberality of Sir Joseph Banks opened every document for my inspection; and admiring the singular facility with which he laid his hand on papers, whatever the subject might be, I could not but remark the method that proved of such sovereign efficacy to prevent confusion. His office, of two rooms, is contained in the space of thirty feet by sixteen; there is a brick partition between, with an iron plated door, so that the room in which a fire is always burning might be burnt down without affecting the inner one; where he has 156 drawers of the size of an ordinary conveyance, the inside being thirteen inches wide, by ten broad, and five and a half deep, all numbered. There is a catalogue of names and subjects, and a list of every paper in every drawer; so that whether the enquiry concerned a man, or a drainage, or an enclosure, or a farm, or a wood, the request was scarcely named before a mass of information was in a moment before me. Fixed tables are before the windows (to the south), on which are spread maps, plans, &c. commodiously, and those labelled are arranged against the wall. The first room contains desks, tables, and book-case, with measures, levels, &c. and a wooden case, which when open forms a book-case, and joining in the centre by hinges, when closed, forms a package ready for the carrier's waggon, containing forty folio paper-cases in the form of books; a repository of such papers as are wanted equally in town and country. Such an apartment, and such an apparatus, must be of incomparable use in the management of any great estate, or, indeed, of any considerable business. At Wintringham, Lord Carrington has a man employed, whose only business is to be constantly walking over every part of the estate in succession, in order to see if the fences are in order: if a post or rail is wanting, and the quick exposed, he gives notice to the farmer, and attends again to see if the defect is remedied." (*Young's Report.*)

3. *Buildings.*

Several good new farm-houses; old cottages of stud and mud, thatched; but new ones of brick, and tiled.

4. *Occupation.*

Farms on the Wolds from 300 to 1500 acres, on the rich lands 400 and 500 acres, downwards; many very small. The late Sir Joseph Banks declined throwing his farms together, because he would not distress the occupiers, though he lost considerably in rental by it. Farmers met with at ordinaries, liberal, industrious, active, enlightened, free from all foolish and expensive show, or pretence to emulate the gentry; they live comfortably and hospitably, as good farmers ought to live; and in my opinion, are remarkably void of those rooted prejudices which sometimes abound among this race of men. "I met with many who had mounted their nags, and quitted their homes, purposely to examine other parts of the kingdom; and had done it with enlarged views, and to the benefit of their own cultivation." Leases rare.

5. *Implements.*

Plough with wheel coulter used in the fen tract as in other fens; the wheel coulter being considered as better adapted for ploughing among stubble and couch-grass than the sword one. Plans given of a cover of canvass and boards for ricks, and a boat with a net fence round for conveying sheep; at best, we fear, but an expensive incumbrance on agriculture.

6. *Arable Land.*

Near Market Deeping the common fields in alternate ridges of pasture and arable, the latter gathered high; three to five horses used in both plough and cart teams; wood extensively cultivated by Cartwright, at Brotherstoft farm, near Boston. Parsley sown along with clover to prevent the rot.

7. *Various.*

"Rich grazing land the glory of Lincolnshire." In some places will carry six sheep per acre, or four bullocks to ten acres. One of the most extensive graziers was T. Fydell, Esq., M.P. at Boston. Very few *orchards*; some considerable young *plantations* on the Wolds, but not much old timber.

8. *Improvements.*

Most extensive drainages and embankments. Deeping Fen drained, which extends eleven miles to Spalding. 10,000 acres taxable, for maintaining the drains and banks, which are managed by a commission. Through all the fens what is called the soak exists; viz. water, supposed to be that of the sea, rising and falling in a subtratum of silt: hence low-lying land always charged with moisture to a certain height. Sticklebacks sometimes sold at a half-penny a bushel, and used as manure. In the Wolds dry straw spread on the land and burned.

Embankments. Since 1630, 10,000 acres have been saved from the sea in the parish of Long Sutton, and 7000 acres more might now be taken in, by altering the channel of the river. Holland Fen is a country that absolutely exists but by the security of its banks; they are under commissioners, and very well attended to.

At Humberstone there is a large piece taken in from the sea by a low bank, which is well sloped to the sea, but too steep to the land; so that if the sea topped it, the bank must break. Great tracts of valuable land remain yet to be taken in from the sea about North Somercots, and other places on that coast; but "I do not find that any experiments have been made in Sir Hyde Page's method of making hedges or gorse facines, and leaving the sand to accumulate of itself into a bank. Mentioning this to Neve, he informed me, that he had observed at least a hundred times, that if a gorse bush, or any other impediment, was by accident met by the sea, it was sure to form a hillock of sand." The extent of sand dry at low water on this coast is very great; the difference between high and low water mark extending even to two miles.

In the reparation of the banks which secure the marsh land from the sea, the frontage towns are at the expense; but in case of such a breach as renders a new bank necessary, the expense is assessed, according to the highest tides ever known, by level over all the country below such level of high water, under the direction of the commissioners of sewers; the distance from the sea subject to drainage will, therefore, vary according to the level of the country.

South Holland, grossly estimated at 100,000 acres, within the Old Sea-dyke bank, has long been an object of embankment. Ravenbank, the origin of which is quite unknown, appears to have been the third bank which had been formed for securing a small part of this tract from the sea, leading from Coubit to Tidd St. Mary's. About six miles nearer to the sea is another bank, called the Old Sea-dyke bank, which is unquestionably a Roman work.

A very curious circumstance is, that a fifth bank, called the New Sea-dyke bank, two miles nearer than the Roman one, remains, but it is utterly unknown when or by whom it was made. The new bank mentioned above takes in about two miles more in breadth. In staking the levels for making the new drain, it was found that the surface of the country, on coming to the Roman bank, suddenly rose six feet, being six feet higher on the sea-side than on the land-side, and then continues on that higher level, being the depth of warp, or silt, deposited by the sea since since that bank was made.

The first navigable canal that was made in England is, in all probability, that which was made from Lincoln to Torksey: it is evidently a part of the Cardike, an immense Roman work, which served to prevent the living waters from running down upon the fens, and, skirting the whole of them, from Peterbo-

rough to Lincoln, afforded a navigation of the utmost consequence to this fertile country.

Some *irrigation*; and *warping*, on the Humber, where, as already described (4444.), it was invented.

9. *Live stock.*

More attended to in this county than the culture of corn. The Durham short-horned cattle are preferred, but any sort fatten well, and there is little dairying.

Sheep. County carries one sheep and an half per acre at an average. Lincoln breed preferred; Leicester much tried, and crosses between them frequent; upon inferior land the Leicester preferred, as fatting easier; since the enclosure no folding; several ram societies.

Horses, of the heavy black kind a good deal bred both for carts and coaches; in various places saddle horses also; some farmers keep their horses all the winter in open sheds, with littered yards for them to go out and in at pleasure. Groundsel eaten, said to cure the grease; oats malted in salt water given for three weeks or a month, found preferable to spring physic.

Rabbits. Several warrens on the wolds.

Geese formerly much kept in the fens, and plucked four or five times a year. "The feathers of a dead goose worth sixpence, three giving a pound. But plucking alive does not yield more than three-pence per head, per annum. Some wing them only every quarter, taking ten feathers from each goose, which sell at five shillings a thousand. Plucked geese pay in feathers one shilling a head in Wildmoor fen.

10. *Political Economy.*

Roads in many places made of silt; "dreadfully dusty and heavy in dry weather: on a thaw or day's rain like mortar." A number of canals, and, as already observed (3802.), the first in England, made from Lincoln to the sea. A fabric of brushes and sacking at Gainsborough; flax spun in various places. An agricultural society at Falkingham, established in 1796.

7802. RUTLANDSHIRE. 91,000 acres, resembling in soil and surface the uplands of the adjoining county of Lincolnshire. The western part of the county is under grass, and the eastern chiefly in aration. The soil is almost every where loamy and rich; and the agriculture partaking of that of Lincolnshire and Leicestershire. The operative classes seem more comfortable in this county, and more humanely treated by the proprietors and farmers, than in many others. The Earl of Winchelsea has made great exertions to this effect. (*Crutchley's Report*, 1794. *Parkinson's General Review*, 1808. *Marshal's Review*, 1812.)

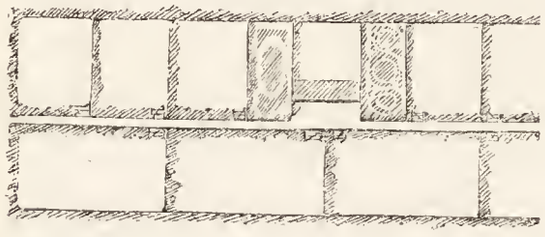
1. *Buildings.*

Some comfortable cottages built by the Earl of Winchelsea, containing a kitchen, parlour, dairy, and cow-house, &c. with two bed-rooms over.

Others for three cows, and with a calf-house, piggery, dairy, kitchen, living-room, and two bed-rooms over.

A third sort for operatives without a cow, containing a kitchen, pantry, closet in the stair over, and two bed-rooms, one with a fire. Several with small farms of from five to twenty acres attached. (*fig.* 1007.)

1007



2. *Arable Lands.*

Generally better managed than in Lincolnshire, and very productive. The barley said to be of very superior quality.

3. *Pasture.*

Chiefly upland. The custom of letting part of it to labourers, and also of taking in labourers' cows at so much per head, prevails, and is encouraged by the Earl of Winchelsea.

4. *Several Orchards.*

In several places the cottagers take small portions of fields from the farmers to use as gardens. At one place, three acres and a half is divided into fourteen gardens; and at Oakham, a field of three acres is divided into twenty-four gardens, and let at five shillings per garden.

5. *Improvements.*

Parkinson, one of the reporters, and a man of sound judgment, has altered his opinion on the subject of irrigation, and says, it is now in conformity with that of a correspondent who thus writes to him:—"In my opinion watering renders the quality of the herbage and the land the worse for the process. Where land is tolerably productive, and in a situation where a quantity of grass food is not required, I should certainly not advise it. I think the land may be turned to better account without it. But I think there are many situations, particularly on gravel, sand, or open soils, where it may be very advantageous; the produce, by such means, is certainly much increased, and, in some instances, rendered larger when very little otherwise would be produced. Though the produce is increased, yet it becomes in time, in a few years, of so coarse a nature, and mixed with rushes and plants, that cattle frequently refuse to eat it; and when it is eaten, the appearance of the cattle proclaims it far from being of a nutritious nature." He adds, "I was formerly an advocate for irrigation, and am still on such soils as are described in the above extract; but having had since opportunities of viewing several water meadows which have been of long standing, which have operated to the disadvantage of both the herbage and land, I have been obliged, in a great measure, to alter my opinion."

6. *Live Stock.*

Not much breeding, but chiefly feeding. P. considers that much depends on the application to fallow, and is of opinion, that the large Durham ox did not eat more food to raise him to that enormous size, than some others would to bring them to half the size or weight at the same age. Nor is it at all probable that Lambert, of Leicester, who arrived at such an astonishing weight, had eaten more food than Powell, the celebrated pedestrian, who was a very thin man. An animal for the shambles is seldom too large if he has an aptitude to fatten: and much depends on the constitution of an animal in this respect.

A good plan for washing sheep at Burleigh; but not so simple as the Duke of Bedford's.

Horses of a very heavy, slow, unprofitable sort are raised in the county.

Of *bees*, 1176 hives kept by the cottagers.

7. *Political Economy.*

The Leicestershire and Rutlandshire Agricultural Society established in 1806, meet at Melton Mowbray and Oakham alternately. Less want of knowledge in this county than in most others.

7803. NORTHAMPTONSHIRE. 617,600 acres of billowy surface, rich in wood lands and pasture lands, but much behind in the culture of corn. The soil is almost every where excellent; and by the introduction of good husbandry, the marketable produce of the county might be amazingly increased. (*Donaldson's Report*, 1794. *Pitt's Report*, 1806. *Marshal's Review*, 1812.)

1. *Geographical State and Circumstances.*

Climate. Favourable both to health and vegetation; exempted from deep falls of snow and long-continued rains; highest point in the county supposed about 800 feet above the level of the sea, and there is neither mountain nor bog. Donaldson found that wheat harvest generally commences here about a fortnight earlier than in Perthshire.

Soil. Great part on a calcareous bottom, limestone, schistus, or slate, and the remainder of sandstone. The surface earths may be classed as strong and deep loam, light thin reddish soil, thin light clay, and fen and meadow.

Minerals. Clay, limestone, marl, freestone, and slate.

2. *Property.*

Almost wholly in large estates; thirty-seven of or above 3000*l.* a year, half of which are from 5000*l.* to 10,000*l.*; managed by stewards.

3. *Buildings.*

Althorpe, Burleigh, and Castle Ashby, noble mansions. Farm-houses "as badly constructed as improperly placed;" built of stone or brick, and covered with slate or straw; farmers and their farmeries crowded together in towns and villages; cottages of mud and thatch.

4. *Occupation.*

No large farms; 130 acres the average of open fields, and 200 the average of inland farms; few or no leases.

5. *Implements.*

"Plough a clumsy piece of work, with a long massy beam and timber mould, being drawn by four or five horses in a line." Donaldson says, a small plough, with two horses abreast, will make better work; but Pitt (who seems to know very little of the matter) joins with Smith of Tuchmarsh, who says, "I have heard and read much on the subject, and tried a great variety of ploughs; but it is ridiculous to assert that two horses can plough abreast in almost any part of this county. I have met with no ploughs which serve so well (!) or run so easy as the ploughs in common uses." So much for the ignorance and presumption of Farmer Smith, and the prejudiced opinions of Pitt the reporter. A ribbed or plated roller, formed by letting in sixteen bars of iron lengthways of the roller, is found preferable either to a spiky or smooth roller for breaking clods.

6. *Arable Land.*

Fallow, wheat, and beans, the common rotation, but others, which include turnips and clovers, beginning to be introduced on the light lands. Most of the other plants in cultivation tried by amateurs or others. Woad cultivated by two woad growers, who live in the county; it requires rich old pasture land, for which the woad grower pays the landlord from 5*l.* to 7*l.* per acre, per annum, for two or three years, the farmer being compelled to give it up for that term, and to take to it again afterwards at the old rent. The land is ploughed early in spring, well harrowed, and sown broadcast, as thick as grain, by handfuls; a great deal of harrowing and dressing is necessary to bring it to fine tilth. When the plants appear, they are hoed, and kept perfectly clean, in a garden style of culture, and the crop appears somewhat like a broadcast crop of spinach; the leaves are gathered by hand, in baskets, three times in a season (except a plot sometimes saved for seed), and carted to a mill, where they are ground to a pulpy mass, by vertical wheels, crossed with iron plates, and moved round by horses: this pounce, or jelly, is then formed into balls, by hand, and dried on hurdles, in a shed; these balls are afterwards broken up, and fermented, and finally dried in small lumps, somewhat resembling horse-dung in colour and appearance; it is then packed up in casks for use.

Onions cultivated to great perfection about Northampton; 220 quarters known to have been sent to Daventry fair at one time.

Tobacco cultivated by some farmers for the purpose of dressing sheep for the scab.

Furze in a few places for oven-fuel.

7. *Grass.*

Supposed to cover 375,000 acres; 40,000 acres in meadow, on the borders of the Nen and other rivers. One farmer says, "A great improvement on all mowing meadows, incapable of

being watered, is to graze, once in two or three years as bare as possible, and finish with store sheep; shut it up at Christmas for mowing; this is as good as a top-dressing." Feeding sheep and cattle the chief application of the grass lands, and next, dairying and breeding horses.

8. *Gardens and Orchards.*

Good market gardens and orchards about Northampton; all common articles grown there well, but melons, grapes, peaches, and pine-apples to be had from London cheaper than they can be grown in the county.

9. *Woods and Plantations.*

Very extensive; there are forests, chases, purlieu woods, and woods and plantations being freehold property. Rockingham forest the most considerable, nearly twenty miles in length, and covering 8 or 10,000 acres. Whittlewood eleven miles, and 7000 acres, with Salcey forest, making in all 20,000 acres: the chases and other classes are supposed to amount to 20,000 acres more, making in all 40,000 acres of woodland in the county. The forest lands are in general very unprofitably managed; the Crown has a right to the timber, the Duke of Grafton and others to the underwood, and the township to the pasturage, &c.; woods which are private and entire property are better managed.

10. *Live Stock.*

Cattle of the county, the long-horned breed: but various others introduced for fatting and the dairy.

Sheep of various breeds; a good many new Leicesters.

Horses of the strong black breed, bred for the coach, the army, or large waggons. Blood horses formerly bred, but left off, as the least blemish renders them unsaleable.

Hogs, a breed between the Berkshire and the Tonquin.

11. *Political Economy.*

Bad roads, but many handsome bridges; some canals. Manufactures; — shoes for the army and navy, and exportation; bone lace, woollen stuffs, as tammies, callimancoes, and everlastings. Several small friendly societies for the promotion of agriculture, consisting chiefly of farmers. The Lamport Society is one of those which was founded in 1797, meets at Lamport; it has a fund for purchasing books on agriculture and domestic economy, and seems to be a description of association very commendable. A great source of improvement would be the breaking up of the inferior grass lands, and the temporary laying down of the continually cropped tillage lands. Donaldson has drawn an able comparison between the management of lands in the Carse of Gowrie, in Perthshire, and those of Northamptonshire, which shows how very far behind the latter county is in arable culture.

7804. YORKSHIRE, 3,698,380 acres divided into three Ridings, each of which is as extensive as the generality of other counties.

7805. West Riding of Yorkshire. 1,568,000 acres of irregular country, hilly and mountainous towards the north, and more level on the east. It contains a great extent of surface well adapted for husbandry, and is the seat of large and extensive manufactures. A survey of this Riding, of singular ability and interest, was made by three Scotch farmers; and the reprinted copy, as it contains the notes of several gentlemen of the county, will in future times be considered as a curious document; displaying as it does local opinions so different from those considered as liberal and enlightened. (*Brown's West Riding*, 1799. *Marshal's Review*, 1818. *Smith's Geological Map*, 1821.)

1. *Geographical State and Circumstances.*

Climate, moderate and healthy, excepting on the low surface near the Ouse; rain at Sheffield about thirty-three inches in the year.

Surface irregular, but the middle and eastern parts nearly level; arable lands generally enclosed with walls and hedges.

Soil various, from deep strong clay to peat.

Minerals. Coal, lime, ironstone, lead and some copper, which have been wrought for ages past.

Rivers. Ouse, Don, Calder, Aire, and Wharfe, all considerable, besides others of lesser importance.

2. *Property.*

Much divided, but some large estates, as those of the Duke of Norfolk, E. Fitzwilliam, E. Harewood, &c.

3. *Buildings.*

Wentworth House one of the largest and most magnificent in the kingdom; farm-houses bad and badly situated as in most English counties; Lord Hawke has erected a commodious and elegant farmery for his own use. Great want of cottages for farm operatives.

4. *Occupation.*

Farms small; for one of 400 acres a dozen under fifty; occupier of 100 acres styled a great farmer; few leases; the tenants on one estate warned off because they had become methodists; tenantry in general much plagued by attorney stewards, who must have business or make it.

5. *Implements.*

Rotheram plough general over the whole district, but one-horse carts and other improved implements, as well as better ploughs, are wanting.

6. *Arable Land.*

Round manufacturing towns great part of the land held by manufacturers, that by farmers not well managed compared with Scotland, but tolerable compared with other districts of England. No grain will ripen on the eastern moorlands at an elevation of 800 feet; but on the calcareous wolds of the East Riding it ripens considerably higher, and at 500 feet better than here at 800. Such is the effect of a calcareous soil. Besides the usual crops, some flax, rape, liquorice, rhubarb, and weld, cultivated. Some excellent remarks on fallows.

7. *Grass.*

Great part of the county under old pastures, including some meadows, chiefly applied to the feeding of horned cattle: cattle generally made fat on grass, and finished by stall feeding on turnips; sheep sometimes fed on turnips, by hurdling. Grazing much better understood than aration.

8. *Gardens and Orchards.*

A particular species of plum grows at Sherborne and in the neighbourhood, called the winesour. It grows well both upon gravel and limestone, is hardy, a good bearer, and answers upon any soil; but does not bear so well, nor is its flavour so good, on any as on limestone or gravel. On a strong deep land, the trees run too much to wood, and do not bear fruit in proportion. These plums blossom better than any other sort, and are produced from suckers. The fruit sells from 21*s.* per peck, when sound and good, to 4*s.* 6*d.* when cracked and damaged. They are easily hurt by rain. Plants are to be had from most public nurseries, and in gardens they should be planted on a layer of lime or chalk.

9. *Woods and Plantations.*

Much oak and ash wood grown, and a ready market found at the shipping and manufacturing towns.

10. *Waste Lands.*

Two hundred and sixty-five thousand acres capable of cultivation.

11. *Improvements.*

Warping the most remarkable; ably described by Lord Hawke, and Day of Doncaster.

12. *Live Stock.*

A great variety of breeds of cattle and sheep in use, but no one generally preferred. Near Leeds, when milk tastes of turnips, a tea-cup full of dissolved nitre is put among eight gallons of milk, which entirely removes the flavour. Horses generally used in draught: not many bred excepting in the eastern part of the district; sort in use among the farmers a small hardy race.

13. *Political Economy.*

Many good and many bad roads; various canals. Numerous manufactures of shalloons, callimancoes, flannels, and every branch of woollen goods. At Sheffield every kind of cutlery, since Chaucer's time; at Rotherham, iron-works. These and other manufactures the cause of the wealth of the West Riding.

14. *Means of Improvement.*

Leases, division of commons, enclosing of wastes, better rotations, &c.

7806. North Riding of Yorkshire. 1,311,187 acres of bold hilly country, with some fertile vales and extensive moor lands, chiefly remarkable for breeding horses, and especially the sort known as Cleveland bays. (*Tuke's Report*, 1799. *Marshal's Review*, 1808. *Smith's Geological Map*, 1821.)

1. *Geographical State and Circumstances.*

Climate dry, like that of other districts bordering on the German Ocean. Cold east winds during the first half of the year. Milder in June, when west winds begin to prevail, vegetation not vigorous till June.

Soil and surface: on the coast, clays, and lightish soil on alum strata; a loam upon freestone, and in some valleys west of Whitby a deep rich soil: of Cleveland, fertile chalk, and surface hilly; vale of York generally a rich soil.

Minerals. Inexhaustible beds of alum in the hills of the coast and Cleveland; and the only alum works in the island carried on there; pyrites being found in the alum mines, sulphur was formerly extracted from them; but as it required a good deal of coal, and pyrites are equally abundant in the coal at Newcastle, the manufactory of sulphur was transferred to the latter place. Some coal and ironstone in the moors, but not much worked; also copper, lead, freestone, slate, marble, marl, &c. little worked or abandoned.

2. *Property.*

One third of the Riding possessed by yeomanry; rent of estates from 500*l.* to 18,000*l.* per annum; many gentlemen's seats, and the proprietors reside most part of the year on them; tenures mostly freehold.

3. *Buildings.*

Mansions and farm-houses, as in the West Riding, but rather inferior; cottages decidedly inferior; small and low, rarely with two rooms; damp and unwholesome hovels. Close wainscoted beds used, as in the poorer parts of Scotland, which are sources of insects and infection, and every way unwholesome.

4. *Occupation.*

Farms on the whole small, many very small: farmers sober, industrious, and orderly; most of them have been educated, and educate their children. Few leases.

5. *Implements.*

Rotheram or Dutch plough: hay sweep for drawing hay together with a horse and a simple sort of cart (*fig.* 1008. *a*) in use, formed almost wholly of timber, and to be drawn by one, two or three horses abreast (*b*); wheels entirely of wood (*c*); when to be emptied, the shaft horse is taken out, but not the others. Another variety for harvest work (*fig.* 1009.).

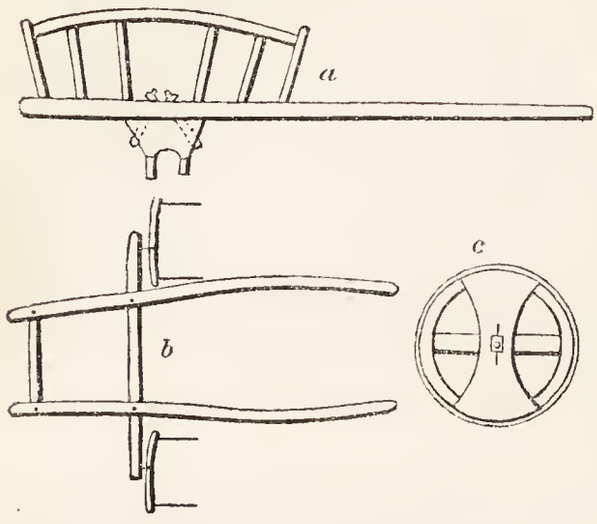
6. *Arable Land.*

In the vale of York one third in tillage; about Cleveland one half; on the moors much less. Culture and rotations as in the West Riding. Rye more frequently sown than wheat on the light sandy soils; often mixed with wheat, and then called Meslin.

Tobacco much cultivated a few years prior to 1782 in the vale of York and Ryedale. In the latter district it did not excite the notice of regal authority; and was cured and manufactured by a man who had formerly been employed upon the tobacco plantations in America; who not only cured it pro-

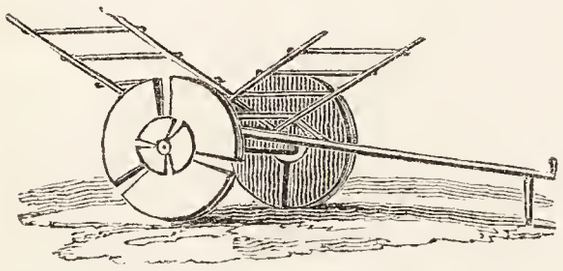
perly, but gave it the proper cut, and finally prepared it for the pipe. But in the vale of York the cultivators of it met with less favourable circumstances: their tobacco was pub-

1008



licly burnt, and themselves severely fined and imprisoned. Penalties, it was said, were paid to the amount of thirty thousand pounds. This was enough to put a stop to the illegal cultiva-

1009



tion of tobacco; but, perhaps rather unfortunately, it has likewise put a stop to the cultivation of that limited quantity, half a rod, which the law allows to be planted for the purposes of physic and chirurgery, or destroying insects.

Mustard grown in considerable quantities in the neighbourhood of York, and fields of it may be met with in other parts of the Riding. It is prepared for use in the city of York, where there are mills and machinery for the purpose; and it is afterwards sold under the name of Durham mustard; sown either on land pared and burned, or prepared and manured as for turnips. Seed, one to two pecks per acre broadcast, in the early part of May. No culture whilst growing, except hand-weeding, if necessary. Shorn with the sickle in September, and generally stacked in the field, and threshed out upon a cloth, at the convenience of the farmer. Two quarters per acre is thought a good crop.

Teasel grown on strong soils; seed, two pecks a little before May-day; surface dug or forked over in June, October, and Lady-day; reaped in August; 10 pecks an acre a good crop; each pack 1350 bunches, of ten teasles each; price, 3 to 5 guineas per pack.

7. *Grass.*

Old pastures and meadows very badly managed; uplands overrun with moss and ant-hills; meadows with rushes; and so neglected, that what would be worth 200*l.* under a proper course of husbandry, is dear at 7*s.*; chiefly devoted to the dairy.

8. *Gardens and Orchards.*

Have made but little progress, in this Riding owing to the want of manufacturing towns to create a demand; farmers' gardens, as in most places, much neglected.

9. *Woodlands.*

Of small extent; a good deal of timber in hedge-rows in various places.

10. *Live Stock.*

Short-horned cattle chiefly prevalent. Stall feeding carried to less extent than dairying. Cows taken in at Martinmas, and fed on turnips, and straw or hay if there are no turnips; butter chiefly made and salted in firkins, and sold to the factors, who ship it to London; a good many cows brought up for London, and any surplus stock for the Lincolnshire graziers.

Sheep. In the bleaker parts, the Cleveland breed, large, coarse-boned, slow feeders, and the wool dry and harsh. All the new breeds introduced, and several professed ram breeders in the vale of York.

Horses. This Riding long famed for its horses, particularly those of Cleveland. In the northern part of the vale of York a light breed for saddle and coach; in Cleveland, a fuller-boned horse, very strong and active, and well adapted for either plough or coach. In all the other districts horses are generally bred; on the western moorlands Scotch galloways are put to the stallions of the country, "and rear a hardy and strong race in proportion to their size." Before the war mules were bred, and sent to the West Indies. Some farmers do not breed, but buy colts and work them till four or five years old, and then shoe them for the first time, and sell them to the London dealers for coach horses.

The farmers who breed horses, generally breed from those mares which are employed in the business of the farm; these are often worked until the very time of foaling, after which they have usually two or three weeks' rest, before they are again taken to work; the foal, during the time the dam is working, especially whilst it is young, is shut up in a stable; and it is the practice of some, before she is suffered to go to the foal, after returning from work, to bathe her udder with cold water, and to draw most of the milk from it, to prevent the milk, which may have been heated by labour, from having any hurtful effect upon the foal. Some continue this practice as long as the foal sucks: others, after the foal has got sufficient strength to travel along with the mare, take it along with her into the fields, and frequently suffer it to suck, from an opinion, that by the milk being frequently drawn, less danger arises of its being heated, or of possessing any quality prejudicial to the foal. The general time of foaling is about May-day (from which day the age of all horses is reckoned), and that of weaning about Michaelmas, when the foals are put into good after-grass, or the best pasture the farmer possesses: they remain there as long as the weather permits (if there be sufficient food), and, on the approach of winter, have a little good hay given them, where there is a stable, or hovel, that they can go into at their pleasure. The colts are usually gelded in the spring following, and in summer are allowed only an inferior pasture; the next winter they make their living in the fields, or in the straw-yard, except they are intended to work in the spring, which is frequently expected of those of a strong kind: such are rather better kept as the time of labour draws nigh, and are only put to light and easy work, and generally work only half a day at once. Some keep their colts a year longer, before the operation is performed, and find that such become the stronger and handsomer horses. The foal always receives a great check by being weaned, which it does not well recover before it gets the fresh pasture of the following summer. The foals which are gelded at one year old receive a second check, at the very time they should begin to recover from the first; whereas at two years old they appear to be in the best condition for the operation, and recover at least as well as at one year old, and are much improved by the keeping of the preceding year.

