v. 7

A Few of the Leading Articles in Volume Seven

WRITTEN AND SIGNED BY SPECIALISTS

FOREIGN EXCHANGE .... FRED I. KENT
Manager Foreign Exchange Department, First National Bank, Chicago

FORESTRY IN THE UNITED STATES .... GIFFORD PINCHOT
Chief of the Bureau of Forestry, Washington, D. C.

FORREST, NATHAN BEDFORD; GORDON, JOHN BROWN .... JOSEPH T. DERRY
Author of "The Story of the Confederate States"

FORT HENRY AND FORT DONELSON; FORT SUMTER; GETTYSBURG .... GENERAL E. A. CARMAN
Of the War Department, Washington, D. C.

FORTIFICATIONS .... GEN. HENRY B. CARRINGTON, U. S. A.
Author Military Text Books

FOUNDRY PRACTICE .... WILLIAM J. KEEP
Author of "Cast Iron," etc.

FRANCE .... NINETEEN SPECIAL ARTICLES
See Department of French History and Development

FRANCIS OF ASSISI; FRANCIS XAVIER .... T. J. CAMPBELL, S. J.

FRANKLIN, BENJAMIN .... JOHN BIGELOW
Author of "The Complete Works of Benjamin Franklin"

FRATERNAL SOCIETIES IN AMERICA .... FREDERICK GASTON
President of the Grand Fraternity

FRIENDS, SOCIETY OF .... EDWIN P. SELLEW
Publisher of "The Friend," Philadelphia

FROEBEL, FRIEDRICH WILHELM AUGUST .... NORA ARCHIBALD SMITH
Author of "The Message of Froebel"

FROST .... W. A. BENTLEY
Author of "Snow and Snow Crystals"

FRUIT GROWING .... WILLIAM A. TAYLOR
Pomologist, United States Department of Agriculture

FUEL, COMPARATIVE HEATING VALUES OF .... WILLIAM MOREY, JR.
Consulting Civil and Mechanical Engineer, New York

FUNCTIONALISM .... JAMES R. ANGELL
Professor of Psychology, University of Chicago

FUNGI .... CHARLES E. BESSEY
Professor of Botany, University of Nebraska

FURNITURE, COLONIAL .... LOUISE COWPERTHWAITE
Of Geo. C. Flint Co., New York

FURNITURE INDUSTRY IN AMERICA .... GEORGE W. GAY
President Berkey & Gay Furniture Co., Grand Rapids, Mich.

GAELIC LITERATURE .... THOMAS GAFFNEY TAAFFE
Instructor in English, College of the City of New York

GALVANOMETER .... J. E. TAYLOR
Western Electric Co., Philadelphia

GAMES .... JESSIE H. BANCROFT
Director of Physical Training, Public Schools, New York City

GARBAGE .... CHARLES EDGERTON
President Sanitary Product Co.

GARFIELD, JAMES A. .... W. N. S. CARLTON
Librarian Trinity College, Hartford

GAS AND GAS MAKING .... WALTON CLARK
General Superintendent United Gas Independent Co., Philadelphia

GAS ENGINE; GASES, LAWS OF; GAS PRODUCER .... WILLIAM MOREY, JR.
Consulting Civil and Mechanical Engineer, New York

GAS ILLUMINATION, HISTORY OF .... SIDNEY MASON
President Welsbach Company

GAS, NATURAL .... F. H. OLIPHANT
National Transit Co., Oil City, Pa.

GASES, KINETIC THEORY OF .... A. D. RISTEEN
Editorial Staff "THE AMERICANA"

GASOLINE .... ERNEST L. FERGUSON
Writer on Gasoline Engines and Components

GEMS; GEMS, ENGRAVING OF .... GEORGE F. KUNZ
Gem Expert, Tiffany & Co., New York

GENERAL PARESIS; GOUT....................Smith Ely Jelliffe
Editor "Journal of Nervous and Mental Diseases"

GENERAL STAFF OF THE ARMY....................W. H. Carter
Brigadier General, Assistant Chief of Staff

GEOGRAPHY....................F. B. Greene
Secretary Geographical Society of Philadelphia

GEOLOGY....................Bailey Willis
Of the United States Geological Survey

GEOMETRY, CARTESIAN; GEOMETRY, MODERN ANALYTICAL...Cassius J. Keyser
Adrain Professor of Mathematics, Columbia University

GEOMETRY, ELEMENTARY....................Edward Kasner
Instructor in Mathematics, Barnard College, Columbia University

GEOMETRY, HISTORY OF ELEMENTS OF....................David Eugene Smith
Professor of Mathematics, Teachers College, New York

GEOMETRY, NON-EUCLIDIAN....................George Bruce Halsted
Professor of Mathematics, Kenyon College, Gambier, Ohio

GEOMETRY, PURE PROJECTIVE....................Edwin Bidwell Wilson
Instructor in Mathematics, Yale University

GEODESY; GRAVITATION....................Simon Newcomb
Scientist and Astronomer, Washington, D. C.

GEORGIA....................Joseph T. Derry
Author of "Georgia, Historical and Industrial"

GERMANY....................Twenty-three Special Articles
See Department of German History and Development

GIBBON, EDWARD....................Oliver Farrar Emerson
Professor of English, Western Reserve University

GLACIERS....................John Muir
Geologist, Explorer, and Naturalist

GLASGOW, SCOTLAND....................Robert Renwick
Deputy Town Clerk, Glasgow

GLASS MANUFACTURE IN AMERICA....................James Gillinder
Of the Franklin Flint Glass Works, Philadelphia

GLUCOSE; GLUTEN....................F. N. Barrett
Of the "American Grocer," New York

GOAT....................George Fayette Thompson
Late of the Bureau of Animal Industry, Washington, D. C.

GODWIN, MARY WOLLSTONECRAFT; GODWIN, WILLIAM........Arthur H. Nason
Instructor in English, New York University

GOLDSMITH, OLIVER....................Austin Dobson
Author of "Life of Goldsmith," etc.

GONORRHŒA....................Prince A. Morrow
Author of "Relation of Social Disease and Marriage"

GORILLA....................J. S. Kingsley
Professor of Zoology, Tufts College

GOSPELS....................J. S. Riggs
Of the Auburn Theological Seminary

GOTHIC ART AND ARCHITECTURE....................Russell Sturgis
Author of "Dictionary of Architecture"

GOVERNMENT....................W. W. Willoughby
Associate Professor of Political Science, Johns Hopkins University

GRAIN, HANDLING AND TRANSPORTATION OF....................H. B. Moore
Secretary Duluth Board of Trade

GRAPE CULTURE....................Lee J. Vance
Editor "American Wine Press," New York

GRASSES IN THE UNITED STATES....................W. J. Spillman
Agrostologist, United States Department of Agriculture

GRAY, THOMAS....................William P. Trent
Professor of English, Columbia University

GREAT BRITAIN....................Fifty-five Special Articles
See Department of Great Britain; History and Modern Development

z	pleasant, rose
zh	azure, pleasure

′ (prime), ″ (secondary) accents, to indicate syllabic stress

THE ENCYCLOPEDIA AMERICANA

Forcing, in gardening, is a term used to designate a process in which artificial heat is applied so that flowers, fruits, or other products of plants are obtained at a date or season other than that at which they may be had in the ordinary course of culture. Thus, for example, kinds of grapes which by the simple influence of the heat of the sun in a vinery do not ripen till September or October are induced by forcing to ripen in March or later, according to the period the process is commenced; and strawberries, which ripen from June to September, in the forcing-house yield their fruit from February onward. Conducted, as the system is, during the short days of the year, the chief obstacle the gardener has to contend with is diminished light. This in the case of forcing fruits taxes his skill to the utmost, because abundant light is essential both to the proper fertilizing of the flowers and to the perfecting of the fruit. Some vegetables and salads and many flowers are, however, more successfully forced in the dark than in light. Rhubarb, seakale, mushrooms, lily of the valley, lilac, are all forced in greater or less darkness.

Ford, Edward Onslow, English sculptor: b. London 1852; d. 1901. He studied in Antwerp and Munich, and was made a Royal Academician of London in 1859. His artistic faculty was displayed in felicitous portraiture, and he executed striking statues of many eminent contemporaries, including Gladstone and «Chinese» Gordon. The Marlowe Memorial at Canterbury and the Shelley Memorial at University College, Oxford, are also from his chisel. A monument to his memory was unveiled in Grove End Road, Saint John's Wood, London, 13 July 1903.

Ford, Henry Jones, American editor: b. Baltimore, Md., 25 Aug. 1851. He was graduated from the Baltimore City College in 1868, was connected with the *American* and *Sun* of Baltimore and the *Sun* of New York, and in 1901 became editorial manager of the Pittsburg *Commercial Gazette* and *Chronicle-Telegraph.* He published ‹The Rise and Growth of American Politics› (1898).

Ford, James Lauren, American journalist: b. St. Louis, Mo., 25 July 1854. He has written several volumes of short stories and essays, among which are: ‹Hypnotic Tales› (1891); ‹The Literary Shop› (1894); ‹Bohemia Invaded›; ‹Dolly Dillenback.› He is also the author of two books for young readers: ‹Dr. Dodd's School› (1892); and ‹The Third Alarm› (1893).

Ford, John, English dramatist: b. Devonshire 1586; d. after 1639. He printed his first tragedy of the ‹Lover's Melancholy› in 1629. This, however, was not his first play, as a comedy of his, entitled ‹A Bad Beginning has a Good End,› was acted in 1613. His genius is seen at its highest in the tragedy, ‹'Tis Pity Shee's a Whore› (1633), though the subject is repulsive. He wrote, or assisted to write, at least 11 dramas. Most of these were exclusively his own composition; but some of them were written in conjunction with Decker and others. Other plays by him are: ‹The Broken Heart› (1633); ‹Love's Sacrifice› (1633); ‹Perkin Warbeck› (1634); ‹The Fancies Chaste and Noble› (1638); and ‹The Ladies' Trial› (1638). Besides the works already mentioned, he wrote an able little manual, entitled ‹A Line of Life, pointing out the Immortalitie of a Vertuous Name› (1620).

Ford, Paul Leicester, American author: b. Brooklyn, N. Y., 23 March 1865; d. New York 8 May 1902. Besides numerous pamphlets relating to American historiography his works include: ‹The Honorable Peter Stirling› (1894), a novel of New York society; ‹The True George Washington› (1896); ‹Bibliotheca Hamiltonia›; ‹Franklin Bibliography›; and an edition of the works of Thomas Jefferson (1807), with notes, biographical introduction, etc.; ‹The Story of an Untold Love›; ‹Tattle Tales of Cupid›; ‹Short Stories›; ‹Janice Meredith› (1899); ‹Wanted — a Matchmaker›; etc.

Ford, Sallie Rochester, American story-writer: b. Rochester Springs, Boyle County, Ky., 1828; d. 1902. She married S. H. Ford in 1855, and with him edited the 'Christian Repository' and the 'Home Circle' for many years. Among her published works are: 'Grace Truman' (1857); 'Mary Bunyan' (1859); 'Morgan and His Men' (1864), and 'Ernest Quest' (1887); 'The Inebriates'; etc.

Ford, Washington Chauncey, American statistician: b. Brooklyn, N. Y., 16 Feb. 1858 He is a brother of P. L. Ford (q.v.). He was chief of the bureau of statistics, Department of State, 1885–9, and of the bureau of statistics in the Treasury Department in 1893–8; was connected with the Boston Public Library 1897–1902, and was chosen lecturer on statistics in the University of Chicago in 1901. He published: 'American Citizen's Manual'; 'The Standard Silver Dollar' (1884); 'George Washington' (1899)

Fordham, fôr'dam, a part of New York in the borough of Bronx. Prior to 1874 it was a village in Westchester County, N. Y Fordham was made a manor in 1671. St. John's College is located here. The poet E. A. Poe lived in Fordham for a number of years and wrote 'The Bells' and other pieces here.

Ford's Theatre, a Washington theatre in which President Lincoln was shot by the assassin, Booth, 14 April 1865. The United States government purchased the building in 1866, and it was at first used as the Army Medical Museum, but after 1887, as the Pension and Records Bureau of the War Department. It gradually fell into ruin, however, and suddenly collapsed with the loss of several lives, 9 June 1893.

Fordun, John of, known as the father of Scottish history: b. probably at Fordoun, Kincardineshire, about 1310; d. about 1386. He wrote the first five books of his 'Chronica Gentis Scotorum,' bringing the history down to the middle of the 12th century, and also a part of the sixth volume, which was completed by Walter Bower, abbot of the monastery of Inchcolm. He enlarged the first five books and added 11 new ones, bringing the history down to 1437. Several editions have been printed, the best probably being that of W. F. Skene (Edinburgh 1871–2).

Forearm. See ARM.

Forecasting the Weather. See METEOROLOGY.

Foreclosure is the right of a mortgagee, or of any one having interest in a mortgage, in the event of the conditions of the mortgage being violated, to compel the mortgagor to redeem the pledge or forfeit his right of redemption. This is done by filing a bill for foreclosure. The court may, on application of the mortgagee, mortgagor, or any incumbrancer of the mortgage, grant, under certain conditions, a sale of the subject instead of foreclosing the mortgage, the money raised by the sale being applied to the payment of the mortgage, any surplus being claimed by subsequent mortgages, or in the event of no other claim, being paid to the mortgagor.

Forefathers' Day, the day celebrated as the anniversary of the landing of the Pilgrims; first commemorated in 1769. Owing to a mistake in the change of Old Style (11 December) to New it was made 22 instead of 21 December.

Foreign Coins and Their American Equivalent. As the monetary value of national coins is subject to frequent change, it is impossible to prepare a statement which would correctly specify the value of any particular coin at any future time. As such changes are correspondingly slight, however, the following list of the coins of all nations will always be comparatively correct, the values in the moneys of account of the United States having been corrected to 1 April 1905 by the director of the mint, United States Treasury Department:

Argentine Republic.— Gold coins: argentine ($4.824) and half argentine; silver coins: peso ($0.965) and its divisions.

Austria-Hungary.— By a law passed 2 April 1892 the monetary system of Austria-Hungary was reformed on a gold basis, with the crown ($0.203) as a unit. The coins issued under the old system are still in circulation, however. They are, gold: eight florins ($3.858), 4 florins, ducat ($2.287), and 4 ducats; silver: florin ($0.5052) and 2 florins. The coins under the new system are, gold: twenty crowns ($4.052), 10 crowns, and 1 ducat ($2.287); silver: one crown ($0.203); nickel: twenty hellers ($0.0405) and 10 hellers; bronze: two hellers, or one kreutzer ($0.0040), and one heller.

Belgium.— Belgium being a member of the Latin Union, its monetary unit is the franc ($0.193), and its coins the gold 10 and 20 franc pieces and the silver 5 francs.

Bolivia.— The boliviano ($0.439) is the monetary unit of Bolivia. Its coins, all silver, are the boliviano, the 50, 20, 10, and 5 centavo ($0.0211) pieces.

Brazil.— The milreis ($0.546) is the monetary unit of Brazil. Its gold coins are 5, 10, and 20 milreis pieces; its silver coins, ½, 1, and 2 milreis.

Bulgaria.— The monetary unit is the lev ($0.185) which is supposed to correspond to the franc of other double standard countries. In fact, but few Bulgarian gold coins are in circulation, the necessary gold coins being supplied by foreign 10 and 20 franc pieces. The silver coins are the ½, 1, 2, and 5 leva pieces; the nickel coins are the 2½, 5, 10, and 20 stotinki ($0.0385), and there are copper coins of 1, 2, 5, and 10 stotinki.

Canada.— The gold dollar ($1) is the monetary unit. The silver coins are the 50, 25, 10, and 5 cent pieces. Some penny (2 cents) and half penny pieces are in circulation.

Chile.— The value of the peso, the monetary unit, is ($0.365). The gold coins of the country are the escudo ($1.825), doubloon ($3.65), and the condor ($7.30). The peso and its divisions are coined in silver.

China.— The monetary system of China is in an extremely chaotic condition. The unit and sole official coinage is the copper cash, 11 of which are equal to one cent. The silver tael, or liang, varies in value in different parts of the country, as follows:

THE CHINESE TAEL.

PLACE	Value	PLACE	Value
Amoy	$0.719	Nankin	$0.712
Canton	0.717	Ninchwang	0.674
Chefoo	0.688	Ningpo	0.691
Chin Kiang	0.703	Pekin	0.701
Fuchau	0.665	Shanghai	0.657
The Haikwan or customs tael	0.732	Swatow	0.664
		Takau	0.724
Hankow	0.673	Tientsin	0.697

In Hong Kong and Labuan, the "British Dollar" has the same legal value as the Mexican dollar.

Colombia.— The gold dollar ($1.) is the monetary unit. Other gold coins are the condor ($9.647) and the double condor. The silver peso ($0.9352) and its divisions are coined.

Costa Rica.— The gold colon ($0.465) is the unit of the country. Two, 5, 10, and 20 colon pieces are coined in gold; 5, 10, 25, and 50 centimor ($0.2326) pieces in silver.

Cuba.— As Cuba is a gold standard country, its monetary unit, the peso, is a gold coin valued at $0.91. The gold doubloon, valued at $5.017, and the Alphonse, valued at $4.823, are also used, as well as several foreign coins The silver coinage of Cuba is the peso ($0.455) and its divisions.

Denmark.— The monetary unit is the crown ($0.268) and gold 10 and 20 crown pieces are coined. The minor coinage, in silver and bronze, is represented by the 50 ore ($0.1247) and its divisions.

Ecuador.— The gold sucre ($0.487) is the unit, but the 10 sucrae piece is the only gold coin. The minor coinage, the 10 and 5 real ($0.0467) pieces, is of silver.

Egypt.— The gold pound, representing 100 piasters ($4.943) is the unit, and 50, 20, 10, and 5 piaster pieces are also coined in gold. The silver coinage is represented by the 1, 2, 5, 10, and 20 piaster pieces.

Finland.— The markkaa ($0.193) is the monetary unit, and the gold coins are 20 and 10 markkaa pieces. The 50 penni ($0.0794) and the 10 and 1 penni ($0.0019) pieces, in bronze, constitute the smaller coinage.

France.— The gold franc, valued at $0.193, is the unit of the country. Gold 5, 10, 20, 50, and 100 franc pieces, and silver 5 and single franc pieces are coined. The minor coinage is represented by the 50, 20, 10, and 1 centime ($0.0019) pieces.

German Empire.— The gold mark ($0.238) is the unit, and 5, 10, and 20 mark pieces are coined in gold. The 50 pfennigs ($0.1039) and the thaler ($0.6928) represent the silver, the 5 pfennigs, the nickel, and the single pfennig the bronze coinage.

Great Britain.— While the monetary unit for the colonies varies, that for Great Britain itself is the gold pound sterling ($4.8665). The pound sterling (the sovereign), and the half sovereign are coined in gold; the crown ($1.0872), half crown, florin ($0.4348), shilling ($0.2174), sixpence ($0.1017), four pence ($0.0724), three pence ($0.0543), and the two pence ($0.0362) in silver, with the penny ($0.02), half penny, and farthing ($0.005) in bronze.

Greece.— The drachma ($0.193) is the monetary unit. Five, 10, 20, 50, and 100 drachma pieces are coined in gold, 5 drachma pieces in silver, 20 and 5 lepta ($0.0096) in nickel, and 1 and 2 lepta pieces in bronze.

Guatemala.—The silver peso ($0.439) is the monetary unit and this coin and its divisions are coined in silver.

Haiti.— The gourde ($0.965) is the unit of the country; 1, 2, 5, and 10 gourde pieces are coined in gold, and the single gourde and its divisions in silver. The smaller coin is the bronze centime ($0.0096).

Hawaii.— Same as United States.

Honduras.— The peso ($0.439) is the monetary unit and this coin and its divisions are coined in silver.

India.— The pound sterling, or sovereign, is the standard coin of India, but the rupee ($0.324433) and its divisions is the money of account.

Italy.— The lire ($0.193) is the monetary unit. The 5, 10, 20, 50, and 100 lire pieces are coined in gold; 5 lire pieces in silver, while the 20, 10, and 1 centesimo ($0.0019) in nickel and bronze represent the minor coinage.

Japan.— The yen ($0.498) is the unit of the country. Gold 5, 10, and 20 yen pieces are coined; 10, 20, and 50 sen ($0.448) silver pieces, with 5 sen, 1 sen, and 5 rin ($0.0024) pieces in bronze.

Liberia.— The only official coin of Liberia is the gold dollar ($1.).

Mexico.— The silver dollar, valued at $0.458, has long been the monetary unit of Mexico, but a change to the gold standard, which is about to be established, will give the country a gold dollar of the value of about fifty cents. The several divisions and multiples of the dollar will also be coined.

Netherlands, The.— The gold florin ($0.402) is the monetary unit. Gold 10 florin pieces are coined as well as ½, 1, and 2½ florin pieces in silver. The cent ($0.004) is of bronze.

Newfoundland.— The gold dollar of Newfoundland is valued at $1.014.

Nicaragua.— The silver peso ($0.439) is the unit, and this coin and its divisions are coined in silver.

Norway.— Same as Sweden.

Panama.— The balboa, valued at $1. in gold, is the monetary unit. At present no gold is coined, the only coin being the silver dollar ($0.50) and its divisions.

Paraguay.— The country has no coinage, but the silver pesos of other South American republics circulate there at the same value as in the countries where they are issued.

Persia.— The silver kran ($0.078) is the monetary unit. Gold ½, 1, and 2 tomans ($3.408) pieces, and silver ¼, ½, 1, 2, and 5 krans are coined. The copper coins are the chai ($0.0085) and the abassi, valued at 4 chais.

Peru.— The sol ($0.487) is the monetary unit. Gold libra ($4.8665) are coined, as well as the silver sol and its divisions.

Philippine Islands.— By act of the 57th Congress the authorized coins of the Philippines are silver pesos of 10, 20, and 50 centavos (cents) value, and of copper ranging from ½ cent to 5 centavos in value.

Portugal.— The milreis ($1.08) is the monetary unit and 1, 2, 5, and 10 milreis pieces are coined in gold. The silver coins of this country are 1,000 reis ($0.9526) and 50 reis; the nickel coins, 100 reis and 50 reis, and the bronze coins, 20 and 5 reis.

Rumania.— The gold lei ($0.193), corresponding to the franc, is the monetary unit. Twenty and 10 leis pieces are coined in gold, 5 and single lei pieces in silver, and 10 and 1 bani ($0.0019) pieces in bronze.

Russia.— The ruble ($0.515) is the monetary unit. Gold imperials, valued at 15 rubles, and half imperials are coined. The ruble, as well as the 50 and 5 copeck ($0.0187) pieces, are of silver, while the single copeck and a 5 copeck piece are coined in copper.

Salvador.— The silver peso ($0.439) is the unit, and this coin and its divisions are coined in silver.

Servia.— The dinar ($0.173) is the monetary unit. The 20 and 10 dinar pieces are of gold, the 5 and 1 dinar pieces of silver, while the 20, 10 and one para ($0.0019) pieces, in nickel and bronze, represent the minor coinage.

Siam.— The monetary unit is the silver fical ($0.28). The other coins current are the salung (¼ fical) and the juang (⅛ fical).

Spain.— The peseta ($0.193) is the monetary unit. The several divisions and multiples of the peseta are coined in gold and silver, while the minor coinage, ranging from one centimo ($0.0019) to 50 centimos, are of silver or bronze.

Sweden and Norway.— The gold crown ($0.268) is the unit, and 10 and 20 crown pieces are coined in gold. The silver coinage includes the 2 crown piece, the single crown, and the 50 and 10 ore ($0.0241), while the single and the 5 ore pieces are of bronze.

Switzerland.— The gold franc, valued at $0.193, is the monetary unit. Gold 5, 10, 20, 50, and 100 franc pieces, and silver 5 and one franc pieces are coined. The minor coinage includes the 50, 20, 10, and single centimes ($0.0019).

Turkey.— The piaster ($0.044) is the monetary unit and the gold coins include the 25, 50, 100 (the lira), 250, and 500 piaster pieces. The ½ piaster, the single piaster, and the 20 piaster pieces are of silver, while a piaster and the para ($0.0001) are of copper.

Uruguay.— The peso ($1.034) is the only gold coin authorized in Uruguay, but the silver peso ($0.403) and its divisions are also coined.

Venezuela.— The bolivar ($0.193) is the monetary unit. Gold 5, 10, 20, 50, and 100 bolivar pieces are coined, while the silver coinage includes a 5 bolivar piece as well as the single bolivar and its divisions.

Foreign Exchange. Foreign Exchange is a name applied to that part of banking which deals with transactions between different countries. Since the earliest days of which we have authentic record of human achievements, different communities have traded commodities with each other. Originally the transactions were confined to barter, and the caravan or ship that carried goods to a foreign country traded them directly for goods of supposed equivalent value, which they took back with them to their own countries. The difficulty experienced in making even exchanges of mutually desirable articles led to the formation of banks (see BANKS AND BANKING) and finally to the development of the Foreign Exchange business in its present form.

Due to the fact that it was the first in the field in a scientific way, and also because of its world-wide political interests, Great Britain can truthfully claim that the bulk of the world's business is carried on in its currency — pounds sterling. See MONETARY SYSTEMS OF THE WORLD.

Foreign Exchange being the same in theory the world over and similar in practice, except where influenced by local conditions, we will consider it from the standpoint of the United States. The foreign exchange banker, whether running a separate institution or a department of a bank organized for the handling of both domestic and foreign business, finances the following propositions, which we will divide into two divisions, viz., Exports and Imports, as because of the effect upon exchange everything can be logically classed under these heads:

Exports.— (a) Merchandise; (b) Expenses of travelers to this country; (c) Securities (government, corporation, firms, or individuals, sold abroad); (d) Remittances to this country; (e) Precious metals.

Imports.— (a) Merchandise; (b) Expenses of travelers from this country; (c) Securities (government, corporation, firms, or individuals purchased abroad); (d) Remittances from this country; (e) Precious metals.

First, consider the exports. Different commodities because of their being perishable or otherwise, or because of the different methods of handling that hurry or retard their delivery, have to be financed according to their nature. Thus, for example, we find that meat, cotton, flour, and machinery are, as a rule, all financed on a different basis. Because of the time necessary to collect drafts against exports, only concerns of large free capital over and above the needs of their domestic business could sell their goods to foreign buyers, if it were not for the foreign exchange banks or departments that pay cash for the goods on delivery of documents. The transactions are consummated as follows: Bids are asked for on bills drawn against merchandise by telephone, telegraph, and over the bank's counter, and are accepted or rejected as they are in or out of line with bids of competitors, with the exception of bills that are placed for deposit regularly with some one concern, in which case rates are applied according to the market. In purchasing bills the following questions arise in the mind of the buyer: Is the responsibility of the seller of the exchange sufficient to warrant the purchase of the bill? If it is a long time bill is it drawn upon responsible banks or buyers? Is the market value of the goods covered by the shipment stable, and if not, is the value at the time of the offer low enough to warrant the purchase? These questions answered satisfactorily, next comes the point of rate to be paid, which is based upon the following conditions (in this country bills are ordinarily drawn in the currency of the country of the drawee). The laws and customs of the country upon which the bill is drawn concerning the class of exchange offered, for instance as to delivery of documents, stamp tax, days of grace, etc., the value of demand exchange in New York on day of purchase, the rate of New York exchange at interior points (when such points are the seat of purchase), the current rate of interest obtainable upon loans, the call money rate in New York, the bank and private discount rates in the country on which the bill is drawn, the market tendency in foreign exchange and the rates for other foreign exchanges, both in this country and in the country on which the draft is drawn.

The rate being made and accepted, the exporter obtains the necessary papers and delivers them to the foreign exchange banker, where he is either given a cashier's check or credit in account for the amount of the bill at the agreed rate, provided the documents are in order. Every piece of paper handled is carefully checked up as follows: To see that the conversion rate when applied to the bill equals the dollars paid the depositor; that bills of lading are drawn to the order of shipper and indorsed in blank; that all negotiable copies of the bill of lading are attached to the draft, which is in nearly all cases drawn in duplicate; that the goods covered by the bill of lading cover the draft at market rates; that the goods are insured while in transit and a certificate in proper order accompanies the draft; that invoices, and where necessary consular certificates, are attached, and that where a general hypothecation is not held, a special hypothecation covering the particular shipment accompanies the other papers. Documents, of course, vary somewhat from the above, but this covers the bulk of the business.

Travelers to this country ordinarily carry travelers' letters of credit, in order to provide for their expenses. Drafts drawn against such letters are cashed by the foreign exchange banker, which further increases his funds abroad. See CREDIT, LETTER OF.

The next division under exports is the handling of stocks, bonds, or other securities purchased from us by foreigners. In such cases drafts are drawn and the securities are attached or notice is sent to the effect that they are going forward under another cover, and where necessary, insurance is carried.

Remittances from foreign countries are also in effect exports, as the amount drawn by foreign bankers is either credited to the account of the payee bank or draft is drawn against balances in this country that were built up in a similar manner.

In all these divisions under exports the foreign exchange banker is in effect paying out funds in his city for which he receives or will receive foreign money at the point of destination for bills, securities, and drafts drawn against letters of credit, and in the case of remittances, at the points from which they originate.

Secondly, we will consider the imports. The importer causes the demand for the exchange that the exporter has made and is accommodated in two ways, either through the direct sale to him of demand or cable exchange and sometimes long bills, or through the issuance of commercial letters of credit. Merchandise, the first division under imports, is usually brought in under commercial letters of credit. In issuing such credits the banker is again confronted with the proposition of financial responsibility, this time of the importer, together with the marketable nature of the goods which he wishes to import, their prices, etc. If everything is satisfactory and the credit is granted, the foreign shipper is authorized by the bank to draw upon some convenient foreign correspondent for the value of the goods, the foreign banker being authorized to honor such draft upon delivery to him by the foreign seller of documents evidencing the shipment, etc., which correspond identically with those required in advancing money to an exporter whose credit is not sufficient without such assurance or where the standing of the purchaser of the goods is not high enough so that the exporter himself is willing to make the shipment without such a letter. The documents delivered to the foreign banker come forward to this country and are delivered to the customer against trust receipt before the draft for the goods matures, or are held for payment of the draft as special cases may require. Where letters of credit are drawn for 30, 60, 90 days, or other maturities, the actual money is not advanced as in the case of the exporter, but credit is extended through the acceptance by the foreign banker of the time bill against guarantee.

The American traveler in foreign countries is really an importer, for he buys in foreign lands amusement, experience, and other trifles to bring back to the United States either in memory or in bulk. See CREDIT, LETTER OF.

Securities imported are handled in the same manner as those exported, with the exception of the fact that more often payment is made out of balances of American banks in the foreign centres than by the foreign banker against his draft.

Remittances to foreign countries consist largely of money being returned by foreigners who are located here. This is ordinarily done by so-called postal remittances or drafts, and is in effect an import, as foreign balances are reduced in order to pay them, the same as if goods had been purchased abroad.

An item that enters largely into the foreign exchange business is the shipment of precious metals. In dealing with the Orient the price of silver enters largely into the price of exchange, as the old Mexican dollar is the accepted standard in Hong Kong, which is the business centre of the far East.

As gold is used more largely the world over for the purpose of settling so-called trade balances, we will consider the part it takes in foreign commerce more in detail. The various countries of the world have moneys of different denominations and values (see FOREIGN COINS AND THEIR AMERICAN EQUIVALENTS), and in order to get a common basis from which to figure values, the relations between the moneys are based upon the actual pure gold value in the principal coin of each country. For instance, in the case of Great Britain and the United States the pure gold in a pound sterling is found to be equivalent to the gold in 4.86656 American dollars, and this rate is called the mint par of exchange. When the exchange rate is enough higher than the par of exchange to make it profitable to ship gold abroad and sell exchange against balances so made, the export point is said to have been reached, and where the rate falls so low that exchange can be purchased and gold shipped in to replace the funds used for the purchase of the exchange, it is called the import point.

The theoretical export and import points are constant, but the actual points at which gold can be profitably shipped vary considerably, the difference between the actual and theoretical export and import points being made up of the following items: Boxing and cartage of the gold, freight to destination, insurance and loss of interest while the gold is in transit. (These costs vary somewhat, depending upon the arrangements different shippers are able to make.) The actual points are also dependent upon other exchanges; for instance, if sterling on London in Paris is abnormally low, gold can be shipped to Paris, and London exchange purchased with the balances so made at a profit, when the rate for drafts on London in this country would not of itself permit of such profit. The price of gold also has a bearing upon the rate, but where gold is exported from this country the cost of the gold is fixed, as the United States Government furnishes gold bars at the rate of four cents per $100, and gold coin can be obtained without premium by demanding same of the United States Government in exchange for gold notes. As this country exports a tremendous amount of cotton, wheat, corn, and other cereals after harvest in the fall, other things being equal, exchange would naturally be lower at this time of year. On the other hand, it would naturally be high during the early summer months, because of the fact that the imports are heavier in proportion at that time. (See EXPORTS AND IMPORTS). This natural condition has been offset largely through the interchange of securities, and also by so-called finance bills. The latter in effect carry over a debt of this country to foreign countries when issued at the time of high exchange to such time as the exports make enough exchange to carry the market down and allow cover at low rates. This often allows the borrowing of money at a very low interest rate, and is much resorted to when discounts abroad are lower than interest rates in the United States, or when exchange is at abnormally high rates without correspondingly divergent interest rates against the transactions. As the bulk of our foreign trade is carried in foreign bottoms, we are obliged to pay immense amounts for freight. Most of our marine insurance is also carried on the other side of the water. Both of these items must be added to the imports before the real balance of trade can be found, but as they can only be estimated and as finance bills are drawn and securities sold back and forth in unknown amounts, there is no time at which the real balance of trade is a known quantity. The demand and supply of exchange that causes fluctuations to reach the gold points is the only real guide to such balance, and even then finance bills in themselves may be sufficient to call forth shipments when the real balance if it were known might be the other way.

The foreign exchange banker in financing the foreign trade of the United States in addition to accepting the ordinary risks entailed in advancing credit to his customers is always at the mercy of the fluctuations in foreign exchange rates, and if it were not for the fact that the two gold points are separated from each other by under ordinary conditions not to exceed one per cent. and usually at a much less difference, it would be impossible for him to work upon the close margins that are now in vogue and that give the exporter and importer the best possible service at an infinitesimal cost. See COMMERCE AND COMMERCIAL TERMS.

FRED I. KENT,
Manager Foreign Exchange Department, First National Bank of Chicago.

Foreign Judgment, in law, is the term applied to the judgment of a foreign tribunal. Such judgment is proved in common law by exemplifications certified under the great seal of the state or country where the judgment is recorded, or under the seal of the court where the judgment remains; the fulfillment of its conditions depends upon treaty stipulations or on international comity.

Foreign Laws, the laws of a foreign country. The courts do not judicially take notice of foreign laws; and they must, therefore, be proved as facts. Exemplified or sworn copies of written laws and other public documents must, as a general thing, be produced when they can be produced. The effect of foreign laws, when proved, is probably referable to the court; the object of the proof is to enable the court to instruct the jury what is, in point of law, the result from foreign laws to be applied to the matters in controversy before them. The court is, therefore, to decide which is the proper evidence of the laws of a foreign country, and when evidence is given of those laws, the court is to judge of their applicability to the matter in issue.

Foreign States. In law, every nation is foreign to all other nations; and the several States of the American union are foreign to each other, with respect to their municipal laws. The reciprocal relations between the national government and the several States, however, are considered not as foreign, but as domestic.

Foreign Trade. While political economists have engaged in fierce disputations over many economic theories regarding money, wages, distribution and similar subjects, they have allowed the theory of international trade, as it was set forth by John Stuart Mill, to remain unchallenged and unchanged. The principle involved is one of advantage. In general, a given nation will export those articles in the production of which it has an advantage over other nations and import such articles as can be produced cheaper by other nations. This advantage may be absolute, depending upon location, soil, climate, etc., or it be merely relative and artificial, depending, for instance, on a system of protective tariff.

Modern international trade, in all its vastness and complexity, is a comparatively recent development. It may be said to have first begun with the multiplication of steamships and the extension of railroads throughout the world. Among important recent changes affecting foreign trade, and destined to affect it even more in the future, may be mentioned: (1) The acquisition by the United States of Hawaii and the Philippine Islands; (2) the construction of the Trans-Siberian Railway; (3) the expansion of steam-carrying trade on the Pacific; (4) the opening of China; (5) the definite assurance of a Panama Canal by the United States. These changes mean new markets for us, with better and cheaper facilities of transportation. The location of Manila makes it the logical collecting point for all articles of trade in southern Asia except tea, and under American control, with changed conditions of shipping, this city is destined to become a great commercial emporium. The fact that our factories are located on the Atlantic coast has placed us at a disadvantage in the oriental trade. This condition will be greatly alleviated by the construction of the Panama Canal; not to mention the advantages we shall gain in our trade on the west coast of South America. Indeed, the trade of that group of countries lying south of us is important. They buy of us manufactures and food-products. Their principal employment being agriculture, they form one of the most important groups of those nations known to political economists as "neutral markets." In recent years special efforts have been made to cultivate the South American trade. Witness, for instance, the assembling of the International American Conference, under act of our Congress for the explicit purpose of extending inter-American trade; the completion by an American company of telegraphic communication with the southernmost cities of South America; the appointment of an inter-American commission to report on a route for an inter-continental railway; the establishment of the Bureau of American Republics for the publication of information for those engaged in American trade; the unification of customs regulations and the monetary conference to study plans for facilitating inter-American exchange; the unanimous recommendation of all the republics to establish an international American bank, with branches in every American republic; the celebration of treaties of reciprocity and the proposal to establish a permanent inter-American court of arbitration for the settlement of all American disputes; and finally, the opening of our great consuming market to our sister republics by continuing the free admission into the United States of coffee, rubber, nitrate of soda and other products, and by the removal of the duties on hides, sugar and wool. In addition to these means of promoting trade must be mentioned the activity and persistence of our American merchants and manufacturers in advertising their wares, and in this way stimulating the market for them.

Nor have our commercial leaders proved less equal to the demands of international trade in the widest sense. In the trade of the world the United States has taken an important place. In fact, the development of our foreign commerce has been almost phenomenal. It is interesting to examine the figures giving the total values of our imports and exports by decimal periods for the past fifty years, and to note the rate of increase:

Imports.

1855	$257,808,708
1865	238,745,580
1875	533,005,436
1885	577,527,329
1805	731,969,965
1905	1,117,512,029

Exports.

1855	$218,909,503
1865	166,029,303
1875	513,442,711
1885	742,189,755
1895	807,538,165
1905	1,518,561,740

With few exceptions the volume of our foreign trade has increased steadily year by year, the figures for the fiscal year 1905 showing the largest imports and exports. For the fiscal year 1904 the imports and exports were $991,087,371 and $1,460,827,271, respectively. The gain of $126,425,258 in imports alone almost equals the total volume of our foreign commerce in 1812, the year in which the United States first made a clear start in the race for recognition as a world power.

The gradual increase of exports over imports is noteworthy and important. Roughly, from 1855 to 1905 imports have increased fourfold, while exports have increased sevenfold. Whereas in 1855 there was a trade-balance of $40,000,000 against us, in 1905 there was a balance of $400,000,000 in our favor. It is further significant that about half of our imports are manufacturers' materials. See COMMERCE; COMMERCE, INTERSTATE; COMMERCIAL ORGANIZATIONS; COMMERCIAL TREATIES; EXPORTS AND IMPORTS, AMERICAN; EXPORTS AND IMPORTS OF THE LATIN-AMERICAN REPUBLICS; ALASKA, COMMERCIAL; CANADA, COMMERCE, TARIFFS AND TRANSPORTATION; UNITED STATES: FOREIGN COMMERCE OF; HISTORY OF THE TARIFF; RECIPROCITY; COMMERCIAL DEVELOPMENT; FINANCES OF THE, ETC.; FREE TRADE; BALANCE OF TRADE.

Foreign Wars, Military Order of, a national patriotic society founded in 1894 in New York, under the name of the Military and Naval Order of the United States, but known from 1895 by its present designation. The objects of this order are (1) to preserve and honor the memory of those who assisted in the maintenance of the government of the United States in the Revolution, the war with Tripoli, the War of 1812, the Mexican war, and the Spanish-American war; and (2) to collect all records and documents appertaining to the wars above mentioned. The order is sub-divided into 22 State commanderies, and includes in its membership commissioned officers of the army, navy, or marine corps who took part in any of these wars (Veteran Companions), and direct lineal descendants of commissioned officers in the main line (Hereditary Companions). The present membership (1903) exceeds 1,600.

Fore'lands, North and **South,** two headlands on the southeast coast of England, county of Kent. North Foreland projects into the sea in the form of a bastion, and consists of chalky cliffs nearly 200 feet high. South Foreland consists also of chalky cliffs, and has two lighthouses, with fixed lights, erected upon it.

Forensic Medicine. See MEDICAL JURISPRUDENCE.

Foreordination, or **Predestination,** a term appropriated by theology; in the Calvinistic system, the assignment of the Deity, at the time of creation, of some of his creatures to eternal life and happiness and others to eternal death or suffering. Of course the decree was not, as usually stated, irrespective of the spiritual merits of the subjects; but if human beings it was irrespective of their actual conduct on earth. This was supposed to be irrelevant, as through the fall of Adam they had lost all possibility of merit, and owed any escape they might have from utter destruction to God's grace and Christ's vicarious atonement, which restored some of them to moral health. As none of them deserved anything, there could be no injustice in leaving such as he chose to suffer the penalty assigned. The first noun or its verb is not taken from the Scriptures, which uses «ordain» instead (Acts xiii. 48; Jude iv. 13). It was not alone Adam's dereliction which had caused this liberty of choice, however, as angels were included: the Westminster Confession says, «By the decree of God, for the manifestation of his glory, some men and angels are predestinated unto everlasting life, and others foreordained to everlasting death.» This implies that no created being has any claim to other than destruction except by divine grace.

Foreshortening, in art, the method of drawing in strict accordance with the rules of perspective, by which objects are so represented as to convey to the observer an idea of their just length, although but a portion of that length is actually given. The method was known to the ancients, and in more recent times has been notably employed by Correggio.

Forest-fly, the British name for the minute parasitic, flea-like flies called bird-ticks, bat-ticks, and the like, in America; specifically *Hippobosca equina,* which is especially a torment to horses by thrusting its long beak through the skin and sucking the blood. See BIRD-TICK.

Foresters, Ancient Order of, a fraternal order founded 1745, at Yorkshire, England, with a membership 1903 of over 1,000,000, divided among 9,000 courts. The order was introduced into the United States in 1832, and despite the fact that over 175,000 members withdrew and organized the Foresters of America in 1895, the order in this country has a membership of 187,000.

Foresters of America, a fraternal, benevolent order known under this title since September 1895. Orignally the order was part of the Ancient Order of Foresters (1745), but freed itself from the High Court of England (1889), and became a separate order. There were 1,600 courts in 1902, with a membership of 195,200.

Foresters, The Independent Order of, was organized in 1874 in New Jersey. It was reorganized in Canada by the Hon. Dr. Oronhyatekha, a full-blooded Mohawk Indian of scholarly distinction, high character, and great ability, who was educated under the patronage of the present king of England, in 1881. In 1881 the society consisted of 369 members and was in debt. It now numbers 214,000 and has a surplus of $6,700,000 in its treasury, having already paid to widows and orphans of deceased brethren about $14,000,000. The membership extends throughout all of the provinces of Canada, nearly all of the States of the American Union, England, Ireland, Scotland, Wales, Norway, Denmark, France, Belgium, India, Newfoundland, and Australia. In 1902 it added to its membership 13,000, and for the first half of 1903 its net increase was about 9,000. During the year 1902 the number of members initiated was 100 per month greater than in 1901. The death rate of the year was 6.60 per 1,000 or a fraction less than the year before. The average age of its membership at the close of 1902 was a little over 36. The society rejects a large percentage of applicants, being very careful in the selection of its risks. Its accumulated funds increased during 1902 by $957,239. This meant a betterment in assets of 18.19 per cent. The increase in assurance at risk during the year was 4.52 per cent. The increase in the premium income of the order in 1902 was 8.37, while the demands upon that income for the purpose of meeting claims was only 1 per cent greater than in 1901. The order is governed by a supreme body, which meets once in three years. The local jurisdictions are governed by high courts of the various States and Provinces. The funds, however, are all forwarded to the head office, there being invested under the insurance law of Canada which prevents investment in anything except first-class gilt-edge securities. The last reports show that no losses have ever been made in investments. The head office of the order is in Toronto, Canada, the building being a magnificent structure known as the Temple Building, which was built and is owned by the order. In addition to the head office it contains a number of banks, loan companies, insurance companies, and is the headquarters of masonry for the city of Toronto. The order pays out daily (1903) $6,500 to widows and orphans. The rates of premium may be judged from the following: Age 35; amount $1,000; mortuary premium $1.38 (small court dues in addition). All premiums cease at 70 years of age, or at any time when the members become totally and permanently disabled, at which time they are allowed to take in cash one half of the amount of their policy, the balance to be paid to their heirs at death. After 70 years of age members are permitted to draw one tenth of their policy for each of 10 years if they live so long, the balance to go to their beneficiaries at death. The order also has a sick and funeral benefit division. It admits lady members, these being called companions, who are gathered in separate courts. Of its total membership of 214,000 about 17,000 are companion members. The growth and progress of the institution is the life work of Hon. Dr. Oronhyatekha. He has been supreme chief ranger for 22 years and is a man of wonderful strength and power. Associated with him are the following: Hon. Judge Wedderburn, Hampton, N. B.; J. D. Clark, Dayton, Ohio; John A. McGillivray, K. C., Toronto, Ont.; H. A. Collins, Toronto, Ont.; T. Millman, M.D., M.R.C.S., Toronto, Ont.; Hon. Elliot G. Stevenson, Detroit, Mich. Benj. Greer, London, Ont., and Charles A. Fitzgerald, Buffalo, N. Y., are the supreme auditors.

Forestry in the United States. Forestry is the art of using the forest continuously to meet the needs of men. In the United States forestry has to do principally with the supply of wood for various purposes, with the maintenance of waterflow in streams, with the prevention of floods, and with the supply of forage for grazing animals within the forest. Nowhere else are forest problems of more vital importance to the welfare of the people than here, and in no other country of similar civilization has so little progress been made in their solution. This condition follows naturally from the vast area of the United States, its comparatively sparse population per square mile, and from the nature, location, and extent of the forests themselves.

The forests of the United States occupy an area of approximately 1,100,000 square miles, or about 36 per cent of the total land surface. They may be divided into five principal regions.

(*a*) The *Northern Pine Forest* extends from western Minnesota east to the Atlantic Ocean and southward to middle Tennessee, northern Georgia, central Virginia, and northern Maryland. Its characteristic tree is the white pine (*Pinus strobus*, Linn.), a tree of the very first commercial importance, which has hitherto supplied much more of the lumber cut in the United States than any other tree. In its western and more important centre of distribution in Michigan, Wisconsin, and Minnesota, the white pine is found both in pure stands and associated with other, principally hardwood, trees. The cut of white pine in the northern pineries reached its maximum in 1890, when the production for Michigan, Wisconsin, and Minnesota was 8,597,623,000 feet. During the census year 1900 the cut had fallen to 5,419,333,000 feet. This reduction in the cut has been accompanied by so marked a fall in the quality of the lumber that at present very many mills are sawing logs of which 50 or 60 are required to produce 1,000 feet of lumber, while the former average of logs to the thousand was seven or less. In the eastern part of the Northern Pine Forest red spruce (*Picea rubens*, Sarg.) is now the principal lumber tree, since the majority of the merchantable pine has been removed. The spruce grows usually in mixture with hardwood trees such as birch, beech, and maple. Formerly used mainly for lumber, spruce is now cut principally for paper pulp. The production of spruce pulp wood in the census year 1900 was 1,160,118 cords, the majority of which was used for news and other coarse grades of paper. In its southern extension the white pine forest penetrates the extensive hardwood belt of the Southern Appalachians, into which it merges as the white pine and its associates cease to be the characteristic trees. In its northern portion the white pine forest is predominantly of value for the production of wood. Its use as a regulator of stream-flow, while very great, is there far less conspicuous than along its southward extension in the Appalachian Mountains, and in many other forest regions of the United States. The loss from floods in streams which head within this forest in the Southern Appalachian Mountains during a certain period of 12 months ending in 1902 was, according to official estimates, more than $18,000,000. Congress has been asked to undertake the control of these floods by the purchase of lands for a Southern Appalachian forest reserve, but the plan, although thoroughly good, has not yet been carried through.

(*b*) The *Interior Hardwood Forest* follows the southern boundary of the Northern Pine Forest from the edge of the treeless region eastward to the mountains of Virginia and southward along the Appalachian Mountains and the Piedmont region, skirting the northern boundary of the Southern Pine Forest until it meets the prairie in western Texas. Its principal trees are the oaks. It is in this forest that the black walnut, now almost exhausted as a timber tree, reached its best size and most important distribution.

(*c*) The *Southern Pine Forest* extends from northern Maryland south along the Atlantic and Gulf coasts and up the valleys of the principal rivers until it meets the open country in western Texas. Its most important and characteristic tree is the longleaf pine (*Pinus palustris*, Mill.), in many respects the most valuable and important timber pine of the globe. Frequently associated with the longleaf pine, and serving elsewhere to delimit the boundaries of the Southern Pine Forest, is the loblolly or rosemary pine (*Pinus taeda*, Linn.), a tree of rapid growth and great dimensions. Other characteristic trees are the shortleaf pine (*Pinus echinata*, Mill.), which occupies the higher ground back from salt water, and the bald cypress (*Taxodium* *distichum,* Linn.), a swamp and tideland tree of high commercial importance, whose wood, for many purposes, is taking the place of the white pine, as clear lumber from that tree becomes progressively scarcer and higher in price. The cut of pine in the Southern Pine Forest in 1900 was 8,523,000,000 feet, and it is increasing with great rapidity. The cut of cypress in 1900 was 495,000,000 feet. The naval stores produced from the longleaf pine in 1900 were valued at $20,344,888.

Along the western border of the Northern Pine Forest, the Interior Hardwood Forest and the Southern Pine Forest extend the region of the Great Plains, destitute of timber except along the margins of the streams and on occasional elevations. There is a strong probability (and in many places conclusive evidence) that great areas of this region at one time bore trees and are still capable of growing forests. The clothing of such areas again with trees is one of the most important problems to be attacked and solved by the American forester. Ultimate success, of which there is now no doubt, will be of enormous value to a region whose principal industries, agriculture and grazing, are both so dependent for their future development upon a cheap and accessible timber supply.

(*d*) To the west of the Plains region lies the *Rocky Mountain Forest,* occupying more or less isolated mountain chains or mountain masses separated by grazing lands, deserts, or cultivable valleys. The Rocky Mountain Forest has its eastern extensions far in the heart of the Plains country, as in the case of the Black Hills Forest in North Dakota. Its predominant characteristic at middle and lower elevations is semi-aridity, and its distribution is limited by a combination of forest fires and deficient rainfall. Its principal timber trees are the western yellow pine (*Pinus ponderosa,* Laws.), the Engelmann spruce (*Picea engelmanni,* Engel.), the red fir (*Pseudotsuga taxifolia,* Lam., Brit.), and the lodgepole pine (*Pinus murrayana,* "Oreg. com.") The principal products of the Rocky Mountain Forest are water, wood, and grass, in the order named. The chief industry of this region is, or is about to become, irrigated agriculture. Since the passage of the National Reclamation Act of 1902, which provides for the reclamation of vast areas of irrigable arid land under the auspices of the Federal government, the watersheds of the region have taken first place in its economic resources, for here water, not land, is the measure of value of the farm. All the industries of this region hang with peculiar dependence upon the forest. The distance from which supplies of timber for mining, for railroads, and for domestic purposes must come if the Rocky Mountain forests are once exhausted makes their preservation an imperative necessity on these accounts, while the existence of summer range in the forest for herds of cattle, sheep, and horses gives value to immense areas of winter range which without it would be of little use, and thus maintains one of the most important industries of the region. Because of the aridity of the country the forests of the Rock Mountain region are destroyed with peculiar facility by fire, by overgrazing, and by overcutting. The reproduction is less rapid and abundant than on either the eastern or western coast, while the preservation of the forest, of vast importance everywhere throughout the United States, is here more peculiarly and immediately essential to the well-being of the people than is the case elsewhere.

(*e*) West of the Rocky Mountain Forest stretches the *Pacific Coast Forest,* probably the most densely timbered and prolific forest region of the earth. In California the forest of the Sierras, characterized by the big tree (*Sequoia gigantea,* Decaisne), the sugar pine (*Pinus lambertiana,* Dougl.), and numerous magnificent firs, is perhaps the most beautiful and attractive in existence, while the forest of coast redwood (*Sequoia sempervirens,* Lamb., Endl.) has a larger stand of merchantable timber per acre than any similar area of which we have knowledge. In Oregon and Washington, the red fir (*Pseudotsuga taxifolia,* Lam., Brit.), the coast cedar (*Thuya gigantea,* Nutt.), and the tideland spruce (*Picea sitchensis,* Bong., Trautv. and Mayer) are lumber trees of the highest commercial value and the chief economic components of the forest, while the coast hemlock (*Tsuga mertensiana*), for the present less sought after than the fir, and the red fir itself alternate as the most numerous tree in the forest. Water is the most important product of the Sierra forest, wood of the redwood belt and of the coast forests of Washington and Oregon. The cut of redwood in 1900 was 360,000,000 feet, the lumber product of Oregon 740,000,000 feet, and that of Washington 2,300,000,000 feet. During the year 1902 the loss from fire in the State of Washington was said to be about twice the cut. Although it is true that wood is by far the most important product of the coast forests of Washington and Oregon, yet the prevention of floods from the heavy rainfall and snowfall of the coast is of critical importance to many agricultural valleys.

Forests of the Philippine Islands.— The forest lands of the Philippine Islands cover an area which certainly exceeds 40,000,000 acres. They are rich both in the number and in the value of their species, and their total stand of merchantable timber is exceedingly large. Except for occasional private or monastic holdings, they are entirely in the possession of the United States, and are being administered by an Insular Bureau of Forestry in competent and reliable hands. The development of practical and systematic forestry in the Philippines is likely to be even more rapid than in the United States, and the returns from the government forests there, already more than double the expense of administration, will form one of the most important sources of revenue from the islands.

Forest Protection.— The early settlers in New England and Pennsylvania, coming as they did from regions where forest protection was rigidly enforced for the sake of the game, brought with them the survival of their habits at home, and made provision among their earlier laws for the preservation of the forest. This transplanted care for the woodlands did not long survive either in legislative or in effective public desire. It was succeeded by a reasonable appreciation that the forest, in the early days on the Atlantic Coast, was the enemy of the settler. The state of mind which was thus produced survived in enmity to the forest long after the progress of civilization had converted it from an enemy of the settler to his best friend, and the eagerness for forest destruction which has characterized the great majority of frontier communities in the United States has, after the early days, had no more legitimate cause. Until the immense expansion of the railroads which followed the close of the Civil War, the demand for timber was comparatively local in character, and the great operations of destructive lumbering had not begun. Since that time forest destruction has increased progressively until the exhaustion of the timber supply has almost been accomplished in certain regions and is imminently threatening elsewhere. Even before the era of gigantic lumbering operations, organized bodies began to take action for the preservation of the forest, but it was not until the resolutions of the American Association for the Advancement of Science in 1873 that such action achieved results. These resolutions called upon the National government to investigate the forest situation of the United States and to move accordingly. In 1876 the Commissioner of Agriculture, through Dr. Franklin B. Hough, one of the most honored pioneers of forestry in this country, organized such an inquiry. The work which Dr. Hough then began developed into the Division of Forestry in the United States Department of Agriculture, which division was greatly enlarged and became the Bureau of Forestry in 1901.

The Bureau of Forestry.— The Bureau of Forestry is divided into six offices. The Office of Forest Management prepares working plans for conservative lumbering for the National forest reserves (see below) and for State and private forest holdings. Its practical assistance to the owners of timberlands is given on the ground, either without cost in the case of small areas, or at the cost to the owner of expenses only in the case of larger tracts. The area of private forest land for which applications for assistance had been made on 1 July 1903 was 5,650,171 acres, an area far larger than the force of the Office of Forest Management has been able to cover. The total area of private lands put under management at the same date was 679,194 acres. The Office of Forest Extension gives assistance in tree planting under conditions similar to those described for the Office of Forest Management, studies methods of re-establishing the forest on areas which it once occupied, and gives special attention to the study and prevention of forest fires. On 1 July 1903 the area for which planting plans had been made amounted to 10,807.47 acres. The Office of Forest Measurements calculates, drafts, and puts into final form the very extensive measurements and maps made in the field by the Offices of Forest Management and Forest Extension. The Office of Forest Products studies the uses of timber and other forest products, makes timber tests and chemical examinations of by-products of the forest, and gives special attention to the preservation of wood. The Office of Dendrology deals with the natural history and nomenclature of trees and forests, and has charge of the forest library and the collection of forest photographs of the United States. The Office of Records is charged with the routine and the business operations of the Bureau. The appropriation of the Bureau of Forestry for the year ending 30 June 1904 was $350,000. It will be evident from what has been said that the work of the Bureau is to forward both the study of the forests of the United States and the application of practical forestry upon them regardless of the character of their ownership.

National Forest Reserves.— Parallel with the development of the Bureau of Forestry, two other lines of National forest work have sprung up, one in the General Land Office, the other in the United States Geological Survey. To the General Land Office the custody and disposal of the lands of the public domain have been given, together with the care and management of the National forest reserves created from time to time by proclamation of the President of the United States under the Act of 3 March 1891. These reserves, situated in all the Western States and Territories except Nevada, occupied on 1 July 1903 an area of 62,343,645 acres. When the first reserves were created, it was natural that their administration should be placed in the hands of the Land Office, which had had charge of these lands before they were reserved, but the development of the other government forest work has made it evident that a change is required.

In 1895 the president of the National Academy of Sciences was requested by the secretary of the interior to appoint a committee to examine the forest lands of the public domain and report a policy for their management. Upon the recommendation of this committee, President Cleveland, on 22 Feb. 1897 created some 22,000,000 acres of forest reserves. The proclamation of these reserves was immediately followed by protests in the Western States and Territories so vigorous that Congress suspended the operation of the President's proclamation for a year in all the States affected except California, whose senators, recognizing the value of reserves to their State, protested against the suspension. At the expiration of the year of suspension the proclamation of President Cleveland became effective in spite of some opposition in the West, and the forest policy of the government has never been seriously threatened since that time. The law of 3 June 1897 conferred upon the secretary of the interior all necessary powers for the management of the forest reserves through the General Land Office, and gave to the director of the Geological Survey, who had been instrumental both in saving the reserves from permanent suspension and in procuring the passage of the law, certain duties in connection with them. He was charged with the survey and description of the reserves, with mapping their topography and timber, and with recommending to the secretary of the interior their proper boundaries and marking them permanently upon the ground. The duplication of work and the loss of energy involved in the dispersion of the National forest work under these three independent agencies has been called to the attention of the Congress by the President of the United States and is likely soon to come to an end.

State Forestry.— While the national government was making the progress described, various States were taking active measures in forestry. Among those Minnesota and Pennsylvania are conspicuous for the excellence of their fire laws, New York and Pennsylvania for their forest reserves, Michigan, California, and a few other States for peculiar excellencies of State organization or public sentiment on the forest question, but except in some of the States already named and a few others the state movements for forest protection have not usually been notable either for efficiency or good results.

Forest Schools.— Instruction in forestry began in this country under the mistaken impression that forestry differs but little from horticulture and botany. But the character of forest teaching has been revolutionized within the last few years, and at present opportunity for education in professional forestry is not wanting in the United States. One of the earliest practical courses of forestry, discontinued shortly after it began, was given in the State University at Bozeman, Montana, under Capt. George P. Ahern, U. S. A., now in charge of the Bureau of Forestry in the Philippine Islands, but the first effort toward the establishment of professional instruction was in the simultaneous opening in the autumn of 1898 of the Biltmore Forest School at Biltmore, North Carolina, and the New York State College of Forestry as a part of Cornell University. The former offered a one year course without entrance examination and is still continuing to do so. The Cornell School, which offered a four year undergraduate training in professional forestry and had begun to graduate students capable of passing the government examinations, was discontinued in 1903. The Yale Forest School, which offers a two year post graduate course to the holders of a bachelor's degree from any recognized institution of learning, was established in 1900. It has already graduated more professional foresters than all other schools combined. The University of Michigan has just instituted a two year post graduate course, the University of Nebraska has established a four year undergraduate course, the State Agricultural College of Minnesota has established a four year course; Harvard University offers some instruction in forestry in the Lawrence Scientific School, and many other institutions afford the opportunity for more or less complete and effective training in various branches of forestry.

American Forestry Association.— The American Forestry Association, organized in 1882 as the American Forestry Congress, has been one of the most effective agencies in the progress of forestry and forest preservation in the United States. Its influence upon legislation has of late years been a notable one, and its summer meetings, held in whatever portion of the country needs its influence most, have been exceedingly effective in educating public opinion. Its official organ, formerly 'The Forester,' now called 'Forestry and Irrigation' because it has become likewise the organ of the National Irrigation Association, is the best forest periodical in the United States and one of the best in existence. In the publicity which it gives to forestry, it has been of late most cordially and helpfully joined by the lumber journals and the daily press of the country. The newspaper press as a whole has been a most effective agent in the dissemination of right ideas of forestry and in bringing about in Congress, among lumbermen, and among the people at large the strong support of practical forestry which is now perhaps the most hopeful sign of the forest situation in the United States.

The Practice of Forestry.— The practice of forestry in the United States naturally falls under two heads: First, those forms of conservative lumbering which were practised by farmers, lumbermen, and others without the assistance of professional foresters. Second, those forms of conservative lumbering which have been introduced under the supervision of the latter. In both cases a factor of the utmost importance is found in the methods of logging adopted or devised by the American lumbermen in different parts of the country.

Destructive Lumbering.— The methods of felling timber, except for variations in the forms of axe and saw, are approximately similar throughout the world, but the methods of handling the felled timber vary greatly. In the United States the mechanical and inventive capacity of the people has led them to develop forms of logging cheaper and more effective than those in use elsewhere. These methods have become highly specialized in response to the requirements of the market, the topography, and the forest itself in the different forest regions. In the Northern Pine Forest the final operations of logging await the fall of sufficient snow to make possible the preparation of solid ice roads over which the logs can be hauled to the bank of a stream or to the railroad. In the Southern Pine Forest and throughout the larger part of the interior hardwood region snow is not a factor in the logging. Its place is taken to some degree by timber slides or by installations of wire rope cables which drag or carry the logs from the stump to a logging train. In the Rocky Mountain region the methods vary greatly, but on the whole they are less highly developed there than in the denser timber on the Pacific slope, where wire rope logging has reached a very high point of economy and efficiency. Here the logs are dragged over specially prepared skid roads by wire cables of great length attached to the drums of donkey engines, which transport themselves about the woods by their own power whenever change of location is required. Forestry being in many respects more closely akin to lumbering than to any other occupation, it is of first importance to the forester that effective and economic methods of logging should be employed. These methods hitherto have been wasteful and destructive both to an unnecessary and to an unprofitable degree, and the future of the forest has been needlessly sacrificed to the idea of immediate gain. Conservative lumbering harvests the present forest crop economically and profitably at the same time that it provides for future growth.

Forestry by Private Owners.— The idea of perpetuating the forest by wise use, which is the essence of forestry, had found hospitable lodgment in the minds of many Americans before forestry had become a recognized profession in the United States. Examples of the treatment of the forest from this point of view were more common in the northern spruce forests than elsewhere, and especially on the Androscoggin River in Maine, where great permanent value was given to very considerable tracts of spruce land by careful handling. Among the farmers of New England, New York, and New Jersey the harvesting of successive crops of hardwood sprouts for fuel, fencing, etc., was a common practice during the last century, but as a rule the methods used, like those for the spruce in Maine, were less effective than they might easily have been.

Beginnings of Professional Forestry.— In 1891 the first example of professional forest management in the United States was begun on the Biltmore estate near Asheville, North Carolina, in a mixed forest of hardwood and pines which had been severely damaged by the mismanagement of former owners. The object of the management was to secure what revenue was possible from the forest while conducting such operations as were required to put it in good condition. Even in the first year the forest work paid for itself, and it has been conducted successfully ever since. No further examples of professional forest management were created until, in the summer of 1898, practical forestry was introduced, under the care of the then Division of Forestry of the Department of Agriculture, on two tracts in the Adirondacks of a total area of more than 100,000 acres. Other instructive examples of co-operation in practical forestry between private owners and the government have been created in Maine, Tennessee, Georgia, Texas, and many other States and Territories, and the plan is still in increasingly effective operation. Under it the great majority of the conservative forest management now in existence in the United States has been brought about. The types of practical forestry which have been adopted or devised for application in these various cases include improvement cuttings of various degrees of refinement, several types of treatment of sprout lands, and a variety of forms of the high forest and selection systems, the most typically American of which is what is called localized selection. In all cases their application has been reduced to the utmost simplicity, and a definite effort has been made to limit interference with the ordinary methods of logging to the smallest possible amount. As a result they have not interfered as a rule with the profits of the forest, while the reproduction and perpetuation of the forest, the other principal object of the management, has been fully secured. Through the application of these simple and effective methods forms of forest management peculiarly adapted to American conditions are growing up. In the early practice of American foresters many of the important tenets of European forestry, such as the doctrine of the sustained annual yield, have wisely and necessarily been abandoned, and effort has been confined to insuring the profitable use of the forest and its continuance in productive condition, not seldom at the expense of a long hiatus in the yield, provided such a form of management was satisfactory to the owner. The conditions of the lumber trade here justify the transportation of forest products for longer distances than is possible in Europe, and localities are far less dependent in America upon the local supply than is the case abroad. A fundamental consideration in determining forms of management in the United States is the extremely moderate price of low grade forest products such as firewood and the cheaper kinds of lumber. This fact, together with the cost of transportation, decides what kinds and grades of timber can be profitably cut and how closely what is cut can be put to use. Logging under the conditions of which not more than 50 per cent of the growing tree ever reaches the market, is still practised in several parts of the United States. The duty of perpetuating the forest is not less imperative under such conditions than where the price of lumber is higher. The methods of the American forester, although they must be the product of ripe training and experience if they are to succeed, are often summary and rough. In every case they must pay and in every case they must insure the perpetuity of the forest. If they succeed in these two essentials, their roughness may be disregarded.

Principal Forest Problems.— The efforts of American foresters are at the present time largely grouped about a few principal forest problems which arise from the nature of the forest, from the dangers which threaten it, and from the economic conditions by which it is surrounded.

The National Forest Reserves.— Since it is the general experience of all countries that the only forests which are permanently safe are those in the hands of a permanent owner, namely the government, the United States has by the creation of forest reserves undertaken to set aside and hold in the public hands those areas within the public domain whose preservation is essential to the public welfare. The establishment of these forest reserves met at the beginning, and in certain instances continues still to meet, unthinking opposition in certain parts of the Western States where lie the 863,000,000 acres which remain of the public lands. But in each State public sentiment is crystallizing rapidly and effectively in favor of forest preservation. This trend of the public mind makes it continually easier for the national government to set aside and hold those forest lands which it should retain, and is rapidly making possible a better administration of the reserves themselves. The latter are located either at the headwaters of streams whose protection is essential to irrigated agriculture on the lands below them, or in more densely forested regions where the preservation of the timber supply is the first consideration. In either case their preservation alone can meet a critical public need. It is unfortunate that the personnel of forest supervisors and forest rangers available for their protection has remained far below their requirements. The natural result has been that the diminution of forest fires, although striking in amount, has been less than might have been accomplished, while the stock ranges have continued to suffer from overgrazing and the reserves have been injured to some extent by timber stealing and by minor depredations. They have nevertheless answered a most important and beneficent public purpose, and under the policy which controls their administration their value to the people will steadily increase. This policy briefly stated is the employment of all their resources for the good of the people, and thus, in the language of President Roosevelt, the making and maintaining of prosperous homes.

Forest Fires.— It is altogether probable that more timber has been destroyed in the United States since the landing of the Pilgrims by fire than by the axe. In every country where timber is plenty and settlers few, fire has been harmfully employed to assist the settler in his warfare against the forest. With the progress of civilization railroads have scattered along their rights of way fires which have destroyed thousands of square miles of timber. The transcontinental railroads are lined for hundreds of miles, where they traverse the forest regions, with the bleached fire-killed remnants of the former stand. Prospectors often set fires in heavily timbered countries to uncover the surface of the mineral soil, and campers, hunters, and others, either by the injudicious location of their fires or by neglect in leaving them unextinguished, have been responsible for much important loss. The use of steam machinery in logging and the supposed necessity for burning away the debris, as in the case of the coast redwood of California before skidding the logs, has been responsible for many fires. The loss from forest fires is confined to no section of the country and its percentage has diminished but little of late years, if at all, in proportion to the total stand of timber which remains. Although exact figures are not obtainable, it probably exceeds on the average a total of $50.000,000 a year. The Hinckley fire of 1894 in Minnesota destroyed property valued at $25,000,000 and cost the lives of 418 persons. For two weeks before the high wind which gave it its destructive power this fire was smoldering in the neighborhood of Hinckley and could have been extinguished easily and cheaply at any time. During the autumn of 1902 fires destroyed property valued at $13,000,000 in the States of Washington and Oregon, while in the spring of 1903 about 650,000 acres were burned over in the Adirondack Forest in New York. Such losses are as unnecessary as they are appalling, for a small fraction of the cost of these fires expended in preventive measures would have rendered their occurrence practically impossible. There is but one effective safeguard against fire in the woods, an enlightened public sentiment with regard to it. Such a sentiment is rapidly being created within and near the National forest reserves and in certain other portions of the country. While the effort to produce it is in progress the National Bureau of Forestry is studying the natural history of forest fires and devising the cheapest and most effective means for extinguishing them. It is studying likewise their effect upon the condition and production of the forest, and the amount of loss, as special means of awakening public opinion. In the dense and moist forests of the northern pine belt, forest fires of importance almost invariably originate in the debris of cut-over lands and not seldom are unable to penetrate the untouched virgin forest. In unusually dry seasons, however, fires may burn throughout any woodlands without distinction, and it is in such seasons that conflagrations like the Hinckley and the Peshtigo fires take place. Except under extraordinary conditions, fires in forests of this type are apt to move slowly, but they are difficult to extinguish because of the mass of inflammable material in the forest floor. Mature trees in the Interior Hardwood Forest and the Southern Pine Forest are seldom killed by fire if the bark is unbroken and sound. Fires in these regions usually travel along the ground with moderate speed and are seldom dangerous to human life. The damage they occasion is in the destruction of young growth and the unsoundness which they produce in trees of larger size. They are especially destructive in those portions of the Southern Pine Forest where the longleaf pine is boxed for the production of naval stores. Where a boxed tree catches fire it is lost for such production, and most often succumbs to the attack. In the Rocky Mountain Forest fires are less uniform in type. Where the timber is dense, and especially where it is composed of a thin-barked species such as the lodgepole pine, not infrequently vast areas of the forest are killed by a single fire. In such cases the trees are not consumed, but stand bleaching long after they have lost their bark, and finally fall in an almost impassable tangle of prostrate trunks, to be consumed later by another fire together with the young growth which has sprung up among them. In the more open forests of the western yellow pine, the damage is to the young growth and to the soundness of the old trees. In many regions it is practically impossible to find a tree of any size that does not bear the marks of fire. The most serious effect of fires in the coast redwood of California is to prevent the sprouting of the old stumps after logging, and thus to convert highly valuable timberland into indifferent pasture. In the fir forests of Oregon and Washington fires are common and difficult to extinguish, but usually slow-burning and not of great extent. It is only in seasons of exceptional dryness that losses of appalling magnitude are to be expected. The State of Washington has recently passed a forest fire law, the operation of which will be watched with peculiar interest.

Some Uses of Wood.— The yearly product of wood in the United States is about 35,000,000,000 feet. In 1900 the lumber industry employed 283,260 wage-earners, to whom it paid $104,640,591. The perpetuation of this industry is of vital concern to all the people. Its ramifications are as wide as the industrial life of the nation, and its perpetuation is a most pressing concern of the forester. The use of wood for the maintenance of railroad tracks, for example, rises to about 120,000,000 ties a year, together with vast amounts of bridge timber, piling, etc. Since the use of metal ties is believed to be impracticable by American railroad engineers, the maintenance of the supply of wooden ties is of vital importance to the railroads, and through them to the nation at large. In a similar way, the permanence and success of the mining industry is dependent upon cheap and accessible supplies of timber. In most portions of the West such supplies can be expected only from the national forest reserves. In the creation of the reserves, therefore, the special needs of mining and other industries have been kept carefully, and it is also believed successfully, in mind.

Summary.— The profession of forestry, which has already reached high standing on the continent of Europe, in British India, and elsewhere, is being born in the United States. Its establishment on a high plane is of the first importance to the solution of every problem of American forestry. The forest wealth of this country, although vastly diminished, is still very great, and the reproductive capacities of its forest are usually of the first grade. Wood is cheap and methods of the lumberman are wasteful. The low cost of transportation permits the movement of forest products from vast distances, so that local markets are supplied from distant points. In view of all these conditions, the task of the American forester is to secure the reproduction of the forest without materially impairing the profit of lumbering, and wherever possible to bring into public ownership whatever forest lands are required to supply in permanence the public need.

GIFFORD PINCHOT,
Bureau of Forestry, Washington.

Forests, Petrified, fossil remains of forest trees and plants found in the Potsdam sandstone formations in America and the Cambrian rocks of Europe. Large forest trees, fossilized and converted into stone are found in many sections of the United States, particularly west of the Mississippi River. Those of Arizona are well known. PALÆOBOTANY.

Forey, Elie Fréderic, ā-lē frā-dā-rik fō-rā, French military officer · b. Paris, France, 10 Jan. 1804; d. there 20 June 1872. He took part in several Algerian campaigns as well as in the Crimean and Sardinian wars, and when the expedition to Mexico was decided upon in 1861, Forey received the command of the French troops. After several sanguinary engagements, he attacked and stormed the strong post of Puebla, thereby throwing open the road to the city of Mexico. For this service he was made marshal of France.

Forfeiture, fôr'fit-ūre, a legal penalty, by which an owner is absolutely deprived of his property for crime or other unlawful act. This applies to personal as well as real property, and forfeiture may be a decree of civil as well as criminal courts. The penalty is of feudal origin. The lord owed protection to the life and property of the vassal; the latter owed fealty and service to his lord. When the vassal failed to yield these, he lost the shelter of the law, became an outlaw, and incapable of holding property. Loyalty to the feudal relation being the condition on which life and property were secured to him, when he failed in loyalty he had no longer any claim on life or property.

Treason was punished by forfeiture long before the Norman Conquest in 1066. After that period forfeiture became the ordinary penalty for felony, which was styled petty treason; while treason, or disloyalty in regard to the sovereign, was called high treason. Forfeiture was accompanied by what was styled corruption of blood. This was the sentence of legal bastardy passed on the offender so that he could neither inherit nor bequeath property.

Felony in the United States has never been considered ground for forfeiture. The Federal and State laws have modified all precedents in the matter of forfeiture, which they restrict within very narrow limitations. See ATTAINDER.

In England civil forfeiture may be incurred by tortious alienation, by wrongful disclaimer, by alienation in mortmain (see MORTMAIN), by breach of condition, and by the commission of waste (see WASTE). In Scotland civil forfeiture may arise either from statutory enactment, at common law, or by agreement. In the United States civil forfeiture is only imposed for acts of waste committed by tenants for life or years, or for breach of contract in violating the conditions on which lands were granted. Some States have abolished even this degree of forfeiture. By particular statutes enacted by Congress smuggling, or importing goods on fraudulent invoices involve confiscation, and forfeiture of the entire invoice (see INVOICE), or the balance wrongly imported. Piracy has always entailed confiscation or forfeiture of the piratical craft.

Forge, Forging, and Forging Machines. A forge is a furnace or open fireplace, having a forced draft, for heating metals, especially iron and steel, to be shaped by hammering or pressure. Previous to the 19th century, most iron work was forged by smiths on avils. Then came the period of cast iron, when everything that could be cast was made that way because it was cheaper, and during the last half of the century the use of forged iron and steel increased enormously owing to improved and cheapened methods of production. Now, in 1893, a vast quantity of steel for machine-made forgings finds its way into machines and structures, giving greatly increased strength and durability. A simple blacksmith's forge is a brick structure, with a chimney at one side. The coals and fire are located at the mouth of the chimney, and a bellows or rotary fan furnishes a blast of air which is driven from underneath through the mass of coal. This coal is usually soft, sometimes being termed blacksmith's coal. Portable forges are made for light work, and a common form of these has four legs made of iron tubing, a shallow bowl to hold the coal and contain the fire, and a hood above. At the rear is a small rotary fan; operable by a wheel-crank. As forges increase in size and capacity, they develop into what are more properly called furnaces, such as the immense heating furnace of a steel works. In forging iron by hand the smith thrusts the metal into the centre of his fire, and its color tells him when it is ready to be worked. As it heats, it becomes black red, then a low red, then bright red, then a white heat, and if the heating continues it next begins to burn. If the smith desires the iron to be very soft, that it may yield quickly to his blows, he lets it come to a white heat, then takes it with his tongs on to his anvil, and begins to hammer it rapidly into the desired shape. Often a helper stands by to strike blows alternately with the smith, in order that as much hammering as possible may be done before the iron cools to a point where it requires reheating. Long practice makes very expert smiths, and many of them will shape a bar of iron into intricate form in a surprisingly short space of time. When the smith desires to weld together two pieces of iron, he must heat both pieces at the same time to a uniform white heat. As the iron approaches a white heat he throws sand on it, which, if done at the proper temperature, adheres and melts, forming a liquid glass-like fluid that flows over the surface of the iron and keeps the air from it, thus preventing its burning. If the ends of two bars are to be welded, each is first brought to a flat point, so that there will be considerable surface to weld together. After the surfaces adhere, the weld may be reduced by reheating and hammering down to the size of the other portions of the bars. When pieces are joined end to end, this is termed a butt-weld, which is not apt to be as strong as a lap-weld. Where forgings are so large that a smith and helper cannot work them satisfactorily, because there is too much and too heavy hammering to be accomplished in the short time the metal retains its great heat, the machine hammer is resorted to. This was made in various forms, and was an important tool during the early part of the 19th century, finding its culmination in the great steam-hammer of Neysmith, which was devised especially for such large forgings as the shafts of paddle-wheel steamships, then coming into use. The trip-hammer and the steam-hammer were the chief tools used for large forgings until about 1890 when the hydraulic press began to supersede the hammer for large work. About 1884, when the United States government began to seriously take up the rebuilding of the navy, and the construction of steel battleships and cruisers, there came a demand to American manufacturers for very large forgings, which had not previously been produced here. The forges of that date were equipped with power hammers, of a capacity suited to welding wrought iron into forgings of moderate size. The introduction of steel rails taught American iron manufacturers that steel forgings were desirable in all classes of machinery, as greatly reducing the size of the parts, because of the increased strength.

The hydraulic compression system of forging, which was introduced in America when our steel plants were called upon to provide the large forgings for the navy, has met with general approval, and is steadily increasing in use. It has been demonstrated that forgings made by hammering were subject to all sorts of internal strains due to differences in compression and differences in cooling. When such a forging is cut, as for making a keyseat, a distortion of form follows as the result of certain strains that have been relieved. A large forging requires a pressure great enough to penetrate to every part of the mass of metal, so that the flow of metal resulting shall take place uniformly throughout. Such a flow requires time and a pressure that can not be obtained by a quick hammer blow, and a series of blows does not produce the same effect as does the persistent pressure of the hydraulic forging machine. Fluid steel begins to crystallize at the point where the degree of heat is reduced so that it solidifies (about 2,600° F.), and the more slowly it is cooled from this point downward, the larger will be the crystals of the ingot. Forging during the cooling tends to check crystallization, just as stirring water at a temperature below the freezing point would check the formation of ice crystals. The more irregular the method of forging is, as in the case of hammer blows, the more it interferes with an even crystallization. The pressure system not only interferes much less than hammering, but forgings are farther improved in modern practice, by reheating above the recalescent point, which is between 1,200 and 1,300° F., depending on the percentage of carbon and annealing to secure a new crystallization, and oil tempering.

An examination of the grain or fibre of hydraulic forgings shows that the steel tends to arrange itself in layers following the outer contour of the piece of metal, thus securing the most strength. A sharp angle in the pattern will tend to cut off the flow of metal, and if such is required, the method is to round out the place in the forging, to secure the best flow of metal, and then machine off the surplus later.

To avoid internal strains as much as possible such large forgings as steamship shafts are preferably made hollow. That is to say, the cylindrical ingot from the furnace after cooling is bored through the centre, mounted on a steel mandrel, heated and forged by compression. Ingots produced with fluid compression are well adapted to being bored and hollow-forged, and this method produces the most perfect forgings. These large forgings are subjected to a hydraulic pressure of about 7,000 pounds to the square inch, which pressure is maintained while the mass slowly cools. Shafts of more than a foot diameter are best bored, as the bore hole not only assists uniform heating, but gives opportunity for inspection.

Small forgings of iron, steel and other metals are now most commonly produced by the method known as drop-forging. A press containing a top and bottom pattern (die and counter) receives the roughly shaped hot metal, and at a single blow brings it to the desired shape. Parts of machines that were formerly made of cast iron or steel are now drop-forged at moderate cost, and the metal is so much stronger that they can be lightened materially in weight, thus sometimes actually reducing the cost, while increasing the durability. See BELLOWS; FURNACE; HAMMER; IRON; PRESS; STEEL; WELDING.

CHARLES H. COCHRANE.

Forgery, the fraudulent making or alteration of a writing to the prejudice of another man's rights, or making of any written instrument for the purpose of fraud and deceit; the word *making,* in this last definition, being considered as including every alteration of or addition to a true instrument. The offense of forgery may be complete though there be no publication or uttering of the forged instrument; for the very making with a fraudulent intention, and without lawful authority, of any instrument which, at common law or by statute, is the subject of forgery, is of itself a sufficient completion of the offense before publication. Most of the statutes, however, which relate to forgery make the publication of the forged instrument, with knowledge of the fact, a substantive offense. A deed forged in the name of a person who never had existence is forgery at law. A writing is forged when a person drawing up a will for an invalid, inserts legacies therein falsely. It is not material whether a forged instrument be drawn in such manner that if it were in truth that which it counterfeits it would be valid. The punishment of forgery at common law is, as for a misdemeanor, by fine, imprisonment, and such other corporeal punishment as the court in its discretion might award. The penalty varies in different States, in some the statutes having been much enlarged to include acts which were not punishable formerly as forgery. The punishments ordained for the offense by the statute law in England were once, with scarcely an exception, capital.

Forli, Melozzo da, mā lōts'ō dä fōr lē', Italian painter: b. Forli, about 1438; d. 1494. He was the first who applied the art of foreshortening to the paintings of vaulted ceilings. About 1472 he painted the 'Ascension' in the great chapel of the Santi Apostoli at Rome for Cardinal Riavio. In 1711, when the chapel was being rebuilt, this painting was cut out of the ceiling and placed in the Quirinal palace, where it still remains.

Form, in philosophy, a term used (1) objectively, to denote the assemblage of qualities which makes a thing what it is. Only the essential and permanent is considered, the accidental or adventitious being disregarded. The word is employed also (2) subjectively, to express the idea which the mind may supply of an object, as distinguished from that object as it is in itself. In this sense it is peculiar to the philosophy of Kant, who postulated two such ideas, namely space and time, supplied to the object by the mind through the operation of experience.

In botany, the term used to designate the unit of ecology, as that division of the study which treats of the relations existing between plants and their environments is now called. The word is frequently met with in such combinations as "form of vegetation" or "plant form." See BIONOMICS; PLANT GEOGRAPHY.

In music, that theory in the general art of composition in accordance with which themes, tonalities, phrases, and sections are so arranged as to obtain a correlated and symmetrical whole. The principal three recognized forms are those of the *lied, rondo,* and *sonata.* These admit of numerous variations. In so-called cyclical forms, as, for example, the symphony, the necessary correlation and symmetry is secured by the relation of the movements as to proportion and key, the succession of various tempi, and sometimes also the employment in one movement of a theme previously used in another.

Formâ Pauperis, fôr'ma pâ'pėr-is, **In,** signifying — in the character of a poor person — is the legal term both in Great Britain and the United States for suits carried on by individuals who are too poor to pay the usual fees. As early as the reign of Henry VII., a statute provided that any one taking oath that he was not worth £5 beyond his wearing-apparel and the subject in dispute, was entitled to have writs, according to the nature of the case, without paying fees, and the judges were to assign him counsel and attorney who should act gratuitously. This indulgence is granted to plaintiffs only at common law, and is granted to defendants only in prosecutions. A plaintiff must have a counsel's certificate of a good cause of action, and an affidavit of the party or his attorney must be laid before court that the case contains a full and true statement of material facts. A person admitted to sue *in formâ pauperis* is not entitled to costs from the opposite party, unless by order of the court or of a judge. In several of the United States the provision is governed by statute, while in others it is considered part of the common law.

Formaldehyde. See BACTERICIDE; DISINFECTANTS; FUMIGATION.

Form'alin, a solution produced by dissolving in 60 per cent of water 40 per cent of what is known as formaldehyde gas, CH_2O. This solution has hitherto been looked upon as a powerful disinfectant. Dr. Charles C. Barrows has recently employed formalin as a specific for sepsis or blood poisoning. The patient was a colored woman, 26 years of age, who was on the point of death; the virulent bacteria of septicæmia, streptococci, had been recognized in her blood, her pulse ranged from 150 to 160 and her temperature was 108. Into one of the large veins of the right arm an attempt was made to inject one litre of formalin solution of the strength of one part of formalin to one thousand parts of water. About 500 cubic centimetres of the solution found its way into the circulation. The temperature fell almost immediately and the pulse showed an instantaneous improvement. The day after another injection was made and examination showed that bacteria were no longer present in the blood. A third injection into the patient's left arm introduced 750 cubic centimetres into the circulation. The temperature fell to normal, no more bacteria were developed and the woman recovered rapidly.

For'man, Harry Buxton, English author: b. London 1842. He entered the Civil Service in 1860 and is an assistant general secretary at the General Post-office, London. Besides editing the poems of Shelley (1876–80), of Keats (1883) and other works, he has published: 'Our Living Poets' (1871); 'Elizabeth Barrett Browning and Her Scarcer Books' (1896); 'The Books of William Morris' (1897).

Formation, in geology, a term used of groups of rock, whether stratified or unstratified, having a similar origin or character. Thus it is usual to speak of a limestone, a sandstone, or a clay formation. The word has also been by some extended to be synonymous with system, or to denote a group of strata of the same age, as Canadian series, Carboniferous system, etc.

Formen'to, Felix, American surgeon: b. New Orleans, La., 16 March 1837; d. there, 4 June 1907. He studied at Jefferson College, Louisiana, and the University of Turin, Italy, and was a surgeon in the Franco-Sardinian army during 1859, and in the American Civil War was chief surgeon of the Louisiana Confederate hospital at Richmond, Va. At one time he was president of the American Public Health Association, later president of the Confederation of State and Provincial Boards of Health of North America, and in 1898 was appointed surgeon to the Louisiana Soldiers' Home. His publications include monographs on cremation, military surgery, alcoholics, etc.

For'mes, Karl Joseph, German-American operatic basso: b. Mülheim-on-the-Rhine, Germany, 1810; d. San Francisco, Cal., 1889. He made his first appearance at Cologne in 1841 as Sarastro in Mozart's 'Flauto Magico.' He quickly obtained an European reputation, and after connection in 1852–7 with the London Royal Italian Opera, came to the United States, where he was received with much approval and remained during the greater part of his life.

For'mic Acid, a monobasic organic acid having the formula CH_2O_2, or H.COOH, the final H in the last of these formulæ being the one that is replaced when the acid combines with bases to form its salts (which are known as "formates"). It is an important substance in organic chemistry, and may be obtained by the oxidation of methyl alcohol, as well as of starch, sugar, and other organic substances. The most convenient method of preparing the acid is by heating anhydrous glycerin with crystallized oxalic acid. The reaction is not a simple one, monoformin being one of the intermediate products; but the obvious part of the reaction is that the oxalic acid is converted into formic acid with liberation of carbon dioxid. Pure anhydrous formic acid is a pungent, colorless liquid, boiling at about 212° F. at ordinary atmospheric pressure (its vapor burning with a bluish flame), and freezing at about 47° F. into a white crystalline mass. Formic acid is completely resolved by strong sulphuric acid into water and carbon monoxid, $H.COOH = H_2O + CO$. It reduces Fehling's solution (q.v.), and also reduces gold and platinum to the metallic state, from their solutions. When boiled with the nitrates of silver and mercury, formic acid precipitates these metals in the form of grayish metallic powders.

Formic acid and its salts are used to a certain extent as disinfectants and preservatives. The acid takes its name from the fact that it exists, in the free state, in the bodies of red ants (*Formica rufa*), from which it may be obtained by crushing the ants and distilling the mass with water.

Formica, fôr-mī'ka; **Formicidæ**, fôr-mĭs'ĭ-dē, the genus and family respectively which contain the typical ants. See Ant.

Formicariidæ, fôr"-mī-ka rī'ī-dē, a family of small, tropical American birds, the so-called «ant-birds.» They are numerous in genera and species, are related to the tree-creepers and plant-cutters, and frequent forests and thickets, flying badly from the shortness of their wings and consequently feeling most at home on the ground, where they devour beetles, spiders, and insect larvæ and berries, but are not known to eat ants at all. The nests are usually made in low bushes. They wear sober colors, as a rule, and the sexes are similar.

Formigé, Jean Camille, zhoṅ kä-mēl fōr-mē-zhā, French architect: b. Bouscat, Gironde, 1845. He was a pupil of Laisné, and received from the French government a commission for a series of plans for, and restorations of, public structures; the latter including the Roman theatre at Orange, Vaucluse. He executed decorations in the Paris Hôtel de Ville, became architect of Paris streets and parks in 1885, built the Liberal Arts and Fine Arts buildings at the Paris Exposition of 1889, and the buildings of the Rumanian government at that of 1900.

Forming Machines, a term has been applied generally to the lathe, planer, shaper, and all that class of tools used by the machinist to produce the parts of machines that he manufactures. It has also been used to designate presses used for drop-forging, and for shaping metal in the cold, particularly to drawing-presses that receive a sheet of metal, grip it between two surfaces and then subject a part of it to slow pressure until it is drawn out to a cup-shape or the like, if properly done without any wrinkling. A form of rope-twisting machine is also known as a forming machine as well as a machine for forming tin cans. See Forging and Press.

Formosa, fôr-mō'sä, called by the Chinese *Taiwan*, an island lying off the coast of the Chinese province of Fu-chien, from which it is separated by a strait from 90 to 220 miles wide. Formosa, which was ceded by China to Japan in 1895, is crossed by the meridian 121° E. and the tropic of Cancer, and has a maximum length of 235 miles, while its breadth varies from 70 to 90 miles; area, 14,978 square miles. Forming one link in the volcanic chain that extends from the Aleutian Islands southward to New Guinea, it constitutes the eastern escarpment of what was once the great Malayo-Chinese continent, and is connected by a submarine plateau with the Chinese mainland. The backbone of the island, extending north and south, is formed of a range of densely wooded mountains, called by the Chinese Chu-Shan, which rise to upward of 14,000 feet, the highest known peak, Mount Morrison, being given as 14,362 feet. Eastward of this range lies a narrow strip of mountainous country, presenting to the Pacific a precipitous cliff-wall with in many places a sheer descent of from 3,000 to 7,000 feet, while a very short distance farther east the floor of the ocean sinks to a great depth at an extremely steep gradient. The western side of the range consists of a single broad alluvial plain, stretching from north to south of the island, seamed by innumerable water channels, and terminating at the coast-line in mud flats and sand-banks. Yet on this side of the island the land is rapidly encroaching upon the sea, as the consequence of the gradual elevation of the western seaboard and the deposition in and around the embouchures of the rivers of the large amount of sediment brought down by them from the mountains. This latter process is primarily due to the heavy rainfall of the northern, central, and eastern portions of the island, where the rain-clouds of the northeast monsoon, after crossing the warm Kiosiwo, or Japanese Gulf Stream, on coming in contact with the mountain barrier of the island become chilled and discharge their contents in rains of excessive violence. Apart from this heavy rainfall, the climate is not exceptional, the insular position ensuring a modification of the heat by sea-breezes. The mean of summer is 80° to 90° F.; of winter, 50° to 60°. Malarial fever is, however, prevalent in the north, and violent typhoons are very common at certain seasons.

The island is famous for the luxuriance of its vegetation; many of the hothouse plants of warm temperate climes grow wild on the mountain slopes and in the valleys, such as orchids, azaleas, lilies, rhododendrons, and convolvulus; besides which there is a profusion of ferns, tree-ferns, camphor- and teak-trees, pines, firs, wild fig-trees, liquidambars, bananas, bamboos, palms, indigo and other dye plants, fibre and paper plants, oil and soap plants, tobacco, coffee, and tapioca. «Rice paper» is prepared from the pith of a tree peculiar to Formosa. Of animal life it is noticeable that there are at least 43 species of birds peculiar to the island, that insects are scarce and that noxious wild animals are few; but that fish is plentiful near the coast. The resemblance of the animals found on the island to those on the mainland is one reason for believing there was once a land connection. However there are a number of animals on the island which appear to be of quite a different species from those found in China. This is especially true of some of the birds, mice, squirrels, and deer. The chief minerals are coal, of which there is a large supply, gold, salt, petroleum, and sulphur. Agriculture is an important industry, but the people engaged in mining are becoming more numerous.

Since the treaty of Tien-tsin, in 1858, there have been ports open for foreign commerce; those opened in accordance with the conditions of the treaty are: An-ping, Tainan, Takow, and Tam-sui. An-ping and Tam-sui have the largest amount of commerce. The principal exports are camphor, tea, rice, sugar, jute, hemp, and dyewoods. The chief imports are a coarse cloth for clothing, opium, fruits, lumber, metal goods, and manufactured tobacco. The most of the trade is with Japan. Formosa controls the camphor markets of the world. The eastern slope of the mountains is covered with the largest camphor forest yet discovered. The amount of camphor exported each year from the forests of China and Japan is about 500,000 pounds; and from

Formosa alone there is shipped between 6,000,000 and 7,000,000 pounds. Since Formosa was annexed to Japan, the Japanese government has made most successful efforts to preserve the sources of supply of camphor. When the island belonged to China the camphor-trees killed to collect the gum were not replaced and the camphor forests were being destroyed. The Japanese government insists that for every tree destroyed another one must be planted; and it is also establishing camphor plantations, so that in future the Formosa cultivated camphor will be a commodity of commerce. The price of the camphor varies because of the dangers incurred in collecting it. Savage tribes which have never been subdued inhabit the camphor forests, and they never hesitate to attack the camphor gatherers unless the latter are well armed and in bands large enough to protect each other. The Japanese government has now a large armed force of policemen, over 1,400, to protect the camphor gatherers, and the cost of protection is added to the selling price of the gum. The sale of the camphor is a government monopoly; it is not difficult to obtain a permit to gather camphor, but every pound must be sold to the Japanese government, which determines the price. Japan limits the amount to be exported, and will not buy a pound in excess of the limit. The cultivation of the tea fields is receiving attention from Japan.

The inhabitants, estimated to number about 3,000,000, consist of Chinese settlers, some Japanese, and the aborigines. Respecting the ethnological origin of these latter there exists some doubt; they seem to consist of several different tribes, mainly of Malayan and Negrito descent. The Chinese distribute them into three classes, Pepohwan, a race of civilized and sinicized agriculturists; Sekhwan, settled tribes who acknowledge Chinese rule; and Chinhwan, the untamed savages of the mountains, who wage fierce and unceasing warfare against the Chinese immigrants. The administrative headquarters were formerly at Taiwan, but on the constitution of the island into an independent province of the Chinese empire in 1887 — it had formerly been incorporated with Fû-chien on the mainland — they were transferred to Tai-pei or Bangka. The island was known to the Chinese before the Christian era, but does not seem to have seriously attracted their attention until the year 605 or 606 A.D. In the 14th century they established several colonies in Formosa, which, however, were withdrawn in the middle of the 17th century. Although Portuguese and Spanish navigators began to visit the island a century earlier, the first European people to establish themselves on it were the Dutch, who in 1624 built Fort Zealandia, near the modern Taiwan. They were, however, expelled in 1661 by a Chinese adventurer, Koxinga, who retained possession of the island for 22 years. Some years later a regular Chinese colonization of the western half of the island was carried through, the colonists coming principally from Fû-chien and Kwang-tung. Subsequently the island became notorious for the piracy of its inhabitants and the ill-treatment they inflicted upon navigators who chanced to be wrecked on their coasts. Accordingly in 1874 the Japanese invaded Formosa; but on the Chinese undertaking to check the evils complained of they withdrew. Ten years later the French, during their contest with China in Tongking, held for a time the coal districts of Kelung. The occupation by the Japanese troops did not take place without opposition from the natives and Chinese "Black Flags," but the Japanese were practically in full possession of the island before the end of 1895, and set themselves at once to the work of reorganization. Consult: Davidson, 'The Island of Formosa' (1903); Guillemard, 'Cruise of the Marchesa'; Girard de Rialle in 'Revue d'Anthropologie' (1885).

Formosa, South America, a province of Argentine, in the northeastern portion of the republic. It has an area of 42,000 square miles, and pop. (1900) 6,000.

Formo'san Deer, a small spotted deer (*Cervus taevanus*), allied to the Japanese sika (q.v.) and a favorite pet among the people of Formosa, who catch the fawns in the mountains.

Formosus, fôr-mō'sus, Pope: b. about 816; d. 896. He became cardinal bishop of Porto in 891 and succeeded Pope Stephen V. in 891. He condemned Photius, excommunicated the Emperor Lambert, Duke of Spoleto, and nominated in his place Arnoul, king of Germania. Stephen VI., his successor, had his body disinterred as that of a usurper, but under John IX., in 898, his pontificate was pronounced valid.

Forms of Address in the United States are neither so complicated nor so rigidly arranged as in countries where careful gradations of rank and title obtain. Usage, however, sanctions the forms given in the following list:

The President of the United States, governors of States ambassadors, and ministers,— "His Excellency."

The Vice-President of the United States, the heads of the executive departments, justices of supreme and superior courts, lieutenant-governors of States, and mayors,— "The Hon. ——."

Senators and representatives of the United States, or of States,— "The Hon. ——."

Ex-presidents, or ex-officials of any of the ranks above cited,— "The Hon. ——."

Archbishops, if cardinals,— "His Eminence the Cardinal Archbishop of ——."

Archbishops, if not cardinals,— "The Most Rev. the Archbishop of ——."

Bishops, in the Roman Catholic and Protestant Episcopal Churches,— "The Right Rev." or "The Right Rev. the Bishop of ——."

Bishops, in the Methodist Episcopal Church,— "The Rev. Bishop."

The designation "Esquire," once chiefly applied to lawyers, is now frequently employed in addressing gentlemen of position.

The forms of address used in foreign countries, particularly those monarchical in government, are arbitrary and elaborate.

Formula, Chemical. See CHEMISTRY.

Form'ulary, National, a volume published by a committee of the American Pharmaceutical Association containing prescriptions with directions for making a large number of widely used combinations of drugs. These combinations have been used in the treatment of disease for many years, and a more extended use of the formulary by the physician would do away with many of the proprietary remedies on the market.

Fornáris, José, hō sā' for-nä'rēs, Cuban poet: b. Bayamo, Cuba, 1826. He wrote the dramas 'The Daughter of the People,' and 'Love and Sacrifice'; and is the author of: 'The Harp of the Home'; 'Songs of the Tropics'; and other volumes of verse.

For'ney, John Weiss, American journalist: b. Lancaster, Pa., 30 Sept. 1817; d. Philadelphia 9 Dec. 1881. He was apprenticed in the office of the Lancaster *Journal* in 1833; was clerk in the National House of Representatives from 1851–5; and secretary of the United States Senate from 1861 to 1868. He was connected with several papers in Philadelphia and Washington. Author: 'What I Saw in Texas' (1872); 'Anecdotes of Public Men' (1873); 'Forty Years of American Journalism' (1877).

Fornix. See BRAIN.

For'rest, Edwin, American actor: b. Philadelphia 9 March 1806; d. there 12 Dec. 1872. In 1820 he made his first appearance in public in the part of Douglas in Home's tragedy of that name, and coming before the New York public in 1826 in the character of Othello, at once gained popularity. In 1836 he crossed the Atlantic and entered on a season at Drury Lane Theatre, London. In the parts of Macbeth, Lear, and Othello he achieved distinguished success, and acquired the friendship of Macready, Kemble, and others. He again visited England in 1845, and on this occasion quarreled bitterly and causelessly with Macready, whom he accused of trying to damage his reputation from professional jealousy. This quarrel crossed the Atlantic, and when Macready was playing in the Astor Place Theatre, New York, in 1849, the partisans of either actor stirred up a riot that was accompanied by serious loss of life. Between 1853 and 1860 he retired from professional life, but when he returned to the New York stage he filled the role of Hamlet with all his former acceptance. Latterly he suffered considerably from illness, and his last engagement was in 1871. He was a man of fine presence, well equipped for his profession, naturally frank and engaging. He left a large fortune. See Rees, 'The Life of Edwin Forrest' (1874); Alger, 'Life of Edwin Forrest' (1877); Barrett, 'Edwin Forrest' (1882).

Forrest, SIR John, Australian explorer and politician: b. Western Australia 22 Aug. 1847. He entered the survey department of Western Australia in 1865, and in 1874 was at the head of a party which explored the interior from Champion Bay on the west to the overland telegraph line connecting Adelaide on the south with Port Darwin on the north coast. After holding various government posts he was returned unopposed in 1890 to the first Western Australia Legislative Assembly for Bunbury, and was premier and treasurer 1890–1901. He was postmaster-general of Australia 1900–1; minister for defence 1901–3; minister for home affairs 1903–4; treasurer since July 1905; and since 1901 has represented Swan in Parliament. His publications are: 'Explorations in Australia' (1876); and 'Notes on Western Australia' (1884–7).

Forrest, Nathan Bedford, American soldier: b. Bedford County, Tenn., 13 July 1821; d. Memphis, Tenn., 29 Oct. 1877. Moving with his father to Marshall County, Miss., he was in a short while, by the death of his father, left to support his mother and family with a small hill farm. He undertook this work with devotion and energy, and, getting into business in Memphis, became able to purchase a large plantation, and was at the outbreak of the Civil War one of the wealthiest planters in Tennessee. Circumstances had forced him to neglect his own education, though he provided liberally for that of his brothers and sisters. On 14 June 1861 he entered the Confederate service as a private in White's mounted rifles, but soon obtained authority to raise a regiment, which he did, purchasing at his own private expense its equipment in Louisville, Ky. These supplies he carried to Memphis, displaying remarkable ingenuity and daring both in eluding the Federal authorities and in defeating a body of their troops with 75 Kentucky Confederates who had come to his assistance. Joining his regiment to the force defending Fort Donelson in February 1862, he was distinguished in the fighting at that point, and, when his superiors had determined upon surrender, led his men through a sheet of icy water past the Federal lines and escaped. Joining Albert Sidney Johnston (q.v.), he was distinguished at Shiloh, where he received a painful wound, which, however, did not long keep him from the field; and by a series of successful movements in Middle Tennessee, then occupied by the Federals, he rapidly rose to great distinction as a cavalry leader, and on 21 July 1862 was promoted brigadier-general. During Bragg's Kentucky campaign he performed great services both on the advance and retreat. Among his most famous exploits in Middle Tennessee was the expedition in which, with less than 1,000 men, he captured McMinville, and, surprising a garrison of 2,000 Federals at Murfreesboro, captured all the survivors of the fight, including Gen. Crittenden. On 8 May 1863 he captured a raiding force of Federals under Gen. Streight, near Rome, Ga., the Federal force being so much larger than his own that he pressed into service all the citizens in reach in order to form an adequate guard.

After highly distinguished service at the battle of Chickamauga, he was so dissatisfied with the failure to reap the full fruits of that great victory that he tendered his resignation. This was not accepted, but, instead, he was promoted major-general and assigned to the command of all the cavalry in West Tennessee and North Mississippi. Entering West Tennessee with a small force, he was reinforced by several thousand hardy volunteers, who, with his veteran troops, were soon welded into an invincible body known as "Forrest's cavalry." In February 1864 he routed Gen. S. Smith at Okatona, Miss.; then swept northward through Tennessee to the Ohio River, capturing Fort Pillow, Union City, and other posts, with their garrisons. In June 1864, with a much smaller force than the enemy, he defeated Gen. Sturgis at Brice's Cross Roads (or Tishamingo Creek), near Guntown, in North Mississippi, capturing all his trains and a third of his men. Gen. A. J. Smith then advanced against him, but after fighting a desperate battle at Harrisburg, near Tupelo, in Mississippi, retreated. Receiving reinforcements from Memphis, Smith advanced again, but Forrest foiled him by making a 60-hour ride to Memphis with half of his force, and by his daring entry into that city compelled Smith's rapid retreat. Then Forrest made havoc with Federal transportation, capturing garrisons and depots in Tennessee, and crowning his exploits by the capture and destruction of $6,000,000 worth of Federal supplies and a gunboat fleet at Johnsonville. Sherman wrote of this as a feat of arms which excited his admiration. Upon Hood's advance into Tennessee, Forrest joined him at Florence and performed important services. As commander of the rear guard of the Confederate army during the retreat from Nashville, his display of heroic qualities and brilliant leadership increased his already great fame. In February 1865 he was promoted lieutenant-general, and to him was assigned the duty of guarding the Confederate frontier from Decatur, Ala., to the Mississippi River. The surrender of the remnant of his command took place on 9 May 1865. During his career he had captured 31,000 prisoners. After the War he returned to civil life.

JOSEPH T. DERRY,
Author of 'The Story of the Confederate States.'

Forrester, Fanny, pen-name of EMILY CHUBBUCK JUDSON (q.v.)

Forsh'ey, Caleb Goldsmith, American engineer: b. Somerset County, Pa., 18 July 1812; d. Carrollton, La., 25 July 1881. He was educated at Kenyon College, Ohio, and the United States Military Academy, was professor of mathematics and civil engineering in Jefferson College, Mississippi, 1836–8, and from 1851–3 was engineer-in-charge of the governmental survey of the Mississippi delta. Though actively opposed to the secession movement, he became lieutenant-colonel of Confederate engineers upon the withdrawal of Texas from the Union. He collaborated in 'The Physics of the Mississippi River' (1861).

Forskål, fôr'skâl, **Peter,** Swedish botanist: b. Helsingfors 11 Jan. 1732; d. Djerim, Arabia, 11 July 1763. In 1761 he was selected by Frederick V. of Denmark to join the scientific expedition to Arabia, to take charge of the department of natural history. He set out on this expedition with Niebuhr, Von Haven, and Kramer, and collected plants in the environs of Marseilles, of which he published a 'Flora' at Malta. Niebuhr collected Forskal's papers, accompanied them with remarks, and published them under the titles: 'Descriptiones Animalium, Avium, Amphibiorum, Piscium, Insectorum, quæ in Itinere Orientali observavit P. Forskal' (1775); 'Flora Ægyptiaco-Arabica, etc.'; 'Icones Rerum Naturalium, quas in Itinere Orientali depingi curavit Forskal' (1776).

Forster, Johann Reinhold, yō'hän rīn'hōlt fôr'stĕr, German naturalist: b. Dirschau, Prussia, 22 Oct. 1729; d. Halle 9 Dec. 1798. In 1753 he became pastor at Nassenhuben, but devoted most of his time to the study of mathematics, natural philosophy, natural history, and geography. In 1772 he received the offer of naturalist to Capt. Cook's second expedition to the South Seas. In association with his son, he published a work on the botany of the expedition, and 'Observations Made During a Voyage Round the World.' He wrote also: 'Introduction to Mineralogy'; 'Flora of South America'; 'Zoology of India'; etc.

Forster, fôr'stėr, **John,** English historical writer: b. Newcastle-on-Tyne, England, 2 April 1812; d. London 2 Feb. 1876. He was educated for the law; held one or two public offices, and finally engaged in literature and journalism and was editor of the London 'Examiner' for nine years. He is best known for his 'Life of Charles Dickens' (1871–4). He also wrote: 'Statesmen of the Commonwealth of England' (1831–4); 'Life of Oliver Goldsmith' (1848); 'Walter Savage Landor' (1869;) etc.

Forster, fôr'stėr, **William Edward,** English statesman: b. Bradpole, Dorsetshire, 11 July 1818; d. London 5 April 1886. He was educated at the Friends' School at Tottenham, and was active in the woolen trade in Bradford. In 1850 he married the eldest daughter of Dr. Arnold of Rugby. In 1865 he became under-secretary for the colonies; in 1868 was appointed vice-president of the council on education and a privy councilor; and in 1870 accepted a seat in Gladstone's cabinet, and carried through Parliament the Elementary Education Bill (1870) and the Ballot Bill (1872). In 1880 he accepted the post of chief secretary for Ireland at a time when that country was distracted by political and agrarian tumults. To mitigate the severity of the numerous evictions he introduced a Compensation for Disturbance Bill (1880), which was rejected by the House of Lords. The following year he introduced a Land Bill and a Coercion Bill, both of which were passed, and in order to check the growing power of the Land League he declared that organization illegal, and imprisoned Parnell and other members of his party. In April 1882 the government resolved to release the Parnellites and adopt a more conciliatory policy, whereupon he resigned his office. Subsequently he was often found acting in opposition to the government, chiefly in reference to foreign affairs, and he was also opposed to a separate Irish parliament in Dublin. His opinion on the latter question carried great weight because of his well-known sympathy for Ireland, his abilities as a statesman, his experience in affairs, and his unquestioned honesty. Consult 'Life of Forster,' by Wemyss Reid (1888).

Forsyth, George Alexander, American military officer: b. Muncy, Pa., 7 Nov. 1837. He served with distinction in the Civil War; was brevetted colonel for gallant services at Five Forks, and brigadier-general in 1868 for his action in an engagement with hostile Indians. He was a member of the board of officers to inspect the armies of Europe and Asia in 1875–6, and on staff and frontier service till 1890, when he was retired on reaching the age limit. He has published: 'Thrilling Days in Army Life' (1900); 'The Story of the Soldier' (1900).

Forsyth, John, American politician: b. Fredericksburg, Va., 1780; d. Washington 21 Oct. 1841. He was graduated at Princeton College in 1799, and was admitted to the bar in Augusta, Ga., in 1802. He was elected attorney-general of the State in 1808, representative in Congress in 1812, and United States senator in 1818. In 1820 he was sent to Spain as resident minister, where he conducted the negotiations concerning the ratification and execution of the treaty by which Florida was ceded to the United States. In 1823 he was again chosen to the House of Representatives, and was one of the main supporters in Congress of Gov. Troup of Georgia in his contest with the national government concerning the removal of the Creek and Cherokee Indians. He became governor of Georgia in 1827, and in 1829 was again returned to the United States Senate. He opposed the South Carolina movement of nullification from its beginning, and voted in favor of Mr. Clay's compromise act of 1833. In the debate in 1834 on the removal of the deposits from the United States bank, he supported the President, who afterward appointed him secretary of state, an office which he retained till the retirement of President Van Buren in 1841.

Fort Adams, R. I., a United States military post established 1841, at Brenton's Point, R. I., near Newport. There was a garrison here during the Revolution. See MILITARY POSTS, U. S.

Fort Anderson. See WILMINGTON, CAPTURE OF.

Fort Ann, N. Y., a village and former fort in Washington County; on Wood Creek and Champlain Canal. The first fort was built here in 1709, rebuilt in 1757. The British captured the fort in 1777, and partially destroyed it. Pop. of village (1901) 430.

Fort Blakely, Siege and Capture of. Fort Blakely was erected by the Confederates as one of the inland defenses of Mobile, on the east bank of the Apalachee River, and opposite its confluence with the Tensas, about 10 miles northeast of the city. It was on high ground and nearly 3 miles in extent, with 9 well-built redoubts or lunettes armed with about 40 guns. In front was a deep and broad ditch, also an abatis. The garrison consisted of Gen. F. M. Cockrell's division of veteran troops and Thomas' division of Alabama Reserves, in all about 3,500 men, under command of Gen. St. John Lidell. On 20 March 1865 Gen. F. Steele set out from Pensacola and, by a circuitous march of 100 miles, reached the rear of the fort 1 April and invested it on the 2d with Garrard's division of the 16th corps, Veatch's and Andrews' divisions of the 13th, and Hawkins' division of colored troops, in all 13,000 men. Gradual approaches were made, accompanied by heavy and constant skirmishing, and by the 8th Steele had portions of his advanced lines within 450 to 600 yards of the works and 28 guns in position. A general assault was made about 6 P.M. of the 9th; there was a severe struggle in overcoming the obstructions in front of the work; but they were carried and the main works taken by assault, with 3,432 prisoners, 40 guns, and 16 battle-flags. The Union loss was 113 killed, 516 wounded. The Confederate loss is not known. The assault on Blakely was the last considerable engagement of the War, and was followed by the fall of Mobile and surrounding forts and by the surrender of the Confederate navy in the harbor. Consult: 'Official Records,' Vol. LI.; Andrew, 'Siege of Mobile.'

E. A. CARMAN.

Fort Bliss, Tex., a former United States military post on the Rio Grande, 3 miles from El Paso, established 1868. For the present post of this name at El Paso, see MILITARY POSTS, U. S.

Fort Bowyer, bō'yėr, Ala. (present site of Fort Morgan), a former United States fort at the entrance of Mobile Bay. It was built in April 1813 and was surrendered to the British 8 Feb. 1815.

Fort Can'by, Wash., a United States military post formerly called Fort Cape Disappointment, established on the north shore of the mouth of the Columbia River in 1864. See MILITARY POSTS, U. S.

Fort Caswell, kaz'well, N. C., a United States military post, established 1825, on Oak Island, Cape Fear River. See MILITARY POSTS, U. S.

Fort Chippewy'an, or **Chipeway'an**, Canada, a trading station on Lake Athabasca, owned by the Hudson Bay Company.

Fort Clark, Tex. See MILITARY POSTS, U. S.

Fort Clinton, N. Y., a fort built on the Hudson River, near West Point, in 1777. It was soon after abandoned.

Fort Collins, Colo., a city and county-seat of Larimer County, on the Colorado & S. R.R.; 74 miles north of Denver. The State Agricultural College is here. Pop. (1900) 3,050.

Fort Columbus, N. Y., a United States military post established on Governor's Island, New York harbor, in 1806. It is the headquarters of the Department of the East and has Castle William, military prisons. See FORTIFICATIONS; MILITARY POSTS, U. S.; MILITARY PRISONS, U. S.

Fort D. A. Russell, Wyo. See MILITARY POSTS, U. S.

Fort Darling (Drewry's Bluff), Attack on, 7 May 1862. President Lincoln, then at Fort Monroe, received a dispatch from Gen. McClellan that his cavalry had made a reconnaissance to Jamestown, on James River, that a Confederate battery at that point had been abandoned, and if it were possible for the Galena and other gunboats to move up James River, it would aid him in his movement up the Peninsula on Richmond. The President directed Flag-officer Goldsborough, if he deemed it proper, to send the Galena and two gunboats. On the morning of 8 May Capt. John Rodgers, with the Galena, Aroostook, and Port Royal, went up the river and engaged two batteries of 10 guns each, one of which he silenced; the other he passed, two Confederate gunboats retiring up the river as he approached. Rodgers worked his way up the river, meeting with no serious opposition until he arrived at Fort Darling, on Drewry's Bluff, eight miles below Richmond, a strong position on the right bank of the river, about 200 feet above it, and mounting five heavy guns, manned by the crews of the destroyed Merrimac and other ships at Norfolk, under command of Captain Farrand, C. S. Navy. The guns were mounted in such position as to give a close and plunging fire upon an advancing vessel. At the foot of the bluff the river had been obstructed by piles and sunken vessels secured by chains, and the shore was lined with rifle-pits, sheltering sharpshooters. Rodgers was now joined by the Monitor and Naugatuck, and on the morning of the 15th ran up and opened fire, the Galena leading and anchoring within 600 yards of the fort. The Monitor could not bring her guns to bear, and the action was principally confined to the Galena, which, after a contest of nearly three and a half hours, withdrew, having been struck 28 times, and losing 24 men killed and wounded. Two of the Confederate guns were dismounted, and Farrand reported a loss of 7 men killed and 8 wounded. Two or three days later, recognizing the fact that the co-operation of the army was needed to carry the position, Goldsborough proposed to McClellan a joint attack, but McClellan preferred waiting until he got his army across the Chickahominy. The Confederates strengthened the position and it remained in their possession until the close of the war, an obstacle to the advance of the gunboats up the James to Richmond, and also to the operation of the army investing Richmond and Petersburg. Consult: 'Naval War Records,' Vol. VII., Allan, 'Army of Northern Virginia.'

E. A. Carman.

Fort Dearborn, a fort built in 1804 by the United States government on the south bank of the Chicago River near its mouth and on the site of the present city of Chicago. At that time the river took a sharp turn to the south just east of the fort and flowed into the lake over a heavy sandbar, which was not capable of being crossed by anything larger than a small boat, and all large vessels bringing supplies to the garrison were compelled to anchor outside and land their passengers and cargoes in small boats. The site of the fort was on a reservation of six square miles which by Wayne's treaty with the Indians, made at Greenville in 1795, had been set aside from the United States. It was named in honor of General Henry Dearborn (q. v.), then Secretary of War.

The fort consisted of a stockade with two block-houses, built in the fashion of all military posts of that period which were situated on the frontier in the vicinity of Indian tribes. The quarters of the garrison were inclosed within the stockade and the first garrison consisted of one company of infantry (of the First regiment).

The growth of the settlement at Fort Dearborn was not rapid until after the War of 1812, owing to the numerous depredations of the Indians upon the white settlers and to the fact that it was so far in the wilderness, being reached from Detroit by a trail through the woods and from Mackinac by lake schooners, generally one in the spring and one in the fall.

Fort Dearborn owes its notoriety, however, to the massacre which occurred near there on 15 Aug. 1812. The second war with Great Britain had broken out and in the beginning in the northwest all the advantage lay with the British forces and their Indian allies. Mackinac had been captured, thus securing control of the upper lakes to the British, and the American government, apprehensive that a post among the Indians, so far from the frontiers, could not be successfully maintained, thought best to abandon it. Accordingly, General William Hull, in command at Detroit, issued orders to Captain Nathan Heald, in command of the garrison, to evacuate the fort and that the surplus stores should be divided among the Indians. These orders were executed and on 15 August the garrison and a body of supposedly friendly Miami Indians, escorting a number of women and children, marched out of the fort and set out for Detroit by a road which wound along the lake shore. At a point among the sandhills about two miles from the fort an ambushed band of about 500 Potawatomie Indian savages, in conjunction with the party of Miami who accompanied the troops, attacked the little expedition and the whole body of whites were either captured or killed. Two of the women and 12 children were butchered during the fight, and a number of the wounded men were killed afterward, but some were fortunate enough to be ransomed later. The Indians then sacked the fort and burned it.

In 1816 after peace was concluded the fort was rebuilt under Captain Bradley and its outlines were much extended, under the protection of its larger garrison a small village springing up. In 1823 the fort was again evacuated, but continued to be occupied from 1828 to 1837 when, the Indians having left the country, it was again abandoned, and finally, in 1856, destroyed.

Fort de France, fōr dé frāṅs, or *Fort Royal*, fōr-rwä-yal, Martinique, French West Indies, a town, seaport and capital of this island of the Lesser Antilles, which, except Guadeloupe, is the largest in the Caribbean chain. It is situated in the southwestern part of the island and on the north side of a deep and well-sheltered bay protected by a fort. The city is important as it is the military and naval headquarters and rendezvous in the French Antilles, the Governor's residence, and the terminus of the French transatlantic steamers, and the West Indian cable system. The principal buildings are the parish church, government offices, the barracks, arsenal, prison, and hospital. Fort Royal is the residence of the French Governor. There is a law school in the city. In the public gardens is a statue of the French Empress, Josephine, who was born in Martinique. In 1839 Fort de France was partially destroyed by an earthquake, and in 1890 fire nearly consumed the entire city. The eruption of Mont Pelée (q. v.), in May 1902, did no material damage to the city, but it became the distributing centre for the supplies sent to the island from outside sources. Pop. (1903), 22,164.

Fort De L'Écluse, fôr de lā'kluz', a fortress in the Department of Ain, France, on the Rhone River, west of Geneva, standing upon a crag 1,385 feet high, at the foot of Mont Credo, which commands the passage of the Rhone River from Switzerland through the defile of the Écluse. It was erected by the Dukes of Savoy, and during the 16th century was repeatedly the object of attacks by the Swiss armies, and was several times destroyed. During the reign of Louis XIV. it was rebuilt by Vauban at the King's command, but in 1815 was captured and demolished by the Austrians. Again coming into French possession it was completely restored and since then the fortifications have been remodelled and much strengthened.

Fort Dodge, Iowa, a city and county-seat of Webster County; on the Des Moines River, and on the Illinois C., the Chicago G. W., and the Minneapolis & St. L. R.R.'s; 135 miles east of Sioux City, 200 miles west of Dubuque, 85 miles north of Des Moines, and 200 miles south of Minneapolis.

Industries.— The city has many natural advantages, being an important railroad centre (the railroad shops employing, on an average, 1,200 men); in the vicinity are large deposits of coal, gypsum, and potter's and brick clay; and it is the jobbing centre for the surrounding territory. Among the industries are a shoe factory, oat-meal mill, several plaster mills, brick plants, pottery works, boiler works, and foundries.

Public Works, Institutions, Buildings, Etc.— The educational facilities comprise high and public schools, parochial schools, Tobin College, and Elmwood school. Nearly all religious denominations are represented in the city. Among the notable public buildings are the County Court House, Government Building, and Public Library. There are five banks in the city, with a combined capitalization of $475,000.

History, Government, and Population.— Fort Dodge was first settled in 1854 by Major William Williams, became a borough in March 1854, and was incorporated as a city in 1869. The affairs of the city are administered by a mayor, city solicitor, and city treasurer, and a council of eight members, four of whom are elected each year. The city owns and operates the water-works. The predominating foreign nationalities represented in the population are Scandinavians, Germans, and Irish-Americans. Pop. (1900), 12,162. C. F. DUNCOMBE,
Editor of 'The Chronicle.'

