THE FRUIT SÍTÚATION

This issue includes summaries of the 1940 outlock reports for the major fruits.

# Summary

Changes in fruit prices in recent weeks have been largely seasonal. Pear prices, however, declined contraseasonally to levels slightly below those of a year earlier.

This movement of pear prices is attributed directly to the decline in exports, which is forcing a larger than usual portion of the late winter pears on the demestic market. Although the total supply of winter pears is substantially smaller than it was a year earlier, the reduced export prospect is likely to result in a supply for domestic use for the remainder of the marketing season about as large as the record large supply available last year.

Apple prices have advanced seasonally in recent weeks. Although a large crop was produced, selective harvesting, heavy early fall marketings, relief purchases and diversions to byproducts and other uses apparently have reduced supplies for the remainder of the marketing season to about normal, even after allowance is made for the probable reduction in exports.

Winter citrus supplies, particularly grapefruit, are semewhat reduced from the record large crops of last season. Marketings from Florida and Texas in recent weeks have been heavy, hewever, and market prices have declined. Lemon prices advanced slightly as shipments of the old crop neared completion and those of the 1939 supply get started.

Consumer demand for fruit crops has improved considerably in recent months and prospects are for some further improvement.

For 1940 as a whole consumer purchasing power probably will average somewhat higher than for 1939. Domestic consumer demand for fruits, therefore, is expected to be somewhat higher in 1940 than in 1939. This will mean an increase in the domestic cutlet for the large supplies available from the 1939 harvests. Export demand, however, will be curtailed. Large supplies of fruits are available this year in the major importing countries. This large supply, together with conditions arising from the war in Europe, is expected to offset much of the favorable effect of increased consumer buying power in the United States.

The average combined production of all fruits during the next 5 years (1940-44) probably will be larger than the average for the 5-year period, 1934-38. Production during the 1939 season is indicated to be well above the 1934-38 average.

During the next 5 years significant increases are expected in the production of grapefruit, cranges, and lemons. Moderate increases are anticipated for peaches, pears, and cherries; and grape production probably will increase slightly. The trend in apple production is expected to continue downward at a moderate rate. Dried prune production probably will decrease moderately during the next few years. No significant changes are likely to occur in the average production of other fruits.

Prices of fruits in general have been relatively low for several years, and it is apparent that as supplies continue to increase it will be increasingly difficult to dispose of the large crops at returns satisfactory to the growers unless there is a marked improvement in the level of consumer purchasing power.

- 2 -

#### APPLES

- 3 -

There was little change in the estimate of the commercial apple crop reported as of November 1 compared with a month earlier. The indicated production of 100,530,000 bushels for the country as a whole is about 22 percent larger than the 1936 crop and 4 percent larger than the recent 10-year average. Production this year in the Eastern States is about 30 percent larger than last year, while it is about double the small 1938 crop in the Central States. The crop in the Western States, however, is about 13 percent below the production of a year ago.

October weather was generally favorable for harvesting of the late varities, but it is reported that because of low prices an approciable part of the total apple crop was left unharvested this season. Also, it is indicated that unusually large quantities of apples have been diverted to processing plants. The Federal Surplus Commodities Corporation began purchasing apples for relief distribution in the week ended October 7 and by November 11 had purchased the equivalent of 5,134 carlcads. Under this program growers have agreed to divert an equal quantity of merchantable fruit to other than fresh market use.

Market prices of apples have advanced 20 to 30 cents per bushel in recent weeks, and it is apparent that the seasonal low point was passed in carly October. Apple prices usually rise from the seasonal low level in the fall to the end of the season since the volume of marketings during this period usually decreases.