Exportation of horses. The horses which are sold for the London market, if for the carriage, are chiefly bay geldings, with but little white on their legs and faces, those which have much white, with chestnut, roan, and other unusually coloured horses and mares, generally do not bear an equal price in the London market; but with other slight and undersized horses, are more sought after by foreigners, and eagerly purchased by them for exportation; or are exported by people of this country, who carry them to the foreign markets, and ultimately obtain a price equal to that obtained for those sold at home: by these means of exportation, contrary to an usually received but ill-founded opinion, has a strong tendency to reduce the price of those horses which are calculated for the home market; and since as many fillies as colts are naturally bred, and one third of the colts at least will either have too much white for the home market, or be of some other colour than that which is fashionable at the time, if the breeder had not a market for those, which appear to be two thirds at least of all he unavoidably breeds, he would be compelled to put such a price upon the one third which happened to suit the home market, or variable taste of the moment, as would pay for the other two thirds; which last would either be unsaleable, or fetch very inadequate prices. The consequence naturally flowing from this would be, that the price of horses used at home would be far greater than at present, when a foreign demand procures to the breeder nearly as good a price for the horses that would otherwise be useless and unsaleable, as for those which are valued at home.

Rabbits are kept in one or two warrens; in one the silver grey is kept, the skins of this variety being worth double those of the greys: not used for felts like the common skins, but dressed as furs, and exported to China to be worn by the Mandarins.

11. *Political Economy.*

Roads in an improving state; bridges better attended to than in most counties; but guide-posts neglected, which an annotator on Tuke's report justly remarks, is a sort of reverting to barbarism; as an attention to these sort of minutiæ is one of the most striking marks of civilisation. Various canals.

Manufactures of sail-cloth and cordage at Whitby and Scarborough; at various places in its neighbourhood, alum works; 4000 tons of this article anually shipped from Whitby; linens, cottons, woollen, and paper manufactured in various places.

7807. East Riding of Yorkshire. 819,200 acres of moderately wavy surface, intersected with numerous, deep, winding valleys; not remarkable either for its arable lands or pasturage; but productive of horses for the coach and saddle, and of the excellent Holderness breed of cows. (*Leatham's General View*, 1794. *Strickland's View*, 1812. *Marshal's Review*, 1812. *Smith's Geological Map*, 1821.)

1. *Geographical State and Circumstances.*

Climate of the wolds severe and variable; N. and N.E. winds prevail in winter and spring; in the vales milder; mild, but not very healthy, on the Humber; rain at Hull twenty-seven inches and a half yearly at an average.

Soil of the wolds calcareous loam; of Holderness fertile clay and stiff retentive clay. On the banks of the Humber, from Paul nearly to Sperm Point, there are 13 or 14,000 acres of warp-land, of a strong clayey loam, the productiveness of which can hardly be equalled.

Sunk Island on the Humber is a modern creation by that estuary. It first began to show itself about 1667, at ebb tide, and as no man pretended title to it (it being a detached island), a grant of it was made by the crown in the same year. In 1787 1600 acres of the land were embanked and under tillage, producing a rental of 900*l.* a year, with a chapel and several farm-houses erected on it. That part of Sunk Island which was first embanked was originally about two miles from the shore, and many persons are still living who recollect vessels passing between it and the mainland, to which it is now united by a

bridge across a narrow channel, serving as a drain to the adjacent country. It contains at present within the banks about 4700 acres and twenty-four families, and is continually increasing in size, an extensive tract having been recently embanked, with a probability of its being still further enlarged.

Minerals. Chalk and a very hard shelly limestone, producing a lime little valued either by the farmer or builder. Chalk of the wolds much harder than that of the southern counties. Marl in many places. Gypsum in some places, but no mineral veins or coal, and in many places not even clay for bricks.

2. *Property.*

Less divided on the East Riding than in other parts of the county; perhaps less than in most parts of England; which arises a good deal from the nature of the county: one half of wolds where land is held in little estimation, and occupied in larger tracts; the other a flat low country, partly rich and clayey, and partly sandy and barren. Most of the families have possessed their estates for many centuries, and some from the Norman conquest: largest 15,000*l.* a year; ten at 10,000*l.* a year. Only three noblemen have seats in this Riding.

3. *Buildings.*

Seventy-four manorial houses, of which twelve are going to decay; nineteen let to tenants, or remain empty; forty-one occupied by their owners (*Temp. Eliz.*); ninety-two families bearing arms resident in the county.

Farm-houses generally good, excepting on the wolds, where they are built of chalk, thatched, and miserably bad; generally in villages, excepting those built lately.

Cottages more comfortable than in many places; generally two rooms below and two bedrooms over them: a disposition in the proprietors to let their cottages go to decay.

Village cow club. A plan for insuring cows having been lately adopted on an extensive scale, and with striking success, in the north of Lincolnshire, from which it appears that an average payment of about three halfpence per cow per week (or six shillings per year) is fully adequate to replace the ordinary losses of cows by death, it is proposed to institute a similar club in the contiguous parts of the East and North Ridings of Yorkshire, with a view of securing to the labourer and his family, at a trifling expense, the great benefits of that useful animal, without his risking more than one sixth part of her value, upon certain conditions.

4. *Occupation.*

Farms in general small; one or two of 1200*l.* per annum, but from 200*l.* to 20*l.* more common. Leases so rare that the surveyor could not recollect of one, unless under suspicious circumstances, where something incorrect is aimed at, some advantage intended to be given or taken; where either the landlord wanted something more than customary from the tenant, or the tenant was disinclined to trust his landlord: great estates are let in full confidence in this Riding, where a lease was never asked for, probably never wished for; because the tenure is equally secure, and more permanent without than with one. Many estates have been occupied by the progenitors of the present tenants, during two, three, or four generations.

5. *Implements.*

Waggons here of a bad construction; but well yoked in the German manner. The four horses are yoked two abreast, in the same manner as they are put to a coach, two drawing by the splinter-bar and two by the pole; those at the wheel drawing also by a swinging bar, which the wheel-horses of every carriage ought to do, as they thereby obtain considerable ease in their draft, and are less liable to be galled by the collar than those which draw by a fixed bar; the driver then, being mounted on the near-side wheel horse, directs the two leaders by a rein fixed to the outside of each of their bridles, they being coupled together by a strap passing from the inside of each of their bridles to the collar of the other horse. In this manner, when empty, they trot along the roads with safety and expedition; and when loaded, the horses being near their work, and conveniently placed for drawing, labour with much greater ease and effect than when placed at length. Were the waggon, indeed, of a better construction, the team would be excellent.

The peas-hook and the bean-hook, both made out of old scythe-blades, and used in reaping peas and beans, are peculiar to this Riding; as was the lime-burner's fork till lately. (See *fig.* 682. *b*, *c*.)

The moulding sledge is a useful implement for levelling the small inequalities of meadow and pasture land, and spreading the dung dropped by the cattle. It is a frame of wood about five feet square (the sides of which are about four inches thick to give it weight and strength), having three bars of iron fixed to the lower side, the points of which are thinned to sharp edges. When in use, some thorns are drawn under the hinder wooden bar, and above the middle one, to which they are fixed by cords. If it is wanted to be removed from one field to another, it is turned the other side up, which preserves the edges of the bars from injury. It is drawn by two horses, and will go over a great extent of land in a day.

6. *Enclosing.*

The taste for this has been carried too far, and land enclosed which has not and probably never will repay the expense.

7. *Arable Land.*

Two thirds of the wolds, and one third of the rest of the Riding, under the plough; fallow, wheat, oats, or fallow, barley, beans, common rotations.

8. *Grass.*

The marshy meadows adjoining the Derwent, a few grazing pastures in Holderness and Howdenshire, and the small garths or paddocks in the immediate vicinity of the towns and villages, form the principal part of natural grass lands.

The *salt-marshes* on the outside of the embarkments are of no great extent. Unless the mud is so elevated as to be constantly above water for a few days at neap tides, no plants take possession of the surface; but when vegetation can go on, the first plant which takes possession is the Salicórnia or samphire, and next the *Pòa marítima*, which in a short time covers the surface with a close short sward. A few sheep are occasionally put on it when not too much dirtied by the mud of the spring tides.

In laying land to grass, caraway and parsley sown among it by some, to preserve the health of the sheep.

9. *Gardens and Orchards.*

Almost unknown, excepting among the higher classes; farmers rarely use any other vegetable than potatoes and turnips; cottagers cultivate their gardens with more care than the farmers.

10. *Woodlands.*

Of no great extent in proportion to the Riding; extensive plantations made on the wolds.

11. *Improvements.*

Holderness drainage an extensive work of the kind, on the east side of the river Hull; it extends over nearly 12,000 acres, and is managed by commissioners. Various other extensive drainages.

12. *Live Stock.*

Holderness cattle, remarkable for their large size and abundant supply of milk, prevail universally. This breed is supposed to have been introduced from Holland about a century ago, and improved by attentive management. The late Sir George Strickland the greatest modern breeder in the district. Breeding a principal object in most parts of the Riding, and feeding in Holderness when the pastures are rich.

Sheep formerly the Holderness breed, resembling that of Lincolnshire and the Wold sheep; now the Leicester and various other breeds.

Horses for the coach and saddle, the grand branch of breeding in this Riding, and as many or more produced, in proportion to its extent, than in any other. But it is allowed by all that the breed has of late much degenerated, owing to the inattention of the farmers. About twenty years ago, a cross of blood was introduced, by which, though good saddle horses were produced, the coach horse was lost. This error discovered, an opposite and still more pernicious one was produced by the introduction of heavy black stallions from Lincolnshire. These produced a mongrel breed, which will not be got rid of for several generations. In breeding, some castrate the foal while sucking, and think it a preferable practice to that of the North Riding.

Rabbits. About twenty warrens, containing together probably 10,000 acres.

13. *Political Economy.*

Not more than 140 miles of turnpike road in the whole Riding; few of these good, and the cross roads and lanes very bad; manufactures few; white lead, glue, glass, iron-foundry, oil-mills, cordage, sailcloth, patent whalebone, brick, tile, pottery, &c. at Hull. White-lead and Spanish-white for whitening prepared from chalk, at Hessel. Howden coarse canvass for mail bags; near Driffield spinning and weaving tow; other manufactures near York. Several agricultural societies; one for books and implements at Howden.

7808. DURHAM. 582,400 acres of surface, in some places mountainous, and in most places hilly; the soil in great part poor; the agriculture generally approaching the best model, that of Northumberland; and the county distinguished by the Durham or Teeswater breed of cattle, and by its lead and coal mines. The celebrated farmer and breeder Culley was a native of this county, and farmed here as well as in Northumberland. (*Granger's General View*, 1794. *Bailey's General View*, 1810. *Marshal's Review*, 1818. *Smith's Geological Map*, 1824.)

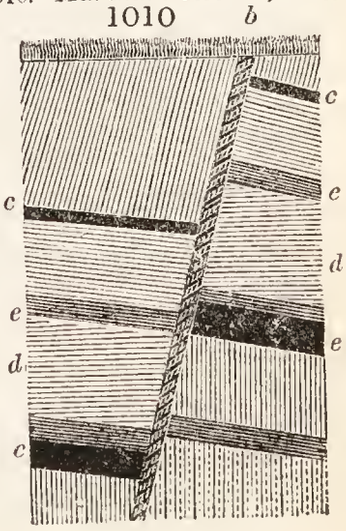
1. *Geographical State and Circumstances.*

Climate fine and mild in the lower districts; but on Crossfell, the highest land in England, being 3400 feet above the level of the sea, snow frequently lies from November till the middle or end of June. General time of harvest from the beginning of September to the middle of October.

Soils principally clay loam and peat; the latter prevails in the western part of the county or lead-mine district; there is a tract of calcareous soil in the interior of the county.

Minerals: coals found over a considerable portion of the county, workable to the extent of 100,000 acres; those in the northern parts of the county wrought for exportation, in the western and southern parts for land sale only. In various parts of the coal districts are dykes or fractures (*fig.* 1010. *a*, *b*), and consequent derangement of the strata, which throw the beds of coal (*c c*) on one side of the dyke often many feet up or down. The fissure between being commonly filled with clay, stops the water in its course along the different beds (*d*, *e*), interrupts the drainage, and greatly damages the working of the coal.

1010 *b*



Lead-mines numerous in the western district; the ore mostly in vertical fissures of limestone and other rocks like the dykes.

Millstones, grindstones, freestones, slates of the grey or freestone kind, silver sand, limestone, whinstone, clay stone or black metal stone, and yellow ochre, also found.

Water. Salmon fishery on the Tyne has greatly declined, owing to the building of wears, which prevent their getting up. Bailey remarks, that if dams of this description were put across the river Tweed, a revenue of nearly 16,000*l.* per year, received for rents of fishings, and 60,000*l.* a year, the value of the fish taken in that river, would be reduced to a mere trifle, in a few years.

Salt springs, from which salt is made near Britt and other places. A spa

or salt sulphur spring near Durham, and another on Lord Durham's estate, with public baths and dressing-rooms. Various others of less note.

2. *Property.*

Largest estates, 20,000*l.* to 22,000*l.* a year; several from 1000*l.* to 3000*l.*, from which they descend by regular gradations to the smallest sums. Some estates let by proposal; but the general mode is to ask a rent, and treat with tenants six or seven months before the existing leases expire.

3. *Buildings.*

Generally of stone and slate; cottages of one story, covered with thatch or tiles.

4. *Occupation.*

Largest farm about 1000 acres, greatest number from 150 to 50 acres. The larger farmers almost only those who have made improvements; among these, Messrs. Culley and Charge first led the way, and have been followed by Messrs. Collins, Mason, Taylor, Trotter, Nesham, Seymour, and many others, by whose exertions and judicious selection of stock this district will be lastingly benefited.

Greatest number of small labouring farmers greater slaves than their servants, being generally employed through the summer, in some kind of work or other, from four o'clock in the morning till eight at night; and in every other season of the year from twilight to twilight; and may truly be said "to rise early, take rest late, and eat the bread of carefulness."

Leases, three, five, and seven years, excepting church and corporation leases for 21 years, and lives. Those farms let for short terms remain stationary, as no prudent man will lay out his money in improvements, for which, when completed, he will be rewarded by an advance of rent, proportioned to the improvement he has made.

5. *Implements.*

Swing ploughs of the Rotherham kind; of late the Small's plough; various other good implements, and in many parts now (1830) the improved forms of Northumberland and Berwickshire.

6. *Enclosing.*

On dry soils hedges are frequently planted on a raised mound, forty inches broad, and the height twelve inches; a small ditch is cut on each side to make it, and the quicks are planted in the middle. In this mode the land may be ploughed nearly to the mound, and when the thorns are grown to a sufficient height, almost close to the hedge. When they are five or six years old, every other stem is cut clean off, within two or three inches of the surface, and the remaining ones stripped of their principal branches; then stakes of thirty inches high are driven in at proper distances, and the splashing stems, having a slight cut on one side to make them bend easier, are wound amongst the stakes at an angle of about twenty-five degrees, and a single edder is wound round the top to keep the stakes tight.

7. *Arable lands.*

Ploughing generally well executed, but in some places the subsoil prevents sufficient depth of furrow, *i. e.* six inches. The turnip culture, rotations, and general management of arable land, the same as in Northumberland; that is, of the most improved kind; seventeen tons of Rùta bàga are equal to thirty-one tons of white turnip in feeding cattle or sheep.

Mustard was formerly much grown in this county, and Durham mustard was proverbial for its excellence. At present a crop of mustard is rarely met with. It is generally sown upon pared and burned land in April, one pound per acre. The produce about twenty bushels per acre; and price from eight to sixteen shillings per bushel.

Potatoes in the village of Hamstely have been the principal article of trade, and the principal employment of several families for eighty years; they are very particular in having good sets, each with two eyes; use reddish or pink sorts, plant in March and April, and both horse and hand-hoe; no curl appears among them, but sometimes they "run wild," or tend to that state, producing more flowers than usual, and continuing flowering much later, sometimes till Michaelmas, and producing few tubers and slender stems. Whenever this is observed, the tubers of such potatoes are no longer used for propagation.

8. *Grass.*

Not much old surface, what there is chiefly upland.

9. *Woods and Plantations.*

Scampston elm, from a place of that name in Yorkshire, but supposed originally from America, will make shoots from grafts, in one year, of 5 or 6 feet; introduced in young plantations by Messrs. Falla, eminent nurserymen of Gateshead; vale of Derwent well wooded; Sir J. Eden a great planter.

10. *Embankments.*

Begun on the Tees in 1740, and about 1500 acres secured between that period and 1800.

11. *Live Stock.*

Short-horned cattle. The famous Durham ox bred by Charles Colling of Kellan, in 1796.

Sheep. Teeswater and Leicester breed; stock bred, reared, and fed in the most scientific manner, especially by the larger farmers mentioned above (4).

12. *Political Economy.*

Turnpike roads first made in 1742; materials, whinstone, limestone, river gravel, and freestone. Roads excellent where materials are broken sufficiently small: they are also in good repair. Milestones on some roads, hollow triangular prisms of cast-iron, with projecting letters and figures. They are two and a half feet high, and fixed on an oak post, four and a half feet long, sunk two and a half feet in the earth. Guide-posts much wanted. No iron railways, and no public roads or canals.

Manufactures. Wrought iron foundries, glass-houses, potteries, salt, copperas, sal ammoniac, coal tar, paper, woollen, cotton, and linen cloth. Several agricultural societies; the first established at Darlington in 1783.

7809. **NORTHUMBERLAND**, including those detached parts of the county of Durham, called Northamshire, Islandshire, and Beddingtonshire, comprehends a surface of 1,267,200 acres, chiefly mountainous or breeding districts, but including 450,000 acres proper for tillage. The celebrity of this county both for its tillage and breeding is well known. Here turnips were first extensively cultivated in the drill manner, and the best principles of breeding practised by Culley. To this gentleman and Bailey agriculture owes much: the latter was, perhaps, one of the most enlightened and accomplished of modern agriculturists. (*Bailey and Culley's General View*, 1805. *Marshal's Review*, 1808. *Smith's Geological Map*, 1824.)

1. *Geographical State and Circumstances.*

Climate subject to great variation of temperature; snow to a considerable depth on the mountains, when there is none in the lower districts; weather runs in extremes; very cold in spring, and seldom mild before June.

Soil and Surface. Strong fertile loam along the coast; sandy, gravelly, and dry loam on the Tyne, from Newborn to Haltwhistle, on the Coquet about Rothbury; on the Aln, from Alnwick to the sea; down Tweedside, but chiefly in the vales of Breamish Hill and Beaumont. The hills surrounding the Cheviot mountains are mostly a dry sharp gravelly loam. Moist loam occupies a large portion of the county, unsafe for sheep, and unfit for turnips, and peat earth prevails in the mountainous districts.

The aspect of the surface is marked with great variety; along the sea-coast it is nearly level; towards the middle more diversified, and thrown into large swelling ridges, formed by the principal rivers. These parts are well enclosed; in some places enriched with wood and recent plantations, but the general appearance is destitute of those ornaments. The western part (except a few intervening vales) is an extensive scene of open mountainous district, where the hand of cultivation is rarely to be traced. Of the mountainous districts, those around Cheviot are the most valuable, being in general fine green hills, thrown into numberless variety of forms, enclosing and sheltering many deep, narrow, and sequestered glens.

Minerals. Coal in abundance in the greatest part of the county: it is like that of Durham of the caking kind, and is found in the south-east quarter of the best quality; quantity exported, chiefly for the London market, 956,250 London chalders. Calculated that the whole coal of the counties of Newcastle and Durham will be exhausted in 550 years. Limestone, stone-marl, clay-marl, lead-ore, and ore of zinc in small quantities; freestone, whinstone, and iron are all worked.

Water. The Tyne and Tweed have been long celebrated for their salmon fisheries: in the latter a rent of 800*l.* a year is paid for a fishing of two hundred yards in length, near the mouth of the river; and the same rent is paid for each of two other fishings above the bridge, not more than two hundred and fifty yards in length each. The fish taken here are, the salmon, bull-trout, whiting, and large common trout, and nearly the whole of them sent to London; in the conveyance of which, a great improvement has taken place of late years, by packing them in pounded ice; by this means they are presented nearly as fresh at the London market, as when taken out of the river. For the purpose of carrying them, and keeping up a constant and regular supply, vessels called smacks sail three times a week, and being purposely constructed for swift sailing, frequently make their run in forty-eight hours. These vessels are from 70 to 120 tons burden; on an average twelve men are employed in each vessel, and make about fourteen voyages in a year; and not less than 75 boats and 300 fishermen are employed in taking the fish in the River Tweed.

2. *Property.*

One estate upwards of 40,000 acres, the rest vary from 10 to 20,000; small estates rare in the northern part of the county. Few counties in which estates have been so rapidly improved; several instances of the value trebled in forty years; principal cause letting large farms on twenty-one years' leases. Usual mode of letting farms is to fix a rent six or twelve months before the expiration of the lease; but upon one of the largest estates in the county (the Earl of Tankerville's), the tenants have an offer of their farms two years and a half or three years before the expiration of the lease, which is a mutual benefit to both landlord and tenant, and is attended with so many advantages, that it is in a fair way of being generally adopted.

3. *Buildings.*

Farmeries formerly very shabby and ill contrived, now totally different. The most approved form of distributing the various offices is, on the east, west, and north sides of a rectangular parallelogram (*fig.* 1011.) which is generally divided into two fold-yards for cattle of different ages, the south being left open to admit the sun; and for the same reason, and also for the sake of cleanliness and health, the farm-house (*a*) is removed in front thirty or forty yards; between which and the south wall of the fold is a small court for coals and young poultry; the barn (*b*) is 18 feet by 60, with threshing-machine driven by horses, water, wind, or steam; on each side are sheds (*c c*), over which are granaries; beyond these, as wings to the main square, are sheds (*d d*), upon which are built corn-stacks. One of these sheds is for wintering yearling calves, the other for holding implements of the larger kind. On the east of the main square is the stable (*e*), and in the west a house for cows and fatting oxen (*f*), each 16 feet by 48 feet. Over the pigsties (*g*) are poultry houses which open into the court-yard of the house, as the piggeries do into the fold-yards for wintering young cattle (*h h*).

Cottages of stone and lime and tiled; floor of lime and sand; the living room fifteen feet by sixteen, and the cow-house nine feet by sixteen.

4. *Occupation.*

Farms generally large in the north, some from 200*l.* to 400*l.* a year; in various parts farms from 50*l.* to 100*l.*, and from 100*l.* to 1000*l.* or 1500*l.* a year. The capital necessary for such farms entitles the farmers to a good education, and gives them a spirit of independence and enterprise, that is rarely found amongst the occupiers of small farms and short leases. Their minds being open to conviction, they are ready to try new experiments and adopt every beneficial improvement that can be learned in other districts; for this purpose, many of them have traversed the most distant parts of the kingdom to obtain agricultural knowledge, and have transplanted every practice they thought superior to those they were acquainted with, or that could be advantageously pursued in their own situation, and scarcely a year passes without some of them making extensive agricultural tours, for the sole purpose of examining the modes of culture, of purchasing or hiring the most improved breeds of stock, and seeing the operations of new invented and more useful implements.

5. *Implements.*

Of the most approved kind; and some of these, as the plough, drill, horse-hoe, &c. owe their chief merits to the improvements of Bailey. A pair of pruning shears recommended as preferable to those in common use for cutting hedges. They consist of a strong sharp knife, six inches long, moving betwixt two square-edged cheeks; the upper handle is two feet six inches long, and the other two feet three inches. (See *Encyclopædia of Gardening*, 2d ed. 1334. *fig.* 122.)

6. *Enclosures.*

Size of fields varies with the size of the farms; in some parts from two to six or eight acres; in the northern parts, where the farms are large, from 20 to 100 acres. The quicks should never be planted nearer each other than nine inches, and, upon good land, a foot. Quicks four or five years old, with strong clean stems, are always to be preferred to those that are younger and smaller. It is a custom in some parts to clip young quicks every year: this makes the fence look neat and snug; but it checks their growth, and keeps them always weak in the stem, and, when they grow old, open at bottom; while those that are left to nature get strong stems and side branches, which, by interweaving one with another, make a thick and impenetrable hedge, and if cut at proper intervals (of nine or ten years), will always maintain its superiority over those that have been clipped from their first planting. In point of profit, and of labour saved, there is no comparison; and for beauty, we prefer nature, and think a luxuriant hawthorn, in full bloom, or laden with its ripened fruit, is a more pleasing, enlivening, and gratifying object, than the stiff, formal sameness produced by the shears.

7. *Arable Land.*

Trench ploughing practised by a few in breaking up grass lands. About 1793, when horses were scarce and dear, a good many oxen were used for ploughing and carting about the farm; but after a few years' trial, they were given up: they were harnessed both with yokes and collars, and only ploughed half a day at a time.

Fallowing on all soils once in three or four years, was general through the county till the introduction of turnips. On soils improper for this root, the naked fallow still prevails; but the quantity of fallow probably on all soils will, after a long series of good culture, become less necessary, and may in many cases be finally dispensed with.

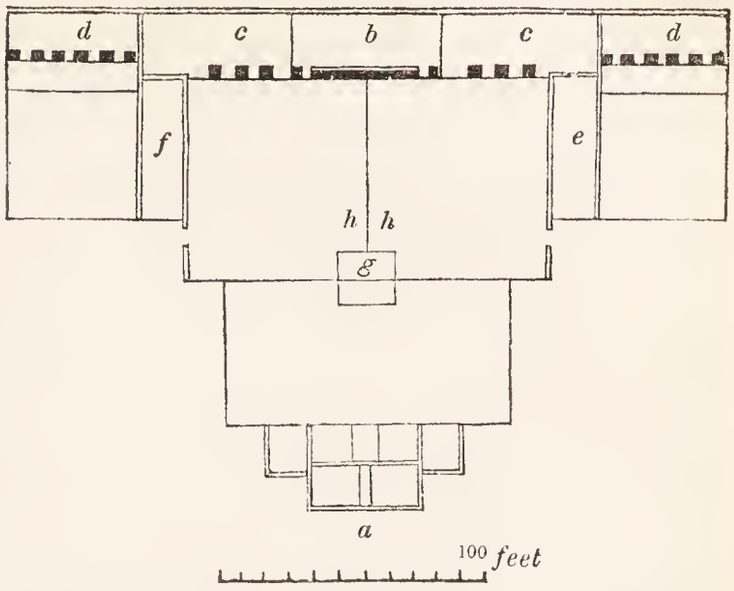
Turnips were first grown in the northern parts of the county about 1723. Proctor, the proprietor of Roch, brought Andrew Willey, a gardener, to cultivate turnips at Roch, for the purpose of feeding cattle; that Willey afterwards settled at Lesbury, as a gardener, and was employed for many years to sow turnips for all the neighbourhood; and his business this way was so great, he was obliged to ride and sow, that he might despatch the greater quantity.

Hoeing turnips was introduced at the same time, and at first practised by gardeners, and other men, at extravagant wages. Ildeston, about thirty years since, had the merit of first reducing the price of hoeing, by teaching boys, girls, and women to perform the work equally as well, if not better than men. The mode he took was simple and ingenious: by a light plough, without a mould-board, be divided the field into small squares of equal magnitude, and directed the boys and girls to leave a certain number of plants in each square. In a short time they became accurate, regular, and expert hoers; and, in a few years, all the turnips in the county were hoed by women and boys, at half the expense, and better than by men.

The broadcast culture of turnips, in the northern parts of the county, was not inferior to any we ever saw; and in respect to accurate, regular, clean hoeing, superior to what we ever observed in Norfolk, Suffolk, or other turnip districts which we have frequently examined. (*Bailey.*)

Drilling turnips was first introduced to the county about 1780. Drilling this, as well as other crops, evidently originated with Tull, whose first work, *Specimen of a Work on Horse-hoeing Husbandry*, appeared in 1731. It appears that Craig, of Arbigland, in Dumfriesshire, began to drill turnips about 1745; and next we find Philip Howard of Corby drilling in 1755; and Pringle drilling "from hints taken from Tull's book," in

1011



1756 or 1757. William Dawson, who was well acquainted with the turnip culture in England, having been purposely sent to reside in those districts for six or seven years, where the best cultivation was pursued, with an intention, not only of seeing but of making himself master of the manual operations, and of all the minutiæ in the practice, was convinced of the superiority of Pringle's mode over every other he had seen, either in Norfolk or elsewhere; and in 1762, when he entered to Frogden farm, near Kelso, in Roxburghshire, he immediately adopted the practice upon a large scale, to the amount of 100 acres yearly. Though none of Pringle's neighbours followed the example, yet, no sooner did Dawson, an actual or rent-paying farmer, adopt the same system, than it was immediately followed, not only by several farmers in his vicinity, but by those very farmers adjoining Pringle, whose crops they had seen, for ten or twelve years, so much superior to their own: the practice in a few years became general.

8. *Grass.*

Not much old grass in the county.

9. *Woods.*

Not very numerous, though a considerable demand for small wood by the proprietors of the collieries and lead mines. Artificial plantations rising in every part of the county.