Fort Donelson, a fort erected in 1861 by the Confederates in Stewart County, northwestern Tennessee, just south of the boundary line between Kentucky and Tennessee, on the left bank of the Cumberland River, and about 63 miles northwest of Nashville, and 12 miles from Fort Henry. It was on a hill 120 feet above the level of the river and, having a line of rifle pits 2½ miles in extent to defend the land approach, and three heavy batteries commanding the river, it was considered one of the best fortified posts along the Confederate line of defense in the Mississippi valley. Here, on 13–16 Feb. 1862, an important battle was fought between General Grant in command of the Union forces, and General Buckner in command of the Confederates, finally resulting in the surrender of the fort by Buckner, together with 57 guns, 14,500 men, and immense quantities of provisions and munitions of war. See FORT HENRY AND FORT DONELSON.

Fort Douglas, a United States military post in Utah, on the Union Pacific R.R., three miles east of Salt Lake City and 37 miles from Ogden. It was established in 1862, occupies a reservation of over 9,000 acres at the base of the Wahsatch Mountains, and has quarters for about 500 soldiers.

Fort Dupont, a United States military post in New Castle County, Delaware, opposite Pea Patch Island. It occupies a reservation of about 175 acres and has quarters for two companies of infantry.

Fort Du Quesne, a colonial fort in Pennsylvania erected at the confluence of the Allegheny and Monongahela rivers and upon the site of the present city of Pittsburg (q. v.). It was begun in February 1754 by a force of Virginians under Captain William Trent, and Ensign Ward, who had been sent forward by Governor Dinwiddie, of Virginia, to erect a fortification of sufficient size to be a warning to the French against further intrusion on English territory. On 17 April, before the work had been completed, the Virginians were attacked by a force of 700 French and Indians and were compelled to leave the fort, which was then enlarged and completed by the French, who named it Du Quesne. Near the fort, on 9 July 1755, took place the terrible defeat of the British General Braddock (q. v.), who was ambushed there by a detachment of French and Indians, while on his way to retake the fort from the French. The fort and surrounding territory remained in the possession of the French until 25 Nov. 1758, when General Forbes, leaving Philadelphia early in July in command of an army of 10,000 British and Colonial troops, with a few Indian allies, met Colonel George Washington (q. v.), and together captured it, not, however, till the French had fired it and fled. It was then, at Washington's suggestion, renamed "Pittsburgh," in honor of the British Prime Minister, William Pitt.

The fort was occupied for the winter by a small garrison, and in 1759 General Stanwix built Fort Pitt, which was the scene of many engagements during the Indian wars, and the French and Indian War. During the period of Pontiac's Conspiracy in 1763 the Indians besieged the fort, then under command of Captain Ecuyer, from 22 June to 6 August, but were twice defeated by the troops from the fort, and were finally driven off by a force of 500 British regulars under Colonel Henry Bouquet, who had been sent by General Amherst. Bouquet, a short time afterward, built a brick blockhouse not far from the fort, and this "Old Blockhouse," which is still standing, is the only remnant of the extensive fortifications erected by the British during their occupancy of the vicinity till the outbreak of the American Revolution. This remnant is now owned and is being preserved by the Daughters of the American Revolution. See COLONIAL WARS IN AMERICA, *1755-63, Seven Years War; 1758, Louisburg . . . Du Quesne; 1763-4, Pontiac's War.*

Fort Edward, N. Y., colonial, on the upper Hudson at its great bend, where stands the present village of Fort Edward; known as the Great Carrying Place during the 17th and 18th centuries (that is, to Lake George and Lake Champlain), and an obvious advanced post for Canadian wars. Francis Nicholson built a stockade there for that purpose in 1709; it rotted away in disuse, but in 1755, at the opening of the French and Indian War, Phineas Lyman began another called by his name. It was finished by Col. Eyre under Sir William Johnson, who after the battle of Lake George (q. v.) renamed it Fort Edward, after the Duke of York, grandson of George II. In 1757 it was raided from Canada and 11 soldiers killed. Later, the survivors of the massacre of Fort William Henry (q. v.) were sent here by Montcalm, and shortly afterward several thousand militia flocked thither to the rescue, but had to be sent home as arriving too late. In March 1758 an expedition from there under Major Robert Rogers was nearly destroyed by the Indians. During this period Fort Edward was known to the French as "Fort Lidius" or "Lydius." Jane McCrea (q. v.) was living in a little settlement near the fort, when she started on her ill-fated journey 27 July 1777 to meet her lover in Burgoyne's camp. After her death she was buried near the "black house" at Fort Edward Centre. Her remains were removed in 1823 or '24 to the old Fort Edward Cemetery; in 1852 her remains were again exhumed and buried in the Union Cemetery between Fort Edward and Sandy Hill. The Jane McCrea Chapter, D. A. R., has erected a marker at Fort Edward near the spot where she was killed. In the Revolution the old fort was successively the headquarters of Schuyler, Burgoyne, and Stark. Consult Parkman, 'Montcalm and Wolfe' (1884), 'Fort Edward in 1779-80,' 'Historical Magazine' 2d series Vol. II. (187). Fort Edward village is located on the Delaware and Hudson Railroad, Champlain Canal, and Hudson Valley Railway. Here through a system of locks the Glens Falls Feeder empties into the Champlain Canal. The manufacture of pulp and paper constitutes the principal industry of the village, and here are large mills of the International Paper Co. Trust. It is noted as the home of the Fort Edward Collegiate Institute, has a good union school system, a flourishing national bank, and five churches. Fort Edward possesses many points of interest to the antiquarian and historian on account of its intimate connection with the events of the French and Indian, and the Revolutionary Wars. Pop. (1900) 3,521.

James A. Holden.

Fort Erie, Canada, a post village in Welland County, Ontario, on Lake Erie at the head of the Niagara River, opposite Buffalo, N. Y., with which it is connected by a railroad bridge. Three railways enter the town which is a port of entry and has an American consulate. Pop. (1900) 1,000. The present town stands upon the site of old Fort Erie which was the scene of considerable fighting during the War of 1812. On 28 May 1813 the British forces abandoned the fort and partially demolished it and during the next few months, with the varying fortunes of war, it was held alternately by the American and British forces. Early in July 1814 Major-General Jacob Brown (q. v.) with 5,000 troops backed by 4,000 New York militia, which had been ordered out and authorized for the war, invaded Upper Canada from Buffalo and one of his first objects of attack was Fort Erie which surrendered to him on 3 July. Two days later at Chippewa he successfully attacked General Riall with a loss of 511 men killed and wounded. After the bloody battle of Lundy's Lane (q. v.) on 25 July, fought between the American Generals Brown and Winfield Scott and the Canadian General Sir Gordon Drummond (q. v.), the American forces, numbering about 2,000 men, under command of General Ripley (both Brown and Scott having been wounded), were forced to return to the fort, having suffered a loss of 743 men as against a British loss of 878. The American forces were shortly afterward (7-14 August) unsuccessfully attacked by Drummond, who, after an almost constant bombardment during the seven days, retired with a loss of 500 men. Brown was, however, blockaded within the walls of the fort until September. The fort remained in possession of the Americans till 5 November, when, upon retiring from Canada, they blew up the fortifications and they were never subsequently rebuilt. See United States — the War of 1812.

Fort Ethan Allen, a United States military post located near Essex Junction, Vt., about five miles east of Burlington, occupying a reservation of 761 acres. It was established in March, 1893, has accommodations for about 800 troops, and was designed to form a link in the chain of military posts along the northern frontier of the United States.

Fort Fisher, in North Carolina, erected by the Confederates on the peninsula between Cape Fear River and the Atlantic to defend the entrance to the port of Wilmington, was one of the most formidable earthworks on the Atlantic coast and was built to withstand the heaviest artillery fire. Its parapets were 25 feet thick, with an average height of 20 feet, and mounted 44 heavy guns. At the close of 1864, when it was determined by the United States forces to reduce it and close the port of Wilmington to blockade-runners, it had a garrison of 1,400 men, under command of Col. William Lamb. The combined naval and army expedition sent against it was under command of Admiral D. D. Porter and General B. F. Butler. Porter's fleet of about 150 vessels, the largest that had ever sailed under the Union flag, left Hampton Roads 13 Dec. 1864 and arrived in sight of the fort on the 20th. As a preliminary to the attack the old steamer Louisiana was loaded with 215 tons of powder which was to be exploded under the walls of the fort, with the expectation that the explosion would dismount the guns, level the works, and demoralize the garrison, thus allowing the troops to land and easily take the work. At 1:40 A. M. of the 24th, without notifying Butler of the fact, when the Louisiana was within 300 yards of the beach and 400 yards of the fort, the powder was exploded, but did no damage, scarcely disturbing the slumbers of the garrison. At daylight the fleet ran in, and at 11 o'clock opened a furious fire, which was continued several hours, doing no material damage, and was responded to with spirit and effect. On the 25th the bombardment was renewed and under cover of it Butler landed 3,000 men two miles above the fort, and was assured by Porter that the navy had so completely silenced the work that all he had to do was to march his troops into it. But Butler and Weitzel, who was in immediate command of the troops, after a careful reconnaissance found the fort uninjured, deemed it unadvisable to attack it, re-embarked the men, and returned to James River to assist in the siege of Petersburg. Porter's fleet lost 83 men killed and wounded. The Confederates had 58 killed and wounded. The failure to take the fort produced great disappointment; it is now generally conceded that Butler and Weitzel acted wisely in not making the attempt. A second expedition against the fort sailed 12 Jan. 1865, and on the 13th 8,000 men were landed under Gen. A. H. Terry, who had been designated to command the land forces, which, as before, were under the immediate command of Gen. Weitzel. At 3.30 P.M. the fleet stood in and began a furious bombardment, which was continued next day, causing a loss to the garrison of 200 men, and silencing many of the guns. A combined naval and land attack was planned for the 15th, and 1,600 sailors and 400 marines were landed to co-operate with the army. The fleet opened fire at 9 A.M. and continued it until 3 P.M., when 50 steam-whistles from the fleet gave the signal for the land assault. The naval column, armed with cutlasses and pistols, charged the right flank or sea-face of the work, reached its foot, and those in advance began to climb the parapet, but the Confederates mounted on it repulsed them, and the entire body retreated in disorder with a loss of 82 killed and 269 wounded. The army was more successful; advancing on the left flank or land-face of the work, it forced a lodgment, and after a hard struggle, which was continued far into the night, carried the entire work, capturing, as reported by Gen. Terry, about 2,000 men, with a loss of over 900. The Confederate defense of the fort was one of the most gallant of the War, and cost them about 500 killed and wounded. The Union loss, army and navy, was 266 killed, 1,018 wounded, and 57 missing. The fall of Fort Fisher closed the port of Wilmington, and was soon followed by the fall of that city. Consult: 'Official Records,' Vol. XLII.; 'Naval War Records,' Vol. XI.; Ammen, 'The Atlantic Coast'; Maclay, 'History of the Navy,' Vol. II.; The Century Company's 'Battles and Leaders of the Civil War,' Vol. IV.

E. A. Carman.

Fort Gaines and **Fort Morgan.** Fort Gaines was a walled work on Dauphine Island, at the western entrance of Mobile Bay, and with Fort Morgan, a much larger work, on Mobile Point, nearly four miles distant, at the eastern entrance, was seized by the governor of Alabama 5 Jan. 1861. Both forts remained in Confederate possession until August 1864, at which time Fort Gaines had 30 guns. Fort Morgan was armed with over 40 guns, and had a mortar battery in front of seven heavy guns. Admiral Farragut attacked and passed both works when he ran into Mobile Bay, 5 Aug. 1864, and virtually destroyed the Confederate squadron. Gen. Gordon Granger landed troops on Dauphine Island on the 4th and began to invest Fort Gaines; on the 6th Farragut shelled it, and on the 7th the fort and its garrison of 818 officers and men surrendered. Fort Morgan held on longer, but Granger transferred his troops from Dauphine Island to the rear of the fort, invested it, got 34 guns in position to bear on it, and on the morning of the 22d, in co-operation with Farragut's fleet, opened his guns upon it, and kept up a continuous fire until the morning of the 23d, when the fort surrendered to Farragut.

Fort Garry, Canada. See Winnipeg.

Fort George, Canada, a former fort on the Canadian side of the Niagara River. On 27 May 1813 it was captured by the American forces under Col. Winfield Scott. On 10 Dec. 1813 the fort was evacuated by Gen. McClure. See Fort George, Battle of.

Fort George, Battle of, 27 May 1813, in the War of 1812. The fort was near the mouth of the Niagara River, on the Canada side, nearly opposite Fort Niagara, and was garrisoned by about a thousand British regulars and several hundred militia under Gen. Vincent. The American force of some 4,000 undertook to take it in rear and capture the garrison; the nominal commander was Morgan Lewis, the real one Winfield Scott. The forces were landed from the fleet, nominal commander Chauncey, real one Oliver Hazard Perry, and a joint attack was made. The fleet enfiladed the beach; Scott advanced along the shore, and made a flanking movement. Vincent evacuated the fort, spiked the guns, and slowly retreated, parallel to the river, beyond Queenston Mt., losing 51 killed and 305 wounded and missing, from his regulars, while most of the militia were captured. American loss, 40 killed, 120 wounded. The other forts on the river were soon abandoned by the British.

Fort Getty, S. C. See Military Posts, U. S.

Fort Grant, Ariz., a United States military post and reservation at the foot of Mount Graham, established in 1863 by the California volunteers. See Military Posts, U. S.

Fort Greble, R. I. See Military Posts, U. S.

Fort Griswold, Conn. See Fort Griswold, Massacre of; Military Posts, U. S.

Fort Griswold, griz'wōld, **Massacre of,** 6 Sept. 1781. Hearing of Washington's southern march, Sir Henry Clinton, as the only available diversion, sent an expedition against New London, Conn., where a quantity of stores were collected, with slight defense from Fort Trumbull on the New London side and Fort Griswold on the Groton side of the Thames, and which was a nest of privateers that had greatly annoyed the British. Benedict Arnold was selected to head it, as a Connecticut man; an ugly method of making him seal his new allegiance. On taking possession of Fort Trumbull, it became evident that the American shipping would escape unless Fort Griswold were captured also; it was reported unfinished and occupied only by 20 or 30 men, and he ordered an attack on it. Shortly seeing that it was stronger than he supposed, and garrisoned by those who had escaped from Fort Trumbull, and that the ships were escaping up the river, he countermanded the order, but too late. The British detachment of 600 regulars had assailed the fort, where 157 militia had gathered; and after 40 minutes' assault, with the loss of 192 men, the British carried it, and despite the appeals for quarter, massacred nearly the whole garrison. Col. Ledyard, the commander, and 70 others were killed, 60 wounded, 35 mortally, and only 26 escaped unhurt. The British officers, however, did their best to stop the slaughter, and the atrocious story formerly told of the murder of the colonel is fiction. The massacre of garrisons *in terrorem,* to teach them not to defend untenable places, was justified by the European rules of war at the time, but had not been practised in America. Even American officers, however, spoke of it at the time as a regrettable but almost inevitable incident of war.

Fort Hamilton, N. Y., a United States military post at the Narrows, New York Bay, established in 1831. See Military Posts, U. S.

Fort Hancock, N. J. See Military Posts, U. S.

Fort Harrison, Battle of (including Chaffin's Farm, Fort Gilmer, and New Market Heights). In the latter part of September 1864 Gen. Grant ordered a movement against the Confederate troops north of James River, defending Richmond. Grant hoped to make Gen. Lee so weaken the garrison at Petersburg that the Union forces might carry it. The great object, however, was to prevent Lee sending reinforcements to Early in the Shenandoah Valley. September 28, during the night, Gen. Ord crossed from the south to the north bank of the James, and on the 29th, with 4,000 men, driving before him the Confederate outposts, appeared before Fort Harrison, on Chaffin's Farm, the strongest work on the Confederate line. Birney, with 10,000 men, moved by roads farther to the right. Stannard's division, which led the advance of Ord's column, moved to the assault of Fort Harrison, under a very severe fire of artillery and musketry, and after a sharp encounter carried it with its 16 guns and nearly 300 prisoners, at a loss of over 500.

Ord, being severely wounded, the command of his corps fell to Gen. Heckman, whose division, following Stannard's, passed to the right of Fort Harrison, attacked Fort Gilmer, and was repulsed with heavy loss. Meanwhile Gen. Birney had advanced on the New Market road, captured some of the advanced rifle-pits, running northeast from Fort Harrison, and established connection with Heckman. Gen. Grant now appeared and ordered an advance on the right. At 3 P.M. Birney made another assault upon Fort Gilmer, but was badly repulsed. Grant ordered the troops to entrench. Gen. Lee transferred seven brigades from his lines at Petersburg to the north side of the river, and massed 10 brigades at and near Fort Gilmer to assault and retake Fort Harrison. The assault was made at 2 P.M. of the 30th by Gen. R. H. Anderson, commanding Longstreet's corps, with five brigades, and was repulsed. Twice the Confederates re-formed and renewed the assault, but were repulsed, leaving a large number of killed and wounded and seven battle-flags on the ground, and the effort to dislodge the Union troops was abandoned. The Union loss on the 29th and 30th was 383 killed, 2,299 wounded, and 645 missing, an aggregate of 3,327. The loss of the Confederates is not definitely known, but it was near 2,000 in killed, wounded, and missing. Consult: 'Official Records,' Vol. XLII.; Humphreys, 'The Virginia Campaign of 1864–65.'

E. A. CARMAN.

Fort Henry and Fort Donelson. These forts were constructed by the Confederates just south of the boundary line between Kentucky and Tennessee, the former on the right bank of the Tennessee River, the latter on the left bank of the Cumberland; the distance between the two being 12 miles. On 28 Jan. 1862 Commodore Foote and Gen. Grant asked Gen. Halleck's permission to take Fort Henry. Halleck assented, and on the morning of 2 February Foote's flotilla of ironclads and gunboats, followed by a fleet of transports, carrying Grant's troops, left Cairo, anchoring 6 miles below Fort Henry on the morning of the 4th. The fort was defended by 17 heavy guns, and its land approach was covered by rifle-pits held by 3,000 men. Gen. Lloyd Tilghman was in command. About 11.20 A.M. of the 6th Foote steamed up toward the fort and attacked it with four ironclads, Tilghman, with about 90 men to work 11 guns bearing on the river, returning the fire. After a contest of an hour and a quarter Tilghman hauled down his flag and surrendered with 78 men, having lost 16 killed and wounded. The 3,000 men in the rifle-pits retreated to Fort Donelson. The fleet had 29 killed and wounded. Grant, who had landed his troops 6 miles below the fort, arrived too late to take part in the action.

Grant reported to Halleck that on the 8th he would take and destroy Fort Donelson. Foote, however, was compelled to return to Cairo for repairs to his fleet, and the movement was deferred until the morning of the 12th, when Grant marched across the country, with about 16,000 men, arriving before Fort Donelson in the evening. The fort was on a commanding hill, 120 feet above the level of the Cumberland, with three heavy batteries commanding the river, and a line of rifle-pits to defend the land approach. On the morning of the 13th the fort and works were held by 18,000 men, under command of Gen. Floyd. The rifle-pits 2½ miles in extent, were held by Gen. Buckner on the right and Gen. Pillow on the left.

Grant formed his line of investment with Gen. McClernand on the right and Gen. Smith on the left, and at dawn of the 13th opened a furious cannonade and sharp skirmishing. In the evening Foote's flotilla and reinforcements for Grant arrived — Crufts' brigade and several regiments from Fort Henry and Cairo. These were formed into a division of 10,000 men, under Gen. Lew Wallace, and put in the line between McClernand and Smith, raising Grant's force to 26,000 men. At 2 P.M. of the 14th Foote attacked the fort, and at the end of an hour and a half was compelled to withdraw, two of his ironclads being entirely disabled and the other two partially so. He had 54 men killed and wounded. It was then concluded that Foote should return to Cairo and repair damages, while Grant should perfect his investment, fortify his lines, and await the arrival of reinforcements and the return of Foote.

The Confederates shaped the course of events otherwise. They decided to break the right of Grant's investing line and escape by roads leading to Nashville. In pursuance to the plan adopted, Pillow, on the Confederate left, supported by a part of Buckner's command, advanced at daybreak of the 15th, with 10,000 men, and after a hard fight gained the right of McClernand's line and forced it back. McClernand called for assistance and, in the absence of Grant, who had gone to confer with Foote, Lew Wallace sent Crufts' brigade to his support, but the Confederates continued to gain the advantage, pushing back McClernand's two right brigades and their supports. Buckner made an attack upon McClernand's left and was repulsed; but rallying his men, he renewed the attack, and the whole right wing of Grant's army was forced back, the Confederates still following up their advantage, when Wallace threw Thayer's brigade to the right and across their line of advance and, after a sharp fight, checked them, driving some back to their entrenchments. It was 2 P.M. when Grant came on the field to find nearly half his army driven from position and the way open for Confederate escape. He ordered a counter-attack. Smith, commanding on the left, formed a brigade in column, led it under severe fire, and seized the Confederate works in his front and on the high ground surrounding the fort. Wallace and part of McClernand's force, advancing on the right, gained the greater part of the ground lost early in the day, and by night the line of investment was re-established. Grant made preparations to renew the attack early next morning, but during the night the Confederate commanders came to the conclusion that escape was impossible, that Grant was too strong to be beaten, and that nothing remained but a surrender. Floyd, senior in rank, announced personal reasons against a surrender and passed the command to Pillow, who in turn passed it to Buckner. Floyd and Pillow, with the aid of two small steamboats, succeeded in getting away with about 1,200 officers and men, principally of Floyd's old brigade, and Col. Forrest, with some 500 cavalry and other small detachments, escaped in the night by the river road.

At an early hour of the 16th, as Grant was about to renew the attack Buckner sent him a note proposing "the appointment of commissioners to agree upon the terms of capitulation," and suggesting an armistice until 12 o'clock. Grant replied: "No terms except unconditional and immediate surrender can be accepted. I propose to move immediately upon your works." Buckner surrendered 14,500 men, 57 guns, and a large amount of ammunition and stores. The Union loss, army and navy, was 510 killed, 2,152 wounded, and 224 missing. The Confederate loss, killed and wounded, was about 2,000. The capture of Forts Henry and Donelson broke the first line of Confederate defense in the Mississippi Valley, and caused the abandonment of Columbus, Bowling Green, and Nashville. Consult: 'Official Records,' Vol. VII.; Force, 'From Fort Henry to Corinth'; Swinton, 'Decisive Battles of the War'; The Century Company's 'Battles and Leaders of the Civil War,' Vol. I.; Grant, 'Personal Memoirs,' Vol. I.

E. A. CARMAN.

Fort Hindman, or Arkansas Post, Battle of. After Gen. Sherman's failure at Chickasaw Bayou (26–31 Dec. 1862), his army and Admiral Porter's fleet returned to Milliken's Bend, where, 4 Jan. 1863, Gen. J. A. McClernand superseded Sherman in command and moved against Fort Hindman, situated on the north bank of the Arkansas River, 50 miles from its mouth, commanding the approach to Little Rock and protecting the valley of the Arkansas. The fleet, 3 ironclads and 6 gunboats, entered White River, and from it passed through a cut-off to the Arkansas, 9 January. The army of 29,000 men landed about four miles below the fort, a large square-bastioned work, on high ground, at the end of a horseshoe bend in the river, mounting 18 guns, and garrisoned by about 5,000 men, under command of Gen. T. J. Churchill. A line of rifle-pits surrounded it. The ironclads began the attack on the 10th, and the entire fleet, gradually moving up, shelled the Confederates out of the rifle-pits and back into the fort. On the 11th the navy opened a furious fire upon the fort, McClernand's artillery joining in the fire from the land side. Churchill's guns were silenced, and McClernand ordered a general assault. After a severe contest the fort was carried with a loss to the Union army of 134 killed, 898 wounded, and 29 missing. The naval loss was 6 killed and 25 wounded. The Confederate loss was 60 killed, about 80 wounded, and 4,791 captured. On the 12th McClernand received peremptory orders from Gen. Grant to return to Milliken's Bend with his entire command. The prisoners were sent to St. Louis, the fort was dismantled and blown up, and the fleet and troops went down the Arkansas to Napoleon, on the Mississippi. Consult: 'Official Records,' Vol. XXII.; Greene, 'The Mississippi'; Mahan, 'The Gulf and Inland Waters'; Maclay, 'History of the Navy,' Vol. II.; The Century Company's 'Battles and Leaders of the Civil War,' Vol. III.

Fort Independence, Mass. See MILITARY POSTS, U. S.

Fort Jackson and Fort St. Philip. Fort Jackson was built between 1824 and 1832 on the right bank of the Mississippi, about 80 miles below New Orleans. Together with Fort St. Philip on the opposite bank, half a mile above, it defended the city from water attack. Both forts were seized by Louisiana State troops 11 Jan. 1861, were strengthened and garrisoned, and remained in Confederate possession until taken by Admiral Farragut in April 1862, at which time they were garrisoned by about 700 men each. Fort Jackson was armed with 74 guns, Fort St. Philip with 52. In March 1862 Farragut assembled a powerful fleet at Ship Island and at Southwest Pass, at the mouth of the Mississippi, for the capture of New Orleans, and 18 April Commodore Porter, in command of a strong flotilla, opened fire upon Forts Jackson and St. Philip. During six days he threw 16,000 shells, but was unable to reduce the forts.

It was found necessary to run past the forts and destroy the Confederate navy above before New Orleans could be taken. On the 24th Farragut, with 17 vessels, in single line, carrying 192 guns, steamed up the river, engaging both forts with heavy broadsides, of shot, shell, and canister, receiving heavy fire in return. Passing the forts and obstructions, he engaged and destroyed the Confederate fleet, in one of the most spectacular naval battles of the War. Within an hour and a half after leaving its anchorage Farragut's fleet had passed the forts and destroyed 11 Confederate vessels. With 13 of his own vessels Farragut proceeded up the river, and at noon of the 25th anchored before New Orleans, which was abandoned by the Confederate troops holding it, and surrendered by the civil authorities. Porter, who had remained below, continued his bombardment of the forts, which were surrendered on the 28th. The Union loss was 37 killed and 147 wounded. The loss in the forts was 14 killed and 39 wounded; that in the Confederate navy is not known. Consult: The Century Company's 'Battles and Leaders of the Civil War,' Vol. II.; Mahan, 'The Gulf and Inland Waters'; Maclay, 'History of the Navy,' Vol. II.

Fort Leavenworth, lev'en-worth, Kan., a United States military post and reservation, three miles from Leavenworth, established in 1827. There is here a military prison and national cemetery.

Fort Lee, N. J., a former fort in Bergen County, on the west bank of the Hudson River. On 20 Nov. 1776 Gen. Greene and the American forces evacuated Fort Lee, and narrowly escaped capture by 5,000 British under Cornwallis.

Fort Logan, Colo. See MILITARY POSTS, U. S.

Fort McAllister, an earthwork erected by the Confederates at Genesis Point as one of the defenses of Savannah. It was 12 miles south of the city and 6 miles from Ossabaw Sound. On 27 Jan. 1863 Admiral Dupont attacked it with five vessels, and again on 1 February, but without effect. On 3 March three monitors, under command of Commodore Drayton, bombarded it, but did little injury. When Sherman, marching from Atlanta, appeared before Savannah the fort prevented communication between his army and the Union fleet, and Hazen's division of the Fifteenth corps was ordered to assault it. Hazen reached the vicinity of the fort about 11 A.M., 13 Dec. 1864, drove in the Confederate skirmishers, and at 4.15 P.M. had deployed nine regiments within 600 yards of the work. At that time the bugle sounded, and the line went forward over exploding torpedoes and under a close and severe fire of artillery and musketry, carrying the fort at 5 P.M. and capturing its garrison of about 250 men, 22 guns, and a large amount of ammunition. The Union loss was 24 killed and 110 wounded. The Confederate loss was about 50 killed and wounded.

E. A. CARMAN.

Fort McHenry, Md., a United States military post, on the Patapsco River, established in 1794. It was bombarded in 1814 by the British fleet, and was used as a rendezvous during the Civil War. See MILITARY POSTS, U. S.

Fort McPherson, Ga. See MILITARY POSTS, U. S.

Fort Macon, a work commanding Beaufort Harbor, N. C., constructed of brick and stone, and mounting nearly 50 guns. It was seized by Gov. Ellis, of North Carolina, about the middle of April 1861. After Burnside's capture of Newbern, 14 March 1862, Gen. Parke was sent to reduce the fort, then garrisoned by about 450 men. Parke captured Moorehead City and Beaufort, and then proceeded to invest the fort He cut off its communications, planted 11 siege-guns, and at 5:40 A.M. 25 April, in co-operation with four vessels of the navy, opened fire, and at 4 P.M. the fort surrendered with its entire garrison. Parke occupied it next morning and it remained in Union possession until the close of the War.

E. A. CARMAN.

Fort Madison, Iowa, a city and county-seat of Lee County, 18 miles from Burlington, on the Chicago, B. & Q. R.R. Here is the State penitentiary and the Catermole Memorial Library. There was a fort here as early as 1808, but was abandoned in 1832 when the town was established. Pop. (1900) 9,278.

Fort Meade, S. D. See MILITARY POSTS, U. S.

Fort Meigs, mĕgz, Ohio, a former fort on the Maumee River, where the Americans made a gallant defense in 1812 against the British and Indians. See FRENCHTOWN.

Fort Mer'cer, N. J., a former fort at Red Bank, on the Delaware River, that figured somewhat prominently in the Revolution. It was destroyed by the British 20 Nov. 1777.

Fort Mif'flin, Pa., a United States military post on Mud Island in the Delaware River. It was built in 1771 as one of the defenses for Philadelphia. It figured in numerous engagements in the Revolution. It is garrisoned at the present time. See MILITARY POSTS, U. S.

Fort Mims, Ala., Massacre of, a massacre of whites by Creek Indians at the temporary stockade, near Mobile, Ala., 30 Aug. 1813. Over 500 men, women, and children were killed by a large force of Indians under Weathersford, a half-breed.

Fort Monroe, Va., a United States military post at Old Point Comfort, commanding the entrance to Hampton Roads. Jefferson Davis (q.v.) was kept a prisoner here for two years after the Civil War.

Fort Montgomery, N. Y. See MILITARY POSTS, U. S.

Fort Morgan, Ala. See FORT GAINES AND FORT MORGAN.

Fort Moultrie, mōl'tri, S. C. When Major Anderson transferred his garrison from Fort Moultrie to Fort Sumter, 26 Dec. 1860, he spiked and dismounted the 52 guns of the fort and burned the gun carriages. The South Carolina authorities took possession of the fort on the 27th, remounted the guns, strengthened the work, increased its armament, and it became one of the strong defenses of Charleston Harbor, resisting all efforts of the Union fleet to pass it, or reduce it, and remained in Confederate possession until the evacuation of Charleston and all the forts in the harbor 17–18 Feb. 1865. See FORT SUMTER; FORT WAGNER. For early history see FORT SULLIVAN.

Fort Myer, Va. See MILITARY POSTS, U. S.

Fort Necessity. After the capture of Jumonville's force (see GREAT MEADOWS), Washington threw up earthworks and made a stockade fort, which he named as above. It soon became crowded with Indians and colonial companies, and a South Carolina company of regulars under Capt. Mackay; and Washington left the latter in command and moved 13 miles farther on, where was a small settlement. But the place was indefensible; and after summoning Mackay and his men it was decided to retreat to Fort Necessity. The next morning the French were upon them, 900 men besides Indians. Washington led out his men to battle, but the enemy kept off and fired from the woods, in a heavy rain. Washington withdrew his men behind the low, flimsy embankment; and after an entire day of mutual firing, with heavy loss on both sides, the French proposed a parley. The English were at the last extremity, with food and ammunition nearly exhausted, and guns in bad condition; and Washington would not consent to let them send an officer to his camp to observe this, and only yielded when they proposed to have him send one to theirs. The French terms were that the English should retire with all their baggage except artillery, agree to build no more forts beyond the Alleghanies for a year, return the Jumonville prisoners, and leave two officers with the French as hostages. The terms were accepted; but had the French held out a few hours more they could have killed or captured the entire force.

Fort Niag'ara, N. Y. As early as 1669 La Salle built a stockade at the mouth of the Niagara River, and Fort Conti, a fortified trading post was built here 10 years later. In 1686 it was called Fort Denonville and in 1725 it was named Fort Niagara. In July 1759 it was captured by the British and Indians under Johnson (see COLONIAL WARS), and was again captured by the British 19 Dec. 1813.

Fort Ninety-six, S. C. See NINETY-SIX.

Fort Payne, Ala., a city and county-seat of Dekalb County, on the Alabama G. S. R.R. It has large coal and iron industries. Pop. (1900) 1,037.

FORTRESS MONROE, OLD POINT COMFORT, VA.

Fort Pickens, a strong work on Santa Rosa Island, Fla., commanding the entrance to Pensacola harbor, and with Forts Barrancas and McRee opposite, defending the harbor and United States navy-yard at Warrington. Early in January 1861 it was under command of Lieut. A. J. Slemmer and practically unoccupied, Slemmer, with a small garrison, being at Fort Barrancas. Fearing that the secessionists would seize the fort, Slemmer, 10 January, transferred to it his garrison of 81 men from Barrancas, and on the 12th the governor of Florida seized Forts Barrancas and McRee, with 175 heavy guns, also the navy-yard, and demanded the surrender of Fort Pickens, which was refused. A second demand was made on the 15th and a third on the 18th, both of which were refused. Slemmer strengthened the work and held it until relieved by the arrival of reinforcements 12–13 April, when Col. Harvey Brown assumed command. Additional reinforcements were sent, and in June a regiment of New York troops, known as Wilson's Zouaves, was landed on Santa Rosa Island and encamped. On 9 October a body of Confederate troops, that had crossed from Pensacola and landed on the island during the night, surprised the camp of the Zouaves, and drove them back toward Fort Pickens, but the Zouaves being reinforced by four companies from the fort, the Confederates were driven in disorder to their vessels, with a loss of about 90 killed, drowned and wounded. The Union loss was 67 killed, wounded, and captured. No other serious attempt was made upon the fort, which remained in Union possession until the close of the War.

E. A. Carman.

Fort Pillow, constructed by the Confederates on the east bank of the Mississippi, about 40 miles above Memphis. It was bombarded by the Union fleet in its descent of the river and attack upon the Confederate fleet near Memphis, abandoned by the Confederates 4 June 1862, and 5 June was occupied by a small Union force. On 12 April 1864 it was garrisoned by parts of the 2d and 4th (colored) U. S. Artillery, and a detachment of the 13th Tennessee Cavalry, in all 557 men, with six guns, under command of Maj. L. F. Booth. At daybreak of the 12th Gen. J. R. Chalmers, of Forrest's cavalry command appeared before the fort with about 1,500 men, and after some hours of hard fighting drove the Union troops from their advanced rifle-pits back into the fort, which was attacked, and the Confederates repulsed, but securing a sheltered position within 100 yards of it. Forrest had come up while the fighting was in progress, and at 3.30 P.M. demanded the surrender of the fort, saying that he had sufficient force to take it, and would not be answerable for consequences should he be compelled to assault. Maj. Booth had been killed, but in his name an hour was asked for consideration. There were U. S. gunboats in the river, and believing that the request for an hour's consideration was to gain time for reinforcements to arrive, Forrest would give but half an hour. When the time was up the bugles sounded the charge, the assault was made, there was a short and severe struggle, many of the garrison were killed in the fort, and those who attempted to escape by the river were shot or, rushing over the bluff into the river, drowned. More than half of the garrison were killed or wounded, a very large proportion being killed. About 160 white and 40 colored prisoners were taken. The defenders of the fort fought bravely, but were simply overpowered. Forrest says in his report: "The river was dyed with the blood of the slaughtered for 200 yards. The approximate loss was upwards of 500 killed; but few of the officers escaped. There was in the fort a large number of citizens who had fled there to escape the conscript law. Most of them ran into the river and were drowned." Forrest reports his own loss as 20 killed and 60 wounded. Consult: 'Official Records,' Vol. XXXII.; The Century Company's 'Battles and Leaders of the Civil War,' Vol. IV.

E. A. Carman.

Fort Porter, N. Y., a United States military post on the Niagara River in the city of Buffalo. It was established in 1867, but prior to that date the government maintained a defensive work at Black Rock.

Fort Preb'le, Me., a United States military post, at Spring Point, in Portland Harbor, established in 1808.

Fort Pulaski, erected by the United States on Cockspur Island, for the defense of Savannah, Ga., and commanding both channels of the Savannah River. It was a brick work, with walls 7½ feet thick and 25 feet high above water. It was seized by Georgia State troops 3 Jan. 1861, and in January 1862 mounted 48 heavy guns and was garrisoned by nearly 400 men. Gen. Q. A. Gillmore was put in charge of operations to reduce it, and in February 1862 2 regiments of infantry, 2 companies of engineers, and 2 of artillery were landed on Tybee Island, mostly a mud-marsh, lying southeast of the fort, and soon constructed 11 batteries of 36 heavy guns, at distances from the fort varying from 1,650 to 3,400 yards. Causeways had to be constructed across marshes, over which mortars of 17,000 pounds were moved; the work was done entirely at night; all difficulties were overcome; and on 9 April the batteries were ready to open fire, the three breaching batteries being established at a mean distance of 1,700 yards from the fort. At sunrise of the 10th the fort was summoned to surrender; its commander, Col. C. H. Olmstead, replied that he was there "to defend the fort, and not to surrender it." Fire was opened at 8 A.M., and an hour later all the batteries were in full play, the Confederates replying vigorously, the fire continuing on both sides until dark. Firing was resumed at sunrise of the 11th, and the Confederates replied steadily; but by noon several of the guns were dismounted; the walls of the fort began to crumble under the weight of metal; and at 2 P.M. the white flag was raised, firing ceased, and 385 officers and men were surrendered, several of whom were severely, one mortally, wounded. The Union loss was one man killed. The result of the fall of Fort Pulaski was the closing of the Savannah River to blockade runners.

E. A. Carman.

Fort Riley, Kan., a United States military post on the Kansas River, near Junction City, Kan. It was established in 1852 on a reservation of 19,000 acres and was first called Camp Centre. It is about 140 miles from Fort Leavenworth, with which place it is connected by a military road completed in 1854. An appropriation of $100,000 was made by Congress in 1855 for the extension of this road to Bridger's Pass, between Nebraska and Utah, making it one of the finest roads in the country. The fort is the seat of the United States Cavalry and Field Artillery School and has accommodations for a large force of cavalry and infantry.

Fort Robinson, a United States military post in the Red Cloud Agency, situated in the western part of Dawes County, Nebraska, and on a fork of the White River, about three miles southeast of Crawford. The post dates back to 1874 and occupies about 20 square miles. There are accommodations for over 500 troops, with stables for the same number of horses.

Fort Royal, West Indies. See FORT DE FRANCE.

Fort Saint David, a town in the presidency of Madras, Hindustan, on the Coromandel coast, situated on the Tripapolore River, about 12 miles south-southwest of Pondicherry. It was besieged by the French in 1746, but withstood the siege and finally forced the French to retire. It remained in possession of the British and was the capital of their possessions in that section of India until 1750, when the French army under Gen. Lally again attacked the fort, this time with success, and razed the fortifications.

Fort St. Philip, La., a fort lying on the Mississippi River about 80 miles below New Orleans and nearly opposite Fort Jackson. The Spaniards originally built the old river front and it was not until the War of 1812 that the works were entirely enclosed by the United States government. Extensive alterations were made by the government after 1841. At the outbreak of the Civil War it was taken by the Confederates, but fell before the attack of Admiral Farragut's fleet in April 1862. See FORT JACKSON AND FORT ST. PHILIP.

Fort Sam Huston, hŭs'tŏn, Texas, a United States military post near San Antonio, established in 1865. There is a reservation here of 469 acres.

Fort Sanders. See KNOXVILLE, SIEGE OF.

Fort Schuyler, New York harbor. See MILITARY POSTS, U. S.

Fort Schuyler (Old), N. Y. See FORT STANWIX; ROME, N. Y.

Fort Scott, Kan., city and county-seat of Bourbon County; on the Marmaton River, and on the Saint Louis & S. F., the Missouri, K. & T., and the Missouri P. R.R.'s., 100 miles south of Kansas City.

Industries.— The chief income of the city is derived from the railroad shops, the Saint L. & S. F. employing 500 hands and the Mo. Pac. 550 hands. The city is situated in a rich agricultural region, this in itself a valuable source of income. Besides these industries there are manufactories of cement, syrup, brick and machinery. Fort Scott is also the largest horse and mule market in the State

Banks, Public Buildings, etc.—There are three banks with a combined capitalization of $200,000. Among the public institutions are the library containing 18,000 volumes, the Goodlander Home for Children, the old government fort buildings which have been preserved, and the National cemetery.

Church and Educational Institutions.— Religious services are held in 11 church edifices. The educational system is excellent, consisting of a high school and seven public schools. There are two commercial colleges in the city and the Notre Dame De Lourdes Academy is also located there.

History, Government and Population.— The city was first settled as a military post in 1844, became a municipality in 1850 and was chartered as a city of the first class in 1882. The public administration is vested in a mayor and a city council composed of 10 members, five of whom are elected each year. The major portion of the population are native born, with a sprinkling of negroes, Germans, Jews, and Irish. Pop. (1900) 10,322; (1905) about 14,900.

GEORGE W. MARBLE,
Editor 'Tribune and Monitor'.

Fort Smith, Ark., city and county-seat of Sebastian County, situated on the western border of the State at the junction of the Arkansas and Poteau rivers, and on the Saint Louis & S. F., Missouri P., Kansas City S., Midland Valley, F. S. & W., and Ark. Cent. R.R.'s.

Industries.— The city is in a rich agricultural region and derives a greater part of its income from this source. There are also coal mines near by. The city has a wagon factory, several furniture and chair factories, a wood-working establishment, machine shops, cotton compress, and oil wells. There are two daily and several weekly papers published.

Schools and Churches.— The city has eight public schools, a high school, two commercial colleges, a Catholic Girl's Academy, three parochial schools, and two conservatories of music. There are 13 churches, representing nearly all denominations.

Banks, Public Buildings, etc.— There are four banks (three national and one savings), having a combined capital of $900,000. Among the notable public buildings are the Federal and County court-houses, the United States jail, and a hospital and an opera-house. A National cemetery is located on the site of the former "Post" burying ground.

History, Government and Population.— Fort Smith was originally a French trading post, and in 1817 became the headquarters for the gathering and distribution of supplies for the United States army in the Southwest. It was called Belle Point by the early settlers, was incorporated in 1842, and received its city charter in 1886. The city is governed by a mayor, a board of public affairs, and a council of 10 members elected for two years. The city is lighted by electricity, gas, and natural gas, owns its water-works, and possesses an excellent system of electric railways. Pop. (1900) 11,587; (1905) about 27,000.

E. B. MILLER,
Secretary Commercial Club.

Fort Snelling, Minn. See MILITARY POSTS, U. S.

Fort Stanwix, N. Y., a former fort near the present site of Rome, N. Y., originally built in 1756, but abandoned, and rebuilt in 1758 by

Brigadier Stanwix. Here in the fall of 1768 a treaty was negotiated by Sir William Johnson (q.v.), the British superintendent-general of Indian affairs in North America, with the Six Nations, about 3,200 Indians being present. For the sum of $10,000, the Indians surrendered title to Kentucky, West Virginia, and western Pennsylvania. Soon after this the fort was again abandoned, but in 1776 it was once more rebuilt and named after that intrepid old soldier, Gen. Philip Schuyler. In 1777 the fort was the object of an attack by Gen. Saint Leger with 1,700 British soldiers and allies, but the garrison held out for 19 days, from 3–22 August when they were relieved by a force of Continentals under Gen. Arnold. In 1781 the fort was destroyed by flood and fire, and when rebuilt was again named Fort Stanwix. It was here on 22 Oct. 1784 that the three United States commissioners negotiated the treaty with the Iroquois Indians, known as the «Treaty of Fort Stanwix,» which provided for the cession to the United States of western lands claimed by them.

Fort Stedman, Assault on. In March 1865 Gen. Lee prepared to abandon Richmond and Petersburg, unite with Johnston at Danville, and attack Sherman, who was marching northward from Savannah. In order that he might wait for favorable weather, he decided on a sortie against Grant, to hold him near the Appomattox. The sortie was committed to Gen. Gordon, with about one half of the army. The point of Gordon's attack was Fort Stedman. At 4 A.M. 25 March the attack was made, and a rush of Gordon's men overcame the pickets and advance guards, took from 400 to 500 yards of the main line (Willcox's), including Fort Stedman, the defenders of which, after a spirited resistance, were overpowered and captured, turned its artillery upon the Union line, captured between 500 and 600 prisoners, and endeavored to sweep down the intrenchments, but met with a repulse. It was so dark that friend could not be distinguished from foe, but Gen. Parke ordered Willcox to recapture the works, Gen. Hartranft to support him. By 7.30 A.M. Parke had regained a part of the line and drawn a cordon around Fort Stedman, and Tidball's artillery had concentrated a heavy fire upon it and the line adjacent. Hartranft advanced at 7.45 A.M., attacked detachments of the enemy that were moving in the direction of City Point, capturing or driving them back, and at 8 A.M. Fort Stedman and the entire line was recaptured, together with 1,949 prisoners and 9 stands of colors, the Federal loss (Ninth corps) being 72 killed, 450 wounded, and 522 missing. The Sixth corps now attacked and captured the Confederate picket-line, losing 440 killed and wounded, and 30 missing; and the Second corps did the same, capturing 365 prisoners, and losing 51 killed, 462 wounded, and 177 missing. The Confederates made several efforts to recapture their own advanced lines, but failed. The entire Union loss in this engagement was 170 killed, 1,323 wounded, and 720 missing, an aggregate of 2,222. The Confederate loss is not definitely known; Gen. Meade estimates it at 5,000 men; it was probably not over 4,000, of whom one half were prisoners. Consult: 'Official Records,' Vol. XLVI.; Humphreys, 'The Virginia Campaign of 1864–65'; Walker, 'History of the Second Army Corps'; Powell, 'History of the Fifth Army Corps'; The Century Company's 'Battles and Leaders of the Civil War,' Vol. IV.

E. A. CARMAN.

Fort Stephenson, Ohio. See FREMONT, Ohio.

Fort Stevens, a United States military post in Oregon, situated in the extreme northwestern part of the State at the mouth of the Columbia River. It is a little more than 100 miles northwest of Portland and about 9 miles west of Astoria, the fur trading post, which was established by John Jacob Astor in 1811. The grounds surrounding the post which was established in 1864 comprise 1,250 acres, and beside the quarters for the officers and artillery men stationed there, has a post office and railway station.

Fort Sullivan, S. C., the early name of Fort Moultrie, in Charleston harbor; notable for its defense against the British in the Revolutionary War. See COLONIAL WARS.

Fort Sumter, built upon a shoal in the narrowest part of the channel of Charleston harbor, three and a half miles from the city, and three fourths of a mile from the north end of Morris Island, was constructed on a rip-rap foundation, its walls of brick being 38 feet high and 7½ feet thick. When South Carolina secede the fort was unfinished and not garrisoned, but men were engaged in the work and in mounting guns. South Carolina passed an ordinance of secession on 20 Dec. 1860, and the secessionists looked to the immediate possession of all the forts in the harbor, one of which, Fort Moultrie, was held by Maj. Robert Anderson, with a garrison of 75 men. Fort Moultrie was indefensible from a land attack, and Anderson, believing that he was about to be attacked, on 26 December, skilfully transferred his command to Fort Sumter, the strongest and most inaccessible work in the harbor. Gov. Pickens demanded Anderson's immediate return to Fort Moultrie. Anderson refused, and the governor took possession of Fort Moultrie and all other works in the harbor, and seized the arsenal, post-office and custom-house in Charleston, raised the Palmetto flag over them, and thus inaugurated war against the United States. He began the construction of batteries on James, Morris, and Sullivan islands to command the harbor and reduce Fort Sumter. On 9 Jan. 1861 the merchant steamer Star of the West endeavored to land reinforcements and provisions for Fort Sumter, but was fired upon by the secession batteries and driven back. Again Gov. Pickens demanded the surrender of the fort, again Anderson refused, and negotiations were transferred to Washington. The construction of batteries continued and 1 March Gen. Beauregard was assigned to the command of all the Confederate forces at Charleston, with instructions to perfect preparations for reducing Fort Sumter. Anderson was now in danger of being starved out and, in accordance with promise given, Gov. Pickens was informed 8 April by a special messenger sent by President Lincoln, that an attempt would be made to land provisions, and provisions only, at Fort Sumter. Beauregard notified the Confederate government, and received orders 10 April to demand the evacuation of the fort, and to reduce it if refused. The demand was made at noon of the 11th. Anderson refused, but made the casual remark to the messengers carrying Beauregard's demand that, if left alone, he would be starved out in a few days, and Beauregard, "to avoid effusion of blood," asked when he would be ready to leave the fort. Anderson said he would evacuate the fort by noon of the 15th, should he not prior to that time receive "controlling instructions" from his government or "additional supplies." The reply was not satisfactory, and 3.20 A.M. of the 12th Anderson was notified that fire would be opened within an hour. At 4.30 A.M. the signal-gun was fired from Fort Johnson on James Island; all the batteries opened fire; Anderson replied deliberately; in 24 hours 2,500 shot and shell struck the fort or fell inside of it; the barracks were burned and the fort much damaged; the relieving fleet could not land; and on the afternoon of the 13th terms were arranged under which, on the afternoon of the 14th, Anderson saluted his flag and, with drums beating and colors flying, marched with his garrison out of the fort, was conveyed to a steamer, and sailed for New York. During the bombardment not a man was killed on either side.

When Fort Sumter fell into Confederate possession it had 78 serviceable guns. Additional guns were mounted in it and it was well garrisoned. The Union authorities sunk a number of old whalers filled with stones in the main channel of Charleston harbor to close the port to blockade-runners, and a blockading force was maintained off the harbor; but it was not until 7 April 1863 that any serious operation was attempted against the fort. Then Dupont, with nine ironclads, made an unsuccessful attack upon it. One of the ironclads, the Keokuk, which had approached nearest to the fort, was struck 90 times, and so much injured that she sunk off Morris Island, and her armament fell into the hands of the enemy, while the others withdrew after an engagement of 40 minutes, most of them being considerably disabled by the fire of the 69 heavy guns brought to bear upon them. The fleet fired 151 shots, not more than 34 of which struck the walls of the fort. Sumter discharged 810 shot, Fort Moultrie and other batteries 1,399, in all 2,209, of which 520 struck the different vessels. It had been expected that the fort would be reduced to a pile of ruins before the sun went down, but the result convinced the Union authorities that the fort and adjoining works could not be reduced by a purely naval attack.

It was now determined that Fort Sumter and Charleston should be taken by combined land and naval attacks, the land attack being by way of Morris Island, the capture of the batteries there, and the establishment of batteries to reduce Fort Sumter. For this purpose Gen. Gillmore was selected. He landed on Morris Island 10 July, made two unsuccessful assaults on Fort Wagner, 11 and 18 July, and then concluded to attempt the destruction of Sumter from ground already in his possession, so that the fleet could enter the harbor and command Charleston. (See FORT WAGNER.) A sufficient number of breaching-guns were in readiness 16 August; fire was opened on the 17th, and on the 24th Gillmore reported the practical demolition of the fort. From 18 guns he had thrown 5,009 projectiles, weighing 552,683 pounds, of which 4,147 struck the fort. Before daylight 23 August five monitors approached to within about 800 yards of the fort and opened fire, which was kept up until 6 A.M. Confederate officers now held a council, and the proposition was offered to abandon the fort, but as a matter of sentiment it was resolved to hold it. On 30 August Gillmore resumed fire, dismounting the remaining barbette guns and leaving but one casemate gun serviceable. As a means of defense against the fleet the work was entirely useless, and it was held merely as an infantry outpost. On 2 September six monitors opened fire on it, but it remained silent, not a single gun being in working order to reply. Early on the morning of 7 September, after the abandonment of Fort Wagner, Admiral Dahlgren demanded the surrender of Fort Sumter, which was refused. Meantime the Confederates were removing the guns from the fort and placing them in other parts of the harbor. During the night of 8 September a naval force of about 400 men, under Commander F. H. Stevens, atempted to carry the fort by assault. It was then defended by about 450 men, under command of Maj. Stephen Elliott, Jr. Stevens' men were in boats, and when towed within 800 yards of the fort the boats were cut loose and rowed for the fort, on approaching which they were met with a fire of musketry; as the men landed, hand-grenades and shells were thrown upon them; and simultaneously, at a signal from the fort, all the Confederate batteries on James and Sullivan islands, with one of their gunboats, opened fire, and the attack was repulsed, all who had landed being killed or taken prisoners. The reported loss was 4 killed, 19 wounded, and 102 captured. On 26 October Gillmore again opened fire with his heavy guns from Forts Wagner and Gregg, aided by the cross-fire of 150-pound rifles on board the fleet, which completed the ruin of the fort, and all aggressive operations for the season against Charleston ended, although a desultory fire was kept up against Sumter during November and December to prevent the remounting of guns. The casualties in the fort from 12 Aug. to 11 Dec. 1863 were 43 killed and 165 wounded. From a tabular statement prepared by an officer in the fort it appears that, from 12 Aug. to 31 Dec. 1863, 26,867 shot were fired at it, 19,808 falling against or into it. On the approach of Sherman's army the fort was evacuated 17 Feb. 1865, and 14 April following the same flag that Anderson lowered in 1861 was raised over it with imposing ceremonies. Consult: 'Official Records,' Vols. I.–XXVIII.; Doubleday, 'Reminiscences of Forts Sumter and Moultrie'; Crawford, 'Genesis of the Civil War'; Gillmore, 'Engineer and Military Operations Against Charleston in 1863'; The Century Company's 'Battles and Leaders of the Civil War,' Vols. I. and IV.; 'Naval War Records,' Vol. XIV.

E. A. CARMAN.

Fort Tot'ten, N. Y., a United States military post, established in 1862 at Willett's Point, on Long Island Sound, near Whitestone.

Fort Wadsworth, wŏdz'worth, N. Y., a United States military post on Staten Island, at The Narrows, in New York Bay. It was established in 1827, and was first called Fort Richmond.

Fort Wagner, a work constructed by the Confederates near the north end of Morris Island, a low, narrow, sandy strip of land, about

3½ miles in length, on the south side of Charleston harbor. It was 2,600 yards directly south of Fort Sumter, to which it was an outpost, and was constructed to hold and control all that portion of the island upon which effective breaching-batteries against Fort Sumter could be established. On the northern end of the Island was Fort Gregg, and the southern end was held by a small force of infantry and artillery. Preparatory to a combined naval and land attack on Fort Sumter and Charleston, it was determined to reduce Fort Wagner and take possession of the entire length of Morris Island, and Gen. Gillmore, an engineer officer of skill, was selected to command the land forces. On 10 July 1863, Gillmore, who had concentrated 6,500 men and secretly placed 47 siege guns and field guns in position on the extreme northern end of Folly Island, attacked the Confederate position on the south end of Morris Island, effected a landing, carried the Confederate batteries of 11 guns, and by 9 A.M. occupied three fourths of the island and pushed his skirmishers to within 600 yards of Fort Wagner. The navy assisted with four ironclads. At daylight of the 11th an attempt was made to carry the fort by assault, which failed, with a Union loss of 172 killed and wounded, and 119 taken prisoners, of whom 40 were wounded. The Confederate loss was 12 killed and wounded. After this failure counter-batteries were established against the fort, and it was determined to attempt, with the aid of the ironclads, to dismount its guns, and either drive the Confederates from it, or open the way to a successful assault. The navy kept up an almost incessant fire upon it, and the land batteries were established at distances ranging from 1,330 to 1,920 yards of it. Soon after midday of the 18th the navy and 41 light guns and siege-mortars opened a furious fire upon the fort, which was continued until nearly all its guns were silenced and its defenders driven into bomb-proofs, when about sunset, after 900 shot and shell had been discharged, Gen. G. C. Strong's brigade of six small regiments, supported by Col. H. S. Putnam's brigade of four regiments, made an assault. As the head of the column left the trenches the guns of Forts Wagner, Gregg, and Sumter opened on it, and as it neared Fort Wagner the Confederates mounted the parapet and poured in such a destructive fire of musketry that the leading brigade was repulsed; but the supporting brigade gained a foothold, which it kept for over an hour, when it was driven back. The Union loss in this second assault was 1,128 killed and wounded, and 389 missing; among the killed or mortally wounded being Gen. Strong and Col. Putnam, John L. Chatfield, and Robert G. Shaw (q.v.). The Confederate loss was 56 killed and 133 wounded.

Gillmore now turned his attention to Fort Sumter (q.v.), which, with the aid of the navy was, by 23 August, reduced to a shapeless mass with almost every gun dismounted or silenced. Meanwhile regular approaches were made against Fort Wagner, thousands of heavy shells were thrown against and into it, and by 26 August the trenches were within 250 yards of it, the intervening space being a flat ridge of sand, scarcely 25 yards wide, and for a great part planted with torpedoes. The Confederates were driven from position behind this flat ridge and the approaches continued until within a few yards of the fort, when the heavy guns of the army and navy opened on it. Final operations were inaugurated 5 September at daylight, and in 42 consecutive hours 17 siege guns discharged 1,411 shells at the work, 1,247 of which struck it, the ironclad New Ironsides joined in the attack, the fort was silenced, over 100 of the garrison killed and wounded, and an assault was ordered for the 7th. When morning came the fort had been abandoned and its garrison, with that of Fort Gregg, had escaped, leaving the entire island with the 25 guns of the two works in Union possession. The Union loss on Morris Island (10 July–7 September) was 381 killed, 1,372 wounded, and 565 missing, an aggregate of 2,318; the Confederate loss was 157 killed, 674 wounded, and 238 missing, an aggregate of 1,069. Consult: 'Official Records,' Vol. XXVIII.; Gillmore, 'Engineer and Artillery Operations Against Charleston, 1863'; The Century Company's 'Battles and Leaders of the Civil War,' Vol. IV.

E. A. Carman.

Fort Wal'la Wal'la, Wash., a United States military post, established in 1857, at Walla Walla.

Fort War'ren, Mass., a United States military post on Georges Island, near Boston, established in 1837. During the Civil War it was used as a military prison.

Fort Washington, Md., a United States military post on the Potomac River, near Washington, D. C. It was established in 1815 as Fort Warburton.

Fort Washington, N. Y., the site of a former fort at 182d Street, New York, overlooking the Hudson River. It was built prior to the Revolution and surrendered to the British under Sir William Howe (q.v.) 16 Nov. 1776, after a terrific engagement. The loss of the fort caused consternation throughout the United States. Consult: De Lancey, 'The Capture of Fort Washington' (1877).

Fort Wayne, Ind., city and county-seat of Allen County. Situated in the northeastern part of the state, 102 miles northeast of Indianapolis, upon the Saint Joseph, Saint Mary's and Maumee rivers, confluence of the first two within the city's limits forming the last named. It is notable as a railway center, the following lines passing through or terminating there: Pittsburg, Fort Wayne & Chicago, of the Pennsylvania Railway system; Wabash; New York, Chicago & St. Louis; Grand Rapids & Indiana; Cincinnati, Richmond & Fort Wayne; Lake Shore & Michigan Southern; Fort Wayne, Cincinnati & Louisville; Cincinnati, Hamilton & Dayton. The city is central in a rich and highly developed agricultural region that produces abundant crops of the cereals of temperate climates. Considerable tracts of hardwood timber yet remain in what once was one of the most richly wooded sections of the northwest.

Manufactures.— These cover a wide range and embrace numerous establishments of large magnitude. In the various industries 10,000 operatives were employed in 1903. The manufactures include carwheels, Corliss and other steam engines, boilers, gas engines, gas machinery, iron and steel bars, freight and passenger cars, locomotives, electrical machinery and electrical fittings and fixtures, hosiery, gloves, caps, oil tanks, organs and pianos, women's garments, road construction machinery, carriages, wagons, washing machines, furniture, paper boxes, lumber, sash, doors, malt liquors, cigars, harness and leather findings and a considerable variety otherwise of products in iron and steel, wood and textile fabrics. The value of the manufactured products in 1903 was $15,000,000.

Municipal Service and Improvements.— The municipality owns and operates the public waterworks system, an abundant supply of pure water being procured from wells bored deeply into the rock, and distributed by means of two thoroughly equipped pumping stations. There is a handsome and substantial city hall and police headquarters and eight modern and thoroughly equipped houses advantageously situated shelter the city fire department. The public buildings in the city are a court-house (county), completed in 1902 at a cost of $1,000,000; United States post-office and court-house; a public library erected at a cost of $100,000 through a donation by Mr. Andrew Carnegie; county jail; high school and manual training school building, completed 1904 at a cost of $300,000, and 15 grammar and ward school buildings, most of which are of very modern construction and beautiful architecture.

Schools and Colleges.— The free-school system maintained by the city embraces a high school and manual training school, a training school for teachers, and 15 ward and grammar schools, together with kindergarten departments. The free-school system is governed by a board of three trustees, elected triennially by the city council, the immediate executive head of the schools being a superintendent elected by the board. There are 6 Roman Catholic parish schools in addition to a high school for boys and an academy for girls; and 6 German Lutheran parochial schools. Concordia College, founded in 1850, is seated in Fort Wayne, and is maintained under auspices of the German Lutheran church. Near the city is an academy maintained under auspices of Catholic sisters, an academy for the higher education of young women. Among other institutions of learning are a college of medicine and surgery, a conservatory of music, a school of art, two business colleges, and a school of oratory, expression and physical culture.

Churches and Charities.— There are 47 religious congregations and 40 church edifices, many of them beautiful and costly examples of ecclesiastical architecture. The congregations are distributed denominationally as follows: Baptist, 2; Christian, 3; Congregational, 2; Episcopal, 2; Evangelical Association, 1; Evangelical Lutheran (English), 3; Evangelical Lutheran (German), 4; German Lutheran, 3; Methodist Episcopal, 5; Free Methodist, 1; African Methodist Episcopal, 1; Presbyterian, 4; United Presbyterian, 1; Reformed (German), 2; Roman Catholic, 7; United Brethren, 1; Baptist Brethren, 1; Christian Science, 2. The city is the see of the Catholic Diocese of Fort Wayne. The city has a central charities organization and many of the religious congregations maintain comprehensive societies for charitable and benevolent work.

Hospitals and Asylums.— There are 4 large hospitals of modern equipment, 1 non-sectarian, 2 under Roman Catholic and 1 under German Lutheran administration. There are 3 orphan asylums, two sectarian and 1 maintained by the county; home for emergencies and a refuge for women. Just beyond the city limits is the State School and Home for Feeble-Minded Youth of both sexes and home for epileptic women.

Finance and Banking.— There are 4 national banks, 3 private banks, 3 trust companies and 6 building and loan associations. The national banks have (June, 1904) a total capital of $1,050,000, total surplus of $771,879 and total deposits of $6,053,992. One of the banks is a government reserve agent. Trust companies have (June, 1904) a total capital of $900,000, total surplus of $105,105, and total deposits of $2,095,835. Private banks have total individual responsibility of $1,000,000.

Parks and Cemeteries.— The total public park acreage of the city is 95.49, distributed as follows: Swinney, 45.24; Lawton, 31.20; Reservoir, 13; McCulloch, 4; Hayden, 1.12; Piqua, .75; Old Fort (site of stockade built by General Anthony Wayne in 1794), .18. There are 5 cemeteries — Achduth Veshalom (Hebrew), Concordia (German Lutheran), St. John's (German Lutheran), New Catholic (Roman Catholic), and Lindenwood (non-denominational).

Government.— The city is governed under a special charter, conferred by the state legislature, which provides for a municipal legislative body of two councilmen from each of the ten wards, chosen biennially, a mayor and city clerk, chosen quadriennially, and a board of waterworks' trustees, chosen biennially. The board of public works, board of public safety, health commissioner and park and street superintendents and city attorney and city comptroller are appointed by the mayor. Council fixes all municipal tax levies and appropriations and has final approval of all contracts and franchises.

Trade and Commerce.— Fort Wayne is an important and flourishing trade centre and has a commerce that embraces extensive wholesale and jobbing operations in dry goods, groceries, light and heavy hardware, drugs, millinery, paper, etc. The total volume of wholesale trade in 1903 had a value of $9,000,000. The total post-office receipts for 1903 were $177,496.

History.— The city takes its name from a fort built on a part of the present site of the city by General Anthony Wayne in 1794. The place, however, had a history that long antedated this. There is evidence that La Salle had visited the locality as early as 1670. It was the site of Ke-ki-on-ga, the "Central City" of the once powerful and warlike Miami Indians. At different times during the seventeenth and eighteenth centuries French and English had military posts at Ke-ki-on-ga. In 1790 General Harmer led an expedition against the Miami City, but was signally defeated in a fierce engagement on the Maumee River within what is now the limits of the city of Fort Wayne. In 1791 General St. Clair in a similar expedition was overwhelmed a short distance southeast of Fort Wayne by the Indians under the famous Miami Chief, Little Turtle. General Anthony in 1794 headed a third expedition against the Indians in the Northwest and after utterly defeating them at the battle of Fallen Timbers on the Lower Maumee in Northwestern Ohio, marched to Ke-ki-on-ga and in September of that year built his stockade on an eminence overlooking the confluence of the St. Joseph and St. Mary's rivers. These was no further serious trouble within the Indians until August 1812, when the conspiracy of Tecumseh and his brother The Prophet ensued in a close investment of Fort Wayne and its meagre garrison. The siege was vigorously pressed for about two weeks, when it was raised by a force that had been dispatched to relief of the beleaguered garrison. Fort Wayne at once assumed importance as a trading post and in 1825 the town itself was laid out. In 1840 Fort Wayne took rank as a city. Between 1850 and 1860 began the era of railroads, when growth received fresh and powerful impetus and Fort Wayne came to be one of the foremost industrial and commercial cities of the State. Pop. (1900) 45,115; (1907, est.) 57,000.

Harry M. Williams,
Managing Editor Fort Wayne 'Sentinel.'

Fort William, Canada, city in Thunder Bay District, Ontario; on Thunder Bay at the mouth of the Kaministiquia River; and on the Canadian P., the Canadian N. and the Grand T. P. R.R.'s; 426 miles east of Winnipeg. It is at the head of the Canadian navigation on the Great Lakes, is a terminus of the Canadian Pacific, and has splendid shipping facilities. Gold, silver and iron ore are found in the neighborhood. Lumbering is an important industry. There are also iron foundries, brick yards, machine shops, flour mills, and other manufactories. Beside elevators with 3,500,000 bushels capacity, the Canadian Pacific has expended over $5,000,000 in the erection of large wheat elevators, which have a capacity of 8,750,000 bushels. Fort William has several churches, a city hall, hign school, Separate school, four public schools, nine banks and two daily and one weekly newspapers. Fort William was founded by fur traders in 1805, became a town in 1887, and a city in 1907. The government is vested in a mayor and council of eight members elected annually. Pop. (1907) 15,000.

Fort Worth, Texas, city, county-seat of Tarrant County; on Trinity River, and on the Fort Worth & D., the Fort Worth & R. G., the Gulf, C. and S. F., the Chicago, R. I. & P., the Texas & P., the Missouri, K. & T., Houston & T. C., International & G. N., Saint Louis & S. W., and Red River, T. & S. R.R.'s; about 32 miles west of Dallas. It was organized as a town, under general State law, in 1873, with a population of 1,100; and chartered as city in 1882, with a population of 11,285. The government is vested in and administered by a mayor, nine aldermen, city marshal and assessor, and tax collector, elected by popular vote; city secretary, auditor, treasurer, superintendent of waterworks, chief of fire department, street commissioner, and other subordinate officials elected by the city council. The city owns and operates the waterworks and the street-lighting plant. The city-hall and fire halls are commodious structures of stone and brick. It has over 80 miles of improved streets; 68 miles of sewers, and nearly 100 miles of pipes. There are eight national banks and two trust companies and savings banks, with a capital and surplus of $2,965,353, and deposits amounting to $7,928,577. Fort Worth is the centre of the cattle interests and grocery trade of the State, and of the grain and milling interests of the northwestern portion of the State. Having 11 trunk lines of railway with 16 outlets, it is the greatest distributing point of the Southwest. The flour mills, breweries, packing houses, and foundry and machine works are the principal industrial enterprises of the city. The county court-house is constructed of granite and marble from the Texas quarries. The passenger station is one of the largest and finest in the country in a town of this size. The banking houses, colleges, medical schools, high-school building are costly and imposing structures. Fort Worth has one high-school building, 11 ward school buildings, Fort Worth University, Polytechnic College, Medical School, Saint Ignatius Academy, and the public free library. There are 42 church buildings, representing all denominations. There are also sanitariums, a free kindergarten, Rescue Home, a local Benevolent Home for Children, the Saint Joseph's Infirmary, and the State Masonic Widows' and Orphans' Home. There is one public park of 50 acres, several small parks, and three cemeteries.

The growth of population has been rapid but not unhealthful. The vital statistics show less than nine deaths to 1,000 for a series of years. There are no local causes for disease. It is nearly 700 feet above sea-level, and is fanned by cooling gulf breezes during the summer, making a pleasant and healthful place of residence. Pop. (1890) 23,076; (1900) 26,688; (1903 est.) 45,000.

B. B. Paddock,
Fort Worth, Texas.

Forth, fōrth, a river of Scotland, rising on the east side of Ben Lomond, in Sterlingshire.

Forth Bridge, The. See Bridge.

Fortifications («to fortify,» precisely following its Latin derivative, is *facere fortis*, «to make strong»), such artificial positions as are required for military use. Primarily, such positions are for defense; but no less important in operations against defensive works already established by an enemy. Two definitions, used in another connection, but officially approved by the late Col. Edward Bruce Hamley, president of the Queen's Staff College, London; by the late William T. Sherman, general of the American army, and by the late Theodore D. Woolsey, president of Yale University, indicate the drift of the subject-matter under immediate notice.

1. «Military Science,» the mother of all such constructive relations, «while that of force, as in all police or other protective law, is founded upon the adaptation of all possible means to meet an impending crisis. The wisdom of the statesmen differs only in degree from that of the ordinary householder, and both alike aim at a wise constraint of offensive elements and the radication of such as are adapted to that end. Hence, to meet the demand adequately, wisely, and successfully, thereby to secure ultimate public safety, is the expressive logic for personal action, municipal action, and military action. The brain-power is banded to various shaftings, and the mental processes differ by virtue of different adaptations, but the prime activities are

the same.» The citizen who is to be protected, equally with the technical expert, should be sufficiently interested to become actively sympathetic in whatever relates to the national defense.

2. «Military engineering,» as the second preliminary definition, «is the application of mathematics and mechanics to the maintenance, or the reduction of fortified positions, the interposition, or the removal of artificial obstacles to the passage of an army, and the erection of suitable works for the protection of territory or troops.» Rival systems of practical military engineering, stimulated by successive inventions, have so multiplied their technical terms, borrowed from many languages as well as from their authors, or local customs, that the ordinary citizen who desires but a suggestive history of that progress would be compelled to have both lexicon and scientific text-book by his side in order to fathom their mysteries.

The origin of artificial defense and the development of primitive types until isolated families or groups of families gradually crystallized into independent and self-supporting nations, are so familiar to the willing reader of general history as to need but brief mention. The defense of the retired domicile from wild beasts and the forays of irresponsible robbers was as distinctly a matter of prime necessity for the head of a family, as for the tiger, the wolf, or the robber, to find in thicket, cave, or mountain fastness, his own protection from pursuit and punishment. The simplicity of weapons of offense and defense harmonized with the demand for artificial protection against violence of every kind. The bow-and-arrow and javelin, with the sling, for long range; and the knife, sword, club, and battle-ax, of stone or metal, for hand-to-hand conflict, required protection from each. The hide-bound protective shield at first, and later, the more impenetrable metallic armor, were but types of the development which gradually evolved the fortification proper, in proportion as weapons enlarged their range of stroke as well as their destructive effect. The shield was, in fact, both the simplest as well as the true prototype of defense against superior force. Under its cover, one man could hold several antagonists at bay. When flanking assailants neutralized its protective value, men, in groups, enlarged its functions, until, by the hollow square, or the solid mass, a phalanx could withstand the onset of many times their number. Their uplifted shields were like a modern bombproof against falling flights of arrows while the men, thus protected, supplied constant reinforcements for those in front who were disabled by ax, sword-thrust, or javelin.

Social Conditions.— The sanctity of the home-domicile was, from earliest times, the basis of its protective and stubborn defense. The Hebrew, the Chaldæan and Egyptian traditions and records, as well as those of Greece and Rome, still later, perpetuated that philosophy; and the ancient German, Goth, Moor, and Briton, through all their feudal, racial, and political rivalries, alike honored precepts thus coincident with the first groupings of families for a common defense.

The «Home, as a Castle,» was not merely of British conception, but a vital factor in human happiness and safety. With the gradual accumulation of both numbers and wealth, the protection of the many became the duty of each individual, and the assertal of tribal or national superiority, on the part of the more numerous and powerful, engendered such competitive conflicts that centres of influence exacted more systematic and elaborate national defenses. Excursions against other states, and responsive invasions, were the means employed by ambitious rivals to increase their territorial domain and subject inferior peoples to their dominating control.

By this complex evolution of warring peoples, led by daring spirits, systems of more speedy intercommunication, transportation, and the accumulation of war material, arms and food included, became indispensable to the public safety, until warehouses, detached strongholds, internal citadels, and organized armies were the result. All draft animals and beasts of burden were utilized for attack or defense, so that the horse of the warrior might, in turn, drag the war chariot with its out-reaching scythe blade; and both camel and elephant carried miniature castles upon their backs for archers and spearsmen, mounted above.

Military Conditions.— The fundamental principle in all substantial fortifications has been the effort to ensure a destructive fire upon every available avenue of approach to the place protected, and, with this, to secure such enfilading and cross-fire that no position remained unprotected. Human competition has ever been the same in essence, and where no reliable historic record responds to inquiry, exhumed ruins, memorial tablets, and deciphered hieroglyphics, solve all doubt as to the proposition that military science and military engineering belonged to all human activity, ever the same in principle, and differing only in application and development. The paramount object was, to eliminate disparity in physical strength and enable the few to resist the many. Personal combat at short range came to a limit as people gathered in cities; and breastworks first, and then solid walls, became essential in proportion as the numbers of non-combatants gathered there for shelter and safety.

Illustrations.— The most primitive forms of which the earth retains an outline were oval, or circular, mounds or entrenchments, even before walled towns were constructed, these being more compact for defense of each front, or exposure, by defenders from the centre. More modern defenses, especially against savages, of the block-house type, had this peculiar value, and even women could prepare arrows, or load weapons, for defenders who in turn acted in all directions.

Such defenses were upon commanding positions, to guard against surprise, with wood and water always within easy reach. These were transient, and usually against predatory or nomadic peoples, of no greatly superior strength. As populous centres increased, defenses were of stone or brick walls of such height and breadth that large armies could mount their summits and chariots convey men and munitions from one point of defense to another. These were surrounded by a flooded moat, or ditch, and were easily made impregnable against an army of equal force and equipment. Towers at angles of quadrangular defenses, and to protect gates of entrance, exit, or for sallies upon an enemy, were supplied with lifting or draw-bridges, and mines and tunnels were excavated under the ditch itself for more ready surprise of a careless adversary. Cæsar describes a mine which he advanced beneath both ditch and wall, supporting the wall with timber until he could fill the shaft with dry branches, and upon setting all on fire, the wall crumbled, and he stormed the breach.

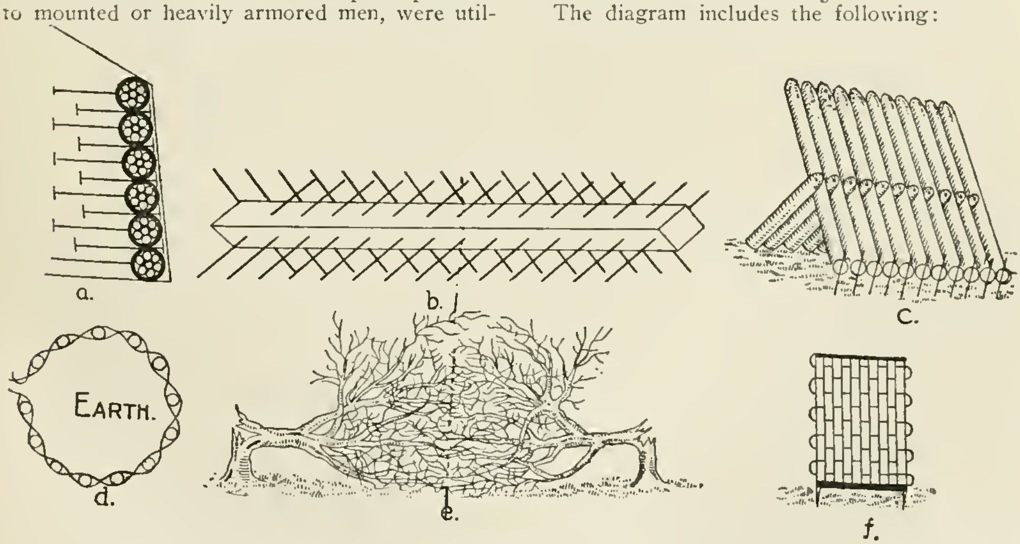
Great machines were made by which to reach engirdling camps, or crush assailants who attempted to bridge, or fill the ditch, and thus gain access to the wall summit by scaling ladders, when unable to force the gates. The catapult and ballista were two of these, which, on the principle of the spring-board and sling, and the increased length of its vibrating arm, the radius of its centrifugal force, would hurl heavy stones at a great distance and send blazing balls of tallow, or pitch, congreve-rocket-like, to destroy a hostile camp.

To meet these mighty forces, corresponding engines of swinging, battering timbers, called «rams» from the device curiously shaped in front, would strike a blow equal to the force of a 30-pound shot, powder-driven. Movable towers, protected by wet hides from fire, were advanced, putting its archers upon a level with those upon the city wall. Titus, at the siege of Jerusalem, brought such towers sufficiently near that, with grouped lances and timbers, he bridged the intervening distance and fought on the city wall itself.

With the increase of territorial domain, subordinate but correlated military engineering had its special province. Territorial boundaries, mountain passes, sharp defiles, river fords, and watercourses, had to be guarded by detached outworks, and these must have close relation, each to the next in order. Swamps, impervious to mounted or heavily armored men, were utilized, and their narrow approaches, or shallow portions, were so fashioned and guarded as to keep assailants from fire-range upon defenders. Outlying summits were made signal stations, both against herds of wild beasts, which in early times were as dangerous to flocks and herds as robbers or hostile invaders were to the inhabitants themselves. Bonfires and flaming torches, as well as a chain of vocal and flag-shaking sentries, became adjuncts to a better external defense. Cæsar had «soldiers who shouted to each other until the alarm reached his camp, through a great distance.» The ancient Persians, and later the Scotch and Swiss, were noted for this signal service, but no experience of the kind has such memorial emphasis as that described by the Hebrew prophet Isaiah, who saw in the system of his own people the forecast of a distant future, when «the watchman, from peak to peak, should see eye to eye, and together lift up the voice» in jubilant rejoicing over universal peace to be proclaimed the world around.

Before treating upon fortifications proper, within the limits of this article, there are subsidiary defenses, pro and con, which have antiquity for their use, and the latest of modern battlefields for their equally advantageous application to-day. Their names are familiar as household words, and yet are generally treated as simple types of barbarous usage, before firearms and the sphere of smokeless powder and electricity alike defied stone and iron defenses, and sent destructive missiles beyond human aim and human sight. A few plain illustrations indicate many which had effective use during the American Civil War of 1861–5.

The diagram includes the following:



(*a*) A parapet forming the front of a modern fort, with fascines, behind which earth is packed as they rise, one upon the other, and are locked into the trampled or rammed earth by hoop-poles or common sticks, the fascine being but a bundle of sticks, hooped, or tied with chain or rope.

(*b*) The Chevaux-de-frise, an iron cylinder, or a trunk of a tree, filled with spikes of iron or wood, to which, in case of wood, sword blades, and bayonets may be applied.

(*c*) Inclined and sharpened posts, really an inclined palisade, or stockade material, fastened to the earth, and its parts fastened together by chains or ropes.

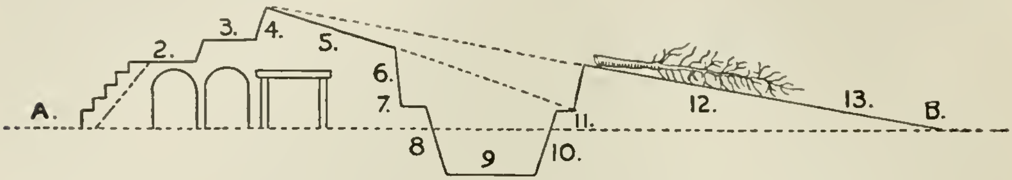
(*d*) A basket, open at both ends, made by inserting stakes in the ground in a circle, braiding them by willow, or other flexible green wood, and when filled with earth, forming material for building a parapet, or strengthening a low breastwork.

(*e*) A sample of felled trees, across roads, creeks, ravines, and obstructive to approach by horse or foot.

(*f*) A species of hurdles, when horizontal sticks, or poles, vertical or horizontal, are interlaced by willow, brush, or modern wire (as in Cuba), making a fence of stout resistance, and holding assailants under deadly fire.

The farmer's common harrow also was utilized extensively.

All these "obstacles" have been utilized in filling a surrounding ditch to prepare the way for storming the fort itself. Only old soldiers who participated in the American Civil War, or the Spanish war, can realize the extent of their use in actual service, and Cæsar himself, when establishing winter quarters, writes: "Having



A.— B. Level of parade ground, occupied by buildings and by bomb-proof magazine and hospital, so far as the same are not included in chambers beneath the parapet.

(1) The interior slope of the parapet, on a slight incline for easy ascent, or with steps, and these broken at intervals for entrance to chambers beneath.

(2) Level ground, or platform (*terre-plein*), for troops supporting guns.

(3) A step (*banquette*) for gun.

(4) Parapet.

(5) Exterior slope of parapet.

(6) A facing of wood, or masonry, or of *fascines* linked into the earth as it is built (see OBSTACLES, *a*), to hold the parapet in place, and called the *revetment*.

(7) A narrow shelf, path, or *berme*, between parapet and ditch.

(8) The side of ditch next to parapet, *scarped* down at an angle, and therefore called the *scarp* or *escarp*.

(9) The ditch itself, and faced with masonry in permanent works.

(10) The opposite side of the ditch, and therefore called the *counter-scarp*.

(11) A path, or border (*berme*), commanded by rifles from the parapet and used for defending the interior slope of the *glacis*, and for sallies through openings outward, or beneath, and called the *covered way*.

(12) The superior slope of the covered way, called the *glacis* because of its smooth descent to the general surface without the fort.

(13) *Abattis*, felled trees, with shortened and sharpened branches, directed outward, with the butt securely fastened at head of the *glacis*.

cut young trees and bent them, by means of their numerous branches extending on the sides, and the quick briars springing up between them, made these hedges present a fortification like a wall, through which it was not only impossible to pass, but even to penetrate with the eye." It will be noticed, later, that at the battle of Franklin, Tenn., during the Civil War, prickly osage-orange was a material factor in a successful defense.

Fortifications Proper.— Impregnable fortresses no longer exist. All along the trend of history the term has been fanciful and merely relative. Even Gibraltar, as an isolated fortress, aside from its political and moral force, has its military value as a well located rendezvous for troops and shipping, and the theoretical guardian of the passage from the Atlantic to the Mediterranean Sea. Of this passage, it has no supreme control, without a sufficient naval contingent. In all other respects, it simply defends itself, with no interior at its back, and when without control of the sea, by fleets, imprisons a valuable garrison. In modern times the stationary must yield to the mobile. The art of destruction is more potent and far-reaching than the skill of man to preserve his own workmanship.

Reference has been made to towers, as well as walls, and even after the invention of gunpowder, systems of defense, as well as isolated forts, had their progressive development, in which the United States followed European antecedents and the progressive systems of one general type until the Crimean war largely revolutionized modern practice. A single profile of a cross-section of defenses, as matured during more than two centuries, is sufficient for this article, with an accompanying sketch of the bastion system, which must under no conditions be neglected in any defense against a superior force.

The Bastion.— The *profile* thus noticed obtains throughout the fort, even when it assumes other forms than that of the simple quadrangle. The *pentagon* and *hexagon* have generally been used, leaving to the province of a simple *redoubt* the simpler outline of defense. Very early *projections* were *built out* from these fortified positions, at their angles, hence their name, *bastion*, to give a wider range of *outward* fire, as well as a more direct *flanking* fire, along the walls covered by these projections. These walls were called *curtains*. The containing lines of the salient angle were called *faces*, and the lines connecting the faces with the main wall were properly called *flanks*.

Before these curtains, or main walls, minor defenses were added, whether *ravelin* or *tenaille*, and these might be again covered by ditch and glacis, subordinate to but protected by the superior fire from the main position. A diagram of the simple bastion, similar to those in use around Washington in 1861–5, and common to all modern works, is added.

Inland Positions.— Isolated defensive positions of inferior type have been sufficiently noticed. Their history is common to every mature reader. Transient and movable defenses will be noticed in connection with army movements, although earth defenses already partake of the character once referable only to walls of solid masonry. As against a foreign enemy, the United States has more need of coast defenses than many other nations, as her commercial centres are largely upon the sea; but, as a nation, her capital may be classed with those of other countries, which look to frontier defenses for a substantial protection against foreign attack. But forts, on a frontier, may be ignored, *turned*, *left in the rear*, as when Paris was taken, while idle thousands of her defenders were lost to the national defense. Hence isolated capitals and commercial inland cities must have detached, but closely related outer defenses, beyond the reach of immediate assault or bombardment by an invading enemy.

During the American Civil War, when internal forces attempted the capital, the city of Washington furnished the best type of a city so assailed; 43 forts and batteries, and 36 additional batteries, mounted 99 rifled cannon in *embrasures* and 25 *in-barbette*, as well as 113 smooth-bore in *embrasures* and 147 *in-barbette*, making a total of 384 guns. But additional platforms were erected and made ready, so that a total of 743 guns could confront any new phases of attack. By direction of Gen. Scott, then in command, the writer was directed to visit all these works during their establishment, and at the time opposing forces were displaying their flag upon Munson Heights, within view from the outer works. The *cordon* of forts, batteries, stockades, block-houses, redans, and bridge-heads was complete.

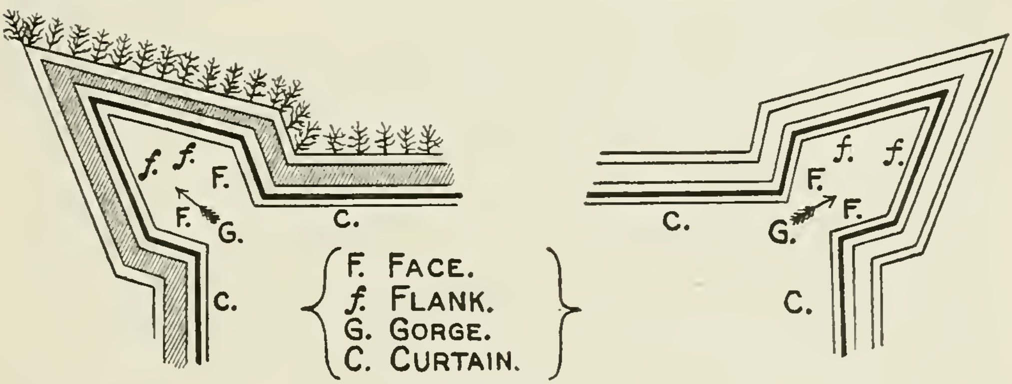
Sea Coast Positions.— Sea coast defenses, from earliest times, have been of massive masonry. Many that still frown innocently upon the American coast, between Boston and New Orleans, are chiefly monumental of obsolete defenses against hostile fleets. Two or three tiers of guns, in as many series of arched chambers, called *casemates*, with a fourth row mounted upon the exposed parapet, or rampart, were expected to cope successfully with the old 120-gun ship-of-the-line. Fort Moultrie, in rude form, in 1776, withstood resistance, with log ramparts, better than with later ones of stone, as in 1861, when sand bags were introduced to support its powers of resistance.

Modern guns, supplied with new explosives, shatter the hardest rock and splinter the toughest timber. The earth alone, and especially sand, will disarm the penetrating projectile of the present day. A single illustration harmonizes with the advent of the new system. Upon the trial of the first 81-ton gun, built at the Woolwich Machine Shops, near London, a mound of sand was erected on the proving grounds against the Thames embankment. Six times a bolt of 1,300 pounds was fired, increasing the powder-charge from 170 to nearly 300 pounds. When the last bolt was dug from the butt, it had entered but 47 feet, 5 feet under the surface of the sand.

Standard tables have long been under consideration to indicate the comparative resistance of earths and gravel, but in all cases, sand, which quickly closes upon what it receives, has been the most obdurate to defy deep penetration. And now, upon the British as well as the American coast, modest mounds or piles of sand present a very indistinguishable target, while, to the nearer view, the abundance of wild grass, daisies, buttercups, and tansy, is its only relieving feature. And yet behind each sand pile, in separate sections, each for a single gun, is to be found the most formidable land defense of modern times. The former "42-pounder" of the casemate and the main battery of a ship-of-the-line, and weighing but 8,750 pounds, is replaced by a gun 40 feet in length, weighing 58 tons, and capable of sending a shot of more than one half a ton, charged by 475 pounds of powder, nearly or quite 7 miles, once each 3 minutes.

A quick release drops the gun below the parapet for reloading. Each battery, however many guns may fall within its control, is operated at will, as if but a single piece were in position. A revetment of solid masonry holds the sand piles in position, and beneath the gun-carriages, which are exposed to the weather, are the necessary passages which communicate with all sections of the battery. Magazines and tackling for handling shot and shell are also under bomb-proof cover, and both placement and independent action of each piece are complete. At suitable distance, but within a practical community of range through adjustable range-finders, sand "pits" for mortars are located. Each mortar revolves upon its own platform, and groups of fours, in closely related pits, can be handled, through signal communication, in connection with the heavy gun batteries, and command a joint delivery of fire upon the same hostile force. As with the gun placements, each mortar pit is independent, in magazine and other appliances, for efficient service.

Floating Batteries.— The battleship as well as the stone fort has also changed character, and become a floating steel fortress. An encircling squadron, in concave formation, can concentrate a weight of metal upon an exposed land defense that cannot be returned by a full equivalent. Other floating batteries, the peer of any, must intervene in support of the land defense, with auxiliary "torpedo boats" and "destroyers." The contingency of landings to take open batteries, in their rear, is increased by swift steam transportation, and the gravity of defense is more serious in proportion as a nation, having a large coast to defend, has distant, dependent territory, equally demanding a mobile naval force



CLASSIFIED DEFENSES.

for its defense. The submarine boat, the dirigible balloon, and wireless telegraphy, menace modern commercial ports with visitations only less fatal than those of the earthquake and volcano.

Field Fortifications.— This branch of military engineering has a duplex character, but of quite uniform general requisites. They may either constitute the chief defense of a city, or neutralize the numerical superiority of an enemy in the field by wise adjustment of their lines. Two illustrations are suggestive of their value:

On 5 April 1862, when both officers and men were alike inexperienced in operations of war, between large armies and over extended territory, remote from their general base, the Federal army was confronted at Pittsburg Landing, Tenn., by a largely superior force under command of Gen. Albert Sydney Johnson, of the Confederate army. Skirmishing occurred during the day; but Gen. Grant, the chief Federal commander, believing, as he advised his superior, Gen. Halleck, and states in his 'Memoirs,' that there was hardly the slightest possibility of attack, as reinforcements were on the way to his support, failed to entrench. On the following morning, an attack was made in force, driving the Federal army back to the Tennessee River, where the arrival of Gen. Buel's division alone averted a serious disaster. Neither Gen. Grant nor Gen. Sherman committed a similar error of judgment later in the war.

On 30 Nov. 1864 Major-Gen. John M. Schofield retired from Pulaski, closely followed by the two-fold superior army of Gen. Hood. After fighting daily for three weeks, and after frequent rains, leaving with night he marched directly to the city of Franklin, Tenn., where in the bend of the Harpeth River, he gave battle. Between morning and 3 o'clock of that afternoon, when the combined Confederate divisions made an impetuous assault, his wearied soldiers had so utilized the shovel, pick, fence-rails, locust trees, and osage-orange hedges that, behind their shelter, he repulsed the assault, inflicted a loss of nearly 7,000 men upon his adversary, including 12 general officers, in killed, wounded and captured, and safely fell back upon Gen. Thomas, at Nashville, with a loss of but 20 wagons and less than half the casualties of his opponent.

Similar entrenchments had their ancient types in those of Cæsar, who invariably established his camp within a quadrangle surrounded by a rampart of the height of from 7 to 9 feet, with gates on four sides, and sufficiently large in area to include all animals and supplies belonging to his command. On one occasion, seeking winter quarters, he carried a parapet, with ditch, 16 miles, from Lake Geneva to Mount Jura, 15 feet high, and with various small redoubts on the line, so that practically he multiplied his numerical strength three-fold. In modern times, the Crimean war introduced a system of earthworks which withstood a heavy fire before which granite walls had crumbled.

Reduction of Fortified Positions.— Field works, against a fortified position, assume an attitude of counter-defense, as well as a cover for siege or assault. The relative strength of the assailing force belongs to another branch of the military art; but it must be proportionately greater, as the circumference of the investment enlarges, and must prove able, at any vital point, to meet any sally of the garrison, either by numerical superiority, or its equivalent, in artificial defense. Inequalities of the ground, commanding summits, a safe communication with the base of supply, are *strategic* conditions; but all are parts of the position to be assured. After estimating accurately the intervening distance, and at what nearer approach the encircling ditch may be filled, or bridged, for assault, the advance begins. A mortar battery in the rear, or guns in an elevated position, may play upon the intervening space to protect the *pioneers* in locating rifle-pits, while establishing the *first line* of works. The general advance, as thus initiated, is that of a ship beating against the wind, and the zig-zag course adopted borrows its name, *traverse*, from marine usage. Successive files of men dig these traverses, throwing the earth outward to the front, as a cover from fire, and thereby open a way for the advancement of guns, as well as of engineers and troops. A second line, *parallel* with the first, is opened to the right and left, where guns are at once placed in position. A third line, or *parallel*, is so planned as to place the defensive works at the mercy of the besieger. At Yorktown, Va., in 1781, with a river base and no sufficient escape by sea, the effectiveness of the advanced parallel compelled surrender. At Yorktown, in 1862, with works open at the rear for retreat, the scientific soldier in command rightly assumed that the scientific soldier at his front would attempt no assault until his third line was perfected and armed. Hence, he wasted the ammunition of the besieger to the last safe limit, and withdrew his own force in good order, to suit himself.

To this suggestive summary of fortifications, for the unprofessional reader, must be added the statement, that topographical and geographical features largely dominate in matters of attack or defense. *Boundary* lines, whether of mountain or river; interior or coastwise positions; the control of only one or of both banks of a navigable river, give character to defenses and methods for their reduction. Notable illustrations are found in the Dardanelles, the entrance to the Baltic Sea, the Suez Canal, and, prospectively, of vast moment, the Inter-Oceanic Canal in Central America. In proportion as Nature lends her secrets of omnipotent power to the inventive genius of man, so will fortifications change their forms and relations until nations shall control the secret which should inspire all such warlike devices, that of substantial and universal fraternity and peace.

HENRY B. CARRINGTON, U. S. A.

Fortifications, Modern Seacoast. The modern science of seacoast fortification wrought marvelous changes during the years intervening from 1893 to 1903. All the great maritime nations expended enormous sums of money to better fortify their coast lines. The United States after 16 years of labor practically completed, during the summer of 1903, the most costly and the most substantial and powerful system of seacoast fortifications in the world. The great improvements made during the latter part of the 19th century in the construction of heavy guns rendered it necessary to revise the system of fortifications formerly in vogue. Iron and steel turrets have taken the place of masonry on exposed sites, where earth cannot be employed to advantage. These turrets are revolving cupolas with spherical roofs, and in most instances even the largest guns are mounted on disappearing carriages. This is essential since the forts are now called upon to prove their prowess against steel-plated warships.

Great Britain concluded the rebuilding of her forts with iron and steel as long ago as 1880, at a cost of $37,000,000 for nine harbors alone. At Dover, England, solid iron turrets of enormous thickness have been built to carry two 80-ton guns to each turret. Steel cupolas of the Gruson pattern to the number of 28 have been constructed since 1890 in various harbors of Germany, Austria, Belgium and Holland. In 1900 the Italian government placed an order for two of these cupolas to mount two 120-ton Krupp guns each, for the defense of the naval station at Spezzia. The order was conditioned on a test shield or segment of the cupola resisting three shots of the Armstrong 100-ton gun — a test which it successfully withstood, though the same gun had pierced every other known form of construction.

The 20th century fortifications of the United States seacoast finished in 1903 are excelled by those of no other nation in the world. The work was outlined if not actually begun in 1886, when a board of military engineers proposed a system of steel turrets, armored casements, barbette batteries, mortar and floating batteries, and submarine mines. So rapid was the advance of military progress that the original plans were largely changed and modified. The vastness of this work and the great cost can be imagined when America has 5,558 miles of seacoast demanding protection of the most improved kind. Between 1886 and 1903, three fourths of the work was finished, and yet huge rifles and mortars to the value of $15,000,000 were required to complete the undertaking. A modern, high-power coast-defense gun is a huge and elaborate machine, the effective management of which requires great skill. A single 12-inch rifle for one of the modern forts cost $45,000, its carriage $41,000, and the emplacement of concrete in which it stands $60,000, or a total initial cost of $146,000. The total expense for each modern fortress amounts to over $2,000,000. The 20th century fortress is not a walled enclosure as of old, but a hole in the ground, or rather a series of holes called emplacements, built of concrete, and each of them containing one or more guns. No lofty, menacing structure strikes the eye of the observer who approaches the works, but instead there is likely to be rolling greensward with shrubbery, suggesting rather the skill of the landscape gardener than that of the military engineer. The real protection consists of 30 feet of iron and masonry and 30 feet of earth, which form a plane sloping outward, so that any projectile striking is promptly buried or glances off harmlessly.

Fort Warren, on Georgies Island, in the harbor of Boston, Mass., which is one of the most notable fortifications in the world, has an armament of 30 guns and mortars. Several of the guns are 12-inch rifles, but the exact character of the armament is kept carefully secret by the military authorities. The mortars are arranged behind the cannon and are capable of throwing explosive shells for a distance of three miles, and with sufficient accuracy to destroy a vessel at that distance. The projectiles carry an enormous charge of maximite which is three times as powerful as gunpowder. Over 600 of these mortars, each of 12-inch calibre, are distributed among the various coast fortifications. They are a vast improvement on the old-style mortars of cast iron with steel hoops. A mortar of the new, modern type is 13 feet long and weighs nearly 30,000 pounds, and requires a charge of 125 pounds to send its conical projectile on its deadly mission. Weapons of this character have not yet undergone a test in actual war. The modern 12-inch rifle is 40 feet long, weighs 104,000 pounds, requires a charge of 520 pounds, and fires a 1,000-pound projectile a distance of 9 miles, with a velocity, upon leaving the muzzle, of 2,100 feet per second. The 12-inch gun could send the same projectile 14 or 15 miles, if the muzzle was sufficiently elevated, but it would be useless in aiming at an enemy who is beyond the limit of vision, for a ship is out of sight only seven miles away owing to the curvature of the earth. These guns shoot three kinds of projectiles. One is the so-called armor-piercing shot, which is nearly solid, having only a small cavity to contain a high explosive. The second is the armor-piercing shell, which has a larger cavity so as to contain more of the explosive. The third is the torpedo shell, which is in effect a torpedo, having thin walls and containing a large bursting charge of maximite. This explosive is a government secret so far as its composition is concerned. Most of the great rifles are mounted upon disappearing carriages, so they are safe from the fire of the enemy except at the very moment of firing. When its fire has been delivered the gun is lowered promptly below the parapet, and after being reloaded is uplifted again to the firing position.

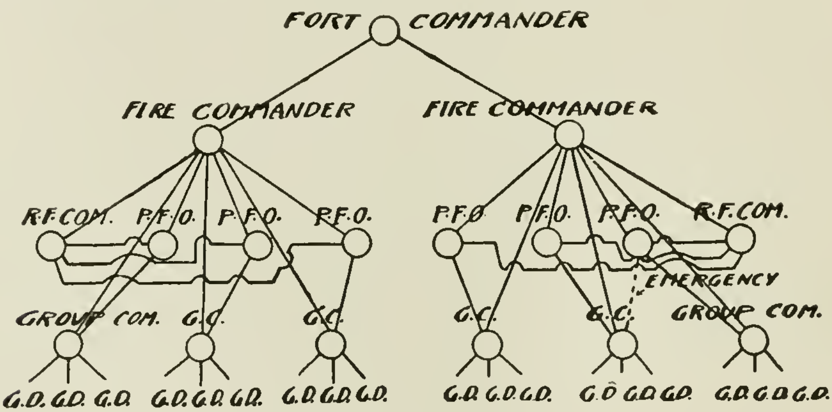
At Fort Wadsworth, on Staten Island, N. Y., at The Narrows, is located another almost perfect system of coast defense, which is regarded by army officers as a model or typical artillery station. The fortification consists of three separate batteries or groups of guns — one battery of five 8-inch guns and two of two 10-inch guns each, a fire commander's station, three position finding stations, a power and electric plant, a storage battery plant of 60 cells for storing of light and power for the stations when the main power plant is not in operation (for example, if it should be wrecked by a shell), two electric searchlights of 60,000 candle-power beam and wires connecting the electric plant with all parts of the fortification and connecting the stations by telephone.

The War Department has prepared the accompanying diagram to illustrate the system of control in the typical artillery station. The diagram is not arranged particularly for the works at Fort Wadsworth. In command of this fortification is a fort commander. Under the fort commander are two fire commanders, each being in control of three groups of guns. Each group in the diagram is composed of three guns, but the number may be more or less. Generally it is the number which one officer can supervise efficiently in action. Each of these officers is called a group commander. Between the fire commanders and the groups of guns is a line of range finders and position finders under a range finder commander and position finding officer. Finally each gun has its firing crew of three, under command of a gun director, who may be an officer or a non-commissioned officer. The guns are of course behind emplacements. At Fort Wadsworth nature has provided a natural defense in a high hill with a slope terraced to the edge of the water. Behind the hill the fortifications are constructed. On the hill above is the fort commander's station, which controls the approaches to the harbor. The telephone places the fort commander in direct communication with those under his command. The printing telegraph, unknown in the days of the Civil War, is also used in the scheme of communication. The fort commander sitting in his station, communicates his orders to the fire commander by telephone, giving information as to the general scheme of defense. The fire commander communicates with the range finder commander, and then on down the line to the group commander and thence to the three gun directors under him. Under this system the fort commander has perfect control over the guns. If a hostile fleet approaches, he can detect it from his elevated station long before the ships' guns have the fort in range. He can direct the attention of the fire commanders to it, if they have not seen it, and inform them with what guns he wants the firing on it opened. In accordance with a map of the harbor which lies before him he can direct that these guns be turned against a certain target or ship. The fire commanders will transmit his order to the position finding officers, who will indicate the position and range to the group commanders. Then the guns will be aimed and fired. The position finder occupies the most important station, because upon the accuracy of his work depends the effectiveness of a shot which will cost the government $1,000 and possibly cost the enemy $2,000,000 or the value of a modern warship. In aiming the guns allowance is made for the moving enemy and for the force of the wind. The firing is done by stop-watch and every second of time is important.

At the outbreak of the Spanish-American war, the government, owing to the parsimony of Congress, possessed no smokeless powder. In July 1903, millions of pounds of this explosive were safely stored at the various seacoast fortresses. When the American forces took possession of the fortifications at Havana, many of the front sights of the Spanish guns were missing. These cannon were made at Spanish arsenals, and it is supposed that the same defect existed in the guns on the Spanish warships, which may account for the slight damage inflicted upon American ships by the guns of Spain.

The modern system of seacoast defenses of the United States, comprises the following fortifications:

Fort Foster, Maine, on Gerrish's Island, in Portsmouth Harbor.
Fort Gorges, Maine, on Hog Island Ledge, in Portland Harbor.
Fort Preble, Maine, at Spring Point, in Portland Harbor.
Fort Scammel, Maine, on House Island, in Portland Harbor.
Fort Stark, N. H., at Jerry's Point, in Portsmouth Harbor.
Fort Warren, Mass., on Georgies Island, in Boston Harbor.
Fort Strong, Mass., at Long Island Head, six miles from Boston.
Fort Banks, Mass., at Grover's Cliff, near Boston.
Fort Adams, R. I., on Brenton's Point, near Newport.
Fort Greble, R. I., on Dutch Island, Narragansett Bay.



ARRANGEMENT OF FORT BATTERY.
Diagram designed by the War Department.

Fort Wetherill, R. I., on Conanicut Island, Narragansett Bay.
Fort Hamilton, N. Y., at The Narrows, New York Harbor.
Fort Lafayette, N. Y., at The Narrows, New York Harbor.
Fort Michie, N. Y., on Great Gull Island, 12 miles from New London, Conn.
Fort Tompkins, N. Y., on Staten Island, at The Narrows.
Fort Wadsworth, N. Y., on Staten Island, at The Narrows.
Fort H. G. Wright, N. Y., on Fisher's Island, entrance to Long Island Sound.
Fort Carroll, Md., at Seller's Point Flats, Patapsco River.
Fort Howard, Md., at North Point, Patapsco River.
Fort Smallwood, Md., at Rockpoint, 10 miles from Baltimore.
Fort Hunt, Va., Potomac River.
Fort Washington, Md., Potomac River.
Fort Moultrie, S. C., on Sullivan's Island in Charleston Harbor.
Fort Sumter, S. C., in Charleston Harbor.
Fort Oglethorpe, Ga., at Savannah.
Fort Pulaski, Ga., on Cockspur Island, Savannah Harbor.
Fort Taylor, Fla., at Key West.
Fort Barrancas, Fla., near Pensacola.
Fort Pickens, Fla., on Santa Rosa Island, near Pensacola.
Fort Gaines, Ala., on Dauphin Island, in Mobile Bay.

Fort Morgan, Ala., at Mobile Point.
Fort St. Philip, La., 65 miles below New Orleans.
Fort San Jacinto, Texas, near Galveston.
Fort Rosecrans, Cal., at San Diego.
Forts Miley, Baker, and Winfield Scott, Cal., in San Francisco Harbor.
Forts Casey, Columbia, Lawton, Walla Walla and Wright, Wash., in Puget Sound.

The foregoing are the new-type fortifications and in addition to these there are nearly 100 other forts along the Atlantic and Pacific seacoasts, not yet remodeled or equipped with the modern appliances of warfare. See ARMY OF THE UNITED STATES; ARTILLERY; MILITARY POSTS, U. S.

Fortiguerra, Niccolo, nē-kō-lō' fōr-tē-gwā'ra, Italian poet and prelate: b. Pistoia 7 Nov. 1674; d. Rome 17 Feb. 1735. A prelate at the court of Pope Clement XI. In his epic poem 'Ricciardetto,' so-called from one of the Paladins of Charlemagne, he wished to show that it was easy to imitate Ariosto. He wrote the first canto of this poem in one night, and continued it to 30 cantos. It appeared (1738) under the name of Carteromaco, which had been assumed by the author during his life. Its principal excellence consists in the description of situations. His short poems and sonnets are to be found in different collections of Italian poets.

Fortu'itism (Lat. *fors,* chance), a doctrine or theory of causation which denies the existence of a final end or object in the course of things. Such a doctrine in the domains of nature results in theories such as that of Darwin, who has been charged with denying design in the changes and developments of organized creatures, that is, the design of a single controlling mind, namely, of a supernatural creator. The opposite to fortuitism is teleology (q.v.), which is the theory of a final end or object in the processes of nature and history, as resulting from the plan or scheme originating in the mind of the Supreme Being.

Fortu'na (Gr. Τυχή), the goddess of success. According to Hesiod she was a daughter of Oceanus; according to Pindar, a sister of the Fates. She had temples at Corinth, Elis, and Smyrna, and worshipped in Italy before the building of Rome, and had a celebrated temple at Antium, in which were two statues, which were consulted as oracles, and gave responses either by signs or by lot. She had also a temple at Præneste, whence she was called *Dea Prænestina.* No less than 26 temples were erected to her in Rome, the first of which was built by Servius Tullius. She is generally delineated with two rudders, with one of which she guides the ship of prosperity, with the other that of misfortune. At a later period she was represented with a bandage over her eyes and a sceptre in her hand, and sitting or standing on a wheel or globe. She is usually dressed as a matron. On a coin of the Emperor Geta she is represented sitting on the earth with her bosom bare, her right hand resting on a wheel, and holding in her left hand, resting on her lap, a horn of plenty.

Fortunate Islands. See CANARY ISLANDS.

Fortuna'tus, a German collection of tales which originated about the end of the 15th century, though many of the tales and legends included in it are of much older date. The substance of the book is that Fortunatus and his sons after him are the possessors of an inexhaustible purse of gold and a wishing-cap, which however, in the end, prove the cause of their ruin. The moral is that worldly prosperity alone is insufficient to produce lasting happiness. The oldest printed edition of the book now extant bears the date 1509. Later German editions mostly bear the title, 'Fortunatus, von seinem Seckel und Wunsch-hütlein.' It has been reprinted in the third volume (1846) of Simrock's 'Deutsche Volksbücher.' Versions of the story have appeared in French, Italian, Dutch, Danish, Swedish, and even Icelandic. The first to dramatize the subject was Hans Sachs, in 'Der Fortunatus mit dem Wunschseckel' (1553), after whom comes the English Thomas Dekker, with his 'Pleasant Comedie of Old Fortunatus' (1600), a work which made its reappearance in German about 1620. The most poetical edition of the story is that given by Tieck in his 'Phantasus' Consult Schmidt, in Ersch and Gruber's 'Encyklopädie' (Sec. 1, Vol. XLVI.).

Fortune, Robert, English author and botanist: b. near Berwick-on-Tweed, England, 1813; d. Scotland 16 April 1880. He learned gardening in early life, and gained a position in the botanical garden at Edinburgh. In 1842 he was appointed collector of plants for the Botanical Society of London in northern China. He published the results of his inquiries in his 'Three Years' Wanderings in the Northern Provinces of China' (1853). In 1848 the East India Company engaged him to visit China to compare the qualities and commercial value of different kinds of tea. He visited the East several times afterward and published an account of his numerous botanical discoveries in 'Two Visits to the Tea-countries of China' (1852); 'Residence Among the Chinese, Inland, on the Coast, and at Sea' (1857); 'Yedo and Peking' (1863).

Fortune Bay. By the fisheries treaty of 1871 with Great Britain (see FISHERIES QUESTION), the American fishermen were granted equal rights on all British coasts. The Newfoundlanders were very jealous of this intrusion on their fishing grounds, and in 1878 the Fortune Bay fishers attacked and drove away some Gloucester vessels. Demand was made on Great Britain for damages, and £15,000 was ultimately paid.

Fortune-telling, predicting the future of an individual, by means of signs or indications noticed by the fortune-teller. Chiromancy is the art of reading the lines or wrinkles on the palm of the hand, as indicative of the future for the person so marked. Necromancy is the art of consulting the dead about the future. In chartomancy playing cards are supposed by their suit or denomination when turned up after being dealt out, to reveal coming events. The ancient astrologer used to decide from the stars the good or bad fortune of an individual, the hour and day of whose birth was taken as data in calculating the planetary conjunctions on which the horoscope was based. In every great city, even of the modern world, there are hosts of people who make a profession of fortune-telling, and there are many more who are credulous enough to believe in their pretensions. The law does not recognize the power of anyone to foretell the future, and the deluded victim of such charlatans, who has paid the wizard for a supposed revelation of the future, can bring the latter to justice for obtaining money on false pretences. In the ancient world there was a strong belief in fortune-telling, or the power to predict the future. At Rome the government appointed official fortune-tellers of the state, who from the flight of birds or the appearance presented by the entrails of sacrificial victims made calculations as to coming events. The oracles of Delphi and Dodona were consulted by the wisest and best pagan Greeks. At Rome fortunes were told, or believed to be told, by Fortune herself in her temple at Antium. The literature of the Middle Ages is full of allusions to fortune-telling, which also played a part in the fiction and drama of all countries up to the middle of the 19th century. The belief in witches, wizards, and fortune-tellers has utterly disappeared among educated people, as fortune-telling has disappeared from literature. This results, to a large extent, from the advances made in physical science, the clearer views which prevail concerning causation, and the limits of human experience. Rationalism, in its newest form of agnosticism, has likewise cleared the intellectual atmosphere, and made delusion and imposture less and less able to obtain a footing or exercise an influence over sane minds.

Fortunes of Nig'el, The, an historical novel, with scene laid in the London of James I., published by Sir Walter Scott in 1822. The introduction to this work contains interesting self-criticism by the author.

Fortuny y Carbo, Mariano, mä-rē-ä'nō fōr-too'nē ē kär'bō, Spanish painter: b. Reus near Barcelona 11 June 1839; d. Rome 21 Nov. 1874. He studied at Madrid, traveled in Morocco, and settled at Rome, where he became the centre of a school of artists in revolt against over-study of the "masters." In 1866 he went to Paris, where his pictures, mostly genre subjects from Southern and Oriental life, had a great success. Among the best known are: 'A Spanish Marriage'; 'A Fantasia at Morocco'; 'The Academicians at Arcadia'; 'The Seashore at Portici.' The Metropolitan Museum of New York contains his 'Lady in Black,' and 'Camels at Rest,' and many other pictures of his are contained in public and private American art collections. He was also known as an able etcher. See Lives by Davillier (1875), and Yriarte (1886): Muther, 'History of Modern Painting' (1890).

Forty, a number that has sometimes been regarded as peculiarly significant. The idea may have originated with readers of the Bible, who notice that Moses was 40 days on the mount: Elijah was 40 days fed by ravens; the rain of the flood fell 40 days, and another 40 days expired before Noah opened the window of the ark; 40 days was the period of embalming; Jonah gave Nineveh 40 days to repent; our Lord fasted 40 days. He was seen 40 days after his resurrection, etc.

The weather on St. Swithin's Day portends, as it is foul or fair, 40 days' rain or dry weather; a quarantine extends to 40 days; 40 days, in the old English law, was the limit for the payment of the fine for manslaughter; the privilege of sanctuary was for 40 days; the widow was allowed to remain in her husband's house for 40 days after his decease; a knight enjoyed 40 days' service of his tenant; a stranger at the expiration of 40 days was compelled to be enrolled in some tithing; members of Parliament were protected from arrest 40 days after the prorogation of the house, and 40 days before the house was convened.

Forty Immortals, The, the members of the French Academy. See ACADEMY, FRENCH.

Forty Thieves, a band of robbers in the tale 'Ali Baba' in the 'Thousand and One Nights.' They dwell in a cave, the door of which opens at the words "Open, Sesame."

Forum (Lat. for a market-place; connected with *foris,* out of doors), the open space in the centre of a city, in Roman times, where the people assembled, as on common ground, for amusement or the transaction of business. Here elections were held; here were the public buildings, civic and administrative. Included in the forum was the comitium, with its tribunals for the orators who addressed the people. The *curia* or senate house stood, with other buildings, on the forum; and between the public edifices stretched lines of shops or *tabernæ.*

In the days of the kings and under the early republic there was but one forum in each city, small or great. In this open space all public business, political and legal, and all mercantile transactions were carried on. Dramatic representations, exhibitions of gladiators, combats of wild beasts and horse races also took place in the forum. The single forum eventually gave place to two forums, one of which was given up to law administration and politics, and the other to mercantile traffic. Eventually, each important commodity had its own forum. There was the *forum boarium,* cattle market; *forum suarium,* hog market; *forum olitorium,* vegetable market; and *forum piscarium,* fish market. The trade shops, as of gold- and silver-smiths, saddlers, blacksmiths, tinsmiths, money-lenders, booksellers, etc., were ranged round these fora, or occupied streets adjacent to them. The temples that edged the forum at Rome, like the mediæval cathedrals, were sometimes used for secular purposes. Thus, the senate often held meetings in the Temple of Concord, while the Temple of Saturn was used as state treasury, and was also the depositary of public archives, before the erection of the Tabularium. There are a great many ruins which enable us to gain a fair idea of the fora of other cities beside Rome. The fora at Pompeii are as follows. The principal forum; 450 feet from north to south: in its north side was the Temple of Jupiter, the Basilica, or law court, and the temple of Apollo; on the west and on the east side the *macellum* (meat market), the *senaculum* or curia, the Temple of the Genius of Augustus, and the *Scholæ* or corporation building. The triangular forum, *forum triangulare,* contained a Doric temple to the south, and an Ionic portico at the entrance.

In the open spaces of the forum were set up many statues of distinguished men. Even in the days of the republic it was necessary to order the clearing out of such statues, together with crowds of altars, arches, and memorial columns which blocked up the place.

The forum par excellence was of course the original Forum Romanum. It was situated in the hollow between the Palatine, Capitoline and Quirinal hills. The early tribes met on this common and neutral ground. Under the Tarquins the consolidation of the tribes is suggested by the completely adorned and enclosed appearance of the Forum. The Temple of Saturn appeared in 497 B.C., that of the Dioscuri in 484 B.C., that of Concord in 367 B.C. The first court-house, Basilica Porcia, was not built before 184 B.C.; three more were built later, and it was this increase of buildings that occupied so much of the vacant space that the fish, meat, hog, vegetable and other markets were obliged to retire to other quarters of the city.

Julius Cæsar was the first to add special forums to those already in existence, and his Forum Julium was followed by the Forum Martis of Augustus, sometimes called Forum Augustus. Then came the Forum Pacis of Vespasian, the Forum Transitorium of Domitian and Nerva, the Forum Trajani of Trajan. These all lay side by side, north and east, with the Forum Romanum. The Forum Julium had in its centre a temple of Venus Genetrix, the patron goddess of the Julian gens round which it formed a sort of sacred precinct. The Forum Augustum was dedicated to Mars and in it was situated the Temple of Mars Ultor. This building was flanked by two triumphal arches, and Cæsar had intended that it should commemorate, with appropriate statues, the extension of Roman dominion. The Forum Nervæ was dedicated to Minerva and contained her temple. As the main thoroughfare through this district of the city crossed this forum it was commonly known as Forum Transitorium. The most gorgeous architectural group in the imperial city was exhibited in the Forum Trajani, which had its own special Basilica, like the great forum. It was entered by a triumphal arch, surrounded by a double colonnade; an equestrian statue of the emperor stood in the centre, flanked on each side by a half circle. The Library, Column and Temple of Trajan completed the cluster of marble structures.

The appearance of the Forum Romanum during the last days of the empire may be described as follows: Looking toward the Capitol the spectator would see the Temples of Concord, of Vespasian, and the Dii Consentes. The Temple of Saturn stood between the slope of the Capitol and the Vicus Jugarius. Beside it was the Arch of Tiberius, near that of Septimius Severus. Between these two arches were the rostra. The political buildings stood on the farther side of the arch of Severus. Here was the Senate house or the Curia, while the Temple of Janus rose side by side with the Basilica Æmilia. On the south and opposite side was the vast Basilica Julia, and the beautiful Temple of the Dioscuri. East from this group of buildings was an open space occupied by the Temple of Julius, side by side with which was the triumphal arch of Augustus, and beyond these is the most interesting tract of the old forum, the centre of antique and primitive Roman religion. The Shrine of Vesta, the Temple of Antoninus and Faustina, the Templum Urbis made up a magnificent range of noble and solemn structures, and we are reminded also that at this point once stood the arch of the Fabii at the opening of the ancient Via Sacra.

The invasions of the Goths did not bring much destruction upon the forum. It was in the 11th century that the buildings were devastated at the sacking of Rome (1084), when Gregory VII. was delivered from the Castle of San Angelo by Duke Guiscard. The rarest monuments of the antique world were employed as fortresses. The 16th century witnessed the antiquarian curiosity and reckless vandalism of the Renaissance. The Forum of Cicero and Augustus became a wilderness with only a few isolated columns to mark the site of temples or palaces. Under the learned and liberal Pius VII. the relics were preserved from further destruction and the archæologist Carlo Fea then began those excavations which have been continued by Lanciani.

Forum Ecclesiasticum, a church tribunal or court. It is either internal or external—*Forum Internum, Forum Externum.* The *Forum Internum* is what is known as the tribunal of penance, the confessional, where the penitent is both accuser and accused; and the confessor is the judge who condemns or acquits or pardons, and exacts satisfaction for wrongs and reparation of injury done to others whether in reputation or property. The *Forum Externum* is any ecclesiastical tribunal outside of the sacrament of penance that is concerned with church government. What are the sanctions by which the judgments of the Church's tribunals are enforced? Has the Church the right to inflict temporal pains and penalties on offenders against her laws? That the Church does possess such power is the teaching of the Church herself: the doctrine which declares she does not possess it has been explicitly condemned. The proposition that "the Pope or the whole Church collectively cannot punish any man, however wicked he may be, with a coercive penalty" unless the civil power gives them authority to do so, is condemned by Pope John XXII., and a similar proposition was condemned by Pope Pius VII. in the bull *Auctorem Fidei:* one of the propositions condemned by Pope Pius IX. in the *Syllabus* (1864) declared that "the Church has no power to employ force." In proof of the necessity of such power in the Church, the case of a bishop is cited who teaches heretical doctrine: has not the Church, it is asked, power to depose him; or must the matter go before a tribunal of the civil power? It is held that to make such resort to the secular courts necessary is to render the Church powerless to execute her divine commission, and to make a civil judge the judge of a purely ecclesiastical cause. On the ground of the canon law the Church has the right in herself "to inflict stripes, to impose fines, to imprison in a monastery" offenders against her laws; in short, to impose all penalties short of the effusion of blood, *citra sanguinis effusionem,* or its equivalent. Practically, the power of the Church at present is confined to the infliction only of her spiritual penalties, and these only when they do not in any degree directly or indirectly impair the civil rights of the person who incurs the spiritual censures; when they do so trench on his civil rights, the person has recourse to the secular courts. Thus in this country cases are often brought into the civil tribunals of rectors of parishes or pastors of churches who have been deposed by bishops or other ecclesiastical superiors; and courts find it within their competence to decide whether the act of the superiors has been done in entire conformity with the constitution and laws of the religious body concerned, and the civil and contractual rights of the complainant.

Forward, Walter, American statesman: b. Connecticut 1786; d. Pittsburg 24 Nov. 1852. He studied law and was admitted to the bar in 1806. In 1822 he was elected to Congress; and in 1841 was appointed by President Harrison first comptroller of the treasury, and was reappointed by President Tyler in September of the same year. On retiring from the cabinet in 1843 he resumed law practice. In 1849 he was appointed *chargé d'affaires* to Denmark, but resigned in 1851.