Cold storage holdings of apples on November 1 totaled only 28.6 million bushels compared with 30.3 million bushels a year earlier and 5-year average November 1 holdings of 29.8 million bushels. In view of the increased production this season, the smaller holdings on November 1, 1939 are noteworthy and indicate that the movement into storage this season is later than it was last year. A similar situation occurred in 1935 when the apple crop was larger than in the previous year but November 1 cold storage holdings were smaller. The December 1, 1935 holdings, however, were about 10 percent larger than a year earlier. Another factor probably accounting for the relatively small cold storage holdings on November 1 this season is the unfavorable prospect for exports this season. During the first 3 months of the current season apple exports totaled only 742,000 bushels compared with 1,716,000 during the corresponding period last season. September apple exports this season were only about 27 percent of those of September 1938. If the export movement for the remainder of the seasen continues at the current low level, the total for the year will not exceed 5 million bushels as compared with 12 million bushels for 1938-39.

A summary of the Apple Outlook for 1940 follows:

Large supplies of apples and other fruits in the United States and in foreign countries, and an unsatisfactory export situation, are unfavorable factors in the apple marketing situation for the 1939-40 season. But an

increase in domestic consumer buying power during the season, and the program undertaken by growers, aided by the Federal Surplus Commodities Corporation, to divort apples of less desirable grades from sales for fresh consumption into commercial byproducts or other outlets, will tend to offset the unfavorable elements in the situation.

Domestic commercial apple supplies for the current season are about 22 percent larger than for last season, and 5 percent larger than the 1928-37 average. Supplies are relatively heavy in some of the important Central and Eastern States, including important export areas. The quantity of apples used for canning and drying is expected to be considerably larger in 1939 than it was in 1933, when about 10,300,000 bushels were canned and dried.

Canada, with a preferential market in the United Kingdom, anticipates difficulty in moving a normal volume of fresh apples to oversea markets in 1939-40. As a result, the Canadian Government new proposes to divert into canning and drying 5,000,000 bushels or more of varieties and grades of apples normally exported. During the last several years Canada has cannod and dried annually an average of only a little over 1,000,000 bushels of apples.

Increased supplies of canned or dried apples in Canada will be a significant competitive factor this season in the movement of United States canned and dried apples into export.

From a long-time viewpeint, the number of apple trees of bearing age in the United States is expected to continue to decrease, and the production trend during the next 5 or 6 years is expected to continue downward at a moderate rate with greater reduction in the total crop than in the commercial crop. If plantings and roplacements continue to be as light as they have been during the last several years, production 10 to 15 years hence may be materially lower than it is now.

In the Pacific Coast and Rocky Mountain States commercial production in recent years has been fairly stable at around 35,000,000 bushels per year. Young trees in these regions are relatively few, and the tendency to remove old and unprefitable trees was continued during last year. The peak of production has been passed for these regions as a whole, and the general downward trend in production is expected to continue at a moderate rate.

In the Contral States the annual production varies tremendously. Increasing commercial production from young orchards probably will offset decreasing production from old commercial and farm orchards for several years, assuming average growing conditions.

Although the hurricane of September 1938 destroyed or damaged many apple trees in the New England storm area, permanent tree loss from the storm will not greatly affect commercial production in the Atlantic Coast States as a whole. Commercial production in this group of States is expected to remain urchanged or to decrease moderately during the next several years.

#### PEARS

The estimate of the pear crop as of November 1 remains about the same as that of a month earlier. Production of pears other than Bartletts, (chiefly winter varieties) in the Northwest totals 6,024,000 bushels, or about 14 percent less than the record large crop produced in 1938 but about 55 percent above the recent 10-year average.

Cold storage holdings of all varieties of pears in the United States on November 1 totaled 2,729,000 bushels. This indicates a net out-of-storage movement of about 595,000 bushels during October. Last year the holdings on November 1 totaled 3,294,000 bushels and the net out movement amounted to 838,000 bushels.

Exports of pears during the first 3 months of the season totaled only 870,000 bushels compared with 1,560,000 during the corresponding period last year. The movement was reduced sharply below that of a year earlier in August and September. If the present low level of exports continues through the remainder of the season not more than 1.5 willion will be exported during the entire year. This would mean that even though November 1 cold storage holdings are smaller than in 1933, the supply available for the domestic market for the remainder of the marketing season will be as large as or larger than it was at this time last season.