10. *Improvements.*

Embanking and irrigation practised in a few places which require or admit of these operations.

11. *Live Stock.*

Cattle the short-horned, long-horned, Devonshire, and wild cattle.

Sheep, the Cheviot, heath, and long woolled. The modern maxims of breeding were introduced into the county by one of Bakewell's first disciples, Culley of South Durham, well known for his work on Live Stock, previous to which, "big bones" and "large size" were looked upon as the principal criterion of excellence, and a sacred adherence to the rule of never breeding within the canonical degree of relationship: but those prejudices are at this period in a great measure done away; and the principal farmers of this district may now be classed amongst the most scientific breeders in the kingdom, who have pursued it with an ardour and unremitting attention that have not failed of success.

Horses for draught brought from Clydesdale.

Goats are kept in small numbers on many parts of the Cheviot hills, not so much as an object of profit, but the shepherd asserts, that the sheep flocks are healthier where a few goats do pasture. This probably may be the case, as it is well known that goats eat some plants with impunity that are deadly poison to other kinds of domestic animals. The chief profit made of these goats is, from their milk being sold to invalids, who come to Wooler in the summer season.

12. *Political Economy.*

Roads of whin or limestone, and mostly good. Manufactures, gloves at Hexham, plait straw for cottagers' and labourers' hats, and also for those of the higher classes. Woollens in a few places; and a variety of works connected with the coal trade and mines at Newcastle. No agricultural societies, these Bailey holds in little estimation; but thinks if public farms were established in each county, and supported by a rate on the income of its proprietors, they would be the most effectual means of promoting agricultural improvement.

7810. CUMBERLAND. 970,240 acres of mountainous district, remarkable for its picturesque beauty, and also of late greatly improved in its agriculture. The exertions of the late Bishop of Llandaff in planting, and of J. C. Curwen, Esq. in field culture, have contributed much to the improvement of this county, which, as far as its soil and climate permit, may be considered as on a par with Northumberland. (*Pringle's General Review*, 1794. *General View, by J. Bailey and G. Culley*, 1804. *Marshal's Review*, 1808. *Smith's Geological Map*, 1824.)

1. *Introductory Observations.*

Pringle informs us that "trees and plants, being altogether passive, accommodate themselves very slowly to a change of climate: but the idea has been already thrown out, that even those of the torrid zone may be made to flourish in the northern regions; may be even gradually inured to the climate; that the climate itself may be changed for the better; and that some thousands of years hence, reposing under their own olive trees, future Britons may quaff their own wine, or sip their own tea, sweetened with the juice of their own sugar-cane."

Pringle "found it impossible" not to mention to the Board that he was remarkably well treated when he surveyed the county, which "filled him with peculiar feelings of pleasure and respect." Some of those feelings he voids on Sir John Sinclair, in the following terms:—"What gratitude is due to him (!) who first called the attention of the nation to its most important interests, and whose unremitted efforts are directed to promote the good of his country! How well does he deserve, and what a sure road has he chosen to, immortal fame that will survive the ravages of time, and smile at the fleeting celebrity

of martial achievements!" "This," Marshal observes, "most assuredly means, not *him*, but *me*.'

In some *preliminary observations* to this report by Watson, Bishop of Llandaff, are suggestions for settling poor people in cottages on the wastes, as has been done in Spain, and on the advantages which would result from planting them, especially with the larch and oak.

2. Geographical State and Circumstances.

Climate. Healthy, though subject to great and frequent falls of rain, especially in autumn, which renders harvest late and precarious: snow on the mountains for six or eight months. Average rain at Keswick seventy inches.

Soil. Clays and loams on the better parts of the valleys and hill sides, and peat earth on the mountainous districts.

Surface. Beautifully and greatly diversified, chiefly mountainous, and incapable of being improved by the plough; but part of the valley and plains are cultivatable soils.

Minerals. Chiefly coal, lime, and lead ore; there are also black lead, copper, gypsum, lapis calaminaris, and excellent slate and freestone.

Waters. Sixty-seven miles of sea-coast, several large and small rivers, and the lakes well known for their beauty, and the excellent char, trout, and other fish which some of them produce.

3. Property.

Few counties where land is in such small parcels, and these occupied by their owners. The annual value of these tenements vary from 5*l.* to 50*l.* a year; generally from 15*l.* to 30*l.*, some few 100*l.* Largest estate in the county 13,000*l.* a year. Tenure of by far the greater part of the county "customary tenure," a species of vassalage, by which the holder is subject to fines, heriots, and various services to the lords of manors. A good deal has been enfranchised. Copyhold and leasehold are rarely met with; what is not customary is freehold.

4. Buildings, Implements, Arable Land, &c.

Approaching to that of Northumberland. A great many young plantations rising on the sides of the mountains.

5. Live Stock.

Cattle of various kinds; breed of the county a small long-horned kind; but the most improved varieties are now introduced.

Sheep bred in the county the Herdwicks, a hardy mountain sheep. Some horses bred by the farmer, and bees very common. In every parish the taking of moles is let at a certain sum, and defrayed by a parochial rate per acre; a plan which will soon eradicate this animal from the county.

6. Improvements

Various kinds, as draining, watering, planting, &c. made by Watson, Bishop of Llandaff, at Colgarth Park. Those of J. C. Curwen, Esq., of Workington, especially in feeding and fatting stock, have made a distinguished figure in agricultural writings; but their practical merits have been questioned. We paid a high compliment to Curwen in the first edition of this Encyclopædia, on which a scientific and practical man, who was personally acquainted with him, made the following note: — "I doubt if Curwen has any right to the compliments here paid him. If I may judge, both from his writings and conversation, he is certainly not a first-rate farmer, and, what in his situation is worse, not very much the friend of farmers. He admitted to me, indeed, that his management was not profitable, which is saying all in one word."

7811. WESTMORELAND. 540,160 acres, chiefly of mountain and moor, but with some few tracts of vale lands, cultivated or capable of cultivation. On the whole it is naturally the most unfavourable county to agriculture or comfortable living in England, owing to its wet and cold climate, ungrateful soil, and rugged surface. (*Pringle's General View*, 1794. *Marshal's Review*, 1808. *Smith's Geological Map*, 1824. *Edin. Gaz.* 1827.)

1. Geographical State and Circumstances.

Climate. S. W. winds and rains prevail for eight months in the year: in 1792 eighty-three inches, medium forty-five or fifty inches, which is twenty inches above the medium quantity that falls in Europe. Air pure and healthy; winters long and severe. In 1791-2 thirty-six pounds were paid for cutting in the snow ten miles of horse tract between Shap and Kendal.

The *soil* most prevalent on the low lands is a dry gravelly mould, and peat on the mountains.

Surface. Mountainous and hilly, and in most places incapable of cultivation by the plough. Large tracts of black barren moors, called the Fells.

Minerals. Some trifling veins of lead; limestone in abundance in most parts of the county; excellent blue slates; gypsum used for laying floors; freestone, and marble near Kendal.

Water. Several rivers and some lakes, corresponding in beauty and products with those of Cumberland.

2. Property.

As in Cumberland; land-owners called statesmen (for estatesmen), as in Ireland.

3. Buildings.

Very indifferent; few mere cottages; the labourer and mechanic generally reside in a small farm-house, and occupy more or less land.

4. Occupation.

Farms small; and farmers, who are generally proprietors, "live poorly and labour hard," in the fields in summer, and weaving in winter; wear clogs, the upper part of leather, and the soles of birch, alder, or sycamore. The culture of arable land is very limited, and, like that of grass land, was in a very backward state at the time the reporter wrote, but gradually improving. Dairying in a small way is generally practised, but little attention to the sort of cow or breeding. The Earl of Lonsdale, and Watson, Bishop of Llandaff, were among the first to set the example as to planting.

5. Manufactures.

Woollen cloth, or Kendal coatings, stockings, silk, gunpowder, &c. A private carpet manufactory at Lowther, by the Earl of Lonsdale.

7812. LANCASHIRE. 1,150,000 acres; (1,155,840, *Brook's Gaz.* 1809, 12,000,000! *Edin. Gaz.* 1827), included in a very irregular outline, extending above a degree, or about seventy-four miles from north to south, containing mountainous and moory surface, and a large portion of low, flat, or moderately varied lands, of good quality. The soil in great part sandy, and chiefly in pasture. The early introduction and successful culture of the potato distinguishes this county, and also the immense extent of its cotton manufactures, and very considerable foreign commerce from Liverpool. It is also the country of Brindley, the engineer. (*Holt's General View*, 1795. *Dickson's General View, prepared by Stevenson*, 1815. *Marshal's Review*, 1808.)

1. Geographical State and Circumstances.

Climate. Air every where pure and salubrious, but on the elevated parts cold and sharp; protected, however, by the northern and eastern ranges of mountains form the N. and E. winds; not much snow or long continued severe frosts. In 1819-20, when the thermometer in gardens near London had fallen ten degrees below zero, that in the botanic garden at Liverpool never fell to zero. Average of rain in the county probably about forty-two inches: in 1792, sixty-five; and in some years fifty. From a register of the times during a series of years, at which potatoes, asparagus, and gooseberries were first brought to the Liverpool market, it appears that the difference between an early and late spring is not less than six weeks.

Soil. On the mountains and moors rocky and peaty; on the northern part of the lowlands moist, cold, and rushy silt; on the rest chiefly sandy loam.

Minerals. Principally coal, copper, lead, and iron; the first and last very abundant; there is also slate, grey-slate, and flagstones, freestone, and limestone.

Waters. Seventy-five miles and upwards of sea-coast, and several rivers and meres.

2. Property.

Very variously divided; a considerable number of yeomanry from 10*l.* to 700*l.* per annum: a general spirit for possessing land and agricultural improvement; tenures, as usual, chiefly freehold.

3. Buildings.

Old farmeries the work of chance and random; houses often there formerly occupied by proprietors, and offices without order or design, but various new erections on the most approved plans; cottages in many places comfortable, with good gardens, especially those occupied by operative manufacturers and mechanics. Those in the less improved parts of wattled studd work, plastered or wrought in with tempered clay and straw; provincially "cat and clay."

4. Occupation.

Farms in general small; education and knowledge of most of the small occupiers very circumscribed; larger farmers more enlightened, and having more command of capital, are improving the culture of their farms.

5. Implements.

Little improvement, but the Northumberland plough and Meikle's threshing-machine introduced; horse pattens are almost peculiar to this county, and are used in cultivating light peaty soils.

6. Arable Land.

Less prevalent than grass; but great attention paid to the culture of potatoes, both by farmers and cottagers; the former generally cultivated in drills, and horse-hoed; the latter in beds or dibbled in rows, and hand-hoed. The method of growing early potatoes, and several crops on the same soil in one season, has already been given. (5321.) Onions are cultivated extensively near Warrington, and rhubarb and madder have been tried, and grown to very great perfection, but not so easily dried and prepared for sale as to induce a continuance of the practice.

7. Grass Lands.

Extensive, but chiefly coarse upland pastures; some good meadows and productive marsh lands. Application chiefly for the dairy for home consumption of milk and butter; not much cheese made, excepting on the Cheshire side of the county.

8. Gardens and Orchards.

Excellent market gardens near most of the large towns. Liverpool remarkably well supplied: great quantities of cabbages and onions used by the shipping, and of dried herbs and onions exported; the dried herbs sent to Africa. "There is a certain farm in Kirkby, about eight miles north-east from Liverpool, the soil of a small part of which is a black loamy sand, and which produces great quantities of early and strong asparagus, and another farm, a part of which is of the same nature at a place called Orrel, about four miles north-west of Liverpool: both which produce this plant with less attention and less dung than requisite in the rich vale of Kirkdale, about two miles from Liverpool, where the greatest quantity of land in any place of this neighbourhood is appropriated solely to horticulture."

Gardens of Mechanics. "A small patch of ground appended to his cottage furnishes the weaver, smith, or carpenter with health and pleasure, and contributes to his sobriety; intemperance not unfrequently proceeding from want of recreation to fill up a vacant hour. This small space is devoted to nurturing his young seedlings, trimming his more matured plants, contemplating new varieties, in expectation of honours through the medium of promised premiums. Thus, starting at intervals from his more toilsome labours, the mechanic finds his stagnating fluids put in motion, and his lungs refreshed with the fragrant breeze, whilst he has been raising new flowers

of the auricula, carnation, polyanthus, or pink, of the most approved qualities in their several kinds; and which, after being raised here, have been dispersed over the whole kingdom. But not only flowers, but fruit, have been objects of their attention. The best gooseberries now under cultivation had their origin in the county of Lancaster; and, to promote this spirit, meetings are annually appointed at different places, at which are public exhibitions of different kinds of flowers and fruits, and premiums adjudged. These meetings are encouraged by master tradesmen and gentlemen of the county, as tending to promote a spirit which may occasionally be diverted into a more important channel. Those little societies for promoting the improved culture of the gooseberry prevail most in the southern parts of the county. They have unquestionably had much influence in bringing the different sorts of this fruit, and the currant, as well as some others, to their present state of improvement. The gooseberry, both of the red and white kind, is now in most places grown to a very considerable size, in some situations as large as a pigeon's egg. This is chiefly effected by keeping the plants much cut in their branches, and having well rotted rich manure applied frequently about their roots, the land being kept perfectly clear about them. The annual publications, called *The Manchester Gooseberry-book*, and *The Manchester Flower-book*, contain the names of the principal societies, and of the prizes awarded each year, and a variety of other information." (*Dickson*, p. 428.)

An *orchard* of sixty-four acres on the banks of the Irwell, near Manchester, and some others in sheltered places near the principal towns; but the prevailing west winds is much against their increase.

9. *Woods and Plantations.*

A good deal of planting going forward in most parts of the county, but not much old timber or copse.

10. *Improvements.*

Of moss bogs and marshes there is great extent, and we have already noticed the principal modes of improving them. (4555.)

A good deal of draining, paring, and burning, and liming has been done, and also irrigation in several places. A good deal of low sod embankment along the northern part of the coast, especially at Rosshall, by Hesketh. It was proposed some years ago to embank Lancaster and Ulverstone sands, by which nearly 40,000 acres of sandy soil would have been gained at an expense of 150,000*l.*, or according to some much less: but owing to the difficulty of getting the small proprietors of fisheries and other trifling interests to agree, the idea was dropped at the time and not resumed. The proposed modes of procedure for this, and other intended embankments, are given in the report. Bog lands have been extensively cultivated by the celebrated Roscoe, of which some account has been already given. (4549.)

11. *Live Stock.*

Cattle, the Lancashire, or long-horned, made the basis of Bakewell's improvements; a good many short-horned also bred, when the dairy is the object. Larger grass farms near the populous towns furnish milk, the smaller ones butter, and the remote farms cheese. 100 cows kept in Wakefield's dairy near Liverpool. Cheese made resembles that of Cheshire, and chiefly from the long-horned, or native breed.

Sheep not very common in this district.

Horses very generally bred of the strong team kind, stout compact saddle horses, and middling size and bone for the stage and mail coaches.

12. *Political Economy.*

Roads bad in most places, owing to the want of good materials, and the moist climate. In the coal tracts about Manchester, Bolton, and Wigan, the roads are all paved, as it was thought no other would stand the heavy traffic on them. These paved roads are said to be the most expensive, and most disagreeable of any; but they have here no other kind of material that will stand heavy cartage.

An ingenious road-maker in the neighbourhood of Warrington has of late exploded the common convex form, and adopted that of one inclined plane; the inclination just sufficient to throw off occasional water. The road between Worsley and Chowbeat was made in this form, but it was found not to answer, as, though it threw off the water, high and heavy laden waggons were exposed to much danger of being overturned.

Various canals and iron railways; those of the Earl of Bridgwater the most celebrated, but others of recent date more extensive. Many different manufactures; cotton in its different branches the most important; also, woollen, flax, iron, and, in short, almost as great a variety as in Derbyshire. Several agricultural societies; that of Manchester established in 1767.

7813. The ISLE OF MAN contains about 220 square miles. (*Edin. Gaz.* 1827.)

General View. The interior is mountainous, ridges of hills being separated by high table lands; the climate is moist, with frequent fogs; and the soil is chiefly loam, on a bottom of stiff clay. No minerals of any consequence are found on the island, except lead, and some copper, and iron. Limestone, thin blue slate, greywacke, and granite are found in several places; an immense tract called the Curragh, which was formerly a bog, extends nearly across the island. It now produces excellent crops; but an extensive stratum of peat is still found under the gravel and clay, containing trunks of very large oaks and pines, which all lie in one direction, as if overturned or deposited by a common impulse.

The Duke of Athol was formerly lord proprietor of the whole island, but the sovereignty was purchased from him by the English government, 1765.

Agriculture has of late years made some progress, though nearly two thirds of the island still remain in a state of nature, and are only used for grazing; there is a good deal of wood in the north part of the island; wheat was formerly not cultivated on account of a prejudice which prevailed respecting its liability to be infected with the smut; large crops are, however, now raised, of the cleanest and best quality. Barley and oats are raised in great quantities, as are also turnips and potatoes. Flax and hemp are grown in rich enclosures. Many of the finer sorts of fruit, however, cannot be reared. The sheep are small and hardy, and their flesh is excellent; the wool of a particular breed, called the Loughton, is thought of a very superior quality. Great numbers of cattle are fattened here for exportation; and 30,000 hogsheads of butter are sent to England annually. Poultry, eggs, and fish, are abundant and cheap. Thin oatcakes are the usual bread of the inhabitants.

Political Economy. The roads to the principal towns are tolerably good, but the by-ways are almost impassable. The island is considered healthy, and the inhabitants generally attain a great age.

7814. CHESHIRE. 665,600 acres of verdant surface, exclusive of upwards of 10,000 acres of naked sands in the estuary of the river Dee. It is one of the most productive grass-land districts in the kingdom, the grass retaining its growth and verdure, in a great degree, during the whole year, owing to the moisture and mildness of the climate. The department of husbandry in which it excels is cheese-making; and it is also noted for its salt-works from brine springs and rock. (*Medges' General View*, 1794. *Holland's General View*, 1806. *Marshal's Review*, 1809.)

1. *Geographical State and Circumstances.*

Climate, supposed the most rainy in the kingdom.

General surface an extended plane, apparently thickly covered with wood. Barren hills on the eastern margin of the county.

Soils chiefly clayey or sandy; clay prevails, but very generally the two earths blended together, producing clayey loam and sandy loam.

Subsoil chiefly clay, or marl; but also rammel, foxbench, gravel, or red rock. Rammel is a composition of clay, sand, gravel, and oxide of iron; it is in strata of from eighteen to thirty inches, on white-coloured sand, or clay marl. Foxbench is iron ore or oxide, which crumbles to pieces when exposed to the air; but is hard and rocky when under the soil, and is more injurious to trees than rammel, as it cannot be penetrated by their roots.

Minerals. Fossil salt and coal both extensively worked. There is also copper, lead, and freestone, but very little limestone. Salt is made from brine springs, as at Droitwich (7792.), and from beds of fossil salt. The former have been worked from time immemorial, and the latter from about 1670. By the operation of blasting, and the mechanical instruments usually employed in mining, the rock is obtained in masses of considerable size, differing in form and purity. The purer rock is pounded and used without other preparation; but the less pure is dissolved and refined in the same manner as brine.

Water. Several rivers and meres; the former are very muddy after rains, and not remarkable for their fish; but the latter abound in pike, bream, perch, dace, and eels.

2. *Property.*

Few counties of equal extent with so many wealthy landowners. Fifty proprietors resident in the county, with estates of from three to 10,000*l.* a year, and as many from one to 3000*l.* "From the advantages which have been derived from trade, and from the effects of the increase of taxes, which have prevented a man living with the same degree of comfort on the same portion of land he could formerly, many of the old owners have been induced to sell their estates, and new proprietors have spread themselves over the country, very different in their habits and prejudices. It may be doubtful whether the change on the whole has been disadvantageous. Land, when transferred, is generally improved by its new possessor. With a view, and often a more enlightened view, of its advantages and resources, he brings with him the means and the disposition to try experiments, and to give to his new acquisition its greatest value. He feels the want of comforts and conveniences, which custom had rendered familiar to a former occupier; he builds, drains, and plants; and, by his spirit and example, stimulates all around him to increased exertions.

3. *Buildings.*

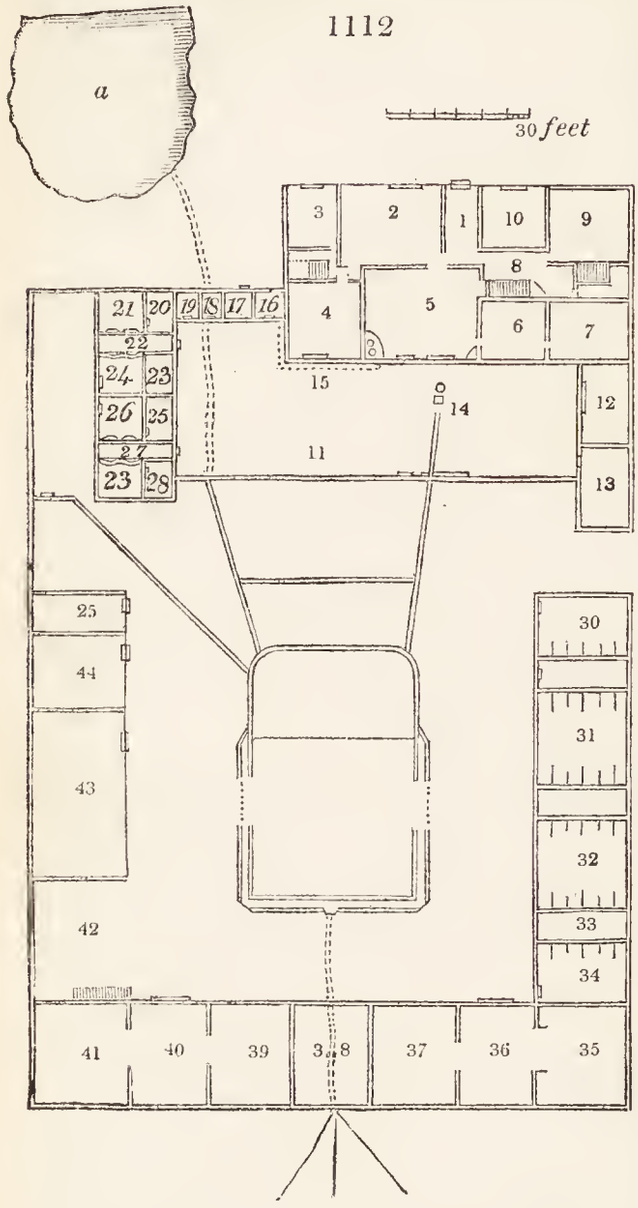
Many noble mansions, especially that of the Earl Grosvenor, at Eaton.

Farm buildings, on the large dairy farms, in the middle of the county, extensive and convenient; in other places the reverse, and crowded in villages; old buildings of shed-work, wattled work, and clay, and covered with thatch; new of brick and slate. An excellent set of buildings (*fig.* 1112.) has been erected at Bromfield, near Warrington, on the estate of Sir P. Warburton. "A gentle descent from the ground at the front of the house has afforded Beckett, the occupier of this farm, the opportunity of conveying from a pond (*a*) a small stream through the farm-yard, with which he irrigates the meadows below the buildings. The superior richness of vegetation in these meadows furnishes abundant proof of the advantage which Beckett derives from availing himself of this assistance."

Beginning with the *dwelling-house* of this farmery, it contains an entrance and passage (1), house-place (2), servants, dining-room (3), back parlour (4), dairy, with whey pans and sink-stone (5), room for the cheese after it is taken out of the salt (6), milking-house and salting-room (7), stairs to cheese-room (8), parlour with a cellar under (9), pantry (10). The immediate appendages of the house chiefly connected with the dairy are ranged on three sides of the inner yard (11), and consist of a coal-house (12), wash-house, with pigeon-house over it (13), pump (14), pipe to boiling-pans (15), boiler for pig meat (16), privy (17), place for ashes (18), privy (19), inner pig-cot (20), outer pig-cot (21), passage (22), inner pig-cot (23), outer pig-cot (24), inner pig-cot (25), outer pig-cot (26), passage (27), inner pig-cot (28), outer pig-cot (29).

The farmyard consists of a court, containing a large duck-pond and dunghill, surrounded by a broad passage, and enclosed on the west, east, and south sides by buildings, the north side being the wall of the inner yard. These buildings

consist of a cow-house (30), double cow-house (31), double cow-house (32), fodder-bin (33), cow-house (34), corn-bag (35), threshing-floor (36), corn-bag (37), corn-bag (38), corn-bag (39), threshing-floor (40), corn-bag (41), cart-hovel, with granary above it (42), stable (43), stable or calf-cot (44), calf-cot (45).



Cottages much the same as in other counties; improving with the age. All the intelligent persons whom Dr. Holland conversed with have invariably found, that the attachment of a small portion of land to the cottage of the labourer has been the direct means of rendering his situation in life more comfortable and easy, and of inducing those habits of honest independence, of temperance, and of industry, which are most efficacious in promoting the happiness of individuals, and, consequently, the general interests of society.

Lord Penrhyn's poultry-houses, at Winnington, are supposed the most magnificent that have ever been built. They are united in a building, which consists of a handsome regular front, extending about 140 feet: at each extremity is a neat pavilion, with a large arched window. These pavilions are united to the centre of the design by a colonnade of small cast-iron pillars, painted white, which support a cornice and a slate roof, covering a paved walk and a variety of different conveniences for the poultry, for keeping eggs, corn, &c. The doors into these are all of lattice-work, also painted white, and the framing green. In the middle of the front are four handsome stone columns, and four pilasters, supporting likewise a cornice and a slate roof, under which and between the columns is a beautiful mosaic iron gate; on one side of this gate is an elegant little parlour, beautifully papered and furnished; and at the other end of the colonnade a very neat kitchen, so excessively clean, and in such high order, that it is delightful to view it. This front is the diameter or chord of a large semi-circular court behind, round which there is also a colonnade, and a great variety of conveniences for the poultry: this court is neatly paved, and has a circular pond and pump in the middle of it. The whole fronts towards a rich little field or paddock, called the poultry paddock, in which the poultry have liberty to walk about between meals. It happened while the reporter was there to be their dinner-time, at one o'clock. At this hour a bell rings, and the beautiful gate in the centre is opened. The poultry being then mostly walking in the paddock, and knowing by the sound of the bell that their repast is ready for them, fly and run from all corners, and rush in at the gate, every one striving who can get the first share in the scramble. At that time there were about 600 poultry of different kinds in the place, and although so large a number, the semicircular court is kept so very neat and clean, that not a speck of dung is to be seen. This poultry place is built of brick, excepting the pillars and cornices, and the lintels and jambs of the doors and windows, but the bricks are not seen, being all covered with a remarkably fine kind of slate from his lordship's estate in Wales. These slates are closely jointed and fastened with screw nails, on small spars fixed to the brick; they are afterwards painted, and fine white sand thrown on while the paint is wet, which gives the whole an appearance of the most beautiful freestone.

4. *Occupation.*

Farms very small; a great many under ten acres; only one or two at 350 or 400 acres; excluding all those under ten acres, the average of the county may be seventy acres. Large and small farmers completely different characters;—different in their habits, and, by consequence, in their ideas. Industry and excellent management of the dairy-women of this county much to be commended; leases generally for seven years.

5. *Implements.*

Rotherham plough and other good implements. A short strong scythe, with a blade twenty inches in length, and concave in the middle, is used for scooping out the crowns of rush stools.

6. *Arable Lands.*

In small proportion to the pastures. Cabbages a good deal cultivated for cattle. Carrots near Altringham for the Manchester market, and also seed for the London seedsmen. Onions also for the Lancashire markets. The soil about Altringham dry and loamy; the carrots large, coarse, and fit only for horses and cattle.

7. *Grass.*

Natural meadows numerous, rich, and fertile. They are situated on rivers, which, from the frequency of heavy rains, overflow and enrich them. Extent of upland pasture very considerable; that on a tolerably stiff clay soil, especially with a substratum of marl, is reckoned the best for the dairy; more milk may be had from cows pastured on a rich loamy soil, but it is esteemed inferior in point of quality. Many farmers complain that their land is too rich for the dairy, by which the adhesive properties of the cheese is diminished: feeding of cattle little practised.

8. *Gardens and Orchards.*

Good gardens to most of the farm-houses. "All the varieties of raspberries, currants, strawberries, and gooseberries are to be met with in the farm and cottage gardens in Cheshire. The culture of the latter fruit has been particularly attended to of late years; and there are several meetings in different parts of the county, where small premiums are adjudged to those who produce, out of their own gardens, gooseberries of the greatest weight. The common fruit trees, such as the apple, pear, cherry, and plum, are likewise grown in almost every garden. Of the latter kind, the damascene plum is by much the most common; and is an article of considerable profit to the cottager.

Orchards not numerous, and rather on the decline.

9. *Woods and Plantations.*

Few of large extent, yet the quantity of timber very greatly exceeds what would be a fair average for the kingdom at large. In the northern and middle parts the number of trees in the hedge-rows and coppices is so considerable, that, from some points of view, the whole county has the appearance of an extensive forest. The most considerable ancient woods in the Earl of Stamford's park at Durham Massey. Few spots can boast such an assemblage of stately oaks, elms, and beeches. During a storm of wind, on the 21st of January, 1802, several hundred trees were torn up by the roots. One of these, when barked, contained 403 feet of timber, and was sold at six shillings and sixpence per foot, to the extent of 373½ feet. An elm blown down at the same time measured 146 feet. A colony of herons had for ages fixed their residence on the summits of these trees; but on one of them being torn up, they retreated to a neighbouring grove of beeches, where they have ever since enjoyed a secure abode.