Forwood, William H., American military surgeon: b. Delaware 7 Sept. 1838. He was graduated at the medical department of the University of Pennsylvania and at Georgetown University, Washington, D. C.; entered the regular army as an assistant surgeon in 1861, and served throughout the Civil War. He also served in many Indian campaigns; was surgeon and naturalist with the exploring expedition through Wyoming, Montana, and Idaho, in 1883; located military hospitals in Savannah, Ga., and the camp hospitals in Montauk Point, during the Spanish war; and was appointed surgeon-general of the army with the rank of brigadier-general in 1902.

Foscari, Francesco, frän chĕs'kō fōs kä'rē, doge of Venice: b. 1372; d. Venice 1 Nov. 1457. In 1416 he was named procurator of St. Mark's, and in 1423 was elected doge. His son Giacopo, being accused of ordering the assassination of a senator Donati, the enemies of the family created such commotion in the state that, unable to clear himself to their satisfaction of the charge, he was banished from the city, the father having to ratify the sentence. Love of his country, and devotion to his wife, compelled the banished Foscari at all hazards to revisit his beloved Venice, where, being discovered by his enemies, he was denounced, again made prisoner, put to the question of the rack, and a second time banished, dying soon after of his wounds, or the torments of his secret punishment, and of grief at separation from his idolized family. The fate of the son had such an effect on the doge that the bereaved father went mad, in which state the enemies of his family compelled him to abdicate. He died three days after in a spasm, upon hearing the bells of St. Mark's announce to Venice the election of a new ruler. Byron has written on the subject a tragedy entitled 'The Two Foscari.'

Foscolo, Ugo, oo'gō fōs'kō-lō, originally **Niccolo,** Italian author: b. Zante, one of the Ionian isles, 26 Jan. 1778; d. Turnham Green, near London, 10 Oct. 1827. A man of passionate temperament, and withal an ardent patriot, Foscolo was bitterly disappointed when by the Treaty of Campo Formio Venice was given to Austria, and his disappointment found vent in the 'Lettere di Jacopo Ortis' (1802), a sort of political Werther. Becoming finally undeceived as to Napoleon's intentions with regard to his native land, he returned to Milan, where he published in 1807 his best poem, 'I Sepolcri,' a work composed in the spirit of the ancient classic writers, and remarkable for its smooth and polished versification. About this time he wrote a translation of Sterne's 'Sentimental Journey,' and two tragedies, 'Ajace' and 'Ricciarda,' both showing political tendencies. In 1809 he was appointed to the chair of eloquence in Pavia. His inaugural address, 'Dell' Origine e dell' Ufficio della Letteratura,' although full of the same love of classic beauty which marks the 'Sepolcri,' is turgid and affected in style. When in 1814 the Austrians entered Milan, Foscolo withdrew to Switzerland, and in 1816 he went to London. There some of his best writings were published, namely: 'Essays on Petrarca'; 'Discorso sul testo del Decamerone'; 'Discorso sul testo di Dante.' His remains were finally deposited in the Church of Santa Croce, Florence, in 1871. His works and letters were published at Florence in 12 volumes by Le Monnier (1850–62). Consult Lives by Pecchio (1836); Carrer (1842); Artusi (1878); Antona Traversi (1884); and De Winckels (1885–6).

Fos'dick, Charles Austin ("Harry Castlemon"), American writer of juvenile books: b. Randolph, N. Y., 6 Sept. 1842. He served in the Union navy in the Civil War from 1862 to 1865. Besides contributions to periodicals, he has published under the pseudonym "Harry Castlemon" over 30 books for boys, among which are: 'The Gunboat Series' (1864–8); 'Rocky Mountain Series' (1868–71); 'Rod and Gun Series' (1883–4); 'The Buried Treasure'; 'The Steel Horse'; 'Jack the Trader'; 'The Houseboat Boys'; etc.

Fosdick, William Whiteman, American poet: b. Cincinnati, Ohio, 28 Jan. 1825; d. there 8 March 1862. He gained some distinction as a poet by a drama entitled, 'Tecumseh.' He also published: 'Malmiztic the Toltec' (1851), and 'Ariel and Other Poems' (1855).

Foss, Cyrus David, American Methodist bishop: b. Kingston, N. Y., 17 Jan. 1834. Having been graduated at Wesleyan University in 1854, he became an itinerant in the New York Conference of the Methodist Episcopal Church in 1857, was pastor at Chester, N. Y. (1857–9), Brooklyn (1859–65), and New York (1865–75). In 1875–80 he was president of Wesleyan University, and in the latter year was elected bishop. He made official missionary tours of the stations of the Methodist Episcopal Church in Europe (1886), Mexico (1893), and India and Malaysia (1897–8).

Foss, Sam Walter, American poet: b. Candia, N. H., 19 June 1858. He has been librarian of the Somerville, Mass., public library from 1898. His published works include: 'Back Country Poems' (1894); 'Whiffs from Wild Meadows' (1895); 'Dreams in Homespun' (1897); 'Songs of War and Peace' (1898).

Fos'sa, or **Foussa,** a large, brown, unstriped carnivorous mammal of Madagascar (*Cryptoprocta ferox*), which has the form of a huge weasel (twice the size of a house-cat), and like a weasel is lithe, active and bloodthirsty. Its systematic place is by no means decided. It is placed by Beddard as representing a distinct sub-family of the civets; while Mivart and Lydekker regard it merely as a genus of civets. Zittel, in view of its dentition and the retractibility of the claws, among other features, regards it as occupying an intermediate place between the civets and the cats, and associated with such composite extinct forms as *Dinictis, Proœlurus* and *Pseudœlurus,* but classifies it in the *Felidæ.* It is the largest carnivore in Madagascar, and preys chiefly on birds and lemurs.

Fossil Footprints. See ICHNOLOGY.

Fossil Plants. See PALÆOBOTANY.

Fossil Vertebrates. See FOSSILS; PALÆONTOLOGY.

Fossilif'erous Rocks, rocks in which are found embedded the petrified remains, or molds of plants and animals. See FOSSILS; PALÆONTOLOGY; etc.

Fossils, the impressions or remains of plant or animal forms preserved in rocks by natural causes. Fossils supply data, from which the geologist can determine the relative ages of sedimentary rocks. The first man to realize their chronological importance was the English surveyor, William Smith, known as the father of historical geology, although acute observers like Leonardo da Vinci had pointed out long before that fossil shells were not freaks of nature, but had been laid down where found in the sediments of some body of water.

Most fossil remains are of marine types; many are of fresh-water and land-and-water types; comparatively few are of land types. The reason is plain. Animal remains lying on the ground are eaten by animals, or if not eaten, soon decay, and the bony skeleton, if buried by sand or loam, is slowly dissolved by percolating water. Plant remains decay even more rapidly. In water, decay is retarded. Thus mastodon remains have been found in swamps where the animals were occasionally mired, but of the infinitely greater number of mastodons that died on drier ground no trace is left. Old lake beds are frequently rich in plant and animal remains. Fishes, insects, birds, and land animals, and the leaves, flowers, and fruits of trees are preserved in the fine-grained shales or the sands and clays of the lake deposits in several western States. In old swamps, plants formed thick masses of vegetable matter, now turned to coal, imprints of leaves and stems being common in the shale overlying a coal-seam. In the sea, conditions are most favorable for the preservation of organic remains, and marine deposits have formed thick and extensive beds. Hence, of all the fossils found, marine types are most numerous. Fossils are preserved in several ways, which may be classified under three heads. (1) Some of the original substance may be preserved, as the carbon in a leaf, or the bone or shell of some animal. (2) All the original substance may dissolve away, but its shape may be preserved. This may happen in two ways: (*a*) the external form may be preserved in the sediments, forming a mold, or (*b*) the internal form may be preserved, forming a cast. A mollusk dies; its soft parts decay; the interior of the shell fills with sand or ooze; the shell is deeply buried. The sediments consolidate; the calcareous material of the shell may dissolve; but both its external and internal form are preserved. (3) In rare cases the structure of organic remains is preserved by a true petrifaction, the organic substance being replaced, atom by atom, by some mineral compound, like silica or calcium carbonate. A striking illustration of this method of preservation is fossil wood, in which the replacing silica preserves minute details of structure. See COAL; CORAL ISLANDS; GEOLOGY; PALÆONTOLOGY; PALÆOBOTANY.

Foster, Abby (KELLEY), American reformer: b. Pelham, Mass., 1811; d. 1887. She was married to S. S. Foster (q.v.) in 1845. At first a teacher, from 1837 she appeared as a platform lecturer in support of the abolition of slavery, being the first woman to assume this role, and she suffered much harsh treatment from the opposition. After her marriage she traveled and lectured with her husband, and later spoke also in behalf of woman's suffrage and prohibition.

Foster, Benjamin, American artist: b. North Anson, Maine. A pupil in New York of Abbott Thayer, and in Paris of Luc Oliver Merson, and Aimé Morot, he obtained various recognition of his excellence in landscape, including a bronze medal at the Paris Exposition of 1900, and the Webb prize of the Society of American Artists in 1901. Among his works are: 'Mists of the Morning,' for which he received the Webb prize, and 'Night Scene at the Paris Exposition,' purchased by the French government for the Luxembourg Gallery.

Foster, Birket. See FOSTER, MYLES BIRKET.

Foster, Charles, American legislator and cabinet officer: b. near Tiffin, Ohio, 12 April 1828; d. Springfield, Ohio, 9 Jan. 1904. He entered a mercantile career at Rome, now Fostoria, Ohio, and became the proprietor of the largest country business in the State. At the time of the Civil War he was active in the recruiting of troops. In 1870 he was elected to Congress in a district previously strongly Democratic, and in 1872, 1874, and 1876 was re-chosen. While in Congress he was for some time a member of the ways and means committee. He was elected governor of Ohio in 1879, and again in 1881, his administration being marked by special attention to the non-partisan management of public institutions. In 1891 he was appointed secretary of the treasury by President Harrison, and in that post he negotiated a loan of $25,364,520 at the unprecedentedly low rate of 2 per cent. Subsequently he was a commissioner on several diplomatic missions of importance and performed his duties with great skill and satisfaction to his government.

Foster, David Skaats, American author: b. Utica, N. Y., 1852. After a common-school education at Utica, he there entered the coal and iron business. His publications include: 'Rebecca the Witch and Other Poems'; 'Elinor Fenton,' a novel; 'Spanish Castles by the Rhine,' and 'Prince Timoteo.'

Foster, George Eulas, Canadian statesman: b. Carleton County, New Brunswick, 3 Sept. 1847. He was graduated at the University of New Brunswick in 1868, studied also at Edinburgh and Heidelberg, was professor of classics and history in the University of New Brunswick in 1872–9, and in 1882 was elected to the Canadian Parliament. In 1885–8 he was minister of marine and fisheries; in 1888–96 minister of finances. Upon his visit to England in 1894 in connection with Dominion finances, he negotiated a loan of $11,250,000. He was government leader in the Commons in 1895.

Foster, Gilbert, English artist: b. Manchester, England, 9 May 1855. He studied art with his father, a portrait painter, and exhibited his first picture at the Academy in 1876, since which date he has been a yearly exhibitor. Among his paintings are: 'Lingering Light' (1890); 'Birds of a Feather' (1891); 'The Last Faint Pulse of Quivering Light' (1892); 'The Azure Mead' (1895); 'Hush of Night' (1898); 'A Garden of Lyonnesse' (1900); 'A Garden of Memories' (1901).

Foster, Hannah (Webster), American novelist: b. 1759; d. Montreal, P. Q., 17 April 1840. Her published works are: 'The Coquette, or the History of Eliza Wharton,' one of the earliest of American novels; 'The Boarding School' (1796); and 'Lessons of a Preceptress' (1798).

Foster, Henry, English scientist: b. Woodplumpton, Lancashire, 1797; d. Isthmus of Panama 5 Feb. 1831. He entered the royal marines, but after the peace of 1815 devoted himself chiefly to astronomical studies. The gold medal of the Royal Society of Great Britain was awarded him for his services on the Arctic Expedition of Capt. Ross in 1818-19. On 27 April 1828, he sailed on the Chanticleer, as commander of an expedition to determine the direction of the principal ocean currents in both hemispheres. He was drowned while exploring the Chagres River in Panama.

Foster, John, English essayist: b. Halifax, Yorkshire, 17 Sept. 1770; d. Stapleton, near Bristol, 15 Oct. 1843. A Baptist clergyman, self-educated and with an advanced point of view, he contributed to the 'Eclectic Review' regularly as well as delightfully; but his volume of 'Essays' (1805) constitutes his chief title to recognition. Four in number, these composiions are respectively: 'On a Man's Writing Memoirs of Himself'; 'On Decision of Character'; 'On the Application of the Epithet Romantic'; and 'On Some of the Causes by which Evangelical Religion has been Rendered Less Acceptable to Persons of Cultivated Taste.' All are marked by great solidity and depth of thought, combined with a lucidity and nervousness of style which no English author has surpassed. Of the four essays the palm is generally given to that 'On Decision of Character,' though in the opinion of Robert Hall the fourth of the series was the work on which Foster's fame with posterity would rest. As a preacher Foster never succeeded in attracting much attention. His discourses, though solid and philosophical, were of too abstract and unadorned a nature to be readily appreciated by a popular audience. In 1817 he wrote his 'Essay on the Evils of Popular Ignorance, in which he exposed the fearful condition of the masses in the large towns of England, and strenuously urged the establishment of a national system of education.

Foster, John Gray, American military officer: b. Whitefield, N. H., 27 May 1823; d. Nashua, N. H., 2 Sept. 1874. He was graduated at the United States Military Academy in 1846, entering the engineer corps. At the outbreak of the Civil War he was assigned to duty at Fort Sumter and was one of its garrison during the siege. In 1861 he was commissioned a brigadier-general of volunteers; took a leading part in the capture of Roanoke Island in 1862; was promoted major-general of volunteers; and became commander of the Department of North Carolina, defending that region with skill. Subsequently he commanded the Departments of Ohio and Florida, and in 1865 was brevetted major-general, United States army.

Foster, John Watson, American diplomatist: b. Pike County, Ind., 2 March 1836. He was graduated at the Indiana State University in 1855; studied law, and was admitted to the bar in Evansville, Ind. After the Civil War, during which he served in the Federal army with distinction, he was editor of the Evansville *Daily Journal* and postmaster of that city; minister to Mexico in 1873-80, to Russia 1880-1, and Spain 1883-5. He was special commissioner to negotiate reciprocity treaties with Spain, Germany, Brazil, and the West Indies in 1891; and United States secretary of state 1892-3. Subsequently he was the agent for the United States before the Bering Sea Arbitration Tribunal at Paris; participated in the peace negotiations with Japan; and in 1898-9 served as a member of the Anglo-American Joint High Commission. He has published a pamphlet, 'The Alaskan Boundary' (1899), and 'A Century of American Diplomacy 1776-1876' (1900).

Foster, John Wells, American geologist: b. Brimfield, Mass., 1815; d. 1873. He was graduated at Wesleyan University in 1834, and having removed to Ohio, studied law and was admitted to the bar there; in 1837 became an assistant in the geological survey of Ohio; and in 1847 was appointed an assistant to Prof. Jackson in a survey of the region about Lake Superior. The results of this survey, executed in connection with J. D. Dana, appeared in several volumes published by authority of Congress. Foster aided in the organization of the Republican party in Massachusetts, and from 1858 was resident in Chicago, where he made a notable study of the ethnology and palæontology of the Mississippi basin. Among his works are: 'The Mississippi Valley' (1869); 'Prehistoric Races of the United States' (1873).

Foster, Judith Ellen (Horton), American temperance advocate: b. Lowell, Mass., 3 Nov. 1840. She was married to E. C. Foster in 1869. She studied law and in 1872 was admitted to the State bar of Idaho. In 1870-84 she was superintendent of the legislative department of the National W. C. T. U., and upon the affiliation of the society with the Prohibition party, joined the Non-Partisan W. C. T. U., of which she was president in 1889-93. Her publications include: 'Constitutional Amendment Manual' (1882); 'The American Renaissance.'

Foster, Lafayette Sabine, American statesman: b. Franklin, Conn., 22 Nov. 1806; d. Norwich, Conn., 19 Sept. 1880. He was graduated at Brown University in 1828 and admitted to the bar in 1830; took an active part in Connecticut politics, and was elected to the legislature in 1839, serving several terms. He was elected to the United States Senate in 1854; was president pro tem. of the Senate in 1865; and, after Andrew Johnson became President, was acting Vice-President of the United States. His senatorial term expired in 1867, but on account of his moderate and conservative course in the Senate his re-election was strongly opposed, and he withdrew his name. In 1870 he was again elected to the State legislature, but resigned in June of that year to take his seat on the bench of the Connecticut supreme court. In 1878 he was appointed a member of the commission to devise simpler forms of legal procedure for State courts, and in 1878–9 was commissioner from Connecticut to settle the disputed boundary question with New York.

Foster, Sir **Michael,** English physiologist: b. Huntington 8 March 1836; d. London, 29 Jan. 1907. He was a surgeon 1860–6; became prælector of physiology at Trinity College, Cambridge, in 1870, and from 1883–1903 was professor of physiology at Cambridge. He was president of the British Association in 1899 and was knighted the same year, and was member of Parliament for London University from 1900. He published: 'Text Book of Physiology'; 'Lectures on History of Physiology,' etc.

Foster, (Myles) Birket, English artist: b. North Shields 4 Feb. 1825; d. Weybridge, Surrey, 27 March 1899. He began his artistic career as a wood-engraver, executing illustrations for 'Punch' and the 'Illustrated London News,' and for several volumes of English classics. From 1859 he drew much in water-color, being particularly successful in his presentation of rural life and landscape. Among his subjects in this genre are: 'Nutting'; 'Feeding the Ducks'; and 'Cows in the Pool.' His works are widely popular in England, where they have been much engraved.

Foster, Randolph Sinks, American Methodist clergyman: b. Williamsburg, Ohio, 22 Feb. 1820; d. Newton, Mass., 1 May, 1903. He was educated at Augusta College (Millersburg, Ky.), entered the Methodist Episcopal ministry as an itinerant in 1837, was transferred from the Kentucky conference successively to Ohio and New York, and was president of the Northwestern University 1857–60. In 1868 he became a professor in Drew Theological Seminary (Madison, N. J.), and in 1872 president of the institution. In the latter year he was also elected bishop, and in 1896 retired from the ministry. Among his publications are: 'Centenary Thoughts'; 'Studies in Theology'; 'Philosophy of Christian Experience.'

Foster, Robert Verrell, American theologian: b. Wilson County, Tenn., 12 Aug. 1845. He was educated at Cumberland University (Lebanon, Tenn.), and the Union Theological Seminary, and from 1877 has been a professor in the former, originally of Hebrew and New Testament Greek, subsequently of systematic theology. Of his publications may be named: 'Old Testament Theology' (1890); 'Systematic Theology' (1898).

Foster, Roger, American lawyer: b. Worcester, Mass., 1857. He studied at the University of Marburg, Yale, and the Columbia Law School, in 1880 was admitted to the New York bar, and was special counsel to the board of health of New York in 1896–8. His writings include, besides many pamphlets and articles in periodicals: 'A Treatise on Federal Practice' (1890–2); 'A Treatise on the Income Tax of 1894' (1895).

Foster, Stephen Collins, American songwriter: b. Pittsburg, Pa., 4 July 1826; d. New York 13 Jan. 1864. He was educated at Athens Academy and Jefferson College, Pennsylvania. He composed the music and wrote the words of over 125 popular songs and melodies, among which are: 'Old Folks at Home'; 'Nelly Gray'; 'Old Dog Tray'; 'Come Where my Love Lies Dreaming'; 'Suwanee River'; etc.

Foster, Stephen Symonds, American abolitionist: b. Canterbury, N. H., 1809; d. 1881. He was graduated at Dartmouth College in 1838; studied theology at the Union Seminary, became an anti-slavery orator, and was known for his radical methods. His attacks upon the Church for its position in regard to abolition aroused hostility against him, and his practice of interrupting church services was the cause of several mob disturbances. He published 'The Brotherhood of Thieves: A True Picture of the American Church and Clergy' (1843).

Foster, Theodosia Toll («Faye Huntington»), American author: b. Verona, N. Y., 1838. She was married to James H. Foster 1869. She was educated at the Oneida Seminary, and was for many years principal of a school at Verona. Her works include a long series of volumes of fiction, such as: 'Ripley Parsonage' (1877); 'What Fide Remembers' (1885); 'The Boynton Neighborhood' (1895); and 'Lewis Elmore — Crusader' (1898).

Fosto'ria, Ohio, a city in Seneca County, 35 miles from Toledo, on the Baltimore & O., and Lake Erie & W. R.R.'s. It was named in honor of Charles Foster, governor of Ohio (1891–3), who was influential in building many factories here. Pop. (1900) 7,730.

Fothergill, fŏth'ėr-gĭl, **Jessie,** English novelist: b. Manchester, England, 7 June 1856; d. London 30 July 1891. Her stories show a keen faculty of observation, and include: 'Healey, a Romance' (1875); 'Aldyth' (1876); 'The First Violin' (1878), in which German life is faithfully portrayed; 'Probation' (1879); 'Kith and Kin' (1881); 'Made or Marred'; 'Borderland' (1886); 'One of Three'; 'The Lasses of Laverhouse' (1888); 'A March in the Ranks' (1890); 'Oriole's Daughter' (1893).

Fotheringay (fŏth'ėr-ĭn-gā) **Castle,** the site of which was near Peterborough, England, 27 miles northeast of Northampton. The castle to which a melancholy interest attaches as the scene of the imprisonment, trial, and execution of Mary Queen of Scots, was demolished by her son James I. Several of the illustrious Plantagenets are buried in its church.

Foucault, Jean Bernard Léon, zhŏñ bār-nār lā-ŏñ foo-kō, French scientist: b. Paris 18 Sept. 1819; d. there 11 Feb. 1868. He was editor of the 'Journal des Débats' from 1845, in 1854 became physicist to the Imperial Observatory, and in 1855 received the Copley medal of the Royal Society of London for his measurement of the velocity of light. His inventions include a device much used in the employment of the electric light in microscopic and optical researches. He also demonstrated (1851) by means of the pendulum and the gyroscope, the rotation of the earth upon its axis.

Foucault Currents, or **Eddy Currents,** are electrical currents generated by induction within the substance of a massive conductor that is moving in a magnetic field, or which is exposed to the influence of a variable field. If the conductor is filiform, like a wire, no current can be produced in it save in the direction of its length. If a massive conductor be thought of, however, as composed of an infinite number of closed circuits, each composed of a single wire, and all tangled up and then melted into a solid mass, it is evident that (in general) currents will be induced in all of these imaginary circuits when the conductor moves, or when the field to which it is subjected varies. In the actual case the conductor is not composed of wires melted together, but currents are nevertheless generated within it just as though these wires had an actual objective existence. Mathematical equations can in fact be written down, from which it is possible to compute the direction and intensity of the current that is flowing, at any given instant, through any proposed point of a conductor in a known but varying field. Such calculations are seldom made outside of college class-rooms, however, because it is known from the general principle of the conservation of energy that the direction of the Foucault currents is everywhere such as to oppose the change (of whatever sort it may be) which produces them. Hence such currents tend to diminish the efficiency of all motors, dynamos and transformers in which they occur, and designers therefore strive to avoid them so far as possible. In armatures and in transformers, for example, it is customary to laminate the masses of iron that are exposed to changing fields, the individual parts being insulated from one another by air gaps or otherwise, and their surfaces of separation disposed (as nearly as practicable) so as to be perpendicular to the direction in which the Foucault currents tend to flow. In galvanometers, masses of copper are often purposely disposed near the sensitive needle with distinct advantage; for while they do not affect the total deflection of the needle, they cause it to come to rest very quickly after the circuit is broken, the motion of the needle inducing Foucault currents in the copper, which tend always to bring the needle to rest. The energy that is expended in the generation of Foucault currents is transformed into heat, and raises the temperature of the mass within which the currents are flowing. The name refers to the French physicist Foucault, who studied the subject with much care.

Foucault's Pendulum Experiment, a curious and remarkable method invented by Jean Bernard Léon Foucault (q.v.), of showing the rotation of the earth on its axis, by observing a vibrating pendulum, and his experiment goes under the above name. In this experiment a graduated disk is seen to turn, while a pendulum freely suspended maintained its plane of oscillation. If a heavy ball is suspended by a fine wire and set to vibrate like a pendulum, it may easily be shown, either mathematically or by experiment, that the point of suspension, with the wire and ball, may be rotated round an axis, passing along the length of the wire, without interfering with the vibration In other words, the pendulum will continue to vibrate in the same plane, although the point of suspension be turned round the axis of suspension. It follows immediately from this that if we could suspend a pendulum at the north or south pole and set it vibrating it would continue to swing in the original plane of vibration; and as the earth is turning on its axis, a marked line on the earth's surface would appear to turn underneath the pendulum; or rather, it would seem to an observer, accustomed to feel as if the earth were at rest, that the plane in which the pendulum vibrates turns round relatively to the marked line on the earth's surface. It is easily shown that a similar phenomenon may be observed in any latitude except at the equator; the amount of rotation, however, that the plane of vibration of the pendulum seems to undergo is not so great in low latitudes as in high latitudes; but still in our latitudes rotation takes place to an extent easily observable. The performance of this experiment requires the greatest nicety. The pendulum is suspended on a fine wire, the support of the wire being constructed with great accuracy, so as not to interfere with the vibrations. The motion of the pendulum must be strictly confined to one plane; and, for that reason, in setting it to vibrate the bob is drawn aside and fastened by a silk thread, and when everything has come perfectly to rest the bob is released by burning the silk thread. During its subsequent motion it is protected from currents of air by glass screens. It need scarcely be remarked, however, that this experiment is nothing more than an illustration. Our knowledge of the rotation of the earth, drawn from astronomical considerations, cannot be strengthened by it. This experiment was first made public in 1851, when it was exhibited by M. Foucault before the Academy of Paris.

Foucaux, Marie Filon, mä-rē fē-lôṅ foo-kō, French author: b. 1842. She wrote several historical studies and works of fiction on the Empire and Restoration periods, among them: 'Les belles amies de M. de Talleyrand' (1880); and 'Une intrigante de la Restauration' (1888). Further publications by her include several volumes on Sanskrit literature under the pen-name "Mary Summer." Of these the most noteworthy is her 'Contes et legendes de l' Inde ancienne' (1878), crowned by the Academy.

Fouché, Joseph, zhō-zěf foo-shā, Duke of Otranto, French politician and detective: b. Nantes 29 May 1763; d. Trieste 25 Dec. 1820. The Revolution, into which he entered with enthusiasm, found him teaching philosophy in Nantes; he became advocate, and was sent to the convention by the department of Loire-Inférieure. Here he was placed on the Committee for Public Education, voted for the death of the king, and was implicated, at least nominally, in the atrocities of the period. In 1793 he was sent to the department of Nièvre to enforce the law against such persons as had incurred suspicion. In 1794 he incurred the hatred of Robespierre, and thus had a strong stimulus to assist in his downfall. In August 1795, he was expelled from the convention, and kept a prisoner till the amnesty in October. In 1796 he communicated important information to the director Barras as to the designs of Babeuf and was rewarded in 1798 by being sent to Milan as ambassador to the Cisalpine republic. Here he labored with Gen. Brune to establish a second 18th Fructidor; both were in consequence recalled. He appeared in Paris in 1799, after Barras had gained the ascendency, and was appointed ambassador to Holland.

Shortly after Fouché was recalled and named minister of police. Here he first had full opportunity to display his great talents, and exercise an important influence on the interior policy of France. The situation gave him great power during the war. After the battle of Waterloo, Fouché urged Napoleon's second abdication, and advised him to seek an asylum in the United States. He placed himself at the head of the provisional government, negotiated the capitulation of Paris, obtained the removal of the army behind the Loire, and thus prevented useless bloodshed. Louis XVIII., whose return to the throne he had not at all supported, made him again minister of police: and it is to his credit that he labored so zealously in favor of moderate measures as to incur the hatred of all the ultra-royalists. He therefore resigned his office in 1815; and went as French ambassador to Dresden. As he was struck at by the decree issued in 1816 against the murderers of the king, he sought an asylum in Prague. He afterward went first to Lintz, and then to Trieste. It was Fouché who made the famous remark on the execution of the Duke of Enghien, of which he disapproved: "*C'est plus qu'un crime, c'est une faute*" (It is more than a crime; it is a blunder). Consult Martel, 'Etudes révolutionnaires: Etude sur Fouché' (1819).

Foucher, Jean, zhŏṅ foo-shā, early explorer and colonizer in South America: b. Cambrai, Flanders, 1508; d. 1567. He was with Sebastian Cabot at the discovery of the Paraguay River, in 1534 shipped as pilot to Mendoza's expedition to Paraguay, led an exploring party to the foothills of the Peruvian Cordilleras, and was a counselor of Cabeza de Vaca (q.v.), with whom he was sent prisoner to Spain. Having received pardon he was appointed governor of Entre Rios, where he maintained a friendly attitude toward the natives and made further explorations.

Fouchet, Jean Antoine Joseph, zhŏṅ äṅ-twän zhō-zĕf foo-shā, Baron, French diplomatist: b. St. Quentin, France, 1763. The date of his death is not known. He was a law student in Paris when the Revolution broke out and published a pamphlet in defense of its principles. Soon afterward he was appointed a member of the executive council of the Revolutionary government, and was French minister to the United States in 1794–5. Subsequently under Bonaparte he was prefect of Var and, in 1805, of Ain. On Napoleon's return from Elba he was made prefect of the Gironde.

Foucquet, Jean, zhŏṅ foo-kā, French painter: b. Tours about 1415; d. Paris about 1485. He received his early artistic training in Italy, where he painted a portrait of Pope Eugenius IV., and later entered the service of Louis XI. of France. For the king he executed several portraits. His best work consists of 40 miniatures in a prayer-book for Etienne Chevalier. Only in comparatively recent times has he been recognized as a founder of the French school.

Foula, foo'la, island, the most westerly of the Shetland group, lying 16 miles southwest of the nearest point of mainland. It is a little over 3 miles in length and is 2½ miles in breadth. Pop. (1900) 326.

Foulis, fowlz, **Robert and Andrew,** Scottish printers: b. Glasgow, the former in 1707; d. 18 Sept. 1781; the latter in 1712; d. 178_. In 1739 Robert commenced business in Glasgow as a bookseller; and in 1742, having obtained the appointment of printer to the university, began in that capacity to issue editions of the ancient classics, which have made his press famous, both from the beauty of their type and their accuracy. In this latter respect one of his editions of Horace stands pre-eminent, and is hence known by the name of the 'Immaculate' edition.

Foulk, George C., American naval officer: b. Pennsylvania about 1860: d. Kioto, Japan, 1894. He was graduated from the United States Naval Academy, and after service on the Asiatic station, was withdrawn from naval duty to act as secretary and interpreter to the embassy of the Korean empire, the first sent by that country to a western nation. In 1884 he became naval attaché to the American legation at Seoul. He traveled widely in the country, and was influential in introducing many western methods and manners. Later he again served in the navy, and became professor in Doshisha University at Kioto, Japan.

Foulke, William Dudley, American author: b. New York 20 Nov. 1848. He was graduated at Columbia in 1869, at the Law School of the University in 1871, practised law in New York, removed to Indiana, and there became a member of the State Senate (1882–6). In 1889–90 as chairman of a special committee of the National Civil Service Reform League, he made important investigations in connection with the United States civil service. In 1893 he was chairman of the Suffrage Congress at the World's Columbian Exposition. His publications are: 'Slav or Saxon' (1887); 'Life of O. P. Norton' (1899); 'Moya' (1900).

Foundation. The term designates either the lower courses of a masonry structure, or a specially prepared surface or bed in contact with the soil or bed-rock upon which a structure of any kind is to be built. In practice there are many cases, however, in which the bed and the lower courses of the masonry structure jointly comprise the foundation proper, and render difficult or unnecessary the drawing of any marked distinction between them. Such combinations generally afford foundations of great permanency and strength, the most important qualities in connection with architectural and engineering works.

Oftentimes, in the erection of such works of great magnitude as well as those of lesser importance, the requisite care and attention are not devoted to the construction of the foundations, thus seriously impairing the integrity of the superstructure. This carelessness, however, appears to develop periodically; but, the errors of one period are naturally so fruitful of injurious results that they not only lead to the exercise of greater care during the period following, but stimulate the development and adoption of more scientific and skilful methods.

This is very clearly shown in the works constructed during the Roman Period. The earlier Romans erected their buildings on the most solid foundations constructed of large blocks of concrete, composed of quarry rubbish, gravel, or burnt earth, bonded by an excellent mortar. This material formed under the superstructures homogeneous basements of veritable artificial rocks capable of sustaining the heaviest of buildings without rupture or settlement. During the later Roman period, however, the foundations were much neglected, so that the architects of the 12th century were afforded so many examples of important edifices fallen on account of bad foundations, and for no other reason, that they were compelled to exercise greater care, and employ more skilful methods.

These remarks are especially applicable to the foundation methods practised at the present time. The architectural and engineering works of to-day have passed from the types of comparatively light superstructures to those of mammoth size and enormous weight, requiring the strongest and most permanent foundations that modern engineering skill is capable of designing, and the application of reinforced concrete or concrete steel methods to the construction of practically all classes of foundations appears to represent the best practice of modern times.

The employment of a particular type of foundation depends upon the character of the soil and the presence of water, and the widely varying conditions met with in practice have developed several classes of foundation structures which may be briefly designated as peat foundations, sand foundations, hard soil foundations, pile foundations, etc., which may be more intelligently described in the special paragraphs following a few very general but necessary remarks on foundation soils.

Foundation Soils.— These vary in character from hard and solid bed-rock, hard-pan, and firm sand to liquid mud, quicksand and silt. It is clear that hard bed-rock, hard-pan, firm sand, and various kinds of compact clays are the best materials to sustain foundation structures; but practical experience has very satisfactorily demonstrated that almost every substance in nature is capable of supporting the weight of any other substance, no matter how small the sustaining capacity of that material may be, provided the weight to be sustained is distributed over a sufficiently large area, and provided the conditions of the soil are permanent. Under any conditions, however, other than those obtaining in the case of solid rock, the adoption of the particular type of foundation requires the exercise of the highest order of forethought on the part of the constructing engineer in arranging for the proper distribution of the weight of the superstructure, and in providing means to counteract the injurious effects of any vibration to which it might possibly be subjected.

The sustaining power of soils depends upon their composition, the amount of water which they contain or which may drain through them, and the degree to which they are confined. Sound hard bed-rock of ledge formation will support loads up to 36 tons per square foot, but if the rock is seamy and rotten its sustaining capacity will be materially less, and will require special treatment in the construction of foundations thereon. In general, the composition of the different kinds of substrata varies so greatly that it is impossible to apply specific rules; but the latest practice assumes the following safe allowable pressures: For hard-pan, eight tons per square foot; compact sand and clean gravel free from lateral movement, five tons per square foot; dry clay, three tons per square foot; and loam, one ton per square foot Soft, watery clays, mud, quicksands, and silt have very little or no sustaining power, and have to be penetrated until firmer material is reached, and require to be compacted by draining, or consolidated by other means. If piles are employed, and they are driven to bed-rock or to refusal, the sustaining power is determined by the crushing strength of the material of the pile — timber, iron, or reinforced concrete, as the case may be.

Peat Soil Foundations.— In soils such as peat, it is almost impossible to carry the walls down to a sufficient depth to reach a solid base. In such cases one of three methods has to be adopted — to lay a strong concrete floor spread over a sufficient area; to use cylinders of iron or brick work; or to employ piles. If a concrete floor is employed, it should cover the entire surface to be occupied by the building, and should extend to some distance beyond the footings of the walls in order to prevent cracks and settlements. These injuries are usually caused by heavy walls being placed too close to the edge of the concrete floor, causing it to buckle and crack, and to settle irregularly under the unequal weights of walls of different thickness. This condition is somewhat obviated under the French system by forming a lip under the edge of the concrete floor, converting it into a kind of inverted tray which confines the substratum within its limits. The material of the foundation should be strong and homogeneous, while that of the superstructure should be of the coursed and bonded, or articulated, construction, so that if necessary it would yield slightly at the joints and thus accommodate itself without fracturing to any slight or unequal settlements during construction.

Sand Soil Foundations.— In hard stable sand or gravel, or in compact dry clay above water level, the construction of strong, permanent foundations require comparatively simple methods. If the location is in cold countries, the preliminary excavation is carried well below the frost line, and the bottom is carefully leveled off to receive the concrete bed, or the broad footing formed by the lower courses of the masonry.

In the case of compressible soils, artificial means in the form of piles, or of beds of concrete are first employed to reinforce the sustaining power of the substratum, and upon the platforms thus obtained the foundation proper is then constructed. On the other hand, if the foundations have to be constructed upon running sand, the greatest care and skill is required to prevent the work from being undermined by pumping out sand with the water during constructing operations. About the only way to handle such a case is to make a good concrete floor the entire width of the trench by putting it in as quickly as possible, sealing up the sides of the trench, and then pumping out the water when it reaches the level of the top of the concrete, and not from a sump. In building dock-wall upon running sand, the probable effects due to the cessation of pumping operations in the course of construction, require to be carefully considered. In such a case, the entering water will exert a varying pressure on the floor of the dock and the foundations of the walls according to the difference of tide levels on the outside of the dock.

Foundations for bridge piers on or across sand are usually constructed by sinking iron tubes or piles equipped with large disks or screw shoes at their lower ends, the diameters of which are regulated to support the weight intended to be placed upon them.

Clay Soil Foundations.— As in the case of sand and gravel free from lateral movement, the construction of foundations in dry clay calls for the application of the simplest methods; but, in clay strata impermeated with water, and having a tendency to slide, especially in the case of hillside excavations, the problem becomes more difficult and complex, and requires special methods for its successful solution. As a rule, such soils do not slide piecemeal, but move as a mass with an almost irresistible energy capable of rupturing the strongest timbers as if they were toothpicks. The only way to proceed in such cases is to disturb as small a section as possible at a time so that any forward impulse may not be communicated to the entire mass, and to provide strong cross walls in the basement to act as buttresses. The foundations should be carried down to or below the ultimate drainage level so as to prevent shrinkage by any subsequent draining of the subsoil which will lead to disastrous settlements.

Pile Foundations.— These consist of groups of piles of timber, iron, or concrete, plain or reinforced, sunk into the substrata and capped with platforms of timber or concrete upon which the superstructure is finally built.

Timber piles are tree trunks of varying diameter and length, with the bark removed and the knots and lateral branch stems cut off. Iron piles are of two kinds: the screw pile, consisting of a shaft of iron or wood, equipped at the foot with an iron casting in the form of two screw blades ranging in size from one to five feet in diameter; and the disk piles, consisting of hollow tubes carrying disks at their lower ends instead of screw blades. Concrete piles consist of cylinders of concrete formed in place, and of columns of reinforced concrete of rectangular cross-section made above ground and subsequently driven into place by means of a pile driver.

Various methods are employed to sink or drive piles into place. Timber piles are driven by the use of hammers which are raised and dropped by some form of engine developed power, and by the aid of jets of water under pressure, as suggested by Sir James Brunlees as early as 1850, and first employed by him in connection with the sinking of iron piles in the construction of the foundations to carry a railway across the treacherous sands of Morecambe Bay. Some of the most notable deep pile foundations constructed by the driving method are those under the new Public Library building, and the Illinois Central Railway passenger station in Chicago, Illinois. The passenger station consists of a structure 180 by 220 feet in plan, 9 stories high, with a tower 13 stories high, and a station 3 stories high connected with a train shed 680 feet long. Borings taken on the site showed the substrata to consist of ten to twenty feet of rubbish accumulated by dumping, and below that, several irregular layers of stiff blue clay and quicksand down to bed-rock, more than 60 feet below the surface. These conditions led to the adoption of a deep pile foundation, and about 1,700 piles, arranged in groups or clusters, were driven under the columns. These piles ranged in size from 40 to 60 feet in length, and from 11 to 16 inches in diameter at the butt. Thirty-two per cent were black gum, 22 per cent pine, 21 per cent oak, 7 per cent basswood, and 15 per cent hickory, with a few maple and elm. They were driven with drop hammers weighing 2,800, 3,200, and 3,800 pounds respectively, the fall ranging from 35 to 50 feet. A cast iron cap was fitted over the heads of the piles to prevent them from being crushed or split, but in spite of this protection over 8 per cent of the heads suffered serious injuries of that character. The piles were all driven in groups until the tops of all were below the leads, then the driving was completed by the use of a follower. Water was kept running continuously around the pile at the surface during the driving operations and was found to materially aid in the sinking of the piles. After the piles had been driven home, the tops were sawed off to a uniform height of three feet below datum, thus placing all the timber below low water level. As this was at least ten feet below the surface, the trenches had to be sheathed, and were kept drained by continual pumping. The earth was excavated to the depth of 18 inches below the top of the piles and rich Portland cement concrete was tamped in flush with the tops. Finally, oak caps 12 inches square were drift-bolted to the centre of each pile, and the space between the timbers was filled with concrete.

When piles are sunk with the aid of jets of water, the work is accomplished much more simply and rapidly than by driving. A pipe two or three inches in diameter is attached to the side of the pile and connected to a pump. The pile is first covered with pitch and then the water is forced through the pipe under the bottom of the pile, so that the sand is converted to a degree of fluidity that allows the pile to descend rapidly to the desired depth. When one pile has been put down home, the feed pipe is detached and spiked onto another and the operation is repeated. The accuracy and certainty of this method is so great, that it is a common practice to make the holes for the bolts in the piles before they are brought into position. After the pile is down and a reasonable length of time has been allowed for the churned up sand to subside, it recovers its solidity and grips the pile so tightly, that it is almost impossible to start it again.

When hollow iron piles are used, the water is conveyed through the centre of the tube under hydraulic pressure, disturbing the sand under the piles and allowing them to sink by their own weight to the proper depth. Upon withdrawing the pressure and stopping the flow of water, the sand returns to its former consistency and holds the pile stationary. Numerous valuable and interesting experiments show that the gripping power of quicksand is equivalent to a uniform supporting power of five tons per square foot, and that such sands possess this power at the depth of only a few feet below the surface, and, furthermore, that an increase in depth is not accompanied by a relative increase in the supporting power. Under favorable conditions the water jet method can be applied equally well to the sinking of cylinders and caissons.

Concrete piles have been used during a comparatively recent period, but their success has been so great that their development in the future promises to bring them into general use in the place of timber and iron piles. These piles, as previously mentioned, are either formed in place, or they are molded above ground. A great many methods have been suggested for forming the hole to contain the concrete when the pile is formed in place. One method consists in driving a double shell of metal into the ground and then withdrawing the inner shell, leaving the outer shell as a mold for the concrete. Another method, shown by Fig. 1, employs a single shell equipped with a concrete or a steel point. The shell is first driven to the desired depth and then withdrawn slowly and the space it occupied filled with concrete, the surface being kept at a sufficient depth below the end of the tube to maintain the head required to resist the pressure of the ground. Concrete piles used for underpinning are usually sunk with the aid of the water jet to a depth sufficient to reach firm strata, and the bottom of the excavation is enlarged by means of a spiral expanding device so as to form a base, as shown in Fig. 2.

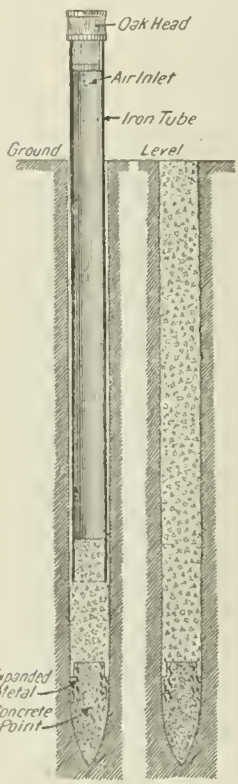

FIG. 1.

Piles made in place may be reinforced, if desired, but usually reinforced concrete piles are formed above ground. They are designed like columns, the reinforcement consisting of vertical bars of steel connected at intervals with horizontal wire rods or plates. Up to the present time they have been made only in square and triangular cross-section, circular molding being too expensive, and the arrangement of the required reinforcement being too complex. The general character of these piles is illustrated by Fig. 3, which shows the construction of the piles designed (but not used) for the foundations of the Hallenbeck building, New York city.

The supporting power of piles depends upon their action as a column resting on a hard base, or upon the friction against their sides developed by the gripping action of the material through which they have been driven. Very often the supporting power is a combination of both actions. The amount of this power may be calculated in various ways, but at their best the results are of necessity only approximations. The supporting power of a pile driven to bed-rock is determined by the crushing strength of the material of which it consists, but if it is supported wholly or in part by friction, its supporting power is calculated by a formula based upon factors obtained by experiment, or upon the distance penetrated by the pile under the blow of the driving hammer. A formula based upon the last named factor and commonly used for determining the safe loading on piles is given by the expression —

$$P = \frac{2Wh}{p + 1},$$

in which P = safe loading in tons upon a pile, W = weight of hammer in tons, h = height of fall in feet, and p = penetration in inches under last blow.

The construction of the pile foundations for the Chicago Public Library building afforded valuable information relative to the supporting power of piles as determined under actual conditions. Piles of Norway pine were driven with a steam hammer having a total weight of 8,300 pounds, the hammer alone weighing 4,500 pounds and delivering 54 blows per minute, with a stroke of 42 inches. The last 20 feet of driving was accomplished by means of a follower. The piles were placed about two and one-half feet centre to centre and the supporting power of four piles was tested by building a platform on top of them and loading it with pig-iron. Levels were carefully taken on each pile. They stood four days with a loading of six tons on each pile, eight days with a loading of 37 tons per pile, and 10 days with a load of 50 tons

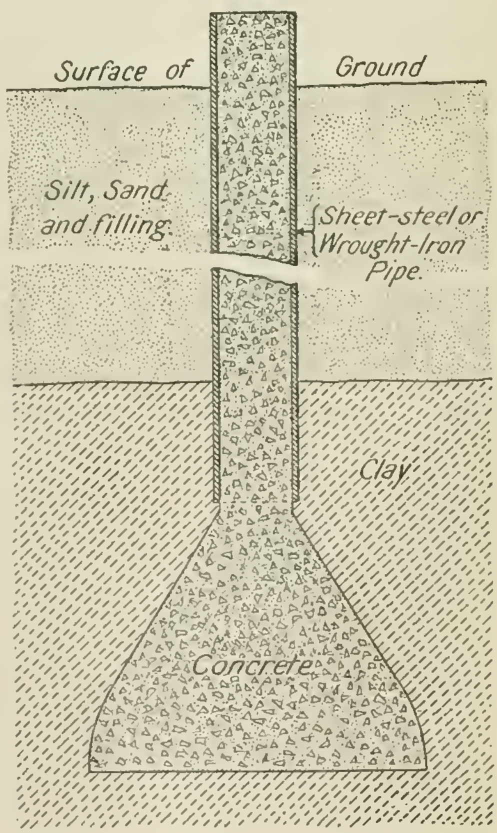

FIG. 2.

per pile. The settlement did not exceed 0.01 of a foot. These tests indicate that if 250 pounds per square inch be assumed for point resistance, the average frictional resistance will amount to about 3.2 pounds per square inch of side surface of pile, or about 432 pounds per square foot. In the case of an ordinary pile, seven inches through the top and 14 inches at the butt, driven to a depth of 45 feet, the point resistance would be 6,000 pounds, and the frictional resistance 59,000 pounds, a total earth resistance of 65,000 pounds, equivalent to the supporting power of the pile considered as a column, and allowing a factor of safety of 3 to 4.

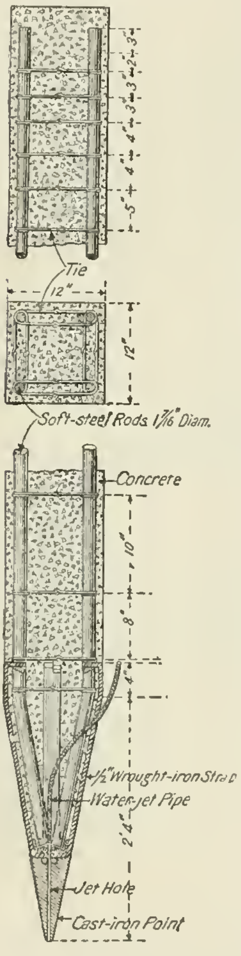

Fig. 3.

Usually, the determination of the point at which a pile is considered as having been driven to a firm bearing depends greatly upon the judgment of the engineer in charge, based upon his experience in the particular locality in which the work is being performed. The best practice, however, affords the following safe specifications of allowable penetration. For piles meeting a hard resistance a penetration of one inch under the blows of a 2,000-pound hammer falling 10 feet, and for piles held by friction, a penetration of three inches under the blows of a 2,000-pound hammer falling 15 feet. The minimum distance between centres usually depends upon the hardness of the substrata and the size of the butts. Spruce piles may be advantageously driven 24 inches between centres, while large and long piles ought not to be driven closer than 30 inches between centres. Another factor that must be carefully considered is the supporting power of the soil as a whole. For example, if that power is equal to two tons per square foot, and each pile is capable of sustaining 18 tons, it is useless to place the piles closer than three feet between centres.

In connection with the use of timber piles in places where the durability of the timber is very liable to be seriously impaired by the attacks of the Teredo worm, the latest practice appears to favor the system of armoring them with concrete. In such cases the timber piles are usually driven in sets of three to a firm

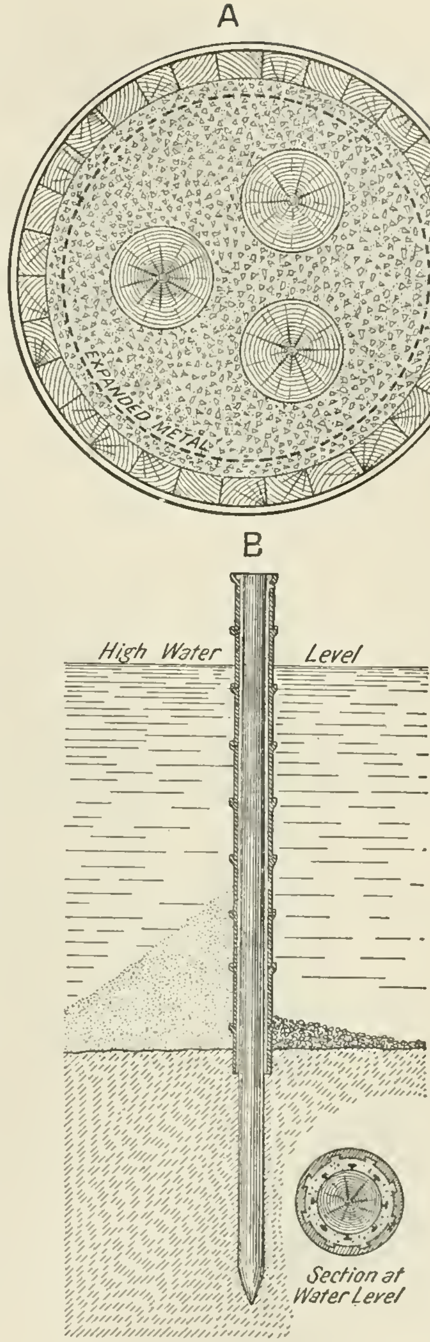

Fig. 4.

bearing. They are then cut off, one two feet, one four feet, and one eight feet, below the level of the wharf platform. A wooden stave cylinder of three-inch planking is then placed around the piles and driven into the mud to a depth of 12 feet, and the bottom of the cylinder sealed. The contained water is then pumped out, and a cylinder of expanded metal is set within the wooden cylinder, and the remaining space filled with concrete. Diagram A, Fig. 4, illustrates this protective method as employed in wharf construction on the Pacific coast.

Another method still more recently introduced consists in the use of terra-cotta pipes as an outer covering for the piles. In this case the armoring is limited to individual piles. Before driving the pile, large-headed nails are driven into the surface of the wood near the level of the water line. The pile is then driven into place and the sections of terra-cotta pipe placed around it. The annular space of about two inches between the inner surface of the pipe and the pile is then filled with concrete. The method is especially applicable to works along the coasts of the South Atlantic and Gulf States, where there are no ice fields to contend with, and where no strong tidal and river currents necessitate the use of heavy masses of stone to protect the piles from the great force thereby exerted against them. This method is illustrated by diagram B, Fig. 4.

Platform Foundations.— These structures are designed to distribute a concentrated weight over a large area in soft substrata when piles are not employed. They may consist of beds

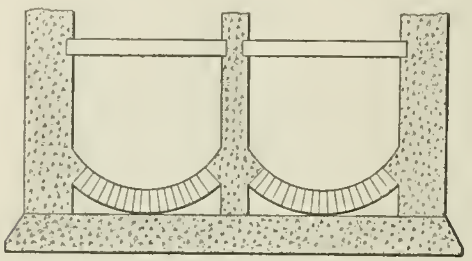

Fig. 5.

of concrete, or of masonry or brick arches sprung between supporting piers or columns, as shown by Fig. 5. They may also consist of platforms of timber grillage — timbers placed across each other in alternate layers, or of platforms of concrete or masonry reinforced with a grillage of steel bars, as illustrated by Fig. 6, which shows the platform foundations of a World's Fair building in Chicago, consisting of a concrete bed reinforced with a steel rail and I-beam grillage, to support the base castings of the main columns.

Subaqueous Foundations are those constructed in the substrata of river beds or other bodies of water, or where the existing conditions necessitate the building of structures in water and below the level of its surface. This class of work is accomplished by the use of cofferdams, cribs and open caissons, pneumatic caissons, by dredging through wells, by forcing cement into the substrata under pneumatic pressure, and by freezing the substrata.

Cofferdam Method.— The use of cofferdams is limited to the construction of foundations in shallow waters where the depth of the necessary excavation to reach a firm bearing is small, or in water bearing substrata on land. They are usually constructed by driving a double row of sheet piles — heavy timber planking — around the area in which the foundation is to be built. The space between the piles is then tamped in solidly with clay, and the water pumped out of the enclosure, so that the work of excavating and the subsequent masonry construction may be carried on in the open air. Cofferdams are sometimes constructed of walls composed of bags of clay piled around the foundation area, and reinforced with barrels of sand banked on the outer side of the walls.

Crib and Open Caisson Method.— Under this method, the foundation bed is first prepared by dredging until a solid material is reached, or by driving piles to a sufficient depth to reach a firm bearing. When piles are employed they are cut off at a uniform depth below the level of the water surface and constitute the supporting bed of the caisson. The caisson consists of a water-tight box-like structure open at the top. It is floated over the position of the bed, previously prepared by dredging, and the masonry work built up in its interior until it gradually sinks and rests upon the bed. The side walls are then removed, leaving the bottom of the structure — the crib — in the foundation between the masonry and the supporting bed. Fig. 7 illustrates the foundation for a pier constructed by this method, the crib being supported by piles.

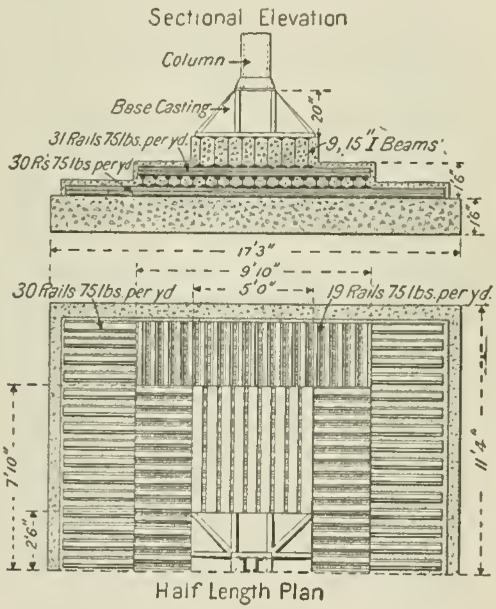

Fig. 6.

Pneumatic Caisson Method.— In this method two water-tight box-like structures built of timber or of metal are used. They are connected together one above the other, the lower caisson being inverted, that is placed bottom up, and the upper one open at the top. This structure is floated and anchored over the position selected for the pier and the masonry built inside the upper caisson until the lower edge of the lower caisson rests on the bed of the body of water. The contained water in the lower caisson is then expelled by compressed air, allowing men to enter and excavate the underlying material within the limits of the caisson. As the excavated material is discharged by being passed out through the top of the caisson, and the masonry work is added to course by course, thus keeping it always above the surface of the water, the caisson sinks lower and lower into the substrata until it reaches solid rock or other firm material. The lower caisson is then filled with concrete, and the sides of the upper caisson are removed, leaving the masonry on the foundation formed by the lower caisson with its concrete filling. Fig. 8 shows the longitudinal section of a caisson of this type.

The pneumatic method, although one of the most effective, is limited in its application to work at a depth of about 100 feet below the surface of the water, as it is impossible for men to work conveniently and effectively under a

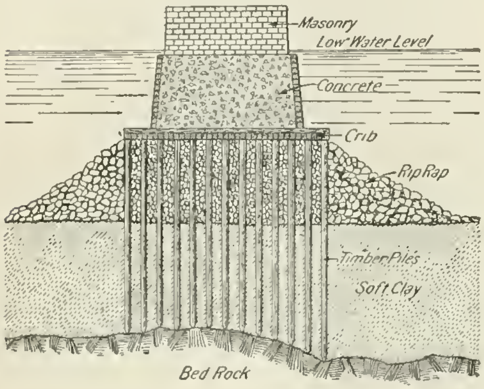

Fig. 7.

greater air pressure than that required to sustain a column of water of that height.

Although the iron-lined timber caissons used in the construction of the first East River or Brooklyn suspension bridge, measuring 102 feet by 168 feet each, with a working chamber 9 feet 6 inches in depth, are among the largest ever constructed, a clearer idea of the application of the pneumatic caisson method to works of great magnitude may be obtained from a description of the caissons used in constructing the foundations for the piers of the second East River or Williamsburg suspension bridge, completed in 1904.

This structure, although having a suspension

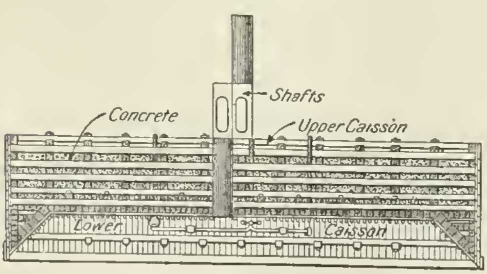

Fig. 8.

span the same length as that of the older bridge, is of much greater magnitude in many other ways. Each of its two steel towers is supported by two piers, as shown by Fig. 9. The following description is that of the north caisson of the New York tower, but it also applies in almost every particular to the other three. As determined by borings, the bed consisted principally of sand, and some clay and boulders. Below this, at a depth varying from 45 to 75 feet below high water level, the formation consisted of gneiss rock with a very irregular surface. The caisson was sunk through the sand, clay and boulders until it rested on the rock, which was then blasted away and stepped so as to make a fair bearing for the edge on all sides. The caisson measured 60 feet by 76 feet on the sides, with a total depth of 19 feet, and a working chamber 7½ feet in height. The walls were two feet nine inches thick and were built of two courses of 12 by 12-inch timbers, the outer course placed longitudinally and the inner vertically. Two layers of 3-inch planking were placed on the outside, and one layer on the inside. The bottom of

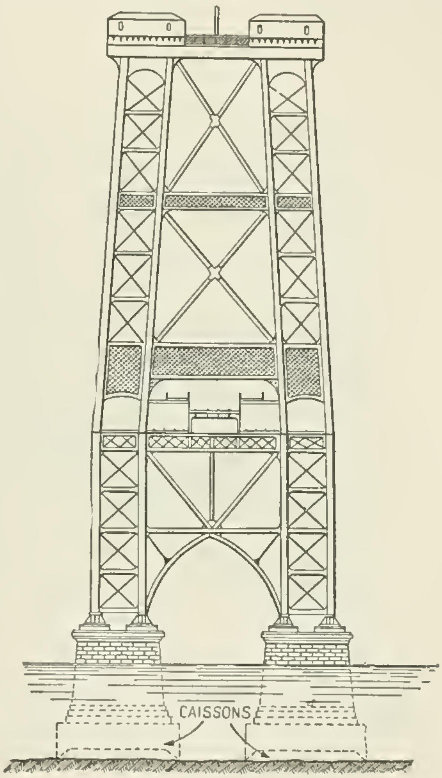

Fig. 9.

the walls was provided with a cutting edge, as shown by Fig. 10, which extended continuously around the whole caisson. This cutting edge was constructed of ½-inch steel plates, stiffened at intervals of 2½ feet of its length by knee braces. It extended two feet below the bottom of the lowermost timbers, and the lower 12 inches were stiffened with reinforcing plates, so that it had a total thickness of two inches. The cutting edge was not provided for the purpose of cutting through the bed of the river, but to enable the workmen to use their tools close to the outer edge of the walls of the caisson, which were nearly three feet in thickness, and also to facilitate the removal of obstacles, such as boulders, which could be dislodged with less difficulty from underneath the two-inch edge than the bottom of the three-foot wall. The roof of the working chamber was five feet in thickness, and consisted of several layers of 12 by 12-inch timbers laid alternately crosswise and covered with alternate courses of 3-inch planks laid diagonally. The roof, and in fact the whole caisson, was stiffened with eight massive steel-plate riveted-trusses, which extended across from wall to wall. All the timbers of the caisson and of the roof were drift-bolted together so as to give great rigidity to the structure, and to make it perfectly water-tight. Additional strength was given to the working chamber by two solid bulkheads, which extended entirely across and divided it into three compartments, openings being provided for the passage of workmen. A massive framework or gridiron formed of 16 by 16-inch timbers was bolted together and to the side walls at the level of the lowermost timbers with 1½-inch steel tie-rods. From each

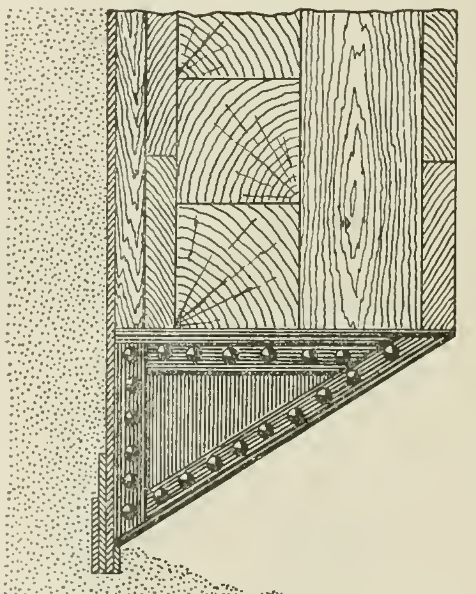

FIG. 10.

intersection of this framework vertical posts reached to the roof and were tied together and stiffened to resist lateral distortion, by diagonal struts and tie-rods, as shown in Fig. 11, practically forming two steel trusses nine feet three inches in depth, with a weight of 10 tons each. They were a novel feature in this class of work, but were rendered necessary on account of the shallowness of the caisson. The roof was pierced with seven shafts, each about three feet in diameter, for the passage of men and material, and several pipes ranging from one to five inches in diameter, for supplying air and water, blowing-out sand, and for carrying electric light wires. These shafts were of circular section, and were put in place in lengths of eight feet as the masonry work was carried upwards.

The piers on the Brooklyn side were constructed in a similar manner, with the exception that they were carried to a depth of 107 feet below high water. The last caisson to be sunk passed through 50 feet of water, 20 feet of sand, gravel and boulders, 30 feet of hard clay and hard-pan, and 12 feet of rock. The excavating of the rock was rendered necessary by the steepness of its slope.

The lower caisson measured 63 feet by 79 feet, and contained 74,700 cubic feet of timber, and 98 tons of iron, the greater portion of which was in the form of drift-bolts. Without the concrete filling it weighed 1,965 tons, and contained 6,000 yards of concrete above the roof of the working chamber. The upper caisson was 50 feet deep and contained 29,000 cubic feet of timber, and 32 tons of iron.

The sinking and concreting was accomplished in three months and six days, a very rapid piece of work considering the great depth to which the caisson was sunk. Down to the depth of 55 feet the men worked in eight-hour shifts. Below this depth the shifts were successively shortened as greater depths were attained. From 55 to 70 feet the shifts were six hours long; from 70 to 80 feet, four hours; from 80 to 90 feet, two hours; from 90 to 100 feet, one and one-half hours, and from 100 to 107 feet, 45 minutes. The pay of the men was increased in proportion to the depth at which they worked, and ranged from $2.50 for the eight-hour shift to $3.75 for the short shifts at the lowest levels. Although the air pressure at the depth of 107 feet was 46 pounds per square inch, there was very little sickness among the workmen, and only one serious case. The piers above the caisson foundation were built of limestone masonry up to low-water level, and, above that, of limestone with a granite facing.

Other notable examples of the pneumatic caisson method, both in the United States and in foreign countries, are the foundations of the centre pier of the Harlem River bridge, New York city; the Benares bridge over the Ganges River, India; the Poughkeepsie bridge over the Hudson River, New York; the Hawkesbury bridge, New South Wales, Australia; and the Jubilee bridge over the Hooghly River in Bengal. The centre pier of the Harlem River bridge supports the thrust of a 510-foot steel arch on each side of it, and stands on a timber caisson 54 feet by 104 feet, with a depth of 13 feet. It is divided into three compartments by vertical partitions, which not only served to strengthen the caisson, but protected the men during the blasting operations necessitated by the greatly inclined surface of the rock.

Foundations for piers or abutments of bridges, or for the main columns of high buildings, where the individual piece of work is of lesser magnitude than those already cited, are usually constructed by the use of cylinders of iron, as illustrated by Fig. 12. The arrangement consists of a cylinder of metal divided into two unequal parts by a horizontal partition — the upper and larger part, essentially a coffer-dam, being the caisson proper, and the lower part within which the excavating operations are carried on being the working chamber. It is provided with one or two shafts made of boiler-plate, which are connected with the air chamber on top adjoining the equilibrium chamber or air-lock through which the workmen and materials must enter. A pipe from the air compressor furnishes the air chamber with compressed air, which is subsequently introduced by a system of locks to the working chamber below.

Dredging in Wells.— Beyond the limit of the effective application of pneumatic methods, about 100 feet below the water surface, all excavating must be accomplished by dredging, and special care has to be exercised in planning the method of operations to prevent any contingency arising at the bottom that would require to be dealt with by the use of human labor, as diving operations are impossible. It is also important to observe that the skin friction, quite unimportant in a cylinder of moderate depth, becomes so great at lower levels that special means have to be employed to overcome it. In the Benares bridge mentioned in the foregoing paragraphs, the principal piers are sunk to the depth of 140 feet below the level of the water, and consist of oval brick wells each 28 feet by 65 feet in diameter, the bottom lengths being cased in iron, as it was necessary to begin operations in the water. Each well is divided into three vertical compartments in which the dredging was carried on. In constructing the Poughkeepsie and the Hawkesbury bridges, almost identical methods were employed. In the case of the former, the caisson is of timber; it measures 60 feet by 160 feet, with a depth of 125 feet. It is divided into 40 vertical cells, and was sunk to a depth of 130 feet by filling in some of the cells and excavating in others. In the case of the latter, the caisson is of steel and iron, of oval form, 20 feet by 48 feet diameters, and splayed out at the bottom an additional two feet all around. It is divided into three dredging wells set on the centre line and parallel to its length. They splay out at the bottom so as to meet each other and the outer skin, thus forming a cutting edge. It was sunk to a depth of 161 feet below the water level by dredging in the wells, and by filling the space between the wells and the outer skin with concrete. This is probably the greatest depth ever reached in the construction of a bridge foundation.

The foundations of the piers of the Hooghly bridge were constructed by the use of similar caissons. The outer skin of the caisson, however, is entirely vertical, and the three dredging wells extend right across the structure, occupying the semicircular ends and the central portion. The weight for sinking was obtained by filling the two 15-foot intermediate spaces with concrete, and by placing a brick lining around the semicircular ends. It will be understood that in all these cases the dredging wells were finally filled up with concrete when the proper depth was reached.

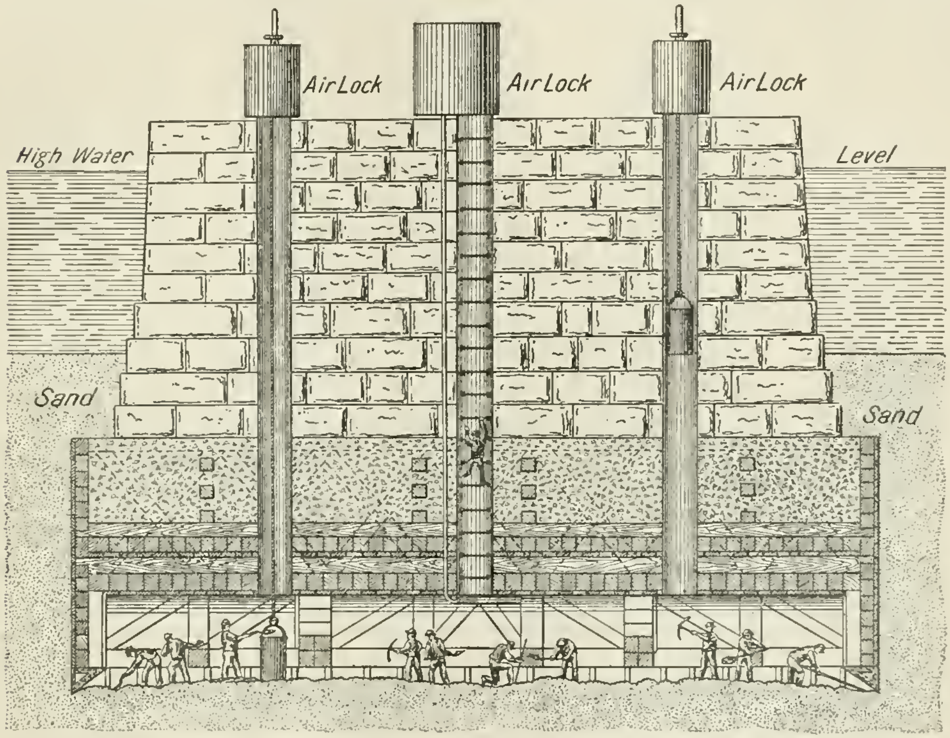

Fig. 11.

Pneumatic Forcing Method.— This is an improved method of constructing subaqueous foundations in sand or gravel substrata by converting it into a solid in the form of sand or gravel concrete. This is effected in place, without excavating operations, by forcing cement in the form of the dry powder in which it is furnished commercially, through a pipe by air pressure into the substrata. The charging pipe, called the lance pipe, has an internal diameter of 1½ inches, and is drawn to a point at the lower end, and perforated with three or more holes ⅜ of an inch in diameter. The upper end of the pipe is connected by means of a bend and rubber tubing with the air pressure supply pipe, suitable arrangements being provided to raise, lower, or move it while in operation. The air pressure supply pipe is provided with suitable branches fitted with stop-cocks to permit of its being connected to an injector device by which any desired quantity of cement powder may be fed into the current of air. In operation, the air pressure forces the cement powder through the small openings at the lower end of the lance pipe and drives it into the substrata of wet sand or gravel, with which it combines and forms sand or gravel concrete as the case may be. The lance tube may be sunk to depths of 16 or 19 feet in a comparatively short time, and in order to insure a uniform mixture in the foundation pit, the foundation area is divided into small fields 8 to 12 inches square, into each of which the proper quantity of cement is blown. The proper amount of the cement charge is determined by dividing the cubic contents of the field by the required proportion of the mixture. Usually, the saturation of the sand is so thoroughly accomplished that when the forcing operations are discontinued, the particles of sand, if allowed to come together, would adhere to each other with a great deal of energy, so much so that it is well known to all makers of concrete, whether by hand, mixer, or mill methods, that the volume of the resulting material is always less than the sum of the volumes of the ingredients in their free and uncombined state. Experience has demonstrated that the best proportions of the two ingredients are one part by volume of cement to five parts of sand, or sand and gravel, measured in the same manner. This method was first suggested by Fr. Neukirch, of Bremen, Germany, and is being extensively used in various ways other than the construction of foundations proper, for such purposes as the consolidation of the soil around brick sewers, in the building of quay-walls, and in many other cases where the driving of cofferdams would be dangerous or impracticable.

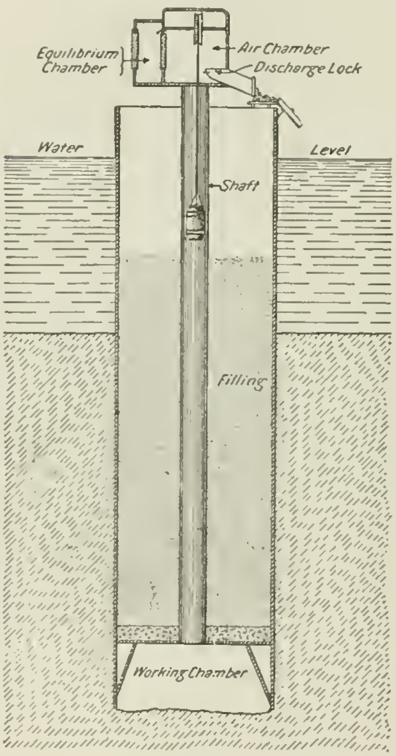

FIG. 12.

Another method by which bodies of cement or concrete may be placed in quicksand substrata employs pipes in the following manner: Two or more iron pipes are sunk through the quicksands to the desired depth, and water pumped into one of the pipes, thus converting the substrata into a condition of fluidity sufficient for the purpose of pumping it out through the other pipe. The cement is then introduced through the forcing pipe and filled into the agitated area at the bottom of the pipes.

Freezing Method.— This method is employed in the construction of subaqueous foundations, or of foundations in quicksand, or in soft water-bearing substrata, where the fluidity or lack of plasticity of the soil requires it to be artificially consolidated before excavating work can be instituted therein. In the Poetsch process, a large number of pipes are distributed as uniformly as the unstable conditions will permit, and are then filled with a strong freezing liquid which is maintained in a state of constant and active circulation until the substrata becomes solidly frozen. The excavation is then made in the frozen material, and the foundation put in and allowed to set firmly, after which the freezing operations are discontinued and the substrata allowed to thaw and assume its normal condition around the work. The method is not one that bears recommendation for works of magnitude. The thawing sands usually return to a state of unstable equilibrium not very conducive to the permanency and stability of the structures built therein, and besides that, the cost of the refrigerating plant, together with the accessory machinery and appliances, is so excessive as to be practically prohibitory in ordinary cases. It may be advantageously applied, however, in many special cases, especially in the construction of subaqueous tunnels and for making repairs to all classes of subaqueous structures.

WILLIAM MOREY, JR., C.E.,
Consulting Civil and Mechanical Engineer, N. Y.

Founder, also called **Laminitis,** consists of inflammation of the vascular sensitive laminæ of the horse's foot. Occasionally the laminæ are strained from severe exertion; more frequently they suffer from the morbid effects of cold, which is especially injurious after excitement and over-fatigue. The shoes must at once be removed, and the toes, if long, reduced, but no further rasping or cutting is permissible. The feet must be enveloped in hot bran poultices, and kept off the hard ground by a plentiful supply of short litter. Purgatives, if required, must be used with extreme caution. See HORSE, DISEASES AND CARE OF.— *Care of the Feet.*

Founders and Patriots of America, The, a society founded in 1896, and incorporated 18 March, of the same year, the object stated in the articles of incorporation being «to bring together and associate congenial men whose ancestors struggled together for life and liberty, home and happiness, in the land when it was a new and unknown country, and whose line of descent from them comes through patriots who sustained the colonies in the struggle for independence in the Revolutionary War; to teach reverent regard for the names and history, character and perseverence, deeds and heroism, of the founders of this country and their patriot descendants; to teach that the purpose of the founders could have had no lasting result but for their patriot sons; to inculcate patriotism; to discover, collect, and preserve records, documents, manuscripts, monuments, and history relating to the first colonists and their ancestors and their descendants, and to commemorate and celebrate events in the history of the colonies and the republic.» The order admits to membership any male citizen of the United States above the age of 21 years who is lineally descended, in the male line of either parent, from an ancestor who settled in any of the colonies prior to 13 May 1657, and whose intermediate ancestors in the same line during the Revolutionary period adhered as patriots to the cause of the colonies.

Founding. The art of making molds in sand, loam, or plaster of Paris, with or without the aid of patterns. The molds thus made are filled with molten metal which is subsequently allowed to cool and solidify into a metal casting corresponding to the form of the mold.

The various founding processes are characterized by the kinds of metal employed in the castings, such as iron, steel, brass, bronze, etc., and by the class of work produced, such as water pipes, car-wheels, ordnance, statues, bells, etc., involving the applications of special methods in the work of molding; in the melting of the metal; in the filling of the mold with the molten metal; and in the manner in which the metal is allowed to cool.

Molding in Sand.— The process of molding in sand by means of patterns embedded in flasks containing sand, is substantially as follows: The flasks, which are box-like arrangements provided with suitable handles by which they may be lifted and moved around, are generally used in pairs — the upper flask being commonly designated the «cope,» and the lower one, the «drag» or «swivel.» The patterns, usually of wood, are made either in one piece when the design of the casting is simple, or in several pieces when the form of the casting is more complicated. In molding, the drag is filled with sand and the pattern embedded in it. The cope is then placed over the drag and the sand rammed in tightly around the pattern. The pair of flasks is then turned over and the loose sand taken out of the drag and replaced by sand firmly rammed in its place. The flasks are now returned to their original position; the cope is taken off and the pattern removed. The cope is then replaced upon the drag, and the mold is thus made ready to receive its filling of molten metal. This is accomplished by pouring the metal through suitably formed gates or holes which extend through the cope and connect with the molded spaces in the drag.

The use of a separate appliance for a drag is very often dispensed with, the pattern being embedded in a bed of sand upon the foundry floor. This method is especially applicable when a large number of small castings are made at each pouring. Also, very often the patterns are made in two parts, that is, divided in the middle horizontally, so that one half of the mold is made in the drag and the other half in the cope. In the case of hollow cylindrical castings such as water pipes and the tubes of heavy ordnance, a cylindrical core of the proper dimensions is suspended in the drag mold before the cope is placed in position, and the annular space between the core and the interior walls of the mold is filled in with the molten metal.

Molds are made either in green or in dry sand. Those in green sand are suitable for the making of small and simple castings; but molds in dry sand are employed in the production of castings of large size and great intricacy of design. In such cases, after the molds have been finished, they are placed in drying ovens until they are thoroughly dried.

Molding in Loam.— In this process, the molds instead of being made by the embedding of patterns in sand, are formed by means of cores of metal or of brickwork which are covered by several coatings of loam — mixed sand and clay, to correspond with the form and dimensions of the desired castings. An outer shell constructed around the core thus thickened, provides the annular space for the reception of the metal. The method is especially applicable to the founding of hollow cylinders, bells, and statues. See titles FOUNDRY AND FORGE SHOP TERMS, and ORDNANCE, in this Encyclopedia.

Foundling, a child abandoned by its parents, and found by strangers. Though infanticide was not punished among the ancient nations, with the exception of Egypt, where the child's corpse was fastened to the guilty parent's neck for three days and nights, yet natural feeling would prompt parents to expose their offspring, and leave their fate to accident rather than kill them. They usually selected places which were much frequented, where there was a greater chance of the child being saved. In Athens and Rome they were exposed in especially appointed places. In the 4th century under the Emperors Valentinian, Valerius, and Gratian, the practice was prohibited. The Bishop of Treves in the 6th century allowed foundlings to be placed in a marble basin in front of the cathedral, thus entrusting them to the care of the Church.

In 787 a foundling hospital was established at Milan; one was established at Paris in 1362, but among the most famous of modern institutions is the foundling hospital in Paris formally established in 1670. It receives not only foundlings strictly so called, that is, deserted children of unknown parentage, but also deserted children of known parents, and destitute children generally, as well as children pronounced incorrigible by the courts or declared to be so by their parents.

England has no foundling hospital properly so called; all exposed children are brought up at the expense of the parish in which they are found. The Foundling Hospital in London, established by Thomas Coram, a master-mariner, in 1739, was originally a hospital for exposed and deserted children. It was for a time extremely popular, and was repeatedly assisted by parliamentary grants; but the enormous increase of abandonments, and the expense which they occasioned, produced such an alteration in public opinion that the hospital was changed to what it now is, a hospital for poor illegitimate children whose mothers are known.

In the United States foundlings are usually consigned to the county poor farm, but Foundling and Maternity Hospitals exist in the principal cities. Foundling hospitals are said to diminish not only the exposing of children, but also to render infanticide and intentional abortion less frequent. The objection that they contribute to the corruption of morals, if they receive children indiscriminately, and that they encourage parents to rid themselves of responsibility, is the strongest which can be urged against such institutions, and is not easily answered. In Massachusetts foundling hospitals are legally forbidden. In New York city foundlings are sent to Bellevue Hospital, and formerly were transferred to the Infants' Hospital on Randall's Island or in the borough of Brooklyn, to Flatbush. The rate of mortality among them was alarming; in 1897 all children received at the Randall Island institution died before reaching the age of two years, chiefly owing to the change of food and neglect before and exposure during abandonment. At baby farms, private institutions where babies were boarded for gain, the same conditions also prevailed. The attempt to remedy these deplorable conditions has met with great success since 1899. The work is supervised by the Joint Committee on the Care of Motherless Infants under the control of the State Charities Aid Association and the New York Association for Improving the Condition of the Poor, and their fifth annual report for the year 1903 shows the rate of mortality has decreased to 11 per cent as compared with 55.9 per cent in 1899, the first year of their work. Foundlings of whose parentage nothing is known are baptized alternately Roman Catholic and Protestant, the Roman Catholic children being in charge of the Guild of the Infant Saviour, while the committee care for the Protestants. In connection with this admirable work is an agency for providing situations in the country for destitute mothers with infants. The *mothering* system has been long enforced in the Chicago Foundling Asylum, and is being adopted in similar institutions throughout the States. Consult: Folks, 'Care of Neglected and Dependent Children' (1901); 'Reports of the Joint Committee on the Care of Motherless Infants'; 'New York Association for Improving the Condition of the Poor' (1903).

Foundry and Forge Shop Terms. The following list of terms includes some of the most significant words and phrases commonly used in connection with foundry and forge shop operations.

Angles.— Strengthening pieces which run around the angular portions of castings.

Annealing.— The subjection of brittle and non-elastic metals to the action of long continued heat, which effects a rearrangement of the ultimate molecules, and makes the metal tougher or more homogeneous. Steel castings, old chains and rods, and other forms of hammered work, which have been used for a long time, are improved by annealing; but, newly rolled plates and bars, the fibrous condition of which has not deteriorated, are weakened in tensile strength by the process. Annealing is carried on by means of "annealing-ovens" into which the "annealing-pots" containing the articles which require to be annealed are run, and exposed to the action of the heat for periods ranging from several hours to several days as the circumstances may require. The function of the annealing-pots is the preservation of the contained articles from the action of the atmosphere during the process of annealing.

Bars.— The stays or bridges placed in molding boxes to support the sand which encloses the pattern. They are purposely cast as rough as possible in order to insure the adherence of the sand. Vertical or "cope-bars" have their edges kept about three-quarters of an inch away from the pattern and about the same distance from the joint of the box. "Flat-bars" or "drag-bars" are placed in the "drag" or bottom-half of the mold, and therefore, do not follow the outline of the pattern.

Battering-off.— The finishing of the surfaces of forged work by hammering while the metal is dropping to a low red or black heat.

Bead Slickers or Bead Tools.— Sleeking tools used by molders for smoothing the impressions of beaded work such as the ornamental fillet or strip curved around the edge of a casting.

Bedding-in.— The method of molding in which the pattern is embedded in a bed of sand on the foundry floor instead of being placed in a box mold and "rammed-up" with sand.

Binders.— Rosin, glue, wheat and rye flour, linseed oil, etc., employed for the purpose of giving strength to "core-mixtures."

Blackening.— Pulverized charcoal, coal, coke, and plumbago or graphite used by molders for sleeking over the surface of a mold in order to prevent the castings from becoming "sand-burnt."

Black Wash.— A solution used on loam-molds and dry-sand molds for the same purpose that blackening is used in green-sand molds.

Blast.— The volume of air artificially forced into furnaces and forges by means of bellows, blowers, and rotary fans, to accelerate the combustion.

Blowers.— Machines employed for the production of blast, ventilation, etc. The principal forms consist of blowing cylinders and pistons, and the rotary blowers or centrifugal fans which are operated by power driven belting. Ordinarily they deliver a blast ranging from four to six ounces, approximating to a pressure ranging from seven to ten inches as indicated by the water gauge.

Blowholes.— Hollow cavities in castings caused by the presence of bubbles of air, or gas in the mold due to imperfect venting. When of a bluish color, they indicate the presence of sulphur in the metal.

Bottom Board.— The board on which the joint of a pattern is placed when it is being rammed-up, either to sustain a weak pattern, or to make the molders' "sand-joint."

Bottom Part.— The "drag" or bottom-half of a mold. In "bedding-in" work, the portion of the mold in the foundry floor.

Burning-off.— A process of tempering springs. The spring to be tempered is first hardened by immersion in linseed oil. When cold, it is taken out and the adhering film of oil ignited and allowed to burn off, thus producing a temperature of at least 600° Fahr., which draws the temper of the spring and coats it with a black surface that makes it practically rust proof.

Burning-on.— The replacing of a broken-off or incomplete portion of a casting. A mold of the portion which is to be burned-on is placed in the proper position against the main casting, and the molten metal poured in. The metal is allowed to flow over the broken face of the casting and out through a gate at the side of the mold, until the broken face is in a state of local fusion. The gate is then stopped, and the metal allowed to coo'. Perfect amalgamation is attained by the method.

CASE HARDENING.—The treatment by which wrought-iron is hardened on the surface. It is first heated to a red heat in the presence of carbon, and absorbs enough of the carbon to transform it into steel on the outside. It is then chilled suddenly to harden the steel.

CHAPLET.— The metallic devices used for supporting the "core" of a mold. Chaplets are of various forms — the single-headed chaplets, the double-headed chaplets, the spring chaplets, and the adjustable chaplets. They are placed under the cores to support them, or above the cores to hold them down, or at the sides of the cores to enable them to resist the lateral pressure exerted by the flowing metal.

CHARGING.— The supplying of furnaces with fuel and ores. In a reverberatory furnace, the "charging-door" or the opening through which the charge is introduced, is located at the side; while in a blast furnace or cupola, it is located near the top at the level of the charging platform.

CHART METHOD.— A method for computing the weight required for holding down the cope and core against the raising effort of the head of flowing metal. It consists in the drawing to scale the outline of the form and size of the lifting surface, and the height of the fluid head, and computing from the figure thus obtained, the cubical contents, which multiplied by the decimal .26 gives the data for the necessary weight.

CHILLS.— Metallic molds into which specially mixed molten iron is poured for the production of chilled or surface hardened castings. They are made of a quality of iron of sufficient strength and ductility to allow for the alternate expansion and contraction to which they are subjected, otherwise they would not last longer than one heat. Chills used for casting chilled-rolls are made in sections. "Contracting-chills" are used for casting chilled car wheels, and are so constructed, that as the metal of the wheel cools and contracts, the chills close in and keep in constant contact with it.

CINDER-BED OR COKE BED.— The first layer of coke placed in a cupola previous to the introduction of the iron. Its weight bears a definite relation to that of the iron, but varies with the condition of the furnace. The term "cinder-bed" is also applied to the beds of cinders sometimes placd under the molds and with which the vents are connected.

CLAMPING.— The weighting down of the cope of a closed mold preparatory to "pouring," to prevent its raising by the lifting force of the metal. It is accomplished by means of various forms of clamps and weights, the latter consist of piles of pig-iron piled in separate pigs on the cope, or cast-iron bars ranging from 1,000 to 2,000 pounds in weight, which are hoisted into position by a crane.

CLEANING OR CLEANING-UP.— The smoothing of the surfaces of a foundry mold with trowel and cleaners, and blackening, preparatory to "closing" and "casting." Also, the removal of sand from castings by means of wire brushes and files, by means of tumbling-barrels, and by various pickling processes.

CLOSING-UP.— The placing on of the top-box or cope of a mold in readiness to pouring in the molten metal.

COLD SHUTS.— When cast metal pours thick, or when it is poured into the mold too slowly, it is liable to thicken and partly solidify in those portions of the mold where the casting is thin, thus preventing the metal which follows from properly amalgamating with it. The imperfectly united contact surfaces thus formed are called "cold-shuts," "cold-shorts," or "cold-shots."

COPE.— The top-box or upper-half of a green-sand mold.

CORE.— A body of green or dried sand placed in a mold to exclude the central or inner portion of a casting. They are made either in boxes called "core-boxes," or struck to shape upon a revolving bar, a mixture of loam being used for the body, and the required outline imparted to it by revolving it against the bevelled edge of a templet board called the "loam-board."

DRAWING OF PATTERNS.— The lifting of patterns from the sand. Also called "rapping," "delivery," etc.

DRAWING PLATES.— See Rapping.

DRAWING OF TEMPER.— The heating of steel to redness and then allowing it to cool slowly in the air. The reverse of "hardening" and "tempering."

DROP FORGING.— The method of forging iron by driving or pressing it into a die placed under a drop hammer. It is employed when a number of forgings of the same pattern are required. A great deal of this class of work is now accomplished by the use of steam-hammers and forging-presses.

FAGOTING.— The piling up of lengths of puddled bar-iron in fagots or bundles for the purpose of reheating and rolling.

FEEDING.— When molten metal cools, the outside portions will set first, while the inside portions will remain fluid for some length of time. As the inner portion cools, it will contract and shrink upon itself and leave a depression on the top face of the casting. To avoid this condition the heavier portions of the casting are fed with metal through a small rod called the "feeding-rod," inserted through the runner or the riser, which by its motion keeps a passage open for the inflow of the fresh metal introduced to compensate for the contraction. The metal used for this purpose is called the "feeding-head."

FLASK.— The box which holds the sand in which the pattern is rammed-up in the making of a mold. Flasks are made either of wood or of metal, and are parted horizontally into two or more sections. In a mold composed of two parts, the lowermost or the one which is molded first is called the "nowel" or "drag," and the uppermost or the one which is on top when the casting is poured, is called the "cope." When a flask consists of more than two parts, the sections between the cope and the drag are called "cheeks" or "intermediates." Flasks are provided with two loose covers called top and bottom boards, and they are designated as "two-part flasks," "three-part flasks," "four-part flasks," etc., according to the number of the component parts.

FLOOR RAMMER.— A flat-ended iron tool employed for ramming over large surfaces of sand.

FLUXES.— Substances used in a smelting, or in a melting furnace for combining with the earthy and other infusible matter present in ores, and which require to be separated from the metal, and which cannot be rendered fluid by itself at the temperature of the furnaces. The flux most widely used is a carbonate of lime in the form of limestone, clam and oyster shells, chalk, dolomite and calcite. Magnesia, fluorspar, feldspar, and calcspar are also suitable for this purpose. This by-product of the furnaces is called "slag."

FORGE.— The structure upon which a smith's fire is maintained. Forges are constructed of brick, of brick and iron combined, or entirely of iron. A forge consists of a hearth, tuyere, chimney, bonnet, and troughs for water and coal. The blast is produced either by bellows, or by rotary blowers and fans.

GAGGERS.— Short, conical projections cast upon the core-plates and the plates of loam-molds for the purpose of assisting the adhesion of the loam. The term is also applied to the hooks of cast-iron or of wrought-iron which are hung from the cross-bars of a molding box into the mold to prevent the sand from sliding out when the cope is lifted. They are necessary when the body of sand is more than sixteen inches square in area.

GATE.— The opening in the sand of a mold, which connects the "sprue" with the interior of the mold. The sprue is the orifice through which the molten metal is poured into the mold. Both terms are also applied to the bodies of metal which occupy the respective passages after the casting has been poured.

HARDENING.— The hardening of a metal is the result of an increase in its density. Few metals are capable of being hardened. The hardening of steel is effected by heating it to a cherry-red temperature and then chilling or cooling it suddenly by plunging it in water, oil, or other suitable solution, or by exposing it to a cold blast. The degree of hardness that may be attained depends upon the suddenness of the chilling. In hardening and tempering tools such as machine knives, taps, long twist-drills, reamers, milling cutters, etc., the danger of warping them by uneven heating, or by cold draughts, is avoided by heating them in special hardening and tempering furnaces. See Case Hardening and Tempering.

LIFTING.— The drawing out of a pattern from a mold. Also applied to the raising up or springing up of the cope or top-part of the mold caused by the pressure due to the head of the molten metal. This tendency is counteracted by the use of screw-bolts, clamps, and dead-weights. See Clamping.

LOAM WORK.— The making of molds in loam, as distinguished from that of molding in sand. The loam used in foundries consists of a mixture of clay, sand, and horsedung, ground up with water by means of a form of mortar mill called the "loam-mill." When cold, the loam has sufficient consistency to be struck up to any desired outline by means of a "loam-board." See Cores.

LYCOPODE.— A material used for "parting."

MATCH-PLATES.— A match-plate is a wooden board or plate of metal on the opposite faces of which two different portions of a pattern are attached. When the boxes containing the impressions are brought together, they constitute a complete mold. In some cases they are very useful for facilitating the making of joints, but they are generally used for making molds for castings having plain outlines, without sharp corners, cores, or projections.

Mold-boards.- Boards used for making molds for small castings having irregular joints. Their chief advantage consists in the saving of time and labor in forming the joints. They are made of various kinds of material. The wooden mold-board is carved out in the desired shape of the joint. The plaster of Paris mold-board is used in cases where the pattern is very crooked, and where the other types cannot be made as cheaply, or to fit with the same amount of accuracy. The sand-and-composition mold-boards are the kind generally used, and obviate the necessity of ramming the sand. The composition consists of twenty parts of fine dry sand to one part of litharge, tempered with linseed oil. The match-plate is a form of mold-board.

Molding or Founding.— The making of molds for metal castings. The molds are made in sand, loam, and plaster of Paris, with or without the aid of patterns. There are three classes of molding — green-sand molding, in which damp sand is used, and the castings are made in damp molds, or in molds the surfaces of which have been "skin-dried;" dry-sand molding in which the damp sand molds are thoroughly dried in an oven preparatory to casting; and loam molding. See Loam Work.

Molding Sand.— Sand is used for molding, in preference to all other materials, on account of its refractory nature, which enables it to resist the destructive action of molten metal at high temperatures; on account of its porosity, which allows the free escape of the gases generated in casting; and on account of its peculiarly compact and adhesive properties, which not only permits of its being molded to any desired shape, but also enables it to resist a great amount of pressure exerted by a liquid. The best molding sand is obtained from the coal measures, and the later red sandstone formations. Sand from the green-sand and chalk formations is also very satisfactory. The most suitable sand is that which contains a large percentage of silica, with alumina and magnesia present in small quantities. The various grades of molding sand are designated as green-sand, dry-sand, core-sand, facing-sand, and parting-sand, according to the purposes for which they are used.

Odd Sides.— See Mold-boards.

Parting.— The act of separating the different parts of a mold-box. Also applied to the process of making the sand-joint between two contiguous mold-boxes. Also to the joint itself.

Pouring.— The filling in of a mold with molten metal in making a casting.

Print.— A projection placed upon a pattern to indicate the position of a cored hole, and to form an indentation for the reception of the end of the core. "Pocket-prints" and "parallel-prints" are used at the sides of the patterns.

Rapping. The process of loosening a pattern from the sand previous to its withdrawal therefrom. This is effected by inserting the pointed end of the "rapping-bar" into the "rapping-hole" bored in the pattern or in a plate of malleable iron called the "rapping-plate," screwed on the face of the pattern. Small round-faced wooden mallets, called "rapping-mallets," are used in the actual process of withdrawal, which, unless carefully performed, will not only damage the pattern, but will enlarge the molds of small castings to a very appreciable extent.

Riddle.— A coarse sand sieve of about half-inch mesh, used for sifting coarse and old sand.

Riser or Air Gate.— A vertical opening which extends from the mold, through the cope, to the outer air. When it fills up with the molten metal it indicates that the mold itself is full.

Tempering.— In foundry work, it is applied to the process of mixing various grades of sand. In forge shop work, it signifies the imparting of a definite degree of hardness, or elasticity to steel. It is effected by either raising or letting down the metal to a certain temperature and then cooling it from that temperature by plunging it in water or oil. The degree of temperature is indicated by the various colors assumed by the steel during the heating part of the process. It may also be determined by the flashing point of a fat.

Venting.— The piercing or honeycombing of the sand of a mold by means of a long wire-rod, one-eighth or one-quarter inch in thickness, thrust in all directions, for the purpose of allowing the free escape of the gases generated by the decomposition of the moisture in the sand by the heat of the inflowing metal.

For further information relative to the various processes such as riveting, welding, boring, etc., which form an important part of foundry and forge shop work, see articles under the titles, Boiler Shop Terms, and Workshop Terms, in this Encyclopedia.

Consulting Civil and Mechanical Engineer.

Foundry Practice. *Casting.*— The casting of brass has been practiced from the earliest times and is mentioned in the oldest books of the Bible. Before the year 1300 wrought iron was made directly from the ore. It is nearly pure iron and cannot by ordinary methods be made sufficiently fluid to run into molds. By special methods in recent years it is made into steel castings (*q.v.*). At ordinary casting temperatures it is pasty and can be forged into various shapes. After 1300 cast iron was made which in addition to iron contains sufficient carbon and silicon to lower its melting point so that it can be made fluid. The presence of phosphorus, sulphur and manganese also influences the quality of cast iron. Until 1700 castings were generally made directly from the blast furnace in which cast iron was made from the ore.

The first casting known to have been made in America was a small round bottomed kettle with a cover. This was made at Lynn, Mass., in 1642 at the first blast furnace erected in this country. During the latter part of that century cast iron was remelted in crucible and in 1722 a French founder made the first primitive cupola in which the fuel and iron were placed in alternate layers. Foundry practice dates from that time. Before the beginning of the last century rarely more than a single casting was made from one pattern. Each new form required a different treatment.

The only foundry equipment until recent years was the cupola, a blower, a gib-crane, ladles, cleaning mills, sweeps for loam work and the molders individual tools: a shovel, bellows, rammer, and trowels, some of which are called slicks. By the duplication of castings from patterns in later years molders have become expert in special classes of work, especially when working by the piece. When large numbers of a single kind of castings are to be made a molding machine can be employed advantageously and these are rapidly coming into use. Machines can be operated with comparatively unskilled labor. Modern foundries are equipped with electricity and compressed air, travelling cranes and trolleys, which are used to transport materials, and to do the heavier part of the molder's work. While permanent metal molds are used for the softer metal castings, they have not been made successful for brass or iron.

Sand of various grades is used almost universally for molds and the founder's art consists in the making of sand molds. Molding sand is a mixture of silica sand and clay with from 10 to 15 per cent of impurities. It is strong if when dampened and pressed into shape it will not fall apart. Fine sand gives light castings a smooth skin. Heavy castings require a coarse open sand. The reddish color of molding sand comes from iron oxide. After the castings are removed from the sand it is shoveled into a row, then with the shovel, opened up and sprinkled evenly with water. The next morning beginning at one end the heap is cut over, giving each shovelful a twist to scatter the sand evenly over a new heap. About once a week enough new sand is added to make up for what is burned out.

Molding.— The different branches of molding have much in common. We will describe the simplest form and then show where the other forms differ.

Bench Molding.— The patterns for toys, hardware, small parts of stoves, light malleable iron, and many brass castings are made of metal, gated together so that the card of patterns is handled as a single piece. Melted iron is poured into a vertical sprue and runs to the mold through horizontal passages called gates. The card of patterns is bedded in a mold-board called a match which closely conforms to every parting or horizontal edge of the pattern.

The molder works standing, his match of patterns being placed on a frame or bench, with his heap of sand beneath and at the side. The mold is made in a snap flask, the lower part of which is the drag and the upper part the cope. These are guided together by flask-pins and both are hinged at the corner and hooked together at the opposite corners. The pattern is thoroughly brushed when the drag is inverted on the match. About half an inch of sand is riddled over the surface of the pattern. The drag is then heaped up with sand with a shovel. Then with a hand rammer, about 13 inches long, in each hand, the molder penes the edges of the drag twice around with the flat pene of the rammers, and levels off the surface with the side of the rammers. With the round butt ends the whole surface is rammed solid. The surplus sand is struck off with a straight edge, a little sand is sprinkled over the surface and a bottom board is rubbed to a fit. This with the drag and match are rolled over and the match is lifted off leaving the pattern bedded in the sand, when all loose sand is blown off with a bellows, and necessary repairs are made with a slick. The cope is put on, the sprue pattern is set on a pin in the gate pattern and a little parting sand is dusted over the surface. This burned parting sand cleaned from castings, prevents the cope from sticking to the drag.

The cope is rammed the same as the drag, the loose sand brushed off, the sprue removed and the hole smoothed with the fingers. The cope is lifted and placed on edge just behind the drag. The pattern is drawn and is held in the left hand while a bag of charcoal facing is shaken over the mold with the other. The pattern is printed back, rapped and drawn. The cope is then replaced on the drag, the flask is unhooked and the sand mold with its bottom board is set on the floor.

A molder in seven hours will make from 70 to 150 molds. They are stacked two or three high. Wooden frames or jackets are slipped over some molds to prevent the iron from bursting out at the sides. In pouring the molds, cast iron weights with slots in them to expose the sprue holes, are placed on the row of molds nearest the bench to prevent the iron from raising the cope. These weights are changed as fast as a row is poured.

Floor Molding. (Stove plate, etc.) — Each piece is molded in a wooden or in an iron flask. The cope is barred with cross bars six or seven inches apart, with the lower edges conforming to the shape of the inside of the pattern and about one inch away. If the bars are of iron they have holes cast in them and if of wood nails are driven in the lower edges to prevent the sand from dropping out. The pattern, usually of iron, is fitted to a wooden mold-board. The gates are generally separate from but set against the pattern. Whenever possible flat gates are used.

The molder's floor is perfectly level and generally of brick or cement. The sand heap extends the whole length and the flasks and mold-boards are piled at one side.

The pattern on its mold-board is placed on the front of the floor. The pattern is brushed, the drag is inverted on the board, sand is riddled on and then heaped up with a shovel.

The rammer for all floor work is about four feet long with a metal pene and butt. Sand is *pened* twice around the edge of the flask to prevent the iron running out and to make a hard parting. The sand is leveled with the hand and then stepping on the sand, by a series of backward jumps, the molder jumps it off, in rows lengthwise and crosswise. He then butts it all over, a little harder under the gates. He fits the bottom board, then removes it, cuts gutters across especially under where the gates will be and runs a vent wire one-eighth of an inch in diameter all over the drag nearly to the patterns. Then replacing the bottom board and clamping together the bottom board, drag and mold-board the mold is rolled over. After knocking the clamps off, the molder removes the mold-board, puts on the cope, and fastens it to the bottom board with clamps opposite each sprue. The sprue pattern is put in place, sand is riddled on, and then shoveled one quarter full. Then with a hand on each side of each bar, the sand is tucked with the fingers under the bar and around the sprues. The cope is heaped with sand and is pened around the sides of the cope and on each side of each bar. Then the sand is gathered by the hands between the bars and jumped off. The molder cleans the bars of sand and butts the sand all over, being careful not to hit the bars or the sand will not lift.

All loose sand is brushed off the surface of the mold and the sprue is removed. Metal wedges are pressed in between cope and drag at each corner, the clamps knocked off, and the wedges pushed clear in. The cope is rolled up nearly perpindicular and held there by an old file or piece of rod. The sprue is taken out and with a bellows all loose sand is blown from the drag and from the front and back of the cope. The sand is sponged at the edges of the pattern and the set gates.

After the pattern is drawn lead facing is dusted from a bag all over the mold to prevent the sand burning into the iron. Then charcoal facing is dusted on to prevent the lead sticking to the pattern. After printing the pattern back in the mold the set gates and pattern are drawn and the flask is closed and clamped. The iron should be poured as dull as possible to prevent the sand from burning into the iron. In the molding thus described the man molds the same piece over and over and becomes very expert, and generally working by the piece makes very good wages.

General Jobbing and Machinery Castings. (Roll Over Work.) — The previous description applies to this class also. Patterns are generally of wood and are made one-eighth inch per foot larger than the casting to make up for shrinkage. The pattern tapers at least one-eighth inch in a foot to help in drawing the pattern. Any overhanging parts of a pattern must be held by dowel-pins and such parts are drawn after the other part of the pattern is out.

It is better to have iron enter a mold from the bottom and for this purpose the sprue passes down to the bottom of the pattern and across to the mold through a hollow core molded into the drag. One or more risers are placed on the highest points of the mold through which the iron will rise after the mold is full. Dirt and gas will rise also and the riser may be large enough to allow churning with a rod to keep open a channel to the centre of the casting and through which melted iron may be poured to prevent spongy spots forming in the parts that cool last.

Flasks may be of three or more parts. Deep molds are rammed up in courses and harder in the lower portions to resist the head of metal. No soft spots, causing swells, or hard spots, causing scabs, must be made near the pattern. For heavy work about one inch of sand mixed with seal coal (ground bituminous coal) is riddled on all surfaces of the pattern to make a smooth casting.

When possible a pattern is made in two parts, divided at the parting line, allowing the drag part to be laid on a flat board. When an odd job is made without a mold-board a cope is inverted on a bottom board and rammed with sand and struck off. The pattern is roughly bedded in this sand.

Parting sand is thrown over the surface and the drag is rammed up. Then the mold is rolled over, the cope is taken off and the sand shaken out. The drag is then finished and the cope put on and the mold is finished.

Where there are deep places in the pattern the molder tucks sand around large nails with the heads down near the pattern, or sticks called soldiers, or gaggers, L pieces of rod or of cast iron the toe being near the pattern and the long end along the side of the bars. These must be tucked with the fingers and pened thoroughly. The molder then finishes the cope, venting thoroughly, especially around the sprues.

Molding by Bedding In.—In the foundry floor are pits filled with molding sand level with the floor. A hole is dug in this sand to take the pattern, around which the sand is packed. To allow for the escape of gas generated by a large quantity of iron, the hole is dug deeper than required for the pattern and a bed of very fine cinders is packed and connected by a pipe with the surface of the floor. The cinder bed is covered with sand. If the pattern is not deep or for open sand molds, the sand is leveled off even with the floor. Sand is packed in four small piles at the corners of the bed and two straight edges are leveled on these piles. Sand is tucked solid about these straight edges. Sand is then shoveled inside and outside and rammed hard outside the straight edges. The sand between is struck off.

After the molder has riddled sand three-quarters of an inch thick over the whole surface he places two strips about eight inches long and one-quarter to one-half inches thick on the ends of the straight edges. With a third straight edge on these strips he with his helper presses down first one end of the straight edge and then the other, moving across the bed, making all of an even hardness. He strikes off and vents all over the surface down to the cinder bed. Then with a fine sieve, a little facing sand is riddled over the whole surface and it is smoothed with a trowel. Strips of wood equal to the thickness of the casting are laid on the bed to represent the outside of the casting and the outside of the mold, and the gates are built up with sand. If pins or lugs are required on the lower surface, a pattern for them is pressed into the sand at the required points. A casting more than three inches thick is made with a cope.

Bedding In with a Cope.—If the upper surface of a casting is to be perfectly flat the cope with sprue holes may be rammed on any flat surface and can be set on the mold already bedded in the floor.

If a pattern with an uneven top surface has been bedded in the floor a cope is set in place and stakes are driven about it in the floor to insure its location, and the cope is then rammed. To raise the cope, flat boards are laid on the sand and with crowbars the corners are started, then it is lifted with the crane.

The cope is replaced and held down with iron weights so that the head of metal cannot raise it. Very large and complicated molds can be made in green sand. The mold may be formed by templets and by parts of patterns.

Sand may be built out from the sides by inserting anchors, or separate cores may be used. Such molds are faced by painting on lead facing with a camel's hair brush or by rubbing facing on with the hand.

Dry Sand Molds.—These are made from sand richer in loam than that used for green sand molds. They are made in iron flasks with iron bottom boards. The molding is substantially the same as green sand except that all joints are bevelled back from the mold so that when the cope is put on the edges will not crush. This causes a fin on the casting which is chipped off. The cope and drag are placed in an oven and thoroughly dried. Dry sand castings are more sound than if made in green sand.

Skin Dried Molds. (To obtain the advantages of dry sand molds, and of green sand bedded in work.)—Ordinary floor sand is used for the mold except the two inches of sand which faces the mold which is as rich in loam as for dry sand work. If the surface of an ordinary mold is to be only slightly dried, molasses water or thin clay water may be sprayed on the surface to make it strong when dry. A mold when finished is generally skin dried to a depth of one or more inches. Iron baskets filled with burning charcoal are hung in different parts of the mold or heated plates may be held near the surfaces or gas flames may be directed against the surfaces.

Loam Molding.—The body of the mold is built on iron plates with ordinary red brick laid in black mud, which is ordinary floor-sand mixed with clay wash. Some mix sawdust with the mud to make it porous and to help in drying the mold. Straw is sometimes laid in the joints for the same purpose. Pushing a vent wire between the joints also gives vent. This body is built about three-quarters of an inch away from the surface of the finished mold. On the brick surface is spread loam which is a mixture of sand, clay and water. This is faced off with trowels or sweeps. If the mold is circular such as a cylinder or a kettle, a spindle is located at the center of the mold. On this is fixed arms on which are fastened sweeps or templates. Made up cores are also used for giving shape to parts of the mold.

The outside or the inside of the mold with the bottom can be finished first as is most convenient. It is then taken to the oven by the crane. While this is drying the other part is built up and finished and dried. All parts are then put together, the bottom and top plates being bolted together with rods. A crib is built about the mold with steel or cast plates bolted together. Sand is rammed between the brick work and the casing, as hard as possible, forming also the gates for taking iron to the bottom of the mold. Water pipes and other specialty castings are made in iron molds fitted for the purpose and molding machines are used to a great extent for such work.

Every different pattern presents problems which require different treatment. Books on molding generally consist of descriptions of the making of molds for special castings and of difficulties encountered, but the ingenious methods familiar to all skilled molders are not described. One of the best descriptions of ordinary special processes is found in 'Appleton's Dictionary of Mechanics' under "Casting".

Cores are used in all classes of molds. An iron anchor may be coated with green sand and set in a mold. Dry sand cores are made of silica sand mixed with a binder such as floor, rosin or oil. When baked these binders make the core hard and strong, and the melted iron burns the binder so that the core sand falls out when the casting is cold. Cores are generally made in boxes. Wires or iron frames are molded in to give strength. Cores are vented by making channels with wires or by molding in a core and then drawing it out. For intricate cores cords of beeswax are molded in which melt out in baking. Cores are located by core prints in the mold left by the pattern and are held in place by chaplets of various shapes placed beneath to prevent sagging and above to prevent the iron from raising the cores. Nails forced into the mold are often used, the core resting on the heads. Tinning chaplets prevents rusting and helps the iron to fuse their surfaces.

Melting Iron.— Iron is melted in a cupola, a firebrick lined vertical cylinder in which is charged layers of coke and iron. A blower forces air through tuyers near the lower end. The melted iron is tapped out at the front into fire clay lined ladles and taken to the mold by hand ladles or by crane. For very large castings several cupolas are used and melted iron may be held in large ladles for some time while more is being melted. Air furnaces are also used for heavy castings.

Quality of Iron for Castings.— Silicon softens cast iron and decreases shrinkage, therefore a standard measure of shrinkage tells whether more or less silicon is needed. Strength depends very largely upon the size of grain, which is not wholly dependent upon the chemical composition. A thin portion of a casting shrinks more and sooner than a thick part which often causes fracture. It has been erroneously said that cast iron expands at the instant of solidification.

Iron becomes rigid at the surface of the mold while the central part is fluid. When all is solid, and just about as it ceases to be red hot, the casting expands more or less at the same time that carbon crystallizes into graphite. In a casting one inch square this expansion occurs about 15 minutes after the iron enters the mold but in a casting four inches square it occurs two hours after. This expansion at different times of parts of a casting of varying thickness, at the same time that the casting is shrinking unevenly from the loss of heat, produces severe strains which often fracture the casting. The remedy is to make all parts of equal thickness and to uncover thick portions as soon as solid.

William J. Keep,
Author of 'Cast Iron', etc.

Fountain, or **Artificial Fountain,** in hydraulics, a machine or contrivance by which water is violently spouted or darted up; called also a *jet d' eau.* There are various kinds of artificial fountains, but all formed by a pressure of one sort or another on the water, namely, either the pressure or weight of a head of water, or the pressure arising from the spring and elasticity of the air, etc. When these are formed by the pressure of a head of water, or any other fluid of the same kind with the fountain or jet, then will this spout up nearly to the same height as that head, abating only a little for the resistance of the air, with that of the adjutage or pipe from which the water spouts, etc., in the fluid rushing through; but when the jet is produced by any other force than the pressure of a column of the same fluid with itself, it will rise to such a height as is nearly equal to the altitude of a column of the same fluid, whose pressure is equal to the given force that produces the fountain. In ancient Greece every principal town had public fountains or conduits, some of which were of handsome design and of beautiful execution. The most famous of these were at Megara, at Corinth (the Pireñe and the Lerna), in the sacred wood of Æsculapius, at Epidaurus, and the two at Messina called Arisinoë and Clepsydra.

The ancient fondness for fountains still exists in Italy and the East. The French are celebrated for their fountains, but Italy, more particularly Rome, is still more so. The fountains of Paris and of the Tuileries, of the orangery at Versailles, at St. Cloud, and other places in the neighborhood, are splendid structures. The principal and most admired fountains at or near Rome are those in front of St. Peter's, of the Villa Aldobrandini at Frascati, of the Termini, of Mount Janiculum, of the gardens of the Belvedere, in the Vatican, of the Villa Borghese, which has also in the audience chamber a splendid fountain of silver, five Roman palms in height, ornamented with superb vases and flowers; the fountains of Trevi, the three fountains of St. Paul, of the Aqua Acetosa, etc.

In the United States the ornamental type of fountain is the one in common use. Large display fountains were attractive features of the Centennial Exhibition, and at the Chicago World's Fair and Buffalo Pan-American Exposition. Among these was the Fountain of the Republic of Chicago, which was designed by MacMonnies, and at Buffalo were costly examples dedicated to Man, Nature, Progress, etc. In Central Park, New York; Fairmount Park, Philadelphia; Lincoln Park, Chicago; Golden Gate Park, San Francisco, and other large parks, will be found numerous fountains of elaborate design. In all the larger cities drinking fountains for men and animals have been erected by individuals and local humane societies.

Fountain Pens. See LITERARY LABOR-SAVERS.

Fountains Abbey, one of the largest and best-preserved monastic edifices in England, in the West Riding of Yorkshire, 3 miles south-west of Ripon. Founded for Cistercians in 1132, it was not completed till the 16th century, and thus presents examples of every variety of style, from Norman to Perpendicular.

Fouqué, Friedrich Heinrich Karl, frēd'rĭh hīn'rĭh kärl foo-kā', BARON DE LA MOTTE, German poet and novelist: b. Brandenburg 12 Feb. 1777; d. Berlin 23 Jan. 1843. He was a grandson of H. A. Fouqué (q.v.); served as lieutenant of the Prussian guards in the campaign of 1792, and was present in 1813 at the most important battles in the War of Liberation. As a writer he is remarkable both for variety and fecundity, and has published poetry in almost all its forms — dramatic, epic, romantic, etc. Several of his short romantic tales in prose, such as 'Der Zauberring,' 'Aslauga's Ritter,' but more especially his 'Undine,' enjoy an extraordinary popularity. The last mentioned tale, a charming mixture of fairy ideality, the reality of humble life, and the glow of chivalry, has gone through many editions, and has been translated into every European language. It must be admitted that Fouqué, while possessing many of the virtues of the romantic school, was guilty of all its extravagances, and that the descriptions of chivalric and feudal life, in which he delighted, are mere fancy pictures.

Fouqué, Heinrich August, hīn'rĭh ow'goost, BARON DE LA MOTTE, Prussian general; b. The Hague, Holland, 4 April 1698; d. Brandenburg 2 May 1774. Fouqué possessed the confidence of Frederick the Great; and the 'Mémoires du Baron de la Motte Fouqué' (1788, by Büttner, the secretary of Fouqué), which contain his correspondence with Frederick the Great, are of great interest.

Fouquet, foo-kā, **Nicolas,** French statesman, VISCOUNT DE MELUN AND DE VAUX, AND MARQUIS OF BELLE ISLE; b. Paris 1615; d. Pignerol 23 March 1680. He received in 1650 the important appointment of procureur-général to the parliament of Paris, and three years later was advanced to be superintendent of finance. His rapid advance made him ambitious of succeeding Mazarin as first minister, but he had a formidable rival in Colbert. Fouquet's plans were, however, brought to naught; for in the first place Louis himself took the reins of power into his own hands when they slipped from the grasp of the dead cardinal, and in the second place, instigated thereto by Colbert, he suddenly arrested Fouquet in September 1661. After a trial extending over three years, Fouquet was sentenced to perpetual exile and the loss of all his property, but the sentence was afterward altered to life-long imprisonment. From the circumstance of his imprisonment at Pignerol, Fouquet, in spite of the fact that he died in 1680, has been identified with the Man With the Iron Mask (q.v.), who, however, lived till 1703.

Fouquier, foo-kē-ā, **Henry,** French publicist: b. Marseilles 1 Sept. 1838. After study of law and medicine he became a journalist in Paris, general-secretary of the prefecture of Marseilles (1870), and director of the press in the ministry of the interior. He wrote much for the *Figaro* and *XIX. Siècle,* but particularly for *Gil Blas,* under the pen-names "COLOMBINE" and "NESTOR," and was a founder of the *Echo de Paris.* In 1889 he was elected deputy for Alpes-Maritimes. His articles have been collected in several volumes under such titles as 'Etudes Artistiques' (1859); 'Au siècle dernier' (1884); 'La sagesse parisienne' (1859).

Fouquier-Tinville, Antoine Quentin, äṅ-twäṅ kĕn-tăṅ foo-kē-ā tăn-vēl, French revolutionist: b. Hérouelles, near St. Quentin, 1747; d. Paris 7 May 1795. As a member of the revolutionary tribunal he distinguished himself by his alacrity in pronouncing the verdict of guilty, and attracted the attention of Robespierre, who gave him the office of public accuser before this tribunal. The victims now became numberless. Fouquier drew up the scandalous articles of accusation against the queen, Marie Antoinette. His thirst for blood seems to have been increased by gratification, until it became a real insanity. He proposed the execution of Robespierre and all the members of the revolutionary tribunal 9th Thermidor, 1794, was himself removed on the 14th Thermidor (1 Aug.), 1794, and arrested. He died under the guillotine. There does not appear to be a trait in the life of this monster which can entitle his crimes to the same palliation as those of Robespierre, who considered the extermination of the aristocracy as a necessary evil. Consult Domenget, 'Fouquier-Tinville, et le tribunal révolutionnaire' (1878).

Four-eyed Fish, a fish of the genus *Anableps.*

Four-horned Antelope, or **Chousingha,** the genus *Tetraceros* of the antelope group, native to India, and differing from all other living ruminants in that the male generally bears two pairs of horns. It is closely related to the African duikerbok (q.v.), which it resembles in the position of its larger horns, and the shape of its eyes, as well as in other ways. The smaller horns rise from just above the eyes. This antelope is a pretty, brownish creature, standing about 25 inches at the withers, and is found from the foot of the Himalayas southward over India, in wooded hill-country, but it avoids dense jungles. It drinks daily, and hence never wanders far from the water. It is exceedingly shy, and escapes, when discovered, in a series of jerky, though very rapid, bounds, into the cover of long grass or low bushes.

Four Lakes, a chain of lakes in Dane County, Wis.; known respectively as First, Second, Third, and Fourth lakes. First Lake, the smallest and lowest of the chain, is about 3 miles long by 2 miles wide; Second Lake is 3½ miles long by 2 broad; Third Lake is 6½ miles long by 2 miles wide; Fourth Lake, the largest and most beautiful, is 6 miles long by 4 wide. The waters of these lakes are navigable for small steamers. The two last are now called lakes Monona and Mendota.

Four-o'clock. See FRIAR-BIRD.

Fourcroy, Antoine François de, äñ-twän fräñ-swä dė foor-krwä, French chemist: b. Paris 15 June 1755; d. 16 Dec. 1809. Having adopted the profession of medicine he applied himself closely to the study of the sciences connected with it, especially to chemistry, and published in 1776 a translation of Ramazzini's 'Treatise on the Diseases of Artisans.' He was professor of chemistry at the Jardin du Roi, 1780-1805. He organized the central school of public works, out of which the polytechnic school afterward sprang, and co-operated in the establishment of the normal schools. In 1799 Bonaparte gave him a place in the council of state, in which place he drew up a plan for a system of public instruction, which, with some alteration, was adopted. His works are numerous, among which the following are the most important: 'Leçons Elémentaires d'Histoire naturelle et de Chimie' (1791); 'Système des Connaissances chimiques, et de leurs Applications aux Phénomènes de la Nature et de l'Art' (1805); 'Philosophie chimique'; 'Tableaux synoptiques de Chimie' (1805); and 'La Médecine éclairée par les Sciences physiques.'

Fourdrinier (foor-drĭ-nēr') **Machine,** a paper-making machine, the first to make a continuous web. It was invented by Louis Robert, of Essonne, and patented by him in France. A Mr. Gamble and the brothers Fourdrinier improved it. The machine was perfected by others.

Fourier, François Charles Marie, fräñ-swä shärl mä-rē foo-rē-ā, French social economist: b Besançon 7 April 1772; d. Paris 10 Oct. 1837. He studied at the college in his native town, and obtained a mercantile position at Rouen; he later entered into business on his own account at Lyons, having inherited a small fortune from his father, but the siege of the city by the troops of the convention in 1793 and the subsequent disorders were fatal to his prosperity; he was arrested and kept a prisoner for some time, and afterward served two years in the Revolutionary army. When he was 19, while employed at Marseilles, his employers retained a cargo of rice in order to keep up the price, and when it became unfit for use ordered Fourier to throw it into the sea. This experience led him to question the righteousness of the existing industrial system and to develop his own social theory known as Fourierism (q.v.). He first published 'Theorie des quatre Mouvements et des Destinées generales' (1808), in which he explained the basis of his system, which he developed more completely in 'Traite de l'Association domestique agricole' (1822), republished under the title 'Theorie de l'Unité universelle,' and in 'Le Nouveau Monde' (1829-30). See Pellarin, 'Charles Fourier, sa vie et sa théorie' (5th ed. 1871; American translation, 1845).