Because of this situation, market prices of pears declined in recent weeks and in mid-November averaged slightly lower than a year earlier.

A summary of the Pear Outlook for 1940 follows:

The upward trend in pear production in the United States is likely to continue during the next few years at a more moderate rate than during the last 10 years, chiefly because of increased yields from a considerable number of young trees reaching full bearing age. Further increases in production are expected in the three Pacific Coast States and in the major commercial areas of the East North Central States.

New plantings of pear trees have been very small during the past year and are confined to replacements in connercial areas. Commercial orchards on the Pacific Coast and in eastern producing areas generally have received good care during the 1935-39 season, but some abandonment has taken place in farm orchards and isolated plantings.

Since 1930, season average prices to growers have been considerably below prices during the period 1919 to 1929. Although prices up to 1937 had recovered somewhat from the lowest point reached in 1932, they experienced a drastic reduction during the 1933 season, declining almost to the level of prices in 1932. During the current season prices for Bartlett pears have been more satisfactory than in any recent season. A smaller crop than last year, improved demand conditions, and larger quantities used in canning are the major reasons for better prices at the beginning of the 1939 season. A further improvement in domestic demand conditions is in prospect for the

remainder of the season. However, the export outlook for the late variaties of pears is a favorable, and imports of Argentine pears into the United States during the latter part of the season may be larger than usual because of a curtailment of shipments of pears from Argentina to Europe as a result of the war.

Exports of fresh pears, which reached a record movement during the 1938-39 season, are expected to be materially reduced during the current season, mainly because of the effects of the European War. Larger crops in the major importing countries of Europe and increased competition from the major pear-producing countries of the Southern Hemisphere would have resulted in a reduction of exports of United States pears this season as compared with last year, even in the absence of war.

## CITRUS FRUITS

The November crop report indicated no change in the prospects for winter citrus crops. The estimate of the Valencia orange crop, the marketing of which is about completed, was decreased 1.2 million boxes to 22.6 million boxes.

Shipments of Florida and Texas citrus gained in volume in recent weeks, and market prices of all varieties of citrus except California lemons declined fairly sharply.

A summary of the Outlook for citrus for 1940 follows:

## Oranges

United States production of winter oranges for 1939-40 is expected to approximate the record winter orange crop of 1938-39. Florida oranges will make up a larger proportion of the winter orange production than they did last season. The production of California Valencias is not determinable at this time. An anticipated increase in the level of consumer demand is a favorable factor in prospect for the 1939-40 season, but a probable reduction in exports due to conditions arising out of the European war and to heavier competition from larger supplies of apples than in 1933-39 are unfavorable factors affecting the outlook for the current season.

Domestic orange production has increased rapidly during the last 20 years. The 1933-39 crop of oranges amounted to 79,500,000 boxes, compared with an average crop of 61,400,000 boxes for the period 1934-37 and 30,100,000 boxes during the 5 years 1919-23. Since about 40 percent of the bearing orange and tangerine trees in the United States have not yet reached full production, additional increases in the average level of orange production may be expected over the next 5 years, provided the producing capacity of the orange groves is not impaired by neglect or by damage arising out of abnormal weather conditions. Production of Valencias and other late varieties is expected to increase faster than early and midseason varieties.

Exports of oranges from the United States have risen sharply in the last two seasons, primarily because of smaller exports from Spain and increased production in this country. On the average, further increases in United States exports during the next few years do not appear to be likely because of the prospect for a continued upward trend in foreign production of oranges and the probability of a recovery in exports from Spain.

The increased orange production in recent years has been accompanied by a decline in orange prices, with prices to growers reaching a record low during 1938-39. Inasmuch as the average United States crop during the next 5 years is expected to be larger than that of the last 5 years, prices of oranges probably will continue to be on a relatively low level compared with commodity prices generally.