A *plantation* of 1000 acres at Taxall, F. Jodrell, Esq.; it was planted by White, the landscape gardener of Woodlands, Durham, at five pounds per acre, half the trees to be firs. Extensive plantations by Ashton, on Delamore forest.

Whitely, an ingenious tanner, at Ashley, near Knutsford, made some experiments a few years ago with the twigs and ends of the boughs of oak, as a substitute for the bark. These ground down, and used in the same way as the bark, manifested strongly astringent properties: but the necessity there was found to be for their immediate application took away very greatly from their value; and their use is now almost entirely discontinued, though the plan at that time was adopted by several other tanners.

10. *Improvements.*

Draining a good deal practised, especially with bricks and stones. Paring and burning, marling, sanding, claying, and liming, also practised to different degrees of extent. Sand of advantage, chiefly by altering the texture of the soil, as that used contains no calcareous matter.

11. *Live Stock.*

Present stock of dairy cows a mixture of the long and short horned, the Derbyshire, Shropshire, Staffordshire, Welsh, Irish, Scotch, and New Leicestershire cattle. Those cows reckoned best which are bred on the farm. Calves reared from the best milkers, and at two years old put to the bull. Cows housed about the middle of November; permitted to go dry ten weeks before their time of calving: usual dry foods, wheat, barley, and oat straw, hay, and crushed oats. The two former kinds of straw are found to make cows go dry much sooner than the latter; and another generally allowed effect attributed to such straw is, that more than the usual time will be required to churn the cream of cows when so fed; but wheat straw is esteemed much more wholesome than barley straw, as having less of those effects attending it. Three or four weeks before calving, hay given; and from calving to turning to grass, some ground or crushed oats twice a day. The cows are turned into an outlet (a bare pasture field near the buildings), about ten o'clock in the morning, and housed again about four in the afternoon the winter through, or earlier if they showed an inclination to return; but have no fodder in the outlet. Turning the cows out to grass in good condition is a matter much attended to, in order that they may, as the term is, "start well;" for if a cow is not in good condition when turned out to grass, or has been too much dried with barley straw, it is a long time before she gets into full milk.

The ox-cabbage and Swedish turnip are the kinds of green food most esteemed and cultivated in Cheshire. The former is

usually given to the cows when the after-grass is consumed; it is sometimes given in the spring to cows that have newly calved. The large sugar-loaf cabbage has been occasionally used, when the pastures begin to fail and the after-grass is not ready; a circumstance which frequently happens, especially in dry weather. Turnips are given to the cattle in the winter, while they are feeding on straw; and as, at this time, no cheese is made, any objection to their use, from the flavour they give to the milk, is of little consequence. The reporter made enquiries from several farmers, with a view of ascertaining whether the stall-feeding of their milch cows might not be continued during the whole year, but he found the general opinion to be against this practice; though it did not appear that any experiments, sufficient for the decision of the point, had hitherto been made. It was suggested to him, however, that it would be an improvement upon the present management, to let the cows stand in their houses during the heat of the day in summer, where, by giving them a few cabbages or tares, the milk would continue forming, and the cattle be defended from the gad-fly, which, by tormenting them in the fields, frequently injures both the quantity and quality of the milk.

Time of calving March and April. At calving-time the cowman, or the master, are frequently up two or three times in the course of a night, to see whether any thing is amiss. The racks and mangers are every day well cleaned out, while due attention is paid to the appetites of the different beasts, and the quantity of food is governed accordingly. After this is done, the master himself generally goes round from stall to stall just before bed-time, and adds to or diminishes the quantity of fodder as occasion may require.

In making butter the whole of the milk and cream is churned together. Cheese made from the whey pressed from the curd used in making cheese.

Cheese-making has remained stationary in Cheshire for many years; best size of cheeses sixty pounds. Cows milked during summer at six o'clock, morning and evening. "The evening's milk (of suppose twenty cows) having stood all the night in the coolers and brass pans, the cheese-maker, in summer about six o'clock in the morning, carefully skims off the cream from the whole of it, observing first to take off all the froth and bubbles, which may amount to about a pint: this not being thought proper to be put into the cheese, goes to the cream mug to be churned for butter, and the rest of the cream is put into a brass pan. While the dairy-woman is thus employed, the servants are milking the cows, having previously lighted a fire under the furnace, which is half full of water. As soon as the night's milk is skimmed, it is all carried into the cheese tub, except about three fourths of a brass pan full (three or four gallons), which is immediately placed in the furnace of hot water in the pan, and is made scalding hot; the half of the milk thus heated in the pan is poured also into the cheese-tub, and the other half is added to the cream, which, as before observed, was skimmed into another brass pan. By this means all the cream is liquified and dissolved, so as apparently to form one homogeneous or uniform fluid, and in that state it is poured into the cheese-tub. But before this is done, several bowls or vessels full of new milk will generally have been poured into the cheese-tub, or perhaps the whole morning's milk. Care is taken to skim off all the air bubbles which may have formed, in pouring the new milk into the cheese-tub. The night and morning's milk, and melted cream, being thus all put into the cheese-tub, it is then ready to receive the rennet and colouring, or, in the terms of the art, to be set together. The rennet and colouring being put into the tub, the whole is well stirred together, a wooden cover is put over the tub, and over that is thrown a linen cloth. The usual time of coming is one hour and a half, during which time it is frequently to be examined: if the cream rises to the surface before the coming takes place, as it often does, the whole must be stirred together so as to mix again the milk and cream, and this as often as it rises, until the coagulation commences. A few smart strokes on different sides of the tub, with the cheese ladder, &c. will forward the coagulation, if it is found to be too long in forming.

The curd is in the next place broke by the knife and hands, and then left half an hour to subside; then it is gently pressed, the curd broken by the hand, and the whey ladled out of the tub as it drains from the curd. Afterwards, the curd is broken in a brass pan and salted, and next put into the cheese-vat, and pressed with a sixty pound weight, till all the whey is removed. It is then again broke, washed with warm whey, and finally put in the press under a weight or power of about 14 cwt. After being forty-eight hours in the press, it is put in the salting tub, where it remains three days covered with salt; it is then taken out and placed on the salting benches, where it is turned once a day; it is then washed in warm water with a brush, and wiped dry with a cloth; in two hours it is smeared over with whey butter, and then put in the warmest part of the cheese-room. In the cheese-room it is well rubbed, to take off the sweat or fermentation which takes place in cheese for a certain time after it is made, and turned daily for seven days, and smeared with whey butter; afterwards it is turned daily, and rubbed three times a week in summer, and twice in winter.

The cheese-rooms are commonly placed over the cow-houses; and this is done with a view to obtain that moderate and necessary degree of temperature so essential to the ripening of cheese, to which the heat arising from the cattle underneath is supposed very much to contribute. On dairy farms, one woman servant is kept to every ten cows; these women are employed in winter in carding, spinning, and other housewifery business; but in milking, the women, both night and morning, during summer, where large dairies are kept, are assisted by all the other servants, men and boys, except the man who drives the team.

Sheep little attended to in Cheshire.

Horses brought from Derbyshire and Leicestershire.

Hogs, a mixture of long and short eared breeds.

Poultry of the common kind abundant in most farms for their eggs. Geese kept by the cottagers till midsummer or later, and then sold to the farmers, who fatten them on their stubbles.

Bees to be found at many of the farm-houses, and at some of the cottages.

12. *Political Economy.*

Roads bad; various canals; an extensive commerce of coal and salt, and manufactures of silk, woollen, linen, and cotton. An experimental farm established at Waverham, near Northwich, by some gentlemen and farmers of the neighbourhood, but it was soon found so expensive and losing a concern as to be abandoned. Those on the plan suggested by Bailey (7809.) seem the most likely to be effective and permanent.

7815. HAMPSHIRE.

A maritime county, which includes also the Isle of Wight: the latter contains 94,000 acres, and the continental part of the county 968,150 acres. The climate of this county being remarkably mild, and the soil in many places being calcareous, and consequently warm, very early arable crops are produced in some places, and peas grown better than in many districts. The culture of the county, however, has little to recommend it, either in its tillage or pasturage. Its woods are extensive. (*A. and W. Driver's General View*, 1794. *Vancouver's General View*, 1808. *Warner's Isle of Wight*, 1794. *Marshal's Review*, 1817.)

1. *Geographical State and Circumstances.*

Climate geuerally mild.

Soil in the central parts a strong flinty calcareous loam: in other parts generally gravelly, or sandy and calcareous. The soil of the Isle of Wight is partly a clayey and calcareous loam, and in part lighter.

Minerals: none of any consequence; potter's clay, sand, and building-stone in different places.

Water scarce in dry seasons in the chalk districts, where it is preserved in tanks, and drawn up from wells 300 or 400 feet deep. In some parishes, after a long dry autumn, there has been more strong beer than water. A good deal of fishing on the coast; of eels after floods in the smaller streams; and some fish ponds on Bagshot Heath.

2. *Property.*

Largest estates on the chalky districts; largest 8000*l.* per annum. Great bulk of the lands held and cultivated by yeomanry; tenures, copyhold and leasehold, from the superior lords or freeholders.

3. *Buildings.*

Houses of proprietors numerous: farm-houses mostly of great antiquity; those of the larger kind were formerly grange or manor-houses; out-buildings numerous, and generally ruinous; cottages often of mud (*provin. cot*) walls, but better on the whole than in some other counties. Some fanciful rustic structures as shelters or temporary lodges for cattle, in the forest district. (*fig.* 1113.)

4. *Occupation.*

Farms various, rather small.

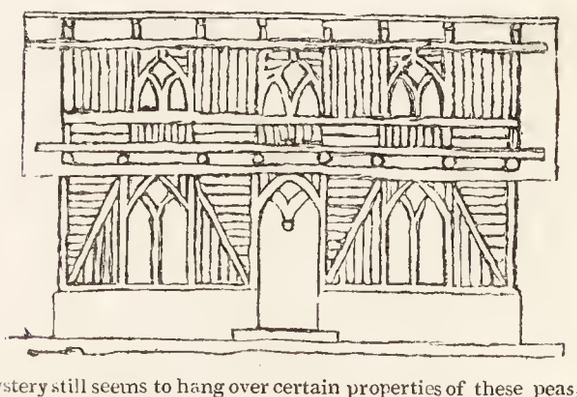
5. *Implements.*

Hampshire plough, an extraordinary bulky clumsy structure; the Suffolk plough is used in the southern parts of the county, and in the Isle of Wight. The patent Hampshire waggon is formed by uniting two carts, corresponding with the fore and hind parts of a waggon, by bolting them together. The thrill of the hind part passes under the bed, and rests on the pillow of the fore-cart. The union is simple, yet so complete as to render this waggon as strong as the common kind, if not stronger.

6. *Arable Land.*

Tillage difficult and expensive in the chalk district, light and easy in the vale of Avon. Peas a good deal cultivated on the chalks, especially the Marlborough grey or partridge, the charlton and pearl; in warm situations they are drilled and often sown before Christmas, or in January. "A considerable

1113



mystery still seems to hang over certain properties of these peas, with regard to their boiling well for soup or porridge; good boilers *being* sometimes sown upon fields which have never been known to refuse yielding a produce possessing a similar quality, but that effect afterwards ceasing, and a hard indissoluble pea has been produced that continued for several successive periods; whilst, on the other hand, land that had never been known or even suspected of being able to communicate a boiling quality to its peas, would unexpectedly give to the produce of a hard and almost impenetrable pea all the properties of being excellent boilers. Through all the cedar-coloured sand and gravelly loams in Devonshire, good boilers are stated to be uniformly produced, and in continued succession. The same kind of soil, and in every respect under similar circumstances, in the Isle of Wight will only occasionally, and by accident as it were, produce good boiling peas. Some opinions seem to refer this effect to a peculiarity in the seasons; but this cannot stand against a well known truth, that good boilers are produced every season."

Saintfoin cultivated with success on the chalky soils, and very productive. Hops on the borders of Surrey. A vineyard was planted at Undercliff, in the Isle of Wight, by the late Sir Richard Worsley, in 1792, and an Anjou vine-dresser brought over to attend it; the extent was about two and a half acres, and a light wine was made; but in 1808, when M. Vancouver called to see it, he found the vines had been grubbed up, and the ground changed to a lawn of turf.

7. *Grass Lands.*

The county famous for water meadows, which are well managed, and productive; they are chiefly in the neighbourhood of Winchester, on the Itchen; but there are instances on most of the other rivers and streams.

8. *Gardens and Orchards.*

Excellent market gardens near Gosport and Portsmouth; Portsea island noted for its broccoli; white-washed mud walls, with copings of thatch used as fences, and for wall fruit in some cases; and fruit walls only half a brick thick, and waving at the rate of one foot in twenty in use. In other cases angular walls are in use, the angles being right angles, and the sides ten feet each. The advantage in both cases is the saving of bricks; but it is evident they cannot be carried very high, nor, subject as they are to the driving and drawing of nails, can they be of great duration. (See *Encyclopædia of Gardening*, 1567.)

Orchards in various places, and cider made both in the county and in the Isle of Wight.

9. *Woods and Plantations.*

Extensive beechwoods on the chalk district, those of Ditcham grove very fine; elm scarce in the county, but abundant in Strathfieldsay Park (now the Duke of Wellington's). Oak abundant in the New Forest district, and many young plantations there, and throughout the county. Cobbett raised a great many American trees of various species at Botley. There are several considerable forests, viz. the New Forest, Alice Holt, Woolmer, and Bere.

The New Forest is situated on the south side of Hampshire; it was formerly bounded on the east by Southampton river, and on the south by the British Channel, being near thirty miles in length, and ninety in circumference; but, since the disafforestations by Henry the Third and Edward the First, its boundaries are much reduced, and now only extend from Gadshill, on the north west, to the sea, on the south-east, about twenty miles; and from Hardley, on the east, to Kingwood, on the west, about fifteen miles; containing within those limits about 92,365 acres, the whole of which does not now belong to the crown, as several manors and freehold estates, to the amount of 24,797 acres, are private property; about 625 acres are copyhold, belonging to His Majesty's manor of Lyndhurst; 1004 acres are leasehold, held under the crown; 902 acres are encroachments; 1193 acres are held by the master-keepers and groom keepers, attached to their respective lodges; and the remaining 63,844 acres are the woods and waste lands of the forest. The other forests are of much less extent and interest.

10. *Improvements.*

Good examples of draining by tapping were exhibited by Elkington, on Cadland Park estate: the strata lying at a small angle with the horizon, enabled the principles of what is called Elkington's mode of draining to be carried completely into effect. In the eastern part of the Isle of Wight are various tracts of marshy ground, the largest of which, Brading Haven, containing about 900 acres, was granted by James I. to one Gibbs, a groom of the bed-chamber. The owners of the adjoining lands contested this grant, which the king was very earnest in supporting. After a verdict obtained in the Court of Exchequer against the gentlemen of the island, Gibbs sold his share for 2000*l.* to Sir Bois Thelwall, a page of the king's bed-chamber, who admitted the famous Sir Hugh Middleton to a share. They employed a number of Dutchmen to enclose and recover the haven from the sea. The first taking of it in cost 4000*l.* and 1000*l.* more was expended in building a dwelling-house, barn, water-mill, trenching, quicksetting, and other necessary works; so that, including the original purchase, the total expenditure amounted to 7000*l.* But after all, the value of the ground did not answer the expectations of the undertakers; for though that part of it adjoining Brading proved tolerably good, nearly one half of it was found to be a light running sand; nevertheless, an incontestable evidence appeared, by the discovery of a well, cased with stone, near the middle of the haven, that it had formerly been good ground. Sir Hugh Middleton tried a variety of experiments on the land which had been taken in, before he sold his share; sowing it with wheat, barley, oats, cabbage, and finally with rapeseed, which last was alone successful: but the greatest discouragement was, that the sea brought up so much ouze, weeds, and sand, which choked up the passage for the discharge of the fresh water. At length, in a wet season, when the inner part of the haven was full of fresh water, and a high spring tide, the waters met under the bank, and made a breach. Thus ended this expensive project; and though Sir John Oglander, who lived in the neighbourhood, confessed himself a friend to the undertaking, which, besides its principal object, tended to render that part of the country more healthy, he declared it as his opinion, that the scheme could never be resumed to any profitable purpose.

11. *Live Stock.*

No exclusive breed of cattle. The Sussex, Suffolk, Leicester, Hereford, Devon, &c. are indiscriminately met with. Several ox teams.

Sheep. In the Woodland district the heath sheep, old Hampshire, or Wilts breeds, but most of the improved breeds also to be met with.

The horses used in teams generally large, heavy, inactive animals. Small horses bred in vast numbers upon the heaths and forests, and which have not improperly acquired the name of heath croppers. Their ordinary height is about twelve hands. They propagate indiscriminately upon these wastes, where they seek their living throughout the year, and at four years old may generally be purchased at above five pounds.

The native hog of this county is a coarse, raw-boned, flat-sided animal, agreeing in no respect with the idea entertained of it in other parts of the kingdom. The great number fed for a few weeks in the close of autumn, upon the acorns and mast which the forests and other woodlands produce, in the county, and the excellent mode of curing hog-meat practised by the housekeepers, have contributed in a far greater degree to establish that superiority ascribed to Hampshire bacon, than any inherent excellence in its native breed of hogs. Very few, however, of the genuine native hog are to be met with, the common stock being either the native Berkshire breed, or a considerable predominance of that blood in the native swine of the county.

12. *Political Economy.*

Roads in general good, especially in the New Forest. Several canals, and various manufactures and public works at Portsmouth and other places. The machinery for making blocks (1830) is reckoned the most ingenious and complete of its kind in the kingdom.

7816. WILTSHIRE. 870,000 acres of varied surface, partly chalky downs, and partly rich vale land; and both a corn and grass county. It produces excellent cheese and butter, fat cattle, pigs, and store sheep. The agricultural report of this county was drawn up by T. Davis, steward to the Marquess of Bath, at Longleat, a man of great experience as a land steward, surveyor, and farmer, and universally respected. He divides the county into two districts, the south-east and north-west; a very judicious plan for giving correct agricultural information. (*Davis's Wiltshire*, 1794. *Marshal's Review*, 1809. *Edin. Gaz.* 1829.)

7817. South Wiltshire.

Wiltshire downs contain about 500,000 acres of hilly surface, mostly unenclosed and in common pasture; the atmosphere cold and sharp, with a chalky soil, seldom varied by patches of loam, sand, or other earths. There is scarcely a river or brook in this district that is not applied in some way or other to the purposes of irrigation.

1. *Property.*

Near large towns property is generally subdivided when sold; in this district, when any is sold it is generally bought up by such as are considerable proprietors: hence estates generally large. Shape of the manors shows that many of them were the property of one lord; each borders on or contains a rivulet to supply water and the accompaniment of rivulets in that district, meadow land, with hill for wood; or, where these were wanting, they were supplied by a grant of those articles from other property. Proprietors generally resident on their estates.

2. *Buildings.*

Farm-houses generally crowded together in villages, for convenience of water. Some of late years erected centrical to their farms, by the Earl of Pembroke, and other proprietors; wells and ponds an important article in these erections.

3. *Occupation.*

Farms of two kinds; those in severalty, or not subject to rights of common, are from 150*l.* to 500*l.*, and one or two at 1000*l.* a year; customary tenements, subject to rights of common, are from 25*l.* to 40*l.* or 50*l.* per annum. There are extensive sheep commons and cow commons, to which the occupiers of both descriptions of lands have a right to turn in stock, according to certain fixed and customary regulations. Leases seven, fourteen, or twenty-one years.

4. *Implements.*

A heavy two-wheel and one-wheel plough in use; the latter sometimes with a foot instead of a wheel.

5. *Arable Land.*

An old error exists, that of over-pulverising the uplands by too frequent ploughings, by which the wheats were thrown out during winter, or if they stood the winter, the March winds blew away the earth from their roots, and "hanging by one leg," and thus not receiving any assistance from the coronal root, the plants are weak in straw, and produce small thin ears. "Many modes have been introduced to prevent this evil, by giving a sufficient texture and firmness to the land previous to a wheat crop. The best farmers have made a point of getting their lands clean ploughed by midsummer, and treading it as firm as possible with the sheep-fold a long time before sowing; while the slovenly farmers have invented, and generally practise, a very short and cheap way of attaining this firmness in the land. They rafter the land (as they call it), that is, they plough half of the land, and turn the grass side of the ploughed furrow on the land that is left unploughed. They do this as soon as they can spare the feed of the summer-field, and leave it in that state till near seed-time, when they harrow it down and plough it for sowing. This rafter is usually ploughed across the ridges, or what is better, diagonally; the latter mode being less subject to drive the land up in heaps before the plough. The land thus raftered is sometimes ploughed twice, but more frequently only once, previous to sowing; and after it is sown they drag it two, three, or four times, and harrow it four, five, or six times. A very heavy kind of drag is used; and as Wiltshire Down farmers are very cautious of ploughing their land too much, they make much use of these drags instead of ploughing, and frequently let in their seed-wheat with them. This practice having been found to answer, has been gradually improved upon. The down lands of this district will not bear fallowing, especially in hot dry weather; they are too thin and light already, and require rest. Two years' rest for wheat is equal to the best coat of dung. Dung may give the quantity, but rest must give the quality.

The *course of crops* was formerly fallow, wheat, barley, oats; but now, even on the common fields, is wheat, barley, clover, mowed one year, and fed two years, till it is necessary to plough for wheat. Turnips, Swedes, and rape grown for winter food for sheep, though less necessary than in districts less amply provided with water meadows. Error that of sowing too much corn.

Gardens near Devizes, Lavington, Warminster, Westhury, &c. Many families subsist by this kind of husbandry, occupying from two to five acres each as garden ground. The produce supplies the adjacent towns in the district, and Frome and Bath, in the county of Somerset, with cabbage-plants, peas, beans, carrots, turnips, and vast quantities of potatoes.

Orchards in some places, and cider made; but as the district

is famous for its barley and ale, the predilection for this beverage renders the want of cider little felt.

Woods not numerous, but a great spirit for forming plantations; and some excellent remarks on the subject in the Report.

Irrigation introduced into this district the end of the seventeenth, or the beginning of the eighteenth century. Many of the most valuable and best-formed meadows, particularly those in the Wyley Bourne, were made under the directions of one Farmer Baverstock of Stockton, between the years 1700 and 1705.

Between 15,000 and 20,000 acres watered; its great value in April between "hay and grass," by which the farmer is enabled to breed early lambs." As soon as the lambs are able to travel with the ewes (perhaps about the middle of March), the flock is put into the water-meadows. Care is, or ought to be, taken to make them as dry as possible for some days before the sheep begin to feed them; and on account of the quickness of the grass, it is not usual to allow the ewes and lambs to go into them with empty bellies, nor before the morning dew is gone. The general hours of feeding are from ten or eleven in the morning, till four or five in the evening, when the sheep are driven to the fold, which at that time of the year is generally in the barley fallow. The grass is daily hurdled out in portions, according to the number of sheep, to prevent their trampling it down; but a few spaces are left in the hurdles for the lambs to get through and feed forward in the rich grass. One acre of good grass will be sufficient for 500 couples for a day: the great object is to make the water-grass last till the barley sowing is finished; the meadow is then laid up for hay.

The *water-meadows of Orcheston*, a village six miles N. W. of Amesbury, have been long celebrated. What is called the long grass of these meadows is said by Davis to be the *Agróstis stolonífera*, or black couch; but this has been subsequently ascertained to be a mistake. The grasses which compose these meadows were examined by Thomas Tanner, a scientific botanist, in 1811, and reported on in the *Farmer's Magazine*, vol. xiv. p. 129.; and the following very interesting extract deserves the attention and reflection of the farmer, for other reasons besides its botanical information. It appears probable from it that deep dry soil, which will admit the roots of saintfoin and other long-rooted herbage plants, may, one year with another, yield as much nutriment as rich irrigated surfaces, and probably at much the same expense:—"Much has been said of the *excellent* quality of the hay, when well made; that, for instance, it will fatten pigs; and that it abounds with the saccharine quality more than other grasses. If the testimony of the present occupier and his neighbours can settle this question (and I see no reason why they should not), the *acreable* produce is not of greater value, take seven years together, than an acre of good saintfoin, or other artificial grasses. There is more risk in making the meadow-grass than the field-grass, it being very soon spoiled by bad weather, arising from its uncommon luxuriancy. I visited this meadow, for the first time, in the month of May, 1811, and found the major part of the crop to consist of *Pòa* triviàlis, or rough-stalked meadow-grass, with a few *culmi* of the *Tríticum* rèpens, or common couch, and meadow foxtail. In the last spring I again examined the meadow *very particularly*, and found the crop to consist of the same grasses as before, varying a little in their proportions. The *Triticum* rèpens made a greater appearance. In the month of August I took another ride to see if fiorin was taking the lead of the other grasses. This I was prepared for, and expected to find; but it was by no means the case: I could discover no more of the stolonífera than before. On examining the hay of the second crop, it consisted of the *culmi* of grasses common to all meadows, with the exception of the *Tríticum* rèpens. The grass, at this season, prevailed. In soils in general, when laid down to pasture, the common couch (*Tríticum*) soon wears out, it *will not* bear the constant treading of cattle. Wherever this grass is found in pasture, it proves either that the field has not long been laid to pasture, or the soil remarkably rich. The latter is the case in this instance. But you will say, What is the long grass of which we read so much? It remains for me to mention a peculiarity in the grasses in this meadow, and some others in its vicinity, which I do not recollect to have seen in any other to the same degree, arising probably from the *warmth* and *richness* of the soil. When the water begins to recede, in the late spring months, the *culmi* of all the grasses (the *Pòa* triviàlis in particular), from their great luxuriancy, lodge on the soil, and form a complete mat, and in this state throw out roots at their joints, and appear, before their *panicles* show, to be the *stolones* of some *stoloniferous grasses*. Let a person, not previously informed of this circumstance, visit the meadow in the latter end of April, and he would probably, with others, suspect the whole, or greater part of the produce, to be a *stoloniferous* production. I have traced the *culmi*, for instance, of the *P.* triviàlis and *foxtail* amongst the mat of other grasses, for *fourteen* or *fifteen feet*, with *roots* at *all* the *joints*, till, at the last, they shot up erect, and were taken off by the scythe only about *two feet* long. The mat of *culmi* on the ground is left untouched by the scythe when mown, very similar to the *stalks of an overgrown crop* of vetches. The *Agróstis* stolonífera is one of the *latest* grasses we have, and never was known, even in a cultivated state, to produce a crop till the autumnal months. But it is asked, 'How is it that it grows so rapidly in its natural state, as to enter largely into a hay crop, cut the last week in May?' Here is the mistake;—the *culmi* of *other* grasses, throwing out *roots* at their joints, have been considered as the *stolones* of this *Agróstis*." (*Farm. Mag.* vol. xiv. p. 131.) These meadows are not laid out in any regular form for watering, the supply of water being too partial, but they depend entirely on the floods; and being situated at a sharp turn of a narrow part of the valley, the water makes an eddy, and deposits its sediments upon them. The substratum of these meadows is an almost entire bed of loose flints.

On examining other meadows in different bournes of this district, we find the same grass uniformly to abound in those situated near the spring-heads, and which in some years have plenty of water, and in others none at all. The same remark on its variation in quality and quantity, according to the wetness or dryness of the winter, is equally just. The most probable way of accounting for it is, that it is almost the only grass common to water-meads that will stand wet and dry; for though it nourishes most when under water, yet no dry weather will kill it.

Live Stock. Cattle few in this district; oxen not generally under the plough; sheep the chief stock and the basis of the Wiltshire Down husbandry; object, folding and wool; breeding a consequence rather than a cause of keeping sheep. Horses a heavy, very unsuitable breed; great error in principle of breeders here as every where among the old school, that of enlarging the size of the animal.

7818. North Wiltshire.

Climate milder than that of the S.E. district; soil not so uniform; under stratum broken stones, and surface reddish calcareous loam.

Property more divided than in the east side of the county.

Buildings. Charlton, a noble pile, by Inigo Jones. Farms generally enclosed, and chiefly under grass, and applied to the making of cheese; leases from fourteen to twenty-one years.

Scotch farmers. "Within these few years several of the great landholders in Wiltshire have introduced into this district Scotch farmers, who, from a supposed superior skill in the science of agriculture, have leases for twenty-one years, with scarcely any restrictions as to husbandry. The ancient pastures are allowed to be broken up; buildings are erected for their accommodation at a low rate of interest; and a degree of countenance and patronage given to them above the other tenants of the day. These men give nominally a large rent for their farms; but as their maxim is to pay neither repairs, tithes, nor parochial taxes of any description (these dues and services being all included in the rent received by the landlord), I have strong doubts whether the advantages held out to the landowners will be, ultimately, any increase of net cash into their pockets. In strong loamy counties, or in richsands, I am aware much profit may be made by an economical system of husbandry in the tillage; but the practice of the Scots farmers not embracing sheep, or water-meadows, will never make them rich on the Down farms of Wiltshire; and if the Downs be broken up by the tenants, who have no stock to maintain them, the land and the farmer will soon come to poverty together." (*Davis*, 174-5.) Among these farmers was the unfortunate Gourlay, who was ultimately ruined by the speculation. Of his farming we know nothing, nor are we aware what description of Scotch farmers they can have been whose husbandry in an inland turnip district did not embrace sheep. On the Earl of Suffolk's estate at Charlton, some Berwickshire farmers were introduced in part through our means, whose chief object was the sheep system. The Lord Suffolk, however, of that time being a weak man, without an opinion of his own, got so alarmed by his family at the idea of breaking up old turf, that he bought up the leases of these farmers almost as soon as they were granted.