Fourier, Jean Baptiste Joseph, zhŏñ bäp-tēst zhō-zĕf, BARON, French mathematician: b. Auxerre, France, 21 March 1768; d. 16 May 1830. He was an active Jacobin during the French Revolution. His later energies were divorced from politics and given up to science. 'Analytical Theory of Heat' (1822) is his most noted work; but in mathematics his speculations and methods are of high permanent utility.

Fourierism, foo'rĭ-ėr-ĭzm, the social system advocated by F. M. C. Fourier (q.v.). It was based on the theory that the social order depends upon fixed moral and intellectual laws, and that man must discover and live according to these laws. According to Fourier society must be so organized as to give freedom to the passions or desires of man, since these are naturally capable of harmony, and, if developed under proper conditions, would, in accordance with the law of attraction, lead to a perfect society. In this society industry should be carried on by phalanxes, each phalanx to be divided into series, and the series combined in groups; each group was to have charge of one kind of work, and each series of one special branch of that work. In the distribution of products a certain minimum was to be assigned to each member of the society, whether capable of labor or not; the remainder to be shared in certain proportions to be previously determined among the three elements, labor, talent, and capital. The capital of the community might be owned in unequal shares by different members of the community; inheritance was to be permitted, and the individuals could expend the remuneration they received as they pleased. The government was to be republican, with elective officers. Fourierism, though socialistic, is not properly socialism, and is related to modern socialism by its sharp criticism of existing conditions, rather than by its plan for the future of society.

Fourierism won many converts in France; among those who advocated the theory were Victor Considerant and Mennier; an association was formed; a periodical, the 'Phalange,' was published for a short time; and a number of communities were organized in accordance with the Fourieristic plan, none of which long survived. Fourierism was introduced into the United States in 1842, by Albert Brisbane, who for a time published 'The Phalanx,' in New York. He was welcomed by the members of the Brook Farm community, and the Fourieristic organization was adopted there. For a time the 'Brook Farm Phalanx' published 'The Harbinger,' the most important periodical published by the Fourierists in the United States. An organization, known as the American Union of Associationists, was formed for the "popular diffusion of the principles of the associative sciences as discovered by Charles Fourier, with a view to their ultimate realization by the establishment of phalanxes." Horace Greeley (q.v.) became its president, and George Ripley (q.v.) secretary. A large convention of the "associationists" was held in New York in 1844. In 1847 'The Harbinger' was transferred to New York under the charge of this association, and was published till 1849. About 34 communities were organized by the Fourierists, of which the most important (besides Brook Farm) were the North American Phalanx, which lived 12 years, and the Wisconsin Phalanx. Most of them existed but a short time, and by 1850 the Fourierist movement had practically come to an end. Consult: Brisbane, 'Social Destiny of Man'; Ely, 'French and German Socialism'; Noyes, 'History of American Socialisms'; Shaw, 'A Forgotten Socialism' ('New England Magazine,' new series Vol. VIII., p. 773). See BROOK FARM; COMMUNISM; NORTH AMERICAN PHALANX; SOCIALISM.

Fourier Series, in mathematics, a trigonometric series first extensively employed by the French mathematician Jean Baptiste Joseph

Fourier, in connection with the theory of the movement of heat in a solid body. It was primarily intended for effecting the development of an arbitrary periodic function in the form of a series whose terms are sines and cosines of increasing multiples of the variable. The subject is too technical for discussion in a general encyclopædia. Consult: Fourier, 'The Analytical Theory of Heat' (translated by Alexander Freeman); and more especially, Byerly, 'An Elementary Treatise on Fourier's Series, and Spherical, Cylindrical, and Ellipsoidal Harmonics.'

Fourth Nerve, one of the pair of cranial nerves, and the chief motor nerve of the superior oblique muscle of the eye. It originates in a group of cells in the floor of the medulla and runs outward over the superior elevator muscle of the eyelid, and is distributed to the orbital surface of the superior oblique.

Fourth State of Matter. See ELECTRON; MATTER; RADIUM.

Foussa. See FOSSA.

Fouthill Abbey. See BECKFORD, WILLIAM.

Fouke (originally Smith), Gerard, American archæologist: b. Maysville, Ky., 25 June 1855. In 1885–8 and 1891–3 he was connected with the United States Bureau of Ethnology in surveys and explorations of aboriginal remains in the eastern part of the country. Further research by him includes explorations for the American Museum of Natural History, New York, on the lower portion of the Amur River, Siberia, and on Vancouver's Island, British Columbia; and excavations of so-called Norse remains in the vicinity of Boston, Mass. His published writings comprise essays on archæological subjects in the bulletins and reports of the Bureau of Ethnology and elsewhere.

Fowl, a word originally synonymous with bird, now used in a stricter sense to designate the genus *Gallus,* of which the common domestic fowl (cock and hen) is a familiar example. The general form and characters of the bill, feet, etc., agree with those of the pheasants, but the crown of the head is generally naked and furnished with a fleshy comb, the base of the lower mandibles also bearing fleshy lobes or wattles — characters which are most conspicuous in the males. The jungle fowl of India (*Gallus ferrugineus,* or *bankiva*) is regarded as the source of domestic poultry; it is known also in southern China and throughout the Malay islands. The male closely resembles the game-cock. The comb and wattles are of the brightest scarlet, the long hackles of the neck and lower parts of the back are fine orange-red, the upper part of the back is deep blue-black, and the shoulders ruddy chestnut. The long, arched, and drooping tail is blue-black, glossed with green, and the breast and under parts black. The word is also commonly applied in such combinations as wildfowl, waterfowl, seafowl, and the like. For the characteristic of domestic fowls, see POULTRY.

Fowler, Charles Henry, American Methodist clergyman: b. Burford, Ontario, Canada, 11 Aug. 1837. He was graduated at Genesee College in 1859 and at the Garrett Biblical Institute in 1861; studied law; was pastor for 11 years in Chicago, Ill.; president of the Northwestern University in 1872–6; and corresponding secretary of the Missionary Society in 1880. He was elected a bishop of the Methodist Episcopal Church in 1884; visited Japan, Korea, and China in 1888; organized the Peking and Nanking universities; was stationed for eight years on the Pacific coast; founded the Maclay College of Theology in Southern California, and assisted in founding Wesleyan University in Lincoln, Neb. He was sent as a fraternal delegate to the Wesleyan Conference in Great Britain in 1898.

Fowler, Ellen Thorneycroft, English novelist. She is the daughter of Sir Henry Fowler, secretary of state for India 1894–5. Her published works include: 'Verses Grave and Gay' (1891); 'Verses Wise and Otherwise' (1895); 'Concerning Isabel Carnaby' (1898); 'A Double Thread' (1899); 'The Farringdons' (1900); 'Love's Argument' (1900); 'Sirius, and Other Stories' (1901); 'Fuel of Fire' (1902).

Fowler, Frank, American artist: b. Brooklyn, N. Y., 12 July 1852. He studied at Florence as pupil of Edwin White, at Paris with Carolus Duran and in the Beaux-Arts, established a studio at New York in 1880, and became known as a portrait painter. His subjects include S. J. Tilden, Archbishop Corrigan, C. A. Dana, and other notabilities. He was elected a National Academician, and has published manuals of art: 'Oil Painting'; 'Drawing in Charcoal and Crayon'; 'Portrait and Figure Painting.'

Fowler, SIR John, English civil engineer: b. near Sheffield 1817; d. London 20 Nov. 1898. In 1844 he was appointed to superintend the construction of the Manchester, Sheffield, and Lincolnshire system, a connected group of railways, and other works of vast extent and complexity. He subsequently was employed on many civil engineering works both in England and elsewhere; but the work with which his name will probably be most lastingly connected is the great bridge across the Forth, of which he was chief engineer, having as his colleague Sir Benjamin Baker. (See BRIDGE.) On its completion in 1890 he was made a baronet.

Fowler, Joseph S., American lawyer: b. Steubenville, Ohio, 31 Aug. 1820; d. 1902. He became professor of mathematics at Franklin College, Tenn., and was president of the Howard Female College in Gallatin, Tenn., in 1856–61. Subsequently he was State comptroller under Andrew Johnson, and was a United States senator 1866–71. In 1871 he retired from political life and engaged in law practice in Washington, D. C.

Fowler, Lorenzo Niles, American phrenologist: b. 1811; d. 1896. He was a brother of Orson Squire Fowler (q.v.). From 1863 he resided in England. He was a publisher of the 'Science of Health' (originally the 'Water-Cure Journal') and the 'American Phrenological Journal,' and wrote 'Phrenology and Physiology' (1844).

Fowler, Montagu, English Anglican clergyman: b. London 12 Nov. 1858. He was educated at Harrow and Cambridge; took orders in the Established Church, was vicar of St. Lawrence, Isle of Thanet, Kent, 1889–93, and has been rector of All Hallows, London Wall, from 1900. He has published: 'Christian Egypt'; 'Some Notable Archbishops of Canterbury'; 'Church History in Queen Victoria's Reign.'

Fowler, Orson Squire, American phrenologist: b. Cohocton, Steuben County, N. Y., 11 Oct. 1809; d. Sharon, Conn., 18 Aug. 1887. He was graduated at Amherst College in 1834, and opened a phrenological office in New York in 1835. In 1836 he and his brother Lorenzo wrote and published 'Phrenology Proved, Illustrated and Applied,' and in 1838 issued the first number of the 'American Phrenological Journal.' Subsequently he lectured on his specialty and allied subjects in the United States and Canada, and wrote and published numerous books, including 'Self-Culture and Perfection of Character'; 'The Self Instructor in Phrenology'; 'Human Science'; etc.

Fowler, Thomas, English philosopher: b. Burton-Stather, Lincolnshire, 1 Sept. 1832. He was educated at Merton College, Oxford, and from 1873 to 1889 was professor of logic in the university. Since 1881 he has been president of Corpus Christi College. His published works include: 'Elements of Deductive Logic' (1867; 10th ed. 1892); 'Elements of Inductive Logic' (1870; 6th ed. 1892); an edition of Bacon's 'Novum Organum,' with introduction and notes (1878; 2d ed. 1889); a little work on 'Locke' (1880); an edition of Locke's 'Essay on the Conduct of the Understanding' (1881; 3d ed. 1890); 'Francis Bacon' (1881); 'Shaftesbury' (1882); 'Hutcheson' (1882); 'Progressive Morality: an Essay in Ethics' (1884; 2d ed. 1895); 'History of Corpus Christi College, Oxford' (1893); 'Principles of Morals' (Part I., introduction written with J. M. Wilson, 1885; Part II., the body of the work, by Prof. Fowler alone, 1887; both in one volume, revised 1894); and 'Popular History of Corpus Christi College' (1898).

Fowler, William Warde, English ornithologist: b. Somerset 1847. He was educated at Marlborough College and Oxford, and has been sub-rector of Lincoln College, Oxford, from 1884. He has published: 'A Year With the Birds' (1886); 'Tales of the Birds' (1888); 'Life of Julius Cæsar' (1892); 'The City-State of the Greeks and Romans' (1893); 'Summer Studies of Birds and Books' (1895); 'The Roman Festivals of the Republican Period' (1899); 'More Tales of the Birds' (1902).

Fowler, William Worthington, American author: b. Middlebury, Vt., 24 June 1833; d. Durham, Conn., 18 Sept. 1881. He was the author of 'Ten Years in Wall Street' (1870); 'Fighting Fire' (1873); 'Woman on the American Frontier' (1877); 'Twenty Years of Inside Life in Wall Street' (1880).

Fowler's Solution. See Arsenic.

Fox, Charles James, English statesman: b. London 24 Jan. 1749; d. Chiswick, Surrey, 13 Sept. 1806. He was the son of Henry, 1st Lord Holland, and was educated at Eton and Hertford College, Oxford. His father procured him a seat for the borough of Midhurst in 1768 before he was of legal age, and in 1770 the same interest procured him the office of one of the lords of the admiralty, which post he resigned in 1772, and was appointed a commissioner of the treasury.

After being a supporter of the administration for six years, Fox was ejected owing to a quarrel with Lord North, and was thrown into the ranks of the Opposition. The adoption of the disastrous measures which terminated in the independence of the American colonies enabled him to take this part without opposing any of the policy which he had previously supported. During the whole of this eventful contest he spoke and voted in direct opposition to the ministerial system, and, in conjunction with Burke, Barré, Dunning, and other eminent parliamentary leaders, displayed the highest talents both as a statesman and orator. On the final defeat of the administration of Lord North and the accession of that of the Marquis of Rockingham, Fox obtained the office of secretary of state for foreign affairs. But the death of the Marquis of Rockingham suddenly divided the party, and on the Earl of Shelburne becoming first lord of the treasury Fox retired and soon after a union took place between his friends and those of Lord North, under the name of the coalition. The temporary success of this party movement served only to render popular disgust the more general; and the dismissal of the coalition excited general satisfaction. Though in the new Parliament Pitt had a decided majority, Fox headed a very strong opposition, and political questions were for some years contested with a display of talent on both sides which the House of Commons had seldom previously exhibited.

In 1790 and 1791 Fox regained a share of popularity by his opposition to war with Spain and Russia, and also by his libel bill, regulating the rights of juries in criminal cases and rendering them judges both of the law and the fact. On the breaking out of the French Revolution he was disposed to regard it as likely to prove extremely beneficial. The contrary views of Burke, and the extraordinary manner in which that ardent politician on that account publicly renounced his friendship, is one of the most striking incidents in parliamentary history.

The opinions formed of this eminent leader as a practical and theoretical statesman have been as various as the shades of party difference. That he was a sincere friend to all the broad and generous principles on the due development of which rest the freedom and best interests of mankind, is not to be doubted, and that they were alloyed by great latitude on the subject of party and political expediency is equally clear. As a powerful and purely argumentative orator he was of the very first class; though as to eloquence and brilliancy he perhaps yielded to Pitt, Burke, and Sheridan; nor were his voice and manner prepossessing, though highly forcible. Of his amiability in private life, after making allowance for a dissipated youth, all accounts agree. Friends and foes equally testify to his ingenuous and benign character. As an author, besides some Latin poetry and a Greek dialogue, by which he highly distinguished himself at Eton, and a few numbers of a paper, entitled 'The Englishman,' he published nothing during his lifetime but 'A Letter to the Electors of Westminster' (1793). To his nephew, Lord Holland, the world is indebted for his posthumous publication, entitled 'The History of the Early Part of the Reign of James II.' It is written with unpretending simplicity, but disappointed expectation, and has never been popular. See Lord John Russell, 'Life and Times of C. J. Fox' (1859–66); Wakeman, 'Life of Charles James Fox' (1890); Trevelyan, 'Early History of Charles James Fox' (1881).

Fox, George, English religionist, founder of the Society of Friends: b. Drayton, Leicestershire, England, July 1624; d. London 13 Jan. 1690. While yet a boy he was distinguished by his gravity and exemplary conduct. When in the 20th year of his age, and for some two or three years afterward, Fox describes himself as having been in a distressed state of mind, but from this condition he was at length delivered by that which he regarded as the voice of God in his soul, directing him to Christ as alone able "to speak to his condition." Very soon after this he commenced his public ministrations at Dukinfield, Manchester, and the neighborhood. From the first his preaching seems to have made many converts and excited much opposition. Fox's first imprisonment took place in the year 1648, in consequence of his opposing the preacher in "the great steeple-house at Nottingham," on a point of doctrine. In 1650 he was imprisoned at Derby under a false charge of blasphemy. One of the committing justices, Bennet, acted with great violence on this occasion, and it was he who on Fox's bidding him "tremble at the word of the Lord" first applied to him and his friends the name of Quakers. Fox lay in prison at Derby for about a year, the time having been lengthened in consequence of his refusal to accept a commission as captain of one of the regiments then being raised by Parliament. To his belief of the unlawfulness of all war, which prompted this refusal, was added at the same time a clear view of the enormity of the punishment of death for crimes affecting property only, and he exerted himself to save the life of a poor woman then in jail for theft. Within 10 years of Fox's appearance as a preacher, meetings of the Friends were established in most parts of England. At the same time, so actively were they persecuted, that for many years there were seldom less than 1,000 of them in prison. Cromwell, though himself favorable to liberty of conscience, seems to have been unable to curb the excesses of popular hostility launched in all quarters against a sect which denounced all state interference with religion and maintained that the gospel should be preached without fee or reward. About a month after the restoration of Charles II., Fox was committed to Lancaster Castle, "on the charge of being a common disturber of the peace, and of endeavoring to make insurrection and embroil the whole kingdom in blood." After lying in jail some months, a habeas corpus was obtained, and the authorities showed their disbelief of these grave charges by allowing Fox himself, unbailed and unguarded, to convey to London the sheriff's return to the writ. The hopes entertained by the members of the young society that they would be allowed a breathing-time from persecution were dispelled at the commencement of 1661 by the atrocious measures which followed the mad attempt of Venner and his Fifth-Monarchy men. The act empowering magistrates to tender the oaths of allegiance and supremacy to any person whom they thought fit to suspect, also operated with great severity against the Friends; under its provisions Fox was committed to prison at Lancaster in the beginning of 1664, whence he was removed to Scarborough Castle, where he lay till the autumn of 1666. In 1669 Fox married Margaret Fell, the widow of one of the judges of the Welsh courts. The year 1670 witnessed the passing of the most stringent of the Conventicle Acts, forbidding under heavy penalties the assembling for religious worship, in any house, of more than four persons besides the family, except according to the usages of the Church of England. Soon after his recovery from a severe illness he sailed for Barbadoes, where he exerted himself greatly in the interests of religion and humanity. It was while in this island that Fox drew up a statement of his own and his friends' belief in all the great doctrines of Christianity — a statement clearly disproving their alleged sympathy with Socinian tenets. After a considerable time spent in Barbadoes, Jamaica, and the North American continent, he returned to England in 1673, where further persecutions awaited him. He underwent 14 months' imprisonment in Worcester jail, and was at length liberated by the Court of King's Bench on account of the errors in his indictment. In 1677, in company with Penn and Barclay, who had joined the Society about 10 years before, he paid a visit to Holland and some parts of Germany, where his services seem to have been well received. The last 15 years of his life were tranquil as regards personal molestation, but he continued to be actively engaged in various ways in promoting the welfare of his brethren. Their persecutions continued throughout the reign of Charles II. In the first year of William and Mary was passed the bill which nullified the Conventicle Acts, and allowed the Friends to make a solemn declaration in lieu of taking the oaths, and Fox had the gratification of seeing the public worship of the Society legally recognized before his death. (See FRIENDS, SOCIETY OF.) His works were issued in three volumes 1694–1700. Consult: Sewell, 'History of the Quakers'; Lives by Marsh (1848); Janney (1853); Watson (1860); Tallack, 'George Fox, the Friends and the Early Baptists' (1868); Bickley, 'George Fox and the Early Quakers' (1884).

Fox, George L., American actor: b. Boston, Mass., 3 July 1825; d. 24 Oct. 1877. He first appeared at the Tremont Street Theatre in the 'Hunter of the Alps'; became known as a low comedian at the National Theatre, New York; was a lieutenant in the Union army at Bull Run, and later became manager of the New Bowery Theatre. Here he gained for himself a distinct position by his burlesque imitations of favorite tragedians of the time, and his pantomimes, the best of which was 'Humpty Dumpty,' in which from 1867 to his retirement in 1876 he appeared as the clown.

Fox, Gustavus Vasa, American naval officer: b. Saugus, Mass., 13 June 1821; d. New York 29 Oct. 1883. He was appointed to the United States navy in 1838, in which he served till 1856, when he resigned with the rank of lieutenant. He was subsequently appointed assistant secretary of the navy, and held this post till the end of the Civil War. He planned a number of operations for the navy, including the capture of New Orleans; and was sent by the government on the Monitor Miantonomoh to convey the congratulations of Congress to Alexander II., on his escape from assassination. His visit to Russia materially aided the acquisition of Alaska by the United States, and was the longest voyage then made in a monitor.

Fox, John William, American novelist: b. Bourbon County, Ky., 1863. He was graduated from Harvard 1883 and has published: 'Hell for Sartain and Other Stories' (1897); 'A Mountain Europa' (1899); 'The Kentuckians' (1898); 'Crittenden' (1900); 'Blue Grass and Rhododendron' (1901); 'The Little Shepherd of Kingdom Come' (1903).

Fox, Margaret, American spiritualist: b. Bath, Canada, 1836; d. Brooklyn, N. Y., 8 March 1893. She was about 12 years old when her family were startled by mysterious rappings. All endeavors to trace them to any physical source proved unavailing. Various experiments were tried, but the "occult" power refused to act save in the presence of Margaret and her sister Leah. The family moved to Rochester, N. Y., but the raps followed and heavy bodies were moved without appreciable agency. In 1849 the sisters appeared in a public hall; when the same phenomena were freely manifested and tested. In 1850 the two girls went to New York, the "manifestations" became the subject of public discussion, and "mediums" sprang up all over the country. In 1888 Margaret made a public exposure of her pretended "manifestations," which she subsequently contradicted.

Fox, William Carlton, American diplomatist: b. St. Louis, Mo., 20 May 1855. He first came into prominence as United States consul at Brunswick, Germany (1876–88). Subsequently he was United States vice-consul-general at Teheran, Persia. He organized the American Missionary Hospital during the cholera epidemic there in 1892, and established and edited the only strictly diplomatic and consular journal ever attempted in the United States.

Fox, William Freeman, American forester: b. Ballston Spa, N. Y., 11 Jan. 1840. He was graduated at Union College in 1860; studied engineering; served in the Civil War; and subsequently took charge of the Department of Forestry of New York State. He is the author of: 'Regimental Losses in the Civil War'; 'The Adirondack Spruce'; 'State Forestry Reports' for 1885–1901; and magazine articles on forestry, etc.

Fox, William Johnson, English orator and political writer: b. near Wrenthaum, England, 1786; d. London 3 June 1864. A weaver's son, he early showed signs of ability and was picked out to be educated for the Independent ministry. Once ordained, his rationalistic opinions cut him off from all the denominations. He became a radical active in politics, and spoke and wrote with persistent vehemence against the Common Laws. He was elected to Parliament in 1847, but was twice defeated at subsequent elections. His vigorous pen and eloquent voice aided the cause of popular social and political progress in England at a critical time in her history.

Fox, one of a group of small, long-eared, bushy-tailed animals of the dog-tribe (*Canidæ*), mostly included in the genus *Vulpes;* specifically, in literary usage, the red fox (*V. vulgaris*), called *renard* by the French and *reinicke fuchs* by the Germans. Foxes differ from wolves and jackals in being smaller, having shorter legs, longer, more furry and pointed ears, a more slender elongated muzzle, and a longer and more bushy tail; and they incline to that yellowish red color called "foxy." But these distinctions are difficult of limitation (see FENNEC; FOX-DOG), and some naturalists refuse to recognize a separate genus for them. One fixed character is found in the pupil of the eye, which when contracted becomes elliptical in the foxes but remains round in other dogs. All the typical foxes are inhabitants of northerly latitudes, and well represented by the common red fox, which may be regarded as distributed throughout the whole northern hemisphere, though variously named in different countries, where local diversities exhibit themselves; thus the American variety is called *V. pennsylvanicus,* but it is not essentially different from those of the Old World. Its variations are as great here as in Europe and Asia, especially among those of the Far North, where certain color-phases have superior value in the fur-trade. Thus a fox marked with a dark line along the spine and another over the shoulders, is called a "cross" fox, and fine specimens are worth an extra price. Wholly black ones are uncommon; but the rarest and most valuable pelt is that of a "silver" fox, that is, a black one in which so many hairs are white-tipped that a hoary or silvered appearance is given to the skin. The red fox is fostered for the sport of fox-hunting (q.v.) in Great Britain, and in some parts of Eastern America, but in most countries he is regarded merely as a fur-bearer, or a poultry thief or worse, and is trapped, shot and poisoned continuously. Nevertheless, the animal survives and multiplies in the midst of civilization, by virtue of its power of comprehension of and adaptation to new conditions; so that he has acquired, very justly, a reputation for alertness, wit and cunning in contrivance for food and safety. In America this species is constantly extending its range southward at the expense of the gray fox. Another species yielding a valuable fur is the Arctic or blue fox (*V. lagopus*), which is found on all Arctic coasts, and although brownish in summer, becomes in winter pure white; but the under fur is always bluish, and in those of Alaska this color prevails over brown in summer. Certain of the Aleutian Islands have lately been devoted by local fur companies to the rearing of these foxes in semi-captivity, where they are cared for, and a selected number annually sacrificed to trade. North America has two other well-marked species. One is the swift or kit fox (*V. velox*) of the plains, which is only 20 inches long, exceedingly swift of foot, expert in digging and cunning at concealment. It has reddish-yellow fur in summer, but becomes dull gray in winter, with black patches each side of the nose. The other species is the gray fox, which was once generally distributed over the United States but has become extinct in the northeastern part since the general clearing and settlement of the country. It is a woodland animal, still numerous in the South and West. Its hair is stiffer and duller in color than that of the red fox, and it is so peculiar in structural respects (among others in having a concealed mane of stiff hairs on the top of the tail) that it has been classified in a separate genus as *Urocyon argenteus.* Several well-known species dwell in Asia, the best-known of which is the familiar fox of northern India (*V. bengalensis*).

Foxes everywhere are burrowing animals or else adapt to family needs holes in rocks, hollows of old stumps, and similar conveniences. They hide by day and go abroad at night in search of small prey, stalking and catching birds on their nests, or at roost on the ground. ground-squirrels, mice, frogs, and insects, and also eating largely of certain roots, fruits and other vegetable food. They are hardy, hunt all winter and climb mountain peaks. They never hunt in packs, as do wolves; and their voice is nearer a bark than a howl. They do not readily submit to domestication, and seem to have contributed little if anything to the composition of domestic breeds of dogs.

Consult for information on Old World foxes, the writings of Bell, Brehm, Blanford, Mivart and Beddard, well-summed up in Lydekker's 'Royal Natural History,' Vol. I. For American foxes, read Richardson, Hearne, Audubon, Merriam, the writings of Nelson, Turner and Murdoch on the natural history of Alaska, and the general remarks in Cram and Stone's 'American Animals' (1902).

Fox Bats. See Flying-fox.

Fox Channel, in the Hudson Bay, Canada, named after Luke Fox, who explored the region in 1631. The channel lies between Southampton Island and Baffin Land.

Fox-dog, a name given by certain naturalists to the wild dogs of South America, because of their fox-like appearance. Among these are the crab-eating dog (*C. cancrivorous*); the zono, or Azara's dog (*C. azaræ*), of which the "colpeo" of the pampas and southward is probably a local variety; the small-eared Brazilian dog (*C. microtis*, of Mivart), and two other aberrant Brazilian dogs (*C. urostictus*, and *C. parvidens*) for which a separate genus (*Nothocyon*) has been proposed by Wortman. All these animals have a striking external resemblance in color and form to the foxes, and connect them with the typical dogs. They are not well known, however. Consult: Mivart in the 'Proceedings' of the Zoological Society of London (1890); Beddard, 'Mammalia' (1902), and writers upon the zoology of South America. See Bush-dog.

Fox-hound, a breed of hounds, concerning whose origin practically nothing is known, save that they were probably first bred in Great Britain. This, perhaps the handsomest and most perfect of all hounds, is essentially a field dog, presenting an eminently powerful, well-built appearance, with his clean-cut, compact body, and giving evidence of muscular strength and endurance in the hunt. The head is full, with a broad brow, a long, wide muzzle, and open nostrils. The ears are set low and lie close to the cheek. The eyes are soft and brown. The chest is broad, and the ribs are deep, so as to afford plenty of breathing space. The muscular body is set on legs as straight as a post, and very strong; and the feet are round and cat-like. The color varies from black to tan and white, and the coat is hard, smooth and glossy. The American breed is lighter and finer in lines than the English fox-hound, has longer, thinner, and more pendant ears; a slightly narrower chest, and a rougher coat. He is used in fox-hunting as is the English fox-hound; but is also employed in hunting the moose, and other large game, especially in the Canadian forests. See Dog.

Fox-hunting, the chase of the fox with horses and hounds, as a recreation. This sport arose in England with the Restoration, when changes in customs and agricultural conditions caused the disappearance of falconry, and has become surrounded by codes of social usage and of legal enactments. It flourishes most in the south-central counties of England, and in Ireland, and some of the principal organizations or "hunts" as the Belvoir, Quorn, Pytchley and Cottesmore, were founded early in the 17th century. A "hunt" is an association for the promotion and regular practice of the sport in a certain district. It acquires a pack or several packs of fox-hounds (q.v.), kennels and perhaps a club-house, is directed by a "master of fox-hounds," and served by paid employees, the principal of whom are the "huntsman" who arranges and leads the sport for the day, and the "whippers-in," who see that the dogs work properly. These officials, and the sportsmen themselves wear "pink" (that is scarlet) coats when in the field. The expenses are paid theoretically by annual subscriptions, eked out by casual subscriptions for temporary privileges, but usually they must be supplemented by a patron,— probably the "M. F. H.," who has inherited the dignity and its responsibilities from ancestors who founded the hunt. Anyone may join in the chase, and at Melton Mowbray and other famous "meets" large numbers of outsiders are often present. In these districts foxes are carefully preserved, and the abode and habits of each family of them are studied with reference to the autumnal and winter sport. At the appointed time the hunters, men and women, mounted and accompanied by a pack of from 25 to 40 hounds, are led by the huntsman toward the place where he expects to "find" a fox. There the dogs are loosed, and range about searching for the scent-traces in the air or on the ground left by the recent passage of the animal. When one finds a trail he gives tongue, the others come to his aid and the pack dash away following the scent. With a bugle-signal or cry of "Gone away!" the hunt follows as straight and fast as possible, keeping to roads, lanes, and gates where possible, but jumping fences and riding over grain-fields and meadows where needful, the hunt paying such damages as follow. This requires a horse of great speed and leaping power, and has developed the English thoroughbred hunter. When anyone catches sight of the fox he shouts "View! halloa!"; and the ambition of all riders is to keep close to the racing animals and be on the spot, or "in at the death," when the fox is seized. It is then the duty of the huntsman, or the nearest rider, to save the body of the fox from the dogs, cut off its "brush" (tail), "pads" (feet), and "mask" (head) to be given as trophies to the foremost riders. The remainder of the fox is cut up and given to the dogs on the spot. Instead of running "straight away" and leading a long chase the fox will often take refuge in a drain or other hole, unless it has been "stopped." This is called "going to earth," and he must then be ousted by the aid of a fox-terrier.

Fox-hunting has been carried wherever Englishmen have settled, but has found few parts of the world favorable to it. In some countries, as on the North American prairies, in California, and in the Argentine Republic, similar methods are adapted to the chase of other animals, as wolves or kangaroos. In the southern and eastern United States, however, where foxes abound, true fox-hunting has flourished ever since colonial days, when each man brought his own hound or hounds to the assembly; and

RED FOX

FOXES.

1. Cape Fox or Lalande's Dog. 2. Arctic Fox. 3. Side-striped Jackal or Quaha.
4. Silver Fox. 5. Corsac.

is still pursued by several established clubs in Virginia, Maryland, and southern Pennsylvania, where the nature of the country and the agricultural habits of the people favor it. These clubs employ a modified form of hound better adapted to the faster and rougher work required of it than would be the English breed. A special strain, the Magnes hound, has been fostered by the Maryland clubs, the foremost of which is the Elkridge. More nearly conforming to the English models is the establishment and hunting of the Meadowbrook Hunt, on Long Island, N. Y., where, in a level open country, largely occupied by extensive estates and within easy reach of New York, the sport has flourished since about 1876, and is likely to be long maintained.

An extensive and pleasing literature has grown up about this subject, and many thousands of titles would be required for its bibliography. A good general view may be obtained by reading the volumes devoted to the sport in the English 'Badminton Library' and in the American 'Sportsman's Library.'

Fox Indians (French name Renards, «foxes,» from their fox-totem; their own name Musquaki, «red-earthers»; Ojibwa name Outagami, «other-siders»), an Algonkian tribe originally on Lake Superior; driven by the Ojibwa and French south of the Wisconsin River, where their losses forced them about 1760 to unite with the Sacs or Sauks. Hence from early in our acquaintance with them the joint tribe has been known as «Sacs and Foxes,» and they have practically coalesced. They joined the British in the Revolution, and again in the War of 1812; their lands gradually taken away, they moved westward into Iowa, were involved in the Black Hawk war and gave up more land, finally gathered on the Des Moines, and in 1842 were removed to the Osage.

Fox Islands. See ALEUTIAN ISLANDS.

Fox River, a river of Wisconsin, called by the Indians Neenah. It rises in Marquette County, near the centre of the State, and after a course of about 200 miles passes through Lake Winnebago; it enters the head of Green Bay. A canal has been cut from Fox River to the Wisconsin, which is a navigable affluent of the Mississippi, and the channel of the river below Lake Winnebago has been cleared to admit steamboats from Lake Michigan and Green Bay. A grant of land was made by Congress to assist the work.

Fox Shark, or Sea-fox. See THRESHER.

Fox-snake, a large harmless snake (*Caluber vulpinus*) of the northern Mississippi valley, light brown in color, marked on the back with small chocolate spots bordered by black, and with a series of smaller spots along the sides and on the yellowish abdomen. It reaches a length of three feet, is irritable and pugnacious, and feeds upon small mammals, especially gophers, mice, and other pests of agriculture.

Fox-sparrow, a large American sparrow (*Passerella iliaca*), notable for its foxy red plumage, and gay song. It is a spring-and-fall migrant in the United States, breeding only north of the Saint Lawrence. See SPARROW.

Fox-squirrel, the largest of the true squirrels (*Sciuriss niger*). These rusty-coated squirrels are denizens of woods. They live in hollow trees or high among the branches, in nests of dry grass, and feed upon fruits, berries, mushrooms, and seeds of various trees. They have been hunted until they have become somewhat scarce in the woods north of Virginia; but southward, they are far more numerous. The flesh is esteemed as food — especially in Florida. Though safe from the depredations of preying birds, because of their size and strength, fox-squirrels are attacked by the foxes and wildcats, which kill and eat them.

Fox-terrier, a small terrier dog modified from the old-fashioned English white terrier of uncertain origin. It has a dense smooth coat white, with black or black-and-tan markings; and a small black nose; and it generally weighs between 15 and 20 pounds, when in good condition. The fox-terrier has a narrow, tapering face, and small, deep-set eyes, usually gentle, but capable of an expression of keen animation; the jaws are strong and well-shaped; and the V-shaped ears droop forward close to the cheek. The compact little body is set on straight, supple legs, and the tail, usually docked, is carried in a rather jaunty fashion. The dog's appearance is one of alertness; and, though originally bred to run the fox to earth, fox-terriers have, latterly, become popular not only as vermin-destroyers about stables, but as house-dogs,— their cleanly, sprightly, and affectionate ways rendering them extremely amiable and entertaining as companions. One variety, the «wire-haired,» has a rather long coat, of rather shaggy appearance. In all other points this is like the smooth-coated variety. See DOG.

Foxe, John, English martyrologist: b. Boston, Lincolnshire, 1516; d. London April 1587. In 1543 he was elected a fellow of Magdalen College, Oxford. Applying himself to theology with great assiduity, he secretly became a convert to the principles of the Reformation. This tendency being suspected, a charge of heresy followed, and by the judgment of his college he was, in 1545, expelled. In the reign of Mary he went abroad, and gained a livelihood by correcting the press for an eminent printer at Basel, where he laid the first plan of his 'Acts and Monuments of the Church.' On the accession of Elizabeth he returned to his native country, and was received in the most friendly manner by his former pupil, the Duke of Norfolk, who maintained him as long as he lived, and settled a pension on him at his death. Cecil also obtained for him a prebend in the Church of Salisbury. His principal work is the 'History of the Acts and Monuments of the Church' commonly called 'Foxe's Book of Martyrs,' first printed in 1563, in 1 volume folio: reprinted in 1632 and 1641 in 3 volumes folio. In 1684 it had reached the ninth edition.

Foxglove. See DIGITALIS.

Foy, fwä, **Maximilien Sebastien,** French military officer: b. Ham, France, 3 Feb. 1775; d. Paris 28 Nov. 1825. He entered the army at 15, and made his first campaign under Dumouriez in 1792. He received his 15th wound on the field of Waterloo, but refused to quit his post till the close of that engagement. He was afterward employed as inspector-general of infantry; and in 1819 was elected a member of the Chamber of Deputies, where he distinguished himself as an orator, and was a great public favorite.

Fra Angelico, än-gĕl'ē-kō, the common appellation of Fra Giovanni da Fiesole, one of the most celebrated of the early Italian painters: b. Vecchio, 1387; d. Rome, 18 March 1455. He entered the Dominican order in 1407, and was employed by Cosmo de Medici in painting the monastery of St. Mark and the Church of St. Annunziata with frescoes. These gained him so much celebrity that Nicholas V. invited him to Rome to ornament his private chapel in the Vatican, and offered him the archbishopric of Florence, which was declined. His works were considered unrivaled in finish and in sweetness and harmony of color, and were made the models for religious painters of his own and succeeding generations. See Cartwright, 'The Painters of Florence' (1901).

Fra Diavolo, frä dē-ä'vō-lō, real name **Michele Pezza**, Neapolitan brigand: b. Itri, Calabria, 1760: d. 1806. He became a monk, but was expelled on account of misconduct. He then became leader of a troop of brigands. The government set a price upon his head; but when Cardinal Ruffo undertook to compel the French to evacuate Naples, Fra Diavolo was pardoned, was employed by the cardinal, and received a colonel's commission. At the head of his band he harassed the French, took refuge in Calabria after the conquest of Naples by Bonaparte, and incited the people against the French. He fell into their hands at San Severino in 1806, and was executed.

Fracastorio, Girolamo, jē-rō'lä-mō frä-käs-tō'rē-ō, Italian poet and physician: b. Verona 1483; d. Tacassi 6 Aug. 1553. He was patronized by Cardinal Bembo, to whom he addressed the most celebrated of his works, a Latin poem entitled 'Syphilis.' In the latter part of his life he wrote a poem on the adventures of the patriarch Joseph, but his poetic fire seems then to have been exhausted, and the virtues of the hero were less happily celebrated than the horrors of the disease. Among the moderns who have exercised their talents in the composition of Latin verse, few have obtained higher reputation than Fracastorio.

Frackleton, Susan Stuart Goodrich, American artist: b. Milwaukee, Wis., 5 June 1848. She received a private education, and became prominent as a ceramic artist. She has won many prizes in American, European, Canadian, and Mexican competition; invented a gas-kiln for firing decorated china and glass; and was the founder and first president of the National League of Mineral Painters. In 1901 she received a medal at the Paris Exposition for her exhibit of pottery. She published 'Tried by Fire,' a work on china decoration (1885).

Fraction, a part of any integer (whole number), or unit. For example, "two and a fraction" means two units and that part of a unit which can be distinguished, as one half, two fifths, and so on. In the fraction $\frac{1}{3}$ in arithmetic, or $\frac{a}{b}$ in algebra, the figure 1, or a, is the numerator, and 3, or b, is the denominator; and they represent that, if a whole number is divided into three or b parts, only one or a parts are taken. In the addition of fractions, the fractions must be brought down to the same denominator, and their numerators (as expressed in the value of their new denominator) must then be added, when we have one whole fraction. Thus, if we want to add $\frac{1}{3}$ and $\frac{2}{5}$, we must find the least common multiple of 3 and 5, which is found to be 15; then, as 3 goes 5 times into 15, and 5 goes 3 times into the same number, we multiply the numerators of the different fractions by these respective quotients, and then add the two quantities together. Thus, $\frac{1}{3}$ added to $\frac{2}{5}$ will be equal to $\frac{5}{15}+\frac{6}{15}=\frac{11}{15}$. The true definition of a fraction may be thus summed up: It is the division of its numerator by its denominator; as seven eights are equivalent to the whole number 7 divided by 8 — whence a fraction is obtained. Decimal fractions simplify calculations greatly, as they are constructed on the principle of having one common denominator — a multiple of 10; and thus fractions can be added, subtracted, and divided without repeating over and over the tedious process of bringing them down to a common denominator. See ARITHMETIC; DECIMALS.

Fracture, a break or solution of continuity in a bone, caused by sudden application of violence from without or by sudden muscular strains. Bone diseases and the changes in bone incident to old age predispose to breaks. Compound fractures are those in which a wound allows a communication between the injured bone and the body surface. A fracture is said to be multiple when there is more than one line of cleavage; when the lines of cleavage are joined, the fracture is spoken of as comminuted. Pain in the affected part and more or less loss of function are usually present. Examination reveals a deformity either as a swelling or a deviation from the normal line of the part; palpation elicits exquisite tenderness on direct pressure at the point of injury and on moving the fragments; the bony irregularity may be felt beneath the skin; frequently an abnormal point of mobility may be discovered; crepitus is present as a peculiar grating sensation transmitted to the examining fingers if the ends of the bone can be rubbed together.

Repair of the injury takes place through certain blood-cells organizing the clot of blood and forming a fibrous callus. Later this callus is absorbed and a bony callus formed, the lime-salts being laid down in orderly arrangement by special cells. Nature is assisted in this process by fixation of the fragments in their normal position. This reduction of the deformity requires surgical skill, and all unnecessary manipulation of a bone supposed to be fractured should be avoided. Where removal of the injured from the scene of the accident is necessary, further damage may be prevented by the careful restriction of motion of the part. This can be done by the application of splints or by otherwise securing the part.

Compound fractures are serious because of the great possibility of infection gaining access to the injured bone, with resulting inflammation and necrosis. Measures of fixation are modified to allow of careful aseptic wound-dressing.

The diagnosis of fracture is frequently a matter of great difficulty, so closely may it resemble in its signs a bruise or dislocation. The X-rays render great service in differentiation and study of the kind of break.

Pott's fracture is the name given to a fracture of the lower extremity of the leg-bones, usually accompanied by a turning out of the foot. The ankle-joint is commonly injured and the ligaments ruptured so that more or less permanent disability is usual. Colles' fracture is a break of the lower end of the radius, having generally a characteristic deformity. The upper fragment is jammed down toward the rest and overrides the lower fragment, which is pushed forward. Falls upon the open hand are often apt to cause this injury. Fractures of the patella or kneepan are difficult to treat, owing to the constant pull of the strong muscles on the upper fragment. Entire apposition of the fragments and bony union is rarely possible unless wiring is resorted to. This injury is frequently a result of sudden muscular strain. The upper end of the femur or thigh-bone is frequently fractured in the aged. When the patient is old or feeble the long-continued rest in the recumbent position which is necessary to proper union so lowers the vitality that deformity is frequently accepted through fear of a fatal termination.

Fractures of the skull-bones present some unique features because of the peculiar structure of the bones in two tables, the globe-like arrangement of the skull as a whole, and of the juxtaposition of the easily injured brain. Lines of fracture may travel far from the actual point of injury, and a breaking force may travel to an opposite pole of the skull. The ordinary signs of fracture are absent except the deformity which usually is found as a crack or depression. The element of depression of the fragments is of the greatest importance, usually necessitating the operation of trephining for the relief of cerebral pressure. This operation consists in the removal of the fragments or of the indented area. Hemorrhage from a fracture may cause pressure and necessitate similar relief. Fatal termination is common, particularly where the inaccessible base of the skull is involved.

Fra'denburgh, J. N., American Methodist clergyman: b. Gouverneur, N. Y., 4 March 1843. He was graduated from Genesee College, was professor of mathematics in the Genesee Wesleyan Seminary (1868–9), of ancient languages in the Fredonia Normal School (1869–73), and principal of the Mansfield (Pa.) Normal School (1873–5). After pastorates at Cleveland, Ohio, and elsewhere, he was settled in 1896 at Clarion, Pa. He has published: 'Witnesses from the Dust' (1885); 'Beauty Crowned' (1887); 'Living Religions' (1888); 'Departed Gods' (1891); 'Fire from Strange Altars' (1891); 'Light from Egypt' (1897); 'Life's Springtime' (1900).

Framingham, Mass., a town in Middlesex County, on the Sudbury River, and on the New York, N. H. & H., and the Boston & A. R.R.'s; about 20 miles west of Boston. It comprises the villages of Framingham, South Framingham, and Saxonville. It has a large industry in woolen goods, and an assessed property valuation of nearly $9,000,000. Pop. (1900) 11,302.

Franc, a French silver coin, containing 10 décimes and 100 centimes. Value in American money 20 cents.

Français, François Louis, frän-swä loo-ē frän-sā, French painter: b. Plombières, department of Vosges, 17 Nov. 1814; d. 1897. He was a pupil of Corot and Gigoux at the Beaux Arts, first exhibited at the Salon in 1837, obtained a medal of the first class at the Salon of 1848, and was admitted a member of the Institute in 1890. He became best known as a landscapist, particularly for his views of the Paris environs and glimpses of the Seine. His finest work, 'Daphnis and Chloë,' is in the Luxembourg, together with three other canvases, 'Evening,' 'Orpheus,' and 'The End of Winter.' His style is peculiarly individual in its combination of realism and idealism.

France, fräns, **Anatole.** See THIBAULT, JACQUES ANATOLE.

France, Joseph, French publicist: b. Lorraine 1787; d. 1869. Having entered the French army in 1815, he had become a colonel in 1834, and in 1836–46 was commander of military police in the island of Martinique, West Indies. The publication of his 'La vérité et des faits' (1841), a work descriptive of the ill-treatment of negro slaves in the island, caused his removal from his post and trial for sedition. He was deprived of his commission, but subsequent to the abolition of slavery in the French colonies (1848) was elected from Martinique to the Constituent Assembly, and from 1852 was a member of the council of the island. His publications include: 'Les corsaires français dans les Antilles' (1857); 'Questions coloniales' (1860); 'Statistique de la Martinique' (1861).

France, fräns, **Lewis Browne,** American author: b. Washington, D. C., 8 Aug. 1833; d. Denver, Col., 8 June 1907. He was educated at Georgetown College, and entered the practice of law in Colorado, of whose supreme court reports he edited volumes III.-XI. He wrote: 'Rod and Line' (1884); 'Mountain Trails and Parks in Colorado' (1886); 'Over the Old Trail' (1894); 'Pine Valley' (1897).

France, in ancient times called Gallia, a maritime country in the west of Europe, since 1870 the largest and most prominent republic in Europe, and the second largest in the world. France is situated between lat. 42° 20' and 51° 5' N.; and lon. 4° 50' W. and 7° 40' E., and is bounded north by the German Ocean and the Straits of Dover; northwest by the English Channel; west by the Atlantic, more especially that part of it called the Bay of Biscay; south by Spain and the Mediterranean Sea; east by Italy, Switzerland, and the German territory of Alsace; northeast by German Lorraine, Luxembourg, and Belgium. The longest lines which can be drawn across France are two diagonals, which intersect each other — the one from the southeast to the northwest extremities, 670 miles, and the other, from the southwest to the northeast extremities, 555 miles. Measured on the meridian of Dunkirk, the greatest length is 600 miles, and measured on the parallel of 48° 20', the greatest breadth is 547 miles. The breadth near the centre is 400 miles, and along the parallel of 46° 15', where it is narrowest, does not exceed 340 miles. The total area of France is 207,054 square miles.

Topography.— While protected by great natural barriers at most parts where it is connected with the continent, a long line of coast on the west and northwest gives it immediate access to the great ocean thoroughfare, while on the south its harbors in the Mediterranean secure to it a large share in the traffic of that most important of all inland seas. France is traversed from southwest to northeast by several chains of mountains forming the general water-shed of the country. This water shed has two slopes, the one toward the west and north, carrying its waters to the Bay of Biscay, the Atlantic Ocean, the English Channel, and the German Ocean; the other toward the east and south, carrying its waters to the Mediterranean. The ranges of mountains and hills forming this water shed include the western and central Pyrenees, the western Corbières in the department of Aude, the Cevennes, the mountains of Vivarais, Lyonnais, Beaujolais, and Charollais, the Côte d'Or, the Plateau de Langres, the Faucilles Mountains, and the Vosges. This general water shed is met toward the northeast by the eastern mountain ranges of France, namely, the Jura range and various Alpine ranges, one of the peaks of which is Mont Blanc, which may be regarded as the culminating point of the European mountains, although not absolutely the highest mountain in Europe. Near the centre of France, and separate from the great water shed of the country, are several groups of volcanic mountains known by the general name of the Mountains of Auvergne, the chief peaks of which are the Plomb du Cantal in the southernmost group, the Puy de Sancy in the central group, and the Puy de Dôme in the northernmost group. The spurs thrown off by the great water shed divide France into six principal basins, five of which are on the northwestern slope, and one on the southeastern.

Rivers and Lakes.— The great rivers of France are the Seine, Garonne, Loire, Charente, Adour, Meuse, and the Rhône. In the basin of the Garonne are its affluents, the Ariège, Tarn, Lot, and Dordogne on the right bank, and the Gers on the left bank. To the north of the basin of the Garonne is that of the Loire and its tributaries, the Nièvre and the Maine on the right bank, and the Allier, Loiret, Cher, Indre, Vienne, and Sèvre Nantaise on the left. To this basin also belong the secondary basins of the Vilaine and the Blavet. In the basin of the Seine are its tributaries, the Aude, Marne, and Oise on the right bank, and the Yonne, Loing, Eure, and Rille on the left bank. The secondary basins are that of the Somme in the north, and those of the Orne and Oise in the south. In the basin of the Meuse are its tributaries, the Sambre on its left bank, to which is added the secondary basin of the Escaut or Schelde. The basin of the Rhône occupies the whole of the territory of France which lies to the southeast of the great water-shed. The tributaries of the Rhône are the Ain, the Saône, the Ardèche, and the Gard upon the right bank, and the Isère, Drôme, and Durance on the left. The secondary basins are those of the Var, Argens, and Arc on the east, and those of the Tet, Aude, and Hérault on the west. France has in all more than 212 navigable streams, with a total navigation of 5,700 miles. The lakes are few in number, and individually limited in extent. The largest, Grand-Lieu, in the department of Loire-Inférieure, covers an area of only 27 square miles, and is altogether devoid of interest. The next largest, St. Point, in the Jura, does not cover three square miles. Others of still less dimensions become more interesting from their localities in the lofty regions of the Pyrenees, or in the deep hollows of ancient craters in Auvergne.

Geology.— France possesses all the geological formations in a greater or less degree of development. The mountains generally have a nucleus of granite, which accordingly forms a prevailing rock in the Alps, on the east frontier, and their branches south to the shores of the Mediterranean, in the Pyrenees, the Cevennes, and the elevated plateau of Langres. In the Vosges it is more sparingly developed, its place being often occupied by porphyry; and in the Jura, where limestone occurs in such enormous masses as to have given its name to a peculiar formation. The other crystalline rocks, consisting chiefly of trachytes and basalts, have received a magnificent development in Auvergne, where whole mountains are composed of them, and where the effects of remote volcanic agency are still presented to the eye in extinct craters and lava streams. The granite is overlaid by primitive stratified rocks of gneiss, and of micaceous and argillaceous slates, succeeded, particularly in the Pyrenees, by mountain limestone. The secondary formation, commencing with this limestone and continued in ascending series up to the chalk, always possesses peculiar interest, because within it valuable mines of lead and iron, and all the workable seams of coal, are included. It is largely developed in many parts of France, and furnishes a considerable number of coal and mineral fields. The Tertiary formation, including all the limestones, sands, and clays, above the chalk, occurs continuously in two great divisions, and partially in a number of isolated spots, and covers a vast extent of surface. The larger continuous division is in the southwest, where it commences at the foot of the Pyrenees, and occupies a very large portion of the basins of the Garonne and of the Adour. The lesser but better known division takes the name of the Paris basin, and has been made familiar to the scientific world by the labors of Cuvier and other distinguished naturalists.

Climate.— The climate of France is greatly diversified, and cannot be described accurately without dividing it into different regions. With a very limited exception, it lies wholly within the more moderate portion of the temperate zone. France may be divided into four climatic regions according to the different vegetable products which different districts are able to mature. Within the first, and warmest, the olive is successfully cultivated. It forms the southeast part of France, and is chiefly confined to the departments which border on the Mediterranean. The second region is characterized by the general cultivation of maize or Indian corn. The third region reaches north to the extreme limit of the profitable culture of the vine, and may be considered as determined by a line stretching between the mouth of the Loire and the town of Mézières, in the department of Ardennes. All the country beyond this line is included in the fourth region. In the northwest the prevalence of winds from that direction often produces a superfluity of moisture, which manifests itself in mists or in frequent and heavy showers of rain. At the opposite extremity, the southeast, a contrary effect is produced, and a sultry, stifling wind wrinkles up

the skin, and not unfrequently spreads fever in its most malignant form. But it is only to a few exceptional districts that these remarks apply. After allowing for them, more than four fifths of the surface remains, under an atmosphere remarkable, more especially in its central districts, for salubrity, serenity, and brightness.

Political Divisions.— Before the revolution of 1789 France was divided into general governments, the number of which has varied at different epochs. Under Francis I., by whom they were instituted, there were 9. Under Henry III. there were 12. Under Louis XIV. the number was fixed at 32, to which a 33d was added by the acquisition of Corsica, under Louis XV. In 1789, when the love of change became paramount, the provinces were not permitted to escape; and it was then determined that the whole of France, including the island of Corsica, should be parceled out into departments, and each department subdivided successively into arrondissements, cantons, and communes, an arrangement which was actually carried out in 1790. This division has since maintained its ground, each department being named after the most important physical feature which it contains. The number of departments was originally 83, but it has been at different times increased and decreased. There are now 87 departments, the last formed being Haut-Rhin (Belfort). As the old provinces, though no longer recognized in legal and other formal documents, continue so familiar to the French themselves, and are so frequently mentioned, not only by earlier writers, but in the geographical, historical, and statistical works of the present day, a table is here given exhibiting these provinces in alphabetical order, and in parallel columns, the chief town in each, and the departments most nearly corresponding to them:

Provinces	Departments	Capitals of Provinces
Alsace	(Now German, except Belfort, or dep. Haut-Rhin)	Strasbourg (German)
Anjou	Maine-et-Loire	Angers
Artois	Inland or southeastern portion of Pas-de-Calais	Arras
Aunis	Maritime part of Charente-Inférieure	LaRochelle
Auvergne	Puy-de-Dôme and Cantal	Clermont
Béarn-et-Navarre	Basses-Pyrénées	Pau
Berry	Cher, Indre	Bourges
Bourbonnais	Allier	Moulins
Bourgogne	Ain, Côte-d'Or, Saône-et-Loire, Yonne	Dijon
Bretagne	Côtes-du-Nord, Finistère, Ille-et-Vilaine, Loire-Inférieure, Morbihan	Rennes
Champagne	Ardennes, Aube, Marne, Haute-Marne	Troyes
Corsica	Corse	Ajaccio
Dauphiné	Hautes-Alpes, Drôme, Isère	Grenoble
Flandre	Nord	Lille
Foix	Ariège	Foix
Franche Comté	Doubs, Jura, Haute-Saône	Besançon
Gascogne-et-Guyenne	Aveyron, Dordogne, Gers, Gironde, Lot, Lot-et-Garonne, Landes, Hautes-Pyrénées, Tarn-et-Garonne	Bordeaux
Ile de France	Oise, Seine, Seine-et-Oise, Seine-et-Marne, southern part of Aisne	Paris
Languedoc	Ardèche, Aude, Gard, Hérault, Haute-Garonne, Haute-Loire, Lozère, Tarn	Toulouse
Limousin	Corrèze, Haute-Vienne	Limoges
Lorraine	Meuse, Vosges, Meurthe-et-Moselle (and German Lorraine)	Nancy
Lyonnais	Loire, Rhône	Lyon
Maine	Mayenne, Sarthe	Le Mans
Marche	Creuse	Guéret
Nivernais	Nièvre	Nevers
Normandie	Calvados, Eure, Manche, Orne, Seine-Inférieure	Rouen
Orléanais	Eure-et-Loire, Loiret, Loir-et-Cher	Orléans
Picardie	Somme, maritime part of Pas-de-Calais, N. part of Aisne	Amiens
Poitou	Deux-Sèvres, Vendée, Vienne	Poitiers
Provence	Basses-Alpes, Bouches-du-Rhône, Var, eastern part of Vaucluse	Aix
Roussillon	Pyrénées-Orientales	Perpignan
Saintonge and Angoumois	Charente and eastern or inland part of Charente-Inf.	Angoulême
Touraine	Indre-et-Loire	Tours

The following territories have been acquired since 1790:

Territories	Departments
Avignon and Venaissin (including Orange previously acquired)	Part of Vaucluse
Nice	Alpes-Maritimes
Savoie	Savoie, Haute-Savoie

Agriculture.— About nine tenths of the soil of France is productive, and about one half of the whole French territory is under the plough. In regard to the management of arable land, the French are still far behind the English, but have nevertheless made great advances during the 19th century. During the last 50 years the production of cereals in France has increased by nearly 70 per cent, while the extent of land under cereals increased by only one quarter. This is equivalent to saying that the productiveness of the soil has increased in that time by fully one third. The cereals forming the great bulk of the cultivated crops are wheat, oats, rye, and barley. The crops next in importance to these are meslin or mixed corn, potatoes, hemp, rape, maize, buckwheat, flax, and beet. This last plant is cultivated extensively in some departments, especially in that of Nord, for the manufacture of sugar. The most valuable crops of which the cultivation on a great scale is not general, but confined to particular districts, are madder, tobacco, saffron, and hops. The cultivation of tobacco is monopolized by the government, and is confined to certain departments. It yields an annual gross revenue to the government of about $75,000,000, but from this total there falls to be deducted the expense incurred in the cultivation and manufacture of the tobacco. In France the grass is on a much more limited scale than the arable husbandry, the land in permanent meadow being in extent only one sixth of that under the plough. The breeding of stock, notwithstanding the stimulus afforded by the establishment of numerous societies, general and local, for its encouragement, is, in France, if not imperfectly understood, very indifferently practised. The races of oxen, instead of being confined to a few of the more perfect types, are almost as various as the different districts into which the country is divided, and include a few good breeds, particularly in the rich plains of Lower Normandy. The rearing of sheep is more successful, and much wool, scarcely inferior to that of the merino, is raised. The general employment of cattle for agricultural purposes gives little encouragement to the rearing of draft horses; but the warlike propensities of the nation have always created an extensive demand for horses. Asses and mules, generally of a superior description, are much used in France. The cultivation of the vine is one of the most important branches of French agriculture. The total quantity of land in vineyards is nearly a twenty-fifth of the whole surface; but as there are extensive and continuous districts where there are no vineyards, the proportion which vine-land on the districts properly adapted to it bears to the whole land under cultivation, attains a much higher ratio. The various first-class wines, under the name of Champagne, Burgundy, Bordeaux, etc., are in high repute and general demand over all Europe. In 1901 France produced 1,784,854,500 gallons of wine. A large part of the wealth of France consists in its fruits. Among the most important fruit-trees are the apple, the fruit of which, in the northern districts, particularly in Normandy, is largely used for the manufacture of cider; the chestnut, which, in barren districts yields an article of food which takes the place of the cereals among the poorer classes; the mulberry-tree, cultivated in 8 or 10 departments in the southeast, both for its fruit and its leaves, the leaves being used as food for the silkworms, on which the French silk manufacture depends; the olive, which grows in the same districts as the mulberry; the pear, plum, cherry, apricot, peach, orange, citron, fig, almond, etc. The forests of France occupy about one seventh part of the whole territory. Their principal localities are the Ardennes, Vosges, and Plateau de Langres, in the northeast; the Jura in the east; and the mountains of Auvergne in the centre. The chief constituents of French forests are the oak, the elm, the pine, the fir, the larch, the birch, the beech.

Mineral Resources.— The coal-fields of France are so numerous that coal-pits exist in no fewer than 33 departments; but most of these are very limited in extent. Several of the smaller fields occur in the northwest, and also in the south, where both anthracite and lignite are found; but the fields whose importance entitle them to particular notice are only two — that of Valenciennes in the northeast, forming the western extremity of the great Belgian coal-field, and that of St. Etienne, to which the manufactures of that town, Lyons, and the surrounding districts, are indebted for much of their prosperity. The annual output is over 30,000,000 tons, but falls so far short of the annual consumption that a large import takes place from England and Belgium, and wood continues to be the common fuel throughout France, at least for domestic purposes. The coal-fields contain seams of iron, which are extensively worked, and furnish ore to a great number of blast-furnaces. Though the number of mines actually worked is great, the quantity of foundry pig annually produced is only about 2,500,000 tons. Few countries have been said to be so rich in lead as France. It occurs in greater or less quantity in a great number of districts, and is generally argentiferous. Manganese is very widely diffused, but is worked only in a few mines. Gold exists both in the sands of rivers and *in situ* in thin streaks embedded in quartz. Attempts have been made to work it, but not with success. A vein of quicksilver was opened about the middle of the 18th century, and was worked successfully for 12 years, and then abandoned. Zinc, copper, arsenic, nickel, and cobalt exist, but not in such quantities as to be workable to profit. The principal saline substances are alum and common salt. The great sources from which salt is derived are the lagoons and salt marshes which line many parts of the coast. Of these the produce is about 300,000 tons. A large revenue is also derived from quarries, and beds of common clay, potter's earth, and kaolin.

France — History from the Revolution to the Establishment of the Empire, 1796–1804. This period is one of the most important in French history, and from beginning to end its events centre about one man — Napoleon Bonaparte. From the outset Napoleon was hampered by popular unrest, for the people had only recently emerged from a bloody revolution and were clamoring for they knew not what; petty jealousies, conspiracies, plots and counter-plots dominated politics; suspicion and distrust of everybody and everything pervaded the atmosphere; the finances were in a disgraceful condition; commerce and industry were in a state of stagnation; the laws were unsatisfactory and, poor as they were, remained unenforced; the army was ill-fed, poorly paid, and lacked a controlling hand; and relations with foreign nations were strained to such an extent that war threatened on every side. The first significant step in his path toward power was the placing of the armies of France under Napoleon's command and at his disposal. Thus the opportunity was within his grasp and the means provided whereby he could carry out his personal ambitions and at the same time promote the progress and welfare of the entire nation. Whether or not his love for the country or his commiseration for the pathetic state in which he found her were secondary in his mind to his personal aggrandizement matters little; it is certain that from that time the destiny of France was indissolubly linked with his rise or fall; upon his success or failure depended the continuance of the French entity; from that time his master mind and subtle genius and mighty hand were the most potent factors in raising France from the pit of anarchy and degradation to the heights of pride as the most powerful nation of the world; from that time his history was French history — Napoleon was France.

In order to understand the conditions existing at this time and to follow the steps by which Napoleon attained his remarkable position, we must go back into the reign of Louis XVI. and study the events which resulted in the Reign of Terror, the Revolution, and the establishment of democracy.

Louis XVI., son of the Dauphin and grandson of Louis XV., ascended the throne on the death of the latter, 10 May 1774. Hardly had he been crowned when war broke out with England, in consequence of the support afforded by France to the revolted American colonies of Great Britain. A treaty of commerce and alliance with the United States was signed 6 Feb.

1778, and was followed by an immediate declaration of war by England. The war was successful in its immediate object, and was terminated by the Treaty of Versailles, 3 Sept. 1783. Three years afterward a commercial treaty was concluded with England. The first difficulty of Louis' government, however, and the rock upon which it split was the hopeless and unmanageable condition of the public finances. Maurepas, Turgot, Malesherbes, Clugny de Nuis, Necker, Joly de Fleury, d'Ormesson, Charles-Alexandre de Calonne, Loménie de Brienne and others signally failed to ward off impending disaster and resigned or were dismissed, and finally the King was forced to convoke the States-General at Versailles 5 May 1789. Owing to disputes between the three parties represented — the nobility, the clergy, and the Third Estate — the attempt to solve the difficulties was abortive. The King assumed a hostile attitude and committed several acts which angered the public, the chief of which was the dismissal of Necker who a second time had been called to the financial portfolio, and in June 1789 it became necessary to bring foreign troops to Paris to overawe the assembly. The people demanded arms and the Hotel de Ville at Paris supplied them; blood was shed there on 12 July; and on the 14th the Bastile was captured and destroyed. The *garde bourgeoise*, formed by the municipality, was now transformed into the national guard with Lafayette as commander. The spirit of insurrection in the meantime had, since the beginning of 1789, been spreading in the provinces, sections of the country were swept by a panic called the "Great Fear," and the urgency of affairs induced the assembly, on 4 August, to take a decisive step. On the basis of a future compensation all privileges were abolished. A banquet given to the foreign troops at Versailles at a time when the populace was threatened with famine excited another insurrection. Versailles was attacked by the mob, and the King brought a prisoner to Paris (5 and 6 Oct. 1789).

In December 1790, the King began to correspond secretly with foreign powers, and a secret convention had been made with Austria, Prussia, Piedmont, Spain, and Switzerland, to advance their troops to the frontiers with a view to a simultaneous occupation of the territory. Louis then made his escape from Paris (20 June 1791), and endeavored to reach Montmédy; but he was recognized on the road, arrested at Varennes, and brought back to Paris escorted by the commissaries of the assembly. A demonstration in the Champ de Mars, in favor of his deposition (17 July), was put down by force by Lafayette and Bailly, under order of the assembly.

On 30 Sept. 1791, the assembly brought its work to a finish, after having redeemed its oath of 20 June. The constitution was sworn to by the King on 14 September, after which he was reinstated in his functions. The constitution embraced all those civil reforms which, afterward incorporated in the code of Napoleon, survived the political changes of the Revolution. It deprived the King of arbitrary powers, and voted him a civil list; it provided liberty of worship, freedom of the press, of commerce, of industry; the laws of primogeniture and entail were abolished, and equal division of property among children made compulsory; confiscation of property for offences was abolished, and personal punishment substituted; titles were abolished; the clergy were reduced to public functionaries, salaried by the state; the territory of France was declared free through all its extent, and a redivision of it was effected (15 Jan. 1790) into 83 departments. This division afterward proved an admirable instrument of centralization, and in repeated emergencies enabled Napoleon at once to lay his hand with ease upon all the military resources of France. One of the measures already mentioned in particular demands further details, as it was the means of meeting the financial difficulty, and at the same time of arming the enemies of the Revolution, at whose expense it was effected. On 2 Dec. 1789, the domains of the church were, in the euphemism of the assembly, put at the disposition of the nation. The minister was authorized to sell these estates to the extent of 400,000,000 livres. Until the sale was effected he was authorized on the security of these national domains to issue a paper money having a forced circulation and a preference in the purchase of them. In 1792 the estates of the emigrants were confiscated in like manner. Thus was created that seemingly inexhaustible treasury of assignats which brought France so speedily into a financial anarchy worse than any she had yet experienced. Among other reforms was the reorganization of the administration of justice. The parliaments were dissolved by indefinite prorogation, and judicial functions were separated from the administrative, district courts were created and judges appointed for 10 years. The assembly closed with an attempt to recall the émigrés, and it prohibited the reelection of its members. Mirabeau, the greatest orator of the assembly, and one of the boldest leaders of the Revolution, had died prematurely 2 April 1791, from the excesses of his life. The constituent assembly was, according to the constitution, immediately followed by the legislative assembly, which began its sittings on 1 October, but before the period assigned by the constitution it gave place to the convention. In the legislative assembly there were two parties of political importance, the Girondists, who led it, and the Montagnards, who subsequently became all-powerful in the convention. The royalists were already powerless. The assembly was compelled at once to take a decisive course. By the declaration of Pilnitz the Emperor of Germany and the King of Prussia threatened an armed intervention to restore Louis to his rights. The King was compelled in March to accept a Girondist ministry, and on 20 April 1792, war was declared against the empire. The first attempts to assume the offensive were unsuccessful, and the French armies were not even able to prevent the enemy from invading home territory. To make matters worse the King maintained a treasonable correspondence with the allies and refused to sanction the decrees of the assembly. Paris grew restless as the enemy advanced; unscrupulous politicians urged the mobs to violence and on 20 June, the people invaded the assembly and the Tuileries, and summoned the King to sign the decrees. He refused, but satisfied them for the moment by allowing himself to be crowned with a red bonnet. On 26 July the Duke of Brunswick issued his celebrated and impolitic manifesto, threatening, if the King were insulted, to deliver Paris to a military execution. The sections of Paris retorted by signing a petition demanding the deposition of the King before the close of the day (9 August). At midnight the tocsin sounded. The Tuileries, after a sanguinary combat, were taken and sacked. The King took refuge with his family in the assembly, which was invaded and compelled to submit to the dictation of the victors by assenting to the suspension of the King and the convocation of a national convention. The convention was an extraordinary assembly, summoned for an emergency, and thus recognized the fact that France was again without a constitution. The war now assumed a more favorable aspect. The victory of Valmy, 20 Sept. 1792, caused the Germans to fall back discomfited; the siege of Thionville was abandoned; and France was freed of her invaders. Savoy, Nice, and Villafranca were seized and occupied by the French; the army of Alsace under Custine took Speier (30 Sept. 1792), Worms (5 October), and Mainz (21 October); Frankfort capitulated to Houchard; and the victory of Dumouriez over the Austrians at Jemappes, 6 Nov. 1792, led to the occupation of Belgium.

The first act of the new assembly, 21 Sept. 1792, was to proclaim the republic. Thus the Year I of the republic began. On 3 December the King was cited to appear before the assembly. On 20 Jan. 1793, he was, by four successive votes, sentenced to death within 24 hours, and on the 21st the sentence was executed. This violent inauguration of the republic shocked public opinion throughout Europe, and armed the neutral states against France. England, Holland, Spain, and the empire joined the coalition. A levy of 300,000 men was ordered. It was necessary to send some of these new levies to suppress the Chouan insurrection in Mainz, Anjou, and Brittany. Nearly all the officers of rank had emigrated, and Dumouriez feeling that hostility was rising against him in Paris resolved to regain his prestige by a bold stroke — the conquest of Holland. He was defeated in the attempt, however, by the Prince of Coburg who administered a crushing defeat at Neerwinden, 18 March 1793. Dumouriez then secretly agreed to evacuate Belgium and turning against the convention deserted to the allies on 4 April. Mainz was also lost by Custine. At home the army lost confidence in its heads and became disorganized. Mutual suspicion and distrust reigned in the convention itself. The convention took measures suited to the gloomy aspect of affairs. A revolutionary tribunal was appointed to try offences against the state, a committee of public safety, with sovereign authority, was appointed (6 April), and the convention renounced the inviolability of its members. The period thus inaugurated is known in history as the Reign of Terror. The struggle between the Girondists and the Montagnards became violent. The latter, defeated in the convention, armed the sections of Paris. The convention, under pressure, ordered the arrest of 31 Girondists (2 June). Some of them escaped and excited insurrection in the provinces. A new constitution was adopted by the convention 23 June, called the Constitution of the Year I, the Republican Calendar being adopted on 5 Oct. 1793. The energy of the dominant party had risen to the danger, but it was accompanied by a ferocity without example. The revolutionary tribunal had already filled the prisons with victims. On 10 Oct. 1793 the constitution was suspended and the government declared revolutionary, a term which included unlimited power. Both in Paris and the provinces executions and massacres followed each other daily, and as new parties succeeded each other in the convention the leaders of the defeated parties were added to the usual list of suspected royalists or reactionaries. Thousands of paid committees were formed throughout France. The Queen was executed on 16 Oct. 1793; the Girondists (against whom public anger had been more deeply aroused by the assassination of Marat on 13 July by Charlotte Corday) on 31 October (10th Brumaire) the Hébertists on 24 March 1794, the Dantonists on 5 April. Robespierre had a new law passed on 22 Prairial (10 June) to facilitate these executions, and from this date to 27 July about 1,400 persons are supposed to have perished. At length the Reign of Terror came to an end by the revolution of the 9th Thermidor and by the execution of Robespierre and his associates on 27 and 28 July 1794.

In the meantime the majority of the southern towns declared against the convention, the French territory was invaded both on the north and south and to all these dangers was added famine. Condé was taken by the allies 12 July 1793; Mainz surrendered 23 July; and Coburg took Valenciennes on the 28th. The convention fixed a maximum price for the sale of provisions. A decree was passed excluding English manufactures from France. A levy was ordered of 1,200,000 men, and Carnot organized 14 armies. The revolted provinces were speedily reduced. At this time Napoleon first became prominent in France. In September 1793 he was commissioned lieutenant-colonel of artillery and sent to Toulon to assist in the reduction of that city which was then in the hands of the English. By his strategy this was accomplished on 19 December, and Jourdan, in the north, was enabled to give his undivided attention toward driving the principal forces of the coalition from the country. During the balance of 1793 and in 1794 the campaigns resulted favorably to the French arms. Jourdan defeated the Prince of Coburg at Wattignies 15 and 16 Oct. 1793. Hoche, after losing the three-day battle of Kaislerlautern (28 Nov.–1 Dec.) and winning the battle of Wissenberg (26 December), wintered in the Palatinate. In Italy and Spain the French had also been able to carry the war beyond their own frontiers. In the spring of 1794 the French armies took the offensive. An attack on Lille by Coburg's forces was repulsed with great loss on 18 May; Jourdan crowned a series of victories by the capture of Charleroi in June; and by the victory of Fleurus (26 June 1794) recovered Belgium, and Pichegru by the beginning of 1795 had completed the conquest of Holland. A treaty of peace was signed 16 May. Holland, under French influence, constituted itself into the Batavian Republic. Tuscany concluded peace with France 9 February. By the successes of Jourdan the allies were driven across the Rhine, and Spain was invaded. These successes induced Prussia and Spain to lay down their arms. By the treaties of Basel (q.v.) signed by the former on 5 April, by the latter on 12 July (ratified 22) 1795, and by Hesse-Cassel on 28 August, these countries acknowledged the French Republic (See PEACE TREATIES). The English during this time had been successful at sea and had made extensive captures among the French colonies. Meanwhile (in February 1794) Napoleon had been promoted to the rank of brigadier-general of artillery and later in the same year was sent to Genoa to study its defences and the political disposition of its inhabitants.

In 1795 the convention gave the republic a new constitution called the "Constitution of the Year III," a chamber of Five Hundred to propose the laws, a chamber of Ancients to approve them, an executive of five members, one elected annually, called the directory. This tame bequest of that once terrible assembly marked the progress of a strong reaction. The royalists conceived sanguine hopes of a restoration. Pichegru was gained, a royalist insurrection organized, and 30,000 men marched on the Tuileries, where the convention sat. Barras intrusted the defence to Napoleon who had lately returned. He with 5,000 men and his artillery, though he had only a single night in which to prepare, not only repulsed the insurgents but poured such murderous discharges of grape into their ranks that within an hour after actual fighting began he had secured victory for the convention. This event is called the affair of the 13th Vendémiaire (5 Oct. 1795). In recognition of his services Napoleon was now appointed by the convention to the command of the army of the interior. The convention was dissolved on 26 October.

With the suppression of the revolution at Paris by Napoleon, the subjugation of the Vendeans and Bretons by Hoche, the crushing of the "Conspiracy of Babeuf," and the pacification of the other sections of the country, came a distinct lull in political passion. For the first time in many years the armies of France were idle and so the directory planned further foreign conquests. Carnot, the "organizer of victory," who was one of the five members of the directory, was depended upon for the military success of the campaigns. He planned an attack on Austria and resolved to strike from three separate points. In 1796 he sent out three armies which were to hem in the Austrians on all sides and descend upon Vienna simultaneously. Two of these armies, each 70,000 to 80,000 strong, were to enter Germany to reach the valley of the Danube, one under Jourdan — the army of the Sambre and Meuse — by way of the valley of the Main, the other under Moreau — the army of the Rhine and Moselle — by way of the valley of the Neckar, both then to descend upon Austria. Napoleon with the third army — the army of Italy — 40,000 strong, was to menace Italy. Let us follow this last army.

One object of the campaign was to make the armies live on foreign territories. Bonaparte's lieutenants in Italy were already experienced generals. He assembled them and unfolded his plans, which silenced the jealousy naturally caused by his appointment. To the soldiers he issued the first of his rousing proclamations: "You are ill-fed," he said, "and almost naked; the government owes you much, and can give you nothing. I am about to lead you to the most fertile plains in the world, and to opulent cities where you will find honor, glory, and riches." During four years the army had been struggling against the Sardinian and Austrian troops, without decisive success, on the southern slopes of the Alps and Apennines. The Sardinians stretched from the Bormida to the Stura, with an entrenched camp at Ceva. The Austrians were cantoned in the neighborhood of Alessandria and Tortona, commanding the roads to Genoa and Milan. Napoleon threatened an attack on Genoa by Voltri, but made his real advance through the valley of the Bormida. Toward the end of March 1796 he set out from Nice and after defeating the allies at Montenotte (11 April) seized that town and thus placed himself in their centre. Having first repulsed the Austrians he pursued the Sardinian army, beat it at Millesimo (13–14 April) and at Mondovi (22d), and drove them before him to Cherasco, where an armistice was concluded (28 April), which was converted, on 15 May, into a definite treaty, by which Sardinia renounced the coalition and ceded Savoy and Nice to France. In the interim Napoleon sent Masséna and La Harpe against the Austrian army and they defeated it at Dego, 14–15 April. Napoleon then by forced marches to Piacenza compelled Beaulieu to retreat toward the Tyrol. He crossed the Po at Piacenza, stormed the Bridge of Lodi (10 May) which was held by the Austrians to cover their retreat, and entered Milan on 15 May. Brescia was entered on the 28th, the passage of the Mincio forced at Borghetto on the 30th; and the Austrians, after garrisoning Mantua, retired into the Tyrol. The English were dislodged from Leghorn and Corsica; and Venice, Genoa, and Piedmont gave in.

Napoleon followed up his successes by negotiations with the Italian princes and the Pope, upon whom he levied contributions. The King of Naples signed an armistice on 5 June. Besides money, so much wanted by the directory, Napoleon provided a pleasing tribute to French vanity by stipulating for the surrender of pictures, manuscripts, and works of art. On Lombardy he levied a contribution of $400,-000,000: the Pope promised $420,000,000. He sent $200,000,000 to the directory, which had not been able to defray the expenses of his campaign. While he besieged Mantua, a fresh army of Austrians under Wurmser advanced against him in three divisions. Here Napoleon's ability to grasp a situation quickly and to discover the critical point in a campaign were remarkably displayed and served him well. He raised the siege of Mantua, beat one division under Quosdanovich at Salo and Lonato, 3 Aug. 1796 and another under Wurmser at Castiglione, on the 5th. Wurmser, reinforced to 50,000 men, again attempted to relieve Mantua. Napoleon, who had entered the Tyrol and had reached Trent on his way to Innsbrück, after defeating 25,000 Austrians under Davidovich at Roveredo, on 4 September and winning the battle of Calliano, descended the valley of the Brenta after Wurmser, defeated him at Bassano (8 September) at La Favorita and at Saint George and about the middle of that month shut him into Mantua.

On the other hand the same success had not attended the armies of the north. The Archduke Charles had defeated Jourdan, and forced Moreau, who had penetrated into Bavaria, to retreat by the Black Forest to Alsace which he reached in October. Thus any relief for Napoleon was checked. At this time also a great expedition to Ireland under Hoche failed and that general was recalled to France to serve with one of the other armies. These events enabled the Austrians to send a fresh army after Napoleon, consisting of 50,000 men, under Alvinczy and Davidovich. In vain, however. After sustaining repulses at Rivoli and Caldiero, he outmanœuvred Alvinczy and defeated him at Arcola 15–17 November. In January 1797 Alvinczy, with large reinforcements, again advanced from Roveredo to the relief of Mantua. The French were driven in at La Carona but Napoleon defeated him on the 14th at Rivoli and on 2 February received the surrender of Mantua from Wurmser. On the same day he put an end to his armistice with the Pope and invaded the States of the Church, defeating the papal troops at Senio, and in rapid succession capturing Faenza, Ancona, Loretto, and Tolentino. A speedy understanding was come to by the Treaty of Tolentino (19 Feb. 1797); the Pope surrendered Avignon, Bologna, Ferrara, and the Romagna to France; these were added to the provinces of Modena and Reggio, taken from the Duke, and formed the Cispadane Republic, as, after the battle of Lodi, Lombardy had been proclaimed as the Transpadane Republic.

The Austrians, however, were preparing for another invasion of Italy under the Archduke Charles, and Napoleon resolved to anticipate them before they should receive their reinforcements from the armies on the Rhine. He therefore entered the Tyrol, driving the Archduke before him, and, crossing the Noric Alps and penetrating as far as Leoben in Styria, he had reached Judenburg, a few days' march from Vienna, when an armistice was accepted (7 April 1797) and preliminaries were signed at Leoben on the 18th, ceding the Austrian Netherlands and Lombardy to France, and indemnifying Austria with Venetia. These preliminaries were confirmed by the Treaty of Campo Formio, signed 17 October. While Napoleon was carrying on these stupendous operations, Hoche and Moreau had conducted equally glorious but less successful campaigns against the Austrians in southern Germany and had pushed them back into the Black Forest when they received the news from Leoben and suspended active operations.

In the meantime the condition of affairs at home was becoming worse. The Reign of Terror had been followed by an excessive dissolution of manners. Brigandage prevailed in the provinces. Barras, a member of the directory, and other high officials, had been guilty of malversation and private jobbing in the public funds. The returned royalists were intriguing for a counter-revolution. The reactionary party had triumphed in the elections of May 1797, and had succeeded in electing Pichegru president of the Five Hundred, and Barbé Marbois, another royalist, president of the Ancients, and had replaced Letourneurre in the directory by Barthélemy. The majority of the directory, relying on the support of Bonaparte, resolved to anticipate them. Hoche had been recalled with his army from the Rhine and from Italy Napoleon sent Augereau, his trustworthy aide, and with these the directory carried out the *coup d'état* of the 18th Fructidor (4 Sept. 1797). On that night Augereau introduced 12,000 men into Paris, surrounded the halls of the councils, and arrested the leaders of the reactionary party. The minorities of the two councils, assembled on the invitation of the directors, condemned 53 deputies to transportation; annulled the elections in 48 departments, and repealed the laws which had been passed in favor of priests and emigrants; and other violent measures were also taken. Moreau, who had betrayed the intrigues of Pichegru, was himself suspected, and deprived of his command; and Hoche in consequence received command of the two armies of the Rhine. Soon afterward, however, he was taken suddenly ill (some say he was poisoned) and died.

It seems to have been the purpose of the directory at this time to invade England and with this object in view a large army had been gathered together. Napoleon was placed in command of it and though at first he professed to favor the design, he readily saw its impracticability and finally persuaded the directory to abandon the project. As an alternative he proposed to ruin the English Indian empire by the conquest of Egypt. His plan was approved; an army consisting of 36,000 men was equipped; and in a fleet commanded by Brueis the expedition embarked at Toulon on 19 May 1798. In passing they took Malta from the Knights 9–10 June. The fleet a few days later set sail for Egypt and reached Alexandria 1 July. Napoleon sent Kléber forward to take that city and then advanced on Cairo but before he reached his destination he encountered a large force of Mamelukes. A long and bloody struggle ensued known as the battle of the Pyramids, but on 21 July Napoleon emerged victorious. He then entered Cairo in triumph. Napoleon thinking himself secure set about reorganizing the civil and military government of the country, among other things establishing on 22 August the Institute of Egypt; but before he had accomplished much in that direction fortune delivered a terrible blow. While he was thus occupied in the interior, Nelson, in command of the English fleet, had pursued the French fleet, found it moored in the Bay of Abukir, defeated and nearly destroyed it in what is called the battle of the Nile, 1–2 Aug. 1798. The French were thus cut off from escape. To make matters worse the Sultan declared war against Napoleon. Beside this in October the people in Cairo revolted and then occurred the fearful massacres when 2,000 people were put to death. Napoleon, however, instead of attempting to return to France resolved to conquer Syria. Early in February 1799 he started with 13,000 men to cross the desert. El-Arish, Gaza, and Jaffa quickly succumbed and he then laid siege to the city of Acre which was defended by a Turkish garrison under Djezzar Pasha, assisted by the English commodore Sir Sydney Smith. It was probably at this time that he heard of the disorders in France and the disasters to French armies. This fact combined with his inability to capture the city undoubtedly influenced his decision to return to France. He therefore on 20–21 May, after a 60-day siege, relinquished the attempt to capture the place and returned to Egypt, laying waste the country by fire and having lost over 4,000 men in the expedition. Napoleon re-entered Cairo on 14 June but not a month had passed before it was announced that a Turkish expedition of 10,000 men was marching against him. On 25 July Napoleon attacked and almost annihilated this force, which the Sultan had landed at Abukir. On 22 Aug. 1799 he transferred the command of the Egyptian army to Kléber and embarking in a frigate landed at Fréjus 9 October after several narrow escapes from capture by the English Mediterranean cruisers.

While Napoleon was conducting these operations in Egypt a second coalition in violation of the Treaty of Campo Formio had been formed against France, embracing England, Russia, Austria, and other German states, Naples, Portugal, and Turkey. To meet this danger the councils passed the law of the conscription (5 Sept. 1798), and ordered a levy of 200,000 men. The campaign of 1799 was disastrous to the French. Jourdan, who had crossed the Black Forest, was defeated by the Archduke Charles at Stockbach in Swabia on 25 March, and forced to retire beyond the Rhine. Schérer, who was intrusted with the command of the army of Italy, was defeated at Magnano on 5 April. Moreau, who superseded him, sustained further reverses; and MacDonald, who came to his assistance with the army of Naples, was totally defeated in the battle of the Trebbia, 17–19 June. Turin, Alessandria, and Mantua were captured. Joubert, who succeeded Moreau, was defeated and killed at Novi 15 August. On the other hand, the Anglo-Russian campaign in Holland failed; and Masséna, after a brilliant campaign in Switzerland, defeated the Russians and Austrians at Zurich on 25 September, which induced the Emperor Paul I. to make peace.

Napoleon, on his return, found the government in great embarrassment. Its credit was wholly gone. It was obliged to fund the interest of its debts or pay it in worthless paper money. It was ill-obeyed by its generals. A revolution had taken place in the government (18 June), but the new directors were as incompetent as the old. In these circumstances was accomplished the revolution of the 18th and 19th Brumaire (9–10 Nov. 1799) by which the directory was abolished. The councils being alarmed with rumors of a Jacobin plot, the Ancients gave orders that both bodies of the legislature should be transferred to Saint Cloud under the conduct of Bonaparte, who was intrusted with the command of the troops. Bonaparte had already secured the co-operation of Moreau and the other generals present in Paris. On the 10th Napoleon entered the Council of the Ancients assembled at Saint Cloud, and insisted on the necessity of a new constitution. On proceeding to the Council of the Five Hundred he was received with cries of *à bas le dictateur.* Gen. Leclerc, by his orders, entered and dispersed the assembly. The members of the two councils who were favorable to Bonaparte then appointed a provisional government of three consuls — Bonaparte, Siéyès, and Roger Ducos, and a committee consisting of 25 members, of each council to draw up a new constitution, which was proclaimed on 15 December, and called the "Constitution of the Year III." The three consuls were appointed for 10 years, and re-eligible. The first had all the executive powers, the others only a consultative voice. This constitution was submitted to the approbation of the people, and accepted by 3,011,107 suffrages against 1,567. The departments were put under prefects directly responsible to the minister of the interior. The prefects, subprefects, and maires of communes had their councils, which were merely consultative, the whole executive power being in the hands of the officer responsible to government.

Bonaparte chose Cambacérès and Le Brun as second and third consuls. He then undertook the task of reforming civil affairs. He recruited the national treasury, repealed many of the more violent laws that had been promulgated during the Revolution, and reopened the churches. He wrote letters to the King of England and the Emperor urging, in theatrical terms, the restoration of peace, but these overtures were refused, and his next business was to prepare for war. He gave Moreau the command of the army of the Rhine, and determined himself to proceed to Italy. Masséna, with the remains of the French army, was shut up in Genoa. On 13 May 1800 he began his memorable march across the Alps and on 2 June to the surprise and consternation of the allies entered Milan. After several unimportant skirmishes he attacked and decisively defeated the Austrians at Marengo on 14 June 1800. He thus for a second time secured to the French possession of all the Piedmontese fortresses. By the Convention of Alessandria, signed on the 16th, Melas abandoned all Piedmont and Lombardy to the Oglio. Napoleon then committed the command to Masséna and returned to Paris. Meanwhile Moreau defeated the Austrians in several engagements during May, and forced them to take refuge in Ulm. For a while Napoleon's time was divided between campaigning and negotiating. The English, however, finally persuaded the Austrians to continue the struggle and late in the year hostilities once more began in the valley of the Upper Danube. Moreau again defeated the Austrians under the Archduke John on 3 December in the important battle of Hohenlinden and after a series of brilliant combats drove the Austrians back till Vienna was in terror. Brune, who succeeded Masséna, extended the Italian conquests in Tuscany and Venetia. Negotiations were then entered on by Austria, and the Peace of Lunéville concluded 9 Feb. 1801. The Rhine was recognized as the boundary between France and Germany. The Adige was to be the boundary of Austria and Italy. The independence of the Batavian, Helvetian, Cisalpine, and Ligurian republics was guaranteed. A treaty was also concluded with Spain at Madrid on 21 March; and by the Treaty of Florence, 28 March, Naples agreed to renounce the coalition, and received French garrisons. Treaties were also signed with the Pope, Bavaria, Portugal, Russia, and Turkey. Russia, Prussia, Denmark, and Sweden then formed an armed neutrality in opposition to the naval privileges claimed by England, which now maintained the war single-handed. This led to a brief war between England and the northern powers, except Prussia, which was terminated by the death of Paul I., and the battle of Copenhagen.

During all this time, the French army in Egypt, though greatly weakened, was unsubdued. On 8 March 1801 an English fleet under Abercrombie debarked 18,000 troops at Abukir; on 13 March this force attacked and defeated the French; on the 17th Sir Sydney Smith reduced the forts at Abukir; and on the 20th 15,000 English again attacked 9,000 French and forced them back to Alexandria and Cairo. Gen. Kléber had been assassinated and so on 30 August Gen. Menou, by a capitulation with the English, agreed to evacuate Egypt. Both England and France were now anxious for peace. Preliminaries were signed on 1 October and the Peace of Amiens was concluded 27 March 1802. France retained her continental conquests. Ceylon was ceded to England by Holland, and Trinidad by Spain; all the other conquests of Great Britain were restored. Malta, which had been taken by the English, was to be restored to the Knights of Saint John. This lull in active warfare allowed Napoleon time to crush an insurrection of the blacks in Santo Domingo.

Napoleon exhibited his wonted vigor in home administration. By means of the senate he silenced the opposition of the tribunate and the corps législatif. He assembled the most noted lawyers in France under the presidency of Cambacérès to draw up a new code of civil laws now known as the «Code Napoleon» (see CODE). He entered into a concordat with Cardinal Consalvi for the re-establishment of the Catholic religion. He undertook public works, constructed roads and bridges, encouraged industry and commerce. On 2 Aug. 1802, Napoleon and his colleagues were made consuls for life.

The external policy of Napoleon was not calculated to conciliate the jealousies caused by the extension of French dominion. The independence of the new republics was merely nominal. The island of Elba was occupied and incorporated with France in August 1802, Piedmont 11 September, and Parma in October; while in the same year Piacenza was united to the country and an armed intervention changed the government of Switzerland. Holland was also treated as a part of France and received a constitution from Paris. By the Treaty of Lunéville the German princes dispossessed by the advance of the French boundary were to be indemnified beyond the Rhine. The process of compensation was not carried out with sufficient promptitude for Napoleon. By his interference, in conjunction with that of the Emperor of Russia, the indemnification was effected by the extinction of the two electorates of Cologne and Trèves, and the secularization of the ecclesiastical estates. Napoleon on 30 April 1803 sold Louisiana to the United States for $15,000,000.

The discontent excited in England by this aggressive policy made it evident that the peace could not be maintained, and the government refused to evacuate Malta. On 16 May 1803, two days before the declaration of war, an embargo was laid on all French and Dutch vessels in English harbors. Napoleon retaliated for this lawless proceeding by seizing as hostages all English travelers in France and Holland, and Gen. Mortier took military possession of Hanover. Russia and Prussia attempted to intervene, but on terms unacceptable to France. Spain and Portugal had to purchase their neutrality from France; but as this purchased neutrality placed the former at the disposal of France, England declared war with Spain. Naples was occupied by French troops, and vast preparations were made ostensibly for the invasion of England. While these events were occurring a conspiracy for the overthrow of Bonaparte and the restoration of the Bourbons was discovered in 1804, in which the British government was implicated. The most distinguished of the conspirators were Cadoudal, Pichegru, and Moreau. Cadoudal was executed, Pichegru destroyed himself in prison, Moreau was pardoned, and retired to the United States.

The legislative bodies were now completely subservient to Napoleon, and the conspiracy of Cadoudal was made a pretext for offering him the empire. The *senatus-consultum* for the regulation of the empire, drawn up by Napoleon himself, was passed 18 May 1804. The empire was confirmed by a popular vote of 3,572,329 against 2,569. The coronation took place at Notre Dame on 2 Dec. 1804, and the empire was established.

Bibliography.— There are numerous and excellent histories of France and other general histories which cover this period both in outline and in detail. Among them are: Lavisse and Rambaud, 'Histoire Générale' (12 vols., Paris 1893–1901); Fleury, 'Histoire de France' (1891); G. W. Kitchin, 'History of France to 1793' (3 vols., Oxford 1882); Crowe, 'History of France' (5 vols., London 1858); Mackenzie, 'The Nineteenth Century' (London 1882); Guizot, 'Histoire de France' (Paris 1870); Duruy, 'Histoire de France' (trans. by Carey, New York 1889); Martin, 'Histoire de France' (Paris 1855–60); White, 'History of France' (1890); Yonge, 'Three Centuries of Modern History' (London 1872); Edwin Emerson, Jr., 'A History of the Nineteenth Century Year by Year' (New York 1901); Thornton's, 'Continental Rulers' and Oscar Browning's 'Wars and Military Development' in vols. VI. and XVII. respectively of 'The Nineteenth Century' (Toronto and London 1902); also for the institutions consult Taine's 'Modern Régime' (Paris 1891–4; trans. by Durand, New York 1894). The 'Cambridge Modern History' (Vol. VIII. 'The Revolution' and Vol. IX. 'Napoleon,' Cambridge 1904–6), beside treating the history of this period in detail cites an enormous number of works, original documents, etc., on each period and on every phase of the subject which the student may consult with profit.

DEPARTMENT OF

FRENCH HISTORY AND MODERN DEVELOPMENT

France:

HISTORY AND MODERN DEVELOPMENT.

1. **French Civilization.** Nationality does not consist in a race, still less in the use of a common language, but in the possession of a corporate tradition. A nation is a body of men distinguished from other bodies around it by the possession of an organic tradition which so moulds the habits of life of those subjected to it as to define them clearly from their neighbors.

The territory the larger part of which is now called France, and the ancient name of which was Gallia, has, since the beginning of recorded history, been inhabited by many million men possessed of and influenced by such a corporate tradition which has given unity to their commonwealth even in its most anarchic or barbaric periods, and which permits us therefore to speak of the French people as of a permanent historical phenomenon in Western Europe. Compared with this solid and recognizable truth, guesswork upon complicated racial origins and still vainer guesswork upon the evidence of language, are negligible.

The characteristics which the Gauls have developed in this national tradition of theirs and which in turn their national tradition has imposed upon them and confirmed them in, are easily recognized by the modern traveller or by the student of the detailed history of the last 300 years. This tradition comports energy working at a very high potential, a potential so high as sometimes to fuse its communications, and so high as to suggest to those unused to it a necessary absence of volume. It comports in philosophy a combination, somewhat paradoxical in character, by which material and tangible things are chiefly regarded and yet treated by the methods of pure thought. Thus no nation has expressed political theory in terms more general than the French, yet none have had less inclination for metaphysics.

In the political sphere the national tradition of which I speak is essentially military, and in the various forms of its expression has never ceased to be so,—by which is not meant that the French are perpetually under arms, or chiefly concerned with making war, but that their conception of the organization of a State is always a military conception: and that as the art of war changes and develops, now tribal, now municipal, now based on castles and at last national, so has Gaul been a loose hierarchy of tribes, a web of Roman municipalities and garrisons, a tangle of feudal relations, or a highly centralized and bureaucratic body. The whole trend and determination of the French mind in civics may be expressed in the formula «Without authority there is no life.» It is on this account that throughout French history promptitude and power are demanded from Government, and that among a people to whom the Oriental ideal of collectivism is highly repugnant, so much is demanded from the State and so many of a citizen's actions are considered only in the light of his relation to the State, as though the duties which he owed to the State were in some way more sacred than the rights which the State should guarantee to himself.

The minor and more superficial characteristics that go with this general picture, are a vivacity and often an excellence in oratory, an exact and somewhat excessive precision in daily life, accompanied by an excessive neglect of such details as are considered unimportant, which neglect is repulsive to those who carry a less precise order more generally over the whole of life; a considerable artistic faculty, waning and waxing with various periods, but fairly constant in dramatic art and in architecture; a lack of appetite for individual adventure (a trait in which the Frenchman contrasts very sharply with the Scandinavian and the Islander of the North, whether Irish, Highland, English or Dane); and finally, a curious power of common action often suddenly inflamed and always extreme, in which the Frenchman contrasts not only with the Scandinavian spirit upon the North of him, but also with the various Germanies, the Spaniards, and Italians of his frontiers, and indeed with every other European community. It is to this trait that France owes the many popular risings and massacres to be discovered in her history, the extreme rapidity with which a leader is chosen and again rejected, the lack of judgment in foreign affairs which cannot but accompany the confused action of a great number of men, and the startling military successes which that common action often produces. Of these of course the main historic examples are the great Eastward march of the Gauls in the third century before our Lord, which led them to the sack of Rome and of Delphi, and to a permanent colony in Asia Minor; the march of the Crusades, and the wars of the French Revolution. But beside these enormous swarmings of the French, innumerable minor phases of the same type are to be discovered in the 2,000 years of Gallic history. It is to be noted also that just as the French are unique in expeditions of this kind, so are they unique in the multitude of their civil wars.

The good or evil of these characteristics I do not propose to examine, nor can they I think be determined; for they will vary according to the very various ethical systems which abound in the modern world, and every reader will determine for himself whether he approves or disapproves of the Gallic temper. It is such as I have described it.

It will next be remarked that the French, such as they are, have had since the fall of the Roman Empire, a very large and disproportionate influence upon the mind of Europe. This truth is so generally appreciated that it needs no expansion here, but a few examples will make it evident to all. French has been the language of a governing class from the River Tyne to the River Euphrates, and from the Atlas Mountains to the mouths of the Rhine.

Feudalism and the whole structure of mediæval society, was Gallic in its origin. The Gothic architecture is a Gallic invention, as is the collegiate university. The systems of military fortification in the 12th, in the 16th, the 17th and the latter 19th centuries, are French; the French framed the first code of laws since the fall of Rome—it became at once the basis for every code throughout Europe. The French road is the model of the German and the Italian road, and to-day the weights and measures of European civilization are French; while, to mention a detail of no great importance, the French language becomes, with every year, more and more the medium of international communication and especially the medium in which is expressed the general result of European thought.

This permanent and, as it would seem, undue preponderance of the French mind, is in part no doubt due to the mixture of excessive energy with excessive precision which is the vice, or virtue, of the French. But a very large part, and the more easily ascertainable part of this influence, must be laid to causes of another kind,—causes more material and dependent upon the sequence of history outside the frontiers of Gaul, and the geographical position of the quadrilateral which the French inhabit; as also to some extent to the influence of soil and climate.

In order to appreciate these measurable causes of French preponderance, let us examine the boundaries of that quadrilateral, and estimate its physical qualities and its historical position.

The French, as I have said above, inhabit *nearly* all the territory anciently known as Gaul, and the boundary which may be set to the Gallic temper runs as follows:

Taking first a point upon the shores of the Bay of Biscay some twenty miles north of the Spanish frontier, the Atlantic Coast is the boundary until the Bay of Quiberon is reached; from that point upon the coast of Brittany the line drawn vaguely north and south to the coasts of the channel, excluding to the East the highly different Armorican type which, if place names and folklore are any guide, has probably lain permanently beyond this boundary since a period prior to the Roman invasion. From the point upon the channel so determined, the boundary proceeds eastward and northward along the coast (including the Channel Islands and their dependencies) to a point about half way between Calais and Dunquerque. Thence it strikes inland, including such places as Tournai, Mons, Charleroi, Namur, Liege, but a few miles east of the latter town and somewhat west of the old castle of Limburg the boundary turns sharply to the south and in a somewhat undulating form, after striking the Belgian frontier at Gouvy, runs a trifle west of that line, passes a mile or two east of Arlon, about half way between that town and the frontier, and so reaches the point where France, Luxembourg and Belgium meet, a point in which artificial and political boundaries curiously correspond with real divisions of men.

The limit of which I am speaking next follows the short Luxembourg boundary, and cuts in a line less defined than most parts of its course from the top corner of Lorraine to within a march or so of the Rhine.

This section is difficult to define, from the fact that the population is not possessed of sharply marked characteristics. Between the Gallic belt of Belgium and the non-Gallic, a boundary as sharp as that made by a river or a wall, can be discovered by the most superficial observer. There is more difference between Liege and Maestricht than there is between, let us say, an Irish and an English town. But in Lorraine no such sharp differentiation of architecture, manners and general way of life is to be discovered. Language is no guide here, the habits and aspect of a German-speaking village are the same as those of a French-speaking village, and one can only speak of a gradual transformation from the purely French town of Metz to the purely German belt which extends, as I have said, to within about one day's march of the Rhine. The belt between can only be described as mixed.

An exact boundary begins again in the neighborhood of Saverne, and follows the crest of the Vosges Mountains, the valleys and Alsatian plain to the east of which seem never to have been impressed with the Gallic type of culture; but whether under the dominion of the Government at Paris, or autonomous, or under the dominion of the Government of Berlin, or of foreign or of native lords and bishops, to have been other than Gallic in temper, and resembling in historic times any one of the minor subdivisions of tribal Germany.

Across the gap of Belfort the line runs just barely including that fortress a few hundred yards to the east of whose town boundaries everything, from the aspect of agriculture to the gait of the peasants, ceases to be French.

The line next proceeds to the peculiar isolated peak known as the Mont Terrible, runs down the middle of the Jura valleys, and from the end of that range of mountains can again with difficulty be determined; the great mass of mountains which lies between the gap of Geneva and the Mediterranean, may justly be regarded as less French in character than the Italian valleys upon the farther sides. French influence and culture and the march of French armies have more deeply affected the Val d' Aoste for instance, than such remote villages of Savoy as Lagrave. But one may say in general that it is safe to exclude Geneva and to include most of the mountain mass lying south of that town until the Mediterranean is reached. The shores of that sea continue the boundary so far as the neighborhood of Perpignan, and though the Catalan language and the Provençal, the highly differentiated climate and the long Roman tradition of this belt make it a thing somewhat apart in France, yet we must recognize the sea as the boundary of Gaul with the exception of a still remaining foreign influence in the town of Marseilles.

In the neighborhood of Perpignan as I have said, and a little before the Pyrenees are reached, the limit which we are defining turns westward and follows the northern base of the hills. So thorough has been the work of French governments since the Revolution, that the valleys running up from that base to the crest of the Pyrenees are, with one exception, now completely transformed in their superficial aspect and seem as French as any other part of the country; but no one well acquainted as is the present writer with the Pyrenean chain can question the identity of the inhabitants upon either slope. Beneath the surface of the modern French system, the manner and cultivation of these valleys is a foreign thing. And the line which we are following may be said, for instance, to include the Canigou and Mont Louis, but not the French Cerdagne; Aix, but not the sources of the Aiège; Bagnieres but nothing beyond it; Tarbes, and perhaps Lourdes but nothing south of Lourdes, and so on all along the chain until, a few miles after the passage of the Adour, the total separate Basque country is reached, where the line strikes northeast and reaches the point upon the Bay of Biscay from which we began to trace it.

It will thus be seen that the political boundaries of France to-day do not exactly correspond to the territory which we are considering, and which as a whole represents the physical basis of the French nation. That territory overflows the political boundaries towards Belgium and Germany, and is within those boundaries in much of its southern and southeastern part as also in the Armorican peninsula. And this lack of identity between the political and the real boundaries of Gaul has existed throughout recorded history. Thus the Romans took the convenient line of the Rhine upon the East, although the German tribal customs, dialect and general traditions have always existed in a wide belt upon the left bank of that river; and again the nominal suzerainty of the King of Paris (though that is hardly a test) for long excluded Bar-le-Duc, which is as French as Canterbury is English.

When the student sees upon the map of Europe the position occupied by this quadrilateral, he may wonder how that position can be called in any way preponderant. It is apparently but a fraction of the great European area, a fraction thrust far to the West, and occupying no central radiating position. The modern map, uninterpreted by history, and by the known effect of climate, leaves inexplicable the material cause of French preponderance. But an examination of these historical and climatic conditions goes far to explain it, and of the two the historical, which is the more important, should be taken first.

European civilization is not a material spread out evenly from the Ural Mountains to the Atlantic and from the Frozen Sea to the Mediterranean; it is an influence whose general expression is Roman, whose permanent seat is within the old boundaries of the Roman Empire, and which while it has radiated eastward and northward of those boundaries through the influence of the Christian missionaries, loses its intensity as a general rule the further it proceeds from its original seat.

This Roman unity was broken by the Adriatic into two halves, originally widely differing and as the centuries proceeded differing yet more widely. In the eastern half (the Balkan peninsula, Egypt and the Levant and Asia Minor) old and stable civilizations, had accepted the hegemony of Rome. The language of the generality of men was Greek, their interests were those of a very aged and perhaps a somewhat exhausted civilization, whose origins went back to the remotest eras, and whose high art and exquisite literature was already in perfection in epochs long anterior to the furthest records of history.

In the West, Latin was the general tongue, though for long the educated and wealthier classes were bi-lingual. And there the Roman genius taught and produced a new civilization common to the Iberian, the Gaul and the Briton, to the Kabyle of the Atlas Mountains, and to the German of the Rhine Valley, introducing to all these people a common art, a common tongue and law, and a common happiness. The boundaries of this Latin unity are very clearly determined: A line drawn from Glasgow to Edinburgh including both those cities shows us what part of the British islands enjoyed this benefit, Wales, the Lowlands and England. The Netherlands, south of the Rhine delta, all the lower left bank of the Rhine, and in its upper reaches both banks,—all the valley of the Upper Danube and the mountains of the Tyrol. All North Africa, from the Bight of Tunis to Tangiers; all Spain and all Gaul,—had in common the vine, the mass, the arch, the column, the municipium, the military way, and were one thing.

Now if this boundary be drawn upon the map it will at once be perceived that Gaul was the centre of gravity, so far as mere area was concerned, of the whole system. And to this mere material fact, important though it was, there was soon added a series of historical accidents which very greatly emphasized this central position.

In the same period which saw the flowering of Roman thought into a definitely Catholic civilization, the long transformation of the Roman army was accomplished. It had become an hereditary and a mercenary thing, drawn largely from those populations which did not enjoy the full civilization of Rome and which were therefore ready to accept a wage more easily than would the free citizen of the Empire. Through the agency of these armies, in a most confused manner, the barbarian pressed more and more upon the civilized area, and he pressed upon it, though never in large numbers yet always with an energy that varied from an infiltration like that of the Franks or the Burgundians to a savage incursion like that of the pirates who overran the eastern part of Britain.

A little later than the first series of these catastrophes the Mohammedan religion suddenly united the non-Roman desert tribes to the South and these destroyed the civilization of Northern Africa which had already been weakened by an anarchy of wandering Germans, revolted slaves, and what not, and finally, by the 8th century the principal islands of the Western Mediterranean, nearly all the Iberian and the ports of Southern Italy were occupied by the Saracens.

The test of Roman, that is of civilized, continuity, is the authority of the town, with its bishop as the successor (he had once been the coadjutor) of the civil authority. And side by side with this test is a secondary one, namely, the authority of the Palatine Writ: of the Writ issued in Latin from the palace (a word borrowed from the Palatine Hill at Rome) wherein resided the centre of government. Now if we take a map of Western Europe as defined within the old Roman limits, and shade with a pencil those Roman municipal areas which lost such a continuity of episcopal government and Palatine, Latin, authority, we shall find that this shading will leave us nothing but Northern Italy and Gaul; and indeed, but for the exception which Northern Italy presents, the vast area of Gaul may properly be regarded as the only survival of Roman civilization in the West. From this survival, as from an unsubmerged rock in a flood, a platform could be made upon which the damaged conditions of civilization might be rebuilt and from which the influence of civilization could again radiate.

The transformation of Roman society when the recivilization of Western Europe began, had made it what is called «feudal.» The slaves had become serfs organized in co-operative agricultural communities; the great Roman landlords had become fighting nobles; from this type of society, in all its changes, onward until the Revolution, and through the Revolution to our own day, Gaul through every vicissitude has remained the pivot upon which the mind of Western Europe has turned. And if at the present moment French armor plating, French road making, the French system of fortification, the French organization of local government, French weights and measures, French field artillery, French submarines, French motor cars, French historians, and the dual polarity of French philosophy, Catholic and anti-Catholic, have imposed themselves upon Europe, this modern accident is but in the general and normal tradition of an historical condition necessary to Western Europe.

Apart from these human and therefore most important factors, certain merely material, limiting and therefore inferior factors must be considered. These will be discovered no less than those to conspire in favor of this permanent position of France.

Of material influences in Europe the two most considerable contrasts are the contrast between the Northern and the Southern type of climate, and the contrast between the tidal ocean and the nontidal Mediterranean.

A vast number of characteristics may be connected with either of these physical contrasts, and with either portion of each. That materialism which was the dominating note of the last generation and which is but slowly passing, regarded climate and such material considerations as we are now discussing as the principal cause of all the differences that could be discovered by the historian. No man would now lend himself to such crudities. The tribal system does indeed roughly contrast with the municipal, in the same way that North does against South, and those who use such terms as «Latin peoples,» etc., conceal beneath their ignorance an appreciation of certain obvious truths which may be roughly connected with climatic conditions. But apart from such speculations, certain very definite material results follow from the pair of contrasts I have mentioned. Thus, the rivers of Northern Europe are highways; they are usually placid and broad and fairly deep, and are penetrated by the tide far within the plains of that region. Even Scandinavia, which has no such rivers, enjoys the corresponding presence of fjords. The Rhone, the Ebro, the Chelif, the Tiber, the Po, the Adige, are not highways. The Seine, the Rhine, the Thames and the Trent, are. Again, the seaport in a tidal sea, to be of value must be chosen in a more particular locality than in a tideless one. Again, the North gives us longer if not fiercer storms. Again the beach in a heavy tide is less suitable for landing; a heavier type of vessel tends to develop, and with it the possibility of further adventures.

It is evident also that with difference of climate a different architecture, a different agriculture and different social habits will arise; and my point is that the contrast between the two zones in Europe is normally a sharp contrast. Nowhere does one feel it more strongly than in the passage from Switzerland of the German sort over or through the St. Gothard to Airolo. Between the two points which are but nine or ten miles apart, the whole of life appears to change.

Now Gaul affords the obvious link between these halves of civilization, and, typically enough, Paris, the capital, is in its aspect now a Northern and now a Southern town. It was southern under the Roman occupation, gradually grew northern again during the Dark Ages, and during the Middle Ages was purely Gothic without a vestige of the South about it (except that it was just on the limit of the wine-drinking country). Then again with the Renaissance it became again gradually the Southern thing which it is to-day.

Again, on a modern battleship, if it be German or English, you will have only the Northern type of man, accustomed as a rule to the tidal sea, with all the quality of seamanship developed under those conditions, while on an Italian battleship you will have men brought up as boys with the latine sail, the absence of tidal currents, the steeper seas, the sudden gust, and the long calms of the Mediterranean. On a French battleship you will have both types of men.

Consider again climate not by meaningless scientific terms of measurement, but as it is expressed in the common experience of life. In the South frost is rare, snow is rare; the long months of cold which render life difficult are not known save in the mountains. The south of Gaul is in this condition. It builds with a flat roof, it knows nothing of skating nor of the preservation of plants through the winter, nor of the isolation which cold elsewhere has produced in the past through long periods of the year. In the North all those conditions are as common a part of life as they are in Holland or in England.

In Northern Europe the sun is the grateful climate; in Southern Europe shade and coolness. In the Southern Europe a low relief was sufficient for plastic art; in Northern Europe a high relief. You find them joined in the art of Mediæval France.

Again, consider food. Wheaten bread is the staple of Roman civilization. To the north of it, oats, rye, and other poorer cereals; to the East, rice; and at this day France grows more wheat than any other of the western European states. France grows more wheat than Italy, England and Spain combined. She grows more than half of Europe, outside Russia. Next to wheat the vine has been the staple of French civilization in the matter of food, but the vine is not easily grown northward of a certain limit (though in the Middle Ages that limit extended far into Britain). Gaul, though mainly wine-drinking, includes a north-eastern belt which has the custom of Eastern Britain and the German tribes, and drinks beer, while it has a larger northwestern belt which follows the custom of Western Britain and drinks cider.

So the northern use of butter, the southern use of olive oil meet in Gaul. The use of and the partial abstinence of flesh—which is largely a matter of climate—depend upon zones which also meet in that territory. Meat cannot be kept in a southern summer; a northern winter cannot healthily be passed without it.

The list of such contrasts could be drawn out indefinitely by any man of average travel and reading; and in nearly every one of them he would find that French territory was a common ground upon which either type met.

It is in the light of the foregoing general considerations that we must regard the history and character of the French people. They will continue to influence the future as they have influenced the past, and they are the major constants in every far-reaching problem of European importance. But a few closing words upon the immediate conditions of the French will perhaps enable the reader better to appreciate the articles that follow.

In general, those immediate conditions consist in this, that upon the general material of a people welded into their unity by ancient customs, and by a method of thought which they are incapable of abandoning, two considerable discussions are at work. Neither can ultimately affect the profound mass and structure of Gaul, but the victory of one of the two parties in either of these discussions, will considerably affect the form or mould into which that mass shall be thrown, and therefore inevitably will affect the general structure of surrounding Europe.

These two discussions are, the discussion upon the purely democratic state, and the discussion upon the authority of the Christian religion.

They are often confused, and nowhere more so than in France itself. But the connection between them is quite accidental, and no accurate conception of the position can be arrived at until each is regarded quite separately from the other.

The modern French experiment in democracy is, in the main, a reversion to the ideal of the old civilization of the Mediterranean. It contains no part of that anarchic ideal of individual liberty common in more rudimentary states: an ideal that inevitably ends in oligarchy and usually in plutocracy. The French experiment in republicanism is an experiment which presupposes a highly organized, a highly centralized and a powerful state, capable of crushing by a common effort all sporadic and particular energies which may be antagonistic to or even separate from the common life. And the experiment is an experiment and not an achieved one, because the machinery for such a state is so difficult to construct. The experiment has never been tried before and it may well fail. Democracies have existed in small city states usually dependent upon slave labor; they have endured indefinitely in small isolated agricultural states; they have never permanently existed in large states under conditions of high civilization. So long as the French experiment endures, so long the conception of democracy at least, and, to some extent, its forms and ideals, will be observed in Western Europe. And it is a matter of intense interest to watch the succeeding phases of the experiment, the moments when it seems nearly approaching success and the moments when the whole conception seems too unworkable for the complexity of the modern world. I repeat, the issue is by no means decided.

The religious question is a more profound and a more vital one. The whole fabric of French life and tradition is so closely interwoven with the Catholic Church that men who should put no credence in the divine origin of that Church would find their easiest temporal explanation for its existence in the action and nature of the French people. Its high centralization, its military defence throughout a thousand years, its rigid conception of dogma, its deductive philosophy, are Gallic, not Italian.

The French cannot therefore respect any revealed religion save Catholicism.

Wherever this conception of religion exists, its counterpiece and converse is rationalism. Rationalism had completely dominated the thinking part of the nation and the leaders of its action in the 18th century; indeed it is only since the middle of the 19th that the arguments against that position have gathered strength among the more cultivated classes of the country. Coincident with the maximum of this rationalistic wave, the French Revolution quarrelled in its first year with the political organization of the clergy; next the Revolution became identified with all the patriotism and all the energies of the people in the course of a long war, and by the time of the Restoration, a great body of French thought and French energy was definitely cut off from and antagonistic to the National religion. The quarrel between the two still endures. The attitude of many a French statesman towards the Catholic

Church in France is not one of neutrality, but one of active enmity proceeding from a conviction that the Catholic Church is not only the permanent enemy of human happiness and liberty, but also of the particular State which it is his function to guide. Conversely, more than one cleric, though of French extraction, has learned to regard the liberal institutions of his country as the necessary and permanent enemies of religion. There is no logical connection between the two ideas: there is but a chance historic association, but that association has acquired great strength with the passage of time and with the succession of some five generations of men who have seen the quarrel continually growing, and no perceptible end to it approaching.

Such are the main combatants in this struggle. But two other factors of importance are present, the Jew and the Huguenot. Neither of these bodies are numerous, but they happen each of them to be extremely wealthy and this wealth with all that it connotes, of education and of power in the Press, is thrown into the scale against Catholicism. It is impossible at this moment to say what the end of the struggle will be. It is only certain that if Catholicism is grievously wounded in France, it will have received a blow far more serious than that which it received in the 17th century. And conversely, if upon the whole the influence of the Church should henceforward grow among the French people, it will be difficult for the forces adverse to Catholicism to prevent the continued increase in political power, both of those populations which are ardently and those that are only nominally Catholic, from Ireland to the Desert. See CHURCH AND STATE.

Upon this struggle, much more than upon the other, depends, one may assert, the future fate of Europe. Each is in active progress, and the combination of the two presents by far the most absorbing spectacle of our time.

HILAIRE BELLOC.

2. France.—History B.C. 58 to A.D. 1796. The quadrilateral of Gaul has possessed a geographical and political unity from prehistoric times, and the inhabitants of that quadrilateral have inherited and transmitted certain political, rather than racial, qualities uninterruptedly throughout the historical period. But the first state in which we find them, when the great mass of them were but barbarians, exterior to the civilization of the Mediterranean basin, was, of course, far different from that strictly organized and disciplined unity which two thousand years ago and again to-day were associated with the territory in question.

The Gallic tribes were a set of loosely organized clans dependent one upon the other in a sort of semi-feudal organization. It would seem that no one clan ever rose to a complete hegemony over the rest, and again that any small or dwindling clan, long before it permitted itself to be absorbed, would seek defence by recommending itself to some superior neighboring clan. The classic instance of such a dependence is the association of the Parisii who inhabited the neighborhood of Paris, with the large and powerful neighboring clan of Senones, whose capital was Sens on the Yonne higher up the Seine valley. It is curious to note that ecclesiastical arrangements, always the most conservative of institutions, preserved a relic of this relation as late as the early 17th century, for until the See of Paris was raised to an Archbishopric in 1622 the Bishops of Paris were suffragan to the Archbishops of Sens.

The languages spoken by these clans we know little of. We know that the civilized observers of antiquity regarded Gaul as presenting three very clearly marked divisions, which the Romans called (going from East to West), Belgic, Celtic, and Aquitanian Gaul. It has been conjectured that the tribes of the first spoke a variety of Teutonic dialects. It may be asserted without fear of error that those of the second spoke a variety of Celtic. As to the Aquitanian or southwestern portions, some will have it that the Basque language once extended throughout its territory; others that its original language was Celtic like that of the central portion. On all this nothing can be certainly known. As to the origins of this stock we are again in complete ignorance, and it would be idle to linger upon the many conjectures of migrations on an «Aryan race» (the very existence of which is but an hypothesis) or of a «Mediterranean race,» a piece of pedantry converse to and only one degree less futile than the last.

The inhabitants of Gaul have in common from the earliest times a National character and a religion which, though they may have sprung from twenty different remote racial sources, gave them a common aspect. This character, which has been sufficiently dealt with in the introductory essay, may chiefly be defined as military. In the earliest, as in the latest of European history, the Gaul appears marching eastward in quest of military adventure. The religion professed by these people is a more precise matter. It was of a definite and highly organized kind, although its mysteries specifically forbade its propagation by anything but oral tradition. It had for its organs a hierarchy of priests known as druids, and professed, as Gaul has always professed in a manner which seems a necessity to her people, specific dogmas the adherence to which was guaranteed by penalty and the expression of which was exclusively confined to the priestly caste. Among these dogmas the immortality of the soul, the necessity for sacrifice and, we may presume, a universal God, were prominent. A sacrament of bread and wine distinguished this cult and a ritual holiness attached to certain objects and shrines, as the mistletoe among vegetables, and the Grotto of Chartres among places.

The reader must here note the surprising continuity of French institutions, a continuity the like of which is not to be discovered in any other part of the Western world. Indeed it would seem as though the prodigious revolutions in philosophy which in ancient times made Gaul Christian and in modern times have moved her to a great though perilous experiment in democracy, did little but re-color the substantial framework of the nation, and that under every regime national unity, a priestly caste, affirmed dogma, and the sanctity of special shrines distinguished the nature of this people.

From very early times the shore where the Gallic quadrilateral touches the Mediterranean had been colonized by the merchants of the East, Greek and Semitic; and indeed the aspect of this fringe, its climate and produce, apart from its exceptionally political history, differentiated it from the rest of the country. Again, the Gallic hordes had overflowed the Alps and largely occupied the valley of the Po. Again, there were presumably spots (as the Plain of Alsace) where the quadrilateral was intercepted by invaders of another stock. But as we have seen in the preliminary essay, the quadrilateral of Gaul is the permanent habitation of the population with the history of which these notes deal, and that population first attains historical importance with the invasion and conquest of Julius Cæsar. This conquest occupied eight years, from 58 to 50 B.C. It was marked by many vicissitudes, the climax of which was the great revolt of Vercingetorix, which was finally crushed at Alesia. Had Cæsar failed in this attempt one can not say that the Roman power would have been diminished or that of the Gauls extended; it was fundamentally never more than a struggle between civilization and barbarism, corresponding to the struggle undertaken later less thoroughly and with less success by Charlemagne against the Germanic tribes.

As it was, the conquest of Gaul affords such a field for the extension of civilization as has never before or since been afforded to its extension in the history of the Western world. For, first, the «Hinterland» thus acquired was in every way suited to the extension of civilizing power, with a perfect climate, a very fertile soil, a numerous and highly intelligent population; secondly, by an accident without which the Roman Empire could never have come into existence, the Gaul was not only suited to the reception of Roman civilization, but avid of it. Within three generations of Cæsar's great experiment, the whole vast territory was Roman, and more thoroughly penetrated by Roman laws, tongue, feelings and manner than any alien territory has been before or since, with the habits of the conqueror.