## Grapefruit

Barring severe damage to trees by bad weather conditions, the trend in production of grapefruit during the next few years will continue upward. The expected increase in production will be most pronounced in the late or seedless varieties of grapefruit which predominate in Texas, California, and Arizona.

The bearing acreage of grapefruit in all producing areas has been increasing rapidly during recent years, and the trend of production has been sharply upward. Approximately 55 percent of the bearing grapefruit trees in the United States at the present time have not yet reached the age of full production. Roughly 80 percent of the bearing seedless grapefruit trees in the United States had not yet reached full production in 1939; only 35 percent of the bearing trees of the early or seeded varietics were less than 16 years old and not in full production.

Assuming that growing conditions will be similar to the average of the last 10 years, and considering recent production trends and potential increases in bearing surface of the present number of trees, production during the next five marketing seasons probably will average one-third higher than during the last five seasons.

The large grapefruit crops produced since the 1935-36 season have returned prices to grovers approximating the low prices received during the depression years of 1932 and 1933. The average price for grapefruit received by growers during the 1938-39 season was the lowest on record. Prices to grapefruit growers are expected to remain at relatively low levels during the next few years, unless the anticipated production is reduced as a result of extremely low yields or damage to the producing plant.

As a result of the European war, exports of fresh grapefruit to European countries during the 1939-40 season are likely to be less than in 1938-39. Exports to other than European markets, however, are likely to be maintained. Purchasing power in Canada is expected to increase, and this may result in increased imports of grapefruit from the United States.

# Lemons

Average annual production of lemons during the next 5 years probably will be about 10,500,000 boxes. Productive capacity of a large part of the present bearing acreage is expected to increase during this period, and total bearing acreage probably will increase by about 20 percent. Lemon production during the 1935-40 season is expected to be somewhat smaller than the record 11,732,000 box crop produced in 1938-39, but considerably larger than the 1933-37 average of 8,500,000 boxes.

Although production has increased at a relatively rapid rate for the last 15 years, the average price per box has declined only slightly. Marketing prospects for California lemons during the 1939-40 season appear to be somewhat better than marketing conditions during the season just passed. In view of a probable average arnual production of over 10,000,000 boxes during the next 5 years, however, it seems probable that either consumption must be developed still further in the United States, or foreign markets must be expanded, if the present level of returns to grovers is to be maintained.

Average annual production of lemons in Italy during the 5-year period, 1933-34 to 1937-38, was approximately 25 percent less than during the preceding 5 years. World production has declined since the record 1932-33 crop, owing chiefly to the reduction in Italy, but a further material decline in the world crop is not likely to occur unless Italian production continues to decrease at a rate similar to that of the period 1933-34 to 1937-38.

Annual exports of Lewons from the United States during the 5-year period, 1933-37, averaged 50 percent more than during the preceding 5-year period. And in 1938, exports from the United States totaled 798,000 boxes more than double the 1933-37 average. The possibility of further increases in exports in 1940 will depend largely upon the extent to which Italian exports are diverted from the United Kingdom to central Europe as a result of the present European wor. Exports from Italy in recent years have declined along with production. The 1933-37 average was 3 percent below the average for the previous 5-year period.

Imports of lemons into the United States have declined during recent years, and are relatively unimportant at present.

Bearing lemon acreage in California in 1939 is estimated at approxinately 55,200 acres; nonbearing acreage, exclusive of 1939 plantings, is placed at approximately 10,500 acres. Forty-three percent of all trees nov in bearing and between the ages of 5 and 15 years, and have not yet reached full producing capacity.

## THE CHERRY CUTLOOK FOR 1940 .

#### Summary

Continuation of the present slight upward trend in the production of sour cherries is indicated for the next 5 years, with production slowly increasing in most of the principal eastern producing States. Recent changes in acreage are too small to affect appreciably the total volume of production, but a further increase in production is to be expected from the large number of young bearing and nonbearing trees.