The *arable* part of this district is on the north-west verge, being a part of the Cotswolds hills, and treated like them.

Grass land prevails almost to the exclusion of arable on all wet and heavy lands: their management of late much improved by draining, manuring, winter burning, early mowing, and feeding and mowing every piece of land alternately. The grand object in these improvements is, to get an early bite for the cattle in the spring, and thereby, in fact, to shorten the winter.

The cheese of this district was many years sold in the London market by the name of Gloucester cheese; but it is now perfectly well known by the name of "North Wiltshire Cheese." It was at first, doubtless, an imitation, and perhaps an humble one, of that made in the vale of Gloucester, but it is now allowed by many to be at least equal, if not superior, to the cheese of the favourite district of Gloucestershire, the hundred of Berkeley.

Gardens not numerous: some near Wootton Basset, for supplying the markets of Cricklade, Cirencester, &c.

Orchards frequent as an appendage to farm-houses, but no cider made.

Wood frequent in hedgerows, but not in masses.

Irrigation not common; springs scanty, and land too absorbent; alleged they produce coarse grass, but this is owing to its not being mown in time.

6. *Live Stock.*

Cattle of the long-horned breed; Devons bred, and found better for fatting, but it is questionable if they are so good for the dairy. Breeding cattle not the fashion. "The dairymen say, that the advantages which their situation gives them of sending their veal to London and Bath markets, makes it more their interest to fat their calves than to wean them for stock; but the opponents of the long-horned cows say, that the oxen are generally so ugly, and the heifers frequently such bad milkers, that the farmers are never certain of breeding such as they would wish to keep; and therefore they prefer buying cows (of which they can have a choice) to breeding them, and to use horses for the plough instead of oxen."

Many sheep bred in the district; some for folding, and others purposely for fatting; for these purposes a kind to walk, and a kind to stand still, necessary: the Wiltshire answers the former purpose, and the Leicester the latter.

There are yet left in North Wilts a few flocks of the native Wiltshire horned sheep, possessing qualities of perfection, both for folding and fatting. They stand short in the leg, with wool under their bellies; are wide and heavy in the hind-quarter, light in the fore quarter and in all their offals, with the Roman nose, and quick piercing eyes. These are in the hands of a few farmers near Broad Hinton.

7. *Political Economy.*

As applicable to both districts it is observed, that the turnpike roads are numerous and good in most places; three canals; extensive woollen manufactures at Salisbury; also cutlery of superior excellence there; carpets at Wilton, and fancy woollens; and of superfine broad-cloths at a great many places. No agricultural society, but many farmers and others are members of the Bath and West of England Society.

7819. DORSETSHIRE.

711,250 acres of undulating surface, in great part chalky soil, and celebrated from the time of the Romans for its pleasantness and fertility. Like Berkshire and some other counties, it is called by the inhabitants the garden of England. It is chiefly under grass, and is celebrated for its

breed of sheep, which bring three lambs in two years; and for its watered meadows, of which Boswell, of this county, has given a valuable account. (*Claridge's General View*, 1793. *Stevenson's General View*, 1812. *Marshal's Review*, 1817. *Edin. Gaz.* 1829.)

1. *Geographical State and Circumstances.*

Climate dry and salubrious rather than mild and bland; supposed colder since the elevated Downs were denuded of their native forests.

Soil chiefly chalk, next clay, then sand, and of loam, gravel, &c. nearly equal and moderate portions. Chalky and sandy soils of the uplands very thin.

No *metallic mines* or cauls, but the peninsula of Portland, four miles and a half in length by two in breadth, one entire quarry of Portland stone, so extensively used, especially in London. Potters' clay found in various parts of the county.

2. *Property.*

Estates large compared with those of other counties; some of the principal under the care of land-surveyors, others of lawyers. Tenures chiefly freehold and leasehold.

3. *Buildings.*

Farm buildings as in other counties; generally ill situated, built of stone, and covered with reeds or thatch.

4. *Occupation.*

Farms very large, 1500 or 2000 acres of sheep farm being frequently to be met with. Many of the proprietors great farmers. Leases of twenty-one years common till the beginning of the present century, now for shorter periods.

5. *Implements.*

Two sorts of uncooth wheel-plough in use. Small's plough tried in one or two places; from the difficulty of ploughing flinty soils, wheels are deemed an advantageous appendage to whatever sort is adopted. Threshing, winnowing, and various other modern implements introduced in a number of places. The wattled hurdles of Dorsetshire consist almost invariably of ten stakes, which the hurdle-makers drive into augur holes, that are made for that purpose in a piece of timber, which is supported at a convenient height from the ground by other pieces of timber, and then the stakes are wattled. Stones set on edge, and rublestone walls used as fences in various parts.

6. *Arable Land.*

Deep ploughing generally less approved of on the chalky soils, and cross ploughing never practised, even for turnips; two or three horses form a team. Fallowing general all along the coast; but what is here termed a summer fallow is, in most cases, no other than a preparation of ley ground for a crop of wheat, by ploughing it three or four times, the first ploughing being given in June or July, and sometimes as late as August.

Upon the thin chalky soils around Blandford, and upon the hills in the neighbourhood of Abbey Milton, the course of crops with the best farmers is as follows: viz. one seventh of the land is in saintfoin, and the rest of the arable is cultivated in the rotation of one, wheat; two, rye, winter barley, or winter vetches, to be fed with sheep in the spring, and the whole followed by turnips, rape, &c.; three, barley or oats; and four and five, artificial grasses, to be followed by wheat as before.

Upon the thin chalks and shallow flinty loams, wheat is generally sown on the back of a two years' clover ley; but, even on those thin soils, a great deal is sown after turnips, rape, &c. fed off with sheep early enough to sow it in the same autumn, and in most instances a good crop is produced of a fine sample. On the better sorts of chalky and gravelly soils, the same practice prevails, except upon the ley-ground, which continues in grass but one year instead of two; the wheat is taken after the first year's ley, and is supposed to answer better than it would in the second year, upon the latter description of soils. Old saintfoin leys broken up without paring and burning. Hemp and flax a good deal cultivated.

7. *Grass.*

300,000 acres, or about three fifths of the county; 6000 acres of meadow in the chalky district irrigated. Application of the meadows; fatting cattle, and of the uplands the dairy.

8. *Gardens and Orchards.*

Both are frequent appendages to farm-houses and cottages; some of the cottage gardens are small enclosures taken from the sides of the highways. The goosefoot (*Chenopòdium bònus Henricus*) cultivated by a few persons here, as in Lincolnshire and elsewhere, and calculations made by Batchelor, to show what would be the expenses and profits of an acre for the London market. The plant is greatly inferior to spinach, but might be used as a substitute for it in spring, as it is a perennial, and very early in leaf. Sea-cale, which grows on the shores near Burton, is now generally introduced into the gardens of farmers.

Orchards to the extent of 10,000 acres; application cider, in making which hops are sometimes added to make it keep; proportion one pound to a hogshead. Twenty bushels of apples will make a hogshead of cider.

9. *Woods and Plantations.*

Timber scarce, and chiefly to be found in parks and hedgerows. Many young plantations lately made on the heath lands.

10. *Improvements.*

Irrigation carried to considerable extent and great perfection, and one of the best books on the subject is by Boswell of Piddletown. A dry meadow of good quality is worth forty shillings; watered, sixty-five shillings per acre; produce of hay two loads per acre. The streams in Dorset are in general shallow, and have a considerable fall; the meadows are narrow, and the water is supplied with comparative regularity, in consequence of its having to filter through immense masses of chalk previous to its exit at the springs; and hence the process of irrigation is much facilitated.

The *sheep* of Dorsetshire are well known as supplying the metropolis with house-lamb at a very early season. Parkinson considers the Dorset ewe as the best horned ewe in the kingdom, those of Somerset excepted; and they are so nearly alike, that few people, save the natives of the two counties, would know the difference. In the Isle of Portland there is a small breed, which some contend is the true breed of the county. Lowman of Portland observes, it is the practice there to fold these dwarfish animals from Candlemas to Martintide, putting them in late at night, and letting them out early in the morning. The mutton is deemed the best in England, and the wool as good as the South Down kind. Some of them have been purchased by sheep-breeders, with a view to obtain a cross between these and the Merinos. Both ewes and wethers are kept, and generally till they are five years old; sometimes they remain till a greater age, but it is not thought a profitable method. Such as are fatted are put into a common, at the northern part of the island, which is pretty good land, and remain there from the 12th of August to the 5th of November, on which day Portland sheep-fair is held. All the sheep of the island are kept pretty generally upon the commons from November the 21st to Candlemas. The Portland mutton is sold by the quarter in general at ten shillings and sixpence. It is never weighed, but would come to one shilling a pound when common mutton is only seven-pence: it seldom weighs more than ten pounds a quarter. Several flocks of pure Merinos, Down Merinos, and other breeds.

General management of sheep. The lambs which are bred for the regular supply of the flock are dropped at Christmas, or soon afterwards, and the couples are kept in the best ewe-leazes, &c. on grass, hay, and turnips, if necessary; and such as have watered meadows, depasture their sheep there, on the early grass, till old May-day, when the lambs are weaned, and the sheep go to fold; but sometimes the two latter circumstances take place as early as Lady-day. The ewes are folded constantly, and kept on the Downs, on artificial grasses and other pastures, till near the ensuing Christmas, at which time they have another crop of lambs, the rams having been put to the flock about the end of July.

There is, probably, no part of England where the practice of sheep-folding is more admired, or more earnestly pursued, than in the county of Dorset. Fifteen dozen of hurdles, with a like number of stakes and withes to confine them together, will enclose a statute acre of ground, and will contain 1200 or 1300 sheep very commodiously. The hurdles are moved every morning; consequently the same number of sheep will manure an acre of land daily. The real value of the fold there is no means of ascertaining; it is undoubtedly very beneficial to the arable land, but it has reduced the Downs to a state of poverty.

Ewes are generally kept till they are four years and a half old, when they are sold to the dealers. A singular custom prevails of colouring them with ochre, for which no other reason is given than that of being able to distinguish them from the Somerset sheep.

Asses were formerly kept by some farmers, but are now given up, having been found destructive to hedges, &c. "It appeared that six asses would plough as much land of any kind in a given time as three horses, and four asses were sufficient to plough broken land. It is believed that two asses will perform as much work as one horse, and they do it more conveniently in the hilly part of the county, as they carry their lading in panniers, where it would be difficult to use wheel carriages.

Geese kept on the corn pastures in Purbeck, from an idea that they promote the health of the cattle.

Bees kept in various places; does not answer to feed them; the only way to render them profitable is, after the honey-season to destroy all hives under twenty pounds weight.

11. *Political Economy.*

Roads of flint, and in general good: an iron railway, of three miles and a half, for conveying potters' clay from Norden to a place opposite Poole, where it is shipped for Liverpool. No canals. Manufactures of flax and hemp at Bridport and Beaminster; upwards of 2000 people employed in making sail-cloth, cordage, sacking, tarpaulin, &c.; flannel at Shaftesbury, and woollens at Lyme Regis; twisting and making up raw silk into skeins at Sherbourne and other places; shirt buttons extensively at Shaftesbury, Blandford, and the surrounding villages; the buttons made of wire and thread; many thousands of children in this manufacture: wicker baskets, with a small hole at top, called lobster pots, at various places on the coast, and a variety of other articles. Many very uncommon provincial terms used in this county.

7820. SOMERSETSHIRE. About one million of acres, chiefly of meadow and pasture land, hilly and mountainous in some places, and with marshes and bogs in others, but on the whole, though far behind in artificial culture, celebrated for its natural fertility. The climate is various, in general cold and boisterous on the elevated parts, but almost without a winter near the sea. The county is divided into the north-east, middle, and south-west districts, by its very able reporter, J. Billingsley, Esq. of Ashwick Grove. (*Billingsley's General View*, 1797. *Marshal's Review*, 1817.)

7821. North-east District.

Surface very irregular, intermixed with lofty hills and rich fertile plains: climate various; soil chiefly clay, and in part peat; application chiefly pasturage; several thousands of acres overflown by the tide in the river Yeo; 4000 acres protected by a wall of stone and lime, elevated ten feet above the level of the land within, but high tides frequently break over it and make breaches.

Minerals. Lead and calomine in the Mendip hills, but little worked, for want of a proper level to carry off the water. Coal abounds, and is worked for the supply of Bath, Wiltshire, and Somersetshire; from 800 to 1000 tons raised weekly.

Property. Many large proprietors from 2000*l.* to 6000*l.* per annum, but the greater part in the possession of respectable yeomanry, from 50*l.* to 500*l.* a year.

Buildings. There are many splendid gentlemen's seats,

ornamented with extensive plantations, in this district, and the farm-houses and cottages are for the most part commodious and comfortable; but, on all the dairy farms, a shameful inattention prevails in respect to outhouses and sheds for their stock to retire to in the winter months. Cattle are almost universally served with their provender in the field; and many a dairy farmer, with twenty cows, scarcely makes, in the whole winter, a quantity of dung sufficient to manure one acre of land.

Occupation. Farms seldom exceed 200*l.* a year; some of the dairy farms are so small as not to exceed 60*l.* or 70*l.* per year; and many instances can be produced of such little farmers bringing up a large family in a very respectable way. In such instances, it is generally found that the wife undertakes the whole management of the cows, and the husband goes to daily labour.

Implements. Plough with a foot or wheel; spade with the blade curved in its breadth, to prevent adhesion of soil; it is much narrower and longer than those used in other counties, eighteen inches by six inches.

Arable land but in small proportion, and little attended to. Teazles and woad grown for the clothiers; potatoes cultivated to a very considerable extent. The reporter has known thirty-two successive crops of potatoes from the same field, and the produce as good at the latter part of the term as at the beginning. This will puzzle the theorist, with his peculiar substances of nutrition. A sack of potatoes is equal to a hundred weight of hay.

Grass the predominating surface. "On the rich marsh land near the Bristol Channel, the grazing system prevails. In the vicinity of Bristol and Bath, the scythe is in constant use; and at a greater distance nothing is scarcely seen but the milking pail: on the stonebrash, and freestone grit soil, saintfoin takes the lead: next to saintfoin, rye grass, marl grass, and white Dutch clover are in deserved repute, when the land is intended to remain some years in grass; but when it is intended to be ploughed again in the course of a year or two, broad clover is preferred to all others.

Hay-tea (1807.) much in use, by which means it is considered as much nourishment is obtained as if the hay were eaten, while after boiling the culms may be dried and used as litter! In some places, however, a prejudice exists against using hay for litter, on the supposition that it breeds vermin in cattle.

Market Gardens for the supply of Bristol and Bath. A clergyman has eight or ten acres of nursery ground, the labour of which amounts to 25*l.* per acre.

Orchards abound throughout the whole district; the favourite apple, both as a table and cider fruit, is the court of wick pippin, a seedling from the golden pippin.

Woods and Plantations not numerous.

Live Stock. Cattle mostly short-horned; the long-horned breed of North Wiltshire have been tried, but the customary breed preferred. Both cheese and butter made.

Roads pretty good; some canals; woollen manufacture extensive, and that of knit worsted stockings considerable.

7822. Middle District.

Between 4 and 500,000 acres of varied surface and soil, and mild climate; including a great extent of marsh and fen land, great part of which has been drained and embanked. Half this district occupied by the owners. Grass the chief product; farms from 40*l.* to 600*l.* per annum, partly grazed with heifers, but chiefly by cows for the dairy: the cows let out to dairymen, as in Dorsetshire.

Arable Land, flax and hemp extensively cultivated, and also turnips.

Orchards numerous and very productive; soil particularly suitable; plantations few.

Live Stock. Small cows, well fed, preferred for the dairy, and the object chiefly cheese; that of Cheddar much admired, the others in general sold in London as double Gloucester. A dairy-maid can manage the milk of twenty cows.

Roads excellent, especially from Wells to Bridgwater; extensive woollen manufactures, many of hemp and flax, and some of gloves.

7823. South-west District.

Rough mountainous hills, and rich fertile slopes and plains; farms rather less than in the last district, but the husbandry much the same; more land in tillage; mountains uncultivated, and pasture with sheep and young bullocks; in the vicinity of these hills the principal corn crop is oats.

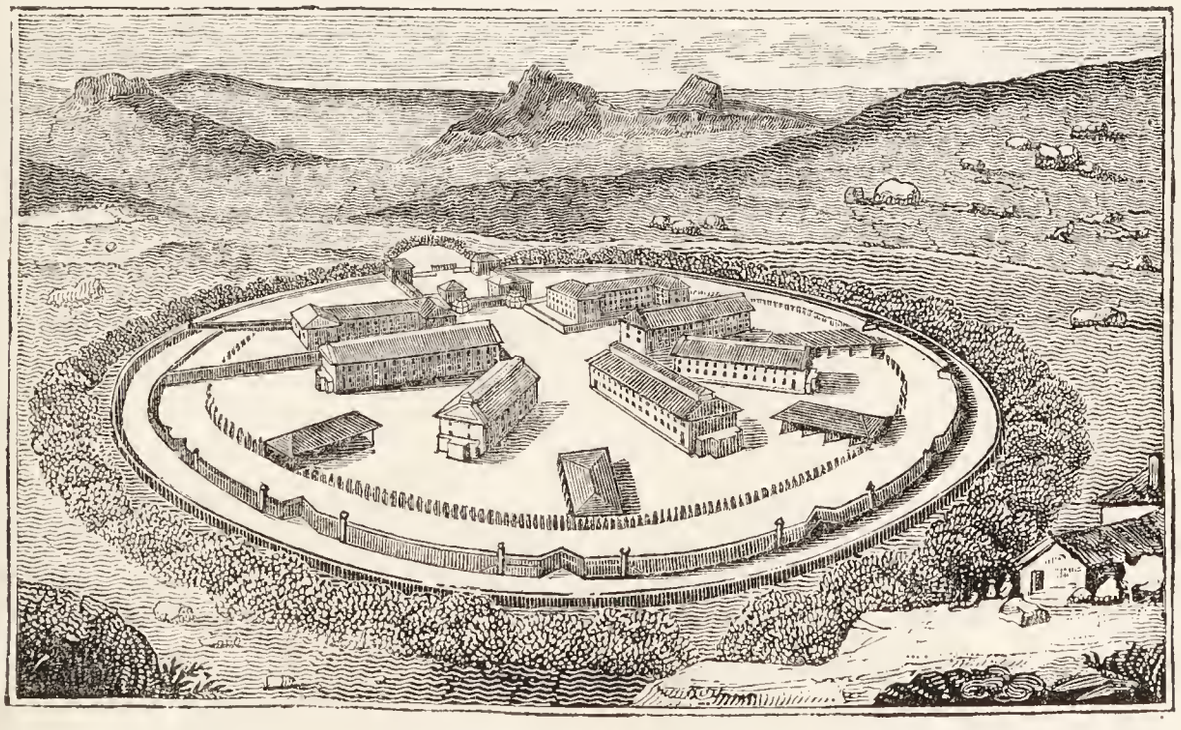
Fences. The beech hedges around Dulverton, Dunster, &c. are not only beautiful to the eye, and excellent fences and shelter, but are a source of annual profit to the proprietors. The banks on which they are planted are six or seven feet high, and between four and five feet wide at the top; the mouldering of the sides is frequently prevented by a dry stone wall, four feet high. There is no ditch; and the hedge consists of three rows of beech, planted on the top of the bank, at about one foot distance. Their growth is very rapid, and they seem to defy the destructive qualities of the sea breezes, so fatal to the white-thorn, and most other plants; when at maturity, the middle row is cut to the ground, and the outside rows plashed. The quantity of fuel supplied by these hedges is very considerable; and the only objection that can be made to them is, that the earth used in the construction of the banks is so considerable a quantity, that a large portion of the field is robbed of its vegetable matter, and rendered for some years unproductive.

Some *Norfolk farmers* introduced on the Barnard estate, and rhubarb cultivated to great perfection by Ball, at Williton, near Watchet. Many orchards, and excellent cider made; not much wood, but elms attain to a large size in the hedges.

Live Stock. North Devon cattle and Dorset sheep used round Taunton Dean; oxen worked chiefly in yokes. Manufactures at Taunton on the decline. A salmon and herring fishery at Porlack, Minehead, and Watchet.

7824. DEVONSHIRE. 1,595,309 acres of strongly marked hilly surface, including the vale of Exeter, "the garden of the west;" the Forest of Dartmoor, a barren waste; and North, West, South, and East Devonshire, each with distinct features. The county is celebrated for its breed of cattle, its dairy, and its orchards, and of late years for extensive improvements undertaken in Dartmoor, where is also the immense depôt for 10,000 prisoners of war. (*fig.*1114.) (*Tyrwhitt's Tracts on the Improvements at Dartmoor*, 1819 *Fraser's General View*, 1794. *Vancouver's View*, 1807. *Marshal's Review*, 1817.)

1114



1. *Geographical State and Circumstances.*

Climate in North Devon less mild than in South Devon, but still myrtles are used as garden hedges; in South Devon the climate is supposed more mild and salubrious than in any other part of England.

Soil in great variety, but in general calcareous.

Minerals. Some iron and copper worked, also freestone, limestone, and marble, &c.

2. *Property.*

Much divided, only a few large estates; formerly letting for lives much in use. It has frequently happened, that in letting an estate, the landlord agreed to discharge tithes and all parochial payments. About the years 1800 and 1801, the rent of several estates in this county was absolutely insufficient to meet such disbursements, and consequently all the estates so circumstanced brought their proprietors in debt.

3. *Buildings.*

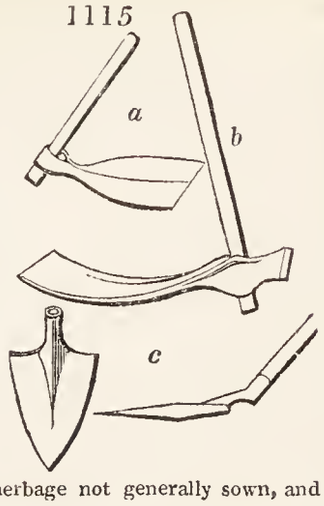
Houses of proprietors too generally going to ruin from non-residence. "We defy ingenuity to plan and place farm-houses worse than they are." "Garden-walls, farm-houses, barns, stables, lime-kilns, village fences, and cottages, are all built

with mud, and left without rough-cast, or whitewash, to conceal the native colour of the loam."

4. *Occupation.*

Farms of all sizes from 10*l.* to 500*l.* a year.

1115



5. *Implements.*

Plough of the swing kind, with a wooden mould board. Scarifiers, called tormentors. Two sorts of grubbing mattocks are in use (*fig.* 1115.*a*,*b*), one called the hoe mattock (*a*), and the other a two-bill or double-bitted mattock (*b*). Paring-shovels (*c*) are very well constructed. Corn-stacks in harvest secured from the sudden and heavy thunder showers to which this country is liable, by canvass coverings, like those used in Middlesex for covering hay ricks.

6. *Arable Land.*

Much less than the grass land; not much to be learned from its culture; artificial herbage not generally sown, and rotations bad.

7. *Grass Lands.*

In the low tracts of good quality; application, breeding and the dairy; butter good, cheese indifferent, and generally consumed in the county.

8. *Orchards, Woods, and Plantations.*

Very abundant in most parts of the county, and excellent cider made in the Herefordshire manner. Fruit trees rather neglected than otherwise; generally pasture beneath; often in the hedgerows.

The Forest of Dartmoor is parcel of the Duchy of Cornwall; extensive improvements have lately been proposed, and in part carried into execution, under the direction of Sir J. Tyrwhitt, the steward of the Duchy. Extensive *salt marshes* on some parts of the coast.

9. *Improvements.*

Draining and irrigation not much practised. The Rev. M. Froude, of Darlington parsonage, communicated to Vancouver a mode of emptying the water from a pond without the necessity of attending to it personally when full. It is more matter of curiosity than ingenuity or use. The water, when the pond is overflowing, flows by a gutter into a basin, suspended beyond the head, which when full, by means of a lever, raises a plug at the bottom of the pond. After a time, the box being leaky, it becomes empty, and when the pond is nearly empty, the plug re-drops in its place. If the plug were placed nearer the surface of the water, it would in general cases be more useful, and less likely to lose the fish.

10. *Live Stock.*

The North Devon cattle well known for their superior adaptation, both for feeding and draught. For the uses of the dairy or for milk, it is a breed by no means held in general estimation, as their aptitude to look well (without being fleshy) is derived from the peculiar nature of the animal, which disposes its secretions in the accumulation of fat, rather than in the production of milk. For the purposes of labour, this breed can nowhere be excelled for docility, activity, or hardihood, in proof of which no stronger circumstance can be adduced, than that it is a common day's work, on fallow land, for four steers to plough two acres with a double-furrow plough; and that a general use is thus made of them, and for most of the other purposes of draught in the county where they were originally found, and in others to which they have been since transplanted.

The rules generally pursued in breeding and raising this valuable animal, may be considered as follows:—The greatest number of calves fall between Candlemas and May, and some much later; but, among the best breeders, such late calves are not so generally approved of. The usual mode of raising them is, to let the calf suck as much as it will three times a day, for the first week; then bring it to the finger, and feed it with warm new milk, in like manner for three weeks longer. This is the ordinary treatment for the first month, and the calf is then fed for two months longer, twice a day, with as much warm scalded skim-milk as it will drink; when, gradually abating its morning and evening meals, at the end of four months the animal is weaned from all milk draughts, and left to itself. Small portions of finely pounded linseed cakes are often used, and recommended to be mixed with the skim-milk, particularly in the first period of its being given in the place of new milk.

The full-sized North Devon cow, when fattened to its frame, will not exceed eight score per quarter; and the ordinary average of its ox, at five years old, and equally well fattened, must not be rated higher than three score per quarter above the weight of its fattened mother.

The usual practice in this district, is to sell the steers, at four or five years old, to the graziers in the county of Somerset, who feed them for a supply to the Bath, Bristol, and London markets. Very few in the proportion raised are fed in the district, which may in a great measure be ascribed to the great indifference hitherto manifested in the culture of green food for a winter supply; and for which, indeed, a sufficient reason may be drawn, from the deplorable wet state in which the lands are suffered to remain from the want of draining.

In South Devon we find a mixture of the North Devon with a larger animal of the same kind, called the Old Marlborough Red. This breed is said to have originated from the South Malton stock, although at this time they differ very materially from them in size, and in having a dirty brown, or rather blackish colour at the ears, nose, and encircling the eyes, and in all such parts as the orange hue prevails in the genuine North Devon breed. A cross with this breed is, however, much preferred, as it produces a greater aptitude to fatten in a given time than is experienced in the South Devon stock, which in all its points is a much coarser animal, and produces a greater offal. There does not appear to be any particular choice with regard to colour in this breed.

Sheep, the Exmoor breed, a horned animal, with a moderately long staple of wool, which heretofore, and before the cloth manufacture fled from this county into Yorkshire, was much used by the clothiers of North and South Malton, Collumpton, Thorverton, Tiverton, and other places in the county.

The sheep most approved in the division of Tiverton are the Bampton Notts. The first cross of this breed with the New Leicester is growing greatly in esteem, from its improving the form, and bringing the animal three months sooner to market.

The sheep generally depastured on the moorlands are the Exmoor, Dartmoor, and the light hardy breed of the lower moors and commons in the county. The autumnal rains frequently inundating the cold clay lands, are very apt to occasion the caw, or rot, among them, and which has been sometimes experienced to an alarming extent.

The Merinos, Ryelands, Downs, and other fashionable breeds have been tried by amateurs; but Devon is less a sheep than a cattle county. Native breed of hogs large, and long-legged.

Horses, a small compact breed; with the exception of the farm-horses in Ireland, those in Devonshire have perhaps as hard a measure of neglect and ill-usage dealt out to them, as is any where to be met with in the united kingdom.

11. *Political Economy.*

Had the roads of this county been laid out in the judicious manner practised by the Indians of North America, they would have been found to follow the water courses in all cases where they might lead in their general direction, towards the point assigned for carrying them. In doing this, infinitely more judgment would have been displayed, and a far greater benefit secured to posterity, than in that which has been adopted by the original projectors of some of the most important and most frequented roads in this country. This is clearly demonstrated by the road between Barnstaple and Chumleigh, which, instead of being conducted through the valley of the Taw, is carried over the highest brows of the river hills, where the traveller is unceasingly compelled to ascend and descend the sharpest hills in the county. The same may be said of the road between Bideford and Torrington, by the great omission of its not being carried along the foot of the river hills, and through the valley of the Torridge river.

Manufactures of woollen of various sorts were formerly common; but are at present on the decline; many manufactures and works employing numerous hands at Plymouth. Two agricultural societies, but both ill attended and on the decline.

Education of the Poor, or Lower Classes. Vancouver concludes his report by some pages of observations which, happily, are seldom equalled in illiberality; and, viewing the subject as we do, they compel us to look on him as an enemy to human nature, and to turn from his book, his name, and memory, with feelings of dislike. "It is an incontrovertible truth," he says, "that the restless disposition of the Irish, and their emigration to America, is owing to their being generally instructed to read and write. The disposition of the Scotch and Germans to emigrate arises from the same reason, and the English peasant under the same influence will be acted on in the same manner." He "respectfully submits to the consideration of the Honourable Board, the propriety of opposing any measure that may rationally be supposed to lead to such a fatal issue." This man, like Charles X. and his ordonnances of 1830, and Wellington, with his speech against reform of the same year, may have done good without knowing it.