Indeed there are but two examples in all history of a success of this kind: that of the Spaniards in the New World, and this of the Romans in Gaul. But the Spanish success, remarkable as it is, does not compare with the Romanization of France. It has achieved a less complete civilization; it was effected at too great a distance from the metropolis.

Other military adventures of the sort have either spread a language or veneered a district with a governing class, without fundamentally changing its daily customs. Such was the Hellenic conquest of the Near East and such was the Roman conquest of Northern Africa, in neither of which were the local dialects extinguished or the local religions uprooted. As for the commercial empires, the Carthaginian, the Venetian or the English, it is not in their genius to impose their will upon subject peoples or to transform these into something after their own image; nor have they commonly made the error of attempting a task so uncongenial to their forces.

This Romanization of Gaul, the most complete, and, in a manner, the most miraculous of historical revolutions, endures in its effect plainly to the present day, and upon it more than upon any other one historical phenomenon the pattern of Western Europe has been based: its bishoprics, its ritual, its law, its philosophy and its social organization. The municipality, with its elected council, European kingship, the legal class, the village with its lord and its prædial serfs—all these proceed from the Romanized town and the Roman agricultural estate, not so much as they appear in their original Italian, but rather as they appear in their later Gallic form.

Some 200 years after the Roman pacification was complete, the preaching of the Christian religion in Gaul began to achieve its remarkable success. Legend, and even to some extent recorded history, shows us the leaven of this new philosophy at work much earlier: thus the famous martyrdom at Lyons took place as early as the middle of the 2d century, and the saints who there suffered were, through Irenæus their priest, in touch with the Apostolic period, for Irenæus was the disciple of Polycarp, and Polycarp of St. John. But it was from the middle of the 3d to the middle of the 4th century that the true revolution in Gallic thought as distinguished from these sporadic origins was effected. And from the middle of the 4th century Gaul becomes, as it has since remained, the chief scene of the struggle between the Faith and its opponents.

The Monastic Institution, Eastern in origin, was then established by the efforts of St. Martin in the West, to produce, after centuries, the university upon one hand and upon the other the representative system. Again, it was then in the middle of the 4th century that the municipalities identical with the sees of Bishops begin to take on a social importance which has made them ever since pivots upon which French development has turned. And it is significant that about the same time the old tribal names of districts reappear, attached to these municipalities. By far the greater part of French towns to-day bear, not their Roman but their second tribal name.

Coincident with the conversion of Gaul and its organization as a complex and highly efficient clerical hierarchy (which, beginning in the 4th century, became within a hundred years the framework of the whole community and the only structure capable of outlasting the dissolution of the Roman world) came the phenomenon loosely and accurately called «the invasion of the Barbarians.»

There was in fact but one true invasion, and that, to the honor of Europe, was utterly defeated. It was the Mongolian invasion under Attila. Even this was provoked by the use of Mongolian soldiers in the Roman armies. He penetrated with his enormous host to within sight of the walls of Orleans, fell back to the great dusty plains north and east of Chalons,—probably much where the camp now stands. He had with him and was joined by every element of disorder and of chaos: German tribes, and, we may presume, the fugitive, the criminal, and the broken men of that declining period. Opposed to them were all the forces of order and they were victorious. But it was the last organized effort of Rome, and within fifty years a local chieftain was to assume power in Northern Gaul without so much as assuming the titles of Roman officialdom.

The wealthier and the more self-conscious the Roman Empire grew, the more defined its social opportunities, the more ancient and fixed its customs and the more beneficent the religion which its civilization had to offer, the more did it attract the perpetual infiltration of Barbarians from beyond the pale. The process may be compared to the increase of potential which is created by the storing up of a head of water, or any other contrast of positive with negative in physical forces. With every succeeding generation there was less and less temptation or need for the Roman to seek adventure outside the Roman pale. The towns were growing in magnitude, the Roman order had existed so long and with such splendid success as to be apparently eternal. Conversely, there was not a Barbarian within a month's march of the border who was not by an irrestible gravitation drawn towards the enjoyment of such privileges. Some small proportion of the more abject savages were attracted by the mere opportunity of loot. These were easily defeated, though the watch against them was a constant care and harassment. They included the few pirates of the North Sea and the cannibal inhabitants of Scotland. The vast majority of the Barbarians were not of this kind. They were men thoroughly acquainted with the advantages of Roman citizenship, men many of whom (in the case of some groups the majority of whom) had served in the Roman armies and who desired the privilege of being Roman rather than the fruits of destroying the only civilization they could conceive. Moreover, the total number was small, and especially small were the numbers of those who achieved political success. First of these in the history of Gaul come the Salian tribe of whose confederation was that limited and fairly definite race which still inhabits the district immediately to the north and west of the Waloon belt of French and Belgian Flanders. The social and even the military organization of Northern Gaul was in dissolution, when, in 1481 a lad whom history calls Clovis and whose actual name may have been spelled in any one of twenty barbaric fashions, inherited the leadership of this little clan. Five years later as a boy of 20 he led them across the border, defeated another body of Barbarians, organized as Roman soldiery, and through the organization of the Church,—notably of the great See of Reims, was permitted to occupy executive rank. It must not be imagined that this, more than any other of the numerous small incursions of the time, violently struck the imagination of contemporaries, still less that it affected the general life of the people. Writs were issued, taxes collected, civil and religious ceremonies performed in the same way, whether the man nominally at the head of the Executive in a province or a district happened to have been born within or without the Roman pale. For quite two centuries this distinction had been of little importance. The new features accompanying the end of the 5th and beginning of the 6th centuries, were merely, first, the advent of a certain though small number of independent warriors who could not be fitted into any known part of the Roman organization (and who were not technically legionaries nor technically Roman officials), and secondly, the break down of the provincial system. City, in the lack of a central power, stood apart from city, each looking to its own affairs. And any petty chieftain, such as Clovis was, would claim to gather taxes, issue writs, enjoy the luxury of the palace, not as the governor of one definite traditional district, but of just so many municipalites as he had troops under him to occupy. It goes without saying that these newcomers at once accepted the religion of the civilization they found, as they did every other of its habits. There was however, one feature, which seems to us of supreme importance, and which the Roman civilization of that date seems to have regarded with indifference: this was the feature of popular language. Semitic dialects lingered unmolested in Northern Africa at this time. And it was a matter of regret to no one or even of curiosity to the learned, whether such a man as Clovis or Theodoric could or could not express himself in Latin. Latin was the only possible tongue for the work of government, for the law courts and for literature. A thousand dialects, Celtic in Britain, Iberian in the Pyrenees, Teutonic in the Rhine Valley, Punic in Africa, which diversified popular speech, played no greater part in the life of the time than private tastes in reading or in cooking do today. Yet the existence of such dialects has warped and distorted the history, especially of Gaul, in that many historians of imperfect information, reading every sentiment of their own time into the past, have seen in language the test of a society, and as we shall discover in a moment, have even made of such a figure as Charlemagne a sort of modern German nobleman.

In this Gaul then, which remained as purely Roman as before, with no perceptible admixture of new blood, and with no change in the methods of government save a gradual weakening and coarsening of them, Clovis established himself in executive power over the municipalities of the North and East; having, that is, the right to issue writs in his name, to gather the dwindling taxes, and to reserve for his part the luxuries and the honors traditionally incident to the position of a great Roman official. For more than a century, till the advent in 628 of Dagobert, the great-great-grandson of Clovis, this local executive power is as vague and changeable as can be. It depends upon personal prowess in battle. Now the petty kinglet in the North stretching his nominal power almost to the Pyrenees; now the whole territority is divided among brothers; now there is an alliance with other Teutonic chieftains of the Burgundian or Visigoths in other parts of the territory; now for a moment the whole is united again in one hand. Save as concerned landmarks, the lives of these Kings are unimportant. The social fact underlying the whole business is the dissolution of one portion of the Roman organization and the survival of another. The portion which dissolved and whose instruments of power became first nominal, then merely legendary, was the central authority and the army upon which it had reposed. The portion which survived and which even increased in strength as the darkness of the time deepened, was the municipality, and above all the clerical organization based upon the municipality.

Meanwhile, like any great body that has gone through a sharp readjustment of conditions, the western districts of the Roman Empire by the 7th century began to organize a new and a debased but yet a stable life. The conditions were these: Britain had been for more than a hundred years quite cut off from the Roman world and the Eastern half of it nearly ruined by pirates. Africa had been overrun by every sort of wastrel, escaped slaves, nomads of the desert, starving peasants, and criminals, gathered round a small nucleus of wandering Teutonic Barbarians called Vandals. It had been temporarily regained by the Imperial power, but was never again the orderly and civilized province which it had been for 700 years, and was destined in the next century to be permanently effaced by the Arab invasion. In Spain and in Gaul the Roman municipality endured, and little bands of Teutonic raiders had established their chieftains as nominal heads of the Executive power. Men had settled down to this conception of the world as to the obliteration of the old central authority; they were long used to seeing upon their parchments the curious names of Germanic origin which had replaced those of the Emperors. Letters and arts had so declined that the past had become a fixed standard of excellence, the attainment of which was despaired, when the ruins of the old Roman order began to group themselves again into something of a stable (though of a coarsened and much lowered) civilization which is generally called that of the Dark Ages. And by an historic accident this civilization was nowhere fully preserved save in Gaul.

This accident was the successful Mohammedan invasion of Spain, a catastrophe which left Gaul the only intact Christian unit, and therefore the only seed plot in which the tradition of civilization could hold its own and be preserved.

Britain was hardly yet re-christianized, and civilization had but just begun to strike its new roots. Theodore had but just organized the Church in that island, and it was still a mass of little warring districts, when Taric landed upon the shore which still retains his name under the Rock of Gibraltar, in 711. In two years the Mohammedans were at the foot of the Pyrenees, and the whole intervening plateau with its Roman municipalities, its organized hierarchy, its European traditions of 900 years, was subject to the Asiatic.

The consequences of this disaster were enormous. The Western Mediterranean, the common highway by which Roman influence has welded all Western Christianity together, was henceforward Mohammedan. Its islands were open to perpetual invasion, many of them to regular occupation (the Balearics were not recovered by Christendom for over 500 years!); every seaport which had escaped actual conquest was open to perpetual insult; Italy, already a mass of independent localities, now lay as to its southern half, open to influences the most antagonistic to those of Rome; Rome itself might henceforward almost be called a frontier town; the balance of the great provincial system was destroyed, and a general observer of history who should not be acquainted with what was to follow might imagine that after this blow Christian civilization and all the traditions of Rome and the West could not but perish. As a fact, by a process with which this paper has not to deal, the indomitable energy of the Spaniard reconquered the Iberian Province and slowly re-established the civilization which we now enjoy. The debt we owe to the crusading spirit of Spain is not calculable; but for it there would not to-day be what we call Europe; its learning and its religion would have perished. As it was, for many hundred years, with Britain hardly civilized, Spain lost and Italy distracted, Gaul remained to the close of the Dark Ages the one intact remnant of Europe.

Meanwhile there had been proceeding in Gaul itself a transformation in the nature of political authority which was destined to have very wide-reaching effects. The spirit of the municipalities, organized and aided by the Bishops, had restored a conception of National unity, and the Frankish Kings were at the head of that unity, the nominal centres from which a political power, debased but still Roman, proceeded. These kings were manifestly unequal even to the moderate task of governing the decline of civilization. The great landowners who formed by this time an intimate mixture of Roman and German families, grew more and more important as communications became more difficult. Chief among these land-owning families was one which had acquired an hereditary position of predominance in the palace. This family had originated in a Roman noble of the territory of Narbonne, nearly 300 years before, but as was the case with nearly every other great Roman territorial family of Gaul, there had been continual intermarriage with families of German-stock, and prior to the Mohammedan invasion of Spain this family is found having its principal seat in that one of its many estates which lay in the eastern part of Gaul in the boundary of German-speaking territory. It was therefore, in the language of the time, an Austrasian family, for the French monarchy was roughly divided into Neustrian or Western, and Austrasian or Eastern, though these divisions did not correspond to anything in race or language, but were convenient categories in which to reckon the topography of the scattered estates. This family was already virtually ruling in the place of the king when the great head of it, Charles, led the combined Gallic forces against the Mohammedan invaders who had passed the Pyrenees in 732. This horde of Asiatics, crossing various parts of the chain of mountains but proceeding mainly by the middle road of the Imus Pyrenæus, sacked the cities of southern Gaul, were turned northward by the resistance of Toulouse, passed through Poitiers and were marching upon Tours and the North when Charles Martel (Charles the Hammer) met them on the plateau of Dissay about half-way between the two towns. Their force was completely destroyed and Europe was saved. The son of Charles, Pepin, was still more patently the head of the State, though for several years he refused to accept the crown; and it is under him that Gaul appears as the protector of the Papacy, an institution which French military power was to support continuously for the next five hundred years. It was not only at the call of the Gallic municipalities and the hierarchy, but also by the direct sanction of the Pope that Pepin in 752 accepted the crown. He died in 768, leaving, as was so constantly the barbaric custom of the time, political authority divided, between his two sons Charles and Carloman: the latter died in 771, and Charles, now 29 years old, became the sole ruler of the great territory which was now the only unbroken piece of the ancient empire, and the only one subject to any sort of central authority; around it upon all sides, in Britain, in the German Marches, in the southern valleys of the Pyrenees and of the Asturias, in Northern and Central Italy, was a confused mass of petty lordships, and beyond that again the external belt of enemies of the Christian faith and Christian civilization, the savages of Scandinavia and of Central Germany, the Mohammedan power of the South. The great Charles, therefore, whose title in history is Charlemagne, stood upon the defensive, as it were, throughout his long and glorious life, holding an island of Christendom against the pressure of these external forces. His defence was successful, and that long respite permitted Christendom to accumulate just so much strength as was sufficient in the next century to repel, though hardly to repel, the final assault of the anti-Christian power.

The reign of Charlemagne extends over 46 years, 43 of which he enjoyed as sole sovereign after the death of his brother, and during the last 14 of which he had mounted to that miraculous position which earned him the title of Emperor of the West and has caused him to fill not only the legends of Europe, but also, as with an original light, all the beginnings of modern European history. His period, therefore, is one of the many of which we can say that the uninterrupted presence of one man at the head of a State for a long period gives that period a peculiar unity and significance. This is often true when the man is merely a symbol; it is particularly true in a semi-barbaric condition of society, when the man happens also to be of military virtue and a successful warrior. That the personal character of Charlemagne determined this wonderful episode in French history, it would be an exaggeration to say, but that personal character made the episode possible; these 40 years and more are full of his individual effort, and they have something personal and epic about them, like the eras which lie behind recorded history at the origin of every civilization.

He was 26 when his father died. Before he was 30 he had determined to extend civilization into the Saxon forests, and he had begun to do so. In his 32d year he crossed the Alps; in his 33d (in 774) he destroyed the power of the Lombards in Italy, and for the second time confirmed, as his father had confirmed, the temporal power of the papacy. The next year he was back again in North Germany, and the next year again in Italy once more; the year after that, for the third time, he was conquering among pagans of Saxony, and this time received at least the oath of their reluctant allegiance. The next year he was off again over the Pyrenees, negotiating with, pressing back, harassed by, but checking, the Mohammedans. The Saxons rose behind him; he hurried North again. In 781 he is yet again in Italy. He was not 40, and these first 14 years of his had been as full of violent and successful war as were the first 14 years of Napoleon. This elegy of rapidity and success, backed by a sort of renaissance of the Gallic spirit, so powerfully struck the imagination of the time as to make him, even in that period of rapid decay or transformation, the necessary leader of a united Christendom. It is from these swarming campaigns that the first new songs, or rather epics, of our modern Christian civilization drew their inspiration, notably from that check or defeat of his rear guard in the pass of the Imus Pyrænæus as he was retreating from Spain, a disaster in which his nephew Roland died, and from whose memory sprang the noblest of Christian poems, the 'Song of Roland.' On Christmas Day of the year 800 the culmination of these campaigns saw him crowned in Rome by the Pope, Emperor of the West. The old title thus revived was but a symbolic name. He himself could exercise central and imperial power in a manner only distantly resembling the old Roman model upon which his title was based; and in the century that succeeded him that title became little more than a name. But it can be said with regard to the title itself and to his individual occupation of it, that it revived just before the memory of such an institution would have decayed, the tradition of an Europe united under a military head. That tradition has never wholly disappeared, and, fantastic as such a prophecy may seem to-day, the future may very possibly see it revived.

The remaining years of his life, though all around the frontiers of his empire the last effort of anti-Christian forces was ready to be made, were full of a sort of tranquillity and splendor which the insufficient knowledge of the time might vaguely compare to the ancient authority of Rome. He died 28 Jan. 814, at the beginning of his 72d year, and was buried exactly upon the confines of the two languages which he spoke, upon the limits of the civilization which he had preserved, in the old Roman watering-place of Aquæ, called since his time Aix-la-Chapelle, his favorite residence. There, in a church long since rebuilt, under the influence of mediæval French architecture, he still lies, surrounded by modern architecture more appalling than most that is to be discovered even in the rapid industrial development of North Germany in our time.

The experiment to which Charlemagne had devoted such energy, and in which he had achieved such success, turned out both at the time and in the judgment of long future generations far more than he or his coadjutors had intended. The vigorous and united symbol of

Christian and civilized Government which his reign had afforded served as a bridge. It prevented Christendom from too much forgetting (though it necessarily largely forgot and blurred) its Roman origins, and it afforded also a halting place to which the Trials and the new youth of Europe could look back in succeeding centuries. The reign of Charlemagne is like a holiday, or like a light in the night. It breaks the continuity of the dark ages, and largely through his intellectual vigor enables us to understand the transformation of Europe from the antique to the modern.

In spite of these qualities in the time, the vital forces of Gallic civilization were still declining. Men built less well and thought less well from year to year, and when the omnipotent Chief of this military episode had died in 814, there broke upon what was left of civilization the heaviest storm it had hitherto endured. In that storm Europe, and therefore its surviving centre in Gaul, was nearly overwhelmed.

The pagan tribes of Scandinavia, a fresh horde of Mongols, a renewed splendor in Islam, all fought together against the Christian name. It was a far stricter ordeal than were the barbarian invasions of the 5th century; indeed, there was but little relation between these infiltrations of that period and the savage attack of this. The numbers were far larger, the opposing forces of civilization were far weaker, knowledge and discipline by which alone civilized men can resist barbarians were at their lowest ebb.

The issue had already been joined in the British Islands by the beginning of what are known as the «Danish Invasions.» Some 30 years after the death of Charlemagne it menaced what was left of the Christian continent, and with the close of the 9th century it came to a climax. In that whirlwind two things of vast importance to the future of Europe occurred. The first was the military success of a Christendom absolutely united in religion; the non-Christian was beaten off by men of one faith and one ritual and of one immutable manner of thinking. The second was that so much was forgotten and so many traditions lost in the struggle as to necessitate the growth of a new society. It is in this close of the 9th century that the old owners of the land, mainly Roman or Gallic in ancestry, become territorial lords. It is in this period of darkness and upheaval that the long process of independence is at last achieved, and that the village communities with their chiefs finally adopt those groupings for self-defense which are later called the Feudal System, and it is in this period that the subconscious national groups of Europe take on conscious form.

Two points of Western Europe determine the struggle in favor of our tradition and of Europe. These are the southwest of England, Somersetshire and Berkshire, in which Alfred outlasted the savage invader and finally defeated him; and Paris, where, just before, the local forces had beaten back the same enemies in a memorable siege in 885.

The second alone concerns these lines.

To understand the city of Paris is essential to anyone who would understand the history of France. The town has played for a thousand years the same part in the Government of that country that the English governing class or plutocracy have played in Britain since the Reformation. Thence have orders proceeded; thither has intelligence flowed, and there has been fixed that specialized organ of administration, round which all national development gathers, and which, though it has many names in many polities, is a necessary nucleus to every great nation.

Paris had risen to its great position through the waterways of northern France. In the breakdown of Roman order the disuse of the roads and the collapse of the posting system had increased the importance of the rivers in a nexus of which the city found itself, and from the last Roman emperors it had maintained a sort of special place, not as a capital (for there was no such thing), but as a chief town—the town of Clovis and of the early kings, the town in which the early Carlovingians came to die and in whose shrine they were buried.

The local chief—who stood the siege of 885—was by name Odo. Of the ancestry of his father Robert we are not over certain, but from that father and his descendants sprang that line of men who symbolized the rejuvenescence of Gaul when the struggle was over, and in whom centered that which was at once the symbol and the organ of the new nation: the Monarchy.

Robert the Second, the brother of Odo, was, like Odo, elected to a rough kingship, in the contempt which all felt for the decaying idea of the Carlovingian Empire, and the grandson of this second Robert, Hugh, was formally crowned at Noyon, and the separation of French Government from the mass of Europe was complete.

From that moment, for exactly 800 years, to the assembly of the nobles under Louis XVI., the monarchy, retained in one house, perpetually increasing its power, is synonymous with and develops the consciousness of the nation. This date, 987, stands as the second landmark in the history of France and our first business before entering the story of that great development is to consider how Gaul looked when the first of its nominal Chiefs was crowned.

Beneath the various episodes which have been described beneath the great names of Clovis, of Dagobert, of Charles Martel, of Pepin, of Charlemagne, of the Robertian House of Paris, whose principal descendant, Hugh, we have just seen crowned, a slow but complete molecular change in society had taken place. The old Roman order had not only decayed, it had also been internally transformed in the 500 years which intervene between the invasion of Clovis and the crowning of the first French King. The slaves of the old Roman landed estates, though still legally slaves, were no longer bought and sold; they had become Christian freemen; the old Roman landed estate had become Christian village and parish; in the breakdown of communications and of learning, agriculture had become, as it were, the sole industry of men. This agriculture had grown to be neither an individual nor a servile, nor what we should call to-day a capitalistic industry, but a co-operative one. The old Roman landlord was now no longer the possessor of the whole territory of a village; only a portion was reserved to himself, and the village population beneath him had grown by centuries of custom and of cohesion to security of tenure and to fixed and customary payments of labor in the place of that surrender of all their energies which their former servile condition had implied. The vast mass of the population, therefore, lived as perpetual holders of land at a fixed and customary due of labor or what-not paid to a local superior; they cultivated the fields together, but apportioned the result in proportion to their respective holdings. The lord with his much larger holding, as he was the richest among them, was also their protector, and, in a modified way, controlled by tradition and by the assessment of his own tenants, their judge. The village so organized was a microcosm of the whole of society. For centuries the noble class, the men descended from the old Gallo-Roman owners of land and of slaves, had tended more and more to regard themselves also as tenants whose absolute ownership, though absolute, was part of a social system involving superiority, social and executive, in some greater man among their number. They had coalesced in groups, usually under the largest landowner of the district, during the pressure of the Barbarian wars; the man owning but one or two villages would «recommend himself» to some local man owning ten or more, and he in turn to some very wealthy personage of the countryside who had accumulated by marriage or inheritance the dues and the lord's portion of, let us say, a hundred villages. And long before the Carlovingian line was extinguished or the new Capetian line was acknowledged, society had become a complicated territorial system with the tenants of the village dependent upon but secure under the village lord, and with the village lords forming indeed one noble class, but arranged in a hierarchy of dependence from the small man, who was but lord of one village, through the big local man of the countryside, up to the overlord of a whole province. What determined the size of these provinces it would be impossible to say; some, like Normandy, were but an old Roman division which had maintained its boundaries; others, like the March, in the centre of France, were vague to a degree, built up of intricate local traditions and customs, and in dispute with their neighbors for all except the very centre of their dominion. Some were quite small, little more or less than a bishopric in extent; others were virtually independent kingdoms, like Brittany; but of all it was true that they formed the true sub-units in the general national unity. The particular house which had been given the symbolical and nominal headship of the nation under the title of King, were the dukes or local overlords of the Isle de France, a territory of which Paris is the centre (they were the lords of Paris, as we have seen), and which extends, roughly speaking, for three days' march round the city. To this house, once the head of it was crowned, the other great houses swore fealty, thus completing the hierarchic system which in its complete later and legal form was called *feudal*. It must not be imagined that the system was as yet symmetrical, even in theory. Not all the efforts of the lawyers during the next three centuries, the 11th, 12th, and 13th, while it was still quite vigorous, could make a thing of such obscure and natural origin symmetrical. But the general arrangement of society, the small farmer secure on his holding under his lord, that lord under a wealthier man of the same countryside, he again under a Duke or Count of the whole province, and he again swearing fealty to the King, who was the symbol of the National unity, is the great social fact we must keep in view if we are to appreciate the development of modern France out of the Dark into the Middle Ages.

This family, the overlords of the Parisian centre who had been crowned King, for a century did nothing but accumulate in their hands more and more manors, and cultivate by an instinct those remaining forces of civilization, the municipalities and the Church, which everywhere unconsciously strove to reproduce the old Roman order which had so nearly disappeared in the Dark Ages. To Hugh, in 996, succeeded his son Robert; to Robert again in 1031, his son Henry; to Henry, in 1060, his son Philip, and to Philip, at the opening of the 12th century, succeeded, first in actual and next in theoretical kingship as well, his son Louis, «the Fighter,» with whom a new expansion of the power of the Crown begins.

Thus four men, each in direct succession, each crowned coadjutor during his father's lifetime, each arriving at the throne in the vigor of his manhood, for well over a hundred years secured the continuity of the new experiment. None save Hugh was remarkable for domination; Robert rather for piety, Henry for a quiet tenacity, Philip for debauch; but all, to some extent in spite of themselves, were accumulators of territorial wealth and influence, and every social influence of the new time worked upon their side. That time, the 11th century, was one in which the energies of Christendom suddenly awoke. No new forms were discovered for it, the old architecture continued, the old customs were observed; but everything from the Rhine to the Atlantic, and from the Tagus to the Channel, was boiling with a vigorous and novel life destined to bring forth the Middle Ages. The advance from the Pyrenees against the Mohammedan begins in the generation just after Hugh Capet's crowning, and the entry of the Christians into Toledo is effected within that hundred years. It is the time when the curious phenomenon of cross-breeding, the vigorous, unique but ephemeral «Norman» race comes into being, spreads civilization through England, conquers, unites, administers, and forever attaches to Europe and separates from Oriental influence the South of Italy and Sicily. It is the time when consonant to the necessities of such new vigors and such new light, the Christian Church redefines its unity, cleanses and organizes all its machinery, and imposes a working discipline under the advice and, at last, the papacy, of Gregory VII.

Many new phenomena advance in parallel, all connected with the general advance of the time, but each following its own path. Architecture does not change, but is everywhere pursued with magnitude and vigor; men are still ignorant of the world outside the Western Christian unity, but although definite learning has not yet been organized, curiosity is wide-awake; and the municipalities which had remained so long anomalies in the agricultural system, osseous relics, as it were, of the old Roman structure, begin again to live everywhere by an independent life. The new roads are not yet built; men still march along the old decayed Roman highways, or make use of the river systems or of the sea; land is not yet bought and sold;

no universities are yet in existence; no Gothic arch has yet been built; vernacular speech is but a tentative beginning, unknown in England, very local and disparate in France, in the Spanish kingdoms and in Northern Italy; no representative system has yet met (save among the clergy), but all these things, the representative system, the Gothic architecture, the universities, vernacular literature, are in seed and are germinating during the 11th century. The outcome of these various energies, their climax, and at the same time the event by which they were to be made fruitful, was the Crusade. The long example of the fighting in Spain, coupled with the unrest of the multitude and with the critical condition of the Eastern pilgrimage, had kindled a flame, and there poured out in successive hordes, mainly from Gallic territory, a host on the march for Jerusalem, the latter and organized portion of which must have been as numerous as that with which Napoleon invaded Russia, the unorganized forerunners of which may have numbered a million souls. Established by the papal sermon of Urban II. in 1095, equipped in the next year in the Summer, they trailed out in a prodigious raid of over 2,000 miles, and three years later, 15 July 1099, the remnant that had survived or persevered stormed Jerusalem and established for close upon a century the curious French experiment of a Christian outpost against Asia, established in French castles, defended (in such a climate!) by French armor mounted upon French horses, in the isolated belt of Palestine and of the Levantine coast.

The effect of that march was overwhelming; the sudden expansion of experience, the awakening of the mind, which accompanied it, produced the Middle Ages. And when from 1100 to 1115 such lords as had not established themselves in the East returned to Gaul, they discovered the monarchy renewed, and the National movement in full strength under the vigorous personality of Louis, who, though the first of that name in the Capetian line, called himself, in memory of the Carlovingians and of the Merovingians, «the Sixth.» The towns, the hierarchy, the populace, everywhere seconded this re-founder of the monarchy, and when he died, in 1137, his son Louis succeeded, heir to an executive power which was no longer founded upon territorial possession nor merely the nominal feudal bond between the great overlords, but possessed a military power of innumerable garrisoned fortresses, of a legal corporation actively allied to the Crown, and of market-towns and great cities which throughout the territory of Gaul were prepared increasingly to insist with every new generation upon the power of the King of Paris in whom they saw the living figure of the nation.

Now, at the end of the first third of the 12th century, France and Europe were fully awake. A whole generation had grown up accustomed to territorial expansion (it was a generation since the Christians had entered Toledo and a generation since the first Christian king of Hungary had died; a generation since civilization had re-entered England and a generation since the first Crusade had brought the West into touch again with the East and had begun again to teach the Christians of the Mediterranean the uses of the sea. It was a generation since the papacy had become a free and self-organized thing, elected from within the hierarchy, and a generation since unity of discipline had been established throughout the West by the powerful will of Gregory VII).

The first effect of the new life was the awakening of intellectual discussion, and of this discussion France, and Paris in particular, were the seat. It turned upon the fundamental problem of all philosophy, the reality of ideas. It had for protagonist Saint Bernard upon the orthodox side, and, in a manner which pretended to compromise but which was really opposing, the brilliant genius of Abelard upon the side that would have led to schisms and perhaps at last to the negation of God. That debate consciously or unconsciously is still in progress; the affections and sympathies of the two parties are to-day much the same. Out of it arose as its first fruit the University. Paris began to found those colleges and to group them into that united organism which soon became the great European model for the collegiate university. Parallel with the growth of a new curiosity came in the same place and from the same people the marvelous symbol of Gothic architecture. Suger, the abbot of St. Denis, the friend and counsellor of King Louis VI., and in a sense the guardian of his son, was the first to light the flame. The south tower of his façade is the first bit of true Gothic in Europe. The same masons who had built it in their youth might have lived in their late manhood to see the beginning of Notre Dame; and with Notre Dame, the first great Gothic building of Northwestern Europe, the style was fixed.

All this movement and advance corresponded to the reign of Louis VII., the son of Louis VI., and to that middle period of the preceding century which is marked by «the Second Crusade,» and in which it was increasingly felt that the French hold on Palestine was doubtful and precarious. This reign was of great length; it stretched from 1137 to 1180; its central episode, the Crusade, was undertaken upon the news of the fall of the frontier fortress of Edessa; it occupied the two years from 1147 to 1149, consisted in a futile attempt to take Damascus, and did little other than weaken the prestige of the Christian name in the East.

As has already been pointed out, not only the Crusades but the new movement and expansion of Europe, the reflowering of civilization had necessarily helped the growth of the power of the Crown; that power, apart from the ceaseless support of the clergy, the lawyers and the towns, reposed upon two territorial bases, the King's political position as superior over the great provincial lords, and the King's economic position as private lord over a number of manors and countrysides. In the first of these he could grow only by the growth of an idea, but in the second he could grow in a material and actual manner. Already the crusading movement had led in Louis VI.'s time to the crown's becoming direct lord of the province of Berri, and thus obtaining direct possession of a district south of the Loire, and in a vast number of minor cases, only a certain proportion of which even are recorded, the commercial and military movement of the time was letting isolated manors and lordships fall by escheat, by confiscation, by disputed possession, and in general by the active presence and effort of the lawyers, into the King's hands; and with every new step in the power of the kingship, the consciousness and unity of the nation increased also.

An accident coming immediately after the second Crusade, an accident which for the moment seemed to check the rise of the Capetian house, proved within half a century the main factor of its definite establishment. The heiress of the crown of England, Matilda, the granddaughter of the Conqueror, and widow of the German Emperor, had married the lord of the great province of Anjou. Her son, Henry, landed as a boy in defense of his mother's rights against Stephen of Boulogne who had contested the English succession and was acknowledged heir. In 1154, therefore, by various relationships Brittany, Anjou, and other lordships, were in the hands of a young and vigorous soldier who also became King of England and Duke of Normandy. Or, to put it as the French lawyers saw it, the Dukes of Brittany and Normandy, the Count of Anjou, etc., were all merged in one person, and that person was the powerful King of England. Nor was this all: The vast territories of Aquitaine, a feudal overlordship which, roughly speaking, comprised all the southwest of France, had ended in the hands of an heiress, Eleanor; the male succession had failed. Eleanor had first been married to Louis VII. of France, and had accompanied him on his crusade; her desperate character had led to a divorce, and immediately upon its pronouncement at Rome, Aquitaine, after its momentary union with the crown of Paris, fell into the hands of this same young claimant to the crown of England, for the divorced woman married him. The position, therefore, on Henry II.'s accession was this: that the feudal lordships of all Gallic territory west of a line drawn roughly from the centre of the Pyrenees to the neighborhood of the mouth of the Somme were in the hands of one man, and that man the King of England. In pure theory the French crown stood as it had stood before: it was still overlord of the whole, and Henry of England had to do homage separately for each province; but in practice three things gravely modified this theory. First, the united control of territories which in the aggregate formed two-thirds of French territory; secondly, the fact that these two-thirds included the maritime and commercial portion of every single great French river (Rouen, Nantes, Bordeaux, were all within Henry's boundaries) and thirdly, the complication by which these maritime provinces were in the hands of an island king. There is little doubt that if the relationship had endured for a couple of generations, its theoretical side would have weakened to such a degree that the Capetian power would have dwindled to a shadow and very soon a Plantagenet would have ruled in Paris. It did not endure. When Louis VII. died in 1180 he was succeeded by his son Philip Augustus, a man in whom the energies and the clear judgment of this new birth of civilization seemed to centre. It is evident that from the beginning of his reign Philip Augustus's great object was to destroy the overwhelming position of the House of Anjou. Fissures were opened in the great fabric by the perpetual revolts of Henry's sons under the impulse of their mother, a curse to her second, as she had been to her first, husband. The fall of Jerusalem in 1187 led to a third crusade. The old king Henry died; his son, Richard I. of England, still nominally the Lord of all these territories, went to the rescue of the Holy Land as did Philip Augustus himself. Richard was imprisoned on his return; the French king intrigued to prolong that imprisonment, and though he failed, fortune was on his side when Richard I. died at the siege of a castle in 1199, leaving England and all the French lordships to his brother John. The opportunity afforded by John's character was exceptional; his premature regency, his license, the envy aroused by his cultivation and his prowess, united against him the feudal aristocracy of England. The claims of Arthur, his nephew, the heir to Brittany, and in strict right his senior in succession to all the territories, coupled with complaints due to his marriage with the betrothed of the Count of la Marche, and the rising of Poitou, gave Philip Augustus a pretext for summoning John as feudal inferior to clear himself before a court of his peers. He failed to do so; his land was declared forfeit; the claims of Arthur were pressed. This was in 1202. In the war that followed young Arthur was captured and shortly afterwards disappeared. John was accused of the murder, and the powerful armies of Philip were supported by the general indignation of Europe. By the end of 1205 only a few towns near the seacoast remained in the hands of the English king. Though the physical conquest of the Angevin territories was thus achieved, the victory was not really ratified till 1214. In that year John, the best diplomatist of his age, rallied against Philip Augustus all the forces which it was possible to bring, moral and material, into the field. The Count of Flanders, against whom Philip Augustus had resolutely set the Roman municipalities of that district, the German Emperor, and the sympathy of the papacy were marshalled in this critical month of July against the French Crown. Philip Augustus won a decisive victory. It was not only a decisive victory for the French Crown at that moment, it was one of the very few battles in which history may be said definitely to have marked the success or failure of a great historical cause, and it affirms for 600 years the power of the French monarchy and for a much longer and indefinite period the unity and existence of the French nation. It had also its reaction upon England, for the aristocratic insurrection against John was emboldened by this defeat of his to press on to the consummation of Magna Charta.

Meanwhile yet another factor had entered into the rapidly growing consolidation of the Capetian hegemony. The Albigensian Crusade had been undertaken and had succeeded.

Contact with the East has invariably produced upon Western Europeans an effect which may be compared with the effect of a spell, and usually of a maleficent spell. Its effects may be clearly observed in those modern nations which have the misfortune to be intimately mixed (especially if their governing class is intimately mixed) with the Asiatic. Oriental customs and vices and Oriental weakening of European health enter in with too much knowledge of the East. The Crusades, now a century old, had cast such a spell over the highly civilized townships of the South of France, and a confused mass of Oriental customs whose origins or nucleus had in the town of Albi overspread the County of Toulouse and its surrounding territory. The danger grew with startling rapidity; the Pope called against it the military power of the overlord, the Northern barons especially answered the call; the fight began in 1208, and the re-establishment of Christian unity and civilization was effected within four years. This campaign, which in the eyes of contemporaries was mainly a campaign for the unity of the health of Christendom, has for these notes the particular importance that it converted what was already a nominal into a real supremacy of the power of Paris over the southern portions of Gaul. The date 1215 may be taken as the term of all this development. England was now pledged to an aristocratic policy which would weaken the growth of a great civilized state. The Lateran Council had affirmed, in its most determined form, the framework of mediæval Catholicism, the Capetian crown had triumphed over all its enemies at Bouvines, the South was definitely in the grip of the monarchy; and on the southern frontiers of Spain the great and successful fight of Navas de Tolosas had extinguished forever the threat of the Mohammedan. Henceforward Islam dwelt only upon sufferance between the extreme boundaries of Andalusia. In Paris, the Louvre, the symbol of the established monarchy was built, and round the city the great new wall, built at civic expense, was the symbol of that new mediæval civilization which was in a way the resurrection of the Roman municipality. The university was chartered and active; the epoch of the 13th century, the climax of the French race and certainly the climax of European development between the Dark Ages and the Renaissance, had come to flower. Philip Augustus died in 1223. The three short years of his son Louis VIII. were mainly distinguished for a triumphant march through the South, and in 1226 the personality who stands most for the 13th century in Europe and in France, that of St. Louis, the grandson of Philip Augustus, was seated upon the throne.

He was but a child, under the tutelage of his mother, Blanche of Castille, but even during the period of her guardianship, which was troubled by civil war, as such minorities invariably were, the power of the Crown was but the more confirmed; and from the time when the King was of age until he undertook in 1248 his first crusade, there was established by example and by vigorous action, so absolute a strength in the monarchy that all the defeats and vicissitudes of the next 200 years were unable to shake it. It had acquired a sanctity that was almost legendary and an actual force which made it coincident with the National life. The crusade of St. Louis was directed against Egypt, for Palestine was now a dependency of Cairo and the recovery of the Holy Land could only be accomplished by the reduction of the Mohammedan power upon the Nile. The five or six years during which the effort lasted were, upon the whole, unsuccessful. St. Louis returned in 1254 with a vastly increased reputation, by far the chief figure in Europe, but there remained of the old French garrisons in the Levant nothing but a few port towns at the mercy of occasional sieges, and doomed to ultimate capture. The 16 years that followed were years of quiet and successful administration, during which the most interesting experiment was that in which St. Louis, after defeating Henry III., the English King in the South, granted him a narrow territory in that region as the price of what was imagined to be a lasting peace. The King, though long past his 50 years, was moved in 1270 to another crusade. The attempt this time was made against Tunis, but at its very inception St. Louis died on the spot that is now marked by his chapel at Carthage. It is possible that the expedition to Tunis was suggested by the position of his brother Charles of Anjou in the south of Italy, for Charles, who 25 years before had married the heiress of Provence (thereby still further increasing the power of the House of Paris) had been called in by the Pope to combat the last efforts of the German Empire in Italy, and held for the moment, but only for the moment, the sovereignty of Sicily and of the Kingdom of Naples. The massacre of the French in Sicily in 1282 put an end to his power, but it did not afford any opportunity for the interference of the Empire with the papacy or with the affairs of the Italian peninsula. With the fall of the last Hohenstauffen, the mixture of the Germans in Italian affairs comes to an end forever and the anarchic welter and ill-organized conception, which had called itself for the last 300 years the Empire, meant nothing more in future but a loose confederation of shifting Teutonic lordships. The Valley of the Rhone, over which a German executive power had nominally existed for so long, though not yet technically subject to the French king, was now virtually within the orbit of which Paris was the centre. The reign of Philip III., son of St. Louis, from 1270 to 1285, contains little of moment. His son Philip the Fair, who came to the throne in this latter year, marks, despite evident signs of internal decay, the summit of the material power of this first unbroken Capetian line. His mother, the heiress of Navarre, brought to the Crown that kingdom or province. His long struggle with the papacy ended in the capture of that institution, the election at Lyons in 1305 of Clement V., and the presence at Avignon of French popes for 70 years. He had the strength to destroy the gross and highly dangerous power of the Templars, a military order which had grown to be an immensely wealthy secret society upon which the just execration of the European populace fell from every side. When he died in 1314 it seemed as though no further advance could be made in the strength of the French sovereigns. Yet it is from that date, or shortly after, that the chief peril of the Nation and of the House itself must be counted. For Philip the Fair left three sons; and, by a catastrophe hitherto unknown in all the three centuries which had seen the rise of this great family, a direct male heir to the succession failed. These three sons, Louis X., Philip V., and Charles IV., each enjoyed a brief reign, and each failed to leave a son who should succeed him. The whole course of the three reigns covers no more than 12 years, and the only chance of a direct succession lay in a man-child, John, who died within a week of his birth. Charles IV. did indeed leave a daughter, but the tradition which had strengthened for so long and whose example had been so glorious, by which a male heir alone could succeed, led through a curious legendary fiction or memory, embodied at last in definite constitutional terms and called by the name of «the Salic Law,» to the rule that only a man should succeed to the throne. The nearest male heir, therefore, if this baby daughter of Charles IV. were to be set aside, was the first cousin of Charles IV., Philip of Valois. Philip the Fair's brother Charles had been granted the title and position of Valois. It was his son who now laid claim to and immediately mounted the throne in the year 1328, 14 years after the death of his uncle. The Capetian House had proceeded without check from father to son in the virtual control of the town of Paris and the Duchy of France for more than 400 years. For 340 it had held that position with increasing magnificence, the son regularly succeeding the father, and crowned in the father's lifetime. It had at last come to be the strong ruler of a great and united nation, a nation which was the centre and core of mediæval civilization. It was impossible that so great a change, though it were but the accession of a near collateral, should pass unchallenged, and the challenge came from Edward III. of England. There was no claim worth calling a claim upon his part to the French throne, nor is it absolutely certain that at first he put forward the plea of blood. To inherit at all he would have to inherit through women, and even so he did not stand first in the succession. The policy of the French King in Flanders, his harassing of the great English trade with the ports of the Low Countries, afforded a pretext in 1336. In 1337 hostilities broke out; in 1339 the English King, Edward III., quartered upon his shield the lilies of France, which were not finally abandoned until the middle of the 18th century. And from that year may be said to date, in legal and heraldic theory at least, the struggle of the Hundred Years' War.

The epoch or trial upon which the French next entered, that of the Hundred Years' War, falls into two very distinct parts: In the first part, which corresponds roughly to the second half of Edward III.'s reign in England, successful and brilliant raids terminate in startling victories, and the French crown consents to abdicate a portion of its territory. During this first part of the wars, the armies proceeding from Britain were commanded by French-speaking nobles and a French-speaking King, and though the English language was in process of formation, and an English national spirit was already apparent, the whole thing was a chivalric adventure based upon the Gallic model. Then there was a lull, corresponding roughly to the reign of Richard II. in England, during which again the English lose ground.

At the end of Richard II.'s reign in England the Cadets of the Royal line, the House of Lancaster, usurped the throne. The usurpation was downright and even cynical—it was, of course, hateful to the morals of that time, nor could the Lancastrians maintain themselves in power save by a sort of reign of terror, coupled with a strict alliance with the wealthy and official class. Of all the elements which had gone to build up the English oligarchy, with the exception of the Reformation, none has been so powerful as this Lancastrian usurpation. The experiment rapidly led, as all such experiments have in all countries, to a foreign diversion. The war with France was renewed, but in a very different manner. The English king now claimed a real power. He was an English-speaking king, a soldier of extraordinary capacity, and very soon became, especially after his first great victory, Agincourt, a national hero. The old mad king of France in Paris was compelled to marry his daughter to Edward V. of England, and the rightful heir of France, the Dauphin, was thrust out, to the advantage of the issue of that marriage, who became the English king, Henry VI. What followed is common knowledge. Henry V. of England died; a vague national sentiment rose throughout French territory, and was embodied in the person of Joan of Arc. After one of those desperate and foot to foot struggles which are characteristic of French military history, the Capetian House gradually recovered all the territory which had been lost. The final expulsion of the last English garrison coincides, roughly speaking, with the close of the Middle Ages. This great struggle was accomplished within a few years of the development of printing and within a generation of the discovery of America.

A recapitulation of the main dates of the Hundred Years' War will not be without value to the reader.

Philip of Valois had his first engagement with Edward III. upon the fall of Cressy in 1346. The English, though a far smaller force, gained a complete victory. Immediately afterwards the town of Calais fell to Edward III. This did not lead to any immediate disintegration of the power of the French crown, though that power was gravely shaken. The next years were occupied with the great plague, the Black Death, which, though its effects have been so greatly exaggerated, especially by English historians, does form so deep a division across the history of Europe. These years indeed, though suffering from the English attack, saw an extension of the power of the King of Paris, for Philip bought the town of Montpellier in the South and acquired in full right a province which had now for 100 years been within the French orbit, the Dauphine.

Philip died in 1350. His son, John, was 30 years old on ascending the throne. The truce which had been established between the two countries had come to an end. The King of England again took advantage of the disturbed state of France (characterised by the convocation of the Northern States General in 1355) to push the attack. In 1356 the Prince of Wales, now a young man and an excellent cavalry leader (Edward the Black Prince), was advancing from the South while his father had sent a powerful army into Normandy. It was again a small cavalry raid supported by bow men that decided the issue. The terms offered to the French king by the Black Prince were refused, a battle was engaged near Poitiers, and not only resulted in an overwhelming victory of the small English forces, but in the capture of the French king. The result of this dramatic victory was the temporary dismemberment of the kingdom. The wealthy merchants and some part of the commonalty attempted a government under Etienne Marcel at Paris in the absence of the king, and convoked the National Parliament.

In 1360 John in his captivity consented to cede the Southwest in absolute sovereignty to England, and for the first time in its history a portion of the territory of Gaul was separated, though temporarily, from the National sovereignty. John returned and died in 1364. In the same year his son, Charles V., not quite thirty, that is, much of the same age as his father on ascending the throne, took over the government. He had already been the virtual head of the government for several years. Under him du Guesclin, against the spirit of the treaty signed with England, but with great courage and capacity, attempted the reconquest of French territory. A long Fabian series of skirmishes followed. The Spaniards defeated the English fleet at La Rochelle and permitted du Guesclin to recover Poitou from the English. Brittany, after the long doubt of the whole generation, began to support the French cause; Edward of England in his old age landed again, but his army was exhausted by perpetual dilatory tactics on the part of the enemy, it was virtually destroyed as a fighting force by disease and fatigue and ill-organization, and the old king of England died, after signing a disgraceful truce, in 1370. Charles V. of France held the throne till 1380. The country was impoverished, although the ancient power of the Crown had revived, and the new king, Charles VI., suffered on his accession from double disability. He came to the throne as a minor and he had madness in his blood. His very long reign (he was upon the throne for 42 years) led to nothing but disaster. The weakness of his character led to a struggle between two rival factions, known by the names of their leaders as the Armagnacs and the Burgundians. The Duke of Burgundy died in 1404, but his successor, John the Fearless, continued the struggle, seized the heirs to the throne and virtually governed Paris

The Armagnac faction, now deriving its name from a marriage of the heir of the Duke of Orleans with the heiress of that family, began to press upon the Burgundian power and was undoubtedly favoured by the people in general, and secretly by the poor king. The Gascons, the chief military element on the Armagnac side, were marching on Paris, a civil war of the most desolating kind broke out; when the moment appeared propitious for a new descent on the part of the English king.

In 1415 he landed in Normandy. It was originally, like the earlier wars, a mere raid, but it was far more successful than former raids had been. Normandy was completely conquered, after the utter breakdown of the French army at Agincourt, and finally on 21 May, 1420, the Treaty of Troyes was signed, whereby Henry V. married Catherine, the daughter of Charles V., and was declared heir in remainder to the Crown, with his descendants. The Dauphin was legally outlawed, and the position seemed secure for Henry, when in 1422 he died, succeeded immediately afterwards by Charles VI. after a reign of 42 years. There immediately began the struggle for the recapture of the territory, and that struggle was successful. Although a son had been born to Henry V. before his death, and had been solemnly crowned on his father's death, as Henry VI. of France and England, at the age of barely 12 months, the armies of the Dauphin began the reconquest. The chief elements in this were the defection of Burgundy, and the appearance of Joan of Arc. When the struggle had continued with doubtful success for seven years, this child of nineteen, confident of a supernatural mission, approached the court of the exiled Dauphin—Chinon, recognized there by some supernatural power both the King and various historic relics presented to her, relieved Orleans, had the Dauphin crowned in Rheims after a successful march across country, and in general roused in the army and the populace a confidence of success. She was taken prisoner in the second year of this marvellous career, outside Compiègne, after being wounded in her failure to capture Paris. She was sold to the English and burnt alive at Rouen. Nevertheless the English garrisons perpetually retreated or surrendered, and in 1435 the Duke of Burgundy himself abandoned the English Alliance, and with that act, of course, after the defection of so many of his supporters, all further English successes became hopeless. A few garrisons still held out, notably the St. Michael in Normandy, but Paris was taken the next year, and Rouen in 1453; and when Charles VII. died, in 1461, the French territory was clear. He was succeeded by a son who had rebelled against him, a man approaching 40 years of age, of a character dark, intelligent, very powerful and tenacious, deeply religious, and a little mad, known to history as Louis XI.

Louis XI., who next succeeded to the throne, had to meet a combination common enough at the close of any great epoch, coming as he did at the close of the Middle Ages; that is, a combination of forces which depended upon the ritual service still paid to old names and old ideas, but which only survived as clumsy anachronisms. In this case the forces with which he had to contend were the last forces of feudalism. Feudalism had long lost its vitality, and instead of having to meet a rebellion of local lords numerous and well-founded in their localities, he had to meet a combination of very great men most of them of blood royal but depending upon feudal theories and technicalities for their rebellion against him. His own brother, Charles of France, the Duke of Brittany, the heir to the Duchy of Burgundy, banded themselves under the name of «The League of the Public Good,» won the battle of Mont l'héry and proceeded as they thought to a complete success. It was here that for the first time Louis XI's powerful if not quite sane character appeared. He immediately gave way, where a weaker man would vainly have resisted, granted Normandy to his brother, made Saint Pol a Constable, and in general did all that could be done with the mouth and the pen. But it is a rule throughout French history that periods in which the French executive acts in this fashion, are those which accompany an increase of force for such an executive, and for the nation. Within three years of the defeat he summoned his Parliament at Tours. The nation as a whole was now, as always, in support of the Crown against the wealthier merchants and the aristocracy. Louis received the strongest popular support, he incited the commercial towns of the Lowlands to rise against his enemy of Burgundy, he organized the military force of Paris, and though Charles of Burgundy, who had now succeeded to that throne and who is known to history as Charles the Bold, was still far stronger than the French king, compelled him to attend the sack of Liege and even to sign the Treaty of Perronne in which Louis granted Burgundy complete independence, the Capetian could not but win. On his return to France he summoned an assembly of the notables, they denounced the Treaty of Perronne, and Charles of Burgundy's invasion of France which immediately followed was checked by the resistance of Beauvais. Everywhere in the Lowlands, in the heart of France, in his parliament and in the small provincial towns, it was the Commons who sustained Louis XI. And the Commons in France were beginning to be that which they had long ceased to be in England, peasants and small tradespeople. For in France the end of the Middle Ages tended to be democratic: in England aristocratic.

The end of Louis XI's reign emphasized at once his curious character and his successful policy. The extravagance of his religion, and the cruelty of his revenge were never more apparent than in the last years of his seclusion; and yet it was during these last years that the death of Charles of Burgundy in battle against the Swiss, gave him that province. When he died on 30 Aug. 1483, with all the provinces he had reunited to the Crown he governed almost automatically by far the greater part of the territory of modern France. Brittany alone was quasi-independent.

His son Charles was only 13 at his father's death, and the kingdom was under the guardianship of his elder sister Anne. She was well served. A second revolt of the great men in the kingdom was crushed at the battle of Saint Aubin du Cormier, and five years later Charles VIII. having now freed himself from his sister's power, married the heiress of Brittany and united that province to the Crown. He next invaded Italy in pursuance to a claim to the throne of Naples. The military result was small, but the moral results large. First, and by far the most important, the military temper of the nation was given an opportunity to exercise after the long and successful diplomacy of his father. Such foreign wars have always been of the utmost stimulant effect upon Gaul. And the second result was the introduction into France of the Italian Renaissance. When Charles VIII. died, still quite a young man, in 1498, he was succeeded by the Duke of Orleans, a distant cousin of his, the great grand-son of Charles V., who was the nearest male heir, and who had led the great insurrection of 12 years before. This prince, among the most sagacious and temperate of all European kings, insisted as a matter of policy upon renewing the Breton marriage, though the experiment was perilously near incest, continued the Italian invasions, effected an alliance with Henri VIII., marrying Mary, a sister of that king, and died on the first day of 1515 with power more complete, a territory more united, and the military organization of the kingdom more thorough, than any of these factors in French history had hitherto been.

This date, the opening of the year 1515, is of such moment for France and for all European civilization, that a short digression is necessary in order to appreciate the change we are about to witness.

The change which fell upon Europe in these first years of the 16th century is not one to which precise causes can be ascribed: it was rather one of those whirlwinds which appear to blow from without the field of material observation and of material causation, though it is indeed true that the mind of Europe had been stirring uneasily and with increasing force for three generations past. The movement which was to be of such prodigious consequence, and to which we owe the modern world, took two forms; the first of which was evidently of vast moment, the second of which at first appeared to be a particular and local phenomenon. The first was an extension of human knowledge and a rediscovery of the past. The second was the revival of those interminable theological discussions which had been wearily familiar in Europe for more than a century past. The revival of learning, the discovery of antiquity, the expansion of the known world and so forth, for a hundred years occupied the chief energies of men, but side by side with that great wave of change, went with expanding force the theological discussions of the time, until their united effect was such as to split asunder the unity of Europe; that unity has not yet been regained, though it very nearly was under Napoleon, and though the trend of things to-day is to achieve it at the expense of bitter conflicts. When this enormous result of pettifogging theological discussions was apparent, even educated men woke up to the importance of what had hitherto been a by-product in the general intellectual movement of the time.

This waking up, so to speak, to the importance of the religious quarrel, took place in the middle and towards the end of the 16th century, but it was not until the 17th century had opened that the schism was irredeemably fixed or that the division of Europe into two camps of opposed thought and morals was reluctantly accepted. This period of ferment is covered in French history by six reigns. That of Francis I., from 1515 to 1547, very nearly contemporary with the reign of Henry VIII. in England, was occupied with the glories of the Renaissance. It also corresponds to the reign of the great Emperor Charles V., and covers the first stage of the theological discussions already alluded to.

The first ten years of Francis I.'s reign were occupied with foreign ambitions, and were closed by his defeat at the Battle of Pavia in 1525. He was defeated, and only obtained his liberty with difficulty. The remainder of the reign is concerned with the transformation of architectural and every form of plastic art under the inspiration of his court, and quite late—in 1535—it was occupied with the beginning of the persecutions, an attitude which is retained during the remaining twelve years of the reign. Meanwhile, however, as the middle of the century approached, and as the principles of the Reformation obtained hold in Germany, the French kings saw the opportunity for maintaining the independence and increasing the greatness of France, against the overwhelming power of the Hapsburg House which surrounded them on every side, in Spain as upon the Rhine, and in the Low Countries. This opportunity was afforded by the Reformation which was supported in Germany as everywhere, by the squires and the great merchants, and all those who desired to break from the central authority of the Crown. From this period, for full 200 years, it was the constant policy, now more, now less active, of the French monarchs, to support the petty Protestant communities against the general authority of the Empire.

The next reign, that of Henry II., was imbued with this idea, although the repression of the Protestant movement at home was continued.

Charles V., who had survived Francis, engaged in war against that policy, but was checked by the defence of Metz. At the end of the reign, in 1559, Henry II. had done little to check the growth of Protestant feeling in France itself, had powerfully aided it in Germany and had secured for the French Monarchy the district of the three bishoprics. The wife of Henry and the mother of the next three kings was a Medici—Catherine, a woman of singular courage, probably corrupt in temper, and certainly in physique. The first two of her sons to succeed, Francis II. and Charles IX., were not quite sane, and were even more uncertain in bodily health than in mental. The theory of monarchical government which was increasing in power daily in the French mind, was weakened in practice by the spectacle of these two debilitated men. The country was in active quarrel between those great families who sided with the Reformers and those who maintained the defence of Catholicism, while the Crown was at times nothing but a pawn in the hands of either. It must not be supposed that the division really lay along philosophical lines. Nothing was commoner than for a man to appear first upon one side and then upon the other; but the progress of the Reformation was producing such an effect throughout Europe that its principles made a convenient line of division for warring factions. Meanwhile the populace, whom these factions of the upper class confused, were very strongly in favor of the national tradition, and consequently increasingly hostile to the Reformers. The feeling became acute in the town of Paris, where the adherents of the Reformation were very wealthy and powerful, and into which were already beginning to crowd those who expected a political or a diplomatic career. The natural jealousy of wealth, coupled with the indignation against the new theories (which were openly placarded in the street, often in the form of violent insults to the popular religion) led to the explosion known to history as the Massacre of Saint Bartholomew, a piece of bloodshed which, though it was less in extent than many, must rank in history as one of the great Parisian days of violence, and takes its place beside the attack upon the Commune and the Massacres of September. (See Bartholomew, Massacre of). How far the Queen Mother took advantage of the popular exasperation against the Huguenots, it is quite impossible to say. The legend that the King fired a shot by way of signal has been exploded, but it is probable that the sympathies of the Court in favor of suppressing one or other of the factions were sufficiently strong to have led to active intrigue, and it is equally probable that the popular feeling was let loose by the Crown.

Whatever the causes—and they will never be fully determined—the effect of the Massacre of Saint Bartholomew was to make Protestantism impossible as the national religion of the French.

But some years later the death of the remaining son of Catherine de Medici, brother and heir to Henry III., who since 1574 had been on the throne, left no male descendant of the Capetian House save Henry of Bourbon, the son of the King of Navarre, to whom he immediately succeeded. Now the House of Navarre had, through the influence of Henry of Bourbon's mother, supported the Reformation: not in its moral aspect but as a piece of protest against the central authorities of Europe. Henry of Navarre had no great attachment to the system on its political side, none on its theological, and an active dislike of it in its moral aspect. He was for his friends a hearty liver, for his enemies a libertine, and above all a highly successful soldier. The town of Paris under the influence of the family of Guise, went so far in its hatred of the Reformation as to refuse the quite unchallengeable claim of Henry to the throne, because his name was connected with the Protestant side, and because in the recent civil wars those who were now the members of his army, had in the main been fighting for the Reformation. Under the authority of what was called "the League," Paris refused to accept Henry of Navarre's heirship to the throne, and when in 1588 Henry III., the reigning king, had procured the death of the Cardinal Guise, and, being excommunicated for that act, joined Henry of Navarre and took refuge in his camp, Paris declared not only against the succession of Henry of Navarre, but also against the reigning and legitimate king.

In August 1589, that king was stabbed and killed by Jacques Clement. Henry IV., as Henry of Navarre must henceforward be called, was successful in the field, but was unable to take the capital; and his final admission within its walls must not be ascribed to purely military success. It was rather his personal character which gave him popularity in every circle that he led, whether military or civil, his tenacity and the growing absurdity of the attempt to put a subject upon the throne, as well as the adhesion of the remainder of the country, that slowly converted Parisian opinion. Henry IV. was ready to meet this process of conversion halfway. Within four years of Henry III.'s death (in July 1593), he abjured heresy at St. Denis just outside the walls of the capital, and next year was secretly admitted by night. The Pope accepted his reconciliation with the Church; he became immediately popular with the town of Paris, and from this date begins his true reign over the French people.

The first and most turbulent period of the religious quarrel in France ends with the Edict of Nantes, signed by this monarch in 1598. It is a document of capital importance, the first of the three great steps by which modern religion has been affected in France; the fourth of which, though already imminent in France, has not yet been taken. These three steps are: The Edict of Nantes, its revocation less than a century after it was promulgated; and the virtual secularization of the State by the French Revolution. This last or the third step, in its turn has been followed by a reaction towards Catholicism which may at any moment produce, as I have just said, a fourth landmark in the history of the French religion; but this modern process does not concern these pages.

The Edict of Nantes was remarkable in several ways: It was the first and almost the only document to grant religious toleration in its time. For three generations during which it was death to say mass in Protestant England, a Protestant in Catholic France enjoyed all the facilities of a citizen and many special privileges as well. The principle was recognized that if a religion alien to the body of citizens was tolerated at all, it must be tolerated as a privileged and exceptional thing. The Huguenot body which was then somewhat more numerous than it is to-day, and may have amounted to 5 per cent. of the population, was not only permitted to hold any office but was allowed to organize its interior life, to hold gatherings at regular intervals; to decide upon the attitude which it should maintain towards the rest of the State; and even to possess special towns as its places of refuge. The settlement was not wholly successful, as will be seen by what follows; but though it worked under an increasing strain, it was not definitely put aside until the reign of Louis XIV. and the two other generations during which it was in vigor, nourished the small but wealthy Huguenot body, permitted it to strike deep roots, and to become what it still is, though it has dwindled in numbers—a powerful alien element in the midst of the French State.

With this date, 1598, and with the signing of the Edict of Nantes, much more than with the end of the reign, the next period of French history may be said to begin.

After the settlement effected by the Edict of Nantes the energies of Henry IV. were given up as his temperament demanded, to aggrandizement, for it is remarkable that all those who acquire power over the French are tempted in a short time after that acquisition to theories of military expansion, finding in their hands the best material in Europe for such a purpose. The plan of Henry IV. was clear enough, and though it has been termed immoral was none the less patriotic. He proposed a destruction of the only strong and centralized power opposed to his own, that of the House of Rothschild, and he would have accomplished this at one stroke by the use of a powerful army, after which it is just possible that he intended to assume the headship of Europe and to impose peace. In this task or ambition he was aided by the great Sully, a man avaricious in temperament, orderly, careless of divine things, but undoubtedly courageous. The plan of the war was to help the petty German principalities in their attack upon the central power of the Emperor. The greater part of these petty principalities were naturally protestant, for protestantism had been for them the religious aspect of their political claim. Germany was therefore supporting them against their traditional authority, whether civil or religious. All was ready for the expedition, when on 14 March 1610 Henry was stabbed by Ravaillac on his way to visit Sully at the Arsenal. Many prognostications and omens had foretold this murder, the motive of which was the popular exaggeration that Henry's plot involved a war against the Pope himself and the Catholic Church. Henry was succeeded by his son Louis, the 13th of that name, then in his minority. The Queen Mother, Marie of Medicis, was Regent. She ruled with great individual power and singular energy, but perhaps with insufficient judgment. And the point was of importance because all Europe was then in the great settlement of the quarrel which the Renaissance and the Reformation had aroused.

Roughly speaking, from this moment the Protestant nations tend (a) to become oligarchic, that is to be governed by a clique of wealthy men; (b) to develop an intense local life; and (c) to deny in practice and in theory the unity of European civilization; for instance, it is amongst them that the Jews began to be treated as citizens not distinguishable from the Europeans round them. Such communities as had preserved the older philosophy tend, on the contrary, to egalitarianism: first, under the form of despotic central powers, later under the form of democratic experience. England, Holland, the Protestant Swiss cantons and the Protestant principalities of Germany and Scandinavia, tend to oligarchy and all its consequences. In England itself a great civil war was about to break out, primarily oligarchic in its origin, that is, having for its motive the determination of the squires and the big shop-keepers and merchants to govern the common people and to oust the King. But France remained the arena. The Protestants were immensely powerful; they had cities of their own, forming as it were a state within a state; they were still very numerous (forming perhaps a quarter, perhaps a third of the well-to-do classes), and the generation which could remember, whether in France or elsewhere, the old unity of Europe in philosophy and government was dead. The force of Protestantism in France lay of course upon the side that Protestantism took all over Europe, against central monarchy, in favor of oligarchic theories, and of the independence of the great landowners and of the great merchants. Had the first years of Louis XIII.'s minority been under the hands of some one strong man, France might at once have become the one thing or the other. As it was, sufficient interval was allowed for the Huguenot theories of independence to take root. It was not until 1617 that Louis XIII., now in his 17th year, began to act upon his own initiative. Much at the same moment there appears in French politics the great personality of Richelieu (q. v.). He was of the squires family, by name du Plessis. He had been trained to the Church, was poor, but had sufficient influence to be made Bishop at the age of 22. The meeting of the French Parliament or States General in 1614 (when he was not yet 30) had brought him into some prominence, for he was a member of the House of the Clergy. Two years later, in 1616, the Queen Mother with her keen Italian eye, picked him out for the ministry. From that moment he is the principal figure in France. A quarrel which Louis XIII. engaged in against his mother eclipsed Richelieu for a moment, but when that quarrel was appeased she used her influence to have him made Cardinal (in 1622), and in 1624 he entered the Council of the King, never to leave it, and to direct it during the remaining 16 years of his life with despotic power.

Richelieu, like all men who count in history, had a very simple plan, if it may be called a plan at all. He was determined to aggrandize the material power of the nation. He had, as have also all great men in history, not a simple but a highly complex and subtle appreciation of the medium in which he lived. To him is due that «rediscovery of the national soul,» which in France is only satisfied by unity and rapid centralized measures. He made short work of the Huguenot pretension to maintain within the State a body of rich men defying the authority of the State. He took, after a most gallant and savage defence, the protestant stronghold of La Rochelle, in spite of the active aid of foreign enemies, whom the Huguenots had at once summoned to their aid, and by the Peace of Alais in 1629 he destroyed their conspiracy. He left them, however, complete liberty of conscience, a stroke of statesmanship as wise as it seemed (at that moment) enormous and paradoxical. At that moment and for long years afterwards it was death to say mass in England and no Englishman could have understood the ideas of toleration at all. Neither did any Frenchman understand it as an idea, and Richelieu probably thought it illogical himself, but he forced it on the French in spite of civil war, as a measure of statesmanship.

He was not content to destroy the root of rebellion; he was also determined to destroy what was left of the ambition of the squires, apart from any religious or philosophical attitude their class might have adopted. He took the occasion of an excess in the practice of duelling to execute more than one great Catholic noble who persisted in flouting his decree against that habit; in a word, before the outbreak of the Civil War in England, he had made of France one united country in which the power of government was observed by all, and in which all tendencies to oligarchy had been utterly destroyed.

Abroad his policy was naturally the very opposite. As he had desired to strengthen France, so he desired to weaken her rivals. With this object he ardently supported all tendencies to division beyond her frontiers, and notably the claim of the German Protestants against what had a hundred years ago been the common civilization of Europe. There had broken out in Germany in 1618 the war known as the Thirty Years' War (q. v.) in which the small Protestant parcels, notably those whose conversion to Christianity was recent and whose foothold in European civilization was still insecure, had determined to break off from that tradition by the sword. Their cause was hopeless in Germany itself, but Richelieu threw the whole weight of French influence upon their side. In about 1635 the Empire and the old traditions of unity were completely successful, and in the same year France declared war against the Empire. The Spaniards invaded and were with difficulty repelled, but in the next few years the French armies occupied the Roussillon (which is now the Department of the Pyrenees Orientales), and when Richelieu died in 1642 and, some months after him, the King, Louis XIII., a definite French success was approaching. The young, brave, eccentric and somewhat taciturn prince of the blood, Condé, then Duke of Enghien, delivered the fortress of Rocroy on 19 May 1643, and five years later in company with the great Turenne, he accomplished for his country after the most striking military successes, the Peace of Westphalia, by which, in 1648, the Protestant principalities,—and notably, the sandy wastes whence has sprung the kingdom of Prussia,—were created independent units, and the power of the Austrian Empire and of the old traditional central authority in Germany, finally wiped out.

The centre of the 17th century, like the close of the 16th, and like the year 1515, is a date upon which all historical students should repose. Another stage in the great quarrel was accomplished, and the schism of Western Christendom was signed and sealed. Within a few months Charles I. was to lose his head and the English were to lose forever the conception of monarchy and perhaps forever, the sentiment of civic equality. Germany, though destined perhaps ultimately to be reunited, was for 300 years left torn between the old Roman civilization and the barbarism of the North. France, the agent of this vast Protestant establishment, had, so far as domestic politics were concerned, welded her unity, re-established her own traditions, and crystallized into the highly definite modern form, which she not only preserves to this day, but seems destined to preserve indefinitely. There was not yet a code of laws, the old gimcrack pretensions of the nobility were still strong, but the whole spirit of the people and of their literature, had become again egalitarian and Roman, and the destiny of the next century and a half might be predicted from the Peace of Westphalia.

Meanwhile Louis XIII. was dead, a little child six years old, another Louis, his son, was upon the throne. The regency was again in the hands of a woman, and when this great development before mentioned was in process, the government was in the hands of Anne of Austria, the Queen, and of her favorite, an Italian of great subtlety and low birth, known to the French as Mazarin (q. v.).

Mazarin was not only lowly born and subtle; he was also extremely fond of money. But he had all the Italian conception of what is august; he had inherited the tradition of Richelieu; he maintained it, not nobly but by successful intrigue. He managed to wear down the tendencies of revolt on the part of the nobles which still remained (the greatest French generals, Condé and Turenne himself mixed in that revolt) and when he came to die he left to the boy, Louis XIV., then but 23 years of age, a complete inheritance of a thoroughly successful foreign policy (the Peace of Westphalia was 13 years old); an altogether independent personal despotism in the hands of the King, and a nation so organized in literature, in self-appreciation and in common morals as to form a completely homogeneous body in the Europe of its time. With that year (1661) in which Mazarin died, corresponding within a few months to the restoration of the impoverished, undignified and salaried monarchy made in England, begins in actuality the peculiar and (in the eyes of contemporaries) the glorious reign of Louis XIV. A boy of 23, as has been said, on his virtual accession, he reigned until 1715, a period of 54 years, and from the habits of the generation formed in that space of time, descend the 18th century and the Revolution in France, and, in a sense, modern Europe.

The reign may be conveniently regarded in three periods. The first, of 17 years, covering Louis' active manhood and taking one to his 40th year, was principally composed of successful warfare. And the Peace of Nimeguen in 1678 terminated a successful and advancing struggle against what had become a coalition of the smaller powers against his throne. From that period till close upon the end of the century, the very rapid perfecting of French life which was setting, as it were, into a clear classical form, tempted him to that great sin of every French leader, which is ambition. With such armies and with such an intelligence as his allies, he began to dream. There was even for a moment a danger of the French Church becoming national and losing the spirit of Catholicism. The combination against him continued to exist, and in the midst of this period the final victory of the English aristocracy over the Stuarts threw a heavy weight into the scale against Louis XIV. He was a man of strict honor, and his policy as well bade him support the claim of James II. and of James II.'s son. He had against him, therefore, from 1688 onward, the whole force of the governing power in England as he had already had against him for 20 years the whole force of the governing power of Holland. To this period also belongs (in 1685) the most disputed act of the whole reign because it was the one which most nearly touched the interests of those opposed to the French people, the interests of their philosophy that is, and by philosophy alone do communities live. This act was the revocation of the Edict of Nantes. From that date it has been a fixed article of French policy that the State shall be one, and that no power within the State shall be permitted to exist. There was a vast outcry against the victims of this determination for unity; logic demands that a similar outcry should be raised against the persecution of the priests under the Revolution, of royalists under Napoleon, of the religious orders in modern France, and of countless other instances of minorities which this cardinal principle has caused to suffer. It was not of course a personal act of Louis XIV., it was but one further stage in the maturing of that principle of absolute unity, which had been growing in the French mind since the opening of the Middle Ages, and which had acquired such open symbols upon the accession of Henry IV.

In the third period of his reign, as an old man, Louis XIV. engaged upon the last great struggle of his life. The King of Spain, Charles II., had left the crown of that country by will to the young grandson of Louis, Philip, Duke of Anjou. This was in 1700. It was debatable whether Louis XIV. should accept this onerous honor or not; he determined to accept it.

It must be remembered that until within living memory, monarchy was a real political principle. Those who now exercise the function, make us forget what a very real thing a reigning family was up to the moment when the French Revolution had worked out its full effect. For members of one family to rule over France and Spain at the same time had something of the same effect on contemporary imagination as would have today the declaration by one great power that it was determined to annex the territory of another. War flamed at once throughout Europe. It was one of those contests in which the French nature was in real peril and in which defeat seemed certain; one of those contests of which the two other historic examples are the invasion of Henry V. and the German war of 1870-71. Upon this occasion, however, there was toward the end of the struggle a rally which prevented the consequences that followed upon the earlier and upon the later occasion, and when the Treaty of Utrecht was signed (as well as those of Restadt and Baden) in 1714, the honor of the country and of the monarchy was saved. All that was lost by France was colonial territory to which at that time no more importance was attached than is attached by us today to the impoverishment of the laboring classes of a nation, or to the loss of its religion, for no generation is capable of foreseeing the future.

The next year the old King died, leaving for successor a little child, his great grandson, who is known to history as Louis XV.

During the minority of this child France was in the hands of the Duke of Orleans, acting as Regent. The Regent had all the qualities that we admire in man, especially that of courage. He was a gentleman, and thoroughly generous; but he was a libertine, and this weakness of sensuality marred both the dignity of his position and the efficacy of his government. His counsel, the Cardinal Dubois, was probably most unworthy, but one must be careful not to exaggerate one's impression of him, for the attack upon authority was already beginning, and the fact that Dubois was in orders was quite enough to make the intellect of his time emphasize his vices. After a period of violent speculation and of great though perhaps exaggerated public distress, the Regent died, having held his authority for eight years. From that moment (1723) Louis XV. began to reign.

Nothing is more difficult than to estimate the character of this man. It cannot be denied that upon this character the history of France during the next 70 years largely depended. For the monarchy was still real and absolute and the method in which it was conducted was the chief factor of the national destiny.

The writer of these lines has minutely examined the acts, the portraits and the handwriting of Louis XV., and in relation to a monograph concerned with that period, has made himself thoroughly acquainted with the personality of the man; and yet he finds it very difficult to give a true judgment. He was profoundly Christian, with a fervor of religion that verged upon superstition; he was undoubtedly courageous, somewhat sensual, in old age excessively so. On the other hand he suffered from an impediment of the will. To say that his will was weak would be to convey a very erroneous impression. But there were a certain number of things he could not bring himself to do, and chief of these was the exercise of authority face to face. He hated and avoided all interviews and all scenes. In his character of gentleman this was well enough, but in his character of King it was fatal. The first war of his reign was upon the whole glorious. And the Treaty of Vienna, signed in 1738, gave France the reversion of Lorraine. But two years later the principal quarrel of the century and the most important event, in its effects between the English Revolution and the French, took place. This was the death of Charles VI., the Emperor of Germany, who left as heir his daughter Maria Theresa. The German anarchy was at once aroused. The attempt to destroy the empire virtually was begun by the Protestant princes, and notably by the rising power of Prussia. At this moment a clear error, one of the very few with which French diplomacy can be reproached, was committed. Two centuries of tradition proved too strong for the French intellect, and the French armies were allied with those of the petty princes and of Prussia against Austria. The origin of the war was marked by the first of those scandalous acts which have brought European civilization into such peril during our own time. Frederick II. of Prussia, a man subject to every vice, with the exception of cowardice, seized Austrian territory without title and without any declaration of hostilities. It was the act rather of an Asiatic than of an European. But the French monarchy, whose whole history had been a protest against such a perversion of public morals, found itself in alliance with this detestable soldier. The alliance was not unsuccessful, and the war which followed will be forever famous in French annals from the great victory of Fontenoy on 11 May 1745, a victory largely due to the Irish exiles who fought under the French flag. The Peace of Aix la Chapelle signed in 1748 did not show the fruit of so much military valor and success; it left France very much as it found her. But the struggle with its false issues and its vanity had luckily converted the French diplomats, and henceforward France wisely associated herself with Austria, with the especial purpose of meeting the rising power of England. Had the French forces been confined to the struggle with England, their success, which was already great at sea, would probably have been final, and the strange spectacle would have been presented in our own time of a France weighted with eccentric, un-European colonies, and probably deprived of its whole national spirit and tradition. The reason that we have no such spectacle to enjoy or deplore is that the government of Louis XV., not content with fighting England abroad and at sea, undertook a continental campaign, and fought side by side with Austria in what is known as the Seven Years' War (q. v.). At the very beginning, in 1757, Frederick of Prussia inflicted a crushing defeat upon the French at Rosbach, a defeat entirely due to the ineptitude of the French command. Meanwhile in the colonies the French lost and the English won. And in 1763 the Treaty of Paris was signed, which for a century destroyed all French effort oversea, left Canada to the English, abandoned India, and, what was graver in the history of European morals, permitted Frederick of Prussia to retain Silesia, thereby acknowledging in a public instrument for the first time since the foundation of Christendom, that lawful succession and inheritance might be waived in presence of force. From this grave crime Europe still suffers. It was the precedent of all the international anarchy which our generation has almost become accustomed to.

The remaining 11 years of the reign were passed in peace, but in dishonor. The nation was profoundly troubled in its pride as in its economic circumstances. The heir to the throne was a lanky, very stupid boy, the grandson of the old king, and men saw nothing in the immediate future for their relief, though the death of Louis was looked forward to as to an event for public rejoicing. He passed, after a few senile years of debauchery, in 1774, and his grandson, Louis XVI., who had been married as a boy (four years before) to the youngest daughter of Maria Theresa, Marie Antoinette, ascended the throne. On the same day the Boston Harbor Act was proclaimed in the American colonies. It is quite impossible in a few short notes such as these to prepare the reader for the enormous convulsion through which France and all civilization was now about to pass. It is enough to say that the mind of that generation was by this time securely fixed in a clear and intense conviction: that lucid, mechanical and direct methods capable of reasonable analysis were in all departments of human energy the only ones which man as a moral being could entertain. It followed that all merely organic things were in peril, the old and merely traditional constitutions of the country, and of course religion. The Catholic faith had never been at so low an ebb since Constantine; its power has been returning for a century, and it is difficult for our generation to understand how completely the faith had disappeared just before the French Revolution broke out. The first years of Louis XVI. were occupied with a renewed struggle against England, which struggle was successful beyond the dreams even of those who most ardently supported the policy of attack. French guns had been supplied to the army which conquered at Saratoga shortly after a French fleet rendered possible the surrender of Yorktown; and it was imagined both in England and upon the continent (such is the impossibility of foreseeing the future) that the power of Great Britain was finally extinguished. Meanwhile, the American colonies and their ideal republic furnished an object lesson, as it were, to the rationalism of the time. And the public mind was moving very rapidly indeed towards a reconstruction of society. The moral equilibrium was utterly unstable. It needed but some material cause for that equilibrium to be upset, and for a new society to arise. This cause was presented by the condition of national finance. France was a very wealthy country and like all the rest of society at that moment, was rapidly increasing in wealth. But the methods of taxation were grossly imperfect, the burden fell upon the wrong people, and was imposed in the wrong way. So that France could with difficulty furnish a sum equivalent to no more than five dollars per head of its population, where today it furnishes with the utmost ease close upon and often exceeding, 20 dollars a head. An assembly of the notables of the kingdom was summoned in 1787 and did nothing. And finally in 1789 was convoked the first great democratic parliament ever seen in Europe since the Middle Ages had declined. The experiment was watched with alarm, especially in England, where the conception of popular government was mistrusted and disliked, not only by the ruling oligarchy but by the people themselves. When the assembly had met, which was in the May of that year, the commons proceeded to claim in practice complete power in the State. They had for their ally the city of Paris, without whose energy and courage their rhetoric would indeed have been vain. The mobs of the capital proved incapable of withstanding regular troops. That was the chief and least understood aspect of the Revolution. Nor can any unacquainted with the military temper of the French people comprehend the movement. It was, for instance, Carlyle's principal error that he imagined a display of public force sufficient to check the Revolution. Public force was used to the utmost, and failed because the people were in a mood of indifference to suffering and to death, a phenomenon so rare that, save in Ireland, the modern world has seen no example of it. It is possible that a democracy would have been established and that the names at least of certain great traditional functions in the State would have been preserved, and that the Revolution would have ended in a compromise, had there been no foreign war. As it was, the attack made upon the organization of religion, and the attempt to withdraw the Catholic priesthood from their normal organization and to make of them a civil service, coupled with the perpetual indignities offered to the King and Queen, and added to the ceaseless effects of violence, moved Europe to interfere. The method of this interference was cautious and long debated, but the threat of it was enough to goad the French people. In June 1791 Louis XVI. and his wife and children fled to the frontier and were recaptured. Two months later Austria and Prussia publicly agreed upon a policy of intervention, though even at this late stage the agreement was conditional, and so far as we can judge by the private letters exchanged in that autumn, the idea was rather to overawe the French democracy by a display of invincible force, than to proceed to actual invasion. In the winter, largely through the action of Marie Antoinette, Austria, ruled by her brother, proceeded to impose minor but direct commands upon the French policy. In the spring war was declared. The allied armies did not cross the frontier until the height of summer, but it appeared certain that they would be in Paris by the end of August, for the disorganization of the French army was complete and it was quite incapable of making a stand. The invasion was accompanied by a manifesto drawn up by advice of Marie Antoinette (who was probably the author of its principal threat) and this manifesto devoted the town of Paris to military execution, if the persons of the royal family were not left inviolate. The answer of Paris to this document was to storm the palace on 10 August. The building was well defended by a powerful force of 6,000 men, and it was the opinion of Napoleon Bonaparte, who seems to have been an eye witness, and who was certainly an excellent judge of military affairs, that the military chances were in favor of the crown. The mob fought with the utmost courage, losing men in numbers variously estimated at 150 and 3,000,—the latter is the nearer computation, for though the losses were heavier of course upon the defeated side, the services of numerous carts and carriers were required for the whole day and the succeeding night in removing the dead. At any rate the populace were completely successful. The royal family was imprisoned and a committee of extreme democracy, the chief of whom was the learned but impetuous Danton, took over the management of the country in the face of the enemy. That enemy proceeded without obstacle, forced the three passes of the Argonne, and met such forces as the French had scraped together on much the same ground as had seen the struggle against Attila, the great plain now occupied by what is called «the Camp of Châlons.» The center of the French position was the windmill of Valmy. What followed is a singular lesson in strategics. There was, properly speaking, no battle. A distant cannonade and an abortive charge made up the whole action. But precisely because the Duke of Brunswick did not press his power home Valmy had all the effect of a thorough defeat. A retreat was negotiated, and from that day, the equinox of '92, the Revolution took on its final phase. The republic was declared, the trial of the King was prepared, the army though still undisciplined and unmilitary gained the haphazard victory at Jemappes, and poured over the frontier into Belgium. On 21 Jan. 1793 the King was executed; within a fortnight Holland, England and Spain, one may say the whole of Europe, was at war with France. The volunteers and other hotch-potch under Dumouriez in Belgium were defeated; at Neerwinden, Dumouriez betrayed the country and ultimately accepted a large salary from England, whose strategy he advised and overlooked, and the French Revolution, for the second time in peril, established martial law. A strict military despotism in the hands of a small committee, known as «The Committee of Public Safety,» governed France with ruthless severity for 16 months, defeated the enemies of the country and began that marvelous series of victories which within a generation transformed the world. During those 16 months the committee was changed; but its principal names give it unity from first to last, and in its latter stages the name most upon public lips was that of Robespierre (q.v.). Robespierre did not command the committee. They were at first jealous of him and toward the end of the period he hardly attended their meetings. He was a man of many virtues, of a high political idealism, and of conspicuous sincerity and candor, but he suffered from the vice of ambition. He loved the popular idolatry that surrounded him, and used it as a lever against the committee. This committee, therefore (in which he had but two friends), being essentially military in its nature, and occupied principally in the military problem of repelling the foreigner, determined to be rid of him. They planned his destruction, and Robespierre was outlawed and guillotined on 28 July 1794.

It so happened that the period of his great popularity had coincided with the height of the revolutionary delirium. Three-fourths of the country was in revolt. Savage acts of repression had followed the crushing of the rebellions and «the Terror,» as it was called, had come, very falsely, to be associated with Robespierre's name. When he fell, therefore, the committee found to their astonishment, that his fall was taken as a signal for the relaxation of their military power. From that date (called in the new revolutionary calendar «the Tenth Thermidor») the active portion of the Revolution ends. It had succeeded in finally establishing the theory of democracy.

In the next year it achieved its most diplomatic success, and imposed peace upon its enemies at Basel in a treaty which considerably enlarged French territory, and shortly afterwards the public assembly which had accomplished this great result was dissolved. England

and Austria alone remained at war. Against the second was despatched into the Plains of Lombardy a young Corsican who had but lately been given his brigade, and who was but 27 years of age. This man was Napoleon (q.v.) and from that date, 1796, the history of France begins to be a record of his exploits.

Bibliography.—The literature relating to the history of France is extensive. For details concerning detached periods and events and for the careers of the great Frenchmen of this period the reader may consult the above mentioned articles, where will be found the most important works relating to each. For a general history of France consult: Bourgeois, 'France under Louis XIV.' (1889); Duruy, 'Histoire de France' (trans. by Carey, New York 1889); Fleury, 'Histoire de France' (1891); Guizot, 'Histoire de France' (Paris 1870); Kitchin, 'History of France to 1793' (Oxford 1881-82); Martin, 'Histoire de France' (Paris 1855-60); White, 'History of France' (1890); Anquetil, 'Histoire de France depuis les Galois jusqua la mort de Louis XVI.' (15 vols., Paris 1820); Bonnechose, 'History of France from the Invasion of the Franks under Clovis to the Accession of Louis Phillippe' trans. by Robson (London 1862); Daniel, 'Histoire de France' (17 vols., Paris 1755); Genoude, 'Histoire de France' (16 vols., Paris 1844-7); Lavallée, 'Histoire des Français depuis le temps des Gaulois jusqui' en 1830' (4 vols., Paris 1856); Michelet, 'Histoire de France' (16 vols.); Hotman, 'Franco-Gallia: or an Account of the Ancient Free State of France' (1574, English trans. by Viscount Molesworth, London 1711); Laveaux, 'Histoire des premiers peuples libres qui ont habité la France' (3 vols., Paris 1798); Picot, 'Histoire des Gaulois, etc.' (3 vols., Geneva 1804); Thierry, 'Histoire de la Gaulle' (3 vols., Paris 1840-7); Bloch, 'Les origines la Gaule indépendante et la Gaule romaine' (Paris 1900); various editions of Cæsar's 'Commentaries on the Gallic War'; Ségur, 'Histoire de France' (11 vols., 1834-5); Royon, 'Histoire de France' (Paris 1819); Hugo, 'Histoire générale de France' (5 vols., Paris 1836); Leroux; 'Les conflits entre la France & l'Empire pendant le moyen âge' (Paris 1902); Duruy, 'Histoire de l'Europe et de la France, 395-1789' (Paris 1892); Capefigue, 'Charlemagne' (2 vols., Paris 1842); Depping, 'Histoire des expeditions maritimes etc.' (2 vols., Paris 1826); Luchaire, 'Louis VII.—Philippe-Auguste—Louis VIII., 1137-1226' (Paris 1902); Lussan, 'Histoire de règn de Charles VI.' (9 vols., Paris 1753); Vallet, 'Histoire de Charles VII.' (3 vols., Paris 1862-5); Beaucourt, 'Histoire de Charles VII.' (6 vols., Paris 1881-91); Poullin, 'Histoire de Jeanne d'Arc' (1893); Maulde-la-Clavière, 'Histoire de Louis XII.' (6 vols., Paris 1889-93); Cherrier, 'Histoire de Charles VIII.' (2 vols., Paris 1868); Kirk, 'History of Charles the Bold' (3 vols., London 1864-8); Legeay, 'Histoire de Louis XI.' (2 vols., Paris 1874); Baird, 'History of the Rise of the Huguenots of France' (London 1880); Lutteroth, 'La Réformation en France pendant la première périod' (Paris 1859); also works on the Reformation by Segretain, Chéruel, Mignet, Poirson, Freer, White, Robson, and others; Jackson, 'The Last of the Valois' (London 1888), and 'The First of the Bourbons' (London 1890); Dussieux, 'Le Cardinal de Richelieu' (Paris 1886); Fagniez, 'La Père Joseph et Richelieu' (Paris 1893); Hassall, 'Mazarin' (London 1903); Bonnemère, 'La France sous Louis XVI.' (2 vols., Paris 1864); Yonge, 'The History of France under the Bourbons, 1589-1830' (London 1866-7); Anquetil, 'Louis XIV. La Cour et le Regent' (1789); Jobez, 'La France sous Louis XI. 1715-1774' (6 vols., Paris 1864-73), and 'La France sous Louis XVI.' (2 vols., Paris 1877-81); Tocqueville, 'Histoire Philosophique du règne de Louis XV.' (2 vols.). On the Revolution the number of works is too great to be enumerated separately but the following books are representative and authoritative: Aulard, 'L'éloquence parlementaire pendant la Révolution française' (3 vols., Paris 1882-86); Aulard, 'Histoire politique de la Révolution française, 1789-1804' (Paris 1901); Bourgoing, 'Histoire diplomatique de l'Europe pendant la Révolution française' (3 vols., Paris 1865-71); Carlyle, 'French Revolution' (London 1837); Chassin, 'La préparation de la guerre de Vendée' (3 vols., Paris 1892), 'La Vendée patriote' (4 vols., 1893-95); Goncourt, 'Histoire de la société française pendant la Révolution' (Paris 1854); Jomini, 'Histoire critique et militaire des campagnes de la Révolution de 1792 à 1801' (3d ed., 15 vols., Paris 1819-24); Jung, 'L'Armée et la Révolution: Dubois-Cranée' (2 vols., Paris 1884); Michelet, 'Histoire de la Révolution française' (1st ed., Paris 1847-53); Mignet, 'Histoire de la Révolution française' (1st ed., Paris 1824); Morse-Stephens, 'History of the French Revolution' (New York and London 1886); Mortimer-Ternaux, 'Histoire de la Terreur' (8 vols., Paris 1862-81); Quinet, 'La Révolution' (1st ed., Paris 1885); Sciout, 'Le Directoire' (2 vols., Paris 1895); Sorel, 'L'Europe et la Révolution française' (4 vols., Paris 1885-92); Von Sybel, 'Geschichte der Revolutionszeit von 1789 bis 1800' (5 vols., Düsseldorf 1853-7; English translation to 1795, London 1867-69); Thiers, 'Histoire de la Révolution française' (Paris 1823-7); Taine, 'La Révolution' (1st ed., Paris 1878-85); Tourneux, 'Bibliographie de l'histoire de Paris pendant la Révolution française'; Wallon, 'Histoire du tribunal révolutionnaire de Paris' (6 vols., Paris 1880-82).

HILAIRE BELLOC,
Author of «Danton,» «Robespierre,» etc.

3. **France—History 1796-1804.** See FRANCE HISTORY FROM THE REVOLUTION TO THE ESTABLISHMENT OF THE EMPIRE.

4. **France — The Empire.** As the fear of socialism helped to found the consulate in 1799, so the royalist plot of 1804 precipitated the foundation of the Empire. Much as France abhorred the execution of the Duc d'Enghein, she was still more aghast at the prospect of the turmoils which would ensue, should Napoleon be suddenly removed from the head of affairs. "The need of repose and stability," says Miot de Melito, "was so pressing, the future so disquieting, the fear of terrorism so great, the return of the Bourbons so formidable that people quickly grabbed at any expedient which might save them from those dangers." Seven days after the Duke's murder, Fouché appealed to the Senate to establish hereditary government. The idea was taken up on every side. Carnot alone opposed it in the Tribunate; the Senate, the Council of state, reported in its favor and after a brief period of affected hesitation Napoleon complied with the general desire. On 18 May 1804, a constitution which had been elaborated by Fouché and Talleyrand was adopted in the Senate with three dissentent voices. It decreed to Napoleon the title of Emperor of the French and settled the succession to the throne on his direct male issue, natural and legitimate. It enabled a childless emperor to adopt the children or grandchildren of his brothers, and designated Joseph and Louis Bonaparte (Napoleon's brothers) to the succession, in case the Emperor should die without natural or adopted children. The civil list was fixed at 25,000,000 francs, a sum established in the constitution of 1791; and other provisions were added with the design of adding brilliance and authority to the throne. Six grand dignitaries of the Empire, irresponsible, irremovable, enjoying the status and prerogatives of princes, were to support the new Emperor. Cambacérès was made Archchancellor, Lebrun, Archtreasurer. The office of Grand-Elector — a title borrowed from the nomenclature of the Holy Roman Empire — was conferred on Napoleon's elder brother Joseph; the office of Constable was given to the younger brother Louis. The remaining two dignities were ultimately conferred upon connections by marriage, and while Napoleon's stepson, Eugène Beauharnais, became Archchancellor of State, his brother-in-law, Murat, was given the rank of High Admiral. Another provision in the Senate's constitution of 18 May 1804, was designed to conciliate the army. There were to be 16 marshals of the Empire, and the marshal's bâton henceforward became the chief prize of military ambition. At the same time the court was furnished with decorative officials, with a grand almoner (Cardinal Fesch), a grand marshal of the palace (Duroc), a grand chamberlain (Talleyrand), a grand equerry (Caulaincourt), a grand master of ceremonies (De Ségur), and with numerous prefects and ladies of the palace. The changes made in the mechanism of the government were even more significant of absolutist tendencies. The restriction placed upon the numbers of Senators was removed and their nomination conferred upon the Emperor. The Tribunate was divided into three sections, dealing respectively with legislation, home affairs, and finance, a measure which effectually destroyed its potency as an organ of protest; and though the legislative body was given the power of discussing measures in a general committee, the discussions, unless invited by the Council, were neither to be published nor printed. As a matter of fact both Tribunate and Legislative ceased to be working parts of the machinery. As the powers of the Tribunes expired, no fresh nominations were made, and so the body vanished from the constitution. A more expeditious method of legislation was discovered. The Emperor governed by means of *Senatus Consulta* or decrees of the Council of State.

The French people acclaimed the constitutional revolution by more than three and a half million votes; that is to say, by a larger majority than was given for the Consulate or the Consulate for Life. Of the opponents, Carnot was the most conspicuous; and it is noticeable that almost all the barristers of Paris were against the establishment of monarchy; but the army was flattered by the elevation of its leader, and the peasantry saw in the change a fresh guarantee for the stability of the revolutionary land settlement. That he might reassure the Catholics, and win the royalists, Napoleon summoned the Pope to preside over the coronation. Pius VII. undertook the journey, but was destined to receive a lesson upon the relations of the spiritual to the temporal power. After he had anointed the Emperor and Empress with the holy oil and as he was proceeding to perform the act of coronation, Napoleon seized the crown and placed it on his head with his own hands. The sword and insignia of Charlemagne were brought from Aix to give significance to the occasion, as if the ceremony of Notre Dame betokened nothing less than a revival of the great Frankish empire.

Meanwhile war had broken out with England. The vigilance of the English fleet prevented that concentration of the French navy in the channel which was essential to the escort of the Boulogne flotilla, but Napoleon had paved the way for a war with Austria, in case it should prove impossible to strike at London. On the pretext that an emperor could not also be president of a republic, it was determined to convert the Italian republic into a monarchy. The Italian crown was offered first to Joseph, then to Louis, but the brothers were too ambitious to renounce their claims on the imperial succession, and Napoleon finally decided to assume the crown himself and to appoint Eugène Beauharnais his viceroy. Italian deputies were summoned to Paris to vote the crown and in May 1805 Napoleon went to Italy to receive it. In the cathedral of Milan on 26 May he placed the old iron circle of the Lombard Kings upon his brow, and though the French Senate and the rulers of Europe were assured that the Italian Kingdom and the French Empire would be kept strictly separate, no one was deceived. The annexation of Genoa to France was a proof that Napoleon's ambition was insatiable, and advertised to the powers that war was the only remedy. By July 1805 Russia had determined to break off relations with Napoleon; on 9 Aug. Austria gave her secret adhesion to the Russo-British alliance, by the middle of September an Austrian army under General Mack was at Ulm. The speed and genius of Napoleon disconcerted all the calculations of his enemies. The army of England (rechristened 29 Aug. the grand army) was swung round, and rapidly pushed through Germany into the valley of the Danube. On 20 Oct. Mack, surprised, surrounded, and overwhelmed, capitulated at Ulm; and on 2 Dec. (the anniversary of the coronation) the Austrians and Russians were defeated with huge loss at Austerlitz. Francis withdrew from the war and on 20 Dec. 1805, signed the treaty of Pressburg with France.

The most obvious political result of the campaign was that the influence of the French Empire was substituted for that of Austria in Italy and Germany. The Hapsburgs were compelled to recognize the Italian Kingdom and the annexation of Genoa, and to cede Venetia, Istria, and Dalmatia to the victor. The Neapolitan Bourbons had received an Anglo-Russian force into their capital, and for this violation of neutrality they were condemned to expulsion. Accordingly no sooner had peace been struck at Pressburg than Napoleon sent St. Cyr (q.v.) and Massena (q.v.) to expel "the guilty woman" who had so flagrantly "violated all that is sacred among men." In this mission they were successful. On 13 Jan. 1806, Ferdinand and Caroline fled to Sicily, where they were secured by the protection of the English fleet. The Kingdom of the two Sicilies was given to Joseph. Elise Bacciocchi, a sister of Napoleon, became Princess of Lucca and Piombino, while another sister, the beautiful Pauline Borghese, received the principality of Guastalla. Thus the whole of the Italian peninsula, save the Papal States, came under French control.

The results of Austerlitz were no less impressive in Germany. Before the war Napoleon had solicited and obtained the alliance of the South German dynasties and after the victory he proceeded to reward his allies. Bavaria and Wurtemburg were raised to the dignity of kingdoms; Baden became a grand duchy, while marriages were arranged between Eugène and Princess Augusta of Bavaria, Jerome and Princess Caroline of Wurtemburg and Stephanie de Beauharnais and the Crown Prince of Baden. By recognizing the independent authority of the three South German Princes Napoleon had practically eliminated Austrian influence from South Germany, but so long as the shadow of the Holy Roman Empire remained, the Hapsburgs still retained a right of intervention in German affairs. This right Napoleon determined to abolish. On 1 Aug. 1806, the Diet of Ratisbon was informed that the Holy Roman Empire was at an end. In place of this ancient and picturesque institution a confederation of the Rhine was formed under the protectorate of Napoleon, a "new Carolingian code" as it was called in Paris, where it was drafted under the direction of Talleyrand. The 16 princes who joined the confederation were bound by a close offensive and defensive alliance to France and compelled to furnish contingents to the grand army. As the price of their subservience to the Protector of the League, they were encouraged to be autocratic in their own dominions.

As Austerlitz gave Napoleon control of Southern Germany, so Jena and Friedland made him master of the north. The Prussian Court, roused by the occupation of Hanover in 1803, the murder of the Duc d'Enghein in 1804, and the violation of Prussian neutrality by Bernadotte's corps in 1805, determined (October 1805) to present an ultimatum to Napoleon and in the event of his refusal to cast in her lot with the allies. But the battle of Austerlitz intervened, and Haugwitz, the bearer of the Prussian ultimatum, was compelled to sign the humiliating treaty of Schönbrunn (15 Dec. 1805), the main object of which was to involve Prussia in war with England by forcing her to accept Hanover. But the war spirit was now high in Berlin, and everything in Napoleon's conduct during the ensuing months — the formation of the Confederation of the Rhine, the obstacles placed in the way of a counterbalancing confederation of the North — was calculated to raise it. Finally Prussia learned that Napoleon was offering Hanover to England, and rushed into war. Napoleon, swiftly marching through the depths of Thuringia, beat the Prussians at Jena and Auerstadt, 14 Oct. 1806, occupied Berlin, compelled the Saxons to enter the confederation of the Rhine, and finally, after the bloody and indecisive battle of Eylau, 6 Feb. 1807, won a crowning victory at Friedland, 14 June, which led Alexander of Russia to decide for peace. The three sovereigns met at Tilsit, and then a peace was signed 7 July 1807. Prussia was not only compelled to pay a heavy war indemnity, and to support a French army of occupation, but was stripped both of her eastern and western provinces. The provinces (save the circle of Bialystock) acquired by the second and third partition of Poland, were formed into a grand duchy of Warsaw, which was attached to the Saxon kingdom, and consequently included in the Rhenish confederation. On the western frontier, the Westphalian province, including the important fortress of Magdeburg were, together with the Duchy of Brunswick, parts of Hanover and the electorate of Hesse-Cassel, formed into a kingdom of Westphalia for Prince Jerome, the youngest brother of the Emperor, likewise included in the Rhenish confederation. The Baltic littoral passed under French control, for, though Danzig was proclaimed a free city, it was to be governed by a French force, and though the Duchies of Oldenburg and Mecklenburg-Schwerin were restored to their respective dukes, they were to sustain a French army of occupation until the general peace. Meanwhile, on 21 Nov. 1806, Napoleon had issued the famous Berlin decrees (q.v.), the object of which was to ruin England by excluding her goods from the continent, and by declaring the British isles to be in a state of blockade. But to make the continental blockade completely effective it was necessary to control all the littoral of continental Europe; and this, accordingly, became the primary aim of imperial policy. The Batavian Republic was converted into a kingdom of Holland, and placed under the control of Louis in 1806, while the refusal of the Pope to accede to the blockade led to the gradual absorption of the Papal States, and to their final incorporation in the French Empire in 1809. This, too, was the primary motive for Napoleon's intervention in the affairs of the Iberian peninsula. While returning from Tilsit, Napoleon commanded Talleyrand to inform the Portuguese that unless they closed their ports to the British by 1 Sept. 1807, he would declare war upon the Prince Regent. As Portugal did not acquiesce, a secret convention was signed at Fontainebleau, 27 Oct. 1807, between France and Spain, providing for the joint conquest and partition of the Portuguese kingdom. The conquest was rapidly effected, and as Junot (q. v.) with 1,500 famished grenadiers struggled into Lisbon, 30 Nov. 1807, the Prince Regent and the royal family fled to South America. But meanwhile Napoleon was preparing to overthrow the Bourbon house in Spain. The court of Madrid had secret grudges against the French Empire, and in a moment of infatuation during the summer of 1806, the Spanish army had been mobilized, with a view of rejecting the treaty of Ildefonzo, which had been the source of the destruction of the Spanish navy. But Jena upset the calculation of Godoy, the miserable favorite, who held the reins of Spanish policy. He explained away his action, protested friendship, showed himself in the treaty of Fontainebleau, prepared to connive at the destruction of the house of Braganza, and did not for a moment deceive Napoleon. The Portuguese campaign, and the dissensions between Charles IV. and his son Ferdinand, gave to Napoleon the pretext for interference. French troops were sent across the Pyrennees, nominally for the purpose of supporting the army of Portugal, really in order to effect the subjugation of the country. Finally the royal family was enticed to Bayonne, and father and son compelled, 5 May 1808, to renounce their claims to the throne. Joseph was sent to govern in Madrid, while Murat, the grand duke of Berg, took his place in Naples. By the middle of May the whole Iberian peninsula had nominally become an annex of the French Empire. In reality the gravest mistake had been committed. An English army under Sir Arthur Wellesley (q. v.) defeated Junot at Vimievo 21 Aug. 1805, and forced the French to evacuate Portugal, while the Spanish people, passionately loyal to the fallen dynasty, hating the French revolution, and impervious to the charms of a scientific administration, everywhere rose in revolt. On 22 July 1808, a large French force under Dupont (q.v.) capitulated at Baylen. It was the first serious military reverse which the French Empire had sustained.

The Austrian war of 1809 was the natural sequel to the insurrection of the Spanish people. Germany was smarting under the hardships involved by the French military occupation and the continental blockade; and the deepest resentment was caused by a decree issued by Napoleon, commanding the banishment of Stein (q. v.), the great reform minister from Prussia. Every German who hoped for better things, looked to Austria as the destined liberator; but again the genius of Napoleon overcame all obstacles. Five brilliant battles (19–23 April) drove the Archduke Charles out of Bavaria. On 13 May, Vienna surrendered to Napoleon. On 6 July he won the hard fought field of Wagram. The English diversion at Walcheren was as ineffective as the gallant raid of Colonel Schill or the march of the Duke of Brunswick's black legion through northern Germany. On 14 Oct. 1809, Francis of Austria accepted the treaty of Schönbrunn, and abandoned the Tyrol, Trieste and the Illyrian littoral to the conqueror. The Tyrolese, who, under the leadership of Andreas Hofer (q.v.), an innkeeper, had made a gallant resistance to the French, were now easily overcome, and while their leader was shot, to the eternal disgrace of Napoleon, their territory was divided between the kingdoms of Italy, Bavaria, and the Illyrian provinces of the French Empire. Nor was this the last affront to Austrian pride. Divorcing Josephine, Napoleon demanded and obtained the hand of Marie Louise, the daughter of Francis. The French Empire had now reached its zenith, though some further rearrangements of territory were effected, mainly for the purpose of improving the mechanism of the blockade. Thus Louis, who was considered to be too lenient to the Dutch, was compelled to abdicate, and the kingdom of Holland was annexed to the Empire on 9 July 1810; while at the end of the year (Dec. 1810) the northwestern portion of the Westphalian kingdom, and all the northwest littoral of Germany, including Bremen, Hamburg, Lübeck were similarly incorporated and organized as French departments. The rigor of the blockade now reached its height. Heavy duties were placed upon all colonial imports by the Trianon tariff, 5 Aug. 1810. The Fontainebleau decrees (18 and 25 Oct.) ordered that all British manufactured goods found in the Napoleonic states should be seized and publicly burnt, while 51 tribunals were established for the purpose of trying persons accused of contraband. So eager was Napoleon to complete the system that in Jan. 1811, he dethroned the Duke of Oldenburg, the uncle of the Czar.

The French Empire by this time consisted of 130 departments, stretching from the Ebro to the Trave, and from the Tiber to the Channel, and girt with a circle of vassal kingdoms and principalities. Throughout this vast area the valuable principles of social equality, religious toleration, and promotion by merit were enforced. Though the codes of the Empire were more perfunctory, more observant of older legal traditions and less liberal than the civil code, which was the work of the consulate, yet they preserved two valuable conquests of the Revolution, the petty jury and public trial. If the essence of democracy was, as Napoleon contended, "a career open to talent," than the French Empire was democratic; but in every other respect it violated the principles of liberty. Special courts were created with summary jurisdiction in the disturbed districts. The censorship of the press (aggravated by the decree of 5 Feb. 1810) annihilated political criticism. Holding that there could be no political stability without "a teaching body actuated by fixed principles," Napoleon created 17 March 1808, a University of France, which was intended to include all the educational agencies in the Empire, and to form citizens "attached to their religion, their prince, their country, and their family." No one could open a school or teach in public without being a graduate of the university, which was to create and administer the public and to authorize and supervise the private schools. The university was divided into 17 academies, one in Paris and 11 in the provinces, and governed by a grand-master, whose appointment and dismissal lay in the hands of the Emperor. The aim of the whole institution was to inculcate habits of military discipline and blind subservience, and to secure complete educational uniformity throughout his Empire. An Imperial catechism, drawn up by Napoleon himself and inculcating obedience to his person, was intended to give a similar direction to the public mind. To fortify the dynasty, Napoleon saw that it was necessary to create an hereditary nobility, but the opposition which had been made to the Legion of Honor in the name of equality warned him to proceed with caution. In the first instance he began by distributing foreign fiefs and titles, carving no less than 17 duchies out of the Venetian states; then (Aug. 1806) license was given to exchange grand ducal fiefs for estates within the territory of the Empire, and to transfer to estates so acquired the privilege attaching to noble tenure. Finally, on 1 March 1809, a new nobility was created, the titles to be hereditary and the noble lands to be entailed. In all, 31 dukes, 388 counts, 1,090 barons, and about 1,500 knights were created under the first Empire; but Napoleon was uneasily conscious that aristocracies were the product of time, and that the nobility of the Ancient Régime despised the upstart dignitaries of the Empire. "I have made princes and dukes," he said at Saint Helena, "but I could not make real nobles."

In France the burden of the Empire was great; but it was still more crushing in the dependencies. It was part of Napoleon's system to reserve half the domains in every vassal state to serve as endowments to generals or favorites, or to help to replenish his imperial treasury. In addition to this, the dependencies were subjected to the conscription and the blockade, compelled to support the French troops who might, from time to time, be quartered on them, and to maintain war establishments quite out of proportion to their financial resources. Thus the benefits secured by the introduction of the French legal codes were largely neutralized; and the French rule became detested all over Germany and Italy. The conscription was everywhere abhorred, while the blockade inflicted great injury wherever, as in Holland or the Grand Duchy of Berg, commerce or industry had been active. If the Italian, Dutch and German merchandise had been permitted a free entry into the French markets the lot of the mercantile and industrial community might have been alleviated; but in this, as in other respects, Napoleon sacrificed the interests of the French dependencies to those of France herself.

The reconciliation with the Papacy, which had been one of the principal achievements of the consulate, was broken under the Empire. The Papal States were annexed to France, 17 May 1809, by a decree recalling the donation of Constantine, and Rome was declared to be a free imperial town. Pius VII. retaliated by excommunicating the despoilers of the Church, and the bull was secretly circulated through the Empire. For this act of temerity he was seized 5–6 July 1809, and carried off to Savona, where he was kept a prisoner. Difficulties, however, soon arose. The Pope refused to institute the bishops named by Napoleon; and Napoleon failed to coerce him. The cardinals and generals of the Orders were convoked to Paris, and the archives of the Roman administration were similarly transferred to the capital of the Empire. By a decree of 17 Feb. 1810, the Pope was guaranteed a salary of 2,500,000 francs, given a palace in Paris, while at the same time it was ordained that all future Popes should at their enthronement swear to observe the Gallican articles of 1682, which were declared common to all the churches of the Empire. This bold and revolutionary measure aroused great protests. Thirteen cardinals refused to attend the Emperor's marriage with Marie Louise, and were in consequence banished to provincial towns and prohibited from wearing the purple. A national council (17 June to 5 July 1810) gave Napoleon no satisfaction, but at last a mutilated remnant of the assembly was induced to declare that the right of institution to vacant sees lapsed to the metropolitan in case the Pope failed to grant institution within six months after the see fell vacant. The Pope signed a brief accepting this conclusion, but in a form which was distasteful to Napoleon, and the sore remained open. At last, after the Russian disaster, Napoleon was induced (concordat of Fontainebleau 25 Jan. 1813) to renounce his claim to the Catholicity of the Gallican articles, while the Pope on his side confirmed the conciliar decree on the institution of bishoprics. But good feeling was never restored, and the alienation of the Catholic Church was one of the greatest errors of the Napoleonic Empire.

The downfall of the Empire was the natural result of Napoleon's ambition. The Peninsula war drained France of her finest troops, relieved the pressure on Prussia, and prevented Napoleon from carrying out the designs on the Balkan peninsula, which had been part of the secret arrangement at Tilsit. Other causes contributed to weaken the Franco-Russian alliance, —Napoleon's encouragement of the Poles, the continental blockade, the Austrian marriage, the annexation of Oldenburg. War broke out in 1812, and Napoleon led a huge army to Moscow. He retreated among the rigors of a Russian autumn (Oct.–Dec.), lost a quarter of a million men, and shattered his prestige. First Russia, then Austria, ranged themselves on the side of the allies. A crushing defeat at Leipzig (16–19 Oct. 1813) compelled the evacuation of Germany, and brought about an invasion of France. Though Napoleon fought a brilliant campaign in the valleys of the Marne and the Seine against the Prussian and Austrian armies, the allies eventually pressed on to Paris. On 30 March 1814, the defence of the capital was surrendered by Marmont, and on 6 April, Napoleon signed an act of abdication at Fontainebleau, and was allowed to retire to Elba. His dynasty was proscribed. On the advice of Talleyrand, Alexander of Russia, who had entered Paris at the head of the allied armies resolved to recall the Bourbons. So perished the Empire in a blaze of military glory, which France will never forget.

On his return from Elba in 1815, Napoleon, realizing the growth of liberalism, made a pretense of liberalizing the imperial institutions, and Benjamin Constant, who had led the opposition to Louis XVIII. was summoned to draw up a constitution. The defeat of Waterloo supervened before any serious trial had been made of the Additional Act, which established an hereditary Chamber of Peers, an elected chamber of representatives, and at the same time guaranteed the freedom of the press; but it cannot be doubted that had Napoleon succeeded in reestablishing his powers, he would have made short work of liberals and of liberalism. At Saint Helena, however, he professed that the despotism of the Empire had been a transitional expedient, and that the future of liberalism and nationality in Europe were bound up with the fortunes of his house; and this was the creed of the Bonapartist party, and the pretext and apology for the second Empire.

Bibliography.—The best short biographies of Napoleon are those by F. R. Seeley (London 1836); J. H. Rose (2 vols., London 1902); A. Fournier (3 vols., Vienna 1886-9; Fr. tr. Paris 1892). The 'Cambridge Modern History,' vol. IX. (Cambridge 1906) gives a more extended treatment, and a very full bibliography. Lavisse et Rambaud's 'Histoire Genérale,' vol. IX. (Paris 1897), is a valuable work of the same type, but slightly less elaborate. H. A. Taine's 'Le Régime Moderne,' 2 vols. (Paris 1891-4), gives a striking criticism of the institutions. For the Empire in Germany, H. A. L. Fisher's 'Studies in Napoleonic Statesmanship: Germany' (Oxford 1903); for the Empire in Italy, J. F. Driault's 'Napoléon en Italie' (Paris 1906), and R. M. Johnston's 'The Napoleonic Empire in Southern Italy' (2 vols., London 1904), may be usefully consulted. An elaborate work by F. Masson, 'Napoléon et sa famille' (7 vols., Paris 1897), in progress, is the best authority on the domestic history of the Emperor. For his statesmanship there are few works so illuminating as 'Pelet de la Lozère Opinions de Napoleon I. an Conseil d' Etat' (Paris 1833, English tr., London 1837). The text of the most important constitutional documents may be consulted in Hélie 'Les Constitutions de la France,' vol. II. The principal original authority for the period is the correspondence of the Emperor himself, which was published in 32 volumes (1858-70); to which great collection must be added some few volumes of supplementary gleanings, 'Lettres inédites ed. Lecestre' (2 vols., Paris 1897); 'Lettres inédites ed. L. de Brotonne' (Paris 1898); and 'Devnières lettres inédites ed. L de Brotonne' (Paris 1903). A handy bibliography has been published by F. Kircheisen (London 1902) but it is distinctly inferior to the bibliography in the 'Cambridge Modern History.'

Author of 'Studies in Napoleonic Statesmanship,' 'The Mediæval Empire,' etc.

5. France—History Since 1815. The history of France since 1815 is the history of the events that led up to the establishment of the Republic and of democracy. This establishment was not the result of a continuous development but of a series of crises followed by periods of reaction, each crisis making a progress, or as Mr. Seignobos says, «carrying off from the old monarchy a fragment that could not be restored.»

The first crisis is the Revolution of 1830 which put an end to the government of the Restoration. When the allies in 1814, at the fall of Napoleon, reinstated the old dynasty, what the people demanded was peace and also the preservation of the chief reforms got from the Revolution, viz., equality of rights, the selling of the *biens nationaux*, the essentials of political liberties and a chamber of representatives elected by the Nation. To these demands the charter of 1814 gave almost entire ratification; besides, the personal temperament of King Louis XVIII. (1815-1824) was of a conciliatory turn. But he had to strive against the «Ultras» who were uncompromising royalists, and whose chief was the King's own brother, the Count of Artois. This party wanted to restore the former régime of absolute monarchy, in its aristocratic and intolerant form. It was the Ultras who led the movement of violent reaction known as the «White Terror,» and who, being the majority in the chamber of 1816 (called Chambre Introuvable), placed the monarchy in such an awkward position that the King had to get rid of them by a *coup d'état*.

For three years, from 1817 to 1820, Louis XVIII. governed with moderate and liberal-minded ministers. This short period is of great importance; then for the first time were adopted in France those customs that are the necessary adjuncts of a constitutional and representative government, periodical election, annual vote of the budget, the liberty of discussion in the Chamber and, within certain limits, the liberty of the press. It was the régime of the *Monarchie Censitaire*, so-called because the political power belonged to the moneyed classes, only those who paid taxes (or *cens*) to the amount of 500 francs being voters, and those who paid 1,000 francs having a right to be elected.

It is easy to conceive that this policy of Louis XVIII. encouraged the liberal aspirations of the Nation; it vexed the Ultras who succeeded in putting a stop to it, thanks to two favorable circumstances. First they obtained the support of the aristocratic governments of Europe (Prussia, Austria, Russia) that had pledged themselves at the Treaty of Vienna to oppose revolution in any country, and that were already growing anxious at the manifestations of liberalism not only in France, but in Germany, Italy, Spain and the Spanish colonies of America. At the Congress of 1819 at Aachen, remonstrances were made to the French embassador. The second circumstance was the murder of the Duke of Berry (1820) by a lunatic called Louvel. The liberal party was held responsible for it, and the Ultras again seized the power, which they retained till the Revolution of 1830 (except for the short interval of the Martignac Ministry, 1828-1829), under the direction of the Count of Villèle (1820-1827) and afterward of the Prince of Colignac (1829-1830). The reaction of the Ultras was both aristocratic and catholic in character: they endeavored to establish the preponderance of the class of the great landlords, and the authority of the Catholic Church. This reaction reached its climax in the reign of Charles X. (1824-1830), the Count of Artois, who succeeded Louis XVIII. Abroad the Ultra government supported the reactionary policy of Metternich; it was a French army, under the command of the Duke of Angoulème that overcame the Spanish Revolution (1823). Afterward they joined with the English and the Russians in the intervention in favor of the Greeks (1826-1829), and began the conquest of Algeria (1830), but without regaining their lost popularity.

Against the Ultras a coalition was formed that included the modern royalists, the Gallicans, the manufacturers and tradesmen, and the whole of the working classes; as a consequence a majority hostile to the Ultras was sent to the Chamber. In the hope that this majority would not again be returned, Charles X. had twice recourse to a dissolution; but this proving of no avail, he resolved to transgress the charter by a *coup d'état*. The elections were annulled, the electoral laws altered and the liberty of the press momentarily suppressed. These were the famous «July Ordinances.» This *coup d'état* was immediately answered by the Revolution of 1830, originated by a small group of republicans that belonged to secret societies and were chiefly recruited among the undergraduates, the workmen, and people of the middle-classes. After three days' fighting Charles X. was dethroned. But a reaction began at once. In the first place the republicans, few as they were, could not prevent the monarchy from being maintained as the form of government; only another dynasty was called to the throne, that of the d'Orléans who were cousins of the former king, and a pledge was exacted from the new sovereign to adhere to the charter. In the second place, on account of the riots that had broken out in Paris and Lyons, and the manifest signs of a new revolution approaching, the republicans were prosecuted and dispersed by the government. So the crisis of 1830 did not end in the establishment of the Republic, but it founded forever the sovereignty of the Nation with a constitutional government.

The second crisis is the Revolution of 1848, which brought to a close the reign of Louis-Philippe (or July Monarchy, so-called from the Revolution of July 1830). The most characteristic features of this reign are with regard to foreign policy the alliance made with England to ensure peace on a durable basis, and at home the ascendency of the well-to-do classes. The electoral *cens* was indeed lowered, but only to 300 francs for the voters, and 500 francs for the candidates, which still excluded from public affairs both workers and people of small income alike. Now the epoch of Louis-Philippe was marked by an unprecedented development of all manufacturing industries, which created in France as everywhere in Europe a vast proletariate. This proletariate began to ask loudly for laws that should protect them against their employers and even alter the conditions of individual property. The socialistic theories were growing more definite, and the socialists as a party were slowly emerging. Of course the Chambers, elected as they were by the capitalists, could not reject these demands that were aimed against them. The natural consequence of their attitude was a campaign of the socialists and republicans, supported by a large majority of the people, in favor of universal suffrage, or at least of an extension of the right of voting. The resistance opposed by the Guizot Cabinet to this movement caused its fall, and at the same time the fall of the reigning dynasty. Once more the republicans allied to the socialists, provoked a revolution in Paris (February 1848), dethroned Louis-Philippe and established a republican government.

This time the reaction did not take place immediately, and had two distinct stages from 1848 to 1851. There was first a reaction of the republicans against the socialists: the two parties, after uniting to found the Republic and institute universal suffrage, disagreed on the subject of social questions. In June 1848, the republicans shut up the «National Workshops» lately opened by the socialists and ordered a ruthless repression of the riot that ensued. Then there was the reaction of the monarchists and of a newly revived party of Bonapartists against the republicans themselves. The fear of a revolution was cleverly directed against the republican government and speculated upon to bring to the presidency of the republic a nephew of Napoleon I., the prince Louis-Napoleon. The monarchists hoped that he would serve their plans, but he only served his own interests: at the head of the different ministries and public services he appointed men on whom he could entirely rely; and with their co-operation and with the help of the clergy he effected the *coup d'état* of 2 Dec. 1851. The Assembly was dissolved, about 100 deputies were exiled and several insurrections that broke out in Paris and the provinces were sternly put down. A new Constitution was then drawn up that was almost a copy of the Constitution of the year VIII. with the addition of universal suffrage; and the following year Louis-Napoleon had himself proclaimed Emperor of the French, under the name of Napoleon III. Thus the crisis of 1848, in spite of momentary success, cannot be said to have established the Republic; but at all events it strengthened the former acquisition of the people, viz., the sovereignty of the Nation, and maintained their more recent conquest, universal suffrage.

The third crisis is that of 1870. The Second Empire was at first a highly despotic government: every newspaper had to be authorized and was under a censorship, the elections were controlled by the government that required from all candidates alike an oath of allegiance and supported openly its own candidates, the Chambers were deprived of the fundamental rights of deliberating assemblies, the rights of initiative, of amendment and of interpellation; their sittings were not public and reports of their proceedings could not be published; lastly a regular system of political inquisition was established. These were, until 1860, the characteristics of the Imperial government which depended upon the same coalition of conservative interests that had brought it to power and chiefly upon the Church, that was rewarded with the liberty of teaching and a kind of control over the university.