A similar upward trend is also indicated in the production of sweet varieties, with sweet-cherry production increasing at a more rapid rate than that of sour cherries. Some increase in plantings is occurring, but in general any production increase in the immediate future will result from increasing production from young trees.

Utilization of cherries in most of the major cutlets has increased during recent years, but a slover rate in future expansion is indicated. The pack of canned red pitted cherries continues an upward trend, with a heavy pack - over 3 million cases - in 1939. The difficulty in moving the pack of canned red ritted cherries during recent years indicates, however, that little further expansion in the pack is to be expected unless consumer demand improves. The pack of frozen cherries has trended upward during the last 7 years and further increase is indicated. The pack of canned sweet cherries, which has trended downward for over a decade, remained relatively stable during the period 1934 through 1937. The heavier packs in 1938 and 1939 were to be expected from the very heavy production in these years, but they do not necessarily indicate a reversal of the past downward trend. The volume of brined cherries continues to increase, although at a much slower rate than formerly. Present conditions in the main outlets for brined cherries do not indicate any appreciable increase in this pack in the immediate future. Fresh shipments of sweet cherries have shown no marked trend either upward or downward during recent years. In these years, when fresh shipments have increased, producers have received low returns.

The continuing upward trend in production, with most of the principal market outlets now expanding at a relatively slow rate, indicates that no appreciable increase in prices to producers is to be expected except as it may accrue from a general increase in consumer purchasing power.

## THE PEACH OUTLOOK FOR 1940

# Summary

A continuation of the upward trend in United States peach production is indicated for the next 5 years. The crops of 1938 and 1939 averaged about 11 percent greater than the 51,000,000-bushel average of 1933-37.

There is danger that the peach industry in some areas is being overexpanded. In the areas that produce peaches for market as fresh fruit,

grovers are reverally optimistic. Large plantings have been made in recent years and or shards have not suffered severely from drought or freezing injury since 1936. Many diseased trees have been removed through Government programs, and orchards generally are in good condition. In the experience of many growers, returns from peaches have been relatively favorable in recent years. Under these conditions in the past, plantings of peach trees have increased rapidly and have been followed by excessive production, low prices, neglect of orchards, and lesses to grovers.

In California, where a large part of the crcp is canned and dried, a slight upward trend in production is indicated. The crop of clingstone peaches in California has been above market requirements in recent years, with consequent low prices.

Exports, which are mostly in the form of canned and dried fruit, averaged only about 5 percent of fresh production for the crops of 1934-38. The export outlook for 1940 is uncertain because of the war situation. Avcrage annual exports of dried peaches were considerably larger in 1914-18 than in 1909-13.

# THE DRIED PRUME OUTLOOK FOR 1940

#### Summary

Very low prices for dried prunes in recent years have caused a decrease in bearing acreage in each of the producing States, namely, California, Oregon, and Washington. Moreover, the present bearing acreage will probably continue to produce more prunes than can be sold at prices which will induce growers to maintain the present acreage and the high production level of recent years.

The total supply of dried prunes in the United States for 1939-40 is between 265,000 and 270,000 tons, or about 10,000 tons smaller than the 5year, 1933-37, average and approximately 10 percent below the large supply of 1938-39. With the large European production in 1939 the world supply of dried prunes is equal to that of last year, but somewhat larger than the average of the past 5 years. Large supplies over the last several years have depressed prices to a very low level. Immediately after the start of the European war, prices rose rapidly. Recently, however, they have declined though not to the low levels existing prior to the start of the war.

War conditions in Europe make the export domand for United States dried prunes uncertain. Large United States supplies and increased European consumption of dried fruits in recent years favor an increase in exports; on the other hand, a heavy European production of dried prunes plus governmental control of prices and imports in certain countries may have a decidedly unfavorable effect.