Marshal, whose considerate and humane spirit justly objects to the term peasantry, as at all applicable to the operative classes of Britain, has the following excellent remarks on this subject:—

With respect to the *emigration* of the Irish, "well it is," he says, "for Ireland and America, that they do so. The one is overstocked with the class that furnishes work-people; the other wants enlightened workmen. Of slaves and savages it has enow. The unlettered Irish stay at home, to riot, plot, and murder; to commit acts of treason, stratagem, and spoil; or emigrate to England, to revel awhile in outrage, and be hanged."

On Vancouver's ideas on education, Marshal observes, "After some other groundless arguments, the reporter sums up in Italics, and with the aid of foreign tongues, in the following ultra-royal manner:—'In short, the peasant's mind should never be inspired with a desire to amend his circumstances by the quitting of his cast' (this, says Marshal, is Hindoo), 'but every means the most benevolent and feeling heart can desire should be employed to make that situation as comfortable and as happy to him as possible; and to which end nothing more essential could contribute than by exciting a general emulation to excel in all their avocations, even to those of breaking stones for a lime-kiln, or for repairing the highways.' 'Hear, hear!' says Marshal—'This is English.' Good heaven! And is there an Englishman (or a Dutchman — they are brothers in sentiment) with nerve enough to write the two first lines above quoted!!! He surely could not know that many men of 'the brightest genius,' and who are much more estimable members of a community,—many great and good men have, in England, been moulded and nurtured in the 'peasant cast.'"

"Fortunately for society in England, the writer's exotic notions have not taken root. Seminaries, for civilising the children of the labouring classes, have been, and are rapidly increasing."

"In a civilised nation, early schooling tends to reclaim children from savage propensities, and to prepare them for civilised society; inculcates a propriety of behaviour, one of the very first lessons a child should be induced to learn in a civilised nation. In the savage state, savage manners may be deemed a virtue, as being, in that state, conducive to self-preservation."

"Attendance in a school inures children to a requisite degree of restraint; and a division of time employs their minds, and prevents idleness, and other vicious habits, from taking root; thus tending to raise them to the rank of rational beings. While the unfortunate offspring of indigence, that are suffered to loiter away their early days on commons, in lanes, and by-places, acquire habits of indolence and pilfering; give a loose to their own wills and unrestrained tempers; commit acts of mischief, and add to them the guilt of lying (the seed-bed of fraud) to screen them from correction."

"The discipline of a well governed school impresses on youthful minds subordination, industry, patience, and its

consequent, perseverance; and thus habituates them to receive instructions."

Where Vancouver is at present we do not know; we hope he may long live to witness the extension of education which is now taking place, not only in this, but in almost every country in the world; and we hope all those whom he designates peasantry, who may ever happen to read the above extracts, will see the necessity of fortifying themselves, by knowledge and good conduct, against the degradation attendant upon ignorance and vice.

7825. CORNWALL. A peninsular hilly surface, of 758,484 acres, remarkable for its mines, and of late greatly improved in its agriculture, the object of which is chiefly corn. It is the country of Sir H. Davy, who may be considered as having eminently contributed to agricultural science by his agricultural chemistry. The inhabitants have been remarkable from the time of the Romans for their mildness and complacency of temper, urbanity, hospitality, courteousness, and liberality. (*Frazer's Cornwall*, 1794. *Worgan'sCornwall*, 1810. *Marshal's Review*, 1817. *Edin. Gaz. abridged*, 1829.)

1. *Geographical State and Circumstances.*

Climate, like that of other peninsular situations lying far to the south and west, inconstant as to wind and rain, and mild as to heat and cold. Plants, shrubs, and even the most hardy trees on the sea-coast, sustain much injury from the violence of the westerly wind, and the salt spray of the sea, which it drives with great force before it; hence crops of wheat and turnips have been totally destroyed. After a storm, the plants have their roots much torn, and their leaves corroded and shrivelled as if scorched, and taste of a pungent saltness. Trees and shrubs shrink and lean away to the eastward, and appear as if clipped by the gardener's shears. The only shrub which seems to bear the sea air is the tamarisk.

Surface remarkably unequal; ascents and descents follow in rapid succession; some hills very steep.

Soil generally slaty and loamy, mixed in a manner that renders it almost impossible to designate the boundaries and extent of each.

Minerals chiefly tin and copper; for the former Cornwall has been famous from the remotest antiquity, as some think, from the days of the Phœnicians.

2. *Property.*

Very much divided, subdivided, and vexatiously intermixed. Estates from twenty acres to 500 acres, very few exceeding 400*l.* per annum. Many gentlemen and clergymen in this county occupy their own estates and glebes, and keep their grounds in a very superior state of cultivation. The management of great estates is generally given to attorneys.

Entailed estates. "I was in hopes that I had been a singular sufferer in Cornwall, from this kind of deceptive tenure; it would then not have been worthy of notice; but in my excursions through the county I have met with fellow-sufferers, and with others who are likely to become so. As such cases have occurred, and may occur again, it behoves every man who is about to occupy a farm for a term by lease, to make enquiry whether it be an entailed estate or not; because the possessor having the power of letting for his own life only, in case of his death, the occupier is left entirely at the mercy of his successor." (*Worgan's Survey*, 22.)

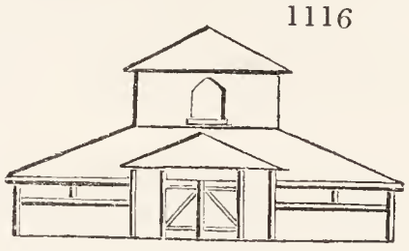
3. *Buildings.*

Old farm-houses of mud and thatch; the lower divisions consist of a kitchen, and an apartment dignified with the name of parlour, but called (provincially) the higher side, a cellar, and dairy-room; but these latter are frequently under a lean-to roof; the rooms very low, not ceiled, and two bed-chambers over; the floors of the chambers are of oak plank; the ground-floor earth, lime-ash, or flag-stone.

The farm-offices, built of the same materials, consisting of a barn, cow and ox sheds, and hog-sties, stand in confusion about the dwelling. The intervening and circumjacent ground is called the farmer's town-place; for as to that essential appendage, a regular farm-yard, it is a convenience not often met with in any part of the county.

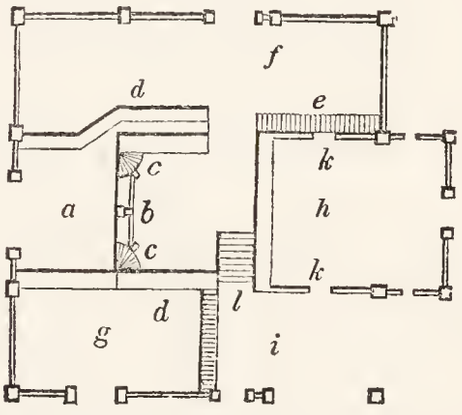
Some good new farmeries erected centrically on newly enclosed lands. One for forty-six acres has a very neat elevation (*fig.* 1116.), and the plan (*fig.* 1117.) contains a feeding place into which the turnips are carried (the cart being backed into it), and from whence the sheep and oxen are fed (*a*); place for a yoke of oxen (*b*), either for soiling or winter-feeding: the oxen are tied to posts (*c c*); there are troughs for turnips (*d*); cribs, or racks for hay or straw (*e*); lean-to, for store sheep (*f*); lean-to, in which half a score sheep are kept to fatten, the number being completed again soon as any are sold (*g*); fodder house, used as a barn (*h*); open shed for tools (*i*); hanging doors with

1116



bolt inside, and through which the fodder is handed to supply

1117



the cattle, and is thus kept always dry (*k*); door and staircase leading up to the wool chamber (*l*). The stairs rise quick, so as to be quite out of the way of the ox feeding in that side of the house.

Cottages. "I had occasion often, in my dreary walks during my survey, to take shelter in some of these miserable dwellings, and found the poor inhabitants busy in placing their bowls, crocks, and pans, to catch the water pouring in at the roof. However, the meanest cottage generally has that great source of comfort, a garden, attached to it." Some very comfortable plans of cottages, by Captain Penson of Ethy, are described by the surveyor.

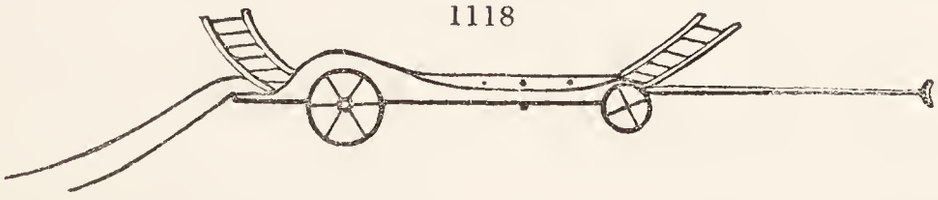
4. *Occupation.*

Farms from three or four to three or four hundred acres, mostly from 30*l.* to 50*l.* a year. Leases on rack-rented farms generally from fourteen to twenty-one years.

5. *Implements.*

No county affords a greater variety of wheel and other carriages. The harvest waggon (*fig.* 1118.) has a lade before and

1118

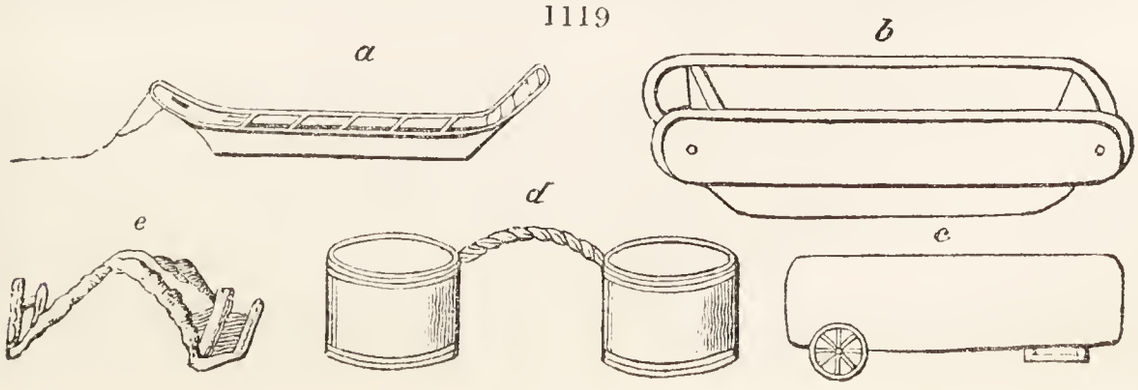


behind, and is open in the middle, it carries about 300 sheave of corn. When drawn by horses, shafts are applied; when by oxen, a pole. An arch of boards over the hind wheels prevents the corn from bearing on them.

The wain is another light useful carriage for carrying corn sand hay. It consists of a light, open, long body, borne upon two wheels; a railed arch over the wheels prevents the load from bearing upon them; it will carry from 200 to 250 sheaves which are secured by ropes, it having no sides or lades.

A sledge for corn, hay, or faggots (*fig.* 1119. *a*); slide butt (*b*);

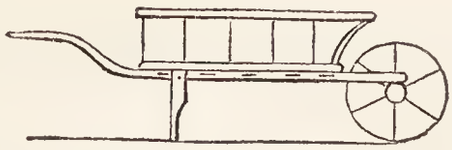
1119



quarry butt for earth or stones (*c*); dung-pots or dung-panniers (*d*) for dung or stones; and panniers with hooks, for faggot wood and sheafed corn (*e*), are also in use.

Box hand-barrows and grass barrows (*fig.* 1120.) are also used on a few farms.

1120



The Cornish plough is a small swing plough with a straight piece of wood as a mould board.

Barn boards for threshing on are four or five planks laid across beams, but about one third of an inch asunder; so that the corn as it is threshed may fall through and not be bruised. In some places wheat is separated from the straw by beating it on a barrel or inclined plane, usually by women. Fences generally made of stone, or raised banks of stone, slate, and earth, sometimes planked.

6. *Arable Land.*

The pilez, or naked oat, cultivated on worn-out ground; its straw very fine, and reckoned nearly as good as hay. A quantity of potatoes exported yearly; but not enough of wheat grown for home consumption.

7. *Grass.*

Chiefly near towns and villages, on sheltered slopes, and the uncultivated lands known as moors, downs, crofts, and wastes; some meadows watered.

8. *Gardens.*

Common to cottages and farms, and better attended to than in most counties; orchards also attached to many farms.

9. *Woods and Plantations* not abundant.

10. *Improvements.*

Draining practised to a considerable extent, and one or two examples of embanking.

The maritime situation of Cornwall presents the farmer with three valuable manures; fish, sea sand, and sea-weed. In some years the farmers who live in the vicinity of fishing towns have an opportunity of buying the bruised and small pilchards; which being deemed unfit for market, are rejected and called "coff;" four cart-loads of twelve bushels are considered as the proper quantity for an acre. The usual mode of management is to bury the coff in a pile of earth, deep enough to secure it from dogs and hogs, adding to the pile a sufficient quantity of sand, well mixing and turning all together after having lain some months. Without this practice the fish would not decay sufficiently for perhaps a year or two. The fish are sometimes used alone; they are then spread thinly over the ground before the plough, and turned under furrow. One pilchard cut up small will amply dress one square foot of ground.

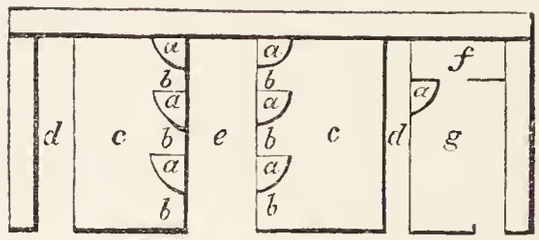
The old salt which has been used to cure the pilchard, and judged to be no longer fit for that purpose, is advantageously applied for a barley or a turnip crop; twenty to thirty bushels per acre. It is commonly hand-sown, in the manner of corn; and it should remain on the land five or six days before the seed is sown. It is best adapted to light lands, particularly furze crops. Twenty bushels per acre have been strewed over grass lands, and over a wheat crop, in the month of March, with evident advantage.

Another article of manure obtained from this useful fish is the liquor which drains from it while under the process of curing, consisting of blood, brine, and some oil which escapes, and which is caught in pits; the diligent farmer carts this away in casks, for the purpose of pouring over and mixing with his piles of earth and sand, which it greatly enriches.

11. *Live Stock.*

Devonshire cattle prevail; but it is only among the more enlightened and spirited breeders that the genuine North Devon are to be met with. Cows are kept in winter in sheds open to the south; one of which for seven cows and a fatting calf (*fig.* 1121.), described by the surveyor, contains cribs for hay or straw in winter, and lucern, vetches, &c. in summer (*a*); troughs for turnips, potatoes, cabbages, &c. (*b*); beds or platforms for the cows to stand and lie on (*c*); gutters sunk two or three inches to receive the dung (*d*); head-way and feeding place (*e*); dark place for fatting a calf (*f*); the division outside (*g*) for a cow that has, or is near having, a calf. She is not tied up.

1121



The cows are tied to posts by means of a strong chain and rope, which by means of a ring runs on a long staple.

Oxen very generally worked both in plough and cart; shod in brakes, and yoked in the bow.

Sheep a mixed breed; Cornish breed lost among crosses.

Horses a small hardy active breed, well adapted to the hilly nature of the county.

Cornish hog always white; a long-sided razor-backed animal; crossing by the Devon, Suffolk, and Leicester breed, has taken off length and sharpness, and added breadth and depth; a mixture of Chinese and Suffolk is another variety.

12. *Political Economy.*

Public roads tolerably good; lanes bad. Some travellers who met Pargan, the reporter, hoped he would notice with reprehension the straw-traps that the farmers lay in some of the cross roads, and which, concealing the deep ruts, endanger their horses, gigs, and their own necks.

Manufactures few; some of woollen carpets, and paper. The three great staple commodities for export, are tin, fish, and copper, the moor stone, China stone for porcelain, barley, oats, potatoes, and some wheat.

7826. *The islands of* JERSEY, GUERNSEY, ALDERNEY, and SARK, which lie in the Bay of St. Michel, and form the remnant of the ancient Duchy of Normandy, though naturally belonging to the continent of France, have yet for nine centuries been subject to the British Government. The agriculture of all of them is nearly the same; but we shall follow the Reporter to the Board of Agriculture in considering first that of Jersey, and next Guernsey. These islands are chiefly remarkable for their breed of cattle, their parsneps, and the degree of perfection to which many plants arrive in the open air, which are kept in England under glass. (*Quayle's General View, &c. of the Norman Islands*, 1812.)

7827. Jersey, 39,580 acres of warm and rather moist climate, diversified soil, and features: the soil is for the most part light, on granite or schistus, and there is some peat and marsh. No calcareous soil or rocks; granite and gneiss quarries worked; and granite pillars of fifteen feet in length extracted. Water abounds; and belief is still entertained in the efficacy of the divining rod for discovering springs.

1. *Property.*

Minutely divided, and mostly in the hands of a resident yeomanry. Some singular laws and customs as to tenures, as, for example, the *retrait lignager* and *retrait seigneurial ou feodal*; also the legitimation of children not born in wedlock, by the marriage of their parents, as in Scotland, and most other countries of Europe except England.

2. *Buildings.*

Those of all classes substantially built of stone, sometimes rough-cast, neatly lined in imitation of squared stone-work. Farm-houses generally covered with thatch or pantiles. Cottages generally of stone, with a vine in front.

3. *Occupation.*

Farms small, and fields diminutive; farmers frugal, and their wives good managers, and industrious.

4. *Implements.*

Plough with wheels, resembling that of Hampshire; sometimes drawn by two bullocks, and six or eight horses; a sort of large plough used for ploughing deep, for parsneps, and held in partnership by several farmers; instances of this plough being drawn by six oxen, and sixteen horses. (p. 64.)

5. *Enclosing.*

Fields very small and irregularly shaped, and the fences of high earthen mounds, often twelve feet wide at least, and six feet high, crowned with a hedge, or timber trees and pollards.

6. *Arable Land.*

Soil deep, and deep ploughing generally practised, but no improvement in it for ages; no naked fallows. The spelt wheat (*Triticum Spelta*), here called *blé tremais, frumentum trimestre*, here enters into rotation; it is sown in February, produces short stiff straw, is difficult to thresh, but never lodges.

Parsneps are grown by every farmer, and either by the spade culture alone, by the plough and spade, or by the small and great plough; any soil in good heart and tilth suits them, but peculiarly a deep loam; and in the same spot generally are raised beans, peas, cabbage, and occasionally potatoes.

When the ploughing or digging is completed, the field is once harrowed; straight lines are then drawn across, by means of a gardener's rake, usually from north to south; women then proceed with dibbles, and set the beans in rows, at a distance of four inches or five inches from bean to bean; in four, three, and sometimes in two ranks of beans, leaving intervals of five or six feet between each of the sown rows. In the use of the dibble, and in dropping the beans, the women have acquired considerable dexterity. In many instances, they are followed by children, who drop into each hole made by the dibble, after the bean, three or four peas; the parsnep seed is then sown, at the rate of one third to one sixth of a bushel to the acre.

The parsnep, not usually relished elsewhere as an article of *human food*, is here consumed by all classes of people; it is eaten with meat, with milk, and with butter; but not, as is the common mode of using it as human food in England, with salt fish: or, as in Ireland, together with potatoes.

The next most valuable application of this root is hog-feeding; at first it is given to the animal in a raw state, afterwards boiled or steamed, and finally, for a week or a fortnight with bean and oat meal. A hog, treated in this way, is sufficiently fatted for killing in about six weeks. Its flesh is held superior to that arising from any other food, and does not waste in boiling.

Bullocks are also fatted with parsneps, in about three months; their flesh is here considered of superior flavour to any other beef, and commands, on that account, an additional half-penny in the pound on the price. To milch-cows they are also usually given; on this diet the cream assumes a yellow colour; by the accounts here given, it appears, in proportion to the milk, to be more abundant than when the animal is kept on any other food whatever. When the cow receives at the rate of thirty-five pounds per day with hay, seven quarts, ale-measure, of the milk produce seventeen ounces of butter. It is generally allowed, that the flavour of the butter is superior to any other produced in winter.

Geese are sometimes shut up with the hogs, to fatten on parsneps, which they will eat raw. The root is also given boiled, and for a week before killing they are fed with oats or barley only. Horses eat this root greedily; but in this island it is never given them, as it is alleged, that when on this food,

their eyes are injured. About Morlais, horses are not only ordinarily fed on parsneps, but they are considered as the best of all food, superior even to oats.

Lucern a good deal cultivated, and found productive.

Hops to a moderate extent; the reporter could not find that the *Teucrium* Scorodònia was employed as a substitute, as related in some botanical works. A species of *Cyperus* (most likely *Carex arenaria*) used for twisting into halters and other ropes.

7. *Grass Lands.*

Of very limited extent, but meadows very productive.

8. *Gardens and Orchards.*

Very productive, and in general carefully attended to. Chaumontelle pears brought to great perfection, and with grapes, bulbs of the Guernsey lily, parsnep seed, and some flower seeds, sent to the London fruiterers and seedsmen.

Orchards generally attached to all farms. Jersey cider in much esteem, and a principal article of export. Most of the farm-houses have large arched doors, made wide on purpose for the passage of cider-casks. A valuable work on the subject of cider by the Rev. F. Le Conteur, entitled *Apercu sur la Culture des Pommes*, Jersey, 1806. The pomeril, lamme, noir-toit, and gros-amer, the cider-apples at present in vogue.

9. *Woods and Plantations.*

Very limited extent, and the waste ground a little more so; only about 300 acres of rocky summits of hills; these might be planted.

10. *Improvements.*

No calcareous manures found on any of the Norman islands. Sea-shells tried on clay with great advantage; and sea weeds (*vraic*, whence *vrack*). Irrigation in a simple manner, practised in the narrow valleys from time immemorial. Sea encroaching in some places, and jetties and embankments proposed, but nothing done.

11. *Live Stock.*

Alderney cattle well known. Though there can be no doubt that the breed was derived from the contiguous Continental coast, yet it is not known that in any part of it at present the same breed is preserved in equal purity. Next, perhaps, to the possession of *vraic*, the treasure highest in a Jerseyman's estimation is his cow. She seems to be a constant object of his thoughts and attention: that attention she certainly deserves, but she absorbs it too exclusively; his horse he treats unkindly; his sheep most barbarously; but on this idolised cow his affections are rivetted as firmly as those of an Eastern Bramin on the same animal. It is true that in summer she must submit to be staked to the ground; but five and six times in the day her station is shifted. In winter she is warmly housed by night, and fed with the precious parsnep. When she calves she is regaled with toast, and with the nectar of the island, cider, to which powdered ginger is added. Could she be prevailed upon to participate in all her master's tastes, there is no doubt but that he would willingly bestow on her the quintessence of *vriac* itself.

To guard the purity of her genealogy, and to prevent others from being conveyed to England, under the semblance of Jersey cows, he has invoked the interference of the insular legislature. On the 8th of August, 1789, an act of the States passed, by which the importation into Jersey of cow, heifer, calf, or bull, is prohibited under the penalty of 200 livres, with the forfeiture of boat and tackle. A fine of fifty livres is also imposed on every sailor on board, who does not inform of the attempt. The offending animal is to be slaughtered without mercy on the spot, and its flesh distributed among the poor. The same act of the States directs, that when cattle of the enumerated descriptions are exported, a certificate of their being natives of the island is to accompany them. On the vessel's return, another certificate is required, that the same identical number, and no more, have been landed.

There is, indeed, at present, little danger of the occurrence of that evil which the Jerseyman so much deprecates, as he will not speedily become a convert to any heretical opinions which he may happen to hear from an Englishman; for in this, as in every thing else, it may be observed, that the rooted opinions of a people are more powerful than any law.

The oxen are distinguished by rising to a stature and bulk much superior to the female. Persons who have not seen any other than Alderney cows, would be surprised to witness the size attained by some oxen of the same breed, which may be seen in the Jersey carts.

The object of the *dairy* is butter: the cows are milked thrice a day from the middle of April to the middle of July, and twice a day during the rest of the year; the milk is kept in glazed earthenware dishes till it throws up the cream, which is separated, kept five or six days, and then churned by itself. The prime milkers are not generally exported. After the young cow has borne a calf or two, it is sometimes significantly remarked, "*qu'elle est bonne pour l'Angleterre*;" and she goes to the cow-jobber.

As to *the merits of the Jersey cows* the reporter observes, if the palm can be contested with them by any, it will be by a breed little known in the south, the Dunlop (in Ayrshire) cattle, cross between the short-horned and the Alderney.

Sheep a bad-shouldered coarse-boned breed, small horned, and between a black and brown colour; largest flock in the island forty! weight of carcass fifty pounds; in the winter many perish from want, and many by dogs.

Horses a hardy small breed, very ill treated.

Swine, white, long-legged, flap-eared.

Geese are plucked alive, when the feathers begin to drop, as a measure of economy, and also to prevent the grazing-ground being injured. It is also thought a relief to the animal.

Pigeons. Here, as in France, the *Droit de Colombier* is attached to certain residences; but not exclusively, as appeared to be the case in France, to those held by a noble tenure.

Bees. The flavour of Jersey honey highly vaunted, probably from the numerous flowering plants, legumes, fruit-trees, garden plants left to seed, &c.

12. *Political Economy.*

Roads numerous, narrow, winding, crossing each other, and consequently intricate; flanked by high earthen fences over-canopied by trees. In rainy weather they are canals of mud. Two carts meeting each other on the *chemin du roi* could not pass; one or the other must back till it reached the nearest field, gateway, or some other recess, to which it might retreat during the passage of the other. To this little circumstance in their internal economy, and the disputes which it engendered, may, perhaps, in part, be attributed the remarkable proficiency of the Jersey populace in swearing.

Manufactures few: some boots, shoes, and cordage exported; an oyster fishery to the east of the island. English law as to poor-rates exists; but as the poor are few, it is not necessary to act on it. Dialect of Jersey a corrupted French, and a bad English.

7828. GUERNSEY. A rocky hilly surface, of which 8000 acres are under cultivation; the climate rather moister than that of Jersey, and the soil generally light, on granite, gneiss, or schistus. The operative classes resemble those of England more than those of Jersey.

Agriculture much the same as in Jersey; Guernsey figs much esteemed. Some land embanked and sold with permission of government, and the produce applied to improving the roads.

Live stock. Guernsey cattle are larger-boned, taller, in every respect more stout and coarsely made than those of Jersey. The front is wide, horns divergent and thick, but not long; never with the graceful short curve observed in some Jersey cattle, and in the short-horned breed. The dewlap is also coarse and pendant. They are deep-chested, and the carcass, compared with their neighbours, more bulky. Their coat is also not so fine: and the colours, though varying as in Jersey, on the whole appear more dark. Some, but not so many, are found cream-coloured, and the breed may safely be pronounced more stout and hardy. In one respect, a similarity appears in the best milkers in each island: these are observed to have a yellow circle round the eye; the hide yellowish; and, in particular, the skin of the tail at its extremity appears of a deep yellow, approaching an orange colour. The same circumstance has been since observed to exist in good milkers of other breeds; but in Guernsey at least, on examination, this yellowness is general and striking. The butter produced by the milk of each breed is also naturally of a rich yellow colour.

As to the question of superiority between the cattle of either island, it is settled most decidedly by the inhabitants of each, as may be supposed, in their own favour. The people of Jersey have gone furthest in support of their opinion. By the third section of their law of 1789, respecting cattle, they expressly apply "*aux îles voisines*" the same penalties and restriction on importation of cows, heifers, and bulls, as on importation from any other quarter. Into Guernsey, where no similar restrictions exist, Jersey cows have occasionally been imported. The comparison between cows of each breed, as milkers, leads to that result which, in the place where it is made, might be anticipated.

Next it may be noticed, that though the exportation of Guernsey cows, compared with that of the same animals in Jersey, is not extensive; yet that their price in Guernsey is higher. One was noticed for which a farmer had offered a price of thirty guineas, for his own use, and had the offer refused. As to the quality of the butter also, in each island, it may be observed, that the preference is usually given to that of Guernsey. In this article, indeed, in some degree the difference may arise from their different practices in the process of churning. The cream is here left unskimmed, till the milk becomes coagulated: on the third day milk and cream are churned together. As little attention has yet been given to the improvement of the breed of cattle, as in Jersey.

Roads improved under the government of Sir John Doyle. Bricks and tiles manufactured, and some spirits distilled, which formerly found its way into England under the name of French brandy.

Sect. II. *Agricultural Survey of Wales.*

7829. *A hilly mountainous surface* of 5,206,900 acres, with a climate colder than that of England, and more moist in the proportion of thirty-four, the average number of the inches of rain which falls in Wales, to twenty-two, the number for England. The soil is generally of an inferior description, and the great proportion of mountainous surface is fit only for pasturage and planting. Little exertion was made in cultivation till the middle of the eighteenth century; from that period to the present agriculture has been gradually improving. A general view of it, as in 1809, has been published by the Rev. W. Davis of Montgomeryshire, whose work we shall adopt as our guide.

7830. NORTH WALES. 1,974,510 acres, chiefly of mountainous surface, in six counties, including the Isle of Anglesea. The climate humid and cold in elevated situations, but warmer in the vales and near the sea. The soil moory, coarse, clayey, and otherwise unfavourable in most places, excepting in the vales on the banks of streams. Minerals chiefly copper, lead, and iron. The famous Mona and Paris Copper mines in Anglesea have been worked since 1768; lead is chiefly worked in Flintshire. Excellent slate

is found in various parts of Caernarvonshire, and worked to a great extent, especially on Lord Penrhyn's estate. Marble is worked in Anglesea; and limestone, freestone, and other stones and minerals abound in different places.