The events abroad obliged the Emperor to modify his policy at home. «The Empire is peace,» were the proper words he had used in 1853 to remove the fears of the French as well as of the foreign powers; yet France under Napoleon III. was engaged in several wars. The first was the Crimean War (1855), which served at the same time the interests of the English and the traditional spite of the French against the Russians. Then there was in 1859 the Italian War into which he was led, perhaps in spite of himself, by a pledge he had formerly taken as a *carbonaro* and by Orsini's outrage, and from which France gained the Savoy and the county of Nice that have been French territory ever since. This war was the most important event in Napoleon's reign, for it opened the «Roman

Question» and dissatisfied the French Catholics who never forgave Napoleon III. his allowing Vittorio Emmanuele to seize the Pontifical States. From that time the Emperor was obliged to form a new majority from the ranks of the liberals and to alter his policy. From 1860 to 1870, and chiefly after 1868, the Empire was liberal: the government became truly representative, the elections were no longer controlled, the press was freed from former restraints and meetings were allowed unconditionally. Napoleon trusted this change of tactics would disarm the opposition of the liberals and the republicans; in fact it furnished them with arms against him. Liberals, republicans, monarchists and Catholics, all joined in an attack against the Empire and were decidedly successful at the elections of 1863 and 1869. The failure of the Emperor's foreign policy brought them further assistance: the «Roman Question» grew so entangled that French troops had to be kept in Rome after the battle of Montana; the Mexican War that partook as much of the crusade as of the financial venture, and that was brought to an end by the intervention of the United States, had a lamentable conclusion; lastly serious differences were growing between France and Prussia whose designs in Germany Napoleon III. neither encouraged nor opposed frankly and toward which he carried on, without the least success, a policy which Bismarck graphically described as «a policy of tips.» The Imperial government thought that a war with Germany would be a convenient way out of all these difficulties: a victory would have consolidated the tottering dynasty. The defeats of Frœshwiller and Sedan completed its ruin. As in 1830 and 1848 it was an insurrection of the republicans in Paris, immediately followed in most of the provincial towns, that upset the second Empire and proclaimed the Republic (4 Sept. 1870).

This time there was, properly speaking, no reaction, but only an attempt at a reaction, and this failed. So long as the war lasted, the republicans retained the power with the *Gouvernement Provisoire*, the most famous member of which was Gambetta. But in order to ratify the preliminaries of the peace, they had to summon an assembly: this was the *National Assembly* that sat first at Bordeaux and afterwards at Versailles. The election took place in most exceptional circumstances: the large majority of the Nation was strongly in favor of peace; on the contrary the republican candidates, like Gambetta, were for carrying on the war to the last, so that the electors, chiefly the peasants, voted for royalist candidates, and the majority in the assembly (some 375 out of 700) was composed of monarchists. But a reaction was not so easy then as in 1830 or 1848; the republican idea had gained ground in the departments of the East, of the South and of the Centre; the party of the Bonapartists had been swept away by the disastrous war, and above all the monarchists themselves were divided in two parties, the *legitimists* who supported the Count of Chambord, a descendent of Charles X., and the *Orleanists*, the Count of Paris, a descendant of Louis-Philippe. These two parties at first silenced their personal ambitions to sign the Treaty of Frankfort and to strive against the insurrection known as the *Commune de Paris;* they further agreed to intrust provisionally the executive power to M. Thiers on whom they officially conferred the title of President of the Republic for this was the only name then available but without feeling bound thereby to accept the Republic as the definite form of government. Both parties hoped they would come to an understanding and ultimately unite, but this hope was frustrated, first by M. Thiers himself who refused to be a party to any restoration and resigned his office 24 May 1873; secondly by the Count of Chambord who persisted in claiming as the National emblem the white flag that was the symbol of absolute monarchy and therefore was as much detested by the Orleanists as by the republicans and Bonapartists. On the other hand, by elections and in every other manifestation of public opinion, it was clearly visible that the republican party was everywhere gaining favor; so that the majority in spite of their monarchic tendencies were at last reduced to vote a republican Constitution which began to work in October 1875, when the *National Assembly* broke up and was replaced by two Constitutional Chambers: the Chamber of Deputies and the Senate.

Then the victory of the republicans could be deemed complete: the government of the country was officially a parliamentary republic with universal suffrage, and the majority in the Chamber of Deputies was republican. Yet both MacMahon (who had succeeded Thiers as President), and the Senate still belonged to the conservative party. The latter resolved once more to try their fortune: on 16 May 1876, the republican minority was dismissed and the Chamber dissolved. But MacMahon shrank from the responsibilities of a *coup d'état,* the elections again sent to the Chamber a republican majority, later on the senatorial elections also placed a republican majority in the Senate; MacMahon had to give up the Presidency and the republicans appointed in his place one of their own men, J. Grévy. Since that date the internal history of France has only to deal with the normal development of her democratic institutions. This development has operated in three principal directions: (1) In the confirmation of political liberties (press, meetings, associations); (2) In the complete secularization of all public services (primary education laicized and made compulsory and gratuitous, divorce, suppression of the religious orders, disestablishment of the Church); (3) In social laws that authorize strikes and trades-unions, enforce certain sanitary regulations in workshops and factories, determine the employer's liability, regulate the work of women and children, limit the working-hours and secure a weekly day's rest to all employees. In spite of the eagerness of the conflict between the different political parties (the moderate or *opportunists,* the radicals and the socialists), the internal peace of the country was not once seriously disturbed. There were, however, two junctures when circumstances assumed a character of particular consequence. The first was what has been called *The Boulangisme* (1887-1889). A coalition was then formed under General Boulanger between the monarchists, the Bonapartists and a fraction of the republican party, dissatisfied at the policy of the *opportunists,* with a view to overthrow the Republic and restore the Monarchy or the Empire under the name of «Plebiscitary Republic.» Boulanger and his supporters took advantage of the *plurinominal* ballot (*i. e.* balloting for a list of persons), to stand candidates in all the departments at once, which amounted to trying a plebiscite. The government checked the movement by restoring the *uninominal* ballot and depriving candidates of the right to stand for more than one constituency at a time; besides it dispersed the leaders of the movement by having them tried for high-treason before the Senate. The second of these junctures was the Dreyfus case, which, owing to its political consequences, had all the importance and significance of a real revolution. First of all it determined a new grouping of the parties: on one side the *Nationalists* recruited from among the monarchists, the anti-semites and a fraction of the progressists, relying for support on the conservative forces (army, religion, capital); on the other side the republicans, radicals, socialists and the remainder of the progressists united into the so-called *bloc* to fight against the same conservative forces in the name of individual right and of justice. The greater cohesion of the parties gave renewed vigor to the political life of the country: from that period date the creation of political leagues as *Les Droits de l'Homme* and *La Patrie Française,* the foundation of the popular universities and of several new journals, and also the interference of the trades-unions in politics. All these influences combined to bring to power such governments as those of Waldeck-Rousseau, Combes, Rouviers, Sarrien, Clemenceau, under which (from 1898 to 1906) the social reforms enumerated above have been accomplished. Since the Dreyfus case two principal tendencies are discernible in the general trend of French politics: one, which brought about the ruin of the denominational schools and the disestablishment of the Church, is irreligious; the other is socialistic: though the party in power still vindicates individual property as the actual basis of society, the nationalizations that are part of its programme are essentially socialistic and at all events can only be worked out with the help of the socialists.

If the progress of democracy has been the characteristic feature of the internal policy of the French since 1870, the maintenance of peace has been the constant object of their external policy. To this peaceful disposition must be ascribed the Franco-Russian alliance and the many treaties signed of late with England, Italy, and even with Japan. May be that to a few individuals these alliances have seemed to offer an opportunity for some underhand action against Germany, but the recent Morocco incident has shown how sincerely the people at large are determined to reprove all manner of aggressive policy.

6. France—The Government. I. *Constitutional Laws.*—Strictly speaking, the political régime of France cannot be defined as a Constitution but as three separate laws, called constitutional or organic, voted in 1875 and amended by two other laws, one in 1879 and the other in 1884. Strange as it may seem, these laws which make up the political mechanism of the Third Republic were prepared and accepted by an assembly in which monarchists constituted the majority. In fact, of the 750 members composing the National Assembly elected by universal suffrage in February 1871, about 420 were monarchists, the peasantry having voted for the monarchists who favored peace rather than for the republicans who wanted war. However, in spite of their majority, the monarchists were powerless to restore royalty in France, and that for two reasons: (1) the views held by French citizens were so manifestly hostile that M. Thiers, minister to King Louis-Philippe and a strong Orleanist, chosen as «chief of the executive power» and provisional president of the new government by the monarchists, who counted on using him to bring about a restoration, openly declared himself for the Republic, thereby causing his downfall in 1875, when he was replaced by Marshal MacMahon; (2) the monarchists were divided into two rival factions, each of which supported a different candidate for the throne, the *Legitimists* being the partisans of the Count of Chambord, a descendant of King Charles X., dethroned in 1830, and the *Orleanists,* adherents of the Count of Paris, a descendant of King Louis-Philippe, dethroned in 1848. At one time harmony or fusion, as it was then called, seemed about to be realized between the two parties, as the Count of Paris had acknowledged the anterior and superior claims of the Count of Chambord, who, on his side, had legitimatized the dynasty of Orleans by accepting as successor the Count of Paris. But the Count of Chambord forfeited everything by obstinately rejecting the tricolored flag, symbol of the new revolutionary France, and favoring the white flag, symbol of the France of the old régime and of the divinely authorized monarchy. Therefore, Orleanists and Legitimatists resumed their former positions and resigned themselves to a parliamentary republic which put them temporarily on terms of agreement by eliminating the two rival claimants. According to an amendment to the law on the organization of executive power, known as the Wallon amendment, it was decided in the name of the new government, to confer upon the chief of the executive power the title of President of the Republic, and in memory of this amendment M. Wallon was jocosely called «Father of the Constitution.»

These circumstances explain the absence of a Declaration of rights and a co-ordinated

Constitution, such as exists in the United States of America and existed in France from the Constitution of '91 to that of 1848.

The following are the three constitutional laws:

1. *The Law of 24 Feb. 1875,* relating to the organization of the Senate. It regulates the number of senators, the conditions of eligibility, the mode of election and renewal and the power of the assembly.

2. *The Law of 25 Feb. 1875,* concerning the *organization of public power.* It defines the exercise of legislative power, the mode of dissolving the Chamber, the ministerial responsibility, the method of amendment, and fixes the seat of government and of the Chamber of Versailles.

3. *The Law of 16 July 1875,* treating of the *relations of public power.* It deals with the meetings of the Chambers, their prerogatives and the connection of the executive power with the Chambers.

The laws of amendment are as follows:

1. *The Law of June 1879,* suppressing the constitutional residence at Versailles and transferring it to Paris.

2. *The Law of 14 Aug. 1884,* excluding from the presidency members of ancient dynasties and forbidding the republican form of government to be called into question and suppressing irremovable senators and public prayers.

Of these five constitutional laws one has now almost completely disappeared, that is the law concerning the Senate. Of the four others, exclusively relative to political organization, only the following facts are constitutionally established:

1. The existence of a *legislative power* divided into two assemblies, the Senate and the Chamber of Deputies, concerning the organization of which the Constitution mentions only the functions, the interior organization, the privileges of members and the election of deputies by universal suffrage.

2. The existence of a *President of the Republic,* the complete enumeration of his functions and prerogatives and directions in regard to the mode of election and the duration of power.

3. The *reciprocal powers* of the President and the Chambers either in regard to each other or to common questions, such as the convocation of the Chambers, length of sessions, form of dissolution, general procedure of amendment, forms of presidential and ministerial responsibility, method of promulgating laws and concluding international conventions.

Everything outside of these matters depends upon legislative action; the electoral system, ministerial organization, communal, departmental, judiciary, military and financial administration, etc. However, one question remaining outside of both constitution and legislation is the form of government. Contrary to preceding constitutions, these constitutional laws give the greatest scope to legislative action and tend to confound the legislative and constitutional authority.

II. *The Principle of the Separation of Powers.*—It is the opinion of the authors of the constitution of 1875 and of those who interpreted and applied it, that its fundamental and, in a way, its vital principle is that formulated according to Montesquieu under the title of separation of powers. «All would be lost,» says Montesquieu ('Esprit des Lois XI,' 6), «if the same man or the same body of leaders or of nobles or of people, were to exercise these three powers, that of making laws, of executing public resolutions and of judging crimes or individual disputes.» It is important briefly to examine this opinion. Montesquieu's idea may be taken in two different senses. It may signify that the same individual or the same body cannot be simultaneously and successively a legislator, an executing agent and a judge; if so, it is a critical reflection upon the absolute monarchy wherein the king claims the right to make, execute and apply the law himself, or to act in like manner through his agents; every superintendent having a jurisdiction and every minister a *lettre de cachet.* Such a system begets not alone tyranny but, above all, confusion and anarchy. Therefore, if, by separation of powers, Montesquieu meant a division of functions, the assignment of a definite function to each, or, better still, the dedication of each function to a special staff, his idea was simple, elementary and just. But it is not more characteristic of the constitution of 1875 than of any other; it is characteristic rather of modern governments nationally organized. However, if Montesquieu's idea is—and it has been thus interpreted, the interpretation seeming a true one—that in every society there exist three self-governing powers whose parallel action must be separately exercised, independent in their origin and in their course and concurring only in their results; and that a constitution is the affirmation and solid organization of these three powers, on the one hand, the principle does not seem to be admitted by the constitution of '75, while on the other it does not appear admissible. The principle of the separation of powers is not admitted in the constitution of '75, (1) because this constitution does not organize an independent judicial power; (2) because, in this constitution, the legislative power chooses and superintends the executive power; (3) because, in this constitution, the legislative holds the judicial functions; (4) because the executive convokes, prorogues and dissolves the legislative. On the other hand, this principle is not in itself admissible because it is antinomical. A first reason for this is that social life is the result of a collaboration, of a reciprocal penetration of the various forms of activity and not of their parallel isolation. A second reason is that all powers, in no matter what government, emanate from a common source, *i. e.* monarchical or national sovereignty, and that, as representative of that sovereignty, the legislator is the common master of him who executes and of him who judges. Hence in the principle of the separation of powers we can admit only the practical distinction between executive and legislative that serves as a basis of the constitution of 1875, and according to which we shall analyze it.

III. *The Legislative Power.*—The two powers established by the constitutional laws have been accurately stated and defined by a combination of laws forming the real constitution.

1. *The Election of Representatives.*—(*A*) *The Chamber of Deputies.*—The application of

universal suffrage was regulated by the laws of 20 Nov. 1875, and of 13 Feb. 1889, both of which bear upon a great many points in the laws of 31 May 1850, and of 2 Feb. 1852. *Electors.*—Any citizen over 21 years of age enjoying civil and political rights, domiciled for six months in a district and enrolled on the electoral lists, is entitled to vote, which right is, however, withheld from all military men actively engaged either on land or sea. *Eligibility.*—Any citizen fulfilling the aforesaid conditions is eligible except in the cases prohibited by law, *i. e.* where one is a member of an old dynasty or holds a government office within his own province. Moreover, numerous *incompatibilities* prevent the cumulation of a public office and a legislative mandate. Exceptions are made in favor of ministers, prefects of the Seine and of police, chief magistrates of the high courts of Paris and professors of the University. All candidates must declare their candidacy at least five days before the voting so as to prevent one individual presenting himself as a candidate in more than one constituency, such plural candidatures being forbidden by the law of 1889. The voting is by ballot, one deputy being named for each arrondissement; however, when an arrondissement has more than 100,000 inhabitants, it is divided into electoral districts, thus bringing the present number of Deputies up to 583. (The vote is by secret ballot on a white paper—«bulletin»—folded and deposited in the ballot-box by the chairman of the voting-bureau, who is always a municipal magistrate, assisted by four assessors appointed by the electors at the opening of the poll; the hours of voting are from 8 o'clock in the morning to 6 in the evening. A rough count by a committee of the electors themselves follows immediately on the close of the poll, before the official recount. This rough count consists in the exercise of the right of such a committee to open all the voting papers.) The law prescribes two ballots at an interval of 15 days; to be elected on the first ballot, a candidate must have an *absolute majority* (half the votes plus one); on the second ballot, called *ballotage,* and brought into play only if the first ballot is inconclusive, a majority of votes cast suffices. Deputies are elected for four years, the full number of the chambers being elected on one and the same day.

(*B.*) *The Senate* is composed of 300 members, the number determined by the constitution. Since the amendment of 1884 all senators are elected to office, the 75 life-senators appointed by the Senate and created by the constitution, having been then suppressed. Senators are elected from each department, their number varying from 2 to 10, according to the population. The suffrage is called *limited;* the electoral body is formed of it: (1) the *departmental representatives* (senators, deputies, general councillors); (2) *senatorial delegates* elected from among the voting citizens of each township by the municipal council and varying from 1 to 24 according to the population. These senatorial electors constitute a college that meets at departmental headquarters under the presidency of a civil magistrate. The election must end on the day of the third ballot, the first two being cast to find, if possible, an absolute and the third failing an absolute majority for a majority of votes cast. Senators are elected for nine years, some of their number being renewed every three years. Hence, the Chamber of Deputies represents the people as a whole and the Senate *local* bodies. Gambetta called the Senate the Great Council of the Communes of France.

2. *Prerogatives.*—(*A.*) The members of both Chambers enjoy the same personal prerogatives, inviolability from arrest and a fixed salary (15,000 francs to Deputies—9,000 to Senators). (*B.*) They exercise the same *legislative* privileges; adopt their own rules and elect their own committees. Their essential privilege consists, as in all other parliaments, in *introducing* and *voting* laws. In this regard the only difference between the Senate and the Chamber of Deputies is that all finance laws must first be voted by the Deputies. All laws must be voted by each Chamber separately. Only the laws of amendment to the constitution are voted on in another fashion; for these both Chambers combine and form a congress held at Versailles. (*C.*) Both Chambers assembled in congress at Versailles exercise an electoral privilege also, that of electing the President of the Republic. (*D.*) The Senate alone enjoys the judiciary privilege and constitutes itself a High Court to judge the President of the Republic and ministers arraigned by the Chamber of Deputies, as also individuals accused of conspiring against the security of the state (the Boulanger affair in 1889 and the Deroulede in 1899). (*E.*) Finally, each Chamber exercises a similar power over the ministry through the right of *question* and *interpellation.* The latter is especially important inasmuch as the minister summoned is obliged to respond and the interpellation is followed by a vote, after which, unless he receive a majority, he must retire. Interpellation is the practical mechanism through which the ministerial responsibility is exercised. Either Chamber may further control the Government by naming a commission of parliamentary inquiry (the Panama and Boulanger affairs, the condition of the Navy, etc.). The Chambers, especially that of Deputies, exert a really dominant influence over the French Government.

IV. *The Executive Power* is exercised by the President and his ministers. (1) *The President* is elected by Congress (Deputies and Senate combined) for seven years, being chosen from among its own members. His power is very extensive, as he can introduce, promulgate and execute laws, make appointments to all civil and military offices, dispose of the armed forces and negotiate and sign treaties. But, since he can exercise it only through the medium of his ministers, this extensive power is practically reduced to that of appointing his ministers. Being politically irresponsible, he can only be summoned before the High Court for felony. He resides in the Palais de l'Elysée in Paris, and receives a regular salary of 600,000 francs, with as much more for expenses incidental to official entertaining. List of Presidents of the Republic: Thiers, 1871-1873; MacMahon, 1873-1879; J. Grévy, 1879-1888 (the only one reelected); Carnot, 1888-1894; Casimir Périer, 1894-1895; F. Faure, 1895-1899; E. Loubet, 1899-1906; Faillières, 1906—. (2) *The Ministers* form a jointly responsible Cabinet under the direction of the President of the Council.

The latter is appointed by the President of the Republic and is free to choose his colleagues: (11 ministers, those of Justice, the Interior, Foreign Affairs, War, Navy, Colonies, Public Instruction, Commerce, Public Works, Finance, and of Labor, the last created in 1907). They are the President's deputies, who, in his stead, sign or veto all executive documents. Their essential character is their *political responsibility*. They are responsible for their acts to both Chambers, whose members, thanks to the right of interpellation, already defined, can put their actions to a vote which, if it place one or more in a majority, will entail his or their resignation. Such a consequence is not explicitly declared in the constitution, but it follows in the logical order and from the practice of the Government. In fact, in case of conflict between a minister and the majority, two solutions may be resorted to: either the minister's resignation or the dissolution of the Chamber, which must be voted by the Senate. Throughout the history of the Third Republic there is but one record of a like dissolution, which was that of 16 May 1876. President MacMahon had formed the conservative ministry of the Duc de Broglie in opposition to the liberal Chamber, which, by a majority of 363, refused to enter into relations with him. The Chamber was dissolved, the elections resulted in a majority of liberal votes, in face of which the conservative ministry had to submit and resign. Since then, all ministers in the minority on a *matter of confidence* have tendered their resignations. During the first 20 years of the Republic ministerial instability was a veritable governmental defect, being due to the disintegration of parties and the impossibility of constituting lasting majorities. There were, however, ministries that last two and even three years as, for instance, the second Ferry ministry and the Méline ministry. But within the last 10 years this instability has disappeared in consequence of the Dreyfus affair and of the new division of the parties into two *blocs*, the radical-socialist and the conservative. The Waldeck-Rousseau and Combes ministries each lasted three years, the incumbents retiring voluntarily, the Rouvier two years, and the Sarrien is being continued with the same party under the Clémenceau ministry.

National sovereignty, acquired through universal suffrage and political liberties — such as those of the press, of meeting and of association — and a parliamentary régime, that is to say, the supremacy of parliament over the ministry, have become the groundwork of the constitution and of the political government of France.

7. France — French Socialism. Socialism is an international theory. The same doctrine, the same conception of property, that is, is laid down by socialists in all countries. But every nation has produced its own form in the development of this doctrine, and these forms have been determined both by historical traditions and by the economic medium in which they have appeared.

Two traits have distinguished French Socialism from the rest. The first is that its character is strongly political, by which is meant that it is perpetually attempting to arrive at the government of the state, the second that it is continually animated by an active hope of immediate success in that effort. The French proletariat has (since the French Revolution) been mixed up with most of the decisive political struggles. It was the proletariat which dominated the Commune of Paris in 1793, and thus indirectly dominated the Convention. The French proletariat had, therefore, at the beginning of the modern period, already put its hand upon the central lever of the Revolutionary power. Somewhat later when the energies of the Revolution began to sink, it was among the populace, among the working people (who were already filled with the communistic spirit) that the vital forces of the Revolution were maintained; and the hopes which the proletariat entertained at that moment were of the most vigorous sort. Their programme at the close of the 18th century is summed up in the name of Babeuf. Babeuf did not look upon himself as the head of a mere party — it was in his character rather to despise party, because party always looks for its success to some chance hazard on the political field: it was rather his object to take up again the whole effort of democracy at the point where Robespierre (*q.v.*) had left it, and to widen it beyond the limits which Robespierre had assigned to it. It was his object to free those energies of the Revolution which had been captive since Thermidor. Babeuf believed the proletariat ready to assume and capable of assuming the responsibility of governing France, and had his conspiracy succeeded he would have changed the destiny of the country. The present writer has been told by a friend of Gambetta's that in his youth, when that leader had just come to Paris, he said freely «If Babeuf had won, the world would have been saved.» It would indeed have been saved from the counter revolution, from militarism and from the Napoleonic dictatorship, and a democracy which should have been based upon egalitarianism and alive with enthusiasm would have proceeded in peace to the organization of labour.

The note of all this is that at the very beginning of modern history the French proletariat had ceased to be «underground» as it were in the state. It thought itself strong enough for the highest tasks and it is this hope and this power of action which are continued obscurely or brilliantly in France throughout the whole of the 19th century. The proletariat recovered these hopes of theirs and put them forward again in a lively manner during the «Days of February» in 1848, on which occasion it was a socialistic inspiration which, for a moment at least, was the driving force of the second revolution. Even the terrible reprisals of June did not destroy the historical pride of the French proletariat. The day after the disaster it restated its leading idea and regathered its strength. Proudhom, in the book which he dated from the Prison of the Conciergerie in July 1851, defied the reaction to proceed to its logical end. "*The Revolution,*" he says, "*is at the present moment so thoroughly consummated in the national thought that to pass from thought to action is but a matter for executive energy. It is too late to avoid its power. The Revolution wills to be, and for her to will to be is to will to reign.*" The Bonapartist coup d'état was the object of this peculiarly audacious expression, and it had the effect of raising the proletariat once more to a conquering height in politics. The same hope, the same ambition permeated the days which elapsed just before the fall of the second Empire. Throughout 1868 and 1869 public meetings were the medium where the communist or the mutualist put forward the socialist doctrine with the utmost strength. The middle classes, especially the middle classes of the republican stamp, held aloof and affected to despise such programmes as "utopias," but in the midst of their disdain the revolutionary working men were planning to lay a hand upon the new régime which was so soon to appear. Among Blanqui's papers, notes have been found upon the rôle which the proletariat would presumably play in the Revolution which he saw to be imminent. Had not the war of 1870 cut into these plans and had not the Empire fallen under that particular blow it would, without the slightest doubt, have fallen a few years later under the blows of a Revolution in which Socialism would have had a very large part. The attempts which were made during the siege of Paris by the Blanquistes on the 31 October, and which later developed into the Commune, would have dominated the new government or at least would have been very largely represented in it. There was even a moment when the republican part of France hesitated between the Commune and Versailles, and once again at that moment the French proletariat might have thought itself upon the eve of obtaining power.

It is evident that a working class with traditions of this sort and with an education of this sort is essentially political. It is evident that such a class will be acutely sensitive to political events, will be ready to watch them upon all occasions, and to seize every chance of penetrating into the very heart of the state and of there establishing its sovereignty.

Nevertheless a man might have asked himself after the Commune whether the socialist idea had not been buried. Superficial observers believed it to be dead, or at least laid for a long time. M. Taine expressed that thought clearly, standing with some friends before the wall where the prisoners had been shot in Père la Chaise: he said, "We are rid of Socialism for half a century," and M. Thiers in his electoral manifesto of 1877, during the great struggle of the Republic against reaction which is known as the "Seise Mai," boasted that he had finally crushed "the insane doctrines." It is true to say, moreover, that Socialism then seemed doomed. The foremost of its fighters had been thrown down by the reactionary government of Versailles, they were transported or they were weary of the fight, or they were forced to fly the country. The people no longer so much as heard the distant voices of the exiles.

It must not be imagined on this account that the French proletariat, which had refused to give up hope or to cease a moment from its effort after the days of June 1848, had lost its ideal after 1871.

What had happened was that the working people of the country were now absorbed by another battle which though it was not fought in the streets was not less tragic than a civil war. This battle was the struggle between monarchy and republicanism. The French proletariat at this moment had the foresight to perceive that before it could raise the socialistic flag again, the republican battle must be won, and therefore, under the appearance of a mere constitutional struggle, a class war arose which lasted until 1877. The point of the struggle was to determine whether France should be governed by an oligarchy drawn from the remains of the old régime, an oligarchy of which the Orleanist and clericalized middle class were the nucleus, or on the contrary by an artisan democracy. But this class war, embroiled and intricate as it was, did not suffice for the socialistic idea once it was thoroughly awake, and the proletariat was but waiting for the defeat of the counter revolution to bring forward the social question and to force it upon the victorious republican party. Just after the Republican elections in which the country replied in October 1877 to the challenge of the reactionaries, Guesde and his friends began their revolutionary and collectivist campaign in their newspaper L'Egalité. The moment marks a decisive date in French socialism.

The first number of this journal appeared on 1 Nov. 1877. The very greatest difficulty confronted the leaders of the movement. In the first place the resistance of Marshal MacMahon and of the survivors of the coup d'état had not yet ceased and the socialist party had to defend itself against the accusation which the Republicans brought against it of creating a diversion in the midst of the struggle. "L'Egalité replied to these calumnies and to the treacherous insinuations which accompanied them by exactly defining its republicanism. It used the following words:

"The appearance of this journal in the midst of a political crisis does not arise from the fact that its founders are under any illusion as to the objections which would be made to them by the Republican party, objections of which the last speech of M. Jules Ferry has given us a foretaste. The moment in which we appear has been said by those who are too honest to calumniate us to be ill chosen. To this we reply that we have not chosen the moment. Week after week our first number has been put back in the hope that the will of the country as it was expressed on the 13 October would have been put into full execution. It is not our fault if the delay in radical reform has been caused by the struggle between a small clique against the whole nation.

"We might further ask whether in the opinion of Republicans who blame us any moment whatever seemed well-chosen for attacking the economic privileges of their class, and we defy them, if they are indeed sincere, to reply in any affirmative manner.

"The only men who have the right to attack us in the matter of our publication are the working men, whose organ we desire to be, and upon that side we are quite at our ease. The working class have too clear a conception of their interest not to understand that the moment just before a battle is the very moment when it is the most essential not to leave the liberal middle classes in any doubt as to the nature of the help which we are willing to give them against a common enemy. The moment before the battle is also the moment for proclaiming in the strongest manner that it is not the business of the working classes to be perpetually pulling the chestnuts out of the fire for professional politicians, but rather to clear the only ground upon which their claims can be successfully established. And that ground, of course, can only be a republican republic."

Another formidable problem arose before the organizers of socialism at this time — that is 1877. What should be their attitude toward universal suffrage? Should they despise it or should they use it? Up to that date universal suffrage in France had always appeared as an instrument of reaction. It was under the heavy weight of the peasantry that the Empire had crushed the republican and socialist thought of the towns. Hardly had that thought been relieved somewhat by the revolutionary forces of September and the fall of the Empire than France was again given up by universal suffrage to the reaction, to the country squires and to the fanatical clericals of the assembly at Versailles. But universal suffrage was destined bit by bit to be enlightened and to emancipate itself. The republican idea alone had had the strength to liberate the country from the assembly at Versailles. Universal suffrage had (again through the republican idea) found the strength to break the counter revolutionary attempt on the 16 May 1877. To despise universal suffrage and not to take advantage of it would be to remain outside the national life. To have done so would have been to reduce the socialist to an anarchic and powerless sect. Guesde and his friends accomplished a decisive act and rendered the French proletariat a vast service when they decided to rely upon universal suffrage, for by this decision the proletariat entered into the main current of the national life. They did not expect democracy would of itself achieve the socialization of property. They believed that only revolutionary violence would succeed and that the proletarian revolution would have to be accomplished by force, as every other revolution had been accomplished, and as more recently in the United States had been accomplished the abolition of slavery. But by relying upon universal suffrage they changed the nature of the class struggle, they took it out of the workshop and brought it into the large world of politics. It was decided that the proletariat should choose men who would represent their class when they should send into parliament men who had no idea of needing a majority there, but who could without ceasing act upon and render anxious the capitalist régime.

The plan was to cast upon that régime so implacable a light that in its exasperation and bewilderment a social revolution far more systematic and far more thought-out than the Commune should at last push capitalism to its last entrenchments and make it deliver a decisive battle. The resources of universal suffrage were for Guesde and his friends only the prelude to an active revolution. What might be called the historical ambition and the historical habit of mind of the French proletariat was awake. It thought itself now as ever on the eve of a final assault and believed that it might enter into the government of the state by some unguarded door, and in its turn become master where the other classes had reigned. From 1877 to 1893 this was the attitude of mind of the French socialists whether they were the friends of Guesde or Blanquists, whose leader Vaillant had been brought back from exile by the recent amnesty. In the same tone of thought were journalists who, like Allemane, represented the Parisian proletariat. The great electoral successes of 1893 which suddenly introduced into the Parliament a body of 40 socialists brought this excitement to a head, and the more enthusiastic of the party were justified in believing that the proletariat had at last reached the goal of their effort. The Republican and the middle class parties, worn out by the long and continual struggles between the opportunists and the radicals and broken by the Panama scandals, seemed condemned to impotence. Guesde believed their régime to be in its death throes, and he thought that the moment had come to turn democracy away from what was now no more a corpse. The socialistic minority needed nothing more than ability and courage in his opinion to become the leading majority, and universal suffrage would vote socialist if only an active and wide propaganda could be inaugurated among the peasantry and the smaller tradesmen, to prove to them that their personal interests lay in an alliance with the industrial proletariat.

It was at this moment that Guesde addressed to the bourgeois parties in the Chamber, the phrase: "We need use no weapon against you but those which you have provided for us in your own legal forms."

It will be seen that by this time the tactics founded in 1877 had changed. But the same hopes and the same courageous spirit of action permeated the socialist proletariat. These hopes undoubtedly contained an element of illusion, but they were not all illusion. The political efficacity of socialism was rapidly growing and although the results had not given the socialist proletariat the full victory for which it had hoped, it nevertheless kept the activity of the party and its general spirit alive. Even when, after 1898, the socialist party had to give up the hope of an immediate and final success, it none the less retained the knowledge that it had become an historical force of the first order and one capable of playing a decisive part in the national life. It is this result which, when one eliminates the details of the struggle, remains the chief fact in the participation of socialists in the defence of the Republic under the Waldeck-Rousseau ministry, and the participation which the party also took in the work of laical emancipation under the Combes ministry. The traditional thread which unites the action of the French proletariat is perpetually showing itself in new forms which arise for the momentary necessities of the Republican democracy and the Parliamentary régime. At the present moment the "parti socialiste uni" is withdrawing itself from the parliamentary system of groups and especially from those which aim at the forming of a ministry, but it is not so withdrawing itself in a sort of contemplative solitude, neither is it so withdrawing itself because it has given up hope of some ultimate decisive action. It is withdrawing itself because its leaders have discovered that the moment had come to rally to itself the general conscience of the whole working class and it could not do so without further propaganda. When that propaganda shall be completed, it will be able to throw all its forces into the general movement of politics without in the least abandoning its ideal. In the first great crisis whether interior or exterior that may shake the troubled modern life of France the Socialist party will throw itself into the centre of the struggle and it will be driven forward by the indomitable and compelling hope which its history has taught it.

So true is this that even those of the French proletariat who imagine themselves to be divorced from political action, are, if their methods be closely watched, only seeking some new form of action which shall be more political. What is known in France as "La Syndacalisme," that is the Trade Union movement which pretends to stand aside and to be able to despise electoral and parliamentary action, is at bottom an essentially political thing. When the leaders of this movement put it forward that a general revolutionary strike may compel the world to a communistic form of production — to put forward such a theory is to inaugurate an action that is, at bottom, definitely political. It would be an error therefore to think that the newer movements in French socialism are an abandonment of the chief political method or a delaying of it. They are rather an emphatic assertion of it, an exaltation of that certitude in the political future which we have called the defining character of Socialism in France.

This note of hope, however, which has been so frequently mentioned in this article would be but a sort of madness if French socialism were to count upon the industrial worker alone. For the industrial development of France, though in the last 50 years it has been accelerated, is relatively far less than that of England, Germany or the United States. France is still largely an agricultural country, and if Socialism were to retain as enemies against itself the 19,000,000 of peasants, nay more, if it did not draw them in the wake of its ideas, it would break itself against an insurmountable obstacle. It is on this account that the party has attacked the problem of converting the peasant. The French Socialists know very well that the millions of peasant proprietors will never allow themselves to be expropriated by law. The party has put forth all its efforts to persuade the small proprietors that no such agrarian communism is in view. The theoretical formulæ which have here arrested the development of German socialism have not weighed upon the French party. It is the opinion of the leaders of that party that the peasant proprietors will bit by bit enter voluntarily into a state organized upon the socialistic basis and this is the future that far-seeing men like Blanqui believed to be nearer than in the event actually proved to be. It is this process of gradual and voluntary acceptation of the collectivist state by the peasant proprietors which Guesde foresaw in 1877 and put forward in his newspaper. "The French peasantry" he wrote "may rest assured that expropriation of their land would remain necessarily outside any programme for a collectivist organization of the great industries or of large landed property." Blanqui also had laid it down as a doctrine of tactics in the admirable notes which he drew up at the end of the Empire. He pointed out that the peasants of the country were permeated by revolutionary memories, that the peasants like the rest of the country had a tradition of hearty political initiative, that the peasants had given battle to the nobles and to the priests, and that the peasant had no love for the "fat bourgeois" who had taken the best of the lands. And Socialism he thought based upon these traditions and these memories would end by attaching the peasant to its movement.

In a word, one does not find in France any ineradicable conservative force nor any permanent trend of affairs which can oppose itself to the action of socialism. The Socialist party has such certitude of this that the future seems assured to it.

It remains to add that French socialism, though perpetually attaching itself to party forms, can never permanently attach itself to such forms. It looks to a revolutionary and decisive achievement and bases itself upon a sort of national habit of revolutionary action. It is not to be imagined that this formula, however true, means that French socialism can in the future detach itself from the universal suffrage which governs the country, nor must it be imagined that it can develop its nature apart from the creed of democracy, which is part and parcel of the French people. But when one says that its character will remain essentially revolutionary and attached to the traditions of rapid political action one means that the French Socialist party will, like its predecessors, be perpetually and rapidly choosing from the mass of political events such a congeries as may be used for producing the maximum effect at the critical moment of a struggle, and that, like every other French party of the past, it will continue to reject compromise and to attempt nothing less than the full success of its clear and definite enterprise.

8. **France—Church and State.*** *Under the Ancient Régime.*—As early as the 6th century when the bishops became influential persons, the Frankish kings began to intervene in the episcopal elections and the two powers—civic and religious—were interdependent. No vital point in the doctrine being ever interfered with by the monarch, the bishops and clergy never found themselves in the necessity of withstanding him, and the Church remained for many centuries the councillor and auxiliary of the king. Throughout the Middle Ages the bishops and richer abbots were great «ecclesiastical lords,» and when the feudal system had made room for the royal supremacy, their order remained on the same level as the nobility and high above the Third Order. The kings of France, Saint Louis as well as Louis XIV. were jealous of the Papal power and carefully fostered in the clergy the national spirit known as «gallicanism» (q. v.).

But although the power of the clergy was so great, one ought not to imagine that their spiritual influence suffered no weakening in the course of ages. The literature of the Middle Ages is full of taunts against the Church, and the Protestant revolt of the 16th century was followed in the 17th by the sceptic spirit of the Libertins, and in the 18th by that of Voltaire and the Encyclopedists. The higher clergy were still a powerful aristocracy when, on the eve of the Revolution, the number of the faithful had dwindled ominously (15 millions out of 27 being only nominal Catholics), and the country clergy had imbibed the spirit of reform which was so soon to cause the great disruption.

The Concordat.—The schism brought about by the *constitution civile,* the banishments and executions made by the Terrorists, the latent persecutions carried on until 1798 and the lack of organization which prevailed during the next three years had left the Church of France in a sorry state, when Bonaparte, then First-Consul, felt in 1801 the necessity of making use of the religious element for his work of restoration. There were very few priests left, numberless churches had been pulled down, or neglected and out of repair, and nine-tenths of the ecclesiastical property had been confiscated by the government or sold and could not be reclaimed without difficulties of all kinds.

It was then that Bonaparte after several months' negotiations with Cardinal Consalvi signed the famous Concordat with Pope Pius VI. The main points of this agreement were the following: The Catholic religion and worship were to be protected by the State, and the clergy to be maintained by the Treasury (the bishops receiving 10,000 francs, and the parish priests 900 francs); in exchange for these advantages the Pope was to nominate no bishop without the consent of the government, and the property lost by the Church during the period of disturbances was to be given up forever. Later on some additional clauses of an aggravating character, known as *Articles Organiques,* were surreptitiously appended to the Concordat; all Papal documents ought to be submitted to the *Visa* of government; the bishops were forbidden to travel out of their dioceses without permission; they might be tried and reprimanded or punished by the State Council; they had no right to hold assemblies between themselves, etc. This arrangement worked for a whole century without any serious hitch, but there were between the Church and the age deep differences which were inevitably to bring on a crisis. There was little real life in the Church. The clergy had been taught to stay at home and dread the worldly visit and they were carefully kept in ignorance of nearly all the scientific movements going on around them.

The only exception was the liberal group formed by Lamennais, Montalembert and Lacordaire, who advocated more freedom for the Church, even at the cost of disestablishment, and pointed out the resemblance between several principles of the Revolution and those of Christianity. But these forerunners of the Catholic democrats of to-day were not heard and the Church was content with the drowsy comfort of her situation. The governments of the Restoration, Louis Philippe, and Napoleon III. looked upon the clergy as a valuable assistant, and while keeping it under control allowed no attack against it. The power of the bishops had never been so great as in the first 10 years of the reign of Napoleon III. (1852-1862).

Meanwhile, an aggressive spirit of unbelief was rapidly developing, thanks to the stagnation of theology, and the success of Renan's works was not long in giving its measure. The politicians who favored the Church were not believers in Christianity. Republican proselytizing was active, too, when the greatest part of the clergy would still support the doctrine of divine right and prayed for a Bourbon restoration. The war of 1870 gave the Republicans their opportunity; the Republic was established, and an overwhelming majority of the clergy found themselves in opposition.

The Disestablishment.—The Concordat was not to be cancelled yet for more than 30 years, but its disappearance was spoken of as possible and easy, and M. Clemenceau never let a year pass without delivering some strong speech against it. He gradually spread a conviction that it was absurd for a democratic and anti-clerical government to maintain a clergy opposed to them and held in subjection by the Pope, *i. e.* a foreign ruler; that the tax corresponding to clerical salaries ought to be levied exclusively on practicing Catholics; and at last that the Catholics themselves would be freer when untrammeled from the state control. For nearly 30 years prime ministers in succession replied that the Concordat was a treaty and could not be cancelled without the Pope's consent; that clerical salaries were part of the public debt, and last, that it was not advisable to give complete liberty to the Church.

In the year 1890 Pope Leo XIII. wrote to the Catholics of France the famous encyclical advising total and sincere loyalty to the Republican government and discouraging the monarchic hopes of the old parties. The younger clergy, who for some years had been republicans at heart, welcomed the Papal letter as a chart of enfranchisement and for a few years the situation seemed altered. The spirit of loyalty gained ground every day among the Catholics, and anti-clericalism was decreasing; for a few years the «new spirit» which M. Spuller had

* Clerical view.

proclaimed in a famous speech really prevailed.

The Jesuits whom Jules Ferry had expelled in 1880 had nearly all come back and filled their old colleges. Most of them were royalists. On the other hand the Freemasons had resumed their anti-clerical campaign, and their influence in Parliament being very considerable, they succeeded in passing several Acts (loi militaire, loi d'abonnement, laicisation des écoles, loi surla comptabilité, des fabriques, etc.) which the Catholics could but look upon as molestations.

The French Free-Masons (Grand Orient of France) differ widely from their Anglo-Saxon brethren. They are above all a political body, strongly tinged with Socialism and so averse to spiritualism and theism that the name of God has been struck from their rituals. They are purely materialistic and aim at nothing short of the total elimination of religion from the body politic.

The last two years of the 19th century were almost entirely occupied by the Dreyfus affair (q. v.). The Catholic papers, especially the *Croix*, showed their anti-semitism in a stupid and shocking manner, and it can hardly be doubted that the increase of anti-clericalism in the following years was mostly a reaction against it. The government of M. Combes was only a long persecution with a dangerous forgetfulness of many vital interests at home and abroad. Its chief act was the expulsion of the religious orders and the confiscation of their property in disregard of the law passed by M. Waldeck-Rousseau. In 1903 President Loubet went to Rome on a visit to the King of Italy and ignored the Pope. Such conduct was considered by the Church hardly reconcilable with the presence of an ambassador to the Vatican. The Pope complained in a circular sent to every Catholic government, whereupon the French ambassador was recalled and all intercourse with the Nuncio suspended, and disestablishment became a certainty in the near future. In fact, the Separation Law was passed by the Chamber in June 1905 and by the Senate in December of the same year.

The main lines of the Act were as follows: The French government ignored the Church as a religious body, and only recognized associations formed according to the law of 1901. These associations were to consist of seven to 25 members who would represent the parish. To these associations the places of worship should be left free, but with the heavy burden of keeping them in repair. The rectories, bishops' palaces, and seminaries should be regarded as state property and taken back from their present owners within five years. The Public Worship Budget was suppressed and the priests were to depend for their maintenance on the associations. The latter were entitled to civic rights, but their property was not to exceed the limits of their needs and their accounts were to be yearly looked into.

The majority of the French Bishops were for submitting to the law, but the Pope, considerably influenced — as was demonstrated through the Montagnini papers—by a few laymen of monarchist and conservative tendencies, vetoed the formation of associations and rejected each successive *modus vivendi* proposed by the French government, so that there is neither a legal status for the Church nor complete separation. The possession and use of the places of worship constitute the last bond. All churches are legally municipal property, but ought neither to be denied to the Catholics nor used for other than religious purposes. On the whole, the Church of France never enjoyed as much freedom as at present, but she never was so utterly destitute. See CHURCH AND STATE. ABBE ERNEST DIMNET.

9. France—Church and State.* At the outbreak of the Revolution of 1789, the Apostolic and Roman Catholic religion was the religion of the State, and, since the Revocation of the Edict of Nantes, no other religious sect, Christian or non-Christan, had had any legal existence in France. Nevertheless, a royal decree two years before had granted a sort of tolerance and legal status to the Protestants. The king had likewise allowed the Jews to live in certain cities in the kingdom, and there to carry on their worship in private: a régime of tolerance, not of freedom of conscience. The relations between the king and the Pope were determined by the concordat concluded in 1516 between Francis I. and Leo X.

The men of the Revolution had no intention at first of secularizing the State or of separating it from the Church, nor even of establishing any real liberty of conscience. The Declaration of Rights of 1789, granted, in fact, only tolerance, and it was not until the 27 Sept. 1791 that the Constituent Assembly placed the Jews on a similar footing with other citizens. While it confiscated the possessions of the Church, it nevertheless tightened the bonds of Church and State by means of the law entitled the «Civil Constitution of the Clergy» (12 July 1790). This gave to the clergy a salary from the State, by which the parish priests especially profited, and this first budget of the Religions rose to about one hundred million francs. As a consequence and climax of the Gallican policy of the kings, the Civil Constitution of the clergy tended to make the Catholic religion national. Thenceforth the bishops and the priests were elected by the people; the bishops no longer received from the Pope their canonical institution; it was given them by another bishop. The newly elected clergyman could not address to the Pope any request for confirmation; he had to confine himself to writing to him, as visible head of the universal Church, in testimony of unity of faith and communion. Thus without any diplomatic notification, the concordat of 1516 came to an end.

But the Catholic religion continued to be the religion of the State, and no salary was allotted to the ministers of other creeds; it was thought that enough was done for them in leaving them undisturbed. Such were the events which, little by little, led the Revolutionaries to loosen the bonds which united Church and State. The Pope, after much hesitation, condemned the Civil Constitution, and the clergy divided into two factions whose numerical proportions are not well known. Those who accepted the Civil Constitution and

*Anti-clerical view.

took the oath it demanded were called *Constitutionals,* or *Assermentés;* those who in obedience to the Pope refused the oath, were called *Refractories.*

There were thus a Papal Catholic clergy and a non-Papal Catholic clergy whose partisans quarrelled for the possession of the churches almost to the point of civil war. The inclinations of both parties alike were adverse to the liberty of sects; but most violent objection to such liberty was made by the papal clergy, who had become an opposing minority. The Constituent Assembly with very ill grace finished by granting the principle of it by the law of 7th of May, 1791, which authorized the Papal party to carry on their worship in the churches in concurrence with the non-Papal party with reservations and irksome restrictions. This was to some extent a recognition and consecration of the existence of the schism, but the people, attached to the idea of religious unity, had no wish for any schism. Consequently, in one part of the country the Papal clergy, in another the non-Papals were harassed; and continual religious disturbances took place during the years 1791-2. It was the recognition of this situation which inclined many enlightened Frenchmen to the then very unpopular idea of the separation of Church and State and the secularization of the State.

Even the National Convention, which passes in history as an assembly of atheists, put aside at first, in Nov. 1792, a project of separation, and formally maintained the Civil Constitution, limiting itself to making laws against refractory priests. But soon, when the Republic had replaced the monarchy, all the Catholic clergy became unpopular. The patriots accused the Papal clergy of conspiring with outside enemies and with the *émigrés,* and also of fomenting the Civil War in the province of la Vendée. They accused the non-Papal clergy of having taken part in the Civil War of the Republic with the Girondins against the party of the Mountain. It seemed to the people that all the priests, Constitutionals or Refractories, were conspiring against the Revolution, and that they were a permanent danger to the Republic. Although the people had not become philosophers, they had the feeling that to put it out of the power of the priests to harm the country, they would have to tear down their altars; and it was thus, much less by philosophy than by patriotism, much less by anti-religious fanaticism than as an expedient of national defense; it was thus, I say, that there arose these popular disturbances which finished by taking the form of an attempt at the dechristianization of France. There was first the cult of Reason, with which the Convention was associated only to a limited extent, principally in permitting the communes to renounce their worship. Through its Committee of Public Safety it strove to prevent violence against persons; it proclaimed the principle of liberty of conscience. But passions were stronger than the laws or the Government. One after another most of the churches were closed and the observance of religious worship was pretty generally suspended in 1794.

A new attempt at a State religion was made the same year by the efforts of Robespierre, who was then the true head of the French government; this was the worship of the Supreme Being, a sort of philosophical religion or purified Christianity, which disappeared entirely, or almost so, when Robespierre died.

Then, when the victories of the French had put an end to the terror which the coalition of priests and foreigners had inspired, the Catholic religion spontaneously reappeared. Then at last, enlightened by experience, waiving all idea of a State religion, the National Convention established the secular régime of separation, which lasted from the end of 1794 to the spring of 1803. Under this régime the State paid no further salaries to any sect, and all the sects, equal before the law, worshipped freely, with the provisional restrictions and the police precautions rendered necessary by the state of foreign and even civil war in which France still labored. A number of the churches were restored to purposes of worship, on condition that the priests who should enjoy the privilege should submit to the laws. Nevertheless, there remained a shadow, a trace, of a State religion; this was the «*culte Decadaire*» or «Ten-Days» religion, a sort of official religion of patriotism, which disappeared little by little under public indifference, when the country was no longer in danger. On the other hand a new religion arose, a kind of unofficial continuation of the cult of the Supreme Being; this was Theophilanthropism.

Papal Catholics, non-Papal Catholics, Jews, Protestants, Theophilanthropists, adepts of the ten-day cult; all these sects acted as counterpoise to each other in a state of liberty, and although the vicissitudes of foreign and civil war brought on acts of intolerance, it may be said that the régime of separation of Church and State became a part of the life of France at the time of Consulate, that it was at least endurable for all sects, and that there was a rich development of religious life.

If Napoleon Bonaparte suppressed this régime of liberty, at which he had himself presided with as much success as talent; if he came at last to desire and to effect the reunion with Rome, to conclude a new concordat, it was not at all from piety but from personal ambition, his purpose being to command, through the Pope, the consciences of men, to realize through the Pope his dreams of power and of universal empire.

When the victory of Marengo had made him sufficiently popular to believe that all things were permitted to him, in the enforced silence of public opinion and the press, he entered upon negotiations with the Pope, and on 15 July 1801, at Paris, an act was signed which, since none dare call it a concordat, was called a Conversion, but which was really an agreement analogous to that which Francis I. had concluded with Leo X. In it Catholicism was not declared the religion of the State, but the fact was recognized that it was the faith of the great majority of the French people. The Pope was to demand or force the resignation of all the bishops then acting, and after a new circumscription of dioceses had been determined on, the First Consul was to make nominations to these bishoprics or archbishoprics, and the Pope was to confer on the persons thus nominated, canonical ordination according to the forms of the earlier concordat. The bishops should nominate the priests, but subject to the approval of the government. The Pope promised that the purchasers of property formerly belonging to the clergy should not be disturbed; and a suitable salary was to be given the bishops and priests by the Government. On the other hand, the First Consul instituted some regulations of policy, called the Organic Articles, by which he received security from the churches, in conformity with the ancient Gallican policy. The Conversion and the Organic Articles became law on the 18 Germinal, year 10 of the Republic (March 1802) and the new concordat was in force from the end of the following April.

The greatest advantage that accrued to the Pope from this document did not appear in writing: this was the suppression of schism. Bonaparte abolished the heretofore constitutional church. He abolished also Theophilanthropy and whatever remained of the «Ten-days» worship. Protestants and Jews were recognized and protected by the State, but not with the same degree of honor and influence. The Concordat promised salaries only to the district priests. When Bonaparte became emperor, he allowed a salary to other priests or curates to the number of more than thirty thousand. The budget of Religions swelled little by little. At the time of the rupture of the Concordat, in 1905, it was about fifty millions of francs.

Pope Pius VI., who had signed the Concordat, came to Paris in person to consecrate the new Emperor, but Napoleon did not find in him the docile tool he was counting upon. Not being able to bend him to every whim of his despotic will, he used force, had him carried off from Rome and kept him a prisoner at Fontainebleau, thus provoking the wrath of the Catholics and bringing upon himself the hatred of all religious persons.

It was in hatred of Napoleon, likewise, that Louis XVIII. planned to make a new concordat more favorable to the Church. This concordat was, indeed, drawn up in 1817, but it was not carried out, and it was the concordat of 1801 which governed the relations of the Catholic church and the State up to the beginning of the 20th century. The charter of 1814, while guaranteeing the freedom of conscience, declared Catholicism as the State religion. This declaration was from the charter in 1830, and the government acted from 1815 to 1905 in the direction of a real liberty of the sects, at least of those recognized by the State: for no legal guarantee was granted to the founding of new sects. On the whole, although some of the liberal party, from the time of Louis Philippe demanded a return to the régime of the separation, the regulations of the Concordat acted without encumbrance and seemed to suit the state of public opinion in France up to the end of the 19th century.

After the promulgation of the dogma of Infallibility, the Catholic Church, now an entirely absolute monarchy, appeared a menace to civil society; especially when the suppression of his temporal power had made the Pope invulnerable. On the other hand, since the loss of Alsace-Lorraine separated from France a large number of Lutherans, Catholicism had no longer any rivals but the Jews, who do no proselytizing, and the Calvinists, who do very little. In the years which followed the Franco-Prussian war, the Catholic clergy showed a desire to govern France and even to plunge her, all shattered as she was, into the perils of a war for the restoration of the Pope's temporal power. The same clergy favored the two attempts at political reaction by Marshal MacMahon. Thus the priesthood lost its popularity. Soon the primary schools, now a lay institution, enfeebled religious faith in France, and free-thought made great strides. Every year in the Chamber of Deputies, lively opposition was made on the vote on the budget of Religions, and the separation of Church and State was demanded in a considerable number of Electoral programs; but there was, nevertheless, no strong popular movement in this direction. Even the Chamber elected in 1902 seemed determined to maintain the Concordat.

An unlooked-for incident changed the situation. In the spring of the year 1904 the president of the French republic returned the visit which he had received from the King of Italy, and moreover returned it at Rome. The Pope, who still claims the sovereignty of his ancient States, declared himself insulted by this proceeding, and addressed to all the Catholic Powers a document in which he complained of the offence committed by the French against his rights and his dignity. This memorandum, when made known, deeply wounded the national sentiment of the French. The government of the Republic recalled its ambassador from Rome and returned to the Papal nuncio his passports. There was a complete rupture of diplomatic relations between France and the Pope, and on 10 Feb. 1905, the Chamber of Deputies, by a majority of 386 votes against 111, declared «that the attitude of the Vatican rendered necessary the separation of Church and State.»

The writer of the project of a law of separation was M. Aristide Briand, Socialist Collectivist, a man of character more moderate than his opinions. He strove, by skillful combinations, to prepare a régime that would be acceptable to the Church, but there were no negotiations, official or direct, with the Pope himself. The Briand plan received, in the course of debate, but few amendments.

The whole bill was passed in the Chamber of Deputies on 3 July 1905, by 341 votes against 233, and in the Senate, on 6 Dec. 1905, by 179 votes against 103. The law was declared 9 Dec. 1905. It forms to-day (1907) the politico-religious system of France.

The particulars of the law are these: the Republic assures liberty of conscience, and guarantees the free observance of religious worship; it does not recognize nor pay nor subsidize any sect. All public religious establishments are suppressed, revenues, factories, councils of elders, consistories and the like. The property of these establishments will be transferred to associations called «cultuelles» to provide for the expenses, the maintenance and the public observance of a sect, and composed of a minimum of 7, 15, or 25 persons, according to the population of the community. The church buildings which belong to the nation (and this means the greater number) will be left free of charge at the disposition of the religious societies, who will be held responsible for repairs of all sorts. Life pensions are granted to ministers of religion of more than 60 years of age and actually in service; those less than 60 years old will receive an allowance for four years. As to the police regulations of the sects, the meetings are public, but take place under the surveillance of the authorities in the interest of public order. Penalties are enacted against such ministers of religion as shall make in the churches any extreme political opposition to the Republic.

The Protestant and Jewish congregations submitted without difficulty to this law, but such was not the case with the Catholic Church, or rather with the head of this Church. The majority of French bishops, in assembly at Paris, agreed to accept the law, after a formal protest, and to organize under the name of Canonical Associations, societies analogous to those the law recommended. There even seemed to be a sort of agreement established between the clergy and M. Briand, who had become Minister of Public Instruction and Religion, and who had charge in this capacity of the administration of the Law of Separation. Moreover, the most eminent of the Catholic laity, the Catholic «Intellectuals,» had publicly advised the Pope to accept the law. The Pope preferred to follow the advice of the Jesuits, who urged him to an uncompromising resistance. He believed that the formation of religious societies would bring democracy into the Catholic Church in France, and from that the destruction of the monarchical hierarchy of the Church would some day result. Not only did he condemn the law but he forbade the formation of the religious societies or anything that resembled them. The French bishops were dismayed, but they obeyed the Pope.

There seemed reason to fear a religious civil war. Already at the beginning of the administration of the law, when the government wished to make an inventory of articles of furniture kept in the churches, the Catholics had forcibly opposed the officials in more than one place, and in some conflicts blood was shed.

This time the government pushed prudence to the point of negative passiveness. It allowed the Catholic priests to continue their services in the churches of which they already had possession, and to this day they keep this possession under provisional title with no legal right nor guarantee. There has not been any religious disturbance in any part of France since the Pope rejected the law. Some of the Catholic laity tried by a sort of schism to form religious associations in defiance of the Pope's orders; their attempt fell flat, in the face of public indifference.

But the decision of Pius X. deprived the Catholics of property whose transmission to the religious societies was assured by law, that is to say, the property of the former establishments of the sect, whose sum total is reckoned at about three hundred million francs. The Catholics thus see themselves defrauded of the resources they would have found in the assessments, collections, and contributions of the religious associations. It will be difficult for them to pay their clergy, it will be difficult to recruit them. Furthermore, the Pope has the advantage of being able to name the bishops without the permission of the French government, and he makes use of this privilege in such a way as to strengthen his absolute power by the choice of bishops of the most tractable nature, and oftener Romans than Frenchmen.

At present the politico-religious question in France seems dormant. The progress of philosophical thought and especially of democratic ideas has turned the attention of the French away from theological discussion, and almost all their intellectual activity seems to be occupied with social questions. The Catholics appear to be resigned to the situation, so troublesome from a material point of view, which the uncompromising attitude of the Pope has forced upon them; the free-thinkers and the anticlericals do not seem to think of contesting with the Catholic clergy the provisional possession, however illegal, of the churches which the tolerance of the government actually leaves to them. There will be, however, one difficulty, namely the very expensive repairs of these buildings. On whom will this expenditure devolve? But it does not appear from the present state of public feeling, that this difficulty will lead to disturbances. At this time the régime of separation of Church and State is acting in conditions of peace which indicate not so much a state of provident wisdom as the weakening, each day more marked, of religious faith in France. See CHURCH AND STATE.

A. AULARD,
Professor of Revolutionary History, in the University of Paris.

10. **France—Education and the Educational System.** I. *The Development of Education.*—The organization of education in France as a public service is of comparatively recent date. Before the Revolution of 1789, teaching was considered as essentially a matter of private enterprise, and little, if anything, had been done to regulate and control it. Naturally enough it was the Church that first understood the importance of instruction and the first masters were members of the clergy. As far back as the 10th century there were monastic and cathedral schools scattered all over the kingdom, which possessed a large population of scholars and attracted students from the most remote parts of Europe. At the end of the 12th century some of these schools had already developed into universities. The University of Montpellier, the most ancient of all, was established about 1125; that of Paris about 1150, and others followed rapidly: Orleans 1200, Angers 1220, Toulouse 1230, Grenoble 1339, etc. In their turn the universities gave birth to a num-

ber of colleges, and after the great revival of learning at the Renaissance, the latter multiplied so, that in Paris alone, there were more than 50 of them. As to the universities, they, too, steadily increased, and when the Revolution broke out in 1789, there were no fewer than 25 in France, Paris being the most important with 6,000 undergraduates. But so far, little had been done for the education of the people at large, and learning had remained the portion of an «élite.» Primary instruction was given in small uncomfortable schools by masters not often qualified for their task: teaching the rudiments was looked upon as a trade, and the customers were few, because few were able or willing to pay. Yet a universal feeling prevailed throughout the kingdom that this state of things was to be remedied, and when the «Etats généraux» summoned by Louis XVI. assembled in Paris, there was a loud cry from the third estate and the clery for better schools and a wider diffusion of instruction among the people. They distinctly asked for a national education of all classes, by means of national schools. But the expense entailed in the execution of such a vast scheme was obviously too much for the public treasury, exhausted as it was by continuous war. «The Constituante» adopted the principle, but two years later when the members of the «Legislative» were asked by Condorcet for 24,000,000 francs as a first outlay, they were obliged to reduce the estimate to a paltry 200,000 (29 May 1792). In spite of repeated discussions in the assembly concerning the opportunity of making education compulsory, and of several decrees trying to enforce its decisions, nothing really effective could be done for the time being. The first practical measure was taken by Lakanal and the «Convention» (27th Brumaire year three) when they granted a subsidy to the primary schools then extant, and created training schools to recruit masters. This was but a very imperfect solution, and one that only partially met the wishes of the people, but it was the greatest effort made by the Revolution to solve the problem of a national primary education. More was attempted in favor of secondary education, which received a common programme of studies combining scientific with classical training, and for which the act of the 7th Ventose year three established the so-called «central schools.» A new plan of secondary education, drawn up by Napoleon, then first consul, with the help of Fourcroy and adopted by Parliament (1 May 1802) brought up to 36 the number of the central schools, which took the name of «lycées» and which were provided with the necessary staff of masters and an effectual budget. And it was only the beginning of a vaster scheme, for in 1808, when he had become emperor, Napoleon with a view to forming a young generation devoted to the Imperial régime, founded the Imperial University, «exclusively entrusted with the mission of teaching and giving education in the whole Empire.» It was a complete organization of education in three degrees, elementary, secondary and superior, placed in the hands of a privileged corporation, which, in the intention, at least of its founder, was destined to abolish private education everywhere and in all its forms. This total abolition, of course, was as yet impossible; so private colleges were tolerated, but only under the control of the omnipotent University and with the main object of recruiting pupils for it afterwards. Moreover, of the national primary schools that were so badly wanted, few, if any, were created; Napoleon's University merely adopted and, so to speak, legitimated those which existed already. Guizot in 1833 for the first time seriously took in hand the interests of popular education; under his influence the primary schools increased in the proportion of nearly 900 a year (24,000 in 1847, against 9,000 in 1830).

However, it belonged to the Third Republic to achieve the task conceived by the Revolutionaries of 1789, unsuccessfully attempted by their successors and only begun by Guizot himself. In 1882 Parliament adopted Jules Ferry's famous education bill that rendered primary instruction compulsory and gratuitous. Nor was its interest limited to the more elementary and democratic form of knowledge, all the departments of education were infused with a new life: 800,000,000 francs (£32,000,000 sterling) were spent on new buildings including Faculties and Lycées as well as schools, and the annual educational budget was raised within 30 years from 44,000,000 francs to 210,000,0000 francs.

These figures, of course, must be understood to represent the share of the State only, not the total of the expenses connected with education; besides the national schools and faculties, there exist a very large number of private institutions, of which further mention will be made.

II. *Organization of National Education.*— The modern «University of France» is still to some extent organized as was Napoleon's «Imperial University»; only it is no longer, as it was then, an independent corporation. Since the creation of the Ministry of Public Instruction by Charles X. (26 Aug. 1824), it has been administered directly by the State, as the other great public services. The supreme authority is officially in the hands of the Minister of Public Instruction, who, however, is helped in his decisions by the directors of the three departments of superior, secondary and primary education, and more effectually still by several deliberating assemblies of professors and officials, the most important of which are the University Council and the Committee of Public Instruction. As direct representatives of the central power, 15 *rectors* residing in the 15 university towns have the supervision and management of all educational matters in their academy (or academic province). Each academy possesses also an assembly of professors elected by their colleagues, the Academic Council, in which are treated pedagogical and administrative questions interesting the academy. Under the rector are placed *Academy Inspectors*, who have the care of secondary and primary instruction, and under them again *Primary Inspectors* who superintend the primary schools.

Thus the three different branches of education are grouped into one vast administrative organism, insuring their homogeneity and the necessary unity of direction. Each of them, however, being destined to meet distinct and separate wants and consequently being managed on a distinct and separate plan, it is necessary to view them each by itself.

Primary Education is compulsory for all children from 6 to 13: those who do not attend the government schools (where it is gratuitous), are obliged to prove that they receive proper tuition either in a private school or at home. The matters taught are reading and writing, orthography, composition, arithmetic, the elements of natural history and natural philosophy, history, geography, drawing and singing and also gymnastics for boys and needlework for girls. At the end of their regular course of studies, those of the pupils who want a more substantial and wider instruction, and yet do not choose to go to a lycée or a college, may get it in one of the 350 «superior primary schools» created within the last 25 years, or attend the so-called «complementary lectures» where superior schools have not yet been established. This «superior primary education,» which in some points is like a sort of cheap secondary education, has, however, a more practical and positive object than the latter and is better suited to the wants of the working and commercial classes. For such of the young men or girls who cannot spare the time to complete their studies in superior primary schools, there exist in all towns and in most villages, evening classes, which, it is true, are due to the masters' own initiative, but which at the same time are officially recognized and encouraged by the academic authorities.

Everyone possessing the necessary diplomas may apply for a post of master or mistress in a primary school; but the government, understanding that good teaching can only be given by well trained teachers, has provided in each department two training schools, one for girls and one for young men, in which the future masters and mistresses are kept and educated for three years at the expense of the State. School-masters and mistresses are appointed and promoted, not by the minister, as is the case for the professors of the other two degrees of education, but by the prefect in each department, with approbation of the Academy Inspector.

Secondary Education is given to the boys in 106 lycées and 246 colleges. A lycée is properly a public school, being the property of the State, kept and administered by the State; whereas a college is a municipal institution. In both the professors are appointed by, and placed under the authority of, the Minister of Public Instruction; in both also the matters taught are the same; yet there is a difference between them as regards their respective importance, the average number of boys in a lycée being 500 to some 200 in a college; and instruction in the former being generally recognized as of a higher standard. In a lycée the masters are divided into two classes: the «agrégés de l'Université» (*i. e.* fellows) who hold a regular professorship, and the licenciés (M.A.) who are simply «chargés de cours» or lecturers. In a college the professors are only licenciés.

Within the last 15 years the secondary curriculum has been repeatedly modified: originally it comprised only two parallel courses of study, of which one was chiefly classical and the other chiefly scientific. It has now become more complex: the division in two sections is kept through the lower forms up to the third, after which the boys have to choose between four sections according to the «specialties» they think will be most useful to them in after life. These specialties, which are part of the staple of secondary education, are coupled into four groups: (1) Latin and Greek; (2) Latin and Modern Languages; (3) Latin and Sciences; (4) Sciences and Modern Languages. At the end of the first form, generally at the age of 17, the boys undergo one of the four examinations corresponding to the section to which they belong, and then spend one year more in the study of philosophy or of the more advanced mathematics, after which another examination (the second of the «baccalauréat») successfully passed gives them the title of «bachelier,» the official conclusion and stamping of secondary education, the possession of which is necessary for most liberal professions, and absolutely requisite for admission in the Faculties.

Up to 1881 the State had provided no regular system of education for girls. In spite of a not very successful attempt of Duruy in 1867 to organize lectures for them with the help of professors from the boys' lycées and colleges, it may be said that the girls had really no choice but between education at home or in private schools, chiefly in convents. Within six years (1881-1887) 35 lycées and colleges for girls were founded in as many towns, and the number has since rapidly increased. In these the lessons are now given everywhere by lady teachers qualified after studying in the universities or in the special training college of Sèvres. There was at first a strong prejudice against these establishments among the families that were accustomed to another sort of feminine education, but it is gradually dying out, though it cannot be denied that, even at the present time, the great majority of girls are still educated in private and congregational schools.

Superior Education.—Of the 25 universities that existed in France before the Revolution, 13 were suppressed in 1793 and have not been reopened since; four new ones have been created, bringing the total to 16. Here they are in the order of their foundation: Montpellier (1125), Paris (1150), Toulouse (1230), Grenoble (1339), Aix-Marseilles (1409), Caen (1431), Poitiers (1431), Bordeaux (1441), Besançon (1485), Nancy (1572), Dijon (1722), Rennes (1735), Lyon (1808), Lille (1808), Clermont (1808), and Algers (1849).

A university consists of four Faculties: Letters, Sciences, Medicine, and Law. At the head of each Faculty is a dean elected by the professors and placed immediately under the rector of the university, who, it must be remembered, is the chief of the academic province of which the university is the centre. The lectures in each Faculty are given by «professors» who must be doctors, and «maîtres de conferences» (tutors or lecturers) who are agrégés (fellows). These lectures are open to all undergraduates that have duly matriculated, *i. e.* who, being in possession of the necessary diploma of «bachelier,» have entered their name on the Faculty's register, and paid the matriculation fee of 100 francs a year. This, with 30 francs for the use of libraries and laboratories, is all that the undergraduates have to disburse. Such small sums of course cannot be regarded as a retribution for the lessons received, but as a kind of duty exacted to ensure the legal status of the student. Officially, superior education, like primary education, is gratuitous.

Two degrees may be taken at a university: The first is the «licence» (the old *licentia docendi*) for letters, sciences and law, and the second the degree of doctor which is the reward of at least one scientific work (thesis) presented and publicly discussed by the candidate that must already be «licencié.» The old medical licence having been suppressed long ago, doctors of medicine make an exception to the otherwise general rule that to be a doctor one must first be a licencié, but the test of their attainments and ability is previously made in progressive examinations during the course of their studies which extend over five years at least.

To the universities proper that have been enumerated above, should be added the Superior medical schools of Amiens, Angers, Limoges, Nantes, Rheims, Rouen and Tours. As regards the University of Paris, one would have a very incomplete idea of it, if one limited it to the four Faculties that have the Sorbonne for their centre. It includes a large number of establishments of which the College de France, Ecole des Chartres, Museum, Ecole des Hautes Etudes, Ecole des Langues Orientales are only the principal. More or less directly connected with it, though not all placed within the authority of the Minister of Public Instruction, are also the Ecole du Louvre, Ecole des Beaux-arts, Ecole des Arts Décoratifs, Conservatoire, Ecole Superieure des Mines, Ecole des Hautes Etudes Commerciales, Ecole des Sciences Politiques. Even if one leaves these schools aside, and only takes into account the former, that are the natural complement of the four Faculties, the University of Paris appears as something unique in the world. To give an idea of its importance it suffices to say that of the 21,033,778 francs annually spent on superior education, 9,952,191 francs, *i. e.*, almost one half, are absorbed by the University of Paris alone, and that the number of its undergraduates exceeds 12,000.

Whether this affluence in Paris is a good thing, may be and has often been discussed; it is a fact that it takes from the provincial universities their best teachers and a large proportion of their students, but at the same time it is undeniable that this very density of the scholastic population of Paris is a strong stimulus to intense intellectual labor: there is no place in the world so replete with illustrious names or so productive of remarkable achievements, both literary and scientific.

III. *Private Education.*—The monopoly of teaching which Napoleon had given to the Imperial University, and which the Royal University retained after it, was abolished, practically in 1830, and officially in 1850 by the Falloux Bill. This bill, though recently modified in many of its clauses, has not been recalled as regards the liberty of teaching.

Since private industry and charity were allowed to compete with the public treasury, the competition has been a sharp one; the development of the national schools was everywhere attended by a parallel increase of the private ones. It is worth remarking, however, that this régime of liberty chiefly served the interests of the Catholics who, opposite the State University of France, built up, as it were, a university of their own, including establishments of the three degrees, primary, secondary and superior. Indeed, so preponderant is their influence in the so-called «enseignement libre», that a private school is generally understood to mean a Catholic school.

The private establishments being as exact a copy as possible of those which belong to the State, there is no necessity to insist much on the subject. Yet a comparison of their respective importance cannot be dispensed with; it will moreover have the advantage of showing that an efficient preponderance is ensured to the National University. As the statistics were made before the recent expulsion of most religious orders, which could not but affect some of the private schools, this comparison is only an approximation; but on the other hand, in most cases the place of departed ecclesiastics having been taken up by Catholic lay teachers, the figures given below may be considered as sufficiently exact. With regard to primary education, the State establishments are far ahead of the others, with 67,340 schools, 100,913 teachers, and 3,671,727 pupils, against 14,331 private schools kept by 41,747 private teachers and receiving 925,301 pupils. It was chiefly in secondard education that the competition of private industry was successful, for the French middle and well-to-do classes are to a large extent favorable to Catholicism. The number of boys is virtually the same in private colleges as in the State lycées and colleges: 86,347 for the former, against 86,371 for the latter. The competition is more successful still as regards the education of girls: the State colleges, it has been said before, attract but a comparatively small numb· of them. Here the Catholics have an undeniable advantage, but they are far behind with their universities. They gave the utmost of their effort in 1875 when they founded three Catholic universities in Angers, Lille and Lyons, and a Catholic Institute in Paris. For these they are wholly dependent upon charitable foundations (superior education being gratuitous, and the matriculation fees being received by the State); so, far from being able to increase them, they experience great difficulty in maintaining what they have created. On the whole, therefore, the superiority of the State establishments is obvious and assuredly sufficient to reward the pecuniary sacrifices of the nation. But in Fra· the religious quarrel has reached almost a crisis; and the fact that the education of the higher classes is almost equally divided between the government teachers and the Catholic masters, seems to many an alarming state of things. What has been called the «crise universitaire» has been and is still daily discussed passionately; and although republicans should shrink from such drastic and unliberal measures, some restriction of the right of teaching may be anticipated—possibly in the near future.

CHARLES PETIT,
Agrégé de l'Université.

11. **France—French Language and Literature.** *Origin.*—French is derived from Latin. The groundwork of the language was formed

not with classical Latin but with colloquial Latin spoken by soldiers and colonists. With the progress of culture, Latin had developed a double growth, a vulgar tongue (*sermo rusticus plebeius,* castrense verbum) and a nobler speech (*sermo nobilis*). Not only were the grammatical forms simplified by the former in point of cases and inversions, but each one had its own vocabulary, *e. g.*:

ENGLISH	PATRICIAN SPEECH	VULGAR LANGUAGE	FRENCH
battle	pugna	batualia	bataille
to help	juvare	adjutare	aider
week	hebdomas	septimana	semaine
to eat	edere	manducare	manger
horse	equus	caballus	cheval

As early as the 1st century A.D., vernacular Latin had superseded Celtic throughout Gaul, Brittany excepted. Strabo no longer looks upon the Gauls as Barbarians. Celtic, not being written, was completely swept out of use. It left but very few terms in the Gallo-Romans' speech, hence in French, *e. g.* alauda (alouette), cervisia (cervoise).

Latin was hardly master of the land, when the Germanic tribes pressed upon the border. Rome held them back for a century or so by a system of military colonies (lètes) filled up with Franks and Burgunds. As a consequence Germanic words referring to war began to take root in Roman Gaul. In the 2d century, literary Latin was flourishing, but the middle class declined, Latin culture with it, and in the 5th century patrician Latin was ruined and the vernacular idiom in general use. The work in progress was not stopped by the invading Franks. They forsook their own tongue and adopted that of the conquered (1) because they numbered hardly 13,000 against some 6 millions; (2) because the Germanic tribes had no uniform language; (3) their conversion to Christianity worked in the same direction. Yet the Frankish idiom left more words than Celtic in the vernacular. Outside war terms, the Franks brought feudal institutions for which there were no words in the language of imperial Rome, *e. g.*:

FRANKISH	FRENCH
alod	allen
bann	ban
skepeno	échevin

About 900 words were thus imported. Meanwhile, the syntax was also changing, but not under Germanic influence. The great change consisted in the prevailing use of the Latin prepositions *ad* and *de* in lieu of cases to denote tendency or possession. *Liber de Julio* led to *le livre de Jules; dono librum ad Julium* led to *je donne le livre à Jules.* This analytic process was also operative in the evolution of auxiliaries in the conjugation. In the 7th century, the «Romanic rustic tongue» was built up quite apart from Latin as well as from Teutonic: it had all the constitutive elements of French.

The first text extant of this infant French is known as the *Reichenau Glosses,* of 768, the year when Charlemagne was king. It is a glossary for a Latin Bible, an evident proof that Latin was no more understood even of such as could decipher MSS., *e. g.*:

LATIN	EARLY FRENCH
galea (helmet)	helmo (heaume)
tugurium (cottage)	cabanno (cabane)
caementarii (masons)	macioni (macons)

So, the subjects of Charlemagne spoke Romanic or Early French. The Church did much to spread it: Council of Rheims, 813, Council of Strasbourg, 842. At the latter place, and in the same year, French was used as medium between Louis the Germanic and Charles the Bald. The *Strasbourg Oaths* are the oldest French sentences on record. Poetry gave it its final consecration under the form of *cantilènes,* short lyrico-epic poems to the memory of saints, *St. Eulalie,* 9th century, *St. Léger,* 10th century.

Early French (10th century-14th century).—Let us now look more closely into the phonetic laws after which the new vocabulary was formed. The main rule is the persistency of the accented syllable, in words of popular origin; 2°, the short vowel just before the accented syllable, is left out: sanitatem=santé; 3° the middle consonant, *i. e.* placed between two vowels, falls off: augustus=août. These rules were disregarded by the scholars, who coined words, when they failed to feel the old Latin stress. Then the same Latin word sometimes gave two French words, one of popular making, the other of scholarly formation, *e. g. advocatum*=one avoué, two avocat; *porticum*=one porche, two portique; *fragilem*=one frêle, two fragile; *organum*=one orgne, two organe. These forms, called *doublets,* are about 800 in French.

The chief character of Early French or *langue d' oil* (as distinguished from the *langue d'oc* spoken south of the Central Plateau) is that it is a semi-synthetic tongue with two cases for subject and object, thus half way between Latin purely synthetic with six cases and Modern French purely analytic with no cases. The analytic process was at once more thorough with the conjugation: the auxiliary *avoir* with the past participle brought about all the compound tenses; the auxiliary *être* gave a new kind of passive verb. The future and conditional were original formations, devised by adding the present or the past of *avoir* to the infinitive: *aimerai*=aimer ai; *aimerais*=aimer ais, contraction of *avais.*

Very soon French gained great credit in Europe owing to the political ascendency of the Kings and to the qualities of the language, further evolved than any, Italian alone excepted. Cp. Dante (*de vulgari eloquio* I, 10); Martino da Canale, Brunetto Latini, etc.

The poetry of Early French was chiefly narrative. The poets were called *trouvères,* inventors (makers). Their tales centered round Charlemagne, Arthur, Alexander; hence three cycles of *chansons de gestes.* The masterpiece of the first was the *Song of Roland,* sung by the Normans on the field of Hastings. It contains 201 verses of lines with *assonance, i. e.* vowel-rhyme only. It is the epic of the feudal aristocracy, painted with vigor, life and touches of pathos. In French, the Arthurian cycle produced the poems of Chrestien de Troyes, full of sweet gracefulness. In the classical cycle we find the 'Romance of Troy' and the 'Romance of

Alexander' written in the 12-syllable line which hence took its name «alexandrine.»

With the play of Adam (12th century) the French drama begins its long career. As was the case in Greece, play-acting was evolved from the ceremonies of religious worship. In the 13th century, the spirit of chivalry is waning and the spirit of satire gives birth to a new kind of poetry, the *fabliau,* a comic tale intended for recitation. The most famous is the 'Romance of the Rose', translated by Chaucer. They combine amorous devices, wit and humor.

On the stage, many plays are produced, some of a religious character (*miracles*), others of a distinctly lay and comic vein (*soties, moralities, farces*). Prose for the first time is brought to eminence by chroniclers of great personal worth, Villehardouin (1213) 'Conquête de Constantinople' and Joinville (1318) 'Memoirs.' With their either stern or winning but ever clear and effective diction, the early period comes to a close.

Modern French.—(1). *14th Century.—Renaissance.* (a) The evolution of languages follows the evolution of societies. After Saint Louis' reign, the highest development of the Christian-feudal civilization, a long struggle begins between the mediæval and the modern spirits. The coming victory of the latter is evinced by the triumph of the analytic process: French casts off its two cases. Then followed a period of grammatical confusion, still enhanced by the wholesale invasion of words brought in by translators and all of scholarly formation. All the 15th century was necessary to build up Modern French, just in time to house the ideas and ideals of the Renaissance. (b) The unsettled state of the language told on the value of the writings. Poetry was much enfeebled. Christine de Pisan wrote loose easy verse; the two poets of the period are Charles d'Orleans (+1465) the last of the *trouvères,* whose perspicuous and refined style is still charming: and Villon (+1470?) the first of the moderns, whose frank confessions are both realistic and romantic. Prose won the day with Froissart (+1410), the greatest chronicler of the Middle Ages, the painter of the most varied, picturesque and living fresco, and Commines (+1511) who worked on entirely new lines in his business-like *Memoirs,* where he goes so far as to anticipate Montesquieu. On the stage, the *Miracles* sometimes struck up an eloquent note in a mass of prosaic lines; the *Mysteries* lived on to the eve of the Renaissance and comedy, a completely original start, was brought to life in the farce of *Pathelin* (circa 1465).

(2). *Renaissance.* — (a) The French language went on ripening. Calvin's 'Institution' (1535) testified to its richness, vigor and force. Owing to political influences (Italian wars and marriages) it was spoiled by Italian words and idioms against which Malherbe (+1630) fought with so much success that he overran himself and made the language not only purer but poorer. He reformed verse too, banishing hiatus, run-on lines, and bringing cæsura to chime in with the sense.

(b) Marot (+1544) is the poet of transition. He left the glory to found French classical poetry to Ronsard (+1585) and his friends, the Pleiad, the most shining stars of which, next to him, were DuBellay and Racan. DuBellay wrote the manifesto of the new school in his 'Defence and Illustration of the French Language.' Setting apart playwriting as the province of Jodelle, Ronsard restored all the forms of ancient poetry, ode, elegy, eclogue, hymn, epistle, satire, and sonnet, stanza both after the Italians. He was a true lyrical genius. His style is somewhat strained with erudition. His group did much to make the poetical diction more pure and supple. They lacked neither enthusiasm nor art-feeling, but perhaps some depth of inspiration. Outside their circle, Agrippa d'Aubigné reached the highest degree of vehement indignation, and woe in his 'Tragiques.' The dramatic vein, then so rich in England, was poor in France, in spite of the learned efforts of Jodelle and Garnier in tragedy and Lariney in comedy. A great creator in imaginative prose was 'Rabelais' (+1553) whose *Gargantua* and *Pantagruel* are household names the world over, whose style was so rich and so precise in his studied copiousness. Amyot translated 'Plutarch,' and Montaigne, with easy-going scepticism, wrote the history of his own feelings and thoughts in his 'Essais' (1580): both of them were read by Shakespeare.

Classical Age (1601-1715.)—(a) As to language, a Spanish mania followed the Italian craze. The new words thus naturalized were dearly paid for by bathos and bombast. Malherbe's purifying work was carried on by a worldly set (Hotel de Rambouillet), by the French Academy (Richelieu, 1635) and by grammarians: Vaugelas, d'Olivet. Henceforth, the story of the language would be the story of the influence exerted by great writers. (b) The first part extends to the early plays of Corneille. In satire, Regnier (+1613) was a follower not of Malherbe but of Ronsard and Desportes, with exceptional humor, popular wit and sense. Hardy was a Shakespeare without genius, powerless to stop the growth of the classical drama. De Balzac gave models of oratory prose: he was the Malherbe of written eloquence. He was followed by the church orators Bourdaloue, Fléchier, even by the greatest of them Bossuet (+1706). Other eminent prose writers were in philosophy Descartes (+1680) and LaBruyère (*Caractères,* 1688). Three ladies rose to literary fame, Mme. de La Fayette, with the first psychological novel (1678), Mme. de Sévigné, and Mme. de Maintenon with their 'Letters.'

Poetry, and especially Tragedy, reached classical perfection with Corneille (1606-84) who introduced upon the stage the struggle between passions, between duty and love ('Cid,' 1636), love and patriotism (*Horace*), human love and divine love (*Polyeucte*). A heroic strain pervades matter and verse. To love Corneille is to love greatness: his work is the dramatic song of the human will. Rotrou (+1650) serves for link between Corneille and Racine. Nothing goes farther away from the Shakespearian drama than Racine's tragedy which, in his own words, "is a simple action with no load of matter, never straying from what is natural to run to extraordinary extremes, by degrees pacing to its end, upheld by nothing else but the feelings and passions of the characters." (*Andromache* 1667, *Britannicus, Phèdre* 1677.)

(3). *18th Century.*—(a) People then esteemed that French was fixed forever. But only dead languages change no more. Yet, new words were few in this period: changes in the spelling were advocated (*ai* for *oi*, by Voltaire). The tendency was to an undue strain after polished noble style which often landed authors on cold and somewhat barren regions. (b) In the field of literature, changes were many. The first period, extending to 1750, is one of reaction tempered by respect; in the second, the fierce struggle bursts out and a sudden revival in spirit, if not yet in manner. Comedy ran on its merry career with Regnard (*Joueur* 1696), Dancourt and Marivaux (†1763) who created a comedy and a style of his own,—pleasant skirmishes of feelings not very deep, marvellously adapted to the stage and expressed in a wilful, skimming, subtle, playful sort of diction that has kept his name «marivaudage.» Tragedy sank deep with Crébillon and could do little more than floating with Voltaire (*Zaïre* 1732, *Mérope* 1743). The 18th century is a great age for prose. Fontenelle (†1757) taught the public respect for science and gave scientists a taste for good writing. As an interpreter of science to the many, he was a forerunner of the *Encyclopédie*. Voltaire took the hint (Newton). Then, in his so-called *Romans*, he scattered all over human thought and feeling the satirical sparks of his wit. His 'Letters on the English' are filled with the sceptical spirit of Bolingbroke. In history, he was not a discoverer but a sagacious writer, (Siècle de Louis XIV.'). Later on, he returned to verse and excelled in *satires* and *epistles*. His vast *correspondence* is the marvel of a versatile mind. His influence was paramount against Christianity and, in spite of himself, against monarchy. Two names only shone as bright as his: Montesquieu (†1755) and Rousseau (1712-78). Montesquieu created the philosophy of history with 'l'Esprit des Lois' (1748). Rousseau had still more influence, and one of a distinctly sentimental nature. His paradoxes are responsible for much in the course taken by the Revolution. His 'Discourse on the Origin of Unequality' 1755) contrasts the so-called *état de nature* with the evils of civilization. In 'la Nouvelle Héloïse,' he enriched French literature with the style of natural descriptions. The 'Contrat Social' is a theory of democracy and 'Emile' a treatise on education. Most revolutionists were Rousseau's disciples. Diderot (—1786) and d'Alembert (—1783) were the two editors of the *Encyclopédie*, a general review of human knowledge conceived in the reforming spirit of the time.

The Revolutionary period, opened by the mirthful satire of Beaumarchais ('Mariage de Figaro') was not favorable to literature; orators caught the public ear (Mirabeau) and the only great poet was revealed only after his death, André Chénier (—1794 'Idylles, Iambes') who poured his rich new wine in old amphoras.

4. *19th Century.*—(a) The Revolution, romanticism, foreign imitations, scientific progress, inventions and journalism were so many causes of new verbal annexations in prose and breaking up antiquated restraints in verse. (b) The death of Chateaubriand and a new revolution (1848) fitly divide the century into two parts. In the former, Chateaubriand is master and king: the 'Génie du Christianisme' quickened a much needed reaction and *René* was the first to catch the melancholy contagion. He displayed his descriptive powers in 'Martyrs.' He was the greatest poet of French prose. Joseph de Maistre supported the same cause with philosophic vigor and stern eloquence. Another reviving spirit was that of Mme. de Staël who, by interpreting *Germany* to France, gave birth to modern criticism (1810). The soul of poetry returned to French literature with Lamartine 'Méditations,' 1820), Vigny ('Poems,' 1822,) Musset and Hugo, the sonorous echo of this universe, the greatest lyric poet perhaps of all literature: 'Odes,' 'Ballads,' 'Leaves of Autumn,' 'Contemplations,' 'The Legend of Centuries.' In opposition with the lyrical self-confessions of romanticism, Gautier surrendered himself solely to the picturesque object. On the stage, Hugo comes out again first ('Hernani,' 'Ruy Blas'), but being over lyrical, the romantic drama was short-lived. Two other literary forms took an unprecedented extension: the novel and history. In its brimful stream the novel was fed with all the living waters of the literary summits: there, George Sand was queen and Balzac king supreme, in fact, the French prose Shakespeare. History was born anew in the works of Thierry and by turns thoughtful with Quinet, stern with Mignet, lyrical with Michelet, business-like with Thiers, philosophical with Tocqueville, achieved wonderful work. By degrees romanticism subsided into the tamer Parnassus school, and Flaubert being the link, naturalism rose from the very excesses of pure fantasy: Zola, Maupassant.

On the first steps of the 20th century, the position of the French language is not quite that of undisputed eminence in the world, as it was at the end of the 18th century. But recent departures in poetry and in prose tend to show that the French language is still evolving in ever-renewed fruitfulness.

12. **France—French Art.** *The Sources of the Renaissance.*—Art in France, as in all European countries, emanated—in its two essential forms, sculpture and painting—from architecture. Frescoes and statues, exclusively of sacred legends, served to decorate the churches and palaces. It was but gradually—during the last five centuries only—that French painting espe-

cially, has been divided into historical painting, landscape painting, genre, and still life, and that sculpture has, according to Spencer (who explains the evolution of the history of art by the law of differentiation), become «heterogeneous» through the variety of subjects, both realistic and ideal, of which it treats.

Mosaics play a prominent rôle in the decoration of basilicas, and later of Christian churches; Byzantine influence extended to iconography and to the miniatures in missals. The development of art, from the Roman churches of the 11th century to the Gothic cathedrals of the 13th century, attained unprecedented perfection. The sculpture of the cathedrals of Chartres, Amiens, Rheims, and Paris—by their simple and exquisitely naturalistic forms—realized the highest ideals. The decoration of the façades and the portals, like a living encyclopedia, fully reflect the faith and the aspirations of an age of earnest religious belief. All the industrial arts, ornamental sculpture, cabinet-work, church windows, missals, and goldsmiths' work, were in unison in the middle ages in France. The director of the work was, at the same time, sculptor and painter as well as architect. In the 13th century French decorators turned aside from Byzantine rigidity and archaism (Sainte Chapelle de Paris, and Donjon of Coucy). Then the workmen were employed in decorating the dwellings of the nobles. Charles V. and the Duc de Berry exercised a great influence over the French school. The court of the Duc de Bourgogne vied with that of France in the magnificence of its art; calling itself the great Bourguignonne school. The Chartreuse de Champniol, near Dijon, is the most significant example. On the other hand the "ravaux," ordered by the popes during their sojourn in Avignon, were not without their influence on French decorators, bringing them in contact with Italian artists.

Jean Fouquet, a portrait painter, limner, and fresco painter, connected with the court of Louis XI., made this progress still more apparent. Jacques de Litemont decorated the chapel of the House of Jacques Cocur in Bourges. The sojourn of the court on the banks of the Loire brought a great many artists to Touraine and those from Italy brought with them the new lessons they had learned from antique art.

Jean Bourdichon of Tours and Jean Perréal, brought back by Charles VIII. when he returned from his expedition to Naples, rivaled the ultramontane artists.

With Francis I. Italian decoration and style reached their culmination: at Fontainebleau, the king placed a great many painters and artists skilled in stucco under the direction of Pri.natice, which resulted in the beautiful gallery of Francis I.—one of the most perfect «ensembles» that the Renaissance has produced. Under Henri II. and Catherine de Medici, the school of Fontainebleau followed their lead. While French architects and builders attached to the kings of France erected the Chateaux of Gallon, Blois, Meillan, Chenonceaux, Fontainebleau, Ecouen, Anet, Chambord, and lastly the Louvre and the Tuileries, which have made the names of Pierre Lescot, Philbert Delorme, and Jean Goujon illustrious, their wonderful tombs and fountains are to be seen everywhere. Conspicuous in French sculpture are the names of Michel Colombe, and of Ligier Richier, and later, in the reign of Francis I., that of Jean Goujon (who was the first, in France, to do bas-relief), and of Germain Pilon.

The 17th Century.—During the great expansion of the Renaissance, wherever the influence of the Clouets (portrait painters of psychical insight) predominated, French art maintained the greatest independence, notwithstanding the official pressure brought to bear in favor of Italian art. At the end of the 17th century, art had but one head—the king: and he expressed but one idea: absolute power. French art became monarchical, reflecting the monotonous majesty of the sovereign, and his servile flatterers, who could and did say of the state: «It is I.» It was now necessary to have a dwelling proportionate to these excessive pretentions. Architecture, painting, and sculpture basked in the sunshine of royalty. It is not quite natural for people to submit to such rigid rules. Even the gardens became monarchical in style, everything was imperial, theatrically pompous; then followed the portraits of a Rigaud, a Nateuil, and even the pompous divinities in the garden of Versailles. The methodical minister, Colbert, formed a comprehensive plan for the protection of art. François Mansard, who built the palace of Mazarin, was imitated by Claude Perrault who constructed the splendid colonnade of the Louvre; and above all by Hardoin Mansard, his nephew, who designed the palace of Versailles, and the chapel and the dome of «Les Invalids.»

Sculpture, in its turn, was held in leading strings, Giradon, Coysevox, Nicolas Coustou, and Lemoyne designed great works along these lines. It was only the genial Pierre Puget whose ardent and passionate temperament would not yield to discipline. Thus he lost the favor of the public, who leaned towards the style of LeBrun in his great decorative enterprises. It was these artists who peopled with marble Versailles, Trianon, Marly, and Saint-Cloud.

In painting there was the same love of display, except in the works of the Lenian brothers, who portrayed the peasant. Simon Vouet, in the reign of Louis XII. ushered in LeBrun. Nicholas Poussin, whose style in historical landscapes is unsurpassed, lived in retirement in Rome, where he formed the style of Claude Lorrain—a wonderful analyzer of light,—aside from this movement in which even the austere Philippe de Champagne and the suave Le Sueur took but little part, LeBrun is the artistic spirit the 18th century in France. The position of Director of the Academy having been created for him, he grouped the artists as he wished. To him is due the stately gallery of Apollo in the Louvre, and his artists Lemoine, Monnoyer, Audron, Berain, Bourdon, Coypel, la Hire, Jouvenet, Van der Meulen, Regaud, and Largilliere painted portraits in a wonderful dashing style. Decorative art reached its apogée in the Gobelins manufactory of tapestries supported by the government, and in the cabinet work of the Boule family.

Exceptionally original talent was now seen in engraving—I refer to Jacques Callot.

The 18th Century.—A very natural reaction from the pompousness of the 17th century resulted in the piquant grace and the sensuality of the 18th. Caprice and subtile delicacy took the place of dull etiquette. «Prettiness» replaced «the Beautiful.» Art declined. The «Rocaille» and «Folies» styles succeeded. Nevertheless Gabriel, the architect, did not as yet abandon the deep-rooted traditions of his predecessors which he embodied in the façades of the Place de la Concorde. Soufflot, in the reign of Louis XVI., inspired by antiquity, built the Sorbonne in that style. But architectural style now aimed rather at «comfort.»

Sculpture was flourishing, after the style of Jean Baptiste Lemoyne. Two eminent sculptors, Pigalle and Houdon, partially escaped this craze, especially Houdon who made such a powerful bust of Voltaire. But the idol of the boudoirs was the voluptuous Clodion, whose very worldly creations seem to be caressed by the hand of Love himself.

Painting was in every way typical of the taste of French society in the 18th century. The pastorals of Franc Boucher; the fascinating «Fetes galantes» of Watteau; the charming nudes of Fragonard, sounding the praises of woman; the great Chardin, a man of the middle class, who escaped the false manner of his time, which engulfed Joseph Vernet, Hubert Robert, Oudry, Lancret, and Pater, painters of marines, of landscape, of the chase, and of gallantries; the sentimentality of Greuze, and the archness of Madame Vigee Le Brun, are offset by the keen penetration of the portrait painter Quintin Latour, a capricious pastel artist.

The 19th Century.—Another reaction took place. David revived the ancient Greco-Romano, and his horror of the license taken by Boncher led him to adopt a very severe style of art. His influence on his time was great. The David school, which had its origin in the painting of 'The Crowning of Napoleon I.,' includes the names of Drouais, Gidoret, Gros, Guerin, Gerard, Leopold Robert, and also Ingres.

Jean Dominique Ingres detached himself completely from the heroic style of his master. He was a forcible and skillful draughtsman, psychological, intense, a sensual «feministe,» and excelled the fascinating founder of French Classicism, but like him he confined himself to an æstheticism which sprang from his «esprit» which was inferior to his temperament.

The gentle and pure Prudhon was inspired, as well as David, by antiquity, but from a different point of view, that of vague dreaminess. Romanticism made its appearance with Gericault, the spirited and bold colorist of 'The Shipwreck of the Medusa.'

Romanticism, therefore, burst forth with a flourish of trumpets. Delacroix made his appearance,—lyrical, agitated, masterly, and ever restless, an excellent colorist, and a dramatic pessimist: he is Byronic, reminds one of Berlioz, ranks with Shakespeare, and anticipates Wagner. Songeur Fulgurant is the embodiment of lyric art separated from schools and epochs. Almost at the beginning of the century Delacroix foretold the end. He was ignorant of the broken tones, which had been slightly discerned by Andrea del Sarto and Watteau, —the theory of complementaries as applied to pictures. This resulted in Delacroix being (1830) fully imbued with the Impressionist revolution which developed towards the year 1865. The feverish earnestness of his great spirit enabled him to surpass Ingres, produce a contrary current throughout the entire country,—a stiff breeze of independence. He repudiated codes and dogmas, and taught that the law of art is the scrupulous cultivation of individual expansion.

The struggle between Classicism and Romanticism was violent, and it soon gave place to another enemy—Realism. Romanticism spontaneously engendered from the soil an admirable school of Romantic landscape—Theodore Rousseau, who set his skies aflame as with precious stones and blood: Daubigny, self-contained and affected: Troyon, an animal painter as vigorous as a Dutchman: and Dias, florid, the votary of a muse too studiedly grounded. These landscape painters, followers of Ruysdael and of Claude Lorraine, possessed—besides the qualities of these masters—great keenness of perception, and the new theory of the vibration of color absorbing the outline without losing the form; and laying less stress on the drawing of the trees and hills than on the feeling for open air values.

And now comes the line of Romantic Realists instituted by Decamps, the orientalist; these will continue in Marilhat and the dainty Fromentin, one of the most limited in range of any of the artists of the Romantic school, and also Daumier, a superb worker in black and white, who, in addition to his celebrated lithographs, did innumerable small panels which are very expressive, thrillingly tragic, and of a grand and sombre spirit. The Romantic Realist Courbet—the grandson of the bitter Gericault — followed; then came Edouard Manet.

Camille Corot, however, the follower of Poussin, bathed his scenes from Virgil, in a diffuse, angelic, and superb light. The damp, chilly charm of the morning, the veiled mysteries of the evening, are the themes he chose. Corot is a unique master in French art. He has a very fascinating, delicate and consummate charm.

Another man standing alone is Jean François Millet, known as being the interpreter of the sad figures of peasants in the fields. He died in the settlement at Barbizon.

Courbet modified the trend of Romantic art; he took the lead in Realism, and was an artless, vehement and capable leader, forming his views directly from life, of excellent health, and in the first rank of historical painters. His style was degraded owing to the influence of the followers of Ingres, and he was fully imbued with the spirit of Flandrin—the conventional and insipid painter of the nude,—

and by Manet,—the Franz Hals of French soil. Round him are grouped Ribot and Bonvin.

At first under the influence of Velasquez, Goya, and Franz Hals, Manet tried his skill and found the bent of his genius. He eliminated all bitumen from the pallette, which left only the infinite combinations of the seven prismatic colors. He transformed Romantic Realism into a vision of modern life, and was noted for representing the manners and customs of the second Empire. He is not understood. The well known and conscientious critic, le Cafouent, paid him tribute 20 years after his death. His 'Olympia' has at last been placed in the Louvre. Manet broke off all connection with the Impressionists, but before taking this important and reactionary step he restored to their rank two illustrious men who, in the midst of Realism, mark the return towards mystic dreaminess: one of them is Gustave Moreau who carried out the heroic and legendary ideals of Eugene Delacroix in the dreamy magnificence of the Hindoo palaces, in the luxurious hieratisms of Hebraic royalty, and in the fabulous Hellas. He was a visionary idealist. The other one is Puvis de Chavannes, so long misunderstood, who is the greatest fresco painter of the 19th century, the author of Sainte Genevieve of the Pantheon, and of the celebrated mural decorations of the Sorbonne. He was not only a great painter, but a great poet. Impressionism now became noted This style however, was followed by neither Fantin-Latour —devoted to Wagner and Virgil, and an earnest and serene portrait painter,—nor by Carriere—happily inspired to paint his Maternities in mono-chrome. To explain better the spirit of these designs let me say that Carriere did not permit himself the use of color.

Impressionism is a special study of light. Claude Monet, a fellow-worker with Manet came into notice about 1867; he encouraged landscape painting founded on the vibratility of ambient light. The Impressionist school took its name from a picture by Monet, modestly entitled 'Impression,' which was ridiculed. The name of this work so ridiculed became a rallying point. Luminous effects predominate in the vibrating marines of Claude Monet. His pictures (a series of cliffs, of mill-stones, of poplars, and of cathedrals), copied at every hour of the day, all from the same angle, are different aspects of the same theme under the effects of the sun's rays. Monet employs the method of separating the tones; under his brush inanimate objects volatilize into iridescent and versicolored phantoms.

Near Claude Monet struggled Sisley, Renoir, and Camille Pissarro, who immediately fell under the spell of the «Petits Maitres,» forerunners of the Impressionists, Boudin and Lepécié.

If Monet affiliated with Claude Lorraine and Watteau, Renoir followed the 18th century and Boucher, but a Boucher of a different power. Exceedingly appreciative of female beauty he embodied it in creatures charmingly natural and glad to be alive, and he thus expanded only beautiful flowers of flesh under the rays of light, that they seemed to drink in at every pore. He was the great painter of the 'Moulin re la Galette,' the gem of the Caillebotte gallery, Luxembourg Museum. Berthe Morisot left a series of water-colors, exquisite, spirited and of refined taste, painted in a style between that of Manet and Renoir.

Alfred Sisley was like Claude Monet, with the exception that he laid much less stress on the experimental demonstration of a theory of art. His subjects, the environs of Paris, are noted for the quick and accurate perception and the light touch with which they are treated. Camille Pissarro sang, in a generous and frank spirit, of shepherds, market-gardens, and Norman villages.

To these names let us add that of Mr. Degas, one of the most keen, and least charitable observers of the life of to-day, a careful student of jockeys an unkind humorist, and a wonderful draughtsman; and also those of Messrs. Raffaelli, the late Monticelli, Lebourg and Guilla.

The teachings of Impressionism, even though denied by the corrupt followers of Ingres, Cabinel, and Bouguereau who was greatly Italianized, and by Meissonier and Gerome, «Petits Maitres» who lose themselves in minutiæ, are of advantage to the liberal minded. Mr. Besnard made some innovations in this direction in his great decorative compositions, and his brilliant portraits, painted in a most fascinating manner, show masterly handling. Henry Martin, a decorator and also a historical painter; Mr. Laurent, a portrait painter; and Mr. Le Sidaner, a landscape painter, all profited from this cleaning of the French palette. And the school of young artists claimed the name of «Neo-impressioniste.»

Before mentioning the names of the young generation it would be well to note those of the «Traditionalists» who defend—and sometimes with great ability—the academic traditions. They are the pure and Giorgionesque Henner, a painter of nymphs with ivory bodies; the classical Delaunay; the severe Jean Paul Laurens, portrayer of a civilation that has vanished; the melancholic Cazin with his fine fancy; the vigorous Roll; the delicate and nervous Henry Levy: in fact all the members of the Institute; Benjamin Constant; Bonnat, a pronouncedly pedantic painter, director of the «Ecole des Beaux Arts»; Mr. Detaille who represents military painting, cold and panoramic, never painting a graceful detail; Mr. Carolus Duran, an elegant virtuoso; Messrs. Flameng, Jacques Blanche, and Antonio de la Gandora, a skillful poser of female figures.

All these exhibit in the salons, either in the «Societe des Artistes Francais»—in which the most noted names are those of Messrs. Jules Adler and Hanicotte,—or in the «Societe Nationale» where Messrs. Cottet, Lucien Simon, Aman Jean, Rene Menard, and George Desvalliere compete with them.

This digression ended, we must—in order to describe those who fell heir to Impressionism, —single out two men who stand apart, whose talent though incomplete is not without great merit; Paul Ganquin the painter of Polynesian scenery and luxuriant vegetation in decorative pages, and Cezanne. From them proceed the rising masters of to-morrow who win distinction in the «Salon d'Autonne» and the «Independents»: Messrs. Vuillard, Signac Bennard, Maurice Denis, George D'Espagnat, Dufrenoy and Marquet. All enthusiastic young men of exuberant vigor, working very hard and taking pleasure in it, and who, notwithstanding their exaggerated colorists, do not despair of attaining renown in the true and liberal French school.

The limits of this brief study compel us to name, only, the illustrious draughtsmen, whimsical painters, or humorists, engravers, water-colorists, and lithographers, who recall Daumier, Constantin Guys, Gustave Doré, Avarni, and Toulouse-Lautrée, who bear witness to the originality and fertility of French imagination and humor; they are Bracquemond, Lepère, Chèret, Willette, Odilon, Redon, Forain, and Louis Legrand.

Sculpture.—From Rude to Rodin, including Carpeaux—the three geniuses who represent the entire French sculpture of the 19th century—much vigorous and delicate talent has been seen. Rude raised the standard of sculpture, which was very low at the beginning of this century. Rude was the unique artistic expression of the Napoleonic spirit, so unfavorable to every kind of art. His hauts-reliefs on the Arc de Triomphe de l'Etoile, are immortal.

Besides Rude, Barye,—a powerful animal sculptor,—the classicists David d'Angers, Etex, and Pradier are conspicuous under the second Empire. Carpeaux, the sculptor of the group called 'The Dance,' on the portico of the Opera House, and the bas-relief of 'Flora' in the Flora pavilion of the Louvre, and of a hundred charming «maquettes,» of masterly execution and refined taste, achieved grandeur through grace, style through fancy.

A brilliant constellation of sculptors was seen in the third Republic; Falguiere, delicately expressive; Dalou, severe and profound; Paul Dubois, subtile; Mercié and Trijalbert, who although declamatory in style are each gifted; and Fremiet, a pupil and nephew of François Rude. All these names and those of the «Rodinisants,» and the original genius Camille Claudel, Emile Bourdelle, Desbois, and Maillol, were overshadowed by the formidable genius of Auguste Rodin.

Rodin is the third term of this trilogy relating to Rude and Carpeaux. At first he was discussed, ridiculed, and disowned by the Institute because he purposely distorted his models so as to better display the intensity of ambient light: he conceived and executed his principal works, which are 'The Age of Brass,' 'The Bourgeois of Calais,' 'Saint Jean Baptiste,' 20 busts, and a hundred groups in marble and in bronze, illustrating the sad poems of love, of nervousness and of revery. He overturned all pre-conceived rules, going for his inspiration as far away as Assyria and Egypt, and the middle ages; his Victor Hugo and his Balzac are statues which caused in the artistic world, a sensation not as yet defined.

Architecture and Decorative Art.—The French Revolution that revived all the institutions of the ancient régime, only apparently influenced the teachings of the arts. At first French architecture was under the yoke of the Greeks and the Romans. Deep study of the chief works of antiquity always inspires earnest artists, such as Percier and Fontaine; Vignon who built the Madeleine, and Brongniart, who built the Bourse.

Duban, Labrouste, and Vaudoyer revolutionized architecture. Viollet le Duc is charged with restoring Notre Dame, (1837). With Lassus who restored Sainte Chapelle, he struggled romantically against the «Academie des Beaux Arts.» Labrouste was the first to utilize iron, which may be seen in the 'Bibliotheque Sainte Genevieve'; Ballard was a bold innovator, who built the 'Halles Centrales.'

The wonderful inspiration of Charles Garnier, architect of the Opera house, is typical of the period of the second Empire. Still notwithstanding the modern spirit set forth in the teachings of Viollet le Duc, architecture is not yet emancipated; the ideas of Vignole and of Palladio, who imitated the antique, will disappear but slowly—with Messrs. Mogue de Baudot, and Vaudrenier. After all the rationalistic modernism of Messrs. Plumet, Chedanne, Gennoys, and Binet has erected monuments and dwellings commensurate to our needs, and to the ideas and customs of our time.

The revolution in applied art corresponds to that of architecture. The followers of Riesener, Gouthiers and Jacob will be the «furnishers,» such as Gallé of Nancy,—a cabinet-maker, and glass painter, who most always found his motives in floral naturalism; carvers, and goldsmiths with exquisite taste, such as Messrs. Dampt and Lalique, and lastly the makers of ceramics, Carriérs and Chaplet who rediscovered the art of the wonderful Japanese pottery.

In the foregoing is given a very short summary of the principles of French art.

The 19th century, was one of such great fecundity that, under normal influences, art should take its part in all events, in the great struggles and in the great hopes that agitate humanity in the present day.

Let us say in conclusion, that art can now, less than ever, be said to be separated from life. French art is no longer, and does not wish to be, a thing apart from or aside from life. It is in itself the expression of life, not only in vague generalities, but in the most contingent phenomena.

Vice-President of the Autumn Salon; Art Critic of the Gil Blas.

13. **France—French Music.** Such were the multiplicity and inaccuracy of the popular forms of primitive French music still in vogue in the Middle Ages, that in the beginning it is only possible to single out the peculiar mode

of expression that each temperament fashioned for itself. For instance, the *Trouveres*, who are considered the creators of lyric art, were hardly more than second-rate musicians who, being poets, sought in song a musical cadence with which to embellish their verses.

Religious music, which had long since been sustained by the voice of the organ, gradually found its way into the interior of churches and alone was quite representative of the mystic mentality of the Middle Ages. Even though it still adhered to liturgical chants which in form and style are subject to invariable musical modalities, it nevertheless began to be more flexible; slowly it expanded and assumed a fervor, an accent, a character hitherto unknown. The time was already near at hand when Josquin Desprez and, after him, Goudimel, were about to enrich with sound the wonderful gifts of life, order, easy grace and spirited joy that illumine the popular French soul.

However, it was outside of the Church that, as early as the 12th century, great interest was manifested in musical invention and research. Adam de la Halle, who, it seems, was the first to conceive melody in several parts, carefully represents that period in which music «d'ensemble,» if we may so express ourselves, already constituted one of the elements of popular amusement.

In the 14th century, during the reign of Charles VI., the instrumental resources of music began to increase greatly, and the minstrels, interpreters who at times were happily inspired, introduced the charming viol. Although very crude in the beginning, stringed instruments were destined to become more flexible, more expressive and more numerous, and those who played them gradually acquired a more delicate, more shaded touch. This evolution eventually gave rise to the first French chamber music, an art that was greatly advanced through the harpsichord, of which Couperin, Daquin, Dandrieu and the great Rameau were perfect masters.

Choral and religious music—which in the 14th and 15th centuries was at times so boldly realistic—was quite as fully and as cautiously developed. During the reign of Louis XII. it was revived by Josquin Desprez, who imparted to it inimitable earnestness and grace, and whether the subject were farcical or pious his motetts for several voices were simple masterpieces of juvenile spirit or emotional gravity. Of Goudimel, who was Palestrina's master, and of Clement Jeannequin, to whom we are indebted for that brilliant production, 'La Battaille de Marignan,' we can only say that in musical language of singular vividness, sincerity and splendor, they have portrayed both the fervent and the picturesque life that surrounded them.

The descriptive talent to which they owed their greatest success, the graceful and brilliant ease that was so preëminently theirs, were also characteristic of the musicians of the 17th and 18th centuries, who used them most freely, at the same time adapting them to the polite requirements of the time. Lulli, Daquin and Couperin at the harpsichord or on the stage showed the limitations of this intellectual spiritual art. Rameau, too, the learned, emotional composer of 'Dardanus' and 'Castor and Pollux,' dominates this brilliant epoch with all the noble pathos and tenderness of feeling that he was the first to bring into the life of music. Technically his work left its imprint upon one of the best periods of French musical history, the time when the beauty of instrumental composition and the varied power, then unknown, of the orchestra, asserted their harmonious influence.

After Rameau's death two other illustrious names lent glory to the close of the 18th century—those of Monsigny and Grétry. If the work of these two musicians, one of whom, Grétry, had a very adequate conception of dramatic truth and movement, does not sensibly elevate French tradition, at least it maintains therein a just solicitude for natural expression and sincerity. It was precisely this commendable solicitude that Méhul was a little later on to make his own, heightening it by the inspiration that he imbibed from the heroic spectacle of the great popular episodes of the Revolution.

French music of the 19th century retained the complex impressions of preceding epochs and, accordingly as the perverted taste of the multitude or the creative originality of great artists predominated, it reflected either the preference of the masses or the choice of the classes. In fact, all the different impulses that impart such brilliancy and tone to this century may be found mirrored in its music, being interpreted by various temperaments, some of which were among the finest identified with French art. The epopœia of the First Republic found in Méhul its most veracious and enthusiastic historian. An ardent admirer of Gluck, whose noble sincerity touched his heart, Méhul, well known to the men of his time, offered a miscellany of passion, valor and ingenuity that raised his work to the level of lyric composition. Undoubtedly the hymns that he composed during the troublous times of the Revolution savor a little of the grandiloquent, pompous air that it was the custom to impart to the smallest efforts in the line of creative thought. This is also the case with his opera 'Joseph,' which impels emotion because of the clearness, breadth and simplicity of its style. Besides, it was at this time when Italianism was so prevalent, that Méhul ably defended the traditions of Gluck, and for this reason alone should he claim our allegiance.

He and Gossec were the last representatives of this sober classicism, and Méhul struggled against the «maestri» with whom the versatile multitude, tired of heroism, began to be infatuated. But he seemed powerless against a fatal reaction. A brillant society eager to be restored to luxury and splendor and to be pleasantly entertained, required a rapid, showy, flattering sort of art which was introduced by fascinating Italian virtuosi, and Rossini and Spontini, assisted by Boïeldieu, Auber and Herold, transformed it and adapted it more closely to French style and taste, thus definitively naturalizing it. Of the Italians who invaded French theatres, Rossini was the most spiritual and most skillful. His cleverness, although extreme, was never enervating; he was both elegant and versatile and his quick, piquant music exerts a seductive influence to which one readily surrenders. If, where he aspires to genuine pathos, as in the opera 'Guillaume Tell,' Rossini's style is stilted and bombastic, in the score of 'Il Barbiere di Siviglia' he is fanciful, sprightly and eminently graceful, although a bit vulgar, hence his prolonged popularity.

But as much may not be said of Meyerbeer, who, like Rossini, won enthusiastic recognition on the French lyric stage. Although a native German, he inherited neither the heart nor the disinterested sincerity of the Latins nor the passionate, daring ardor of which the musical German is such a worthy exponent. Anxious to please, rather than to be original or to introduce novelties, he certainly knew how to cater to the taste of a public that wanted nothing but brilliant fiction. This rapid composer, to whom we owe 'Les Huguenots,' 'L'Africaine,' 'Le Prophète' and so many other productions, was also—the two attributes being singularly compatible—a technician of consummate skill; but these attributes seem rather to envelop than permeate his pompous, diversified music, somewhat grand at times and of which the great Schumann said: «It is all composition, outward show, hypocrisy!»

Rossini, an Italian, and Meyerbeer, a German, were, therefore, the admitted masters of the hour and the leaders of French musical fashion. Frenchmen unhesitatingly acknowledged the supremacy of these two foreigners over our dramatic music; and, at the time, the utter superficiality of contemporary life was more conducive to the discouragement than to the stimulation of artistic vocations. Of a care-free, brilliant temperament, the French adopted the course that seemed to beckon them to success, and as music of the touching, more learned type was not wanted, they produced comic opera.

What, then, should be retained of this period that was so poor and yet so well filled with musical history? Boïeldieu, Auber, Herold and Adam labored to endow our stage with animated, pleasing productions which breathed more or less of grace, sentiment and color. Some were successful in this line, notably Boïeldieu, whose 'Dame blanche,' M. Alfred Bruneau says has «much easy cleverness, chivalrous charm and spiritual sentimentality,» and Auber, who was the merriest, the smartest and most garrulous of all.

In order to conform to a mawkish conventionality French music had, as it were, to become subservient to the mediocrity of the public to which it catered, hence it was but timely that a powerful personality, revolting against the fashion and spirit of contemporary society, should transfigure it by imparting to it a love of strength and life. It was the hour of Romanticism. . . . What Victor Hugo was to do for literature, what Géricault and later Delacroix were to accomplish for painting, Hector Berlioz did for music. It is to him that, in this century, French inspiration owes the most famous and the most fruitful if not the finest of its tendencies.

Ardent, passionately fond of strife, Berlioz carried into it unparalleled enthusiasm and independence. The multitude treated him with indifference or hostility, but he stood his ground and each of his works continued to broaden the narrow limits within which, before his time, French music had been confined. Spontaneously he supplanted the affected elegance of his predecessors, their nervousness, their conventional agitation and the poverty of their musical resources, by a cordial sincerity, a pathetic sensibility, an ardent, noble inspiration, and a wealth of technical invention that place him first among our symphonists. The majestic 'Symphonie fantastique' and the terrifying 'Requiem' bespeak the excellence of his descriptive genius and lyric ability; the beautiful 'Enfance du Christ,' calm and peaceful as a fresco, shows us what a tender, delicate painter he can be, but it is in the 'Damnation de Faust,' and even more so in the 'Troyens,' that his full talent manifests itself. In these works he is no less compassionate than severe. He seemed to have inherited from Gluck a majestic and tragic simplicity in expressing the griefs or hopes of mankind. He was known as a trembling observer, an ardent, audacious delineator of the nature which he understood how to portray with a thousand daring orchestral strains then unknown, and we behold him posing as a depicter of the the human heart!

Underestimated during his lifetime, Berlioz nevertheless ruled the future of French music. If he did not inspire those who came after him, at least the example of his work impelled them to turn to nature and to life. Thus it was with Félicien David, composer of 'Le Désert,' that melancholy, expressive work, with Ambroise Thomas and Charles Gounod, the author of 'Faust' and of 'Mireille,' a pleasing musician with an easy, attractive style, and of whom Alfred Bruneau said that «he had created a language of tenderness that was deeply agitating.»

Finally came the admirable Bizet, another undervalued genius. The genuine candor, vivacity, daring, passion and sincerity that gave the French mind its individuality, fell to the lot of the composer of 'Carmen.' But it was only at his death that these were observed, and it was a tardy enthusiasm that was shown for the scores—masterpieces indeed—of 'Carmen,' wherein brilliancy and dramatic truth abound, and of 'L'Arlesienne,' which breathes of tenderness and life.

Two movements to which French music owes some of its most beautiful strains seem to have been simultaneously under way during the last 25 years of the century. The one, illustrated by names that are justly celebrated and popular, is characterized by the advancement of dramatic music; the other, perhaps more glorious, although less well known, is the revival in France of the symphony. The excellence of the former was attained through the efforts of Reyer, Massenet, Saint-Saëns, and later still through the labors of Bruneau, Gustave Charpentier, Leroux and Erlanger, whereas the latter movement has been immortalized by the names of César Franck, of Lalo and of Chabrier, while Vincent d'Indy, Paul Dukas, Guy Ropartz, and a few others have made its influence felt down to date.

In the line of dramatic music few countries have been able to show such a diversity of temperaments, and this is attested by the efflorescence of the works that have rendered the French lyric stage peerless. To be sure, these great operatic composers could not all boast of being innovators: some yielded complacently enough to the exigencies of a public that loves ease above all else, while others were powerless to withstand those influences by which their individuality was sometimes circumscribed.

It is in this sense that Reyer may be said to have been the first disciple of Richard Wagner in France. While it is true that the author of 'Sigurd,' a sincere, energetic musician, seems to have inherited from Wagner and Berlioz, as also from other sources, a love of pathetic sonority, dramatic passion and picturesque coloring, he is nevertheless an essentially French composer. If he has not Wagner's decided German labyrinthian scope and the heroic, masterful touch which, at times, cause the masterpieces of this genius to assume titanic proportions, he tempers his romantic tendencies by a thoroughly French sense of equilibrium and equipoise. Moreover, whatever Reyer may lack in the way of grandeur, he makes good in that of sense and clearness. The score of 'Salammbo,' emotional, strong and remarkably well carried out, is a most eloquent example of the order that he knows so well how to preserve in his noble, forceful lyricism.

If, like Wagner, Reyer desires to impress and to affect, Massenet seeks only to captivate, which he does by easy means. Diffuse, sensitive, elegant and refined, he appears as the restorer of gallant music, the best musical interpreter of delicacy and grace. 'Manon,' 'Esclarmonde,' 'Thaïs' and 'Ariane' manifest the skill with which he portrays the charm and the sensualism of love. His talent, however, is rather meagre. Although deeply appreciative of the eloquence of melody, he is hardly a symphonist. He sings and the orchestra dutifully sustains his song. With the exception of 'Marie-Madeleine,' which is perhaps his most beautiful work, his operas seem to be principally *suites*, although often exquisite ones, of «accompanied airs.»

On the other hand, Camille Saint-Saëns, who is a symphonist in the fullest sense of the word, likewise belongs to one and the other of the summary classifications heretofore indicated. A fascinating technician, conducting with rare power and marvelous presence of mind that many-voiced instrument, the orchestra, he has some of the finest qualities of the classic French mind: clearness, proportion, and will. He may be accused of lacking the spirit and adventurous freedom that is generally peculiar to men of genius and, reasonably enough, he may also be said to be more scientific than passionate or humane, but he is none the less a master.