# THE GLAPE OUTLOOK FOR 1940

# Sum ary

Average production of grapes in the United States during the next few years is likely to be larger than the 1925-37 average of 2,215,000 tens,

but smaller than the indicated average of 2,686,000 tons for the last three years, 1937-39 inclusive. Most of the change is expected in California, with a gradual decline in production taking place in other States. The carry-over of grape products (raisins, wine, and brandy) into the 1939 season was extremely large and, unless consumption of those products during the 1939-40 marketing season is increased materially over present expectations, inventories of these products at the beginning of the 1940-41 season will also be very large.

Preliminary estimates indicate that the 1939 bearing acreage in California will be about 490,000 acres divided according to varieties (based upon principal use) as follows: Eaisin varieties, 240,000 acres; wine varieties, 170,000 acres; and table varieties, 80,000 acres. Although the acreage of bearing grape vines in California during the next few years will be smaller than the average acreage for the 10 years, 1928-37, the average annual production from this smaller acreage will probably exceed the 1928-37 average of 1,934,000 tons, but may be less than the average of 2,420,000 tons for the bumper crops of 1937, 1938, and 1939. This larger than average production from smaller than average acreage is expected because moisture conditions, age, and general condition of the vines will probably give higher yields per acre than the 1928-37 average. There has also been a shift from nonirrigated land with low-producing vines to higher producing varieties on irrigated land.

The 1938-39 crop year was another difficult marketing season for the California raisin industry. The 1938 crop was the largest on record. This record crop, together with the carry-over from the previous year, gave the largest total supply of raisins since 1928. While this supply was substantially reduced by diversion and by relief purchases, nevertheless, the large crop in prospect for 1939 plus the carry-over from the 1938 season will still give total supplies for the 1939-40 marketing year considerably in excess of normal trade requirements. The increasingly important export market has been made very uncertain by the European War.

Stocks of wine, particularly of sweet wine, have been reduced from the high levels existing at the start of the 1938 vintage season. Stocks of dry wine are much larger in relation to consumption than stocks of sweet wine. With the exception of a few months in the early part of 1938, wine consumption has increased steadily since the repeal of prohibition, and it is anticipated that this increase will continue, provided consumer incomes are maintained. On the basis of probable utilization of the indicated grape crop, the production of wine in 1939-40 will be larger than consumption. Therefore, larger stocks of wine can be expected at the beginning of the 1940 vintage season.

Stocks of beverage brandy as a result of the large production under the 1938 prorate program are at an all-time high, being approximately 5 times larger than at any previous time on record and equivalent to more than 12 years' supply at the average annual rate of disappearance of beverage brandy since the repeal of prohibition. The marketing of this large amount of beverage brandy will undoubtedly cause difficulty in the future

even though it is strongly controlled and marketed, as planned, on a definite schedule over a period of years.

Supplies of table grapes in California, including Thompson Seedless, will probably show an increase in the next few years ewing to relatively large plantings of the Emperor variety in 1937 and 1938 and of the Thompson Seedless variety in 1938. Effects of this expansion will probably be seen in the production of 1940.

Exports of American grapes to Europe have expanded rapidly in recent years, reaching an all-time high in the 1938-39 season. The re-entry of Spain in the fall and winter grape deal together with the effects of the European War indicates that exports of California grapes to Europe are likely to be considerably reduced. Shipments to Western Hemisphere markets, however, are expected to remain at about the levels of recent years.

There has been no pronounced trend in the acreage of grapes in principal producing regions outside of California, although some decline will probably occur in the next few years. Production of grapes outside of California during the next few years is expected to average slightly less than the 1928-37 average of 2°1,000 tens. Reports from all regions, excluding California, indicate few plantings in recent years.

## THE STRAWBERRY OUTLOON FOR 1940

# Sumary

October estimates indicate about 197,000 acres of strawberries for picking in 1940. The indicated acreage is the largest since 1929, and 9 percent above the 1928-37 average; but it is only about 2 percent larger than the 1939 harvested acreage. Should yields in 1940 be average, production would be somewhat loss than in 1939, when the per acre yield was about 10 percent above average. Higher consumer incomes in 1940 probably will result in a better demand for strawberries than existed in 1939.