1. *Property.*

Estates from thirty shillings to 30,000*l.* The effect of the custom of gavelkind, which prevailed all over Wales, was a too minute division of property. Equality and poverty went hand in hand. But when the custom was abolished, and alienation permitted, an accumulation of property was the necessary consequence, which became very prevalent in the two last centuries: and having arrived at its maximum early in the eighteenth century, it has, since that period, shown some instances of retrogradation: but subdivision and accumulation of estates will naturally fluctuate. Here are petty lairds or tacksmen, as in Scotland and Ireland.

Gentlemen of moderate income, and residing in the country, transact the affairs of their own estates. Those of greater property commit the whole care of rents, repairs, and contracts of sale or purchase, to the management of agents; who, in general, are persons well qualified for the undertaking, brought up solely to the business, and make it a point of honour and integrity to do justice to the landlord, and a point of conscience not to oppress the tenant. Some of the lawyer agents, having by their own indiscretion and rapacity destroyed the very *vis vitæ* of litigation in the people, necessarily diminished the number of their successors.

Only two copyhold tenements have been noticed in the whole district. All the other estates are held either mediately or immediately *in capite* of the king, by a kind of mixed tenure, between the feudal and allodial, going under the common appellation of freehold.

2. *Buildings.*

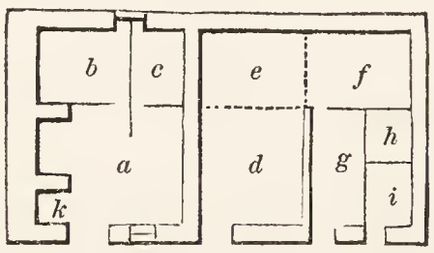
Some fine castles, as Powys, Penrhyn, and Chirk. Of farmeries, about seven in ten are in a very wretched state; good new ones in Anglesea, and Caernarvonshire, Flintshire, and Merionethshire.

Cottages in these and other counties are truly the habitations of wretchedness. One smoky hearth (for it should not be styled a kitchen), and one damp litter-cell (for it cannot be called a bedroom), are frequently all the space allotted to a labourer, his wife, and four or five children. The consequences are obvious; filth, disease, and, frequently, premature death: and they would be more obvious, had not these evils an almost unsubduable vigour of constitution to encounter. Three fourths of the victims of the putrid fever perish in the mephitic air of these dwellings. However, in some parts, especially near lime-works, mines, collieries, &c., the example of one neat cottager is followed by others. Here, their dwellings are frequently white-washed; their children are industrious in collecting road manure, which is preserved within circles of loose stones, for the use of their gardens. These minutiæ, though trifling, are worthy of record, as they are descriptive of their general character.

Some exeeptions in different places, and especially on Lord Penrhyn's estate. The reporter gives an excellent plan of a cottage for a cottage farm, and also plans of farms of different sizes, adapted to such cottages.

The *cottage farm-house* (*fig.* 1122.) contains a kitchen (*a*), bedroom or parlour (*b*), pantry (*c*), barn-floor (*d*), two bays (*e* and *f*), cow-house (*g*), calving place and calf-house (*h*), pigsty (*i*), and stairs (*k*) to garret and bedrooms.

1122

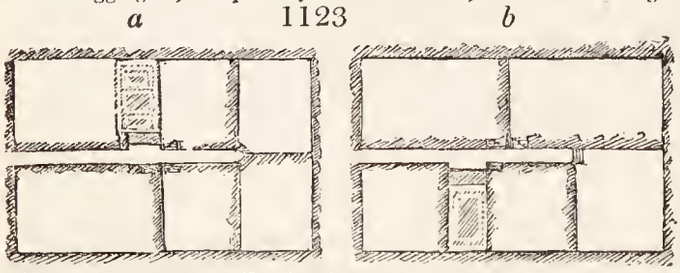


One *cottage farm* for the same house, and nine acres of land, contains seven small enclosures (*fig.* 1123. *a*) including the garden. One for six acres, contains six enclosures (*b*) including the garden.

3. *Occupation.*

Largest farm of cultivatable land about 600 acres, on the mountains 1000 acres and upwards, at one shilling, or one shilling and sixpence per acre: size on the increase, and admitted to be favourable to wealth by the reporter, who adds, "yet that wealth should be valued, not in proportion to its national aggregate, or quantity in the abstract, but as it is

a 1123 *b*



widely and generally diffused. An analogy exists between monopoly in all its forms and a macrocephalous constitution, which never can possess the energy of a body symmetrically proportionate.

Farmers, properly so called, are, as we may naturally expect them to be, rather too tenacious of old customs. It is, however, illiberal to charge them with obstinacy, in delaying the adoption of pretended improvements; for, as it is not all gold that glitters, neither are one half of the patent implements and machines, nor one tenth of the writings of visionary theorists, better than lumber and trash; for which the farmer should not throw away his hard-earned money, before they are put to the test of experience, by those who have opulence enough to bear disappointment; and who, from the advantage of superior education, may be better qualified to form a judgment of the probable effects. Show the farmers their true interest, and, in general, their minds are as open to conviction, and as susceptible to reason, as any other class of men whatever.

Leases out of repute. It cannot be denied that leases have done good in Scotland. We are, therefore, driven to the necessity of supposing, that the Scotch and Welsh tenantry are very different kinds of beings. The circumstance that renders the Welsh leases ineffectual, is the want of capital; and what enhances the evil of this want is, the ignorance of many farmers in the right application of what small capital they have. By tilling too many acres, they, as well as the public, suffer loss in every acre. Many a farmer, who has means barely sufficient to manage a farm of 50*l.* a year tolerably well, thinks a farm under 100*l.* or 150*l.* beneath his notice; and granting a lease to such a tenant, who has not one fourth of the capital requisite to carry on improvements, would be preposterous.

Lord Penrhyn executed draining, fences, roads, and all improvements requested by his tenants, and approved of by his agents, at five pounds per cent on their amount added to the rent.

4. *Implements.*

The original Welsh plough, a clumsy wooden fabric, still in use in Caernarvonshire, and a few places in other counties; about 1660, Lammas's variety of the Rotheram introduced, and now common; Scotch plough now generally known and approved; the other improved implements tried by the amateurs.

5. *Arable Land.*

"That farmers convert too much of the lands which were formerly in tillage, into pasture, is but a groundless cause of alarm. Farmers should, and always will, consult their own interests; and whether the conversion of their lands into tillage or into pasture be found the most profitable to themselves, the same will eventually be found most beneficial also to the public."

The corn raised in North Wales not equal to its consumption: fallows general and defended as necessary. In Anglesea, a rotation of five white crops in succession; most of them barely return the expenses. Very little wheat grown, main corn-crop oats, and next barley. Scarcely any flax or hemp grown; potatoes beginning to become a general crop. On the whole, the management of arable land wretched, excepting by the amateurs or proprietors.

6. *Grass.*

Land well adapted for tillage; is commonly left too long in pasture; by which neglect it becomes mossy, and in some instances covered with ant-hills. It has been said of some meadow-lands in Wales, that a man may mow in them all day, and carry home his day's work at night. This may appear hyperbolical; but it is so far true, that in some meadows the mark of the swath never disappears; and a mower may be certain of having followed the same line, to a half-inch width, for twenty or any number of years back. In such meadows, the trouble of raking the hay together is the great work of harvest.

In the eastern parts of the counties of Denbigh, Flint, and Montgomery, consisting of the most fertile vales, the principal object of the farmers is to convert their hay and grass, as much as possible, into butter and cheese.

In the hilly parts of the afore-named counties, and in Anglesea, Caernarvon, and Meryonydd, their peculiar province is to rear cattle, to be sold lean to the graziers of other districts. There are but few acres of land that will fatten cattle; the vales of the Severn and Vyrnwy in Monmouthshire, the banks of the Dee in Flintshire, and the vale of the Clwyd in Denbighshire, are the principal places where the pastures afford sufficient nutriment for that purpose.

7 *Gardens.*

Much wanted for the cottagers, especially in Caernarvon and Merionethshire. Too many poor cottagers have not as much as a leek or a potatoe, except what they either beg or buy. In the greater part of the district, the planting of orchards would be thought a very wrong application of the soil. On the borders of England are some orchards; and in plentiful years, a few farmers make either cider or perry for their own beverage.

8. *Woods.*

Have been abundant in former times, especially in Anglesea; now very scarce there and in Caernarvonshire; more in Denbighshire, especially round Chirk Castle, Wynnstay, Erthing, Vale of Clwyd, &c. Extensive young plantations made in these counties, especially at Wynnstay and Lord Penrhyn's. A great deal of wood; various young plantations in Merionethshire, and much timber, wood lands, and plantations in Montgomeryshire, which will long be the best wooded county in North Wales. Proprietors planting upon a large scale, and not raising trees from seed in their own nurseries, formerly used to procure seedlings of larch, firs, and pines, &c. from Scotland; but owing to their heating in close bundles, and otherwise damaging upon the road, not above one fourth, and frequently not above one eighth of the number could be expected to grow. They are now more given to encourage nurserymen at home, and nurseries are accordingly established in different parts of the district. "One and two year old seedlings of all sorts of forest trees, nearly as cheap as in Scotland, reckoning carriage, and one thousand worth two of theirs." This is true when the tenderness of seedlings, distance of carriage, and length of time, are considered. Williams, and other nurserymen, insure trees of their own growth and planting for a number of years.

9. *Improvements.*

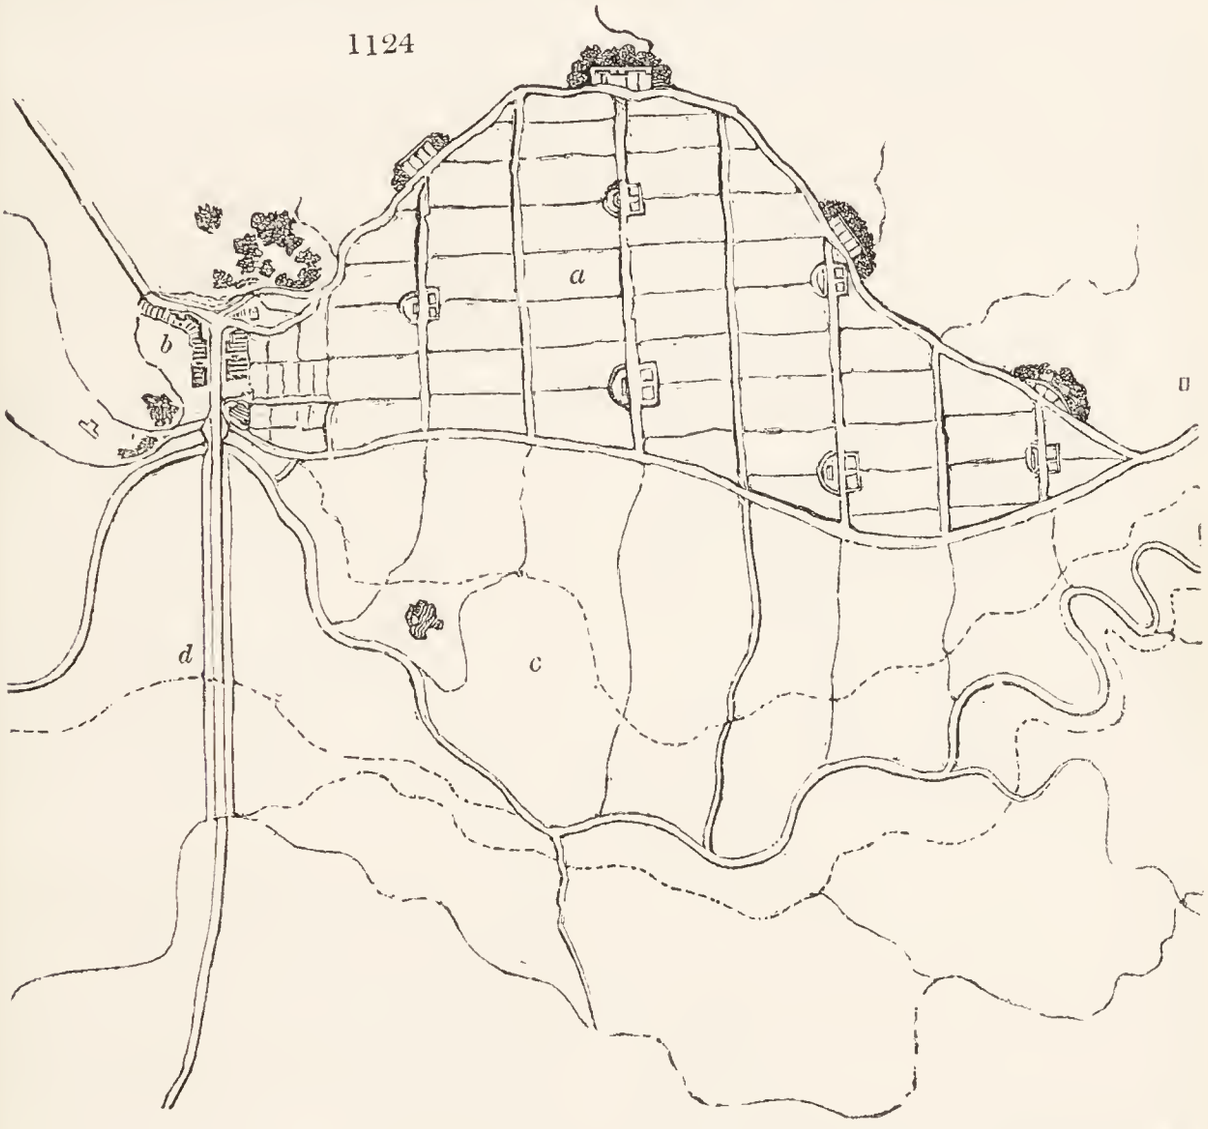
A marsh of 3000 acres in the southern corner of the island of Anglesea attempted to be embanked in 1790. The embankment was brought forward from both sides at the same time, and was intended to be joined in the middle of the marsh, where the force of the tide was greatest; when within about twenty roods of a complete junction, owing to some of the proprietors withholding their dividends, the work was deserted, after expending nearly 12,000*l.*, and when a few pounds

more would have completed the whole, as the materials were already carried on the spot. On the 23d of January, 1796, an uncommonly high tide added twenty roods more to the breach, in which state it now lies. The bank was made of furze faggots, bound with double cordage, covered with sand, then with sods, and on the sea-side with a stone pavement, eighteen inches deep at the top, and diminishing to nine inches at the bottom. It was fifty-one yards wide at the base, four yards at the summit, and five yards high; the slope of the sea-side to that of the land-side, as seven to four.

The *embankment and improvement of Traeth-Mawr and Traeth-Bychan sands*, between Caernarvon and Merionethshires, have been above 170 years in contemplation, and never yet performed. In 1625, Sir John Wynne, of Gwydir, intended to have brought over Sir Hugh Myddleton, the celebrated engineer, to undertake the work; but no materials were wasted, save ink and paper. In the year 1719, some Dutch adventurers made a proposal to the proprietors, but to no effect. In 1770, the late Bell Lloyd, Esq. who was always active in works of public utility, and others, brought the subject afresh under consideration; at the same time proposing a nearer road from London to Dublin, across the Traeth-Mawr sands, when embanked. Golborne, the engineer, was sent down by the Duke of Ancaster, and two estimates were made. The late Dr. Worthington was peculiarly active in forwarding the work. He had gone so far as to procure subscriptions to the amount of 29,000*l.* and upwards, when the whole scheme was frustrated by the mean spirit and refractoriness of some neighbouring proprietors.

In 1809, W. A. Madocks, Esq. M.P., having a considerable estate on the Caernarvonshire side, and having there embanked Penmorva marsh with great profit (*fig.* 1124. *a*), and founded the village of Tremadoc (*b*), commenced embanking the sands of Traeth-Mawr (*c*), by carrying out from both shores an immense bank (*d*) of stony materials deposited and left to find their own slope by the washing of the tides. The two banks were within less than a furlong of being joined in the middle; but owing to the force of the tides, and the embarrassments of the very spirited proprietor, it was not completed before he was ruined. The persons, however, into whose hands the property fell brought it to a successful conclusion; and its proprietor, who had settled in the neighbourhood, and is lately dead, yet lived long enough to see realised by others all that he had anticipated, and for which he had sacrificed a very considerable fortune.

1124



The *River Dee Company*, established by Act of Parliament in 1740; by several embankments made in the years 1754, 1763, 1769, and 1790, on the river Dee, in Flintshire, to keep out the tide and land-floods, they have been enabled to gain 3100 acres, which are now covered with good crops of corn of lucern, and of artificial grasses; and the whole redeemed waste is incorporated into a township, bearing the very appropriate name of Sealand.

"In various parts of the coast of Anglesea, and the other maritime counties of North Wales, there is still much to be done by embanking. Caernarvonshire has been eminently fortunate in the acquisition of W. A. Madocks among its leading improvers. Indeed his improvements are of such magnitude and variety, designed with such taste, and executed with such facility, that a minute report of them would appear, to those who have not personally visited the place, more like the reveries of romance, than the narrative of genuine description. In harbours, embankments, canals, buildings, roads, plantations, and rural and commercial improvements in general, nothing less than a *Tremadoc Guide* pamphlet can do justice to the founder."

10. *Live Stock.*

Cattle and copper the staple exports of Anglesea. When numerous herds are bought in the island for the English markets, they are compelled to swim in droves across the strait of the Menai; and although numbers of the weaker sort are sometimes swept down by the force of the current for some miles, yet losses seldom or never happen. A chain bridge has been thrown across this strait.

The characteristics of a choice Anglesea ox, must agree in most points with those of a Roman one, as described by Columella: coal-black colour, with white appendages; remarkably broad ribs; high and wide hips; deep chest; large dewlap; flat face; and long horns, turning upwards. Bakewell thought, that in some points they were nearer his idea of perfection in shape, than any other he ever saw; his own improved breed excepted. Some farmers aspiring at a select stock, by having their he-calves gelt under their dams, their horns become of a yellower colour, longer, and finer than common; and, upon the whole, nearer the present idea of symmetry. The average weight of their quarters, when fat, at three or four years old, is from eight to eleven score pounds.

The promontory of Lleyn and Evionydd, in Caernarvonshire, having the same kind of undulated surface, though not altogether so good a soil as Anglesea, has likewise a breed of cattle similar in several of their characteristics.

The cattle in the remaining part of Caernarvonshire, and in the whole of the county of Meirionydd, some few select stocks excepted, seem to be diminutives of the above breeds of Anglesea, Lleyn, and Evionydd; having nothing to recommend them, save their extreme hardiness, and consequent cheapness of rearing. The highlands of the counties of Denbigh and Montgomery abound with the same puny race. In the vales, and in the county of Flint, the cattle are of a superior kind, larger, and of all varieties of colours. The natives of the sea-coast from Abergelen to Holywell, and thence along the Dee towards Cheshire, are reckoned very quick feeders.

Neither good butter nor cheese are made in North Wales by ordinary farmers.

Sheep. The largest of the native breeds is that of Anglesea; they have white legs and faces, and are generally without horns.

The second kind of sheep in North Wales is that peculiar to the mountains. They have generally white faces and legs; some have horns, and others none. The smaller sort of them weigh from seven to nine pounds per quarter; and give wool from three quarters of a pound to one pound and a half.

The third kind is peculiar to the Kerry hills in Montgomeryshire; being, perhaps, the only species in North Wales which produces perfect wool: that of every other Welsh

breed being more or less mixed with coarse long hairs, called by the manufacturers kemps, making the articles in which they appear of much less value. The characteristics of this breed are, large woolly cheeks, white hunchy foreheads, white legs covered with wool, no horns, and a broad beaver-like tail. They are very hardy, and comparatively tame; being not so much disposed to ramble as most other wild sheep. In shape, however, they are far short of compact symmetry; and were this defect improved by the care and attention of the farmers, the breed would be worthy of being universally adopted throughout the principality. They weigh, when fat, from ten to fourteen pounds per quarter. The average of wool, including the whole flock, is ten stone, of fifteen pounds each, from every 100 sheep.

The fourth kind is the black-faced and fine-woolled sheep, bred on the Long Mountain, near Welsh Pool; and on other hills, on the borders of England, in a line from thence to Wrexham.

The flavour of the mutton of the sheep feeding upon the Llanymyneich and Porthywaen lime-rocks is reckoned very delicious, by the nice-palated pupils of the Epicurean school: and their wool is as fine as any in England; that of the Ryeland breed, perhaps, excepted. A person in travelling through the country may observe several other kinds of sheep; being crosses from some or other of the above four distinct breeds: but they are in general the offspring of chance and instinct, without being directed by any choice or system.

The Merinos with their different crosses; the Leicester, Downs, and others, bred by amateurs.

Horses. In Anglesea, for want of fences, the horses, as well as the sheep, are commonly fettered. Were colts of the best-shaped breed in existence thus fettered as soon as they are weaned from their dams, and the practice used from generation to generation, their natural gait and shape must necessarily be changed, at length, into awkwardness and deformity. Few English stallions have as yet been introduced into the island; and those that have do not appear to have done much towards improving the native breed.

In the county of Meirionydd, and the hilly parts of Montgomeryshire, great numbers of ponies, commonly called merlins, are reared. They are exceedingly hardy, having, during winter as well as summer, only the range of the hills, from whence they are never brought down until they are three years old, and fit for sale. What has tended to, and will in time destroy, the shape and good qualities of this hardy race, is, that in the propagation of their species they are left entirely to chance and instinct.

They are driven from the hills to fairs, like flocks of wild sheep; and the place of sale exhibits, in some degree, an amphitheatre, where manhood and ponyhood strive for the victory. When a chapman has fixed upon his choice at a distance, the wrestler, being generally the seller's servant, rushes into the midst of the herd, and seizes the selected animal; which, never before touched by human hand, struggles with all its might to extricate itself; and in some particular situations, both have tumbled topsy-turvy from the summit of a steep hill down into a river beneath: the hiped still continuing his grasp, and the quadruped disdaining tamely to submit.

Another breed, somewhat larger than these, and probably raised by a series of crossing between the English and the natives, are hardy, handsome, and exceedingly active. Some of them are too small for the team; but for the road, under moderate weight, they have no rivals. "They will ascend and descend our mountainous staircases" with the greatest agility; and without giving their riders, who have more fool-hardiness than humanity, the trouble of alighting. The larger kind of them is exceedingly well adapted for the team, on small or steep mountainous farms; where the great strength and sluggishness of the heavy kind of horses would be egregiously misapplied.

The vales of Montgomeryshire have long been noted for an excellent breed. Some attribute this superiority to a stud of horses kept by Queen Elizabeth at Park, near Caer Sws, in the Severn vale, and to others brought into this part of the country from Spain by Robert Earl of Shrewsbury.

Gentlemen in most parts of the district, and farmers in the vales of the three counties bordering on England, have for some time furnished themselves with excellent draught horses, both for the coach and the waggon; which, when the markets are open, are sold in great numbers. They are generally either black or bay, strong, active, well made, and measure from fifteen to sixteen hands high.

A custom, very injurious to the growth, strength, and soundness of horses, prevails over the greatest part of the six counties; that is, working them too young, when their bones have not attained firmness from their cartilaginous state, nor their power of elasticity, contraction, and extension, which is necessary to endure exertion and labour. Instances have, however, occurred of horses being worked from two to twenty years old, without any apparent detriment saving a diminution of their natural size.

"The predilection which farmers manifest in favour of horse teams may, in time, reduce the nation to the dilemma of enacting a law to repeal the Mosaic law, and enjoin the flesh eatable."

Tender furze, bruised with mallets or ground in mills erected for the purpose, was formerly a great article of fodder in the counties of Anglesea and Caernarvon. Farmers were then accustomed to sow furze for their horses, and sometimes to let the crop at a certain price per acre, which was frequently found to pay better than a crop of wheat; but Ceres at length seems to have grown ashamed of such husbandry, and the lands are in general converted to bear more useful crops.

Hogs. The original Welsh breed had small ears, which, probably by a cross with the Berkshires, produced the slouch-eared hogs, which were lately general through the country. They are slow feeders, and the rearing of them is now upon the decline, and giving place to that of more improved breeds, especially Berkshire.

Bees. "The ancient Welsh held these industrious insects in great veneration, and believed them to be of Paradisiacal origin." (*Wotton's Leges Wallicæ*, p. 254.) For this reason their priests taught that the chanting of mass was not acceptable to the Deity unless the lighted tapers were made of their wax. Out of their dulcet stores they brewed their national liquor, metheglin, or the medicinal beverage.

When the country was almost one continued wilderness, almost every hollow oak was an apiary. Their nests on the wastes were the property of the lords of the soil, and rented by some of their vassals. On freehold lands they were claimed by the respective proprietors. The discoverer of a swarm was entitled by law to a reward of one penny, if they were domesticated bees; and one penny and a dinner, or in lieu of these the whole of the wax, if they were of the wild race. Whoever cut a tree upon another person's property, in order to get at the nest of bees, was to be amerced the full value of both tree and bees. The respective prices of different swarms were ascertained by law.

Early swarms were reckoned of full value by the first of August; such as swarmed after that day were not valued above fourpence until the following May.

In comparison with the prices of other articles at the time the Welsh laws were framed, bees seem to have been very dear, and consequently scarce; but the price set upon them by law was much above the real price in commerce between buyer and seller. This was owing to the veneration they were held in by the legislature, and intended to deter the subject from offending against the statutes made to preserve them. As a confirmation of this opinion, every thing that belonged to bees had its value exaggerated in law; even a bee-hive was appraised at two shillings, when a new plough without irons was valued only at twopence, a cow forty-eight pence, a yearling calf fourteen pence, and a suckling calf one penny.

The sacred esteem in which bees were held at length declining, apiaries were gradually reduced to their present fewness of number. However, several persons still execrate the profane act of disposing of their bees for money; but will nevertheless let them out for one half share of the honey and wax when they are killed annually in autumn, and the whole live stock to be parted equally between them at the end of the fourth year.

In Wales, as in Poland, when spirits and beer became more common, the use of metheglin declined, and bees were neglected. Hence it may be inferred, that the veneration in which this insect was held in these and other countries was owing to its affording almost the only, and at all events the cheapest and most powerful, means of indulging in that which man, in all ages and countries, has considered the *summum bonum* of enjoyment — intoxication; an enjoyment which, whether, with Noah, it be procured legitimately from that "transcendant liquor" wine; with the American Indians, from cider; or, with the Turks, from opium, has these advantages over all others, that it is more immediate and more intense; that it is within the reach of every one; that every one can have it to the full; and that for the enjoyment of it no man is envied by his neighbour.

11. *Political Economy.*

Great improvements have been made in the roads and bridges of late years, especially by Lord Penrhyn, Wynn, Madocks, and government, under the direction of Telford. Previously to the year 1785, the annual export of slates from Lord Penrhyn's quarries at Dolawen did not exceed 1000 tons; which, owing to the ruggidness of the road, were conveyed from the quarries to the port, a distance of six miles, in panniers on horses' backs. His lordship formed a new road, which gave immediate employ to about 120 broad-wheeled carts and waggons; and from the quarries he extended the road nine miles further to Capel Craig, through Nantffranco and the romantic interior of Snowdon, at his own expense, the whole tract being his property. The increase of the slate trade caused his lordship afterwards to have an iron railway, the length of six miles, from Dolawen quarries to Port Penrhyn.

The chain bridge erected across the Menai by Telford is one of the most extraordinary works of the kind in existence.

Of canals there are several, with stupendous aqueducts and bridges. The aqueduct of the Ellesmere canal, thrown over the Dee, is the first in Europe. It was opened in November 1805.

Manufactures chiefly blue cloth, blankets, flannels, and Welsh plains or cottons. The best Welsh flannels manufactured in Montgomeryshire. Welsh flannels made since the time of James the First have the warp of fleece wool, and the woof a mixture of one third or one half of Welsh wool. Knitting stockings and caps very general among the females of cottages and small farms. Argillaceous schistus is converted into slates for the roofing of houses and other purposes, to a very great amount within this district.

Pyroligneous acid extracted from brushwood, at Hope in Flintshire, for the use of cotton dyers. A variety of other manufactures to a moderate extent. Several agricultural societies.

7831. SOUTH WALES. Six counties, and some islets, comprising together 2,470,400 acres of hilly and mountainous surface; generally of a salubrious climate; cold on the mountains; but, on the whole, more temperate than the air of North Wales. The soil argillaceous red loam, or calcareous, but generally rich in the vales and declivities. Of minerals there is abundance of iron, coal, lime, and a good deal of lead.

1. *Property and Buildings.*

As in North Wales. In South Wales the custom of white-washing cottages is prevalent. In Glamorganshire, not only the inside and outside of houses, but barns and stables also, walls of yards and gardens, the stone banks of quickset hedges, and even solitary stones of large dimensions, house blocks, &c. near the houses, are white-washed. This practice is traced to a very remote antiquity. Diodorus Siculus is quoted as mentioning the British custom of white-washing houses. Gentlemen's seats are distinguishable from cottages, not only by their size and plans, but also by their colours. In Glamorganshire gentlemen mix ochre with lime, to make their

seats of Isabella yellow. In the north of Pembrokeshire, &c. the taste is reversed; the cottages are of a very dingy colour, and gentlemen's houses are white-washed; the maxim is — not to be what the lower classes are; not to coincide with the vulgar in their practices.

2. *Occupation.*

Farms of all sizes; two mountain farms of 1400 acres each; general run from thirty to one hundred acres; average of the district between fifty and sixty acres. In the uplands rearing of stock is the main object, without neglecting the produce of the dairy; whilst they find convenience, though without profit, in a scanty and precarious tillage. In the lowlands, or moist loams, especially in the more humid climature of the western counties, grazing is considered, and generally recommended, as the most profitable.

Upon an average of the whole, the district may be said to be occupied in that kind of system called mixed husbandry; breeding, dairying, and tillage; varying in the proportion of each in different places, according to the imperiousness of existing circumstances, which will be hereafter more fully explained.