In the 'Symphonie en Ut avec orgue,' and in some of his symphonic poems—expressive forms to which he was for a long time devoted—he gave forth his full power, and we admire the breadth and ease of his constructive and logical ability. In 'Henry VIII.' and 'Samson et Dalila' he is the ardent dramatic composer who, with consummate skill, places the expressive resources of the symphony at the service of theatrical action. Saint Saëns deserves to be called, above all, a great harmonist.

But the mention of these three great names that reflect such honor upon our dramatic music at once calls up others, as, of late years, there have been many able contributors to this very French form of lyric art. Alfred Bruneau, the austere, pathetic composer of 'Messidor,' 'L'Attaque du Moulin' and 'L'Ouragan'; Gustave Charpentier, to whom we are indebted for 'Louise' and those beautiful symphonic pages of the 'Vie du Poète' and the 'Impressions d'Italie,' impregnated them with a vivid, realistic romanticism; Bourgault-Ducoudray, Leroux, P. L. Hillemacher, Vidal and many others have devoted their splendid, expressive talents to the French lyric stage.

But, side by side with the advancement, however glorious, of lyric drama, came the magnificent revival of the symphony in France. Whilst the dramatic composers were contributing to the stage beautiful works which, presented in the effective setting of light and decoration, imparted to the plastic art a share of their expressiveness, there appeared on the scene César Franck, a man of simple, calm, emotional genius. Although in his day he also wrote the memorable dramatic poems 'Ruth,' 'Rebecca,' and 'Les Béatitudes,' that were pure and luminous as the Gospels, César Franck ennobles and simplifies music by restricting its horizon to the human heart. If he robs it of some of the picturesque descriptiveness that is one of its most attractive charms, it is to render it more sensitive, more humane, more chaste, it is the better to harmonize it with the misery, the hope, the blighted aspiration of a soul straining after the infinite. All the woes, all the joys that in turn can depress or animate the heart of a man, when he is a believer and a genius combined, are described by Pascal in a few lines which, to perpetuate them, César Franck put to music. He wrote a sonata, selections for organ and piano, a *quartette*, and a *quintette*, all exhaling passion, grief and faith, also a *Symphonie* and *Chorals* which are ardent, despairing, divine and may be said to be admirable dramas without words.

This power of symphonic expression that indicates César Franck's masterful talent, characterizes the work of two other composers, Edouard Lalo, and later, Chabrier, who, like Franck, were not duly recognized in their own time. Lalo's 'Symphonie espagnol' and 'Namouna,' and Chabrier's 'Gwendoline et Briseis' attest, under different temperaments, marvelous polyphonic richness. Saint-Saëns, Lalo and Chabrier were, it seems, the first in France to extend to the stage that new form of lyric expression wherein the orchestra becomes not the complement of song, but the very soul of the production.

César Franck's excellent artistic perception, the serenity of his life and the philosophical example of his work were no less ennobling in their influence than was his musical genius, and to all who have approached him this master bequeathed some of his earnestness, his depth, his discipline and his dignity. They have inherited his faith in pure music, and to-day they zealously propagate French symphonic tradition, on the stage as well as in concert. Vincent d'Indy, the most faithful of all to these teachings, has elicited applause for 'Fervaal' and 'Wallenstein,' strong, serious works in which musical power equals character. To Guy Ropartz we are indebted for Psalms and a fine *Symphonie*. Paul Dukas, the most personal, has pushed orchestral science and the power of independent musical expression to the extreme limit. In his 'Apprenti Sorcier,' which is dazzling, abstruse and heavy, intelligence eclipses sentiment.

However, it were rash to claim that the latest French music still bears the impress of César Franck's moral and technical influence. On the contrary, it displays a brilliant individuality and a contempt, lucky at times, for the traditions of the masters. Of all these musicians, the strongest, the only one who now deserves notice, is Claude Debussy, whose ardent, subtle, expressive music is that of a pagan and a sensualist quite destitute of humanity, as understood by Beethoven; it excites more sentiment, is more penetrating and more mysterious than any others and seems to assimilate the bewitching charms of nature that it so admirably reveals. 'L'Après-midi d'un Faune' and 'Pelléas et Mélisande' represent two important dates in the history of French music, and will probably prelude a renaissance of the descriptive music in which France has always excelled.

PAUL-LOUIS GARNIER.

14. **France—The Drama.** Dramatic art, more than any other, is the reflex of its time and surroundings and the mission of the stage has ever been to reproduce, after duly magnifying them, those sentiments and ideas that have exerted the strongest influence over the mind of a people at each successive period of its history. This has been the case in France, as elsewhere, and to follow the evolutions of the French drama is to trace those of French society itself.

In the Middle Ages mysticism and religion were the foundation of popular life, hence the stage was eminently religious and its *mysteries* and *miracle plays* depicted Scriptural legends and the Passion of Jesus Christ. But, by degrees, profane life reasserted itself and engendered the Gallic spirit pervading the *allegorical satires* and *moralities*. The gay farce, 'L'Avocat Pathelin,' is a standard model of this style.

The Renaissance being the revival of antique types, dramatic themes were thenceforth taken from Greek tragedy and Latin comedy instead of the Bible, and this revolution begun by Jodelle and Robert Garnier in the 16th century, was carried into the 17th first by Rotrou and then by Corneille, being finally completed by Racine and Molière.

Corneille, sublime and bold, adapts himself but poorly to the rules set down by Aristotle, especially the three unities, but Racine, graceful and pleasing, conforms to them wonderfully well. Classicism is largely made up of effacement, if not servility, and is quite satisfied to clothe modern characters in antique raiment. It bids the contemporaries of the great king, the simple, rugged heroes of Corneille and the delicately complex heroines of Racine express themselves in the alexandrines of the classic stage and presents the psychology of great chieftains and their love in the guise of Greek and Roman fable.

Molière portrays perhaps even more vividly the period in which he lived. His comedy wears a mask, his most extravagant farces are but a shield for the heaviest tragedies. Domestic troubles, conflicting interests or opinions, the delineation of the most unbridled passions or the vilest conceits are presented to us in a medium whose effect it is to emphasize contrast: his work is in chiaroscuro and he exaggerates in relief the vices he holds up to view. An Alceste, a Harpagon, a Tartufe or an Argan can readily evoke, as the poet says:

> Cette mâle gaieté si triste et si profonde
> Que lorsqu'on vient d'en rire on en devrait pleurer
> (A. de MUSSET).

The 18th century, although rich in ideas, was poor in dramatic authors. The prescribed form of ancient art was disappearing and the new form had not yet been established. Voltaire's tragedies lacked strength and his comedies were purposeless. Classicism became extinct. Shakespeare, whose plays were only clumsily adapted by Ducis and Voltaire, was no better understood by the public than by his translators. Sedaine and Diderot were happier in their bourgeois comedies and showed a tendency, albeit an awkward one, toward society comedy by showing up the social and political conditions of the day, the enactment of the great bourgeois comedy.

Histrionic literature, as well as all other kinds, helped to pave the way for the French Revolution. In spite of the Censure, Beaumarchais attacked those men who «have taken the trouble to be born, but nothing more,» and, in the imperishable character of «Figaro,» immortalized a type of the populace which had fallen to be so little and had just begun to demand their old position.

During the revolutionary disturbance theatrical representations were an additional spur to revolt and Marie Joseph Chénier(a dramatist of the hour, endowed his heroes with the souls of sans-coulottes. Toward the end of the Republic and under the First Empire the drama in France was neglected as an art; it failed. The scene of tragedy was far greater and more real; it was shifted to the battlefields of Russia and Germany. Some very acceptable comedies were written by Andrieux, Collin and d'Harville, but there was not one original writer of great drama.

To the 19th century was reserved the glory of seeing a new form of dramatic art arise. The influence of foreign literature triumphed over the classical conventions; Shakespeare and Byron, Goethe and Schiller were set up against Corneille and Racine. Unheard-of liberties were taken; paraphrasing such as Delille's was scorned; a spade was called a spade, and that without any apology. Of course, such innovations raised a storm. Alfred de Vigny was hissed for his unvarnished translation of Othello, and Hugo was severely upbraided for daring to mention the «private-staircase» in the first lines of 'Hernani.'

Hence the necessary reaction of romanticism. Tragedy was replaced by drama, the old notion of the unities of time and place was cast aside, only the unity of action being retained, and heroes were borrowed from mediæval legends, the banks of the Rhine, the mysteries of Venice or the *romanceros* of Spain. A Ruy Blas or an Esmeralda, a Ruy-Gomez or a Lucretia Borgia was brought forward and in some of deMusset's fanciful creations could be traced the dim outlines of a Perdita or a Marianne. Nor was this all; contemporary life was mirrored in certain *Proverbes*, the 'Caprice, Il ne faut jurer de Rien' and in Alexander Dumas' 'Antony.'

From that time onward all varieties of drama were presented in uninterrupted succession, but the kind that appealed most strongly to the public was that which depicted contemporary society. Emile Augier pictures to perfection the spirit of the French *bourgeoisie* from 1830 to 1870, the business man being portrayed in the 'Effrontés' or in 'Maitre Guérin,' and the absurdly vain in the character of M. Poirier, while in 'Vautrin' and 'Mercadet' Balzac holds up to view the parasites of modern society.

Belonging to our own day and side by side with Sardou, who is admirable in stage technique but only mediocre as a psychologist, and Labiche, who is a skillful and finished writer of vaudeville, is Alexandre Dumas, Fils, who strikes out into *problem plays*. The problems that are stirring society to its very depths are exploited, discussed and analysed; the limelight is thrown upon the social status of the courtesan, the illegitimate child and the girl-mother, the worlding and the prostitute. The stage begins to act as though it meant gradually to get a hold on public opinion and to bring about reforms in legislation and morals.

This last mentioned style of dramatic art is daily gaining ground and is being strongly encouraged.

However, it is by no means the only kind patronized. Indeed, rarely has there been found in the history of French letters a larger or a worse variety. Seldom have brutality and bestiality been more highly indulged than in the wrestling matches of so-called athletes and boxers and even bull-fights where the æsthetic and dramatic character is supposed to predominate. Seldom, too, does one come upon literature inferior to that of the concert-cafés or of certain vaudevilles where all the author's genius has expended itself in combining suggestive deshabille with ribald joke and indecorous acting. Far too many look upon blackguardism as the *ne plus ultra* of dramatic art and some works, although abounding in humor, do not escape this ban. But these new theatrical fashions which, it must be admitted, are of foreign origin, are certainly not among the greatest boons conferred by the craze for copying foreign models.

However, in them, the undesirable element is merely superficial. Our theatrical men have never been more concerned with the questions of the hour nor more bent upon catering to the public taste. For every light operetta and amusing vaudeville performance we have ten heavy plays that cause one to think, that start ideas and are leading toward a radical reform. If divorce has given rise to a few humorous works it has been the theme of a great many serious ones wherein its advantages and its dangers have been exploited. We have Paul Herview showing in the 'Loi de l'Homme' and the 'Tenailles' woman's present state of subjection; Abel Hermant, Emile Fabre and the Brothers Margueritte, the ones inimical and the others favorable to the reform, showing us the family irremediably divided and human personality emancipated and reclaimed.

Or again we have François de Curel telling us in the 'Repas du Lion' of the bitterness of social strife and in the 'Nouvelle Idole' of the beauty and severity of science. Then, in his 'Avariés' and 'Avortment,' Brieux sets forth the great medico-social problem, daring to excuse, perhaps even to justify, the killing of the unborn infant whose coming into the world would bring naught save shame and misery to its mother and itself, while in the 'Robe rouge' the pharisaism of human justice is challenged. On all sides society is being summoned to the theatrical bar. Again the drama 'Biribi' depicts a revolt against the *penitenciers militaires* and the *compagnies de discipline;* the popular verdict passed upon the play determined the enactment of a reform of the law as to these *compagnics disciplinaires.*

A further character of this dramatic reform apart from the varied and conflicting opinions it has excited, is that foreigners have been given generous recognition. The French public has made the acquaintance of Ibsen, Tolstoi and Gehrardt Hauptmann, and under the impulse of younger men Anthony, King Lear and Julius Cæsar have been retranslated, fitted for the modern stage and have shown the French public a new and hitherto unknown Shakespeare. Marvellous stage-settings—an imitation of English excess—form the frame in which the characters of these masterpieces move and live, but for the historian their interest is that each drama is a revelation to the public of a new and foreign spirit.

Judging from the present, the future of the French stage may be easily conjectured. At no other time has it manifested such effervescence, such vitality, and the French world at large is subject to no more powerful influence than that exerted over it by the stage. It is the chief literary expression of our time and bids fair to remain so for long. See DRAMA.

GUSTAVE RODRIGUES.

15. **France—The Army and Navy.** The President of the Republic controls all land and sea forces. He appoints officers of all grades and presides over the council of national defense, which includes the President of the Cabinet Council, the Minister of War and Minister of the Navy with their chiefs of staff, the Minister of Foreign Affairs and the Minister of Finance.

Military expenses are annually estimated in the budget (a statement of national income and expenditure), and in 1906 they amounted to 718,690,800 francs for the War and 325,000,000 for the Navy Department.

THE ARMY.

The Minister of War is the head of the administration of the Army. He is assisted by a general staff comprising four departments, devoted respectively to mobilization and general organization, the investigation of foreign armies and of the theatres of operation, army instruction and military operations and military transportation; and three sections, namely, the staff personnel, the historical, and the African section.

A geographical service insures the making and publishing of topographical maps dealing with France, Algeria and foreign countries.

The chief of staff is assisted by three immediate subordinates, one of whom conducts the geographical service.

The Central Administration of the Army includes the several branches of the War Department: infantry, cavalry, artillery, engineering, administrative services, the «powders and saltpeters,» medical service, colonial troops and the *contrôle* service, which verifies ministerial orders, decrees, etc., for the entire service.

In the study and investigation of plans and reforms the Minister is still further assisted by several technical boards, committees and sections. He is president of the *Conseil supérieur de la guerre* (a board that deliberates on questions of mobilization, concentration, supplies, etc.), the vice-president being the commandant selected from the principal *groupe d'armeés* (*i. e.* all the armies operating in one theatre of war and under the supreme command of one general), the other members of the board consisting of eight generals with high commands in mobilization, and also the chief of the general staff.

The Army comprises the active army and its reserve, the territorial army and its colonial troops.

Recruitment.—Every Frenchman owes his country personal military service which is equal for all. It is of 25 years' duration, two of which must be spent in the active army, 11 in the reserve of the active army (with two calls to four weeks' drilling); six in the territorial army (one call to 15 days), and six years in the reserve of the territorial army (one call to one day).

Annually, all young men who, before January 1 have completed their 20th year, are called to the army. Those who are or who have become unfit for armed service are classified in the *services auxiliaires* (any services performable by noncombatants) and are assigned to duty in the *dépôts du territoire*, in the departments, in the artillery, engineering and *intendance* establishments, etc.

Besides those summoned to enter the service the army counts a certain number of re-enlisted soldiers. Corporals, brigadiers and soldiers may re-enlist for one year, 18 months, two years, two and one-half years and three years. The noncommissioned officers of the metropolitan or home troops and all the soldiers of the colonial troops may re-enlist for four or five years, until they will have completed 15 years of service.

Territorial Organization.—With a view to the recruitment, mobilization, organization and assignment of troops, France is divided into 19 «military districts» numbered from 1 to 20 (Algeria-Tunis being the 19th). The headquarters are at (1) Lille; (2) Amiens; (3) Rouen; (4) Le Mans; (5) Orleans; (6) Châlons; (7) Besançon; (8) Bourges; (9) Tours; (10) Rennes; (11) Nantes; (12) Limoges; (13) Clermont-Ferrand; (14) Lyons; (15) Marseilles; (16) Montpelier; (17) Toulouse; (18) Bordeaux; (19) Algiers; (20) Nancy.

Paris and Lyons are the seat of special military government.

Each of these military districts (except the 19th) is subdivided into eight smaller districts (four in the 6th and 20th), each of which corresponds to an active regiment, a regiment of reserves and a territorial regiment of infantry.

Each regiment has a permanent place for mobilization, where the men required for active service meet and where the regiment's supplies and rolling stock are kept. It draws its reservists from a certain limited district which is its regional subdivision for reserves.

With a few exceptions France is divided into as many of these sub-districts as there are units of organization in each arm (145 for the active infantry, reserve and territorial regiments).

In every regional subdivision a recruiting bureau directs the men of the reserve and of the territorial army, assembles them for drill and summons them for mobilization.

The military districts answer as regional subdivisions of reserves for their *brigade d'artillerie* (two regiments to each corps except the 6th); the cavalry, engineering, light infantry and zouaves have special limited subdivisions.

Hierarchy and Recruitment of Officers.—No one can be admitted to a grade unless some form of military duty be connected with it; the duty is distinct from the grade. Colonels make appointments to the rank of corporal or brigadier and petty officer (sergeant, sergeant-major and adjutant in the infantry and engineering; sergeant, sergeant-major and adjutant in the other arms). Officers are promoted by order of the President of the Republic.

Officers are recruited (1) From the petty officers admitted after competitive examinations to the military schools of St. Maixent for the infantry, Saumur for cavalry, Versailles for artillery, engineering and the train, and who, after a year these schools, pass a successful graduation examination. (2) From the young men who, after a competitive examination, are admitted to the Polytechnic (artillery and engineering) and the School of St. Cyr (infantry and cavalry), and who, before entering these schools will have finished a year's service in the regiment.

The *officers of the reserve of the active army* are recruited from the young men admitted to certain schools—the *Ecoles forestières* for training administrators of the forests belonging to the state and to the communes; the *Ecole des manufactures* for training private engineers and manufacturers; the *Ecole des mines*, which cannot be entered save after a stage in the Polytechnic and the *Ecole des Ports et Chaussées* (in which former Polytechnic students are prepared for civil engineering) and after having completed a year's service in a regiment, and also from those of the contingent who, agreeing to take three supplementary periods of training during their stay in the reserve, submit to a competitive examination at the end of their first year of service. The students then follow a special six months' course in the regiment, and if at its completion they pass a successful examination, they finish their fourth year of service as officers of the reserve.

In time of peace, promotion in the active army is made in the following manner: all sub-lieutenants having held that office for two years become lieutenants. The promotion is made one-third by selection and two-thirds by seniority for the rank of captain, and half by selection and half by seniority for the rank of major of infantry or major of artillery. To the higher grades, those of lieutenant-colonel, colonel, major-general and lieutenant-general, promotion is by selection.

Make-up of the Active Army.—The active army comprises metropolitan or home and colonial troops. It has a total strength of about 28,000 officers and *assimilés* (*i. e.* noncombatants ranking as officers), 528,000 corporals and privates and 123,000 horses.

The *gendarmerie* is 24,000 strong; the infantry about 350,000; the cavalry 60,000; the artillery 72,000; the engineering 13,000; the train 6,800, and the administrative troops are 14,700.

At the head of the great units is the staff of the army, the first section of which includes 110 lieutenants-general and 22 majors-general, on the active list or unemployed.

The second section is formed of generals placed in the reserve.

The personnel of the staff service is made up of officers not on the rolls of a statutory organization (640 at most in time of peace) who have successfully followed the course at the War Academy and have received the staff college certificate.

Troops.—The *Infantry* is composed of 163 regiments, of which 145 are called *subdivisional*, that is to say, drawing their reservists from one of the regional subdivisions, having three battalions of four companies (some have a fourth battalion with a variable number of companies); the 18 other regiments with four battalions are called *regional* because, for recruiting purposes, they draw from a military district.

The subdivisional regiments have a supernumerary staff of field officers, eight captains and four lieutenants, who contribute to the officering of the corresponding regiment of the reserve, 30 battalions of light infantry with six companies (12 being Alpine battalions); four regiments of zouaves with five battalions of four companies, plus two depot companies; four regiments of Algerian rifles with six battalions; two foreign legions with six battalions; five battalions of light infantry for African service; four companies for the Sahara oases; four *compagnies de discipline* (punishment companies); one regiment of the Paris fire brigade with two battalions and six companies.

The regiments of metropolitan infantry are grouped into 80 brigades and 40 divisions, numbered from 1 to 42 (numbers 37 and 38 being missing).

The *Cavalry* comprises 89 regiments with five squadrons; 13 of Cuirassiers, 31 of Dragoons, 21 of light cavalry, 14 of Hussars, six of light cavalry for African service, and four of Algerian cavalry. The regiments stationed in France constitute 19 cavalry brigades attached to the army corps and eight independent cavalry divisions composed of two or three brigades.

The *Artillery* includes 18 battalions of artillery having a variable number of batteries, the total being 113, and 40 regiments of field artillery constituting 20 brigades (one to an army corps), with 442 mounted, 52 horse and 14 mountain batteries. The regiment numbered lowest in each brigade usually has 12 mounted batteries forming two half regiments (with two groups of three batteries each), each assigned to one of the two divisions of the army corps. The other regiment, which generally has three groups of three mounted batteries and one group of two horse batteries, constitutes the *corps artillery* of the army corps. Two horse batteries are attached to each of the eight independent cavalry divisions. The artillery includes, moreover, 10 companies of artificers or laboratory men and three companies of workmen.

The field batteries have four guns of 75m/m. Besides the troops, the special artillery staff, assisted by administrative artillery officers, is destined for the service of establishments (schools, arsenals, etc.).

The *Engineering* branch of the army comprises a special staff and seven regiments, six of engineer soldiers and one of railroad engineers; that is, 26 battalions, 20 of engineer soldiers, three of railroad engineers, one of æronauts, one of telegraph operators and one detailed to service in Algeria. The train includes 20 squadrons of three companies. The administrative troops consist of 21 sections of clerks for staff and recruiting duty, 25 sections of workmen, mechanics, etc., and clerks, enlisted as such, for military service, and 25 sections of hospital orderlies.

The *Gendarmerie* embraces 27 departmental legions and the *gendarmerie* of the city of Paris, which has three battalions of infantry and four squadrons of cavalry.

Besides the troops, must be included the personnel of the various services; of the *contrôle* service (whose duty it is to watch over and inspect the *administration* or the *gestion*); the *intendance*, the medical service, the corps of administrative officers, the veterinarian corps.

the "powders and saltpeters," military justice, the interpreters' corps, etc.

Reserve Troops.—These comprise 145 regiments of infantry and three battalions formed of the supernumerary officers of the 145 subdivisional regiments of the active army, and the officers, corporals and privates of the reserve; 30 battalions of reserve *chasseurs;* 40 regiments of reserve cavalry; 41 reserve squadrons; and, to each artillery brigade, 12 reserve batteries, namely, 216 battalions.

Colonial Troops.—These are connected with the War Office and destined, principally, for the Colonies. One part constitutes in France an organized army corps of three divisions. The Colonial troops are distributed as follows:

France: 12 regiments of infantry, three of artillery, five companies of workmen and one company of artificers or laboratory men.

Indo-China: Four regiments of infantry, four of Tonkinese rifles, two of Annam rifles, one battalion of Chinese rifles, one of Cambodian rifles, two regiments of artillery and two mixed companies of workmen and artificers.

Eastern Africa: One regiment of infantry, three of Malagasy rifles, one of Senegalese rifles, one of artillery and two companies of mixed workmen.

Western Africa: Three regiments of Senegalese rifles, one of Congo rifles, one battalion of Zinder rifles, one regiment of artillery and one company of drivers.

China and China Reserve: Two regiments of infantry, one of Tonkinese rifles.

The Territorial Army.—The troops of this army may, when mobilized, be detailed to garrison fortresses or fortified town posts, lines of halting-places, strategic points and coast defenses. They may also be formed into brigades, divisions of the army corps destined to remain in the field, and finally may be drafted as part of the active army.

The Infantry comprises 145 regiments of three battalions, that are connected with the active corps of their subdivision, seven battalions of light infantry with four companies (on the Alpine frontier) and 10 battalions of zouaves (Algeria).

The Cavalry varies in the number of squadrons which it allows to a military district, there being usually one squadron of Dragoons and one of light cavalry and three territorial squadrons of light artillery for African service.

The Artillery in an army corps consists of two territorial groups, each corresponding to one of the active regiments of field artillery, and 15 territorial groups of foot artillery distributed among 11 military districts (on the frontiers and seacoasts).

In each army corps there is also formed a battalion of engineers and a territorial train squadron.

Finally, to these troops must be added 31 battalions of custom-house inspectors, seven battalions, 19 companies and 14 sections of custom-house inspectors detailed to duty at fortresses, 45 active companies and 16 sections of *chasseurs forestiers* (riflemen recruited, on mobilization, from the personnel of the forestry department), and three companies and 25 sections of *chasseurs forestiers* assigned to fortress duty.

THE NAVY.

The Minister of the Navy is assisted by a general staff composed of three sections. The object of the first is the study of foreign naval forces and coast defenses. Among the duties of the second is to arrange for the defense of military ports, naval strongholds, metropolitan and colonial coasts, to secure coast protection by submarine-mines and to look after the torpedo and submarine flotillas. Finally, the third section superintends the preparations for military and naval operations, the mobilization of the fleet and all that concerns naval training.

Besides the general staff there is a hydrographic service comprising seven sections.

The Administration of the naval forces includes: (1) The department of the armed fleet (personnel and administrative services); (2) The building department of the fleet, comprising the branches of naval architecture, naval artillery, hydraulics and *bâtiments civils.* We must add the departments of finance and *comptabilité* (accounts), *contrôle* (keeping of muster-rolls, etc.), navigation and maritime fishing, and the establishment called *Invalides de la Marine.*

The principal schools in which the *cadres* and specialties are taught are: the Naval Academy, naval school, school for midshipmen, for torpedo gunners, for torpedo officers and engineers for sea-coast practice, for practical gunnery and steerage, for armed seamen, for paymaster cadets (administrative), for medical service, etc.

The Navy establishments outside of military ports and navyyards are the foundry at Ruelle, the artillery factory at Indret for machines and boilers, and the iron works at La Chaussade. Moreover, the Navy places some of its orders with private business concerns.

Territorial Organization.—For the administrative service of ports and the governing of young men under *inscription maritime* (naval registration) the coast of France is divided into five *arrondissements maritimes,* with headquarters at the five military ports of Cherbourg, Brest, Lorient, Rochefort, and Toulon.

Algeria and Tunis form a sixth naval district.

Each arrondissement is divided into two or three sub-districts, the latter having headquarters at Dunkirk, le Hâvre, Cherbourg, St. Servan, Brest, Lorient, Nantes, Rochefort, Bordeaux, Marseilles, Toulon, and Corsica.

Each sub-district is under a paymaster, who has charge of the *quartiers,* while in each *quartier* resides a passed assistant or assistant paymaster of the Navy, commissioner of the *inscription maritime,* who has for his special agents seamen exercising police duty in the maritime domain, also coast-guards and naval gendarmes.

A vice-admiral or maritime prefect is at the head of each of the five *arrondissements maritimes,* his authority extending along the coast line of the arrondissement and over all the departments represented within the territory that he governs.

He is assisted by a rear-admiral, chief of staff in charge of the navy-yard, a resident commissioner, a chief of naval ship-building, a chief of hydraulics, a director of submarine defenses in charge of torpedoes and torpedo-boat sea-coast defense, a director of *mouvement du port* (*i. e.* of vessels entering and clearing of the port), a chief of artillery and a chief medical officer.

All these officers, except the director of vessels entering and clearing the port, form a part of the administrative council of the navyyard.

The navyyards include a central shipbuilding factory, docks, dry-docks, covered or uncovered ship-yards, magazines and workshops. They also provide storage for disarmed or reserve ships.

The reserve ships are 1st, 2d or 3d class, according as their armament fits them for setting sail in 8, 15 or 30 days.

In each of the five great military ports is a station for reserve men and *disponsibles* (unattached men) of the navy.

Sea Forces.—(a) *Personnel.*—The personnel is made up of staffs and crews.

The staffs are composed of 2,050 naval officers, 327 engineers, 153 naval ship-builders, 27 hydrographers, 253 paymasters, 344 surgeons, 54 apothecaries.

There are, moreover, 364 reserve naval officers. The crews comprise the officers of inferior rank, quartermasters, sailors, engineers, etc., numbering about 53,000 strong and assigned to duty along various lines, viz.: practical gunnery, musketry, steerage, manœuvring, carpentry, sailing, and caulking.

Naval officers are recruited from four sources: (1) From the naval school, into which, after a competitive examination, young men from 14 to 18 are received. At the end of two years they are named naval cadets, and after a year at sea become midshipmen; (2) From the Polytechnic, which furnishes four midshipmen a year; (3) From the petty officers, who, after an examination, are appointed ensigns; (4) From deep-water captains, admitted as auxiliary ensigns and who may become commissioned ensigns.

Midshipmen, after two years' service in that grade, become ensigns.

For the grade of lieutenant it is necessary to have served two years at sea as ensign, promotion being one-third by selection and two-thirds by seniority.

For the grade of commander promotion is half by selection and half by seniority, and for the higher grades of captain, rear-admiral and vice-admiral, it is now by selection only.

Recruitment.—The annual quota of naval recruits is jointly supplied by the *inscription maritime* in conjunction with voluntary enlistments and the applications made by young men to the recruiting board.

All fishermen and men engaged aboard merchant ships are on the *inscription moritime* and are bound to naval service; they number about 100,000.

Between the ages of 18 and 50, those on the *inscription maritime* are at the disposal of the State; before the age of 20 they cannot be called to active service except in case of war and by order of the President of the Republic, but once they have attained that age, if they have not entered the navy before the legal date set for such entry, they must submit to a seven years' service, including five years of active duty and two of *disponibilité* («status of men allowed to return to their homes before the completion of their full term of service»). The five years' duty includes an active service of variable length, not exceeding three years, most of the time being spent in respites, exemptions, or unlimited leave of absence. During the reserve period, the *inscrits* (those registered on the *inscription maritime*) cannot be levied unless by order of the Head of the State.

The *inscrits* enjoy certain privileges; they are exempt from the *droit de potente* (license tax), the *redevance personelle* (rent-tax), and they have the temporary grant of parts of the shore, are given pensions and receive pecuniary aid from the *Caisse des Invalides.*

The administration of the *inscription maritime* is conducted on the sea-coast according to arrondissements, sub-arrondissements, and *quartiers* in charge of naval paymasters.

There are two classes of reserves in the maritime army: (1) The reserves of the naval crew; (2) The *inscrits maritimes.*

The reserves of the naval crew are those who have voluntarily enlisted in the naval army or have been assigned to it by the law of recruitment and remain thus assigned for 10 years from the date of their entrance into the service.

In time of peace *inscrits* from 25 to 35 not in actual service may be recalled for two periods of four weeks' practice.

(b) *Vessels.*—The naval fleet comprises 35 battleships, 9 of which are in reserve, 1 is on trial and 10 are in the course of construction; 26 armored cruisers, 7 of which are in the reserve, 2 on trial and 4 in the course of building; 25 1st, 2d and 3d class cruisers, 14 of which are in reserve; 58 torpedo-catchers, 15 of which are being built; 19 gunboats, 8 of which are armored; 9 despatch boats; 9 torpedo gunboats, 40 seagoing torpedo-boats; 215 1st class torpedo-boats, 70 of which are being built; 40 2d and 3d class torpedo-boats; 39 submarine boats, 14 of which are in the course of construction, and 45 submersibles, the greater number in the course of building.

The vessels are distributed: (1) Between the squadron of the Mediterranean and the Levant; that of the North and the naval divisions of Tunis, Algeria, the Atlantic, the Extreme East, Indo-China, the Indian Ocean and the Pacific; (2) Between 14 torpedo flotillas: 2 of la Manche, 3 of the Ocean, 5 of the Mediterranean, 2 of the China Sea, 1 of the Indian Ocean and 1 of the Atlantic. Besides the torpedoes, which vary in number, these flotillas generally carry 1 torpedo gunboat and 1 or 2 torpedo-catchers. (3) Between 6 submarine flotillas: 2 of la Manche, 1 of the Ocean, 2 of the Mediterranean, and 1 of Cape St. Jacques Saïgnon, an important *point d'oppui.*

Submarine mines, batteries, lines of torpedoes, etc., protect these *points d'oppui* of the fleet which serve as a base of operations and are Cherbourg, Brest, Lorient, Rochefort, Toulon, Bizerta (Tunis), Saïgnon, Fort de France (Martinique), Diego Saurez (Madagascar).

Finally, the coasts are protected by 12 ironclad coast defense vessels. To the ships heretofore enumerated we must add 11 gunboats, 9 torpedo launches, 12 transports, 6 *oviso* transports and small vessels used for port service, stations and schools.

The number of guns on board the different vessels of the fleet is about 3,700.

LIEUTENANT-COLONEL ROLLIN,
Of the General Staff.

16. France—French Railways. *Historical,* 1823-1859.—The principles underlying the present system of railways in France will perhaps be made clearer by a brief account of the several phases that have preceded it.

The earliest experiment in railroading on French soil was a line between Andrezieux and St. Etienne, intended solely for coal and freight and operated by horse traction. The grant for it was made in 1823 by a simple royal ordinance. It was a grant in perpetuity, without subsidy or guarantee. About the same time grants were made on the same conditions for several other small lines.

In 1832 the first locomotive made its appearance. This was on the line from St. Etienne to Lyons, and thenceforward passenger service was added to freight traffic.

The Government, divining the future importance of the new mode of transportation, worked out a general scheme of trunk lines and submitted it to parliament. The first debate brought out two contrary principles which were destined to clash frequently thereafter. According to the one principle the State ought to construct and operate the railways; the other principle was that of private enterprise. After some fruitless discussions several grants were made, but a financial crisis which followed forced the recipient companies to ask for a revision of their contracts. The State had to assist them, and in 1840 it guaranteed to the Paris-Orleans Company, for 47 years, 4 per cent. interest on a maximum capital of 40,000,000 francs. This was the beginning of an arrangement which afterwards became general.

The law of 1842 decided on the creation of the trunk lines radiating from Paris to, respectively, Lille and Belgium; Nancy and Strasburg; Lyons and Marseilles; the centre of France, Bourges and Toulouse; Tours, Bordeaux and Bayonne; Nantes; Rouen and Havre; and lastly from Bordeaux to Marseilles by Toulouse, and from Mulhouse to Lyons by Dijon.

The State undertook the acquisition of a part of the lands, the departments being responsible for the remainder. The State built at its own expense the embankments and other artificial works and the substructures of the stations. The companies had to furnish the permanent way and the working stock, which at the expiration of the grant were to be bought by the State at an expert valuation. The work was begun and pushed forward energetically, but in a short time a financial crisis precipitated by speculation endangered the existence of the companies. The Republican Government of 1848 proposed repurchase, which was not accepted.

The Empire from the first favored an amalgamation of the various companies, the large number of which was a cause of weakness and of inconvenience to the public. By a series of decrees it constituted the great corporations, unifying the conditions of their contracts and extending the duration of their grants to 99 years. In this way were founded the principal French systems, whose grants expire as follows: That of the Northern Company in 1950; of the Orleans in 1956; of the Southern in 1960; of the Eastern in 1954; of the Western in 1956; and of the Paris-Lyons-Mediterranean in 1958.

Feeling their position strengthened, the companies accepted grants for secondary lines, to serve as feeders to the main lines, and from 1852 to 1857 more than 2,000,000,000 francs were expended, when a fresh financial crisis supervened.

At the end of 1858 the situation was as follows:

LENGTH OF LINES.

In operation	8,770 k.
Granted	16,174 k.

EXPENDITURE.

By the State and sundry	780 millions
By the companies	3,334 millions

1859-1875.—The situation of the companies having become critical, the Government, on 11 June 1859, induced parliament to ratify agreements between the State and the companies of the following nature:

In order to restore the companies to the situation they had enjoyed before the grants of secondary lines, the system of each was divided into two sections, called the old and the new systems. The capital appropriated to the new system received a guarantee of 4.65 per cent. interest for 50 years, beginning with 1865. Working expenses were included in a single account. Beyond a certain sum, representing the dividend guaranteed to the old system and the redemption of its capital, the excess of the net profits had to be expended on the new system, so as to cover partly, at least, the revenue guaranteed by the State, which was advancing the difference. This scheme has been named the «Overfall» (deversoir). The sums advanced by the State for the guarantee were regarded as loans, the companies paying interest on them at 4 per cent.

On the other hand it was specially agreed that after 1872 the companies should share with the State such portion of their revenue as exceeded a certain fixed figure, called the «partition point.» This figure was determined so as to allow the old system a higher dividend than at first, and to ensure to the new system, over and above the redemption charges, a revenue of 6 per cent.

If at the expiration of the grant the companies should prove to be debtors to the State, their working plant was to be assigned for the repayment of the sums due. Moreover, the State might redeem the grant at the end of 15 years by paying for the remainder of the time an annuity determined according to the revenue of the preceding seven years. The working plant was to be bought in at an expert valuation.

Such were the chief clauses of these agreements which enabled the companies to place their finances on a firm basis and to add about 700 k. yearly to their lines in operation.

At the close 1875, in spite of the loss of 800 k. with Alsace-Lorraine, the system «of general interest,» that is, the main system, showed the following development:

LENGTH OF LINES.

In operation	19,744 k.
Granted	26,423 k.

EXPENDITURE.

By the State and sundry	1,412 millions
By the companies	7,991 millions

To faciliate the economical construction of lines, a law, dated 12 July, 1865, had authorized the departments and communes to create secondary lines for themselves in their neighborhood. These railways, which were called «lines of local interest,» attained, in 1875, to an extension of 1,500 k., representing an expenditure of 41,000,000 francs.

1875-1883.—During the preceding period, alongside of the great companies, a number of minor companies had sprung up, such as that of the Charentes, that of the Vendée, of Dombes, of the North and East, etc.; but their position had become very much embarrassed. Several of these lines—of «general» as well as of «local interest»—were connected with the systems of the great companies. The Company of the Charentes, one of the most important among the minor organizations, showed an annual deficit of from 4,000,000 to 5,000,000 francs. The Government submitted to parliament for its ratification an agreement whereby the Orleans Company was authorized to buy up the Charentes Company, and other secondary lines, taking over their indebtedness under certain guarantees. At this particular time there was a great deal of ill-will toward the companies in parliament and the agreement was thrown out, Government being invited to introduce a repurchase bill, which was voted in 1878. The State thus acquired the Charentes Company, and several others, which formed the original nucleus of the State System. The cost was 500,000,000 francs, and it was covered by the issue of the 3 per cent. redeemable.

Since 1876 Government had been preparing a scheme for completing the railway system. Several commissions were at work on it, and in 1879 M. de Freycinet, Minister of Public Works, procured their consent to a scheme which provided for the construction of 8,700 k. of new lines, and 8,300 k. of lines granted but not yet operated, or a total of 17,000 k., within a period of 10 years.

The cost per kilometer was estimated at 200,000 francs, making a total sum of 3,400,000,000, or an annual outlay of 340,000,000 francs, a very reasonable figure compared with the outlay for the companies during the period 1855-1865, when it averaged 430,000,000 francs a year. The Freycinet Scheme, as it has since been called, refers to the whole of these new lines, together with considerable works to be carried out in the ports.

The agreements of 1879 began to be carried out at once, but the operation of the first lines showed a deficit, which, added to the cost of constructing the new lines, considerably increased the burden on the State. It became necessary, therefore, either to proceed more slowly with the work, or else to have recourse to a financial operation to ensure the completion of the proposed lines.

Owing to a recent crisis it did not seem feasible to make a loan. The State accordingly fell back on the credit of the companies, and the Government, in spite of lively opposition, succeeded in 1883 in carrying through parliament a fresh set of agreements which regulate the French railway situation to-day.

The main features of these agreements may be summarized thus: (1) The companies accept the grant of about 1,200 k. of new lines. They undertake to supply, in addition to the working stock and plant for these lines, a sum of 25,000 francs per kilometer, the rest of the cost falling on the State. The companies agree to carry out the works according to plans approved by Government and to advance the necessary funds which shall be repaid by annuities. (2) In regard to guarantee the previous distinction between the old and the new systems is done away with. There is only one account for working expenses. The net proceeds from this account are assigned by each company to the service of its debt and to the payment of a guaranteed minimum dividend. If there is a deficiency, the State gives its guarantee. If there is a surplus, it is used for the repayment of the advances made by the State as guarantee, and after the extinction of that debt it goes to the shareholders until the dividend touches a figure known as the «reserved» dividend, after which the profits are divided in the proportion of two-thirds for the State and one-third for the company. (3) With a view to reducing the amount of the annuities guaranteeing the interest, the companies are authorized to carry over till a fixed time the deficits on new lines to a special account, called «Account of Partial Operation,» where the deficit is covered each year by an issue of bonds. (4) A settlement was carried out in respect of the «Initial Outlay» account of the old systems, and also of the value of the stocks, on 31 Oct. 1882. However, the companies may still, by obtaining a simple ministerial authorization, execute supplementary works and charge them to Initial Outlay. (5) The companies which had used the guarantee of interest under the agreements of 1850 liquidated their debt by constructing works up to an amount agreed upon. (6) The State reserves the right of repurchase at any time. Lines which have not completed 15 years' existence are to be valued according to the actual expenditure on them, and the same rule holds good for supplementary works. In regard to the other lines, an annuity is to be paid, determined, as under the agreements of 1859, by the net profits of the last seven years, the guarantee of interest being included. (7) Finally, the companies agreed to a considerable reduction of the passenger rates, and further promised to revise and unify the slow freight tariffs.

The brilliant situation of the companies in 1883 had raised the hope that the burden of the guarantee would not weigh too heavily on the budget. But a period of depression followed the prosperous years, and it was necessary, in order to reduce the expenditure, to proceed more slowly with the works. Accordingly the completion of the proposed lines seems deferred to 1908 or 1910. Subsequently the receipts gradually rose, and in the last few years the calls on the State guarantee have been decreasing; some companies have even begun repayment. However, it is to be feared that the fresh out-lays imposed on the companies may defer to a still distant date their entire liberation from indebtedness to the State.

SITUATION OF FRENCH RAILWAYS (OF «GENERAL INTEREST») IN 1904.

LENGTH OF LINES.

In operation	39,300 k.
Granted	42,250 k.

EXPENDITURE.

By the State and sundry	5,616 millions
By the companies	11,832 millions

Characteristics of the Present System of French Railways.—We have seen that the railway system which has prevailed in France is rather due to circumstances than to the realization of theoretical ideas.

It is a mixed system, which, while respecting the supreme rights of the State and according it a very extensive control over the companies, leaves the latter as much independence and initiative as are necessary for the proper management of their business.

The companies enjoy a monopoly and operate the lines, while the State continues to own them, and only concedes them for a limited period. Entrusted with a public service the rights and duties of the companies depend on contracts made with the State, which exercises over their management a threefold control, financial, technical and commercial, in virtue of the threefold character of the railway system. The exercise of this control comes under the powers of the Minister of Public Works, who is assisted by various commissions, according to the nature of the questions at issue. The most important of these commissions is the Advisory Railway Board, whose functions are chiefly commercial.

Financial System.—The financial system of the companies is regulated by agreements, viz.: Those of 1883, which are actually in force, and of which the details have been given above. The State, having refused to divest itself of its proprietary rights over the railways, and on the other hand having compelled the companies to construct costly lines, has been led not only to undertake a part of the initial outlay but also to guarantee a minimum interest on the capital invested. Consequently, the State must satisfy itself as to the correctness of the companies' accounts in respect of initial outlay and working expenses, since these determine the amount of the guarantee of interest, and also of the annuity to be paid the companies in reimbursement of their advances. The State also controls the financial situation of the companies. It sees that the issues of bonds are sufficiently guaranteed, and that a right proportion is observed between the shares and the bonds. Lastly, the law of 27 Dec. 1890, places the statutes of the companies' pension funds under ministerial control.

Technical System.—The State intervenes also in technical questions. When the companies are constructing new lines, the plans and estimates must be submitted to the Minister, who has the draught verified, and sees that all the works are planned in accordance with scientific requirements and satisfy the terms of the accepted estimates. Moreover, he causes the execution of the works to be supervised. When the companies wish to improve existing lines or to increase the working stock, they must likewise submit their plans and estimates to the minister's approval. There is government control also over all regulations touching the working of the lines, over the speed of the trains, the limitation of hours of labor, and various internal matters. The railway police is regulated by the law of 1845 and the ordinance of 1846, modified in 1901.

Commercial System.—Railway tariffs affect public wealth too deeply to have escaped government control. To begin with, in the terms of contract appended to the grants, maximum tariffs were laid down for passenger and freight services; these cannot be exceeded by the companies though they may reduce them as much as they please. However, such reductions cannot come into force till they have been confirmed or approved by the minister, who has the right to withhold confirmation or only to accord it subject to certain modifications. This gives the government a means of exercising pressure on the companies in such direction as it may desire.

An elaborate method enables the minister to get information as to the seasonableness of the proposed change, and constant shifting of rates, which is so harmful to the public, is carefully guarded against. In some cases, *e. g.*, of export tariffs or transit tariffs, the ordinary regulations are modified so as to enable the companies to meet foreign competition.

Tariffs.—The terms of contract fix the maximum amount of the taxes which the railway companies are allowed to collect. That is the legal tariff. But the companies have exercised their right of introducing lower tariffs. When freight is conveyed with all the guarantees and under all the conditions laid down in the terms of contract, the general tariff is enforced. But when the public consents to some modifications of those conditions, then special lower tariffs are applied.

The tariffs are based on the rate paid per kilometer or per unit of transportation. This base may be constant, and then the rate is proportionate to the distance traversed, as happens in the passenger service. Or it may vary with the length of the journey, so as to stand, for instance, at 8 centimes for transits below 100 k., 5 centimes for those below 300 k., and 4 centimes for those beyond 300 k. Coal and mineral products were treated thus after 1863. It was a drawback of the system, however, that the rates came higher for journeys of just less than 100 k. than for journeys of just more than 100 k., and this was true also about journeys in the neighborhood of 300 k. To remove this anomaly, it was specified that in no case should the rate in one section exceed the minimum rate in the section following. This rule, however, produced an intermittent scale (barême à paliers), the rate not changing for a number of kilometers.

To get rid of this defect in turn it was decided to adopt the Belgian tariff, so-called because it first came into general use in that country. Here the base varies only when you pass from one section into another. Thus, to return to our previous figures, the first 100 k. are reckoned on the base of 8 centimes, the next 200 k. on the base of 5 centimes, and those beyond on the base of 4 centimes. So that we get a diminishing base. The Belgian system is commonly used in France to-day both for rapid and for slow freight; but such has not always been the case.

At first the tariff had a fixed base, but in order to encourage this and that special traffic the companies introduced for certain freights and between certain stations fixed rates called «steady rates» (prix fermes), lower than those called for by the general tariff. The number of these «steady rates» increased so rapidly, however, that the handling of the tariffs was much complicated. Moreover the principle involved in the «steady rates» was much attacked. Accordingly, after the agreements of 1883 the companies proceeded to recast their tariffs. They were simplified and partly unified; freights were divided into six series; the diminishing base of the Belgian system was adopted; and a slight reduction of rates has been the general result.

However, the «steady rates» have not yet altogether disappeared, for they meet a real need, but their number is much smaller.

Economic and Financial Results of the Agreements.—The Question of Repurchase.—Under the agreements of 1883 the railways of France have attained to a development which seems not far removed from the limits imposed by the nature of the soil and by existing economic conditions, and beyond which they could not perhaps be profitably worked.

For each thousand inhabitants in France there is 1.26 k. of railroad, while England has only 0.86 k., Germany 0.94, Belgium 0.97, and the United States 0.41. Thus France has the lead in this respect. In proportion to area France has 9.2 k. of road for each square myriameter (=6 miles 1 furlong 28½ poles); England, 11.5; Germany, 10.0; Belgium, 22.7; and the United States, 4.3. Here, even setting Belgium aside, the order is reversed.

It must be remembered that, owing to the very variety of the regions traversed by them, the several lines of the French system show marked differences in the importance of their traffic. To become convinced of this one only has to glance at a map on which the thickness of the lines is proportioned to the gross receipts by kilometer. There one will quickly perceive a number of great arteries standing out clearly. These constitute the nuclei, as it were, of the great companies, and they are connected together by a network of other lines mostly slender, and with meshes which are larger or smaller according to the nature of the districts they cover. If the creation of the lines had been left entirely to the initiative of the companies, it is certain that the principal arteries would long have remained the only routes opened up, while their ramifications would have been constructed but slowly. It was the influence of the agreements which enabled the less productive lines to be opened and operated.

From the financial point of view the most important result of the agreements has been the consolidation of the companies' credit. In some instances it has made it possible for them to borrow at lower rates than the State itself could have done. But as the increase of their capital made their indebtedness more burdensome, and on the other hand the operation of new lines caused a deficit, they were obliged to call on the guarantee of interest for sums which before the conventions of 1883 amounted to 545,000,000 francs, and between 1883 and 1903 rose to 951,000,000 francs.

It must be borne in mind, however, that although the sums asked for under the guarantee appear each year among the outgoings of the budget, they are in fact loans bearing interest at 40 per cent. and secured by a valuable working stock; that is to say, they are really very good investments for the State.

Another outcome of the agreements has been that the State has had to liquidate part of its debt. The companies having advanced some of the funds for initial outlay, the State pays them back with annuities of which the sum total is usually much larger than that of the guarantee—evidently an excellent operation for the State.

Moreover, to get an exact idea of the influence of the companies on the budget, one must offset the outgoings with the receipts and savings secured to the treasury by them, which the administration reckoned as follows for 1904:

EXPENDITURE.

Interest on capital borrowed directly	129 millions
Annuities to companies, capital supplied by them	92 millions
Guarantee of interest	27 millions
Costs of control	5 millions
Total	253 millions

RECEIPTS AND SAVINGS.

Repayment of guarantee loans	5 millions
Costs of control	5 millions
Taxes on transportation	108 millions
Shares and bonds	57 millions
Savings for the public service	95 millions
Total	270 millions

These figures leave out of count the guarantee of interest for lines "of local interest."

Thus the account would be found to give a balance of 17,000,000 francs in favor of the State.

The financial position of the companies has distinctly improved of recent years; three of them have entered the stage of repayment, and one, the Northern Company, has never had recourse to State subsidies. If events follow a normal course, one may legitimately expect this improvement to go on increasing progressively, and one may look forward to a time when most of the companies will be free of all indebtedness toward the State.

A glance at the manner in which they discharge their task will show that their «coefficient of operation» is lower than that in any other country, and that on most points they will bear comparison favorably with the best foreign companies. In particular, French engines have been the subject of the most flattering criticisms both in England and in America.

In these circumstances what motives could be strong enough to induce the State to involve itself in the task of repurchase? It is evident from the parliamentary history of French railways that the question has nearly always been regarded from a point of view quite foreign to economics and financial questions. And this seems to be the case to-day.

In reality, State operation of the railways finds few supporters among competent men, and the example of countries adjoining France, where the railways are nationalized, is by no means conclusive. In these very countries indeed the French system has more than once been quoted as a happy union of public powers and private initiative. Consult particularly 'La politique francaise des Chemins de fer,' by R. von Kaufmann.

The highest authorities have always been of opinion that repurchase in existing conditions would be a disturbing operation for the public finances; whereas by the mere action of the agreements the State must necessarily, in the middle of the century, come into possession of a completely developed and liquidated system, and that without opening its purse. It might then dispose as it pleased of the net income of the railways which already amounts to more than 700,000,000 francs, and ought by that time, it has been calculated, to be more than 1,000,000,000 francs. Such will be the final outcome of the agreements, if they succeed in weathering the violent attacks which are once more being made on them.

Statistics.—The development of the lines and the paid-up capital by decades was as follows:

Years.	Length of the lines in operation up to 31 December.	Corresponding Capital of Initial Outlay.
	In kilometers.	In mill. francs.
1830	38	6½
1840	435	146
1850	3,010	1,363
1860	9,439	4,726
1870	17 440	8 168
1880	23,738	11,065
1890	33 550	14 271
1900	38,122	16,442
1904	39,200	17,442

The division among the several companies in 1904 was as follows:

Company.	Average length in operation during the year.	Capital Enlisted: Expended by the Companies.	Capital Enlisted: Subsidies.	Shares and Bonds issued by the Companies: Shares.	Shares and Bonds issued by the Companies: Bonds.
	Kilometers.	Millions	Millions		
Nord	3,765	1,711	100	525	4,425
Est	4,857	1,577	671	584	5,447
Ouest	5,829	1,785	793	300	5,750
Orléans	7,384	1,976	861	600	6,264
P. L. M.	9,283	4,024	1,009	800	13,024
Midi	3,764	1,090	552	250	3,820
Ceintures	173	93	26		
Petits Réseaux	1,392	835		215	567
Etat	2,916	843			
Total	39,200	17,442		3,274	39,298

RECEIPTS, EXPENDITURES AND NET PROFITS.

Years.	Gross receipts with tax taken off.	Working expenses.	Net profit.	Coefficient of operation.	Rates of remuneration on the capital.
	Millions.	Millions.	Millions.	Per cent.	Per cent.
1841	13	8.3	4.7	64	
1850	96	45	51	47	3.75
1860	418	188	230	45	4.87
1870	634	313	321	48	3.95
1880	1,061	538	523	50	4.75
1890	1,154	607	548	51	3.85
1900	1,517	824	693	54	4.10
1904	1,515	787	728	52	4.20

The division for 1904 among the different companies was as follows:

Company.	Gross receipts with tax taken off.	Working expenses.	Net profit.	Coefficient of operation.	Rates of remuneration on the capital.
	Millions	Millions	Millions	Per cent.	Per cent.
Nord	239	128	111	53½	6.19
Est	192	108	84	56¼	3.73
Ouest	192	108	84	56¼	3.26
Orléans	236	111	125	47	4.4
P. L. M.	459	217	242	47¼	4.80
Midi	116	54	62	46½	3.75
Ceintures	16	15	1	94	0.84
Etat	52	38	14	73	1.66
Petits Réseaux	13	8	5	61½	0.6

In these two tables the coeffcent of operation is the relation of working expenses to gross profit. The rate of remuneration on capital has been determined by comparing the net profits with the capital of establishment. The liquidation charges on the capital are not taken into account.

Traffic.—The progressive development of traffic and lowering of rates from 1841 to 1904 was as follows:

Years.	Total distance covered: Passengers.	Total distance covered: Freight.	Mean tariff per kilometer: Passengers.	Mean tariff per kilometer: Freight.	Mean receipts per kilometer.
	Millions of k. passrs.	Millions of Kilometric tons.	Centimes.	Centimes.	Francs.
1841	112	38	7.00	12	26,000
1850	797	462	6.66	7.7	32,700
1860	2,921	3,120	5.64	6.92	45,600
1870	4,272	5,057	4.95	6.14	40,800
1880	5,863	10,350	5.04	5.95	46,000
1890	7,943	11,759	4.40	5.46	35,000
1900	14,063	16,557	3.67	4.69	39,800
1904	13,699	16,551	3.70	4.60	38,600

Division among the companies of the traffic for 1903 was as follows:

Company	Total distance covered.		Mean tariff per kilometer.		Mean receipts per kilo-meter.
	Passengers.	Freight.	Passengers.	Freight.	
	Millions of k. passrs.	Millions of Kilometric tons.	Centimes.	Centimes.	Francs.
Nord.....	1,998	3,401	3.83	3.86	63 671
Est......	1,804	2,276	3.40	4.40	38,917
Ouest....	2,180	1,325	3.60	5.45	32,792
Orléans...	1,988	2,402	3.66	5.01	32,171
P. L. M...	3,480	5,298	4.09	4.57	49,292
Midi.....	1,024	1,221	3.56	5.09	31,381
Ceintures.	216	113	3	7.38	30,000
Etat.....	556	466	3.13	5.14	17,654
Petits Réseaux..	87	82	4.03	8.68	5,651
Total....	13,335	16,585	3.70	4.63	38,489

The number of kilometric passengers or tons, is the sum of kilometers covered by each passenger or by each ton of freight.

M. de Saint Amand,
Engineer to the Chemin de Fer du Nord.

17. **France—French Industries.** In order to study French industries methodically we shall divide them into four classes: (1) Great Industries; (2) Small Industries; (3) Domestic Industries; (4) Agricultural Industries.

1. *Great Industries.*—In the first rank of great industries stand the textile industries, which really include cotton, wool, lame, flax, hemp, and jute, and also a certain number of secondary industries, each one of which consists of two principal branches—spinning and weaving. To avoid mistakes we shall examine them separately.

(1) The cotton industry consists of spinning-mills containing 6,150,000 spindles and 108,000 power looms. Spinning-mills are confined to three centres: Normandy, where they are in the vicinity of Rouen; Nord, where the centres of Lille and Roubaix stand out prominently; and Vosges, including the department of the same name; Meurthe-et-Moselle and the Territoire de Belfort. Weaving, on the other hand, is much more extended, and can be divided according to specialties into 16 districts: (1) Amiens, ribbed velvets; (2) Condé sur Noireau, striped cotton; (3) La Ferté Macé, coutils of various designs; (4) Flers in Orne, stripes and oxfords; (5) Evreux, corsets and bed linen; (6) Haute-Saône, striped weaves; (7) Mayenne, specially for what is called Laval; (8) le Nord, flannels, bedquilts and sateenes; (9) Normandy, shirtings and long-cloth; (10) Paris, napkins and Turkish toweling; (11) Roanne, blue cotton goods; (12) Tarare, muslins and hand embroideries: (13) Thizy, cretonnes and peruviennes; (14) Saint-Quentin, mousselines and gauzes for furnishing; (15) Vosges, cotton-cloth and satinet; and (16) Troyes, cotton hosiery.

(2) The wool industry uses 1,600 heckling-machines of different styles, 2,000,000 spindles in combing mills, 390,000 spindles in the spinning mills of carding, and 55,000 power-looms. A certain number of these looms are used by turns for cotton and for wool. The wool-carding mills are most important and form a separate industry. They are situated in Roubaix and in Reims, and the shoddy-mills are in Elbeuf and Vienne. The representative spinning-mills are at Roubaix, Fourmies, Reims, Vienne and Belfort. As for weaving mills, they have 15 different centres: (1) Amiens, noted for serges called du Barry; (2) Saint-Quentin and Bohain cashmeres and light novelties; (3) Beauvais, tapestries; (4) Tours, blankets; (5) Elbeuf, cloth; (6) Fourmies, colored and mixed weaves; (7) Lisieux, printcloth; (8) Louviers, novelty goods; (9) Mazamet, curried fustians and military cloth; (10) Paris, double-milled goods and sateenes for uniforms; (11) Reims, merinos; (12) Roubaix and Tourcoing, novelties for dresses; (13) Sedan, cloth for clothing; (14) Vienne, novelties for ready-made suits; (15) Vosges, articles for footwear. The wool industry of France is considered the most important in the world.

(3) The silk industry consists of 13,000 bassines for separating the threads from the cocoons, 35,000 power-looms for weaving, and 35,000 hand-looms. The silk mills are situated in Cevennes and Gard; silk is made both by machine and by hand in Rhône and the neighboring departments, and the principal centre for selling it is at Lyons; for ribbons the chief centre is Saint Etienne; and for galoons, laces for shoes, etc., and braids, Saint Chamond and Izieux. A new industry—artificial silk—was first made in 1889 by Chardonnet, its chief centre being Besançon.

(4) Flax and hemp, together with jute, contain—in all their factories—500,000 spindles; and in weaving, 22,000 power-looms and 20,000 hand-looms. The flax-mills are chiefly situated in Nord; the manufacture of thread called «sec» (dry) is in many respects like that called «mouille» (wet). Sewing thread of flax is also made in the same section of the country. As for woven goods, strictly speaking, their manufacture is divided into a certain number of groups, that can be classed as follows: (1) the factories of the Nord, the chief centres of which are Armentieres, Lille, and Bailleul, where smooth goods, colored or white, are made in every width; Dunkerque, Beauval and Flixecourt manufacture jute goods, and several places in Somme awnings and damask; (2) Normandy is celebrated for shirtings, pillow-cases and table covers; (3) Brittany and Anjou for handkerchiefs, canvas, etc.; (4) Vosges for table and bedroom linen; (5) South for coarse cloth. We may add that in all these sections «ramie» silk is manufactured.

It is estimated that the textile industries, properly speaking, employ 825,383 workmen in France, furnishing occupation to 1,053,588 workers on suits and other garments. They also feed as many cotton as silk mills. 2,076 tulle looms are working in Caudry, Calais, Saint Pierre and Lyons. This is the official account of the hosiery business in flax and in wool in Somme, Nord, and Vosges; in cotton in Roanne and Troyes; and in silk in Hérault, Gard and Hautes-Pyrenées. Hand-made lace forms one of the most artistic industries of Puy, Bailleul, Bayeux, Mirecourt, etc. Besides these there are innumerable embroidery factories in successful operation in Saint Quentin, Angers, Tarare, and Nancy, and of passementeries in Lyons, Nimes, and Paris.

(5) After the textiles, the industry which employs the most men in France is the mining of coal. The coal mines are divided geographically into five districts: (1) the coal mines of the North, covering a surface area of about 109,000 hectares, distributed in the departments of Nord and Pas de Calais, in about 40 grants, the chief of which are those of Anzin, Vicoigne, Noeux, Bethune, Lens, Aniche, Marly, etc.; (2) the coal mines of the East, principally near the Moselle, to which are joined the mountainous branches in Savoie where anthracite coal is found; (3) the coal mines of the Oise, which include the basins of Basse-Loire, Vendée, etc.; (4) the coal mines of the centre, the most important after those of the North, which include the basins of Saône et Loire (Autun, Creuzot, Blanzy, Montceaux, Montchanin 875 hectares); those of Allier and Auvergne (Ahun 2,200 hectares; Commentry, 2,480, etc.); those of Loire (Saint Etienne, Saint Chamond, Rive de Gier, Firminy), with a surface area of 25,000 hectares; those of Savoie and Loire, 42,972 hectares; of Nievre, 8,000 hectares; of Allier, 7,367 hectares; of Correze, 5,432, etc.; (5) the coal mines of the South, situated near Lot, Hérault, Gard, which contains several basins, two of which are exceedingly important—that of Aveyron, 12,000 hectares, and Gard, 26,888 (Grand Combe, Besseges, Alais, etc.). Besides these, there are in Hérault the small basins of Neffiez, Ronjan, Graissessac (8,800 hectares), and Bousquet d'Orb (15,129 hectares), and in Tarn, the basins of Carmeaux (8,800 hectares). To coal mining there is always attached the secondary industry, the manufacture of coke and agglomerates.

The great mineral industries of France are naturally near the coal deposits. The only way they can be divided geographically is under the same divisions as the coal mines. But the chief centres can be especially noticed as follows: in Besseges (in Gard) where there are iron mines, are blast-furnaces, foundries, machine-shops, turning-plate factories, smelting works, etc.; Commentry-Fourchambault has blast-furnaces, forges, foundries, wire-mills; there are machine-shops for the manufacture of steel at Montlucon and at several points where these manufactures are exported, extending through Cher, Allier and the Nievre; at Creusot there is one of the most important metallurgic establishments in the world, which is situated in the centre of France. Henrichement is joined to the railway of Bourgogne and Bourbonnais and connected with the canal du Centre by a private railroad. Decazeville is the most important metallurgic centre in the South; here are made rails, various iron merchandise, cast-iron pipes for conduits, boilers, etc.

There are factories in Fives-Lille (Nord) and Givors (Rhone), chiefly making machinery used in the manufacture of silk and plush, steam-engines, locomotives, materials for constructing railroads, pig-iron, and heavy metal work, etc. Indre, in the department of the Loire, makes a specialty of marine constructions, torpedoes, large pieces of cast-iron boilers, etc. In Maubeuge (Nord) are the most important metal works; and there are others in Longwy (Meurthe-et-Moselle), both near Belgium; and in Montataire, which contains other factories besides the one of that name; then comes Creil, celebrated for its parquet flooring, and the remelting of old iron, extensively used in the manufacture of tin; and then again the factories of Frouard, near Nancy, Bagugson in Meuse, and Outreau (near Boulogne sur Mer); Rive de Gier is an important centre for foundries, the manufacture of steel, steam-engines, wheels, and materials for building railroads; Saint Chamond, especially is celebrated for the rolling of iron and steel; and lastly comes Terrenoire, where the pig-iron of Ardeche is made into iron.

The glass industry is brilliantly represented in France. Besides the manufacture of bottles carried on in the glass works of Blanzy, Rive de Giers, Givors, Saint Galmier, Vauxhot, Reims, Epernay, Fourmies, Valenciennes, and some localities in the Jura, mention may be made of the celebrated factories for making plate glass in Aniche (Nord), Chauny and Saint Gobain (Aisne), and those for making cut glass in Baccarat (Meurthe-et-Moselle), where the industry has reached great artistic excellence, in consequence of which a considerable amount is exported.

Mention should also be made of the chemical works for the manufacture of sulphuric acid and soda. These have warranted the erection of quite large buildings; for instance, the chemical works in the North, the works in Saint Gobain Malétra, etc. At all these places there are mineral deposits. Other industries of a chemical character can be included in this group, like that of coloring matter, the most representative of which are Saint-Denis and Rhone; fecula and amidine works, which are all in Nord; white lead, made in Nord and in the vicinity of Paris; tallow candles, chiefly made in the departments of the Seine, Rhone, Hérault, and Bouches du Rhone; dyeworks, always located near textile factories.

Ceramics are among the great industries of France. The manufacture of porcelain is especially centred in Limoges; square tiles in Maubeuge, faïence in Choisy le Roy, Gien, etc. In this group can be classed the manufacture of cements in Boulogne sur Mer, and in the outskirts of Grenoble; and the mining of asphaltum principally found in Savoie.

We can also count among the great industries of France the manufacture of machine-made boots and shoes in Blois, Fougeres, etc.; writing pens and pencils in Boulogne sur Mer; clocks in Besançon; marble-cutting in Cousolre; cutlery in Chatellerault; perfumery in Paris and in Grasse; gloves in Grenoble and its environs; soap in Marseilles and in the North; hats in Lunéville, Paris, etc.; the picture trade in Tours, Epinal, and Paris; the most celebrated manufactures of automobiles in the suburbs of Paris, etc. Certain specialties, such as stalls, on some of which the French have a monopoly, are made in large quantities, and there are a great many tobacco and match factories. Arms are manufactured in Saint Etienne, cannons in Bourges, and tapestries (Goblins) in Paris.

II. *Small Industries.*—The principal small industries for which the French are especially noted—on account of the taste they have shown for this kind of manufacture—are «Articles de Paris,» so called because manufactured in that city or its suburbs. They can be divided into 13 groups: (1) the toy trade—dolls, dressed and undressed, mechanical toys, various games, all kinds of playthings, heads for modistes, cotillon favors, masks, etc.; (2) the manufacture of buttons in horn, bone, vegetable-ivory, papier verni, hardwood, etc.; (3) pasteboard articles, such as bonbon boxes, and all decorative pasteboard articles; (4) false hair and hair work, the demand for which has greatly increased owing the present style of coiffure worn by women, which requires much false hair; (5) fans, certain kinds of which are manufactured in the vicinity of Beauvais; (6) artificial flowers, many of which are exported; (7) the sheath trade, which includes the manufacture of knife boxes, cases for spoon, fork and knife, cases for surgical instruments, pipes, cigars, opera glasses, cases of white manna-ash, and especially jewelry cases; (8) the manufacture of workboxes, which includes certain small articles used by children as playthings; (9) umbrellas, parasols, and horsewhips; (10) combs in horn, buffalo-horn, real and imitation tortoise shell with hinges, gilt backs, carved, inlaid, etc.; (11) feathers, which are chiefly worn on women's hats; (12) portfolios and morocco leather work, which is an industry distinct from sheath-making; (13) fancy articles, such as billiard balls, crucifixes and other religious objects, in ivory or in wood, mountings for canes, lunettes, opera glasses, lorgnettes, knife-handles, games of dominoes, toilet articles, and articles used by smokers, etc.

Let us mention, as essentially French, the industries that owe their existence to fashion, in which Paris reigns supreme, the term «Mode de Paris» being used in many foreign countries to make their productions sell. It is especially the workwoman herself who invents, modifies, improves, and, trying the effect on herself, chooses the best and calls it a new mode. In this industry, ratan, wire, and whalebone are used for forming and supporting hat frames, and these are made in the ordinary factories; the modistes, strictly speaking, select and arrange the materials, flowers, feathers, and laces.

The goldsmith's trade also takes a high rank in France, especially in Paris, not only on account of the large goldsmith shops that make only large pieces—all silverware used to ornament the table and buffets—but also the small goldsmith's shops that make a specialty of knives and forks for fish, mugs, sauce-pans, knives and various kinds of utensils, and also religious goldsmith work, such as brass and pewter plates. To this industry can be added that of argentry, for which certain Parisian firms have acquired quite a reputation.

III. *Domestic Industries.*—Although domestic industries are very prominent in France, it is difficult to locate them, because in so many places they are annexed to the great industries. For example, in the textile industries, a certain number of localities, such as the environs of Lille and the manufacturing town of Cambrai, flax-linen has its home; the workmen use all their skill to get suitable thread from their employers, and then, after weighing it, they take it home; so also in Saint Etienne, the manufacture of silk ribbon is made in great part in the homes of the workmen, whose looms work by electricity controlled from a central factory from which the power is distributed; the same is the case in the entire lingerie industry, concentrated in Saint Omer and in Vosges, the work being taken home under the direction of forewomen and contractors, as is almost all the lace manufactured in Bailleul, le Puy, and other localities; and much of the labor of the 1,000 mouselenne de coton factories in Tarare. The large stores where ready-made clothing is sold have in their employ many men and women who do the work at home. In the small industries, as well as in the large, part of the work can be done in the homes of the workmen. For instance, all varieties of «Articles de Paris» are usually made away from the factories.

Besides these branches of the chief centres, there are other industries that may be considered as family industries in the sense that the manufacturer needs only one, two, or three workmen at most on each article, like real or imitation jewelry, the manufacture of effervescents, pharmaceutical specialties — many of which are exported; dyeing and scouring, etc., and numerous others.

IV. *Agricultural Industries.*—The most important of French agricultural industries is the manufacture of wines, for which France has a world-wide reputation. The departments of Gironde, Cote d'Or, Marne, Drome, Savoie, and Loire yield the most noted vintages, as well as the most abundant, but fine grapes are also grown in the departments of Hérault, Gard, Aude, Gers, Pyrenées-Occidentales, Charente, etc. They can, broadly speaking, be divided into three great classes; Bordeaux, Bourgogne and Beaujolais. Especially noteworthy are the Normandy wines, and the matchless champagne. Next in importance after wines come distilled liquors. There are two kinds of brandy, betterave (beet), manufactured only in the North and consumed there, and wine brandy exported all over tne world—a sufficient guarantee of its worth. This last can be divided into three varieties: (1) cognac brandies, which are called (after the places where they are made), Fine Champagne, Borderies, Bois ordinaires, and Deuxiemes Bois; (2) Armagnac brandies, which are known by the names of Bas-Armagnac, Ténareze, and Haute-Armagnac; (3) Montpellier brandies. The first are made exclusively in the departments of Charente and Charente-Superieur; the second in Gers, Landes, Lot et Garonne; and (3) in Hérault. Besides the above mentioned kinds, in all these wine districts Mare brandy is made with the help of the Mare of the vintage, and in the department of Indre another brand of local brandies, which goes by the name of Calvados, has gained a certain reputation.

Next in importance to brandies is beer. This is not exported, but a greater quantity has been brewed in the last few years. A great many departments in France situated near the frontier have brewed beer after the German fashion so successfully that its general consumption has exceeded that of Munich and Vienna.

The manufacture of granulated sugar is one of the great agricultural industries of France. This gives rise to three different industries: (1) the cultivation of beets for the sugar contained in them, with nurseries for the scientific cultivation of seeds which are exchanged between France and Germany. These extend over the millions of hectares in the North. (2) The manufacture of beet sugar in Nord, Aisne, Somme, and many northern departments that have refineries annexed. (3) The refineries of colonial sugar, which is imported and made into sugar in the ports.

Besides these great manufactures, that form the base of French agricultural industries, we might mention a great many more that are developing rapidly: as the preparation of chickory in Nord, successfully used with coffe; the digging of peat in Somme, used instead of coal; the manufacture of olive-oil in all the southern departments; that of wax and honey which has been greatly extended in the eastern portion of France; butter, which has necessitated the erection of large factories in the district of Avesnes (Nord); the manufacture of biscuits at Marseilles, Nantes, Bordeaux and Suresnes, etc.; chocolate manufacture; glue manufacture, etc.

The manufacture of agricultural machines is an important industry, and notwithstanding the competition of American machines, the making of heavy implements like threshing-machines is carried on on a large scale, especially in Liancourt, Fumay, Vierzon, Dourdan, and Algeria.

Alfred Renouard,
Editor of "l'Industrie Textile."

18. France — Commercial and Banking System. The history of French commerce and industry, like the history of France itself, naturally falls under two heads: the old *régime* and modern times.

Previous to modern times, the development of French industry was limited by the guild-system on the one hand, and on the other by the numerous obstacles, inherited from feudal times, which lay in the way of exchanges from one province to another. Many of those obstacles were still in existence on the eve of the Revolution. However, a progressive element was to be found, ever since Colbert's days, in the royal manufactures. They did not belong to the king, but were protected against the guilds' monopolies by privileges conferred by the crown. We may mention among them the tapestry manufactures of the Gobelins and of Beauvaris and the porcelain factories of Sèvres. The private factories of Aubusson (tapestry); Rouen, Marseilles, Lunéville (earthenware); Lyons (silk), and the glassworks in the Dosges — where glassworkers were long styled *gentilshommes verriers* — also deserve notice.

Foreign commerce was effected principally through the French ports; Marseilles, where the tradition of commercial navigation is as old as the town itself; Dieppe, the birthplace of the famous Angot, and the harbors of the Atlantic, which sent out ships to the New World; the old French colonies in the West Indies; Louisiana, Canada, and the Indian Ocean are witnesses to their activity. The establishment of the *Compagnie des Indies* (1664), shows us the metropolis taking an interest — unfortunately one too weak and too fugitive — in commercial matters. The reader may also be reminded that the commerce between England and France which, if circumstances had been different, might have developed under the treaty of 1786, was at stake throughout the long duel fought by the First Consul and the Emperor against the English people.

The home commerce was necessarily purely local; the means of communication being strictly limited to the rivers, the few canals, and fewer good roads; the towns were compelled to be self-supporting, and the country people had to depend, both for their food and their clothes, on the produce of their labor and on the housewives' industry.

Before the middle of the 19th century the new canal and road systems and the railway and telegraph lines had given an incalculable power to the latent forces of the country, bringing about a complete transformation of industry and commerce. We may here notice that the impulsion thus given to commerce and industry never equaled in France that which made itself felt in England and in America about the same time.

Among the principal characteristics of the commercial revival of the 19th century, we must mention the specialization of goods, the indefinite extension of the fields open to manufactures, a considerable increase in the cash balances and clearing-house statistics, an ever-growing demand for capital and its tendency to concentration and association. Henceforth we see, more and more frequently, societies taking the place of individuals, and joint-stock companies substituting themselves to the ordinary copartnerships (those among the latter which have sleeping partners bear the name of *sociétés en commandite*). The coöperation just mentioned was in France as elsewhere of more frequent occurrence among manufacturers than among tradespeople, and there exists in France in the towns and in the villages a large class of small retailers which ha e the political strength to destroy any great combination that might attempt to drive it out of the market.

As early as the beginning of the modern period, the government had encouraged industry and commerce and given them the institutions they wanted. The *Code de commerce* was issued in 1807. In order to entrust its application to fully competent magistrates the French produced a unique and admirable system of *commercial courts*. The judges of these are returned by an electoral body exclusively composed of those subject to their jurisdiction. Jurisdiction of *Prud'hommes* was organized on the same lines, finally the Chambers of Commerce, to be elected very much in the same way as the courts, were instituted (1803), their functions being to look after the general interests of trade, to advise the public powers when requested, and to lay before them the desiderata of the trading classes. Important rights were conferred upon these Chambers of Commerce, including that of raising certain taxes. One of the most useful works undertaken by the Chambers of Commerce has been their contribution to the organization of commercial education in France. So far that education was practically nonexistent; at the present time it is still comparatively little spread. It is only given in special schools where pupils are admitted after completing their general education.

The interference of the government makes itself felt in another way, more prejudicial than favorable to the expansion of trade, namely by the manifold regulations which are constantly claimed by the working class. The government also has to regulate the system of customs which is largely based on the principle of protection, in France as elsewhere favorable to some producers and a source of grave difficulties to others.

It is practically impossible to give a numerical estimate of the amount of business transacted in France. Mr. Maurice Block put it at 1.000f. ($200) per inhabitant in 1875. It would certainly be more now, even without including the business carried on at the Stock Exchange; to give an example of the latter it was estimated in 1888 by Mr. Neymarck that the stocks negotiated on the Paris Exchange alone reached a yearly total of from 30 to 35.000.000.000f.

As to importation and exportation, the following statistics will give an idea of the commercial movement in France. We first extract a few figures from the tables drawn under Louis XVI. by Arnould, *chef du bureau de la balance du commerce*.

Exportation from France to Holland.

	Exportation from France to Holland.
1658	72.000,000 f.
1716	31,000.000
1787	46,000,000

	Import from England into France.	Export from France into England.	Total.
1686	18,000,000 f.	23,300,000 f.	41,300,000 f.
1716	13,900,000	8,000,000	21,900,000
1787	58,600,000	37,600,000	96,200,000

We may add that the total importation of France in 1787 seems to have reached from 400 to 500,000,000f. as against somewhat less than 100,000,000 in 1716, and the total exportation at the same date from 50 to 500,000,000f. as against a little over 100,000,000f. in 1716. The imperial policy considerably reduced our exchanges with foreign countries, especially with England, with the effect that even under the ultra-protectionist government of the Restoration the figures representing our imports and exports hardly equaled those reached during the last years of the old *régime*.

In the following columns we give the yearly average reached by the *commerce général* and the *commerce spécial* respectively during the five ten-years' periods from 1827 to 1876. (The *commerce général* includes all imports and exports of any sort, coins excluded; the *commerce spécial* only includes among imports foreign goods meant to be consumed in France, and among exports goods wholly or partly manufactured in France and sent to foreign countries. The sums given represent millions of francs.)

	Commerce général.		Commerce spécial.	
	Import.	Export.	Import.	Export.
1827-1836	667	698	480	521
1837-1846	1,088	1,024	776	713
1847-1856	1,503	1,672	1,077	1,224
1857-1866	2,987	3,203	2,200	2,430
1867-1876	4,262	4,202	3,408	3,307
1877	4,570	4,371	3,670	3,436
1878	5,089	4,112	4,176	3,180
1879	5,579	4,270	4,595	3,231
1880	6,113	4,612	5,033	3,468
1881	5,996	4,724	4,863	3,561
1882	5,962	4,764	4,822	3,574
1883	5,887	4,562	4,804	3,452

(The figures for 1904 are only provisional.)

The revival of the French commerce and industry after the Revolution and in the course of the 19th century was bound to have its effect on the working of the banks which, being the organs of the public credit, are the natural auxiliaries of exchange. The financial system of the state has also been subjected to a complete reorganization; public works of all kinds, military expenses, etc., have brought about a considerable demand for capital; all the financial markets have come to share in the greater operations of credit and an ever closer solidarity has been established between the various financial markets themselves. The function of bankers, formerly mere money-lenders to the sovereigns, has thus evolved, being placed by circumstances on a broader basis. Hence it is true to say that, although some banking firms can proudly trace their origin several centuries back, the constitution of the banking system in France was the work of the 19th century.

The French banks are divided as follows: (1) The two official institutions, viz., the Banque de France and the Crédit Foncier; (2) the so-called "Haute Banque" and some credit societies of the same kind; (3) the other credit establishments; (4) the discounting banks. We must point out at once that, from a legal and fiscal point of view, the name of *banquiers* is officially given to financiers whose function is, in fact, that of brokers and who are designated in professional slang by the name of *coulissiers* (as though operating behind the scenes, *dans la coulisse*). The latter name was given to them at a time when they could only practice their business by tolerance, being theoretically excluded from the market by the stockbrokers' privilege.

1. The Banque de France was founded in 1799 by the First Consul and finally organized

by him, as Emperor, in 1806. Its constitution was inspired by that of the Bank of England, but not made similar to it; it belongs to the system which, with some variants, now prevails in most European countries, and is entirely different from that of the United States. The Banque de France has, to begin with, an official function, viz., the issue of bank notes, which it owes to a privilege conferred upon it by law as early as 1803 and renewed ever since (for the last time in 1897). The bank notes are balanced in metal, the sum total in gold and silver being now about 4,000,000,000f. (2,925,000,000 in gold and about 1,060,000,000 in silver); and in bills, the amount which they represent varying from 5 to about 850,000,000f. The limit of the circulation of bank notes, fixed at 4,800,000,000f. in 1897 was raised by a recent law (Feb. 1906) to 5,800,000,000f. They are recognized as legal currency. An invaluable reserve is thus secured which could easily be disposed of in a crisis — as for instance in case of war, by enforcing the currency of bank notes.

The Banque de France has, on the other hand, a commercial function, consisting in the discounting of commercial bills on condition that they bear three signatures, represent a minimum value of 5f. and can produce a minimum interest of 0f., 10c. The rate at which the commercial bills are discounted varies according to the circumstances of the money and financial markets, but the right enjoyed by the Banque de France to reimburse its notes in silver enables it to keep that rate considerably more even than is the case in countries in which gold is the only recognized standard.

The capital of the Banque de France, originally 30,000,000f., has been raised successively to 45, later on to 90, and finally to 182,500,000f. (9 June 1857), in 182,500 shares of 1,000f. each. They are worth today about 3,900f. The banque is administered by a committee of 15 régents, five of whom are to belong to the commercial or manufacturing class and three are to be taken among the *trésoriers payeurs généraux* (the representatives of the French Exchequer in the various *départements*). It has a governor and two subgovernors appointed by the government. The banque has a total of 445 branches in the country.

The following statistics will give an idea of the rate at which bills have been discounted at the banque during the last 50 years:

	MAXIMUM RATE.	MINIMUM RATE.	AVERAGE RATE.
	%	%	%
1854	5	4	4.30
1864	8	4½	6.50
1874	5	4	4.30
1884	3	3	3
1894	2½	2½	2.50
1904	3	3	3

The Crédit Foncier, the governor of which is also appointed by the government, has an organization very similar to that of the Banque de France. Its special function consists in granting first mortgage loans to persons, villages, towns, and *départements*. The Crédit Foncier appeals to the public for the funds necessary to its operations by issuing bonds called *obligations foncieres* or *communales*. It has a capital of 200,000,000f.

2. The firms which compose the *Haute Banque* are often older than the Banque de France itself. We find them at the origin of all great modern enterprises: their heads were the founders of the Banque de France and of the great railway and insurance companies and their successors still have seats in the councils of both. The government rewarded their efforts at the time by creating among them the *barons de la finance*. Most of them have kept up the tradition and occupy an important place in the management of the financial market. The loans and other greater financial operations which they used to claim as their own are now partly in the hands of the financial societies which differ from the credit establishments in the receiving of money deposits; the discounting of bills is but a secondary part of their functions.

3. The discounting banks are organized on the three signature principle and work in connection with the Banque de France. The majority of tradesmen use them and they in their turn apply to the banque where they get their bills discounted. They are of varied importance. Their number, which used to be very great in the provinces, tends to decrease owing to the constant development of the credit establishments.

There are three great establishments of that kind in France, viz.: the Crédit Lyonnais, the Société Générale and the Comptoir National d'Escompte de Paris, which all date from the middle of the 19th century. They occupy an intermediate position between the English joint-stock banks and the greater German societies. The credit establishments appeal to the public for funds, which they keep as deposits, they have created among a large part of the population the habit of having their money deposited in banks, and the parallel habit for bankers of relying for their operations upon the public's deposits as much as, if not more than, upon their own capitals. The credit establishments, like the joint-stock banks, use the greater part of their deposits for discounting purposes, they also devote a certain amount of them to investments and even to loans, although their extreme parsimony in granting the latter somewhat justifies the saying that in France "the credit establishments give no credit." At all events they never subscribe to an issue of commercial or industrial shares except in a very cautious manner and they are no more anxious to make issues of capital themselves than to invest in the ventures of others.

To complete the description of the organs of credit in France we have still to mention: (1) the popular and coöperative banks, as yet but little developed; (2) the land and estate banks (*banques foncières*), the operations of which are carried on in connection with those of the Crédit Foncier; (3) the postal transactions; (4) the savings banks; (5) the land credit establishments, recently created, whose action is still uncertain; (6) the *magasins généraux* where goods can be warranted; and last but not least the colonial banks, which are constituted under special laws and have a half-official existence. The two more important ones are the Banque de l'Algérie and the Banque de l'Indo-Chine.

The French banks are but scantily represented outside of France; there are only a few branches of the credit establishments in England, Belgium, Switzerland, Spain, and in Constantinople. Inversely each year sees the establishment in Paris of new branches of the foreign banks, a consequence of the plenty of capital which has made the French maket in our time the money-lender to the whole world.

It is impossible to give an estimate of the banking operations carried on in France. By the side of the joint-stock-companies whose statistics are made known to the public there exists a large number of private firms whose joint capital certainly exceeds that of the said companies and whose balance-sheets, statistics and other results remain unknown. There is, it is true, a clearing-house *(chambre de compensation)* in Paris, but it is only composed of a dozen members (they were 12 including the representative of the Banque de France, until April 1906, when their number was raised to 13), and the amount of business settled there is far from representing even the totality of operations transacted in Paris alone. We can, however, subjoin the following statistics, while warning the reader that under the conditions of secrecy prevalent in French private banking the returns are given below the full total. They are taken from the tables of the "Chambre de Compensation" from August 1905 to July 1906.

August	1,307,980,105.34 f.
September	1,341,564,109.98
October	1,603,870,535.92
November	1,683,615,955.76
December	1,614,230,136.30
January	1,903,637,453.28
February	1,601,753,330.76
March	1,529,573,040.80
April	2,047,658,568.36
May	2,096,259,438.48
June	1,820,128,657.44
July	2,115,685,423.50
	20,665,956,765.02 f.

The average per day during the same months was given as follows:

August	52,319,204.21 f.
September	51,598,619.61
October	61,687,328.34
November	67,344,638.23
December	64,509,205.45
January	73,216,825.12
February	66,739,722.49
March	56,650,853.36
April	85,319,107.01
May	80,625,363.01
June	72,805,146.29
July	84,627,416.04

Of the three great credit establishments of the state we have of course full statistics which we here append:

Cash, etc.	292,700,000 f.
Loans and reports	915,000,000
Discounted bills	2,389,400,000
Stocks, shares, bonds	139,000,000
Check accounts	3,054,200,000
Creditor accounts	217,100,000
Undue bills	357,800,000

to which we may add a few more figures:

Capital	550,000,000 f.
Reserve funds	159,400,000
Net profit	45,904,052.40
Dividend	41,042,968.75

M. DELCOURT,
Professor of English, University of Montpellier.

19. France—The Colonies in 1907.—*Colonial Possessions in 1870.* On the establishment of the Republic after the defeat in 1870, French Colonial possessions were Algeria, and the Protectorship over 60,000,000 hectares, with 4,500,000 inhabitants. Of these about 3,500,000 were natives who submitted to French authority. In 1907 French trade with the colonies amounted to 560,000,000 francs, of which one-half was accredited to Algeria. The colonies have been converted into an empire across the sea—a greater France—which now comprises (besides Senegal, Guinea, Réunion, Mayotta and St. Mari in Africa; India, Cochin-China, Cambogia, in Asia; the Caledonia Islands and Tahiti, in Oceanica; Guiana, Martinique and Guadeloupe, in America; St. Pierre and Miquelon), Tonkin, Annam, Laos, Tunis, Madagascar, the Ivory Coast, Dahomey, Kongo, the coast of Somalis, the Comoro Islands, etc., 720,344,400 hectares in area (against 52,860,000 for continental France); nearly 45,000,000 inhabitants, of which 00,000 are Europeans, not counting Algeria and Tunisis. The commerce exceeds 1,500,000,000 francs. The report of the minister for the colonies shows an increase from 13,000,000 to 110,000,000 francs, and the reports from all the Colonies bring the amount up to 200,000,000 francs.

These figures suffice to show how France has reorganized the colonial domain that was lost from 1713 to 1763, and in 1815. These possessions are steadily and rapidly increasing. The French colonies are of sufficient importance to merit consideration.

ALGERIA.

France conquered Algeria in 1830, but the conquest took 17 years. It is no longer one colony, but a group of three provinces, governed like the metropolis. Algiers has 90,000 inhabitants; Oran, 90,000; Constantine, 52,000; Bone, 35,000; Philippeville, 20,000. The country consists of three sections: Tell, on a fertile region which includes the cities on the coast, and Kabylie, mountainous and fertile; the high plateaux; and the Desert of Sahara. It is ruled by a Governor-General, prefects, and army officers. The area of Algeria is 670,000 square kilometres. The climate is balmy, and some 12 000 strangers pass the winter season under its blue skies. In the region far from the coast the changes of temperature are more sudden. The population is 4,700,000, of which 700,000 are Europeans. It is the most important of the French colonies. Some 1,900 ships stop at Algiers. Its foreign commerce in 1906 amounted to 66,000,000 francs, against 55,000,000 in 1905. The importations from France average from 350,000,000 to 380,000,000 francs; and its exports amount to 278,500,000 frances. Railroads are to be extended 650 kilometres. The receipts, which amounted to 23,000,000 francs in 1896, have increased to 39,000,000 in 1906. In the departments of Constantine and Alger there are the fewest Europeans. It is well watered. Early fruits and vegetables and grain (hardy wheat and barley) are cultivated. It is rich in cork-trees, forests of oak, iron mines, phosphates of Tebessa, coral, and Spanish grass. In the department of Oran there are many settlers, especially Spaniards. Grapes and wheat are the chief products. The land is watered by the Chelif, the longest river in Algeria. The plateaux serve for breeding sheep. The towns are connected with each other by railroad, and with Marseilles by lines of steamships; also with le Sud, Oranais, Cette and Morocco. In 1847 the celebrated Arab chief, Abd el Kader, instigated the people of Morocco to revolt, but was defeated in the battle of Isly. The security and the development of Algeria require the French to take a prominent part in the affairs of Morocco; a country given over to anarchy, and whose tribes constantly trouble the frontiers.

Sahara borders Algeria. It is arid, but encloses great oasis, which have been made fertile by means of artesian wells. The nomads (Touaregs) have been forced to respect the caravans. The government of Algeria is a heavy task for France, which has become one of the greatest Moslem powers of the world.

TUNIS.

Tunis has been under the protection of France since 1881. In 25 years, by establishing ports, building railroads and roads, and by tilling the soil, this country has been transformed.

It is ruled by a Resident General assisted by delegations of financiers, and by an Advisory Council. It has an area of 13,500,000 hectares, of which 6,000,000 are under cultivation. Its climate is ideal. The land, being better watered than Algeria, is more fertile. The valley of Medjerda is the wheat land. The country is covered with olive trees and vines. The forests of Kroumrie, and fishing along the coast and in the lakes are sources of income. Its population of 1,800,000 is composed of 30,000 French, 25,000 Portuguese, 12,000 Anglo-Maltese, 80,000 Italians, and 4,000 of other nationalities. Of the 637,000 hectares under cultivation, 577,000 belong to the French, who have constructed 1,000 kilometres of railroad and 3,000 of roads. Steamers make the trip between Marseilles and Tunis in 35 hours.

The chief products are grain, wine, olives, oil, hides, oranges, dates, cork, Spanish grass and wool. Importations have increased 170,000,000 francs and exports even more. Its trade with France is 70,000,000 francs. Its report gives 40,000,000.

Tunis is a beautiful city of 250,000 inhabitants, including the outskirts. It is the residence of the Bey, and of the French minister. Its port is Goulette. It is connected by railroad with Bizerte, where a French naval station is established.

The other cities are: Sousse, Sfax, Gabes, and the holy city, Kairouan. The railroad (1,200 kilometres) connects Tunis with the frontier of Morocco by way of Constantine, Algiers and Oran. 1,500,000 tons of merchandise and 150,000 travellers enter its ports every year.

FRENCH WESTERN AFRICA.

Since 1626 France has possessed large territories in Africa, called the Colony of Senegal and Dependencies.

The vast possessions of France in Western Africa, since June 1895, have been under one central government the organization of which united (in 1904) a group of five colonies, each one ruled by a Lieutenant Governor who is under the Governor-General. They are (1) Senegal; (2) French Guinea; (3) The Ivory Coast; (4) Dahomey; (5) Upper Senegal and Niger (the colony of Soudan). To these must be added the political division of Mauritanie, ruled by a Government agent. Titdjilka is its chief city. The Governor-General is assisted by a council appointed by the Government. The seat of this liberal government is at Dakar. The general trade report is 42,000,000 francs. This pays the government expenses and the duties. Dakar has many large structures of public interest, built on made foundations. Its area is 5,600,000 square kilometres. The water-courses are dammed, and on the Ivory Coast and in Dahomey wharves have been built. The Senegal and the Niger are the two great rivers of the country. The climate is very variable and the heat, which reaches 45°, is exceedingly trying. It is inhabited by musulmans and many other races.

Senegal.—Senegal is under two different administrations: (1) that of the coast, where the inhabitants are French; (2) the Protectorate country. The principal city is St. Louis (24,000 inhabitants). The other important cities are Roufisque (20,000 inhabitants), the emporium for peanuts and the centre of business; Dakar (24,000 inhabitants), the centre of navigation; and Gorée, on the island of the same name. The total population is 1,200,000 inhabitants.

Trade has increased from 45,000,000 in 1894, to 100,000,000 francs in 1906. (60,000,000 imports, and 40,000,000 exports.) Of this amount the French importations do not reach 30,000,000. The products exported are chiefly peanuts, gums, india-rubber, almonds; also birds, feathers, and elephants' tusks. The railroad connects Dakar with the Niger.

Senegambia-Niger.—This government extends to Lake Tchad and to Tombouctou. The budget gives a little more than 6,000,000 francs. The principal cities are Kayes (15,000 inhabitants), 911 kilometres from St. Louis—the terminal of the railroad between Senegal and the Niger; Segou, the cotton city and the centre of the india rubber trade; Zinder 30,000 inhabitants. The capital will soon be transferred to Bammako. The cultivation of cotton is developing rapidly in this region.

Mauritanie.—This is a country for breeding cattle and sheep. Salt meats are exported. This territory was annexed to French Western Africa.

Guinea.—Its principal city is Konakry on Tourbo island, opposite the Loos islands, which were recently ceded to France by England. Business houses and stores are numerous. In the last 10 years commerce has increased from 10,000,000 to 35,000,000 francs. (18,000,000 exports; 17,000,000 imports.) The principal products are india rubber (which has increased from 3,000,000 to 12,000,000 francs); palmettos, peanuts, sesamun, hides and bananas.

The Ivory Coast.—The chief town is Bingerville, adjoining the new city of Abidjan, from which the railroad will soon be built as far as Kong (280 kilometres distant). The trade amounts to 10,000,000 francs imports, and 8,000,000 exports. From America is received lard and tobacco. The exports are oil, almonds, india rubber, mahogany and kola nuts. Coffee and cocoa are being cultivated. This colony, whose most important town was formerly Grand Bassam, dates from 1843.

Dahomey.—The seat of the government is at Porto-Novo. The railroad (built for 205 kilometres) will go as far as the Niger. Porto-Novo (76,000 inhabitants) is superseded by Cotonou, which is connected with it by an iron wharf 208 metres long. The products are the same as in the preceding colony. The imports amount to 12,000,000, and the exports to 10,000,000 francs. Great attention is being given to the cultivation of cotton. The natives live on Indian corn, manioc millet and rice.

CONGO.

The origin of the colony of French Congo dates back to 1843; it became a colony in 1881. The present state of Congo, with its dependences, comprises (1) the colony of Gabon; (2) the Middle Congo; (3) Oubanghi-Chari; (4) Tchad. It is governed by a Commissary-General who resides at Brazzaville, and also by a Lieutenant-Governor at Gabon. The general-domain was organized in 1899. Its products are the same as those of the preceding colonies. Trade amounts to 7,000,000 francs imports, and 10,000,000 francs exports.

THE SOMALIS COAST.

This territory was bought in 1858 and in 1862, and settled in 1883. The seat of the government was transferred to Djibouti, and in 1896 the colony took the name of the French Coast of Somalis. It is connected by cable with Perim and large steamers touch here. It is a protectorate. The principal exports are ivory, gold, hides and coffee, amounting to a trade of 11,000,000 francs exports and 8,000,000 francs imports.

The importance of Djibouti is the result of its railroad connection with Addis Abbaba, the capital of Ethiopia. It is the point of departure for caravans, and the products of the country. Djibouti has a population of 600 Europeans and 6,000 natives. Cheik-Said is a French possession, notwithstanding that the Turks have unlawfully placed a garrison there. The island of Perim has the advantage of being supplied with soft water. Its situation commands the entrance to the Red Sea.

MADAGASCAR.

The colonization of Madagascar by the French began in 1642, under Louis XIV. Napoleon III. made a treaty with the queen in 1862. The Hovas having neglected it, the French took the capital, 30 Sept. 1895. The island was declared a colony shortly after the insurrection of 1896-98. It is 2,500 leagues from France, and 150 leagues from Réunion. Its area is 580,000 square kilometres. Although it is as large as France, Belgium and Holland together, it has only 2,500,000 inhabitants, including 850,000 Hovas in the interior, 500,000 Betsilleos in the South, and the Sakalaves in the East. The coast is unhealthy, but thus far the high plateaux have been salubrious.

The annual report amounts to 24,000,000 francs. In 1895 the imports were 14,000,000 and the exports 4,000,000 francs. These figures have increased to 38,500,000 francs and more than 28,000,000, making a total of 65,000,000. The principal exports are india rubber, raffia, cattle, vanilla, cloves, gum, cocoa and coffee. There are important cotton plantations in the west. The native industries consist of the making of rope-bands, lace, and straw hats, and there are many other enterprises. The railroad from Tananarive to Tamatave is in course of construction. Its terminus is connected with the sea by the means of the Pagalanes canal. The principal cities are Tananarive (50,000 inhabitants), Tamatave, the chief port on the east coast, and Majunga on the west coast.

The magnificent roadstead of Diego-Suarez serves as a base for naval operations. The colonization has been directed by General Gallieni, who is an organizer, and ruler, as well as an energetic military leader.

THE COMORES.

Mayotte.—The archipelago of the Comores consists of four islands. Mayotte, the seat of government, has been a colony since 1843; Anjouan has been under our protection since 1886, and the Large Comore and Moheli since 1887. All these belong to Madagascar. The area is 2,124 kilometres. The population consists of 50,000 Musalmens. Mayotte was devastated by a cyclone in 1899. Anjouan has prospered thanks to its vanilla, coffee, cocoa and cotton. Its trade amounts to 1,800,000 francs imports, and 2,400,000 francs exports.

GUADELOUPE.

Guadeloupe has been a French colony since 1674, and suffered vicissitudes in French continental wars. It consists of two islands; Basse Terre, and Grande Terre, separated from it by a short arm of the sea; Basse Terre has but one port (of the same name); Grande Terre has five ports, the principal one of which is Pointe à Pitre. Its trade amounts to 17,000,000 francs imports, and as much in exports, which consist in sugar, rum, coffee, cocoa, vanilla and logwood. Population 140,000. Its dependencies are the islands of Désirade, Petite Terre, Sainte, Marie Galante, two-thirds of St. Martin, and St. Bartholomew.

MARTINIQUE.

Martinique has been a French colony since 1664. The island is 70 kilometres long and 31 wide. It is volcanic, the same as Guadeloupe, and the eruption of Mt. Pelée in 1902 destroyed the city of St. Pierre which had 25,000 inhabitants. The population of Fort de France, the principal city, is 15,000. Its trade amounts to 20,400,000 francs imports, and 15,000,000 exports—about the same as Guadeloupe. The colony has recovered from the disaster, and is resuming its business enterprises.

GUYANA.

Guyana is one of the oldest French colonies It lies between Dutch Guiana and Brazil. It dates from 1674 and it only has 33,000 inhabitants, 12,600 of whom are in Cayenne, the principal city. Notwithstanding that gold has been exported since 1855, ebony forms its chief export. The exports are valued at 13,000,000; the imports amount to 10,500,000 francs. Besides its gold deposits, the country has magnificent forests. It has been neglected because criminals have been transported there. However, it possesses the same elements of growth as its neighbors, British Guiana and Dutch Guiana.

ST. PIERRE AND MIQUELON.

The first French settlements were made there in 1604. These islands were taken from France in 1713 (Treaty of Utrecht) restored in 1763 (Treaty of Paris), and ruined during the war of American Independence. The English banished the inhabitants in 1778. The treaty of 1783 gave France jurisdiction over them. They have only 6,500 inhabitants. The imports amount to 8,000,000, and exports to 10,000,000 francs, and consist of codfish, oil, lobsters and salmon. The islands are the chief fishing station for French vessels on the shores of the Atlantic.

RÉUNION.

This colony dates from 1671. It used to be called Bourbon. Its climate is excellent. It is 71 kilometres long, 51 wide, and has an area of 2,600 square kilometres. Its hot springs of Salazie, Cilaos and Massate are celebrated. In the mountains the temperature is sometimes below zero. The summers are very warm. The island was ravaged by cyclones in 1904 and 1905. There are two ports: St. Denis, the principal one (38,000 inhabitants), and St. Pierre (27,000 inhabitants). Its report is 4,500,000. Imports, 22,000,000 and exports, 20,000,000 francs, consisting of sugar, coffee, vanilla, rum, tapioca and tobacco. The spice trees of the Sonde Islands were introduced there in 1770 by the commissary, Poivre. Its nearness to Madagascar also gives it an outlet for trade. It is thoroughly French. The French of Maurice—its neighbor which has become English—still speak their own language.

NEW CALEDONIA AND NEW HEBRIDES.

France took possession of New Caledonia in 1853. Its dependencies are the Isles of Pines, Loyalty and Huon; but the archipelago of New Hebrides—which is 30 hours' distant from it by steamer, and four days from Sydney—was (February 1907) the subject of a convention which established joint rule with England. The area of New Caledonia is 2,100,000 hectares, of which one-half is mining land, 500,000 hectares of pasturage and lands under cultivation; the remainder is forest. The annual report amounts to 4,000,000 francs. The climate is excellent and favorable for colonization. In August, which is its coolest season, the temperature is as low as 13°. The population is 13,000 colonists, more than 10,000 convicts, and 30,000 natives. No convicts have been sent there since the beginning of this century. The colony is connected with Brisbane, Australia, by a line of steamers and a cable. Its trade amounts to 21,800,000 francs, of which 10,800,000 are imports, and 11,000,000 exports. The latter are the finest quality of coffee, valuable woods, and especially minerals—nickel 130,000 tons; chrome, 45,000; cobalt, 8,000. Blast furnaces are about to be constructed, and the coal and copper mines are being worked.

This colony lies on the route to Australia, San Francisco and Panama, on the one side, and on the other it lies on the route from Panama to Indo-China, and China-Seas. Its vast harbor of Noumea must consequently become the chief port of the Pacific.

New Hebrides.—The New Hebrides, in the same archipelago, comprises 70 islands, whose area is 1,600,000 hectares. The French possess 950,000, and the English 235,000. Agriculture and commerce are in the hands of 400 French colonists, against 100 English—70 of these are only Wesleyan missionaries. These very fertile islands are the granary of the Caledonia islands, a mining country. They are inhabited by 70,000 Canaques and furnish laborers for the same archipelago. It is contended that France has much more right to these islands than England; but Australia wanted them bestowed upon her and the convention of February 1907 established a French-English protectorate over them. It is thought that this *modus vivendi* is only temporary. The situation of the archipelago will assume great importance when the Panama canal is opened.

OCEANICA.

Tahiti.—The colony of Tahiti comprises the archipelago of the Society Isles, the Marquises, the Tuamatou, the Gambiers, the Tubuai, and, in the centre of the Pacific the small island of Clipperton, the advance sentinal of Panama. It is 1,200 leagues from the main land, and has belonged to France since 1842.

Tahiti's climate is charming, and the people are very kindly. It has 30,000 inhabitants. Trade amounts to 4,000,000 francs imports, of which 1,700,000 come from the United States, 665,000 from New Zealand, and 600,000 from France. The exports amount to 4,700,000 francs, of which 80,000 are sent to France and 200,000 to foreign ports. The exports are copra, vanilla, cotton, cocoanuts, oranges, and mother-of-pearl. The colony has no maritime or postal connection with the metropolis. The transportation of mail and passengers, and of most all the merchandise is done by the Union Steamship Company, which connects Tahiti with New Zealand; and by the Ocean Steamship Company, which connects it with San Francisco. These two companies are subsidized by the colony and by France. It is thought that the postal service will be established when the Panama canal is opened.

INDO-CHINA.

Indo-China is the most important of the French colonies. It is 14,000 kilometres distant from France. It is divided into five parts: Cochin-China, settled in 1858; the Protectorate of Cambodia, in 1853; Annam, in 1874; Tonkin, in 1885; Laos (direct possession), in 1893; and Quang Tcheou (off the coast of China), in 1898. The area is 712,000 square kilometres, and there is a population of 23,000,000 of very diverse nationalities—Annamites (three-quarters of the inhabitants); Cambodians and Chinese; Laotians, 132,000 Kiams and 800,000 Mais or Khas (savage tribes). 18,000 of the inhabitants are French. The annular expenditures are 105,000,000 francs, 78,000,000 of which are for the general budget and 35,000,000 for the six countries. Its foreign commerce, which was 205,000,000 francs in 1897, has been 400,000,000 francs since 1904. Nearly 2,000 steamers of 2,250,000 tons and 3,300 of 50,000 tons frequent its ports. American steamers come here for rice. A network of railroads, of more than 2,000 kilometres, is being built—valued at 266,000,000 francs. The public works and the domestic affairs of the colony are progressing rapidly. The principal exports are rice, tea and coal. This colony has not been forced into union, it was naturally united.

Cochin-China.—The area of Cochin-China is 57,600 square kilometres; population 3,000,000, of which 5,000 are French. Saigon is 40 miles from the sea, and one of the most beautiful cities in the far East. Decortications are prepared for three times as much rice as they have. The rice export in 1867 was 14,000 tons; it is now a million. Other exports are pepper, 3,000 tons; cotton, sugar and copra. Cho-len on the outskirts of Saigon, is the most important centre of native and Chinese trade. Tonkin has an area of 174,560 kilometres, and 10,000,000 inhabitants, 4,000 of whom are French. The climate is more supportable than Cochin-China. The chief cities are: Hanoi, 150,000 inhabitants; Haiphong, 15,000, and Namdinh—the commercial, artistic and literary centre—50,000.

Annam-Hué, the capital of the kingdom, and the seat of the French Legation, has 40,000 inhabitants. The area of Annam is 133,760 square kilometres; population 6,000,000. The vicinity of the sea renders the climate very agreeable to Europeans. The chief cities, after Hué, are Tourane, with its mines of coal, copper and gold, and its tea plantations; and Fai-fo, an emporium for native trade, which exports 2,000,000 francs worth of cinnamon to China.

Cambodia.—The area of this colony is 200,000 square kilometres; population 1,800,000, of which 600 are Europeans. The climate is very warm. The products are rice, cotton, silk, pepper, gums, cardamon, sugar, tobacco and the fish caught and salted by the 30,000 fishermen of the great lakes. Cambogia has only one small port—Kampot. The capital is Phrompenh, 60,000 inhabitants. It is a great river port at which steamers stop all the year round.

Laos.—The area of Laos is 300,000 square kilometres; population 1,000,000, of which 500,000 are Thais; 400,000 Khas; 5,000 Khmers; 2,000 Annamites; 300 Chinese; and 150 Europeans. The two capitals are Luang-prabang, 25,000 inhabitants, situated in the northern part; and Vien-charh in the centre Its products are cardamon, benzoin, india rubber, gum-lac, tin. Its gold, iron, salt, and gem mines are to be worked.

Kouang Cheou Wan.—Its area is 1,000 kilometres; population 160,000. The chief town and most important port is Pointe Nivet. Its products are the same as in the southern part of China. It is a free port frequented by 210 ships. The total commerce amounts to 8,600,000 francs. This territory will be connected with Tonkin by railroad. The colony is a base for extensive business transactions, and its commercial activity will extend to the countries which consume rice —those bordering the China seas and the Pacific.

INDIA.

French settlements in India, the chief cities of which are Pondichery, Chandernagore, Yanaon, Karikal and Mahé, are all that remain to us of the immense empire of Dupleix, which has become the Empire of British India. Area 51,000 hectares; population 175,000. The trade amounts to 9,300,000 francs imports, and 28,000,000 exports, consisting of blue-cotton cloth, peanuts, coffee, saffron, tamarins and salt fish. The cities are connected with the railroads of India, and a line of French steamers runs to Pondichery. The population consists of 125,000 natives and 1,000 creoles.

CANADA.

From the fact that French emigration is only 20,000 per year, we must not conclude that the French do not colonize. They know how to please the natives, and the survival of the French spirit in the colonies we have lost is proved by the fact that 2,000,000 Canadians still speak the French language.

LOUISIANA.

There are 1,500,000 French in Louisiana in the United States, and 500,000 in the Antilles, no longer French possessions; as Haiti, half of which France once owned; and there are also many French emigrants in the republics of South America. The following tables show (1) the value of the commerce of the French Colonies; (2) their respective value in economics; and (3) their size, population, expenditures, and commerce (both imports and exports).

RECAPITULATION OF THE ECONOMIC VALUES OF EACH COLONY (CAPITAL INVOLVED).

	Francs.
Réunion	100,000,000
Guadeloupe	138,000,000
Martinique	100,000,000
Guiana	80,885,000
The Indies	63,241,000
New Caledonia	114,464,000
French Settlements in Oceanica	11,822,000
Saint-Pierre and Miguelon	21,244,000
Indo-China	544,709,000
Western Africa	223,643,000
Madagascar	190,044,000
Comores	13,483,000
French Coast of Somalis	64,300,000
Congo (Capital of the Societies)	60,490,000
Total	1,726,325,000

Thus the increase in value resulting from industrial and commercial enterprises and the investment of capital amounted, in 1907, to nearly 2,000,000,000 francs.

RESUMÉ.

From the above data it can be seen that French domain is of vast extent and is rapidly increasing in value. Its internal affairs, and its business enterprises show a steadily increasing prosperity, and the future outlook is full of hope and involves great responsibility.

M. CHARLES LEMIRE,
Conseiller du Commerce Exterieur.

France, Isle of. See MAURITIUS.

Francesca da Rimini. See DA RIMINI, FRANCESCA.

Francesco di Paula, frän-chĕs'kō dē pō'lä, or **Saint Francis of Paola,** Italian monk: b. Paula or Paola, Calabria, 1416; d. Plessis-les-Tours 2 April 1507. At the age of 13 he was the inmate of a Franciscan convent; and at 19 retired to a cave where he inflicted on himself every species of self-mortification. The fame of his piety having attracted to his cell several emulators of his austere life, he obtained permission to erect a convent, and the new community received from Pope Sixtus IV. the title of the Hermits of St. Francis of Assisi; but the title was changed by Alexander VI. to Minim-Hermits of St. Francis of Paola. The founder established numerous communities in Italy, Sicily, France, Spain, and Germany, but the Minims were never settled in Great Britain or Ireland. To the usual conventual vows, Francesco added one of the most rigorous abstinence — flesh, eggs, cheese, and milk being strictly forbidden the entire year, except in illness. In Spain they were called the Brothers of Victory, in commemoration of the deliverance of Malaga from the Moors. Twelve years after his death he was canonized by Leo X., and the Roman Catholic Church celebrates his festival on 2 April.

Franchetti, frän-chĕt'tē, BARON **Alberto,** Italian composer: b. Turin 1860. He was a pupil in Coccon and Magi, studied at Dresden and Munich, and in 1888 produced his most successful opera ‹Asraele.›

Fran'chise, in law, a right belonging to a subject of exercising a branch of the sovereign or government prerogative, either in virtue of a grant conferring such right, or by prescription, which always presupposes such a grant. The corporate franchise, that is, the right of being incorporated, and of holding fairs, ferries, etc., are among the most important franchises, which are, however, almost infinite. In politics it is the right of voting upon proposed legislative measures, where such measures are accepted or rejected by the people generally; or for representatives to a legislative assembly (the parliamentary franchise) or to a municipal body.

Francia, frän'chä, easel name of FRANCESCO DI MARCO DI GIACOMO RAIBOLINI, Italian painter: b. Bologna 1456; d. there 5 Jan. 1517. He assumed his name of Francia from that of the goldsmith under whom he began his art studies. He was a pupil in painting of the Ferrarese, Lorenzo Costa, and shows the influence of his master's style. He painted portraits and history, his greatest work being the Bentivoglis altarpiece, in the Church of San Giacomo Maggiore, Bologna.

Francia, José Gaspar Tomas Rodriguez da, hō-sā' gäs'pär tō'mäs rō-drē'gēs frän'sē-ä, Paraguayan dictator: b. Asunçion 1756; d. there 20 Sept. 1840. He was sent to the University of Cordova, with a view to entering the Church; but his plans underwent a change, and on his return to his native town with the degree of doctor of laws, he began his public career as a barrister. His high reputation for learning, but still more for honesty and independence, procured him an extensive practice; and he devoted himself to legal pursuits for 30 years. In 1811, when Paraguay threw off the Spanish yoke, he became secretary of the junta appointed by congress. In 1814 he was appointed dictator for three years, and in 1817 he was continued in authority for life. No sooner had he reached the goal for which he had been striving than he began to display the utmost tyranny in his administration. He was kindly disposed toward foreigners, till they excited his jealousy by the culture of Paraguay tea, of which he made a state monopoly. After everything had been placed completely at his beck he seemed, in 1824, disposed to return to milder courses, but a new attack of his constitutional malady led him again to a renewal of his tyrannical proceedings; but as Paraguay had improved under his government, and the inhabitants had become reconciled to his tyranny, he was able to continue his system till his death.

Franciabigio, frän-chä-bē'jō, (the easel name of FRANCESCO DI CRISTOFANO BIGI), Italian painter: b. Florence 1482; d. there 24 Jan. 1525. He was a pupil of Albertinelli, where he met and made a friend of Andrea del Sarto. The two artists painted in collaboration the frescoes in the Santa Annunziata Church at Florence. In these paintings the influence of del Sarto is very apparent, as well as in the ‹Last Supper,› which Franciabigio painted in the refectory of San Giovanni, and the oil painting at Dresden, ‹David and Bathsheba.› He has left many excellent portraits, one of which is in the Berlin Museum.

Fran'cillon, Robert Edward, English novelist: b. Gloucester, England, 25 March 1841. He was educated at Trinity Hall, Cambridge. He was admitted to the bar in 1864 and was on the staff of the London *Globe* 1872-94. His novels are: ‹Earl's Dene›; ‹Pearl and Emerald› (1872); ‹Olympia›; ‹Strange Waters›; ‹Zelda's Fortune›; ‹A Real Queen›; ‹Queen Cophetua› (1880); ‹Under Slieve-Ban› (1881); ‹King or Knave› (1888); ‹A Dog and his Shadow›; ‹Jack Doyle's Daughter›; ‹Ropes of Sand›; ‹Gods and Heroes›; etc.

Francis I., king of France: b. Cognac, France, 12 Sept. 1494; d. Rambouillet 31 March 1547. He succeeded to the throne in 1515, on the death of Louis XII., who died without male issue. As grandson of Valentino of Milan, he put himself at the head of an army to assert his right over the Milanese. The Swiss, who opposed him in his entry into the duchy, were defeated at Marignano (or Melegnano), and Milan fell immediately after this victory. After a short war with England, the famous interview between Henry VIII. and Francis took place, in 1520, in Flanders, which, from the magnificence displayed on the occasion, was called The Field of the Cloth of Gold (q. v.). In the same year, Charles V. of Spain having inherited the empire after the death of Maximilian, Francis laid claim to the imperial dignity and declared war against his rival. In this struggle, however, he met with nothing but reverses. After the defeat of Marshal Lautrec at Bicoca, in 1522, the retreat of Bonnivet, and Bayard's death, Francis was himself, in 1525, beaten at Pavia, and taken prisoner. The fight had been a fierce one, and the king wrote to his mother, «All is lost, except honor.» Led captive into

Spain, he recovered his liberty only at the cost of an onerous treaty, signed at Madrid in 1526; but which Francis subsequently declared null and void. He immediately recommenced war in Italy, met with fresh defeats, and concluded a second treaty at Cambrai in 1529. He once more invaded Italy, in 1536, and, after various successes, consented to a definite arrangement at Crespi, in 1544, by which the French were excluded from Italy, though Milan was given to the Duke of Orleans, the second son of Francis. Francis was a friend to arts and literature, which flourished during his reign; and he was called the "Father of Letters." Justice, also, began to be better administered in his reign. He founded the Royal College of France, the Royal Library, and built several palaces. He was succeeded by his son, Henry II.

Francis II., king of France, son of Henry II. and Catharine of Medici: b. Fontainebleau 19 Jan. 1544; d. Orleans 5 Dec. 1560. He ascended the throne on the death of his father, 10 July 1559. The year previous he had married Mary Stuart, only child of James V., king of Scotland. During his short reign of 17 months were sown the seeds of those evils which afterward desolated France. The uncles of his wife, Francis, Duke of Guise, and the Cardinal of Lorraine, held the reins of government. The latter stood at the head of the clergy, and had charge of the finances. The former had the direction of military affairs; and both used their power solely as a means of gratifying their pride and avarice. Antony of Bourbon, king of Navarre, and his brother Louis, Prince of Condé, provoked that two strangers should govern the kingdom while the princes of the blood were removed from the administration, united with the Calvinists to overthrow the power of the Guises, the protectors of the Catholics. Ambition was the cause of the quarrel, religion the pretext, and the conspiracy of Amboise formed among the French nobility, especially the Calvinists, with the object of removing the king from the influence of the Guises, the first symptom of the civil war. The war broke out in March 1560. In December of the same year Francis died, leaving the kingdom loaded with debt, and a prey to all the miseries of civil war.

Francis I., emperor of Germany: b. 8 Dec. 1708; d. Innspruck 18 Aug. 1765. He was the son of Leopold, Duke of Lorraine. He inherited this duchy from his father in 1729, and six years afterward exchanged it for that of Tuscany, which the death of the last of the Medicis had rendered vacant. In 1736 he married Maria Theresa, the daughter of the Emperor Charles VI. On the death of the latter, he disputed the imperial dignity with the elector of Bavaria, whom France supported, and who took the name of Charles VII.; he was, however, defeated, and Francis reigned peaceably for 20 years. He had 16 children, among whom were Joseph II., who succeeded him, and the unfortunate Marie Antoinette. See Maria Theresa.

Francis II., emperor of Germany, and **I.** of Austria: b. Florence, Italy, 12 Feb. 1768; d. Vienna 2 March 1835. He succeeded his father, Leopold II., in 1792, as emperor of Germany, king of Bohemia, Hungary, etc. At the very commencement of his reign, he had to sustain a war against France, in which he was defeated, and was, in 1797, obliged to sign the treaty of Campo Formio, which deprived him of the Netherlands and Lombardy. Another war taking place with the same power, he was not more fortunate than in the first, and was beaten at Marengo, and lost, by the Treaty of Lunéville, in 1801, all his possessions on the Rhine. In a third campaign, undertaken in 1805, the French were victorious over his armies at Elchingen, Ulm, and Austerlitz; and the Treaty of Presburg still further diminished his territory. Renouncing now the title of emperor of Germany, he took that of Austria, under the name of Francis I. He tried again the fate of battles in 1809; but the defeats of Eckmühl and Wagram led to the Peace of Schönbrunn, to cement which more strongly his daughter Maria Louisa was, in 1810, given to Napoleon I. Notwithstanding this alliance, however, he, in 1813, joined the coalition against his son-in-law and contributed considerably to his overthrow. The treaties of 1815 put him again in possession of the greater portion of his territory, and he reigned peaceably till his death.

Francis I., king of the Two Sicilies, son of Ferdinand I.: b. Naples 19 Aug. 1777; d. there 8 Dec. 1830. Twice during the lifetime of his father he carried on the government of the kingdom under the name of viceroy; first in 1812, when a constitution was granted to Sicily; and afterward in 1820, during the troubles which broke out in Naples and Palermo. He mounted the throne in 1825, and died 1830, without having achieved anything remarkable. He was succeeded by Ferdinand II.

Francis II. (Francesco d'Assisi Maria Leopold), king of the Two Sicilies: b. Naples 31 Jan. 1836; d. 27 Dec. 1894. He succeeded his father, Ferdinand II., in 1859, and attempted to carry out the monarch's policy. His dominions were invaded by Garibaldi in 1860 and Gaeta, his last stronghold, fell in 1861. Subsequently the deposed ruler lived in France in retirement, occasionally organizing abortive expeditions against the Italian kingdom.

Francis Joseph, Charles, emperor of Austria: b. Vienna 30 Aug. 1830. He became emperor 2 Dec. 1848, and found the empire shaken by internal dissensions; and his first step was to promise a free and constitutional government to the country. The course of events, however, compelled him to close the national assembly, and to assume absolute power. He centralized the governments of his heterogeneous nationalities at Vienna, and, aided by Herr Von Brück, inaugurated a series of fiscal and commercial reforms favorable to the interests of the middle classes. In 1853–4, the emperor endeavored, though in vain, to induce the Czar Nicholas to abandon his ambitious designs against Turkey, and further excited that autocrat's displeasure by refusing to assist Russia against the western powers, whose rulers also felt aggrieved because he resolved to remain neutral and declined to throw the weight of his name into their scale. The unwillingness of Austria to make common cause with the western powers has been severely punished, for had she joined the alliance against Russia in 1854, in all probability Louis Napoleon would not have crossed the Alps and dictated the Peace of Villafranca. It is, therefore, more than probable that her reluctance to act against Russia in that war was the cause of her losing Lombardy three years later. At Solferino the emperor gave proof of bravery amounting almost to rashness. In April 1854 he married the Princess Elizabeth Amalie Eugenie, daughter of the Duke Maximilian Joseph, and cousin, on her mother's side, to the king of Bavaria. The plenipotentiaries of Austria, Prussia, and Denmark, assembled at Vienna to consider the terms of a peace, 26 July 1864, which was concluded 30 October. The convention of Gastein signed 14 Aug. 1865, transferring the government of Schleswig to Prussia, and that of Holstein to Austria, was a few days after confirmed by the emperor and the king of Prussia at Salzburg. The emperor issued an important manifesto to his people, 20 September, in which he expressed very conciliatory intentions toward the peoples of Hungary and Croatia. At the beginning of 1866, the armaments against Prussia commenced, and an imperial order was issued 6 May, placing the whole army on a war footing, and concentrating the army of the north on the frontiers of Bohemia. In 1867, the emperor put an end to the hostilities of Hungary by re-establishing the constitution of that country; and on 8 June, he was crowned at Budapest as king of Hungary, with extraordinary pomp. In December of the same year, a new constitution, one of the most liberal of continental Europe, framed by the Reichsrath, was approved by the emperor, and promulgated as the fundamental law of the empire. His only son, Rudolf, committed suicide in 1889, and the emperor's nephew, the Archduke Francis Ferdinand, is heir-presumptive. See AUSTRIA.