Increases in 1940 over 1939 acreages are indicated in the late and intermediate States. In the second early and the early States some decrease in acreage is expected.

During the last ducade acroage has increased markedly in the late States, and in 1940 is expected to be the largest on record. The upward trend in acreage in the intermediate States is expected to continue in 1940. In the early States acreage has declined somewhat, while in the second early States there has been no pronounced acreage trend in recent years.

# THE OUTLOON FOR TREE INJTS FOR 1940

#### Summary

The basic trend is production of tree nuts is expected to continue moderately upward during the next few years.

- 12 -

Combined 1939 production in the United States of walnuts, almonds, pecans, and filberts is expected to amount to approximately 11,900 tons. This is 20 percent more than the 1938 total crop, and 18 percent more than the average for the 5 years 1935-37.

Prices received by growers for tree nuts fell to low levels in 1930 and 1931. Although almond prices have made a substantial recovery since then, they remain well below pre-depression levels, and prices of other nuts still average approximately as low as in the depression years.

Inasmuch as further increases are expected in the production of tree nuts, prices received by growers during the next few years for their nut crops probably will not average much, if any, higher than they have in the last few years.

Foreign demand is an unfavorable factor in the present cutlook for tree nuts. It may be expected that the European belligerents will drastically curtail imports of nuts, unless these are obtainable at very low prices. With a reduced European demand, United States export programs for walnuts and pecans would be adversely affected, and it also seems probable that the United States market would be called on to absorb at least part of the large volume of Brazil nuts normally exported to Germany and the United Kingdom.

Consumption and imports.- In a comparison of the period from August 1925 to July 1930 with the period from August 1934 to July 1939, imports of tree nuts into the United States are 20 percent less in the latter period. A large increase in imports of cashew nuts was more than offset by large decreases in imports of walnuts, almonds, and filberts. Reflecting the decreases in imports, apparent consumption of these three kinds of nuts in the United States declined substantially between the two periods in the face of increasing denestic production of walnuts and filberts and of large almond crops in 1937 and 1938. Current total apparent consumption of tree nuts is at a level below that of the 1920's but above the depression level.

The basic trend in the production of English walnuts continues upward. A crop of 59,500 tons is expected in 1939, or 17 percent more than in 1938.

The production of improved (budded) variaties of pecans is expected to continue to increase gradually during the next few years, given average growing conditions. The 1939 crop is expected to amount to about 10,700 tons, 22 percent more than in 1938.

The seedling pecan crop varies greatly from year to year; practically no trend is discernible through the last 15 years. The basic tendency in production is believed to be stationary or slightly upward. A crop of about 19,200 tons, 19 percent mere than in 1938, is expected in 1939.

An almond crop of 19,000 tons is expected in 1939 - 1,000 tons short of the record 1937 crop. Given average growing conditions, an average

- 14 -

5-year period. New plantings have been heavy in the last 5 or 6 years, and nost of them have been made on irrigated land, where growing conditions are favorable. Apparent consumption of almonds ranged between 0.23 pound and 0.30 pound per capita annually during the 1920's, but for the last 7 years it has ranged between 0.10 pound and 0.17 pound per capita annually (shelled basis). The difference is accounted for by a large decrease in imports.

Commercial production of filberts is a young and rapidly expanding industry. From 60 tons in 1927, the first year officially reported, United States production has increased to an expected 3,500 tons in 1939. A crop as large as 5,000 tons is possible by 1945. Apparent consumption of filberts, like that of almonds, is at a low level. Since the marketing year 1931-32, it has ranged between 0.03 pound and 0.05 pound per capita annually, as compared with an average of approximately 0.10 pound during the 1920's (shelled basis). The increase in domestic production has not been sufficient to offset a rapid decline in imports.