Farmers may be classed as proprietors farming a part of their own estates, small proprietors or yeomen, farmers of the old school, and book-farmers.

"*Book-farmers*, the aerialists of Marshal, are those who know agriculture only by reading about it. Theory is their *ne plus ultra*, as they generally grow tired before they are much acquainted with practice. The practice of the country they come to reside in is all wrong, and the inhabitants all savages. They bring ploughs and ploughmen generally from a distance; and when the masters retire, the ploughmen return and the ploughs are laid aside. They hold the farmers of the old school, as they call them, in sovereign contempt; who in return deride their puerilities, and, in their own quaint phrase, style their ineffectual attempts to establish a system of improved agriculture '*a flash in the plan.*' They do considerable good in the vicinity they dwell in by employing labourers; and by their imported implements they open the eyes of mechanics. Most of the harm they do is to themselves. They injure others mostly by an exorbitant advance in the wages of servants, especially of such as pretend to be farm bailiffs. They give double the wages that the old established farmers in the best cultivated counties, Salop or Hereford, &c. will give. They have generally very exalted notions of the value of land, and the powers of soil. They read of the high returns of crops in England or elsewhere, and calculate there upon the value of land in the uplands of Wales; which, if they have farms to let, makes it extremely difficult to deal with them. Their opinion of manure depends on the book they have read last. If Jethro Tull is their favourite author, soil requires nothing but ploughing and stirring. With *A. lime is every thing*; with his brother B., only a few miles distant, and on the same kind of soil, *lime is nothing.*"

3. *Implements.*

The Welsh plough is in common use; and perhaps a more awkward, unmeaning tool is not to be found in any civilised country. It is not calculated to cut a furrow, but to tear it open by main force. The share is like a large wedge; the coulter comes before the point of the share sometimes, and sometimes stands above it; the earth-board is a thing never thought of, but a stick (a hedge-stake or any thing) is fastened from the right side of the heel of the share, and extends to the hind part of the plough: this is intended to turn the furrow, which it sometimes performs, and sometimes not; so that a field ploughed with this machine looks as if a drove of swine had been moiling it.

The Rotheram and other improved ploughs are in use among the proprietor and book-farmers, and the Scotch plough is coming into very general use. A gentleman, a naval officer, in Cardiganshire, introduced the light Rotheram, and insisted on his ploughmen using them. As soon as he turned his back, the new ploughs were dismissed the service, and the old ones brought into the field. One day, in a rage, he committed the old to the flames, and set the new ploughs a-going. Afterwards taking a ride to cool himself, and returning, he found the new ploughs in the ditch, and old ploughs borrowed from the neighbours at work: the master then thinking it useless to persevere, gave up the contest. "I have," said he, "seen various kinds of human beings, in different parts of the globe, from latitude ten to latitude fifty-four, but none so obstinately bent on old practices as the Welsh."

H. Lewis, Esq., of Gallt y Gog near Caermarthen, being equally unsuccessful in effecting a revolution at once, tried the plan of altering the old ploughs in a slight degree, and hopes, by one alteration after another, at length to transform them into Rotheram ploughs "unawares to his sturdy ploughmen."

Waggons and clumsy two and three horse carts are in general use; almost every farmer of forty pounds a year rent has a waggon. Single horse carts gain ground but slowly. They were introduced into the vale of Towy, several years ago, by Lord Robert Seymour; into Cardiganshire, by the late Thomas Johnes, Esq.; and into Brecknockshire, by Sir Edward Hamilton.

A hay rake, with the head forming unequal angles with the handles, is in use in Glamorganshire, the only advantage of which is said to be that of not obliging the raker to step his foot backward at every reach.

4. *Arable Land.*

In general wretchedly managed, especially the fallows. The reporter proposes to send farmers' sons to improved districts to serve apprenticeships, as better than examples set by strangers, which have been tried without success. A patriotic land proprietor brought what were considered as enlightened farmers from Scotland into South Wales; but as Hassel very judiciously observes, "New practices in husbandry will be most likely to succeed through the medium of the natives of the country. They have an unconquerable dislike to every thing introduced by strangers; and not without some reason, as most of the people who have come into this country from the English counties, and commenced farmers, were in bad circumstances at the outset, and therefore have not succeeded in their undertakings; and the natives, eager to reprobate any thing new, readily attributed their failure to defective practice, rather than to the real cause, want of capital. This observation will be found to be generally true in every country. Few persons in good circumstances can be tempted to migrate; whilst others of a different description are frequently under the necessity of doing it; and, generally, it can only tend to hasten their total failure. Then the teaching of the natives, as recommended above, would have a much superior effect in establishing the doctrines of the new schools, than the introduction of any strangers into the country.

The sand banks checking the progress of the tides into a flat tract in Glamorganshire, in order to render them more firm, they are matted with the roots of the sea mat-weed (*Arúndo arenària*). The Hon. T. Mansell Talbot binds each of his tenants, who rents land in the adjoining marshes, to give yearly the labour of a day or more, in proportion to his holding, as a kind of statute duty, for the planting of this reed; and experience has proved its good effects.

5. *Grass.*

By a correct map of the rivers of a district, with a scale of their fall in a given number of furlongs or miles, and of the mountains from which they flow, and those distinguished by kinds of "quality colours," a geologist might give a fair estimate of the quality of the soils and grasses of the respective valleys intersecting that district, though anomalies frequently form exceptions in valleys as well as on sideland places.

The practice of fogging pastures, almost peculiar to Cardiganshire, has been already described. (5837.) The reporter saw a piece that had been fogged successively for sixteen years; and according to the tenant's information, was improving annually. When land has been mowed too long, one year's fogging is supposed to recover it. Mossy pastures are benefited by it. It replenishes the soil with seeds, that by this means are suffered to ripen and shed on the ground; and it is said that two years' fogging will recover lands, let them be ever so run out by tillage or mowing. Cattle used to fog will quit hay that may be given them, and clear away the snow with their feet to get at the fog. The fields proper to be kept in fog must be of a dry, sound, and close soil; the argillaceous rather than the siliceous earths should prevail in it: but not so much as to be over-retentive of water.

The late Thomas Johnes, Esq., of Hafod, observes, "Fogging is getting out of repute: it must have originated in chance, and want of a summer stock of cattle."

Clover is grown in some few places for seed, which is separated from the heads in a common corn mill, the upper millstone being replaced for a time with a square piece of oak furnished with eight wings studded with nails on their upper surfaces. These spokes, by their rapid motion, soon beat out the seed.

8. *Gardens.*

On the maritime coast of South Wales generally very productive; those of the cottagers better attended to than in other parts of the district; a pleasing mixture of flowers, small fruits, and vegetables.

Orchards in Radnorshire and Brecknockshire thrive well in the valleys, but more especially in the vales of Wye and Usk. Not much cider made, except on the Wye.

7. *Woods and Plantations.*

"It appears from old deeds, that estates were formerly sold at an inferior price, in consequence of their being crowded with timber. Times are now changed."

There are a great many oak woods and coppices in hilly parts of the district, and many thriving plantations in every part of it. It is calculated that at an average six millions of trees are annually planted; if this be the fact, it is probable nine tenths of them either die or are doomed to come to nothing: for at this rate, in fifty years, there would be 150 trees for every acre in South Wales, which, added to the old wood and copse, would give 300 trees, or enough to render the country one entire forest.

8. *Improvements.*

Numerous enclosures have been made, and fencing, draining, and, in some cases, watering practised as in other counties. There are nearly 15,000 acres of fen and sands on the coast of Cardiganshire, which are considered highly improvable, and which it has been at different times in contemplation to embank. Of one of the worst parts of this land, the late agriculturist Dr. Anderson, who was much with Johnes of Hafod, said he could make it carry wheat in five years.

9. *Live Stock.*

From ancient records it appears that the colours of Welsh cattle were white, with red ears, like the wild breed at Chillingham (6804.); they appear to have been in a wild state so late as the time of king John. The present stock are of four kinds: the coal-blacks of Pembrokeshire; the brownish blacks, or dark browns, of Glamorgan; the black runts of Cardiganshire, Caermarthenshire, and the western parts of the counties of Brecon and Radnor; introduced breeds, from Herefordshire and Shropshire, into the eastern and more fertile parts of Brecon and Radnor.

Cows are kept for breeding, and making butter and skim-milk cheese. Johnes has proved, that at Hafod cheese may be made at will so nearly resembling Parmesan, Stilton, Gloucester, or Cheshire, that the difference cannot be perceived by good judges; and that the whole mystery consists in various modes of producing it from the milk.

The sheep of South Wales are of four kinds: mountaineers, Glamorgan vale sheep, Glamorgan Down sheep, and crossed and intermixed breeds.

Mountaineers occupy the hills in the several counties of the district.

The Glamorgan vale sheep is the only breed in Wales, not introduced within memory of man, that produces combing wool.

The Glamorgan Down sheep is a beautiful and excellent small breed. Feeding upon the oldest and sweetest pastures of the limestone tract, their mutton is superior in quality to most, and inferior to none; their wool is of the short clothing kind, and fine. They are generally polled.

With crossed and intermixed breeds many experiments have been tried within the district, and most of them confessedly without the expected success. Particular breeds of sheep have their peculiar diseases, which continue in their constitution, wherever they are removed. The limestone tract may be considered as the healthiest for sheep within the district, but even there the imported modern breeds have brought with them the scab, the foot-rot, the goggles, maggots, and a long train

of diseases never heard of before in Wales; these are to be ranked among the profits of commerce.

Horses. The small Welsh merlins or palfreys are now in many parts nearly extinct: they are a pigmy race, and may now and then be found in the hilly walks of the interior of the district. There were formerly a very good breed of hardy strong punches, fit for riding and walking upon the farm, being a cross between a good-sized horse and the small merlins; and very useful they were; but the breed has almost been totally neglected and lost: for they cross now too much with the large and sluggish cart-horses.

10. *Political Economy.*

Roads as in North Wales, or worse. Road ploughs in use; a characteristic both of their state and of the nature of the materials. Good limestone, however, in the coal districts, and especially in Glamorganshire. Manufactures of woollen in many places; and, owing to the abundance of oak copses, many hides tanned. Potteries on a large scale at Swansea, Cardiff, and other places. Extensive iron and coal works, lime works, and a slate quarry in Cardiganshire, &c.

The Lias limestone, (lime and iron combined, the stone of a bluish or greyish colour,) though found in many parts of England, is nowhere so valuable as that at Aberthaw. When burnt into lime, it is of a buff colour, the characteristic, according to the engineer Smeaton, of all limes setting in water. Lias limestone in all parts has a peculiarity of stratification and exterior character, so that a rock of it may be known at a distance. The strata are of various thickness, from a few inches to a few feet; and those commonly separated by a few inches' thickness of marley clay. The ferruginous ingredient seems to be concentrated in the interior part of each stratum; the outer sides thereof being more porous, and of a paler colour. In inland places the strata are burnt altogether, the argillaceous as well as the ferruginous calcite. Here, at Aberthaw, or other maritime coasts, the strata tumbled down, within reach of the tides, are broken and rolled about, until they are reduced to rounded pebbles or nodules, from a few ounces to many pounds weight; and these consist only of the nucleus or kernel part, the more useless shell being worn off by the abration of the furious tides. These rounded lias pebbles are driven on shore in inexhaustible quantities.

Of agricultural societies there are several; that of Brecon instituted in 1755, the earliest in Britain after that of Edinburgh.

Sect. III. *Agricultural Survey of Scotland.*

7832. *The surface* of this country is estimated at 18,944,000 acres, in three natural divisions. The first lies north of the chain of Highland lakes, which stretches from Murray to Mull, and consists of little else than dreary mountains and some moors: the second, or middle division, extends from this chain of lakes to the rivers Forth and Clyde; it is mountainous, but cultivated in the valleys, and on the eastern shore to a considerable extent: the remaining division is covered by hills with some mountains, but almost every where cultivated or improvable, and highly favourable for most branches of agriculture. Though Scotland, as elsewhere observed (770.), was far behind England in cultivation till the middle of the last century, it has now greatly outstripped that country, especially in arable husbandry; a proof that this is the general opinion of enlightened men may be deduced from the notices just given of the English and Welsh counties, in which it appears that the improvements introduced or attempted to be introduced on arable land are, with few exceptions, the implements and practices of Scotland. In the management of meadows or old pasture, Scotland cannot be conspicuous; as the climate is not naturally calculated for that kind of husbandry. The winters are too long and severe, and the surface too irregular. In regard to live stock, the palm of improvement was till lately borne away by England; but though there is not that enthusiasm in Scotland, nor such large prices given for capital specimens, it may be safely asserted that breeding and feeding are conducted as systematically and successfully there as in England. We shall glance at the different counties in the order of their proximity, beginning with that containing the capital. It may be sufficient to mention here that leases are universal in Scotland, generally for nineteen years, often for twenty-one, sometimes for fourteen, but seldom for a shorter period. The poor are supported by voluntary contributions at the church doors; though an assessment on property, half paid by the proprietors and half by the tenants, may be made if necessary, which is not generally the case. Assessments for the poor are common in the border counties and the Lothians, and occasional assessments, imposed upon the same principle, are resorted to in most of the other counties. Voluntary contributions are found inadequate, except in the most thinly-peopled districts. It is therefore a great though common mistake in England, to suppose that there are no poor-rates in Scotland; but they are comparatively moderate, and will likely continue so while the power of assessment remains with those (the landed proprietors) who have to bear an equal share of the burden with their tenants. It is here that an essential distinction exists between the poor-laws of England and Scotland. Tithes were commuted for their value in land and land's produce at an early period. Every parish has a schoolmaster, who is paid jointly by the proprietors and the farmers. There is a professorship of agriculture in the Edinburgh University, ably filled by Dr. Coventry, a man of whom it may be truly said, that he is universally esteemed and beloved. The best account of the agriculture of the Scotch counties is to be found in Black's edition of the *Encyc. Brit.* Edinburgh, 4to, 1829.

7833. MIDLOTHIAN, or EDINBURGHSHIRE, contains 230,400 acres; one third hilly and inaccessible to the plough, and two thirds in tillage, pasture, or wood. The store sheep farming is practised on the hills, and a mixed agriculture on the low grounds. Green crops and potatoes are extensively cultivated for the Edinburgh market, and most farmers are more indebted to the manure they receive in return, than to the soil, or their superior skill: many of them are townsmen, amateurs, and speculative cultivators. The Dalkeith Farmers' Society, one of the most useful that has been formed, and which still exists, belongs to this county; and in it also was founded the British Wool Society, now extinct. A variety of interesting information respecting the progress of improvements in this county, and in East and West Lothian, will be found in *Rural Recollections*, 8vo, 1829, by George Robertson, author of several county surveys, and whose personal knowledge extends from 1765 to the present time. (*Robertson's Survey*, 1795. *Edin. Gaz. abridged*, 1829.)

1. *Geographical State and Circumstances.*

Climate free from extreme heats or colds; snow seldom falls on the low parts of the country before December, lies from three to ten weeks. In eight years, the greatest quantity of rain that fell in any year was 36.8 inches, and the least quantity 9.6 inches.

Soil much diversified; lands hanging to the north always the most fertile.

Minerals. A bed of coal extends across the county from S. W. to N. E. from seven to eight miles in breadth; worked for two centuries. Limestone, freestone, granite, and whinstone very abundant. Millstones in the parish of Pennycuick, also marble. Some copper and iron ore, marl, and jasper pebbles on Arthur-seat.

Water. Streams inconsiderable. Esk (*Usk*, Gael.) the largest river; few fish from the rivers or streams, but abundance from the firth or sea.

2. *Property.*

About 540 estates in the county, divided by the reporter into seven classes; first class from 2 to 3000*l.* or upwards; fifth class 100*l.* and upwards; sixth class, least properties; seventh class, properties of corporate bodies. Total rental in 1795, 191,000*l.*; Duke of Buccleugh the first proprietor.

3. *Buildings.*

Many gentlemen's seats, and some fine ruins of castles and religious houses.

A *farmer's mains*, as it is here called, consisted formerly of a set of low buildings, in the form of a square; one side was occupied by the master himself, whose habitation was composed of two or three dismal apartments, on an earthen floor, having a low ceiling and a few diminutive lights. On another side stood the barn, in which the roof timbers, from the idea of giving more strength, were built into the wall from the foundation; the wall itself not being more than five feet in height. Opposite to the barn were the stables and the byre, or cow-house. The stables were totally without division, and the horses fed in common; but the neat-cattle, less passive, were each confined to their stakes. The cottages occupied the remaining side; in the midst of all lay the dunghill. These buildings were made of turf and stone alternately, or with stone, and clay for mortar: the roof of thatch, or of thatch and *divot* (turf or sods) intermixed. Further details on this subject will be found in *Robertson's Rural Recollections*, p. 70.

Farmeries now in the first style of commodiousness. An example given of Gogarbank farm.

Cottages formerly very mean, now much improved. Robertson, in his *Recollections*, gives a figure of a modern Lothian cottage in its last stage of refinement, which is by no meaus inviting.

Farms vary from 100 to 300 acres. Farmers divided into three classes; speculators, converts from other professions; industrious labourers who have acquired some property; and farmers sprung from farmers.

Speculators. "In the immediate vicinity of the town, the greater part of the lands are cultivated, not by actual farmers, but what may be more properly termed speculators in agriculture, people with whom farming is but a secondary object; their chief employment being still what was their original profession, as bakers, brewers, innkeepers, or some other distinct occupation; and who are oftener to be found in their town lodgings, or in their compting-houses, than in the midst of their farms, attending to the operations of husbandry. One certain effect, which the speculations of this class produce, is, that the rent of land is raised above its natural level; for, as they have always some other business to live by, they are

enabled to afford more rent; and in fact give more than an actual farmer, whose sole dependence is upon husbandry, is able to pay; while their exertions in agriculture, though in general founded on good principles, commonly end in disappointment to themselves, for want of that unceasing attention which is indispensable to good cultivation, but which their other avocations prevent them from bestowing."

The *moor-land farmers*, as if in conformity to the soil, which has undergone very little melioration, and to the climate, which is naturally severe, seem still to retain a strong cast of the manners of their forefathers, and to live and toil under the same uncomfortable circumstances. Their houses are damp, smoky, and diminutive; their fare simple and limited; and their labours hard and even oppressive. But they have days of relaxation, in which they enjoy themselves at fairs and markets; their marriage festivities are almost boundless, and their funerals are pompous and ostentatious. Religion is maintained in all the austerity of Oliver Cromwell and the covenant.

These farmers are the only ones in a county containing a capital town, who are likely to better their condition. Being inured to the practice of the most rigid economy, they will, when translated to a warmer climate and more genial soil, very forcibly feel a melioration in their circumstances; and if they have fortitude enough (as the first race of them generally will) to persevere in their original habits of frugality, they may, by dint of mere saving, at the rate, perhaps, of two and a half per cent yearly on their capital, accumulate, in a lifetime, a sum that may be esteemed considerable. But this thriving state will only last during the first generation. Their sons habituated in time to an easier mode of life, will, amid the great luxury with which they are surrounded, lose their primitive simplicity of manners, and with it the faculty of saving, on which alone their prosperity depends.

4. *Implements.*

Old Scotch plough, long and heavy, and drawn by four or six horses or oxen, and till about 1768, when Drs. Grieve and Carlisle, clergymen, tried wheel ploughs of a lighter construction, which they had seen in use in Dalkeith Park. Soon afterwards Small's improved plough came into notice. Robertson mentions that the olden race of farmers were very generally their own plough-wrights, and makers of their own implements of husbandry, with very little assistance from the professional mechanic. These implements were indeed made in a very clumsy manner, but otherwise strong and handy enough. They had all of them a set of wright's tools for the purpose. (*Rural Recollections*, p. 84.) The late Mr. Thomas Shiells, at Grothill, near Edinburgh, made with his own hands the first winnowing machine used in the Lothians, from a model of one imported from Holland. (*Ibid.* 148.)

5. *Enclosing.*

No commons or common-fields. Hedges first planted about 1760.

6. *Arable Land.*

When ridges are raised high, they should not be laid south and north, as the crop on the east side of such ridge is commonly found very defective. The same thing holds in the county of Lancaster.

7. *Grass.*

Very little permanent grass exclusive of the hills and moorlands. Alluvial lands on the banks of streams so liable to immense floods, bringing down soil, &c. that if in grass it would often be much injured; considered therefore more profitable to keep them in corn. There is some very productive meadow land near Edinburgh, irrigated by the water which flows from town, carrying along with it night-soil, &c. The produce of twelve or fifteen acres of this meadow sold in 1826 at an average of 42*l.* per acre; part of it reached nearly 60*l.*, the purchaser cutting and carrying it off, and incurring all other charges. This, of course, is only for one summer, but it will yield four or five cuttings during that season, or rather between the end of spring and the beginning of winter.

8. *Gardens and Orchards.*

Henry Prentice, who died about 1786, was the first who cultivated white peas, potatoes, turnips, and sundry other culinary plants, on an extensive scale, for the Edinburgh market, about the year 1746. Before that period, the supply was limited to what could be carried in baskets; his cart being the first that appeared with kitchen stuff in the streets. He even raised cucumbers in the fields; but his cart-load of these met with so little sale, as not to encourage a repetition. Though he died a pensioner on the poor's funds of the Canongate, his name deserves to be noticed with respect, not only as having introduced several of our best vegetables into cultivation, but from his practice as a cultivator, which was spirited and judicious, however little it turned out to his own account.

Strawberries About 200 acres on the banks of the Esk, and chiefly near Roslin. Crop continued on the same ground without end; but digging down and replanting every fourth year. To change every twenty or thirty years esteemed a better practice. Lands in nursery 200 acres. Mawer's hothouses at Dalry, and hotwalls of his invention, figured and described. The hothouses heated by steam. Mawer was a Lancashire man, and formerly gardener and steward to the Earl of Abercorn. He was an excellent gardener and farmer; a man of very general information, and highly respected. He was extensively employed as a layer out of gardens and roads, and had the general charge of the gardening and tree department on some gentlemen's estates. The compiler of this Encyclopædia was his pupil, amanuensis, and draughtsman for the three years preceding his death, which happened suddenly from apoplexy in 1800.

9. *Woods and Plantations.*

About 5000 acres so occupied, the greatest part artificial, and planted since 1750. Hedgerow trees never come to any thing for want of shelter; belts do no good unless twenty rows thick at least.

10. *Wastes.*

None: but extensive tracts very poor.

11. *Improvements.*

Draining well understood and extensively practised. Johnston, who wrote an account of Elkington's mode of draining, a native of the county. Edinburgh and Leith afford about 40,000 cubic yards of street dung annually, which is commonly laid on the lands within five miles of town. Horse dung, however, carried twelve miles or further.

More need for weeding on the arable lands of this county than in those of any other in Scotland; supposed from more town manure being used. The town manure contains the seeds brought in from the country in hay and straw, which are of various kinds; but chiefly wild mustard, wild radish, dock, thistle, poppy, couch-grass, &c.

12. *Live Stock.*

Little attention was formerly paid to this department; but it is now conducted on improved principles. A great many cows are kept in Edinburgh, and well kept as well as judiciously selected. See the art. *Dairy* in *Sup. to Ency. Brit.* art. *Agriculture*. Galloway and Ayrshire cows preferred, and Clydesdale horses. Some buffaloes of the Mysore variety introduced by Col. Murray: not supposed to turn to any advantage, either as milkers, or for work, or the butcher, but form a variety in parks. Lord Morton subsequently introduced the quagga (*Equus Quágga*) on his park at Morton Hall for the same purpose. Bees a very popular species of live stock with all classes.

13. *Rural Economy.*

Well supplied with work-people from the highlands and Ireland. With the exception of some farm servants in the immediate vicinity of Edinburgh, they are, in general, orderly and moral. Children taught in the parish schools; reading at one shilling and four-pence, writing and arithmetic at two shillings and sixpence per quarter; Latin, &c. in proportion. The cottages of ploughmen consist generally of two rooms on the ground floor, with a pigstye, and 100 square yards, or upwards, of garden ground. The furniture consists of two beds, a few chairs or stools, table, chest of drawers, clothes-press, &c.; and they are all ambitious of having a time-piece, if it were only a cuckoo clock. The whole may be worth from ten to twelve pounds. The Sunday's dress of a young ploughman consists generally of a coat of blue cloth, at five shillings and sixpence the yard; velveret vest, corduroy breeches, white cotton stockings, calf-skin shoes with black silk shoe-knots, shirt with ruffles at the breast, white muslin fringed cravat, and a hat worth eight or ten shillings. The shoe-knots and ruffles are, indeed, rather uncommon, but all the other articles are very much in use. They make a very good appearance, and even pay attention to the fashion. In their food they still live in much the same simple way as their forefathers. Oatmeal forms the basis, or principal part of their sustenance. They have it regularly to breakfast and to supper, made into pottage, which they eat with a small allowance of butter-milk. At dinner they eat it in bread, in addition to their kale, a kind of soup made of barley-broth, intermixed with greens and pot-herbs. To this they add at times potatoes, and fish of different kinds; seldom wheat bread, and still more rarely butcher's meat. This mode of living, in which, although with no great variety, there is always abundance of food, seems to be very conformable to the natural constitution of the people, as they are found to go through their labour without feeling themselves oppressed, and enjoy a state of health which is very seldom interrupted. At an average, they are not above two days sick in a year.

What is above stated refers chiefly to the condition of farm servants, who are hired by the year, and whose principal employment is about the horses, in the fields, or on the road. There is, however, another class of work-people attached to a farm, who are hired by the day, or by the week, and whose employment is usually in jobbing about the barns, the fences, or the water furrows. These are called labourers, and in their circumstances and mode of living there is a considerable difference between them and the others.

Although their wages are in general at a higher rate than the hired servants, yet they make not such a good appearance in their dress, nor are so well seen to in their victuals, as these. They are generally, as we term it, *from hand to mouth*, always in want; which seems to arise principally from getting their whole wages in money from week to week, which leads them continually to market, providing their daily sustenance; a province left generally to the charge of their wives, who, from this constant running about, get into habits of idleness and want of attention to that good housewifery which is the glory of a decent cottager's wife.

The quantity of coal used by the common labourers is about three fourths of a ton for each person in the family yearly, by farmers about two tons, and in families of the highest rank about six tons. The price at the pit is from five shillings to seven and sixpence the ton, according to its vicinity to Edinburgh.

Such was the state of things in 1795. Now (1830), at the distance of five and thirty years, they are doubtless materially altered. The use of wheaten bread is general; butcher's meat much more common, and cottages more commodious.

14. *Political Economy.*

Roads so bad previously to 1714, that wheel carriages for the purposes of agriculture were very little used; even till 1760 hay and straw carried to Edinburgh on horseback, and the dung taken back the same way in bags. Sledges a good deal employed in those times: they are mentioned in the turnpike act of 1751, but unnoticed in that of 1755, which shows they had been disused; a proof of the extraordinary progress of improvement when once commenced, in consequence of a demand or desire for it. Forced improvement goes on very differently. The roads of this county are now under one of the M'Adam family. Some recent canals and rail-roads have been formed. One of the most important improvements is the Union Canal from Edinburgh to the Forth and Clyde Canal at Falkirk, which has added greatly to the value of property on each side of its line. See *Edinburghshire*, and *Canal*, in *Sup. to Enc. Brit.* and also Robertson's *Rural Recollections*. Glass, ropes, and soap the chief manufactures. Iron works at Cramond, where nails, spades, files, &c. are extensively fabricated. Several paper mills, flour mills, and various minor manufactories and works for local consumption.

15. *Obstacles to Improvement.*

Illiberality of landlords, game, thirlage, the dogs of Edinburgh, who greatly harass the sheep, the chief obstacles.

16. *Miscellaneous Observations.*

The Farmers' Society of Dalkeith, for the prosecution of thieves and encouragement of agriculture, instituted in 1760, still exists, and has done much good. It is composed almost entirely of practical farmers. Small's plough, the winnowing

and threshing machines early noticed and recommended by this society. The farmers in this county have long had in contemplation to get instituted by legal authority a society for the creation and management of a pensionary fund for the widows and orphans of farmers, on principles similar to those which govern the widows' fund of the ministers of the Church of Scotland.

An appendix to the report contains thirteen papers, some of which are curious in an historical point of view; and as showing how soon, in a rapidly improving age, a man's best ideas and remarks are distanced by those of a few years afterwards. One of these papers describes the origin and progess of the British Wool Society, which was begun in this county by Sir John Sinclair, in 1791. The economy of Johnston's dairy is deserving of notice for accuracy in the details, and for new practices, such as making butter from whey, feeding cows on whins, &c. Macknight, another amateur, and Hepburn, an ingenious landlord and cultivator, are also worth reading.

7834. EAST LOTHIAN. 190,363 acres of surface, under an exceedingly variable climate, the greater part of excellent soil, and well adapted for cultivation; but the southern district, Lammermuir, hilly and mountainous, with a moory soil, severe climate, and chiefly under native grass and herbage. Some of the most distinguished Scotch agricultural patriots, authors, and mechanics belong to this county, as Cockburn of Ormiston, Thomas sixth Earl of Haddington, Fletcher of Salton, Adam Dickson, Robert Brown of Markle, the projector, and for a long time editor, of the Farmer's Magazine, Somerville, author of the agricultural Report, Meikle, inventor of the threshing machine, and various others. (*Somerville's General View*, 1805.)

1. *Property.*

Generally in considerable estates; the largest about 15,000*l.* and not many under 100*l.* a year. Tenure generally of the crown (*i. e.* freehold), some hold of subjects superior (copyhold), and some of the corporate towns of Haddington and Dunbar.

2. *Buildings and Implements.*