Francis, David Rowland, American politician: b. Richmond, Ky., 1 Oct. 1850. He was graduated from Washington University, St. Louis, 1870, entered business and in 1877 established the firm of of Francis Brothers, grain merchants, St. Louis. He was mayor of St. Louis 1885–9, governor of Missouri 1889–93, secretary of the interior under President Cleveland 1896–7, and became president of the Louisiana Purchase Centennial Exposition in 1901.

Francis, Joseph, American inventor: b. Boston, Mass., 12 March 1801; d. Cooperstown, N. Y., 10 May 1893. He was the inventor of a number of life-boats and life-cars which came into general use and by means of which 200 persons were saved when the British ship Ayrshire was wrecked on the New Jersey coast in 1850. It is estimated that in four years as many as 2,150 lives were saved.

Francis, M. E. See BLUNDELL, MRS. FRANCIS.

Francis, SIR **Philip,** British statesman: b. Dublin 22 Oct. 1740; d. London 23 Dec. 1818. He is the best accredited of the candidates for authorship of the 'Junius' letters. He entered the civil service, and was rapidly advanced, owing partly to his abilities and partly to personal influence curiously accordant with partialities shown in the 'Letters.' Suddenly raised to the lofty position of one of the resident India council appointed by Parliament to control those affairs, he went out to India; spent his time there in a furious contest for supremacy with Warren Hastings; was finally vanquished, but achieved a terrible revenge after his return to England, by inciting Hastings' impeachment and coaching Burke; entered Parliament, prepared many pamphlets and made many speeches of much ability and unfailing acrimony. The 'Letters'— savage assaults on the heads of the party in power, up to George III. himself— appeared in the 'Public Advertiser' of London from 1867 to 1772; ceasing with the dispersion of the party faction most liked by Francis, and a year before his great promotion and his departure from England. The case for his authorship is effectively put in Macaulay's 'Essay on Warren Hastings.' See JUNIUS.

Francis of Assisi, ăs-sē'zē, **Saint,** Italian founder of religious order: b. Assisi, Umbria, Italy, 1182; d. Assisi 4 Oct. 1226. St. Francis of Assisi is the founder of the Friars Minor, who are usually styled Franciscans (q.v.). His family name was Bernardone. At baptism he was called John. Whether it was because his father, who was a merchant, was at the time largely engaged in French trade, or because of the saint's own familiarity with the French language, the name Francis eventually superseded that of John. As a youth he was remarkable for his ardent piety and the spotless purity of his life, but is reproached with a worldly vanity in dress which his wealth enabled him to indulge in. A change of heart came over him in consequence of a year's confinement as a prisoner of war; a serious illness helping the transformation. He began to dispose of his property for the purpose of repairing dilapidated churches. Irritated by his extravagance his father treated him with the greatest cruelty; the trouble ending by the saint's abandonment of everything, even his worldly apparel, and he assumed the dress of a common laborer. His zeal for church restorations grew in intensity, and being no longer able to devote his own patrimony to the work he obtained the necessary means by begging; he himself laboring at the buildings with his own hands. His affection was lavished also on the poor and especially upon lepers. He lived in the extremest poverty, practised the greatest austerities, and for a time was looked upon as a madman. Distinguished and learned men, however, began to associate with him and follow his way of life. Though not a priest (and he never became one) he began to preach everywhere on the necessity of penance. As those were the days in which Barbarossa was raging against the Church, both religion and morality needed reformation, and the preacher was eagerly listened to by all classes. When the number of his followers increased, the desire to institute a new religious order developed, and for that purpose he betook himself to Rome, but Innocent III., then sovereign pontiff, treated the proposal with indignation. Francis persevered, and the request was granted. The new community, known first as the Preachers of Penance, increased with astonishing rapidity, and at the first general chapter more than 5,000 friars assembled; some from the humble classes of life, others already famous in Church and state. The foundation of the order coincided with the great Lateran Council, the spirit of which was against the formation of any new religious order. In spite of this, however, there seemed to be a tacit consent to allow the new movement to proceed. It was when Pope Honorius finally gave the necessary authorization that Francis met the Spanish canon Dominic, who was in Rome to found his own Order of Preachers, commonly known as Dominicans (q.v.). The two saints met in church and instinctively recognized each other, becoming immediately most devoted friends. The visions and miracles reported of Francis are bewildering in their number and character. In the hope of martyrdom he made several attempts to preach the gospel to the Mohammedans. His prayer and austerities were continued, his ecstasies frequent, and while on Mt. Alverno he received on his person what are known as the *stigmata*, namely, bleeding wounds on the hands, feet, and side, corresponding to the marks on the crucified body of the Saviour. Wherever he went he was honored as a saint; and his preaching was irresistible in its pathetic and stirring appeals to repentance. The rule of life he laid down for his followers was based on the strictest poverty, that is, no property, and dependence on the alms of the faithful. This extreme rigor almost immediately brought dissension in the order. Parties were formed, and the Friar General Elias, who had been appointed by Francis, was its bitterest opponent, going so far as to leave the order and to side with Barbarossa, who was then in open warfare with the Church. Nevertheless, the friars continued to increase in number and to spread everywhere, preaching the gospel and carrying the faith into distant countries. Besides his order for men, he established another for women, commonly known as the Poor Clares, so called from Saint Clare, the first superior. There is still another section called the Third Order of Saint Francis, for men and women living in the world, who follow a mitigated and adapted form of the rule of the friars. All three have given a vast number of saints and scholars to the Church. Francis died at the age of 45, 19 years after the establishment of his order. The extreme beauty, simplicity, and amiability, and perhaps the poetry, of the saint's character, but especially his love of created nature, have had the effect in our own days of developing a singular cult for him on the part of many outside the Catholic Church. The movement was started by Paul Sabatier, a French Calvinist minister, and Franciscan societies for the study of the life of the saint and of everything connected with him have been established in several countries of Europe.

THOMAS J. CAMPBELL, S.J.

Francis de Sales, sālz, Fr. săl, **Saint**, French prelate, founder of the Order of Visitation: b. of a noble Savoyard family, in the château of Sales, near Geneva, 21 Aug. 1567; d. Lyons 28 Dec. 1622. He was educated by the Jesuits at Paris, studied law at Padua, and having a strong bent to theology and a religious life, entered the Church. Earnest and successful as a preacher, he was sent in 1594 with his kinsman, Louis de Sales, to preach in the duchy of Chablais, and bring back, if possible, to the Roman Catholic Church the followers of Calvin. He had a large measure of success. His conferences with Théodore de Bèze, Calvin's successor, at Geneva, were, however, without result. He went to Paris in 1602, preached there with great success, and steadily refused the offers of dignities made by the French king. The same year he was appointed bishop of Geneva, and taking St. Charles Borromeo as his model, applied himself zealously to the reform of the diocese and its monasteries. He was disinterested and free from worldly ambition, and declined the offer of a cardinal's hat and the renewed invitations of the king of France. In 1610 he founded the Order of the Visitation, of which the first directress was his friend, Madame de Chantal. His best known works are the 'Introduction to a Devout Life,' which has been translated into many languages, and 'A Treatise on the Love of God.' He was canonized by Pope Alexander VII. in 1665. See 'Life' by Camus.

Francis Xavier, zăv'ĭ-ėr, Fr. ksăv-ē-ā, **Saint**, Spanish Jesuit missionary: b. Castle of Xavier, Navarre, 7 April 1506; d. Island of Sancian 2 Dec. 1552. Saint Francis Xavier was born in Spain, of one of the noblest families of the kingdom of Navarre. After the usual collegiate studies in his own country, he went to Paris for a course of philosophy in the University. In spite of his extreme youth, his extraordinary ability secured for him a professorship in the affiliated College of Beauvais. It was in Paris that he met the man who shaped his destinies, Ignatius of Loyola (q.v.). Abandoning his professorship, he took up the study of theology, practised the rudest austerities, bound himself to a life of evangelical poverty, chastity, and obedience, and with Ignatius and five other companions established what is known as the Society of Jesus.

The original purpose of this organization was to evangelize Christians living in the Mohammedan countries of the East. Failing in that, they offered themselves to the Pope and were employed by him in most responsible trusts in various parts of Europe, which, however, they combined with labor in pest houses, prisons, and among the abandoned poor. A demand coming from John III. of Portugal for 10 missionaries to evangelize the new Portuguese possessions in India, Francis Xavier was chosen, but went alone, invested, however, with the dignity of Apostolic Nuncio, a dignity which he sedulously kept out of sight.

The day after the command was given to go he left Rome for Lisbon, making the journey on foot, preaching and teaching on the way. In Portugal his influence was so instantaneous and so great that the king purposed to keep him in his dominions. But nevertheless Xavier set sail for the East, 7 April 1541, having refused even to see his own relatives before leaving. The journey meant more than a year of great sufferings, and he reached Goa only on 6 May 1542. The ignorance and immorality which prevailed there were deplorable and a complete and immediate revolution in conditions followed his arrival.

Then began his series of amazing apostolic journeys. They can only be appreciated by recalling the methods of travel of those days: the perilous character of the seas through which he continually sailed, and the savage or barbarous nature of the people he had to evangelize. From Goa he went around Cape Comorin and Ceylon, then back to Goa again, then through every principality of Hindustan, off through the scattered islands of the coasts, until he reached the distant Moluccas; establishing missions everywhere, and managing all the complicated and multiplied works which necessarily resulted. The story of his life is simply a series of surprising evangelical conquests, bringing thousands to Christianity by the efficacy of his preaching, the prodigies he wrought, and the extraordinary sanctity of his life.

On 15 Aug. 1549 he reached Japan. He remained there only two years and four months, but succeeded in penetrating almost all the little kingdoms into which the country was then divided; breaking down the opposition of the Bonzes who were the chief enemies of the Gospel, winning vast numbers to the faith, and establishing his followers in the favor of both rulers and people. The sway which he exerted over the Japanese mind may be inferred from the reverence with which he is still regarded there. The thoroughness with which he and his successors taught Christianity is evidenced by the fact that 25,000 Catholics were found in Japan after three centuries of persecution. They had handed down the faith from father to son without any ecclesiastical ministrations.

To obtain laborers for this new field he returned to Goa in 1551. We then find him venturing on a new project, attempting to win China to Christianity. Its conversion he thought essential for the maintenance of the faith both of India and Japan; for the corrupting influences in both those places he considered to be largely due to their relationship with China. He never reached that country but died on the Island of Sancian, about six leagues from Canton, being only 46 years of age. This last fatal voyage had lasted nine months.

His entire apostolate in the East extended over only 10 years, but he is said to have planted the faith in 52 kingdoms, preached the Gospel through 9,000 miles of territory, and baptized more than 1,000,000 persons. Fifty years after his death Pope Paul V. by a bull, dated 25 Oct. 1605, declared him blessed, and, 16 years subsequently, Gregory XV. canonized him, but on account of the pontiff's death, which occurred just at that time, the bull of canonization was issued by Urban VIII. on 6 Aug. 1623. He is honored in the Church on 3 December and is usually styled "the Apostle of the Indies." The devotion to him is universal and countless churches are erected under his invocation. His relics are still preserved in Goa, and in 1859 the body was found to be incorrupt.

Thomas J. Campbell, S.J.

Francis'cans, the designation borne by the members of the three great religious orders founded in the 13th century by St. Francis of Assisi. The first of these orders is that of the Friars Minor, known as the Greyfriars, and in France as the Cordeliers. The second order is that of the Poor Clares, called in Italian *Povere Donne* (Poor Ladies), and in France the Clarisses. The third order is that of Penance, or Tertiaries.

1. Francis, keenly alive to the evils which in his day seemed to threaten the very existence of the Church and society, strove to counteract their baneful influence by establishing an order, the members of which were to observe the most absolute poverty, and to be devoted to the service of the Church. The goal which he aimed at was to reproduce the ideal of the divine life on earth, therefore neither he nor his were to possess anything temporal, but were to go about doing good and preaching to all the world the kingdom of heaven. A little band of disciples to the number of seven, aglow with enthusiasm, gathered around the saint, and the little chapel of Sta. Maria degli Angeli, near Assisi, which he called Portiuncula, "the little portion, or inheritance," was the place where the order was first planned. It was truly a humble origin, an insignificant beginning, but Francis had a presentiment of the future world-wide extension of his order. In 1210 he obtained from Innocent III. a verbal approbation of the rule he had drawn up for it. Forthwith it appeared how accurately he had gauged the wants of his age, for his order sprang at a bound into popular favor. So rapid was its growth that 10 years afterward at a chapter held near Assisi, more than 5,000 of his religious assembled, and not half a century had elapsed when they counted missionaries in every known country, as may be learned from a bull of Alexander IV. in 1258. In 1260, when a chapter presided over by St. Bonaventure was held at Narbonne, the order had 1,400 houses. At the dissolution of the monasteries in England there were 65 houses of Franciscans, and even in 1680, in spite of severe losses in Protestant countries, the order numbered 100,000 members. The order is ruled by a general minister, who, with his council or *definitorium*, resides in Rome. It is divided into provinces to govern which provincials are elected. Each province is composed of a certain number of houses or convents, whose superiors are termed guardians.

Owing to the absolute nature of the poverty prescribed by the second rule drawn up for the first order and approved by Honorius III. in 1223, some of St. Francis' immediate followers showed tendencies inimical to it even in the saint's lifetime. After his death these tendencies became more marked, and were covertly connived at and effectively encouraged by the second minister-general, Elias of Cortona. This was the rift in the lute which widened as time went on. Some zealous upholders of the purity of the rule, such as St. Anthony of Padua, Adam de Marisco, Cæsar of Spires, protested against all innovations, and labored strenuously to maintain intact their sacred inheritance, receiving the distinctive name of Cesarines, but eventually returning to the body of the order in 1256. Other reforms were initiated, such as that of Peter of Maccerata, 1294; that of Philip of Majorca, 1308; that of John of Vallées, 1336; and others. They met with varying success, until in 1415 a final split took place, one section of the order adopting the mitigations which had been introduced in the matter of poverty, this being the bone of contention all through. They became known as the Conventuals, while the members of the other section were called Observants, as observing faithfully the Franciscan traditions. These latter still adhere strictly to the original austerity of their rule. St. Bernardine of Sienna, St. John Capistran, and St. James de la Marcha were mainly instrumental in promoting the interests of the Observance. In 1517 Leo X. issued his famous bull, *Ite et vos in vineam meam,* decreeing that a general minister of the whole order was to be chosen from among the Observants, and that the Conventuals were to elect a master-general. The Observants, however, did not satisfy the zeal of some, and thus we find certain groups, such as the Reformati, originating in Italy; the Alcantarines, or those who follow the reform of St. Peter of Alcantara, in Spain; and the Recollects.

There were now the two great families of the first order, the Observants and the Conventuals, these latter being governed, as said above, by a master-general, and notwithstanding their dispensations in regard to poverty, they have always rendered important services to the Church. The great Pope Sixtus V. was himself a Conventual.

In 1525 there arose a third family, known as the Capuchins (q.v.).

The Franciscans did not devote themselves exclusively to the apostolic life. From the first they took an active and leading part in the study of Holy Scripture and in all the branches of sacred and secular learning. They have filled with honor the first chairs in the most celebrated universities. Such great names occur among them as Alexander of Hales, St. Bonaventure ("the Seraphic Doctor"), Blessed John Duns Scotus, called "the Subtle Doctor," who as defender of the Immaculate Conception became the leader of the Franciscan school, Francis Mayronis, and Nicholas de Lyre. In England during the centuries immediately preceding the Reformation, there were 67 friars professors at Oxford and 73 at Cambridge, among them being Adam de Marisco, Duns Scotus, Roger Bacon, the pioneer of the modern discoveries in the physical sciences. Thomas de Celano, who wrote 'Dies Iræ,' and Jacopone da Todi, author of 'Stabat Mater,' were Franciscans. Nuncios, legates, archbishops, 50 cardinals, and 5 popes have been chosen from among the Franciscans.

The relations of the Franciscans with America began with its very discovery. Father Juan Perez, guardian of the Franciscan monastery at La Rabida, the adviser and personal friend of Columbus, with several companions, accompanied the discoverer in 1493. The first convent was erected for them at what is now the city of Santo Domingo, on Haiti; another arose at La Vega, on the same island. Connected with these convents were the first schools in the western hemisphere.

Owing to the enthusiasm among the religious in Spain, and to the docility of the Indians, the order spread so rapidly in the West Indies that King Ferdinand found it advisable to issue a decree forbidding the erection of a new convent except at a distance of at least five leagues from one already existing. In 1505, only 13 years after the discovery, there was a sufficient number of convents to form a province, under the name of Holy Cross. The first diocese to be erected was Santo Domingo, in 1504; its first bishop was Father Juan de Padilla, a Franciscan.

After the Spaniards had set foot on the mainland, the king, ever anxious for the spiritual welfare of the aborigines, sent over a great number of friars under the leadership of Father Juan de Quevedo, who was appointed bishop of Darien, the first bishop on the American continent. The Franciscans entered Venezuela in 1508, Brazil in 1519; in 1535 they were able to form a province in Peru, whence were founded the missions farther south in the Andes and Pampas. Saint Francis Solanus, called the Apostle of Peru on account of his extraordinary missionary labors, evangelized these regions; he died at Lima in 1610.

In 1521, if not before, the first Franciscans came to Mexico. Together with 12 friars known as the Twelve Apostles of Mexico, there labored here from 1533 to 1572 the famous Brother Gante. He wrote a catechism in the Aztec language, erected over 100 churches, and with one companion frequently baptized 8,000 Indians in one day. Many schools were erected, in which often as many as 600 and 800 boys received an elementary education. Owing to their stainless lives, abstinences, and contempt for gold, the friars obtained marvelous results among the natives. In 1535 the 70 convents in Mexico were organized into a province. At the end of the 16th century there were three provinces; others have been formed since then, besides several missionary colleges, whence zealous missionaries set out to convert the natives to the north, notably in Florida, New Mexico, Arizona, Texas, and California.

Florida was the first of the States that beheld the Franciscan garb. Five friars came with Narvaez in 1528; their superior, Father Juan Suarez, was the first bishop in the United States. In the course of time the missionaries succeeded, though not without heavy sacrifices of life and labor, in establishing flourishing missions all along the coast and in the interior as far west as Mississippi and as far north as Georgia. In 1634 there were 34 friars, who maintained 44 mission stations, where they attended to about 30,000 converts. These missions suffered greatly by invasions from Carolina and Georgia, and when Florida was ceded to the English in 1763 they ceased to exist.

Arizona and New Mexico were first visited by Franciscans in 1539; in the course of time a great many missions and churches were established, to most of which were attached schools for boys, as we learn from an official report of 1632. Beginning with 1689, about 160 friars labored in Texas up to the time of the Mexican independence, when the missions were ruined.

The Franciscans came to California in 1768 under the renowned Father Junipero Serra. The first mission founded was San Diego. Up to 1823, 21 missions were organized, forming a chain which extended a distance of over 700 miles. At the height of mission prosperity 30,000 Indians lived under the paternal guidance of the friars; they were fed, clothed, and educated, with no expense to the government, the missions supporting themselves by agriculture and stock-raising; everything was manufactured at these establishments by the Indians. In 1834 the Mexican government began to confiscate the missions and took them from the control of the friars; this work was finished by 1846 and brought about the complete destruction of the once so flourishing missions.

While the Spanish Franciscans were thus extending their labors in the south from the Atlantic to the Pacific, other bands of Friars Minor were emulating their example in the north. Champlain induced the French Franciscans, formerly called Recollects, to come to Canada as early as 1615. Thence they penetrated into Maine, New York, Pennsylvania, Michigan, Illinois, Minnesota, and Wisconsin. The best known of these missionaries is Father Louis Hennepin. He accompanied La Salle on his expeditions, and was the first to publish a description of the Niagara Falls. While a captive among the Sioux he saw and named the Falls of Saint Anthony. About this time we find the English Franciscans laboring in Maryland and adjoining colonies for full half a century. In the beginning of the 19th century the Rt. Rev. Michael Egan, a Franciscan and first bishop of Philadelphia, intended establishing a province of his order in Pennsylvania, but he died before accomplishing his design. In 1845 Franciscans from the Tyrol came to Cincinnati; in 1854 Italian friars formed a community in western New York, and in 1858 German friars settled in Illinois. The "Kulturkampf" was the cause of many more coming to the United States.

At present (1905) there are in the States 1,033 Franciscans, who are distributed as follows: The Custody of the Immaculate Conception (New York city) in the Eastern States has 8 houses, with 37 members; the Province of the Holy Name (Paterson, N. J.), also in the Eastern States, has 12 houses, with 132 members; the Province of Saint John the Baptist (Cincinnati, Ohio), chiefly in the Central States, has 33 houses, with 343 members; the Province of the Sacred Heart (Saint Louis, Mo.), in the Central and Northern States, has, including the houses in California and Arizona and the Polish communities in Wisconsin, 44 houses, with 521 members. Most of these friars are engaged in regular parish work; some preach missions throughout the States; others are on the Indian missions in Michigan, Wisconsin, California, Arizona, and New Mexico. They also conduct one seminary (Allegany, N. Y.) and six colleges (Allegany, N. Y., Cincinnati, Ohio, Teutopolis, Ill., Quincy, Ill., Pulaski, Wis, Santa Barbara, Cal.).

The Conventual Friars Minor came to the United States in 1851, and at present (1905) form a province in New York and New Jersey numbering 120 members. Besides these there are in the States 134 Franciscan Brothers and some 7,800 Sisters, all belonging to the third Order of Saint Francis. In 1897 the four abovementioned groups, namely, Observants, Reformati, Alcantarines, and Recollects, who had always been under the same minister-general, dropped their distinctive traits and are now known simply as Friars Minor or Franciscans. They number at present (1905) 16,801, are distributed into 77 provinces, and have 1,498 houses. In 1893 the Conventuals numbered 1,462, which number has since decreased, and had 172 houses.

Rev. P. Hugoline Storff, O.F.M.

Franck, César Auguste Jean Guillaume Hubert, sā'zar ō-gust zhŏn gē-yōm übār, fränk, French composer: b. Liège 1822: d. Paris 1890. He studied in the conservatory of his native town and at Paris, and in 1872 succeeded his master, Benoist, as teacher in the Metropolitan Conservatory. His talent as a composer was for a long time unrecognized, and in 1846 his oratorio 'Ruth' fell flat. Twenty years later it was revived and created a furore, and Franck found himself leader of a new school. The popularity which his works still enjoy at Paris has to some extent spread to the United States, where his oratorio 'Les Beatitudes' has been much appreciated.

Francke, August Hermann, ow'goost hĕr'män frän'kė, German Lutheran clergyman and philanthropist: b. Lübeck 22 March 1663; d. Halle 8 June 1727. In 1692 he obtained the professorship of Oriental languages at Halle, which in 1698 he exchanged for that of theology. A pupil of Spener and the teacher of Zinzendorf, Francke belonged to the ranks of those who carried forward the pietistic movement; his activity, however, took the practical direction of founding, endowing, and organizing various educational institutions at Halle. Among these were a school for the poor, a pædagogium, a burgher school, a Latin school, and a seminary for training teachers for these establishments, all founded in one year, 1695; and with them was associated an orphanage, which became in the course of time the most important of all Francke's institutions. At the time of his death his schools were frequented by more than 2,300 pupils. Francke's principal aim was religious instruction, but he founded also a printing-office, and an apothecary's shop, and taught natural science and physical exercises and manual trades. At the present time all Francke's foundations exist with but little alteration; in addition to those mentioned there are also a real-gymnasium, two schools for girls, and a free school. The number of pupils is more than 3,000 annually. See 'Lives' by Kramer (2d ed. 1885); Stein (2d ed. 1886).

Francke, Kuno, American educator: b. Schleswig, Germany, 27 Sept. 1855. Was educated at Kiel; came to the United States and has been professor of German literature in Harvard University for many years. His notable book 'Social Forces in German Literature' appeared in 1896; followed by 'Glimpses of Modern German Culture' (1898); 'History of German Literature' (1901); etc.

Francken, Frans, fräns fränk'ĕn (called The Younger), Flemish painter: b. Antwerp May 1581; d. there 6 May 1642. After a trip to Italy he was received into the Guild of St. Luke at Antwerp, where he worked at first in the brilliant colors of the old masters and later in the realistic style of Rubens. Most prominent European galleries have examples of his art.

Francken, Frans (called The Third), Flemish painter: b. Antwerp 1607; d. there 2 Sept. 1667. He was admitted to the Guild of Saint Luke in 1639. His works, patterned after Rubens, are unsigned and therefore difficult of identification. Specimens of his religious subjects are to be seen at Augsburg ('Moses Striking Water from the Rock') and Vienna, Liechtenstein collection ('John the Baptist Preaching'). In later years he also conducted a linen-draper's shop. He was a son of Frans Francken called The Younger (q.v.).

Franco, Giovanni Battista, jō-vän'nē bät-tēs'tä frän'kō, Italian painter, called Il Semolei: b. Udine 1510; d. Venice 1580. He visited Rome, where his Venetian manner was much influenced by that of Michelangelo. He was a very busy and uneven artist, doing his best work in decorative lines. Upon the victorious entry of Charles V. of Spain into Rome in 1536 he embellished the triumphal arch with scenes descriptive of the city's history. His principal canvas is a 'Baptism of Christ' in the Venetian Church of San Francesco della Vigna. His etchings, including such plates as 'The Adoration of the Shepherds' and 'The Scourging of Christ' (after Titian), are by many preferred to his paintings, which are criticised for defects of color.

Franco-German or **Franco-Prussian War,** the stupendous conflict between France and Germany in 1870–1, which resulted in the total defeat of the French, the overthrow of the Napoleonic dynasty, the establishment of the Third Republic in France, and the consolidation of Germany into an empire under the leadership of Prussia.

The remote causes of this war are to be sought in the jealousy which had long existed between France and Prussia, and which was strengthened on the side of France by the Prussian defeat of Austria in 1866, which secured to her rival the unquestioned leadership in Germany. The immediate occasion of the war occurred in June 1870, when Gen. Prim, commanding in Spain after the deposition and abdication of Queen Isabella, offered the crown of that country to Leopold of Hohenzollern, a prince belonging to the reigning house of Prussia. It was thought in France that the acceptance of this offer would endanger the balance of power in Europe, and more particularly would threaten the safety of France, by putting Prussia in a position to attack it both in the east and in the south. Accordingly, the government of Napoleon III. demanded of the king of Prussia that he should forbid the candidature of the prince. The prince voluntarily retired from his candidature, but the French ambassador offensively insisted that this renunciation should be formally made by the king, and a guarantee given that the candidature would not be revived. This demand was refused, and a formal declaration of war by France against Prussia was received by Count Bismarck, the chancellor of the North German Confederation, on the 19th of July. The war was welcomed by both sides with equal enthusiasm. While the French were the first in getting their troops to the frontier it soon became manifest that instead of being in a complete state of readiness, as the minister of war had declared, the army was defective in almost everything essential to its equipment. Owing to the prevalence of the system of paying for substitutes who never appeared, and were yet registered as belonging to the army, it was also discovered that the numbers of the army did not reach anything like the amount at which they were represented in the official estimates.

In contrast to this the arrangements for mobilizing the Germany army, which had previously been tested in Prussia in 1864 and 1866, were again found to work admirably. Each section of the army was completely organized in the headquarters of the district which it occupied in time of peace, and was only sent to the frontiers after being furnished with everything it required. In addition to this, Prussia, against which country alone the war had been declared, was not only joined according to treaty by all the states of the North German Confederation, but also by those of the south, upon whose neutrality, perhaps even upon whose alliance, Napoleon and the French had counted. The whole of Germany north and south was thus in arms, and was able to muster forces far outnumbering those of the French. While the whole French army brought into the field at the commencement of the war numbered no more than 310,000 men, the troops of the Germans in the field amounted in all to 477,000, to which must be added strong reserves ready, with the exception of such as were necessary to protect the interior and to resist a threatened landing on the north coast by the French fleet, to be brought to the scene of war at any time, giving a total strength on the side of the Germans of more than 1,000,000 of men.

The German forces were divided into three armies; the First Army had its headquarters at Trèves under Gen. Steinmetz; the Second Army occupied the Bavarian Palatinate under Prince Frederick Charles; while the Third Army, under the Crown-prince of Prussia, was stationed in northern Baden. The cavalry of each army, instead of being attached in separate divisions to each of the corps d'armée composing the army, were in this way massed together into one body, and in this formation rendered very important services during the war. The commander-in-chief of the whole forces was King William of Prussia, who was supported by a staff of general officers, with Von Moltke at their head. The French army, under Napoleon himself, had its headquarters at Metz, and two advanced divisions were stationed on the borders of France and Germany, the one in the north on the Saar, under Gen. Frossard, the other farther south at Weissenburg, under Gen. Douay. The first overt act of war took place on 2 August, in which a part of the northern division of the French army, in the presence of Napoleon and the prince imperial, compelled a few Prussian troops belonging to the First Army, after some hours' firing, to evacuate Saarbrücken. After this Von Moltke assumed the offensive. His plan was to unite the three armies in the line of the Moselle in order to attack the enemy's centre with the view of obtaining the shortest line of operations in the direction of Paris, and in this he was completely successful. On 4 August the army under the crown prince defeated the advanced southern division of the French army at Weissenburg, and on 6 August MacMahon's army at Wörth; on the latter date also the first and second German armies had routed the northern division of the French army at Forbach, with terrible loss on both sides. In two separate armies, commanded respectively by Marshal Bazaine and Marshal MacMahon, the French retreated. To prevent their union Steinmetz and Frederick Charles pursued Bazaine, defeated him at Courcelles on 14 August, at Mars-la-Tour on the 16th, at Gravelotte with awful slaughter on the

18th, and shut him up in Metz. The crown prince and his army following MacMahon, advanced to Nancy; there reinforced by a newly formed army under the crown prince of Saxony, they advanced on Châlons, where MacMahon's army had been reorganized and strengthened, and was expected to retreat on Paris. Following instructions, however, MacMahon moved northward to make a descent upon Metz and relieve Bazaine. He was overtaken near Beaumont, and on 27 August and on the days immediately succeeding a number of engagements and strategic movements resulted in MacMahon's army being surrounded at Sedan on 1 September, by a force of overwhelming numbers. On the following day both army and fortress were forced to capitulate. Forty generals, 4,000 officers of all grades, and 84,000 soldiers became prisoners of war. Among the prisoners was Napoleon III., who was unexpectedly found to have been present with the army of MacMahon. On the day after the battle he had a personal interview with King William of Prussia, who assigned to him Wilhelmshöhe, near Cassel, as a place of residence during his captivity.

At the news of this disastrous defeat the Parisians in an outburst of rage demanded the dethronement of the Napoleon dynasty, and on 4 September a republic was proclaimed. A government of national defense presided over by Gen. Trochu, military governor of Paris, was formed, but before any effective measures could be adopted Paris was invested by the Germans on 19 September. A day or two before a delegation from the central government had escaped from Paris and established themselves at Tours, where they were joined on 9 October by Gambetta, who escaped from Paris by balloon. It was some time before the French were able to organize a new army, and in the meantime, 27 September, Strasburg fell into German hands and on 28 October Metz, which had been invested by the second German army under Prince Frederick Charles, capitulated. By the beginning of November war in the open field had been resumed at various points: in the north, in the southeast, and on the Loire in the neighborhood of Orleans. The army of the Loire, under Gen. Aurelle de Paladines, compelled the Germans to evacuate Orleans on 7 November, but was unable to follow up this temporary success, and on 4 December and on 12 January was severely defeated by Prince Frederick Charles. The army of the north, under Gen. Faidherbe, which had been hastily formed to attempt the relief of Paris, after many gallant attempts which were checked by the first German army under Gen. Manteuffel, was finally defeated at St. Quentin on 19 January. In the east and southeast the results were equally disastrous to the French. Gen. Werder defeated the French troops under Cambriels in the Vosges, the irregular forces under Garibaldi in Burgundy, and at Héricourt on the Lisaine on 15, 16 and 17 January kept in check the army of Bourbaki until the approach of Manteuffel compelled Bourbaki and 84,000 troops to escape into Switzerland, where they were disarmed and remained till the conclusion of the war. Meanwhile Paris had held out for a much longer period than even the most sanguine on the side of the French had expected. Desperate sallies were frequently made, but not in sufficient strength to have any decisive effect. On the failure of the last sally on 19 January, Gen. Trochu resigned and was succeeded by Leflô as head of the government of defense, and by Gen. Vinoy as commander of the troops of Paris. But by this time the city was at the point of starvation, and after a three weeks' bombardment was in such a desperate condition that the government could no longer help seeing that a capitulation was inevitable. The terms were settled on 28 January, the chief being that all the forts around Paris should be immediately handed over to the Germans, and that the city should pay a contribution of 200,000,000 francs ($40,000,000). An armistice of three weeks was at the same time concluded, to allow of the election and assembling of a National Assembly to decide upon war and peace. This armistice, however, was not to extend to the scene of war in the southeast until a separate arrangement had been made regarding it. Here the fortress of Belfort still held out, but at last, on 16 February, it agreed to capitulate. The garrison, on account of its gallant defense, was allowed to march out with full military honors. On the same day the armistice became general. The fortress of Bitsch in the department of Moselle, did not surrender till after the conclusion of the preliminaries of peace.

The elections for the assembly had taken place on the 8th; it met at Bordeaux, and on the 17th appointed M. Thiers head of the executive; and on the 21st he arrived at Versailles with a diplomatic commission to negotiate for peace. After the armistice had been thrice prolonged the preliminaries of peace were signed at Versailles on 26 February, and accepted by the assembly at Bordeaux on 1 March. On the same day the German troops entered Paris; on 18 January King William, who had taken up his residence at Versailles, had by acclamation been proclaimed Emperor of Germany. The principal terms of peace were: (1) That France should cede to Germany one fifth part of Lorraine, including Metz, together with the whole of Alsace except Belfort and the surrounding district. (2) That France should pay to Germany a war indemnity of 5,000,000,000 francs ($1,000,000,000). (3) That certain departments of France should remain in the occupation of the Germans, and should not be fully evacuated until after the payment of the whole indemnity. The definitive treaty of peace, which was signed at Frankfort on 10 May and ratified on the 21st, confirmed in all essential particulars the preliminaries of Versailles. The last instalment of the war indemnity was paid on 5 Sept. 1873, and France was completely evacuated by the Germans on the 13th of the same month.

François, Kurt von, koort fōn frän-swä, German explorer: b. Grand-duchy of Luxembourg 2 Oct. 1853. After active service in the Franco-Prussian war, he joined, with the rank of lieutenant, the Wissmann expedition to explore the river Kassai, a tributary of the Congo, and subsequently published his work 'In the Interior of Africa, the exploration of the Cassai, during 1883-5' (1891). He then explored with Grenfell two southern tributaries of the Congo and published his 'Exploration of the Tschuapa and Lulongo' (1888). He was on his return promoted to be leader of an expedition which the government despatched to the German colony of Togo, and 1890–1 accompanied the military expedition into South Africa and in 1892 traversed the Kalahari Desert.

François, Luise von, German novelist: b. Herzburg, Saxony, 27 June 1817; d. Weissenfels 24 Sept. 1893. Her first considerable story, 'The Last Reckenburgerin' (1871), was very warmly praised by the critics for its power in character delineation; it was followed by: 'Frau Erdmuthen's Twin Boys' (1872); 'Climacteric Years of a Lucky Fellow' (1877); 'Judith the Housekeeper' (1868), a peasant counterpart to 'The Last Reckenburgerin,' and next after that her best story. She wrote a 'Popular History of the Prussian War of Liberation, 1813–15'; and a comedy, 'Woman's Station' (1882).

Fran'colins, a genus of small partridges of Africa and southern Asia, much resembling the American bobwhite in behavior. One species (*Francolinus vulgaris*) used to be common in the south of Europe, but has been exterminated.

Franco'nia, Germany, a district lying to the east of the Rhine, and traversed by the Main. After the dismemberment of the Carlovingian empire this district became attached to the German division, and ultimately formed one of the grand-duchies of Germany. Between 1024 and 1125 it furnished a series of emperors to Germany. (See GERMANY, *History*.) It was one of the ten circles into which the empire was divided by Maximilian I. in 1512. Its capital was Nuremberg. In 1806 it was partitioned among Würtemberg, Baden, Hesse-Cassel, the Saxon duchies, and Bavaria. The last received the largest share, and still retains the name in the three circles of Upper, Middle, and Lower Franconia. (1) Upper Franconia has an area of 2,702 square miles and pop. (1900) 607,903. Baireuth is the capital. (2) Middle Franconia has an area of 2,925 square miles and pop. (1900) 815,556. The capital is Anspach. (3) Lower Franconia has an area of 3,243 square miles and pop. (1900) 650,758. Würzburg is the capital. The name of Franconia has been rendered familiar to the traveler and the geologist by its picturesque scenery, which has procured for part of it the name of Franconian Switzerland, and by its caverns, filled with fossil bones, among the most remarkable of which is König Ludwig's Höhle (King Louis' Cave), between Baireuth and Muggendorf.

Franconia Mountains. See WHITE MOUNTAINS.

Fran'gula, the bark of *Rhamnus Frangula*, used in medicine as a purgative.

Fran'gulin ($C_{20}H_{20}O_{10}$), a dyestuff extracted from the root, bark, fruit, and seed of the alder buckthorn (*Rhamnus frangula*). It is a bright yellow, silky, crystalline mass, without taste or smell, which fuses on heating, and can be sublimed in golden needles. It is not soluble in water, and though soluble in hot alcohol separates very completely on cooling. It dissolves in alkalies with a purple color, and is decomposed by sulphuric acid with a succession of colors. It forms lakes with metallic hydrates, and dyes silk, wool, and cotton. In its chemical constitution it is a glucoside, and it is probably the same as *cascara sagrada*.

Frank, Jakob, yä'kōb fränk (properly **Lebowicz**), Jewish pseudo-Messiah: b. Galicia 1720; d. 10 Dec. 1791. The name Frank was obtained during travel in the east from the Turks, who employed the word as a generic term for an European. Originally a distiller, he settled, after his eastern journey, in Podolia, where he professed himself a second Messiah, basing his teachings, in opposition to the Talmud, on the Sohar, the source of the Cabbala. He finally removed to Offenbach, where he lived regally on the gifts of adherents, and finally became a Roman Catholic. His death by apoplexy broke down popular belief in his immortality. The sect of Frankists persists in Poland, Turkey, and Moldavia, its tenets being a Judaized form of the Roman Catholic faith.

Frank, Royal Thaxter, American military officer: b. Gray, Maine, 6 May 1836. He was graduated at the United States Military Academy in 1864, and during the Civil War was brevetted major and lieutenant-colonel for bravery at Fredericksburg, 13 Dec. 1862. He was in command of the Artillery School at Fortress Monroe 1888–98, and was promoted brigadier-general in 1898.

Frank'enstein, or the Modern Prometheus, a psychological romance, by Mary Wollstonecraft Shelley (daughter of Mary Wollstonecraft Godwin and wife of the poet Shelley), published in 1817. It has a morbid power which makes it one of the most remarkable books of its kind in English. Frankenstein conceives the idea of creating by mechanical means a living being, who, independent of the ills of the flesh, shall be immortal. Like Prometheus of old, he hopes to bring down a vital spark from heaven to animate the human frame. After a long series of laboratory experiments, in which he sees himself gradually approaching his goal, he succeeds. But his creation turns out to be not a blessing but a curse. He has made a soulless monster, who will implacably pursue Frankenstein and all his loved ones to the dire end. In vain the unhappy scientist flees from land to land, and from sea to sea. The fiend he has brought into existence is ever on his track, and is the evil genius of his whole family. Finally, in an ice-bound sea, worn out by his hideous experiences, he dies, and over his dead body hovers the horrid shape of the man-machine. The monster then leaps over the ship's side, and disappears in the ice and mist.

Frankfort, Ind., city, county-seat of Clinton County; on the Louisville, N. A. & C., the L. E. & W., the St. L. & K. C., and the Vandalia R.R.'s; about 40 miles northwest of Indianapolis, and 91 miles southwest of Fort Wayne. It is in an agricultural section, and its chief manufactures are flour, crackers, lumber, tiles, bricks, agricultural implements, and some furniture. Natural gas is used extensively for light and heat. The trade is chiefly in the manufactured articles and grain, fruits, and vegetables. The city has a fine public library and a well organized system of public schools. The electric-light plant is owned by the city. Pop. (1900) 7,100.

Frankfort, Ky., city, capital of the State of Kentucky, county-seat of Franklin County; on the Kentucky River, the Chesapeake & O., and the L. & N. R.R.'s; about 50 miles east of Louisville and 65 miles southwest of Cincinnati. The city was founded by Gen. James Wilkinson (q.v.) in 1786, and for a time it was made the seat of his intrigues when he was trying to detach Kentucky from the Union and affiliate it with Spain. When Kentucky was admitted as a State in 1792, Frankfort was made the capital. During the Civil War it was for a time the headquarters of the Confederate forces under Braxton Bragg (q.v.). On 4 Oct. 1862 Richard Harves was inaugurated here as the Confederate governor of Kentucky. In 1900 there was great excitement in Frankfort as to who was elected governor of the State. It was decided that William Goebel was the governor-elect. In the midst of the agitation Goebel was assassinated. Frankfort owes much of its present prosperity to its location in the "Blue Grass" section of the State. Its chief manufactures are flour, whiskey, lumber, carriages, twine, shoes, furniture. The city is the trade centre for an extensive region; the river is navigable and by artificial means it is made to furnish a large amount of water power. The city contains the State arsenal, a State Home for Feeble-Minded Children, the State penitentiary, the State Normal School for colored pupils, and Saint Joseph's Academy. The State government buildings and the State library with over 100,000 volumes add to the interests of the city. Franklin cemetery contains the grave of Daniel Boone (q.v.) and other noted men connected with the history of Kentucky. Pop. (1900) 9,487.

Frank'fort-on-the-Main, măn, Prussia, the capital of a district of same name, on the Main, 20 miles above its conflux with the Rhine. It is divided by the river into two unequal parts; the one on the north bank, called Frankfort proper, being considerably larger than the other, which is called Sachsenhausen; and the two communicate by a stone bridge. Frankfort was formerly fortified; but most of its outworks are now converted into gardens and promenades, and it is entered by nine gates. The principal streets are wide; there are also many squares and a number of large buildings; among which may be named the Rœmerberg, or old palace, in which the emperors of Germany were elected, and place of the assembling of the Diet; the Taxis palace, a place of residence of the emperors; the Sallhof, a modern imperial palace; an academy of painting, and the Senkenberg Museum. Its manufactures include carpets, table-covers, oil-cloths, cotton and silk fabrics, woolen stuffs, jewelry, tobacco and printer's black. It has also large printing, lithographic and stereotyping establishments. Frankfort was founded by the Franks in the 5th century. Charlemagne, who had a palace in this city, summoned a council in 794, and it was surrounded with walls by Louis I. in 838. It was the capital of the Eastern Franks from 843 to 889, when Ratisbon was selected. Frederick I. was elected at Frankfort in 1152. From that time it became the place of election of the emperors. Frankfort was made a free city in 1257. The bridge over the Main was built in 1342. Frederick of Prussia signed a treaty known as the Union of Frankfort, with the empire, France, and Sweden, at this city 13 May 1744. The French captured it 2 Jan. 1750, and again in 1792; but the Prussians wrested it from them 2 Dec. 1792. It was bombarded by the French 12 July, and surrendered 19 July 1796. It formed part of the Confederation of the Rhine in 1806. Napoleon I. erected Frankfort into a duchy in 1810. The Declaration of the Allied Powers was issued at Frankfort 1 Dec. 1813. By the Congress of Vienna, in 1815, it was made one of the four free cities of Germany, and the seat of the Germanic Diet. It was made a free port in 1831. The constituent assembly, elected in 1848, held its sittings at Frankfort. It was occupied by the Prussians 16 July 1866, and is now incorporated with Prussia. Pop. (1900) 288,489.

Frankfort-on-the-Oder, Prussia, the capital of a district of the same name, province of Brandenburg, 48 miles from Berlin. Its university, founded in 1506, was in 1811 transferred to Breslau. Manufactures are woolens, silks, leather, earthen-ware, tobacco, mustard, etc. Near it is Kunersdorf, the scene of the victory of the Austrians and Russians over Frederick the Great (q.v.) in 1759. Pop. (1900) 61,835. The district has an area of 8,000 square miles, with a population of 1,000,000.

Frankfort Black, a fine black pigment used in copper plate engraving. It is said to be made by burning, in the manner of ivory black, the lees of wine from which the tartar has been washed.

Frankfort Land Company, 1686. Francis Daniel Pastorius, an able young German lawyer, had joined the sect of Pietists (q.v.), and to escape from the atmosphere of Lutheranism, concerted with his co-religionists an emigration to America. A number of wealthy and distinguished Germans and Dutchmen were induced to join; but they soon gave up the idea of emigrating themselves, and wished Pastorius instead to head a colony of German and Dutch Mennonites and Quakers to a land where they need not be harried. Pastorius had made Penn's acquaintance in England, had become a Quaker, and wished to be near Penn; some Crefeld merchants bought from Penn 15,000 acres near Philadelphia, and in 1683 Pastorius conducted a colony thither, and at once laid out Germantown (q.v.). In 1686 the Frankfort Land Company was organized, and bought 25,000 acres more.

Frankincense, frank'ĭn-sĕns (O. F. *francencens;* Mod. Lat. *francum incensum*), a name given to various oleo-resinous substances. The frankincense employed in religious ceremonies (called also *incense* and *olibanum*) is a gum resin obtained from *Boswellia thurifera* (or *serrata*), a tree somewhat resembling the sumach, belonging to the *Amyridaceæ,* and inhabiting the mountains of India. The frankincense so highly prized by the Greeks, Romans and Jews was probably chiefly of this variety. Substances derived from other trees, such as Croton and Protium, are frequently employed as substitutes for *olibanum.* American turpentine, from which Burgundy pitch is obtained by melting and straining through a cloth, is frequently called frankincense. The frankincense familiar to pharmacy is procured from the European silver fir.

Franking Privilege, that of sending postal matter gratis. In England peers and members of the House of Commons had it till 1840, and till 1837 could also frank their friends' letters wholesale, and even leave franks with them to use at will. In the United States it was first accorded to Revolutionary soldiers in actual service; then to the executive body, chiefs of departments and bureaus, and some special clerks;

and all public documents were franked. Senators and Congressmen, postmasters for official correspondence, also had it; likewise newspaper exchanges and petitions to Congress; and later, exchanges of the Smithsonian institutions, and medals and testimonials to soldiers. The first four presidents had it for life, and it has been granted to the widows of ex-presidents. It was totally abolished from 30 June 1873, an allowance of stamps being made to the departments; but restored a few years later for public documents, seeds to constituents, etc. There is a penalty of $300 for unlawful use of envelopes marked "official business."

Frankl, Ludwig August, lood'vïg ow'goost fränkl, Chevalier von Hochwart, Austrian poet: b. Chrast, Bohemia, 3 Feb. 1810; d. Vienna 14 March 1894. His literary début was made with 'A Lay of Hapsburg' (1832), a series of historical ballads, followed (1836) by the romantic epic 'Christopher Columbus'; the biblical romantic poem 'Rachel' (1842); a poem 'The University' (1848), the first publication in Austria not subjected to the official censorship; 'Don John of Austria,' a heroic poem (1846); 'Lyric Poems,' and 'Epic and Lyric Poetry.'

Frank'land, Sir **Edward,** English chemist: b. Churchtown, England, 18 Jan. 1825; d. Norway 11 Aug. 1899. He made the discovery of the union of organic radicles with metals, announcing in 1850 the preparation of compounds of zinc with methyl and ethyl. From this he deduced the conclusion that an atom of the metal could only attach itself to a definite number of the atoms of other elements, which discovery led to the theory of "equivalents." He was appointed professor of chemistry at Owens College, Manchester, in 1851, and there developed the process of making water gas. Becoming professor of chemistry in the Royal School of Mines in 1865 he turned his attention to water analysis, the purification of sewage and the means of preventing pollution. Subsequently he proved that compressed gases are capable of giving out a flame of constant spectrum, from which he concluded that the photosphere of the sun was atmospheric. He also investigated the chemistry of foods. He published 'Experimental Researches on Pure, Applied and Physical Chemistry' (1878); 'Water Analysis for Sanitary Purposes' (1880).

Frankland, Percy Faraday, English chemist: b. London 3 Oct. 1858. He is a son of E. Frankland (q.v.). In 1880 he became demonstrator and lecturer on chemistry at the School of Mines, a post which he held till his appointment in 1888 as professor of chemistry in University College, Dundee. In 1894 he became professor of chemistry in Mason College, Birmingham. His published works, which deal mostly with micro-chemistry, the chemistry of fermentation and bacteriology, include 'Agricultural Chemical Analysis' (1883); 'Our Secret Friends and Foes' (1894, on micro-organisms); 'Micro-organisms in Water' (1894); 'Life of Pasteur' (1897); and many lectures and papers in the transactions of various societies. In several of his works he has been assisted by his wife, the sister of the philanthropist Arnold Toynbee (q.v.).

Franklin, Benjamin, American statesman and philosopher: b. Boston, Mass., 17 Jan. 1706; d. Philadelphia, Pa., 17 April 1790. The youngest son of the 17 children of a Boston tallow-chandler named Franklin was born a subject of Queen Anne of England, and on the same day received the baptismal name of Benjamin at the Old South Church in that city. He continued for more than 70 of the 84 years of his life a subject of four successive British monarchs. During that period, neither Anne nor either of the three Georges who succeeded her had a subject of whom they had more reason to be proud, nor one whom at his death their people generally supposed they had more reason to detest. No Englishman of his generation can now be said to have established a more enduring fame, in any way, than Franklin established in many ways. As a printer, as a journalist, as a diplomatist, as a statesman, as a philosopher, he was easily first among his peers

On the other hand, it is no disparagement of the services of any of his contemporaries on either side of the Atlantic, to say that no one of his generation contributed more effectually to the dissolution of the bonds which united the principal British-American colonies to the mother country, and toward conferring upon them independence and a popular government.

As a practical printer Franklin was reported to have had no superiors; as a journalist he exerted an influence not only unrivaled in his day, but more potent, on this continent at least, than either of his sovereigns or their parliaments. The organization of a police, and later of the militia, for Philadelphia; of companies for extinguishing fires; making the sweeping and paving of the streets a municipal function; the formation of the first public library for Philadelphia, and the establishment of an academy which has matured into the now famous University of Pennsylvania, were among the conspicuous reforms which he planted and watered in the columns of the Philadelphia *Gazette*. This journal he founded; upon the earnings of it he mainly subsisted during a long life, and any sheet of it to-day would bring a larger price in the open market probably than a single sheet of any other periodical ever published.

Franklin's Almanack, his crowning work in the sphere of journalism, published under the pseudonym of "Richard Saunders,"— better known since as Poor Richard,— is still one of the marvels of modern literature. Under one or another of many titles the contents of this publication, exclusive of its calendars, have been translated into every tongue having any pretensions to a literature; and have had more readers, probably, than any other publication in the English or indeed in any other language, with the single exception of the Bible. It was the first issue from an American press that found a popular welcome in foreign lands, and it still enjoys the special distinction of being the only almanac ever published that owed its extraordinary popularity entirely to its literary merit.

What adds to the surprise with which we contemplate the fame and fortunes of this unpretentious publication, is the fact that its reputation was established by its first number, and when its author was only 26 years of age. For a period of 26 years, and until Franklin ceased to edit it, this annual was looked forward to by a larger portion of the colonial population and with more impatience than now awaits a President's annual message to Congress.

Franklin graduated from journalism into diplomacy as naturally as winter glides into spring. This was simply because he was by common acclaim the fittest man for any kind of public service the colony possessed, and especially for any duty requiring talents for persuasion, in which he proved himself to be unquestionably past master among the diplomatists of his time.

The question of taxing the Penn proprietary estates in Pennsylvania, for the defense of the province from the French and Indians, had assumed such an acute stage in 1757 that the Assembly decided to petition the king upon the subject; and selected Franklin, then in the 41st year of his age, to visit London and present their petition. The next 41 years of his life were practically all spent in the diplomatic service. He was five years absent on this his first mission. Every interest in London was against him. He finally surmounted all obstacles by a compromise, which pledged the Assembly to pass an act exempting from taxation the unsurveyed lands of the Penn estate,— the surveyed waste lands, however, to be assessed at the usual rate. For his success the Penns and their partisans never forgave him, and his fellow colonists never forgot him.

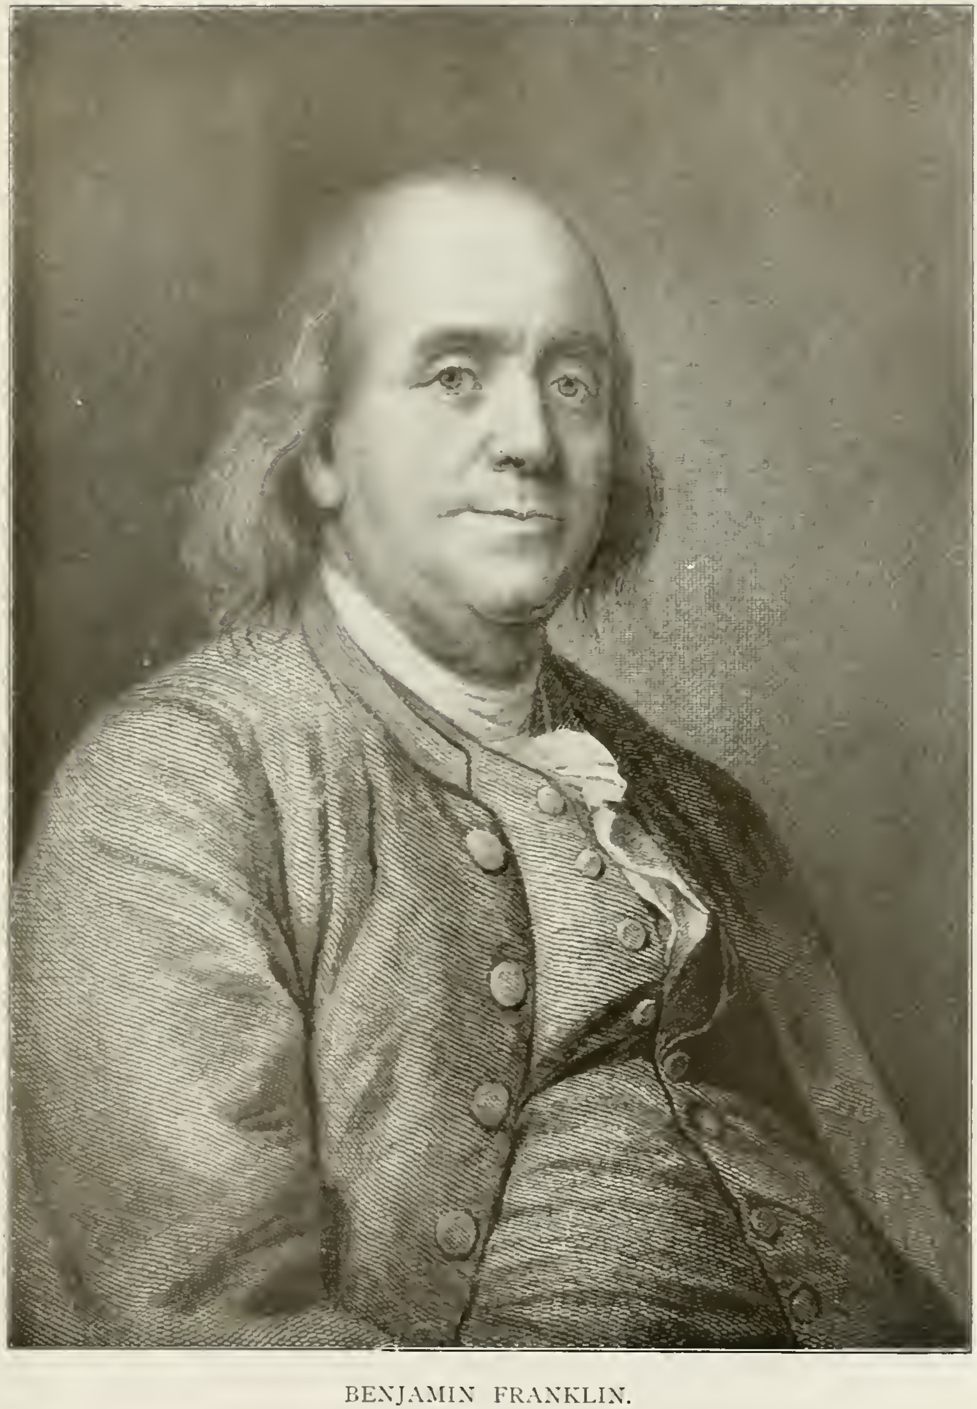
Franklin returned to Philadelphia in 1762, but not to remain. The question of taxing the colonies without representation was soon thrust upon them in the shape of a stamp duty, and Franklin was sent out again to urge its repeal. He reached London in November 1764, where he remained the next 11 years and until it became apparent that the surrender of the right to arbitrarily tax the colonies would never be made by England during the life of the reigning sovereign, George III. Satisfied that his usefulness in England was at an end, he sailed for Philadelphia 21 March 1775; and on the morning of his arrival was elected by the Assembly of Pennsylvania a delegate to the Continental Congress which consolidated the armies of the colonies, placed Gen. George Washington in command of them, issued the first Continental currency, and assumed the responsibility of resisting the imperial government; his last hope of maintaining the integrity of the empire having been dissipated by recent collisions between the people and the royalist troops at Concord and Lexington. Franklin served on 10 committees in this Congress. He was one of the five who drew up the Declaration of Independence in July 1776, and in September following was chosen unanimously as one of the three commissioners to be sent out to solicit for the infant republic the aid of France and the sympathies of continental Europe. In this mission, the importance of which to his country can hardly be exaggerated, he was greatly favored by the reputation which had preceded him as a man of science. While yet a journalist he had made some experiments in electricity, which established its identity with lightning. The publication by an English correspondent of the letters in which he gave an account of these experiments, secured his election as an honorary member of the Royal Society of London and undisputed rank among the most eminent natural philosophers of his time. When he arrived in Paris, therefore, he was already a member of every important learned society in Europe, one of the managers of the Royal Society of London, and one of the eight foreign members of the Royal Academy in Paris, where three editions of his scientific writings had already been printed. To these advantages must be added another of even greater weight: his errand there was to assist in dismembering the British empire, than which nothing of a political nature was at this time much nearer every Frenchman's heart.

The history of this mission, and how Franklin succeeded in procuring from the French king financial aid to the amount of 26,000,000 francs, at times when the very existence of the republic depended upon them, and finally a treaty of peace more favorable to his country than either England or France wished to concede, has been often told; and there is no chapter in the chronicles of this republic with which the world is more familiar.

Franklin's reputation grew with his success. "It was," wrote his colleague John Adams, "more universal than that of Leibnitz or Newton, Frederick the Great or Voltaire, and his character more beloved and esteemed than all of them. . . . If a collection could be made of all the gazettes of Europe for the latter half of the 18th century, a greater number of panegyrical paragraphs upon *le grand Franklin* would appear, it is believed, than upon any other man that ever lived."

A few weeks after signing the definitive treaty of peace in 1783, Franklin renewed an application which he had previously made just after signing the preliminary treaty, to be relieved of his mission, but it was not until 7 March 1785 that Congress adopted a resolution permitting "the Honorable Benjamin Franklin to return to America as soon as convenient." Three days later, Thomas Jefferson was appointed to succeed him. On 13 Sept. 1785, and after a sojourn of nearly nine years in the French capital, first in the capacity of commissioner and subsequently of minister plenipotentiary, Franklin once more landed in Philadelphia, on the same wharf on which, 62 years before, he had stepped, a friendless and practically penniless runaway apprentice of 17. Though now in his 79th year, and a prey to infirmities not the necessary incidents of old age, he had scarcely unpacked his trunks after his return when he was chosen a member of the municipal council of Philadelphia, and its chairman. Shortly after, he was elected president of Pennsylvania, his own vote only lacking to make the vote unanimous. "I have not firmness," he wrote to a friend, "to resist the unanimous desire of my country folks; and I find myself harnessed again into their service another year. They engrossed the prime of my life; they have eaten my flesh, and seem resolved now to pick my bones."

He was unanimously re-elected to this dignity for the two succeeding years, and while holding that office was chosen a member of the convention which met in May 1787 to frame the Constitution under which the people of the United States are still living. With the adoption of that instrument, to which he probably contributed as much as any other individual, he retired from official life; though not from the service of the public, to which for the remaining years of his stay on earth his genius and his talents were faithfully consecrated. Among the fruits of that unfamiliar leisure, always to be remembered among the noblest achievements of his illustrious career, was the part he had in



BENJAMIN FRANKLIN.

organizing the first anti-slavery society in the world; and as its president, writing and signing the first remonstrance against slavery ever addressed to the Congress of the United States.

In surveying the life of Dr. Franklin as a whole, the thing that most impresses one is his constant study and singleness of purpose to promote the welfare of human society. It was his daily theme as a journalist, and his yearly theme as an almanac-maker. It is that which first occurs to us when we recall his career as a member of the Colonial Assembly; as an agent of the provinces in England; as a diplomatist in France; and as a member of the conventions which crowned the consistent labors of his long life. Nor are there any now so bold as to affirm that there was any other person who could have been depended upon to accomplish for his country or the world what Franklin did in any of the several stages of his versatile career.

Though holding office for more than half of his life, the office always sought Franklin, not Franklin the office. When sent to England as the agent of the colony, he withdrew from business with a modest competence judiciously invested mostly in real estate. He never seems to have given a thought to its increase. Frugal in his habits, simple in his tastes, wise in his indulgences, he died with a fortune neither too large nor too small for his fame as a citizen or a patriot. For teaching frugality and economy to the colonists, when frugality and economy were indispensable to the conservation of their independence and manhood, he has been sneered at as the teacher of a "candle-end-saving philosophy," and his 'Poor Richard' as a "collection of receipts for laying up treasures on earth rather than in heaven." Franklin never taught, either by precept or example, to lay up treasures on earth. He taught the virtues of industry, thrift, and economy, as the virtues supremely important in his time, to keep people out of debt and to provide the means of educating and dignifying society. He never countenanced the accumulation of wealth for its own sake, but for its uses,— its prompt convertibility into social comforts and refinements. It would be difficult to name another man of any age to whom an ambition to accumulate wealth as an end could be imputed with less propriety. Though probably the most inventive genius of his age, and thus indirectly the founder of many fortunes, he never asked a patent for any of his inventions or discoveries. Though one of the best writers of the English language that his country has yet produced, he never wrote a line for money after he withdrew from the calling by which he made a modest provision for his family.

For the remaining half of his life both at home and abroad, though constantly operating upon public opinion by his pen, he never availed himself of a copyright or received a penny from any publisher or patron for any of these labors. In none of the public positions which he held, even when minister plenipotentiary, did his pay equal his expenditures. He was three years president of Pennsylvania after his return from France, and for his services declined to appropriate to his own use anything beyond his necessary expenditures for stationery, postage, and transportation. It is not by such methods that men justly incur the implied reproach of "laying up treasures on earth," or of teaching a candle-end-saving philosophy.

Franklin courted fame no more than fortune. The best of his writings, after his retirement from journalism, he never gave to the press at all; not even his incomparable autobiography, which is still republished more frequently than any of the writings of Dickens or of Thackeray. He always wrote for a larger purpose than mere personal gratification of any kind. Even his bagatelles and *jeux d'esprit* read in the salons of Paris, though apparently intended for the eyes of a small circle, were inspired by a desire to make friends and create respect for the struggling people and the great cause he represented. Few if any of them got into print until many years after his decease. Franklin was from his youth up a leader, a lion in whatever circle he entered, whether in the printing-house, the provincial assemblies, as agent in England, or as a courtier in France. There was no one too eminent in science or literature, on either side of the Atlantic, not to esteem his acquaintance a privilege. He was an honorary member of every important scientific association in the world, and in friendly correspondence with most of those who conferred upon those bodies any distinction; and all this by force of a personal, not to say planetary, attraction that no one brought within his sphere could long resist.

Pretty much all of importance that we know of Franklin we gather from his private correspondence. His contemporaries wrote or at least printed very little about him; scarcely one of the multitude whose names he embalmed in his 'Autobiography' ever printed a line about him. All that we know of the later half of his life not covered by his autobiography, we owe almost exclusively to his private and official correspondence. Though reckoning among his warm friends and correspondents such men as David Hume, Dr. Joseph Priestley, Dr. Price, Lord Kames, Lord Chatham, Dr. Fothergill, Peter Collinson, Edmund Burke, the bishop of St. Asaph and his gifted daughters, Voltaire, the habitués of the Helvétius salon, the Marquis de Ségus, the Count de Vergennes, his near neighbors De Chaumont and Le Veillard, the *maire* of Passy,— all that we learn of his achievements, of his conversation, of his daily life, from these or many other associates of only less prominence in the Old World, might be written on a single foolscap sheet. Nor are we under much greater obligations to his American friends. It is to his own letters (and except his 'Autobiography,' he can hardly be said to have written anything in any other than the epistolary form; and that was written in the form of a letter to his son William, and most of it only began to be published a quarter of a century after his death) that we must turn to learn how full of interest and importance to mankind was this last half-century of his life. Beyond keeping copies of his correspondence, which his official character made a duty as well as a necessity, he appears to have taken no precautions to insure the posthumous fame to which his correspondence during that period was destined to contribute so much. Hence, all the biographies — and they are numberless — owe almost their entire interest and value to his own pen. All, so far as they are biographies, are autobiographies; and for that reason it may be fairly said that all of them are interesting.

It is also quite remarkable that though Franklin's life was a continuous warfare, he had no personal enemies. His extraordinary and even intimate experience of every phase of human life, from the very lowest to the very highest, had made him so tolerant that he regarded differences of opinions and of habits much as he regarded the changes of the weather,— as good or bad for his purposes, but which, though he might sometimes deplore, he had no right to quarrel with or assume personal responsibility for. Hence he never said or did things personally offensive. The causes that he represented had enemies, for he was all his life a reformer. All men who are good for anything have such enemies. "I have, as you observe," wrote Franklin to John Jay the year that he retired from the French mission, "some enemies in England, but they are my enemies as an American; I have also two or three in America who are my enemies as a minister; but I thank God there are not in the whole world any who are my enemies as a man: for by his grace, through a long life, I have been enabled so to conduct myself that there does not exist a human being who can justly say, 'Ben Franklin has wronged me.' This, my friend, is in old age a comfortable reflection. You, too, have or may have your enemies; but let not that render you unhappy. If you make a right use of them, they will do you more good than harm. They point out to us our faults; they put us upon our guard and help us to live more correctly."

Franklin's place in literature as a writer has not been generally appreciated, probably because with him writing was only a means, never an end, and his ends always dwarfed his means, however effective. He wrote to persuade others, never to parade his literary skill. He never wrote a dull line, and was never *nimious*. The longest production of his pen was his autobiography, written during the closing years of his life. Nearly all that he wrote besides was in the form of letters, which would hardly average three octavo pages in length. And yet whatever the subject he touched upon, he never left the impression of incompleteness or of inconclusiveness. Of him may be said, perhaps with as much propriety as of any other man, that he never said a word too soon, nor a word too late, nor a word too much.

The Doric simplicity of his style; his incomparable facility of condensing a great principle into an apologue or an anecdote, many of which, as he applied them, have become the folk-lore of all nations; his habitual moderation of statement, his aversion to exaggeration, his inflexible logic, and his perfect truthfulness,— made him one of the most persuasive men of his time, and his writings a model which no one can study without profit. A judicious selection from Franklin's writings should constitute a part of the curriculum of every college and high school that aspires to cultivate in its pupils a pure style and correct literary taste.

There was one incident in Franklin's life, which, though more frequently referred to in terms of reproach than any other, will probably count for more in his favor in the Great Assize than any other of his whole life. While yet in his teens he became a father before he was a husband. He never did what men of the loftiest moral pretensions not unfrequently do,— shirk as far as possible any personal responsibility for his indiscretion. On the contrary, he took the fruit of it to his home; gave him the best education the schools of the country then afforded. When he went abroad, this son accompanied him, was presented as his son wherever he went, was presented in all the great houses in which he himself was received; he entered him at the Inns of Court, and in due time had him admitted to the English bar; made him his private secretary, and at an early age caused him to be appointed by the Crown governor of New Jersey. The father not only did everything to repair the wrong he had done his son, but at a time when he was at the zenith of his fame and official importance, publicly proclaimed it as one of the great errors of his life. The world has always abounded with bastards, but with the exception of crowned heads claiming to hold their sceptres by divine right, and therefore beyond the reach of popular criticism or reproach, it would be difficult to name another parent of his generation of anything like corresponding eminence with Franklin, who had the courage and the magnanimity to expiate such a wrong to his offspring so fully and effectively.

Franklin was not a member of the visible Church, nor did he ever become the adherent of any sect. With the Unitarian creed Dr. Franklin had more in common than with any other, though he was much too wise a man to suppose that there was but one gate of admission to the Holy City.

Franklin made a somewhat more definite statement of his views on the subject of religion, in reply to an inquiry from President Styles of Yale College, who expressed a desire to know his opinion of Jesus of Nazareth. Franklin's reply was written the last year of his life, and in the 84th of his age:

"You desire to know something of my religion. It is the first time I have been questioned upon it. But I cannot take your curiosity amiss, and shall endeavor in a few words to gratify it. Here is my creed. I believe in one God, the creator of the universe. That he governs it by his providence. That he ought to be worshipped. That the most acceptable service we render to him is doing good to his other children. That the soul of man is immortal, and will be treated with justice in another life respecting its conduct in this. These I take to be the fundamental points in all sound religion, and I regard them as you do in whatever sect I meet with them.

"As to Jesus of Nazareth, my opinion of whom you particularly desire, I think his system of morals and his religion, as he left them to us, the best the world ever saw or is like to see; but I apprehend it has received various corrupting changes, and I have, with most of the present Dissenters in England, some doubts as to his divinity; though it is a question I do not dogmatize upon, having never studied it, and think it needless to busy myself with it now, when I expect soon an opportunity of knowing the truth with less trouble. I see no harm, however, in its being believed, if that belief has the good consequence, as probably it has, of making his doctrines more respected and more observed; especially as I do not perceive that the Supreme takes it amiss, by distinguishing the unbelievers in his government of the world with any peculiar marks of his displeasure.

"I shall only add, respecting myself, that, having experienced the goodness of that Being in conducting me prosperously through a long life, I have no doubt of its continuance in the next, though without the smallest conceit of meriting such goodness. My sentiments on this head you will see in the copy of an old letter enclosed, which I wrote in answer to one from an old religionist whom I had relieved in a paralytic case by electricity, and who, being afraid I should grow proud upon it, sent me his serious though rather impertinent caution."

John Bigelow.

Franklin, Fabian, American mathematician and editor: b. Eger, Hungary, 18 Jan. 1853. After his graduation from Columbian University, Washington, in 1869, he engaged in civil engineering and surveying. In 1877 he became a fellow at Johns Hopkins University, and his advance to the associate and then full professorship of mathematics quickly followed. During his connection with Johns Hopkins, which lasted until 1895, he was a frequent contributor to mathematical and other journals. In 1895 he became editor of the Baltimore 'News.'

Franklin, Sir John, English navigator: b. Spilsby, Lincolnshire, 16 April 1786; d. Lancaster Sound 11 June 1847. When only a boy he went to sea, and later entered the English navy. In 1806 he was present at the battle of Trafalgar, in 1814 at that of New Orleans, and in 1819 was appointed to head an overland expedition from Hudson Bay to the Arctic Ocean. After suffering many hardships and being frequently on the verge of death from hunger and fatigue, he reached home in 1822. In the following year he married a Miss Purden, the daughter of an architect, and the author of several poetical effusions. In 1825 he submitted to Lord Bathurst a plan "for an expedition overland to the mouth of the Mackenzie River, and thence by sea to the northwest extremity of America, with the combined object also of surveying the coast between the Mackenzie and Coppermine rivers." This proposition was accepted, and six days after he left Liverpool, in the same year, his wife died. In 1827 Capt. Franklin arrived at Liverpool, where he was married a second time, and in 1829 had the honor of knighthood conferred upon him. In 1845, Sir John set out on a third expedition with two ships, called the Erebus and Terror, and spent his first winter in a cove between Cape Riley and Beechey Island. After that period many expeditions were dispatched, both from England and America, in search of Sir John, of whom there were no tidings, and not till 1854 did the intelligence reach England that the navigator and his companions had, in all probability, perished in the winter of 1850-1. This intelligence, however, wanted confirmation, and Lady Franklin, who deserves all praise for the intelligent persistency of her efforts, resolved to have the mystery cleared up. Accordingly, a last expedition was fitted out, and the news was, in 1859, at length confirmed by the return of Capt. McClintock, in the yacht Fox, after a persevering search for the lost adventurers. This officer brought with him indisputable proofs of the death of Sir John and the loss of his crew. Several articles belonging to the unfortunate explorers were found at Ross Cairn and Point Victory. At the latter place a record was discovered, wherein it was stated that Sir John Franklin had died 11 June 1847. Other traces were found on the west coast of King William's Island, as the various survivors of the expedition had strayed from each other, perhaps in search of food, or the means of escaping from their dreary and desolate situations. C. F. Hall, the eminent Arctic explorer, returned in September 1869 from a five-years' search for the remains of Sir John Franklin's companions, and brought back about 150 relics of the expedition, purchased from the natives of King William's Land. It remained, however, for Lieut. Schwatka to find the bodies of the Franklin party in his expedition of 1879–80. Franklin was the author of 'Narrative of a Journey to the Shores of the Polar Sea in the Years 1819–22' (1823); 'Narrative of a Second Expedition to the Shores of the Polar Sea in 1825–27' (1828). Consult: McClintock, 'Narrative of the Fate of Sir John Franklin' (1860); Osborn, 'Career, Last Voyage and Fate of Sir John Franklin' (1860); Beesly, 'Sir John Franklin' (1881); Markham, 'Life of Sir John Franklin and the Northwest Passage' (1891); Traik, 'Life of Sir John Franklin' (1896).

Franklin, Samuel Rhoades, American naval officer: b. York, Pa., 25 Aug. 1825. In 1841 he entered the navy as acting midshipman, in 1862 became lieutenant-commander, served in the western gulf blockading squadron (1863), and as assistant to Palmer at New Orleans (1863–4), and was hydrographer to the Bureau of Navigation 1877–80. From 1884 to 1885, when he attained rear-admiral's rank, he was superintendent of the Naval Observatory, and from 1885 until his retirement in 1887 was in command of the European station. He was president of the Washington International Marine Conference (1889), and wrote 'Memoirs of a Rear-Admiral' (1898).

Franklin, William, American colonial governor: b. Philadelphia 1729; d. England 17 Nov. 1813. He was a natural son of Benjamin Franklin (q.v.). He served with the Pennsylvania forces on the Canada frontier, obtained a captain's commission before 1750, in 1754–6 was comptroller of the general post-office, and during a portion of that time clerk of the provincial assembly. He studied law in London and was admitted to the English bar in 1758. In 1762 he became governor of New Jersey. During the Revolution he was a Loyalist, and kept under guard by the patriots from January 1776. In June 1776 he called a meeting of the Colonial

Assembly, then abrogated, for which he was kept prisoner in Connecticut till 1778, when he was exchanged, and later went to England.

Franklin, William Buel, American military officer: b. York, Pa., 27 Feb. 1823; d. Hartford, Conn., 8 March 1903. He was graduated at the United States Military Academy in 1843. In the Mexican war he served on the staff of Gen. Taylor as a topographical engineer; and carried Taylor's orders at the battle of Buena Vista. At the outbreak of the Civil War he was assigned to the command of a brigade in Heintzelman's division. He took part in the battle of Bull Run, served with distinction in the Peninsular campaign and was promoted major-general in 1862. Subsequently he served under McClellan in Maryland and under Burnside at Fredericksburg, was assigned to the Department of the Gulf, under Banks, in 1863; and in 1865 was brevetted major-general in the regular army, but resigned a year later to engage in manufacturing. He was appointed United States commissioner-general to the Paris Exposition in 1899.

Franklin, William Suddards, American physicist and electrical engineer: b. Geary City, Kan., 27 Oct. 1863. He graduated from the University of Kansas in 1887, and the same year was appointed assistant professor of physics there. After studying at Harvard and Cornell and the University of Berlin, Germany, he was appointed in 1892 to the chair of physics and electrical engineering in Iowa State College, remaining there till 1897, when he received his appointment to the same chair in Lehigh University. In 1901 he was a member of the jury of awards of the Pan-American Exposition. He has written 'Elements of Physics' and 'The Elements of Alternating Currents.'

Franklin, a title bestowed upon the English landholders previous to the Norman conquest, who held their lands of the crown free from any feudal servitude. They were bound together by the Frank-pledge, by which the members of each decennary or tithing, which was comprised of 10 families, were held responsible for each other and forced to make reparation if any member committed an offense. In later years they lost their power and dignity, which was usurped by the Normans and became simply wealthy yeomen.

Franklin, Ind., city, county-seat of Johnson County; on the Pittsburg, C. C. & St. L., and the C., C., C. & St. L. R.R.'s; about 75 miles east of Terra Haute, and 16 miles south of Indianapolis. It is in an agricultural section and its chief manufactures are agricultural implements, flour and lumber. Its trade is principally in grain, flour, and boards. It is the seat of Franklin College, founded in 1834 by the Baptist Church. Pop. (1900) 4,005.

Franklin, Ky., city, county-seat of Simpson County; on the Louisville & N. R.R.; about 145 miles southwest of Lexington, and 5 miles from the boundary line between Kentucky and Tennessee. The manufactures are woolen goods, flour, bricks, and lumber. The trade is in the agricultural products of the surrounding country, and the manufactures of the town. It is the seat of the Franklin Military Institute and the Franklin Female College. Pop. (1900) 2,166.

Franklin, La., a town and parish-seat of Saint Mary Parish, 100 miles southwest of New Orleans and 30 miles west of Morgan City, on Teche Bayou, and on the Southern Pacific R.R. It is in the centre of a very fertile district, and as the bayou is navigable for steamers, the town deals in a considerable quantity of cotton, sugar, fruits, etc. There are also several saw-mills located in the town. Pop. (1900) 2,166.

Franklin, Mass., town in Norfolk County, 27 miles southwest of Boston, on the New England R.R. The town also includes the village of Unionville. Dean Academy, an endowed coeducational school, is located here, and the town also has an almshouse, a public library, and six churches. There are manufactories of pianos, straw, woolen, felt and cotton goods, an iron foundry and a canning factory. It was originally a part of the town of Wrentham, but in 1778 was separated and incorporated. The affairs of the community are administered by town meetings. Pop. (1900) 5,017.

Franklin, N. H., a city in Merrimac County, situated at the junction of the Pemigewasset and Winnepesauke rivers, which here unite to form the Merrimac, and on the Boston & M. R.R., 95 miles northwest of Boston. Owing to the abundant water power, numerous mills have located here, among which are paper and pulp mills, machine shops, wood-working shops, hosiery and knitting machine mills, woolen mills and one of the largest needle factories in the world. It is famous as the birthplace of Daniel Webster, and on the farm once owned by him now stands the New Hampshire Orphans' Home. The city owns and operates its waterworks. It was incorporated as a town in 1828 and as a city in 1895. A mayor and council administer public affairs. Pop. (1900) 5,846.

Franklin, Ohio, village in Warren County, on the Great Miami River, and the Miami and Erie Canal, 40 miles northeast of Cincinnati. There are six churches, one high and one primary schools, five paper mills, two wood pulp mills, and three large tobacco warehouses. It was founded by Gen. William Schenck in 1796. Pop. (1900) 2,724.

Franklin, Pa., a city and county-seat of Venango County, 123 miles north of Pittsburg, on the Allegheny River, at the mouth of French Creek, and on the Allegheny V., the Erie, the W. N. Y. & P, and Lake S. & M. S. R.R.'s. The chief business is in oil, as the city is in the heart of the great oil region, but there are also flour mills, planing mills, machine shops, carriage factories, brick works. The city has two beautiful parks and a public library; the streets are provided with sewers and paved with brick. Franklin was first settled in 1753, and was incorporated in 1795. The government is vested in a mayor and council elected annually. Pop. (1900) 7,317.

Franklin, Tenn., town and county-seat of Williamson County, 20 miles south of Nashville, on the Harpeth River, and on the Louisville & N. R.R. The Tennessee Female College, which was established in 1856, and the Harpeth Male Academy are located here, and there are also several public schools and a Masonic Temple. It has flour mills, a furniture factory and a planing mill, several steam cotton gins, and carriage manufactories. It was the scene of two battles during the Civil War, the first on 10 April 1863, between the Federal forces under Gen. Granger and the Confederate forces under Gen. Van Dorn, the latter being defeated; the second on 30 Nov. 1864, between the forces of Gen. Hood and those of Gen. Schofield, and which is famous as the Battle of Franklin (q.v.). Pop. (1900) 2,180.

Franklin, State of, now Tennessee (q.v.). Fifteen years after the Watauga Association was formed (1769), and when four counties west of the present North Carolina had been organized, with some 10,000 people, that State on request of Congress ceded the district to the United States, giving it two years to accept. The inhabitants, already aggrieved at having no supreme court or militia protection, and being left to fight the Indians and keep public order without help, and now, feeling abandoned to at least two years' anarchy, decided to revolt, set up a State, and ask Congress for admission. On 23 Aug. 1784 deputies from three counties met at Jonesboro, resolved on measures, and issued an address to the people. Each county chose five representatives, which met in convention at Jonesboro in November, but were unable to agree, and adjourned to 14 December. Meantime the alarmed North Carolina legislature established a supreme court and proper officers, and formed the Watauga militia into a brigade, commanded by the leader of the revolt, John Sevier. He advised the convention to accept this redress of their grievances; they refused and made him president, drew up a constitution to be ratified by another convention the following November, and named the new State perhaps at first Frankland: if so, they soon changed it to Franklin, after the philosopher. A governor — Sevier — and a legislature were elected; courts established, sheriffs and justices appointed, etc. For the next three years there were two conflicting governments, each levying taxes, disallowing each other's official acts, and making war on each other. The North Carolina militia invaded the Franklin court-house at Jonesboro, seized the papers, and turned the judge and counsel outdoors; a Franklin mob did the same service to a North Carolina court; the North Carolina commander took the papers by force from Sevier's house, and Sevier gathered a force and recaptured them from his opponent's house. At last, in 1788, the North Carolina party prevailed and put an end to Franklin; Sevier was carried off and tried for high treason; a great Watauga militia gathering attacked the town, rescued him from jail, and carried him back home. Finally the North Carolina legislature sensibly passed an act of oblivion and made Sevier a senator, and in 1790 the lands were ceded to the United States. See U. S.— WESTWARD MOVEMENT.

Franklin and Marshall College, located at Lancaster, Pa., was formed in 1852 by the consolidation of Franklin College, founded at Lancaster in 1787, and Marshall College, founded at Mercersburg, Pa., in 1836. Franklin College was organized with a view to meet the needs of higher education in the interior of the State, especially among the Germans, who formed so large a part of the population. Dr. Benjamin Franklin, after whom the college was named, took a deep interest in its welfare, contributed liberally to its endowment, and in his old age made the journey from Philadelphia to Lancaster to be present at its formal opening. Although the college had in its faculty men like Henry E. Muhlenberg, the distinguished botanist, and Frederick V. Melsheimer, the entomologist, and on its board of trustees some of the most prominent men of the commonwealth, its work was that of a first class high school.

Marshall College was founded by the Reformed Church in the United States, when its theological seminary was removed from New York to Mercersburg, to meet the educational requirements of her own communion, and with limited resources accomplished a wonderful work. Among the eminent men in its faculty were its first presidents, Drs. Frederick Augustus Rauch and John Williamson Nevin, and later on Dr. Philip Schaff, all of whom took high rank as philosophers and theologians. The college had a brilliant career, but declined for lack of endowment and pecuniary resources.

When the two colleges were united, James Buchanan became president of the new board of trustees, and the institution entered upon a prosperous career, although it had to make its way in the face of many obstacles and limitations. Its growth was checked by the Civil War, from the effects of which it but slowly recovered. During the last fifteen or twenty years, however, its growth has been rapid, and it now compares favorably in point of equipment, grade of scholarship, and number of students with its sister colleges in the State of Pennsylvania.

Franklin and Marshall College makes no pretense to be a university. It lays stress upon the college course as a means of liberal education, with sufficient elasticity in the way of electives to make first class preparation for technical or professional study. It confers the degrees of A.B. and Ph.B. for undergraduate work, and A.M. for graduate work, after the completion of the prescribed courses and satisfactory examinations.

The site of the college is exceptionally fine. The principal buildings are: the main building, the halls of the literary societies, the Daniel Scholl Observatory, the gymnasium, the Academy building, the De Peyster Library, and the new Science building, with admirable equipment for physics, chemistry, and biology. The libraries contain altogether about 42,000 volumes. The students in the college proper and the academy number 357, and the faculty 21. This account does not include the Theological Seminary of the Reformed Church, which, although in close proximity to the college, is a separate institution.

JOHN S. STAHR,
President.

Franklin, Battle of. On 12 Nov. 1864 Gen. Sherman turned back from his pursuit of Hood to begin his march from Atlanta to the sea, leaving Gen. Thomas to act on the defensive in Tennessee or to take the offensive in Alabama. Hood was at Florence and Tuscumbia, on the Tennessee River, threatening Nashville, with an army of 44,000 men. Thomas' command, much smaller, was widely distributed from Chattanooga to Nashville. Gen. Schofield was at Pulaski, Tenn., 80 miles south of Nashville. With the Fourth corps under Gen. Stanley, a part of the Twenty-third corps, under Gen. Cox, and a division of cavalry. Thomas instructed Schofield to delay Hood, should he advance, until the army could be concentrated and Nashville reinforced. On the 21st Hood moved on Schofield's right. Schofield withdrew from Pulaski on the 22d, reached Columbia on the 24th, and remained there until the 27th, when Hood forced him to withdraw to the north bank of the river. On the 28th Schofield learned that Forrest's Confederate cavalry threatened his line of withdrawal through Spring Hill, 11 miles in his rear, and early on the morning of the 29th all his trains and three divisions of infantry were put in motion for Spring Hill. Stanley led, and arrived at Spring Hill just as Forrest reached it. Stanley checked Forrest and took defensive positions. Hood followed Forrest, and during the night Schofield's entire army passed through Spring Hill, in sight of Hood's bivouac fires, for Franklin, 12 miles distant, which the advance reached before daylight of the 30th. Being unable at once to cross to the north bank of the Harpeth River, Schofield, who was closely followed by Hood, had to fight to save his trains, with a river at his back. He threw up a line of entrenchments, and a division of the Fourth corps under Stanley crossed to the north bank of the river, all those remaining in the works south of it being under command of Gen. Cox. By noon the trains were in, and most of them crossed to the north bank. Not anticipating a general attack, Schofield gave orders for the withdrawal of the troops at sunset. He was mistaken as to the intention of Hood, who had closely followed his rear with Forrest's cavalry, and when Wagner's division, acting as Schofield's rear-guard, had halted and thrown up barricades about 280 yards beyond the main line, Hood rapidly advanced his infantry and ordered a desperate assault to drive the Union forces into the river. Two of Wagner's brigades were on either side of the Columbia road; Opdycke's brigade had come into the main line and was massed 200 yards in rear of the entrenchments. Wagner's orders were "to develop the enemy, but not to attempt to fight if threatened by too strong a force." Hood formed his lines with celerity on either side of the Columbia pike, Cleburne's and Brown's divisions of Cheatham's corps on the east and west sides of the road respectively, in two lines of battle. When within 400 yards of Wagner's line, at 3.30 P.M., the charge was ordered and, with a wild shout, they rushed forward. Wagner was enveloped on both flanks and fiercely attacked in front, the Confederates rushed over his barricades, and his men gave way in the greatest disorder, closely pursued by the exultant enemy. When within 100 yards of the main line the Union artillery and infantry opened fire. Cleburne, who was leading his division, was shot dead, great gaps were made in the ranks, but the line pressed on, carried the centre of the Twenty-third corps' line for the length of a brigade, went over the works, captured two batteries and many prisoners, reached an inner line of intrenchments, 68 yards in rear of the main line, and here they were checked. Col. Opdycke, who had massed his brigade in rear, when he saw Wagner's men falling back in disorder, and that the works in front had been captured, ordered his men forward. Deploying as they advanced, they rushed upon the Confederates, and a desperate hand-to-hand encounter took place, resulting in the retreat of the enemy to the outer line of works, the capture by Opdycke of nearly 400 prisoners and 9 battle-flags, and the recovery of the captured batteries. Gen. Thomas says Opdycke's prompt action "saved the day." Meanwhile the battle had extended to the right and left, involving all of the Twenty-third corps and the left brigade of Kimball's division. The Confederates reached the works in many places, but were unable to carry them. On both sides the fighting was most gallant. At midnight the Union army crossed to the north bank of the river and marched to Nashville.

The Union army engaged at Franklin, not including cavalry, numbered about 23,000 men, of whom 189 were killed, 1,033 wounded, and 1,104 missing. Of this loss 1,241 were in Wagner's division. The Confederates engaged numbered about 22,000. There are no official reports of Hood's losses, but Schofield reports that 1,750 were buried on the field, 3,800 were disabled and placed in hospital, and 702 captured, an aggregate of 6,252, to which must be added the slightly wounded, probably 2,000. Consult: 'Official Records,' Vol. XLV.; Cox, 'Battle of Franklin' 'The March to the Sea, Franklin and Nashville'; The Century Company's 'Battles and Leaders of the Civil War,' Vol IV.

E. A. Carman.

Franklin College, a coeducational institution in Franklin, Ind.; founded in 1834 under the auspices of the Baptist Church; reported in 1905: Professors and instructors, 17; students, 200; volumes in the library, 12,300; productive funds, $300,000; grounds and buildings valued at $75,000; income, $33,000; number of graduates, 394.

Franklin Institute of the State of Pennsylvania for the Promotion of the Mechanic Arts. A famous school in Philadelphia, established in 1824, which now embraces schools in mechanical and architectural drawing, machine design, naval architecture, etc. The objects of the institute are obtained by means of a journal (begun in 1826), lectures, libraries, reports, exhibitions and school instruction. The library now contains 55,000 volumes and 38,500 pamphlets. The institute grants medals, premiums and certificates for mechanical inventions. The Institute building is located at 15 South 7th Street, Philadelphia.

Franklinism. See Electricity.

Frank'linite, a native oxide of zinc, manganese and iron, containing these metals in rather widely varying proportions. It crystallizes in the isometric system with octahedral habit, and also occurs in massive and granular forms. It is opaque, slightly magnetic, and iron-black in color, commonly with a metallic lustre. Its hardness varies from 5.5 to 6.5, and its specific gravity from 5.1 to 5.25. In the United States it occurs in considerable quantity in the neighborhood of Franklin Furnace, N. J., taking its name from the locality, where it is mined as an ore of zinc, its manganese and iron being melted into "spiegeleisen," an alloy used in the manufacture of Bessemer steel.

sistant in the British Museum in 1851; and served as keeper of the Department of British and Mediæval Antiquities for many years. He was knighted in 1888; and was president of the Society of Antiquities from 1892 till his death. His publications include 'Recent Excavations and Discoveries on the Site of Ancient Carthage' (1860); 'Guide to the Christy Collection of Prehistoric Antiquities and Ethnography' (1868); 'Catalogue of a Collection of Oriental Porcelain and Pottery' (1876); etc.

Franks ("Spearmen"), **The.** In the 3d century A.D. (the name first appears in 240, under the Emperor Gordian), the scattered Teutonic tribes north and east of the middle and lower Rhine, in the present Westphalia, Hesse, Gelderland, etc., united in a loose confederacy; very probably compacted by the ancestor of the Meroving family, to whom the Franks clung so loyally and even stupidly for centuries. The tribes themselves were known from the early empire: Ampsivarii, Attuarii, Batavi, Bructeri, Chamavii or Gambrivii, Chatti, Cherusci, Sali, Sigambri, Usipetes, etc. In 253 under Valerian they raided Belgic Gaul, and half a century later had permanently settled south of the lower Meuse in Brabant. They are early distinguished as Salian and Ripuarian Franks: the former (from their chief tribe, perhaps originally on the Isala or Yssel) on the lower Rhine; the latter (*ripa*, bank) on both banks of the middle Rhine. The Salians, after heavy defeats by the Romans, became their allies and wardens of the marches; but when the pretender Constantine withdrew the Roman garrisons in 406 for his attempt on Italy, they flooded central Belgium, and Colonia Agrippina (Cologne) shortly fell into their hands. By 450 they had reached the Moselle and the Somme, or Luxemburg and northwest France; but still acknowledged Roman sovereignty. They sent forces to help the Romans against Attila at Châlons; but when the Huns had retreated from the fortresses whence they had expelled the Romans,— Trier, Mainz, Metz, etc.,— the Franks occupied them and the lands on the Rhine and Moselle instead of the Romans. The Salians now held the territory from the Scheldt to the Somme and Meuse, or most of Belgium and a little of France; the Ripuarians from the Meuse to the Rhine, and the lands along that river from the Lippe to the Lahn. They were still pagans; backward in the arts of war; had no political union or common head, though their chiefs all claimed Meroving descent; and were credited with being treacherous and perfidious even beyond barbarian wont, which their history makes probable.

When the Western Empire fell, the Rhone and Saône valleys were occupied by a Burgundian kingdom; central and northern France by a Roman province with no one to obey; below which was the great Visigothic kingdom of Euric, taking in south France and nearly all the Spanish peninsula. Five years later (481) a Salian prince of the upper Scheldt named Chlodovech (Latinized Clovis) acceded, and in 485 fell on the Roman province in alliance with other princelings. In three years he had conquered it, making Gaul to the Loire and Brittany a Frankish possession; refusing to share the spoil with his allies, he attacked and subjugated all the Ripuarians, slaying every Merovingian prince he could seize, to exterminate all rivals. In 492 he married Clotilda, the Catholic niece of the Burgundian king. In 496 he subdued the Alemanni, and Frankish settlers founded Franconia. On returning from this campaign he was baptized a Christian, in the Athanasian creed; and in a single generation the entire Frankish body, now consolidated into one, renounced paganism. He then conquered nearly all Visigothic Gaul. But Burgundy was too strong for him. He died in 511. The chance of Chlodovech becoming an Athanasian instead of an Arian had the most important consequences: alone of all the barbarian conquerers of Rome, his subjects were in religious sympathy with him, and his work endured, while the Arian kingdoms crumbled to pieces. This also began the career of the Frankish monarchy, for centuries, as the champion of the Church, helping it and helped by it.

Chlodovech began the practice of dividing the kingdom among his sons, which his successors followed; again and again death or the strong hand united the realms, again a legacy would divide them; and the records of the ferocious, half decrepit, perfidious Merovingians are the blackest in all European history for unredeemed wickedness and unprogressive anarchy. Scarce one of them for a century lived to be 40, and scarce one showed any gleam of statesmanship to justify his atrocities or his even worse weakness. At last in 613 the dominions — which had generally followed the fourfold divisions of Austrasia, Neustria, Burgundy, and Aquitaine — were united for a seeming finality, but the Merovingian kings ceased to have any but a nominal sovereignty. The great provincial governors, in the anarchy, had made their offices hereditary; the officers of state likewise — chamberlain, keeper of the seal, etc. Of these the mayors of the palace became the *de facto* rulers; keeping the kings as puppets, but making them live as country gentlemen, only attending court functions annually, in a farm-cart and with long hair. This mayoralty in Austrasia fell into the hands of one of the most wonderful families of the world, the Karlings or Carlovingians, who mostly held possession of it for a century, till one of them became king; and later the mightiest of them, Charlemagne, became emperor of the Romans in a revived empire. Pepin, or Pippin of Landen, "the Elder," was the first, dying 639; then his son Grimwald, murdered 656; the latter's sister married the son of Arnulf Bishop of Metz; and their son was Pepin the Younger or Pepin of Heristal, who, after 30 years of anarchy and partition and reunion following Grimwald's death, finally and forever reunited the Frankish realms by a crushing defeat of the allied forces of Neustria and Burgundy at the battle of Testry, 687. His son, Charles Martel (Hammer), who held power 717–41, carried civilization at the sword's point among the Germans, and in 732 routed a great Saracen army at Poitiers, saving France from the Mussulman. His son Pepin the Short, after 10 years of mayoralty, deposed the last driveling Meroving and ascended the throne. Pepin's son Charles (Carolus Magnus, Charlemagne, perhaps with a confusion of the title with the name Carloman), acceded in 768. As warrior, statesman, and lawgiver, he stands among the foremost of all time. The Frankish realm as such attained by far its greatest extension under him — though it is incorrect to say, as is usual, that his work perished with him, for the pieces of his realm never went back to their old anarchy. He ruled a vast congeries of races, from north Spain to north Germany, and from the Hungarian plains to the English Channel; and he brought them all under the reign of law and Christianity, inheritors of the memories and civilization of Rome. In 800 he crowned the career of the Franks begun by Clovis, becoming secular head of a Holy Roman Empire, of which the Pope was the spiritual head. Whether it was well judged or beneficial to the world, historians are still divided. The history of Charlemagne's successors is not the history of the Franks: after this they have become merged in a wider aggregation.

The Frankish dominion was the conduit through which the treasures of Rome, political, social, and ecclesiastical, were given to the world. Roman law, Roman literature, and the Christian religion were forced on the barbarians through the Franks: that Europe is what it is, we have to thank them first of all. The best modern compendium is Oman's 'History of the Dark Ages' (1901).

Franz, fränts, **Robert**, German composer: b. Halle 28 June 1815; d. Berlin 24 Oct. 1892. He studied under Schneider at Dessau 1835–7, and in 1843 published his first set of 12 songs, which won the warm praises of Schumann, Mendelssohn, Liszt, and other masters. From then till 1868 he held various appointments at Halle. He published over 250 songs with pianoforte accompaniments, a Kyrie, and several chorales and four-part songs, besides arrangements of the vocal masterpieces of Bach and Handel. Franz's best songs rank with those of Schubert and Schumann.

Franz-Josef Land, fränts'-yō'zĕf-länt, an Arctic archipelago, north of Nova Zembla, extending, so far as it has yet been explored, between lat. 80° and 83° N. It consists of two large masses of land, Wilczek Land to the east, and Zichy Land to the west, separated by Austria Sound, and Rawlinson Sound. Between these two sounds lies Crown Prince Rudolf Land, while to the north of this again comes Petermann Land, and to the northwest King Oscar Land. The southern shores are deeply indented with fjords; and the whole archipelago, which rises into isolated flat-topped or dome-shaped mountains of basalt, 5,000 feet high, is sheeted with ice. Owing to the open water round its shores in summer, and the comparative abundance of its animal life — bears, walruses, foxes, and numerous birds occurring — Franz-Josef Land is regarded by many experienced Arctic explorers as the most favorable base whence to make an attempt to reach the North Pole. The archipelago was discovered and partly explored by Payer and Weyprecht in 1873–4; its southern shores were explored by Leigh Smith in 1880–2, and much of it by the Jackson-Harmsworth expedition in 1895–6. See POLAR EXPLORATION.

Franzensbad, fränt'sĕns-bät, **Egerbrunnen**, ā'gĕrbroon-nĕn, or **Kaiser-franzensbad**, Bohemia, a celebrated Austrian watering-place, about three miles north of Eger, with which it is connected by a fine avenue. It is situated amid low bare hills, and consists of four rectangular streets lined with trees. The mineral springs here were known in the 16th century, and even at that time the waters were made up in bottles to be sent to a distance. It was selected as a watering-place in 1793 by the Emperor Francis II., from whom it received its present name. The bathing establishment consists of an irregular building erected over the springs with a long colonnade extending to the Kurhaus, where the visitors assemble, and the balls and concerts are given. The springs, 12 in number, are alkaline, taline, chalybeate, and are very efficacious in cases of anæmia, dyspepsia, catarrh of the bowels, uterine disorders, etc. The mud baths of Franzensbad are much used by those suffering from gout, rheumatism, skin diseases, etc. Pop. (1890) 2,330.

Fra'ser, Agnes, («FRANCES MAC NAB»), English traveler and writer: b. Halstead, Essex, 7 Dec. 1859. She studied art in London 1882–4, and has since traveled extensively in Algiers, Norway, British Columbia, Morocco, and South Africa. She has published: 'No Reply' (1888); 'Relics: Fragments of a Life' (1893); 'On Veldt and Farm in Bechuanaland, Cape Colony, the Transvaal, and Natal' (1897); 'British Columbia for Settlers' (1898); 'A Ride in Morocco among Believers and Traders' (1902).

Fraser, Alexander Campbell, Scottish philosophical writer: b. Ardchattan, Argyleshire, 3 Sept. 1819. He was a lecturer on mental philosophy in the New College, Edinburgh, 1846; editor of the 'North British Review' (1850–7); professor of logic in Edinburgh University 1856–91. His principal productions are: 'Essays in Philosophy' (1856); 'Rational Philosophy' (1858); a memoir of Bishop Berkeley, with a collected edition of his works (1871–90); an annoted edition of Locke's 'Essay on Human Understanding' (1894); 'Philosophy of Theism' (1898), etc.

Fraser, Augusta Zelia Webb («ALICE SPINNER»), Scottish novelist. She was married to Affleck Fraser 1889. She has published over the pseudonym «ALICE SPINNER,» 'A Study in Color'; 'Lucilla'; 'A Reluctant Evangelist.'

Fraser, Charles, American painter; b. Charleston, S. C., 20 Aug. 1872; d. there 5 Oct. 1860. He studied law, was admitted to the bar in 1807, but withdrew from practice in 1818, and acquired, particularly in the South, a considerable reputation as a miniature-painter. His sitters included Lafayette (1825) and most prominent South Carolinians for 50 years. He also painted interiors, landscapes, genre, and still-life scenes, and historic subjects. An exhibition of his works at Charleston in 1857 comprised 313 miniatures and 139 other canvases in oils. Publication: 'Reminiscences of Charleston' (1854).

Fraser, MRS. Hugh. See FRASER, MARY CRAWFORD.

Fraser, James, English prelate: b. Prestbury, Gloucestershire, 18 Aug. 1818; d. Manchester 22 Oct. 1885. He was educated at Lincoln College, Oxford, took orders in the English Church and was rector at Cholderton, Wiltshire, 1847–60; and of Ufton Newet, Berkshire, 1860–70. In the year last named he became bishop of Manchester, in which position he gained the approbation of churchmen and nonconformists alike. Under his administration the diocese made a most remarkable advance.

Bishop Fraser was greatly interested in educational matters and visited the United States and Canada in 1865 as a commissioner of education, subsequently publishing a ‘Report on the Common School System of the United States and of Upper and Lower Canada’ (1866). A bronze statue of Bishop Fraser stands in the square before the Town Hall of Manchester, and in the Fraser Chapel of the Cathedral of Manchester is a recumbent statue in marble of the much beloved prelate. See Hughes, ‘Memoir of Bishop Fraser’ (1887).

Fraser, Mary Crawford (MRS. HUGH FRASER), English novelist: b. Rome. She is a sister of F. M. Crawford (q.v.), the novelist, and was married to Hugh Fraser, English minister to Japan, who died in 1894. She is the author of ‘The Brown Ambassador’ (1895); ‘Palladia’ (1896); ‘A Chapter of Accidents’ (1897); ‘The Looms of Time’ (1898); ‘A Diplomatist's Wife in Japan’ (1899); ‘The Customs of the Country: or Tales of New Japan’ (1899); ‘The Splendid Porsenna’ (1899), etc.

Fraser, Simon. See LOVAT, TWELFTH LORD.

Fraser, William Alexander. Canadian author: b. Picton County, N. S., 24 March 1859. He traveled widely and became a mining engineer, but subsequently turned his attention to writing. He has contributed much to English and American magazines; published an interesting collection of animal stories, ‘Mooswa and Others of the Boundaries’ (1900), and also ‘The American Animal Book,’ and ‘The Outcast’ (1901).

Fraser River, the principal river in British Columbia, rising in the Rocky Mountains, in lat. 53° 42′.; lon. 119° W. It flows northwest for about 270 miles, then turns south, and after a total course of over 700 miles falls into the Gulf of Georgia, in lat. 49° N. Gold is found both on the Fraser and its affluents. Its principal affluents are the Thomson, Quesnelle, and Stuart rivers.

Fraserville, or Reviere du Loup, rē-vē-ār dü loo, Canada, a town and county-seat of Temiscouata County, Quebec, on the south shore of the St. Lawrence at the confluence of the Reviére du Loup, 116 miles below Quebec. It is on the Intercolonial Railway and is the terminus of the Temiscouata Railway. Its permanent population is almost entirely French Canadian. It has a good trade and manufactories of pulp, leather, lumber, furniture, iron products and woollens. There are three churches (2 Angelican and 1 Catholic), a convent, hospital, and collegiate institute. It has a creamery, banks, and newspapers (French), and is a popular summer resort. Pop. (1901) 4,569.

Fraternal Insurance. See INSURANCE, FRATERNAL.

Fraternal Societies in America. A fraternal society is defined as a corporation or voluntary association organized and carried on for the sole benefit of its members and their beneficiaries. It has no capital stock and is not operated for profit. Every such society must have a representative form of government, and is supposed to operate on the lodge system, with a ritualistic form of work for the meetings of the lodges or other designated subordinate bodies. It has power to adopt its own constitution, by-laws, rules and regulations for the orderly conduct of its affairs, and in general terms may manage its internal interests as it may deem best. Although the American fraternities have the same basis as the friendly societies (q.v.) of England and Scotland, they are a purely American institution, organized without reference to, and at the outset of their career, in entire ignorance of the fact that the same system was in successful operation elsewhere. At the present time the laws governing the fraternal system are in a state of transition, and as the fraternal societies are the creatures of, and governed by the laws of the different States, any change in those laws will necessarily change or modify the system as at present operated.

There are two representative bodies, claiming to act for, and represent a large constituency among the fraternal associations. The National Fraternal Congress, organized in 1886, represents the larger number of leading societies. From its official reports it appears to aim at eventually securing the adoption of a uniform law throughout the United States and Canada, defining as fraternal society, as above expressed, with the addition, that every society shall pay a death benefit on the death of a member, and may pay disability payments, resulting from accident, disease, or old age. During the years 1900 and 1901 the Congress made a vigorous effort to secure the passage of a uniform bill in the legislatures of all the leading States, restricting the benefits, coupled with a provision requiring all the newer organizations to charge adequate rates, but allowing the older societies to continue their low rate assessment system. This action was bitterly opposed by the minority of the Congress and by a still larger number of other associations, that were not affiliated with the Congress. The result of this opposition was the defeat of the proposed law in every State where a contest was made.

The outside societies that participated in this contest, feeling the need of a union, for mutual protection thereafter, immediately after the contest was ended met together and in March 1901, organized the Associated Fraternities of America, with the avowed object of opposing any further changes in the laws of the different States until public sentiment was ripe for the adoption of a uniform law on the basis of the largest liberty to each society in the matter of benefits, provided adequate rates are charged therefor. This dissension among the fraternal societies induced the convention of the insurance commissioners of the different States to formulate a proposed law for the government of fraternal societies, containing many new and startling features.

All the early fraternal associations collected their contributions from their members by means of assessments, the rate of which, except in two instances, was graded according to age at entry, and each member was required to pay such a number of assessments each month as might be needed to meet the death losses. As these older organizations advanced in years, their death losses necessarily increased in number, and with increased death losses the number of assessments each month also increased. During this period many new societies were organized on the same system and while young, naturally had a low death rate, and a low mortality cost per member. Being much cheaper they naturally attracted members from their predecessors until they were displaced in popular favor by other new creations on the same plan. Whatever differences of opinion may now exist among fraternalists as to the need of the systems at the present time, they all agree that the old assessment system has been a failure, and should be superseded by rates based on the recognized mortality tables. The newer organizations profited by the experience of the older societies, and generally started with higher rates, and this fact has made it much easier for them to provide for their deficiencies. A large number of the younger organizations are, and for some years have been, charging adequate rates, and the protection they furnish is as safe as the insurance supplied by any insurance company.

The real basis of the fraternal system in America is the fraternal bond of union, uniting the members together in a common cause for mutual beneficial and protective purposes. The lodge system requires meetings of the members at least once a month, and therefore directly tends to draw the members closer together. Every member thus participates in the work of the organization and the emulations aroused among the different lodges naturally produces the best results at the least outlay. Bread cast upon the waters will return, and it is the act of casting that produces that wonderful change in the human heart, which constitutes the return. A mother is fonder of her offspring than the father, and both parents love a crippled child more than the sturdy members of the flock, and the reason is the same. The mother suffers more and bears more than the father, and both do more for the cripple than for the healthy child. No one ever did a good deed, or thought to do a good act without feeling the better for it, and thus no person ever did or can participate in the good work that the various lodges of the fraternities are engaged in without growing to love the work and the organization which does the work. This ennobling influence upon the membership is not by any means the least of the many blessings conferred upon the American people by the fraternal system. This same influence naturally impels the members to labor without compensation for the growth and prosperity of the organization and thus at a low cost produce results beyond the dreams of avarice to the insurance companies.

Every society is required to have a representative form of government and is governed by its constitution and laws, as enacted, or from time to time amended, by the constituted authorities. Its constitution and laws therefore constitute the contract between the members in their relations to the society. The protection furnished by such societies is not insurance in the ordinary sense, in which that word is understood and used. No society can issue a certificate in favor of a creditor of the member and the benefits furnished under the certificate cannot be attached for the debt of the member. The beneficiaries are limited to husband or wife, affianced husband, or affianced wife, or, some heir, blood relative, or dependent of the member. In insurance anyone having an insurable interest in the life of the policy holder may be named as beneficiary while under a fraternal certificate the beneficiary is limited by the bonds of affection and duty. In the one case a beneficiary has a vested interest in the policy and it cannot be changed without her consent, while in the other the beneficiary has no vested rights whatever until the claim matures; and the member may have his certificate changed in favor of another beneficiary without her knowledge or consent.

Among the prominent large fraternal societies in the United States are the Odd Fellows, founded in 1810; Knights of Honor 1873; Knights of Pythias 1877; and Royal Arcanum 1877. The insurance paid by these varies from $500 to $3,000. There are numerous other societies conducted on the same principle. According to the reports of the supreme bodies of these organizations for 1904, the membership of the principal fraternal organizations in the United States and Canada was as follows:

Odd Fellows	1,341,375
Freemasons	1,011,655
Modern Woodmen of America	700,359
Knights of Pythias	594,883
Ancient Order of United Workmen	423,015
Knights of the Maccabees	375,000
Improved Order of Red Men	355,662
Royal Arcanum	303,597
Foresters of America	299,081
Independent Order of Foresters	224,000
Woodmen of the World	217,128
Ancient Order of Hibernians	193,832
Benevolent and Protective Order of Elks	190,000
Order of Eagles	165,000
Junior Order of United American Mechanics	130,977
Ladies of the Maccabees	140,000
Knights of the Modern Maccabees	127,000
Knights of Columbus	122,645
Ladies Catholic Benevolent Association	87,400
Tribe of Ben Hur	85,267
Knights and Ladies of Honor	76,761
Court of Honor	70,426
Knights of the Golden Eagle	69,385
National Union	69,000
Improved Order of Heptasophs	62,860
Catholic Mutual Benefit Association	58,035
Protected Home Circle	56,000
Knights of Honor	52,600
Brotherhood of American Yeomen	47,025
Order of B'rith Abraham	46,234
Order of Gleaners	46,000
United Order of American Mechanics	42,691
New England Order of Protection	39,098
Ancient Order of Foresters	38,898
Sons of Temperance	34,789
Independent Order of B'nai B'rith	31,500
Catholic Benevolent Legion	28,000
Knights of Malta	28,000
Smaller organizations	284,541
Total	8,278,779

All the older associations operate on what is known as grand jurisdictions, consisting of representatives elected by the subordinate lodges within the limits of the grand jurisdiction. It in turn sends delegates to the supreme body, which is the highest authority in the organization. As a general rule the supreme body assumes all liability for death or disability payments that are permanent in their nature, and the subordinate lodges assume and pay the sick or other temporary disability benefits. Each member pays his share of all benefits through the local lodge, of which he is a member, the dues going to the supreme office, being remitted direct, and not through the grand jurisdiction. As a rule the grand jurisdiction covers a State, and has supervision over the growth and general management of all the lodges within its territory. Of late years the tendency has been to do away with the plan of grand jurisdictions and have the supreme body composed of delegates elected either directly by the lodges or by districts composed of a number of lodges. The officers are usually elected by the supreme body, but in some cases are elected by a direct vote of the members.

To sum up in a word: a fraternal society is a brotherhood of members, bound together by its fraternal bond of union. It is organized and carried on for the sole benefit of its members and their beneficiaries. It operates on the lodge system, and uses a ritual in the meetings of its lodges and the initiation of its new members. It has a representative form of government, in which the management is responsible to the members for the faithful performance of their duties. It is governed by a constitution and laws enacted by the representatives of its members, and it furnishes its members, in all the States, with protection in case of death, and in many of the States with protection in case of disability resulting from illness, accident and old age, after the expectancy of life, and in some of the States with still more liberal benefits. See INSURANCE, FRATERNAL, and the articles on the different fraternal organizations.

FREDERICK GASTON,
President the Grand Fraternity.

Frater'nities, religious societies for pious practices and benevolent objects. They were often formed during the Middle Ages, from a desire of imitating the holy orders. From the 12th to the 15th century nothing was considered more meritorious than to form and belong to such orders. The laity, who did not wish to pronounce the monastic vows, entered into associations in order to gain some of the advantages of the religious even in their worldly life. These societies were at first formed without any ecclesiastical interference, and on this account many of them, which did not obtain or did not seek the acknowledgment of the Church, had the appearance of separatists, which subjected them to the charge of heresy. The pious fraternities which were formed under the direction of the Church, or were acknowledged by it, were either required by their rules to afford assistance to travelers, to the unfortunate, the distressed, the sick, and the deserted, on account of the inefficiency of the police, and the want of institutions for the poor, or to perform certain acts of penitence and devotion. Of this description were the Fratres Pontifices, a brotherhood that originated in Tuscany in the 12th century, where they maintained establishments on the banks of the Arno, to enable travelers to cross the river, and to succor them in case of distress. A similar society was afterward formed in France, where they built bridges and hospitals, maintained ferries, kept the roads in repair, and provided for the security of the highways. A bridge of 18 arches over the Rhône at Avignon, built by St. Bénézet in 1177, and another of 22 arches over the same river at Pont St. Esprit, built between 1265 and 1309, were among their greatest achievements in bridge-building. They gradually amassed great wealth by alms and gifts. In 1519 they were secularized on account of the abuses that had crept into the order.

Similar to these were the Knights and Companions of the Santa Hermandad in Spain; the Familiars and Cross-bearers in the service of the Spanish Inquisition; the Calender Brothers in Germany; the Alexians in Germany, Poland, and the Netherlands, etc. The professed object of the Alexians was to visit the sick and imprisoned; to collect alms for distribution; to console criminals, and accompany them to the place of execution; to bury the dead, and to cause masses to be said for those who had been executed, or for persons found dead. They derived their name from Alexius, their patron saint, and were at first principally composed of persons from the lower classes of the people in the Netherlands. They were afterward increased by the addition of the female branch, the Black Sisters. Although lay brothers they had houses, and formed their order into two provinces under an ecclesiastical government. They still exist, in the societies for burying dead bodies, in Antwerp, Utrecht, and Cologne. The Brothers of Death, of the order of St. Paul, were dressed in black, like the Alexians, and were distinguished by a death's head on their scapulary. They were suppressed by Pope Urban VIII.

There were also Gray Penitents (an old fraternity of an order existing as early as 1264 in Rome, and introduced into France under Henry III.), the black fraternities of Mercy and of Death; the Red, the Blue, the Green, and the Violet Penitents, so called from the color of their cowl; the divisions of each were known by the colors of the girdle or mantle. The fraternity of the Holy Trinity was founded at Rome in 1548 by Philip de' Neri for the relief of pilgrims and the cured dismissed from the hospitals. The Brothers of the Christian Schools are a fraternity founded near the end of the 17th century, the statutes of which were approved by Benedict XIII. Their labors have been of great service in the cause of elementary and secondary education in France, though their work is not confined to France but extends over a large part of the world, including Belgium, North and South America, and England. They take religious vows, wear a suit of clerical dress, and always work in pairs. In Ireland there is a body of Christian Brothers modeled on the French one, the first of its schools having been opened at Waterford in 1804. Their schools have spread over Ireland, and their system of education has received the approval of various Royal Commissions.

The Brothers of Common Life, founded at Deventer in Holland by the celebrated theologian, Gerald Groot, toward the end of the 14th century, and formally approved by Gregory XI. in 1376, were a fraternity which performed great services to learning, especially theological learning. From Holland they spread rapidly over Germany, and increased so greatly in numbers that 500 houses belonged to the order in 1460. The Roman Catholic Church is indebted to it for a text of the Latin version of the Bible by St. Jerome, most carefully prepared by a collation of the most ancient manuscripts. This text was consulted as an authority by the editors of the Bible prepared at the command of Sixtus V. The same order prepared some texts of the Christian fathers.

The Brothers of Charity are another fraternity whose hospitals are found in the principal cities. It was founded by St. John de Dieu in Spain in 1540. Much better known in Great Britain are the Sisters of Charity (called also Gray Sisters, Daughters of Charity, Sisters of St. Vincent de Paul), a Roman Catholic order founded in 1634 at Paris by St. Vincent de Paul for the purpose of nursing the sick in hospitals. The sisters take vows of poverty, chastity, and obedience, besides a vow binding themselves to serve the sick. Besides conducting hospitals and nursing, they sometimes undertake the manage ment of poor schools. They attend the sick of every nation and religion. There is also a body of Irish Sisters of Charity, separate from the one just mentioned. See ORDERS, RELIGIOUS.

Fraternities, College. See GREEK-LETTER SOCIETIES.

Fraticelli, frăt-ĭ-sĕl'ī, a name applied to several heretic sects in the Middle Ages. They were generally opposed to existing ecclesiastical and social order and were similar to the Brethren of the Free Spirit, Beghards and other sects. They had no fixed place of residence. In 1260 to 1300 the Fraticelli made considerable progress and attracted more or less attention in northern Italy. They declared the existing Church as in a state of apostasy and looked upon poverty as an absolutely essential condition.

Fratricellians. See FRATICELLI.

Fraud, in law, all deceitful practices in defrauding or endeavoring to defraud, another of his known right, by means of some artful device, contrary to the plain rules of common honesty. It is condemned by the common law, and punishable according to the offense. All frauds and deceits for which there is no remedy by the ordinary course of law are properly cognizable in equity. Where a fraud can be clearly established, courts of law exercise a concurrent jurisdiction with courts of equity. Wherever fraud or surprise can be imputed to, or collected from, the circumstances, equity will interpose and grant relief against it. Where a person is party to a fraud, all that followed by reason of that fraud shall be said to be done by him. A party prejudiced by a fraud may file a bill in equity for a discovery of all its circumstances. Mere inadequacy of price alone is not a ground for a court to annul an agreement; but if there be such inadequacy as to show that the person did not understand the bargain he made, or was so oppressed that he was glad to make it, knowing its inadequacy, it will show a command over him which may amount to a fraud. If a person be fraudulently prevented from doing an act, equity will consider the act as done; and equity also relieves against bargains made under misconception of rights. In treaties, concealment of a material fact by one of the parties, in order to keep the other in ignorance, whereby to profit, is a gross fraud, and the contract will be set aside in equity. Constructive or legal fraud is applied to such acts or contracts as, though not originating in any actual evil design or contrivance to perpetrate a positive fraud or injury upon other persons, yet by their tendency to deceive or mislead other persons, or to violate public or private confidence, or to impair or injure the public interest, are deemed equally reprehensible with actual fraud, and are prohibited by law, as within the same reason and mischief as acts and contracts done *malo animo*. Gross criminal frauds are punishable by way of indictment or information. Frauds are not indictable at common law unless they be such as affect the public — as vending unwholesome provisions, or using false weights or measures; or by way of conspiracy; or unless they affect the crown or the administration of justice. See FRAUD, STATUTE OF; FRAUDULENT CONVEYANCES.

Consult: Browne, 'Construction of the Statute of Frauds' (1895).

Frauds, Statute of. Perhaps one of the most important statutes ever enacted in England or the United States was the Statute of Frauds (29 Charles II. ch. 3). It was passed in the year 1673. Its object is stated to be the "prevention of frauds and perjuries," and its effect is to make writing essential to the validity of many contracts or transactions. The most important sections are those relating to contracts; namely, the 4th and the 17th, almost every word of which has been the subject of numerous decisions. It is provided by the 4th section that no action shall be brought on the contracts therein mentioned unless the agreement or some note or memorandum thereof, shall be in writing and signed by the party to be charged therewith, or some other person thereunto by him lawfully authorized. The contracts referred to are the following: (1) Any special promise by an executor or administrator to answer damages out of his own estate; (2) any special promise to answer for the debt, default, or miscarriage of another person; (3) any agreement made upon consideration of marriage; (4) any contract or sale of lands, tenements, and hereditaments, or any interest in or concerning them; and (5) any agreement that is not to be performed within the space of one year from the making thereof. This section, however, does not make the contract null and void, but only unactionable. The 17th section has reference to sales of goods for the price (or value) of £10 and upward, which are "not allowed to be good" unless some memorandum of the bargain has been made in writing, or unless the buyer shall accept part of the goods so sold, and actually receive the same, or give something in earnest to bind the bargain, or in part payment. In the statutes of the American States the principal alteration made in these terms is by the specification of a different sum of money. The sum usually established is $50, but in some of the States it is $30, or $40. The importance of this statute has been so fully recognized in this country that it has been substantially re-enacted in every State in the Union, and in some of them its provisions have been made still more comprehensive and stringent. See FRAUD.

Fraudulent Conveyances, in law, a fraudulent conveyance is a conveyance the object, tendency, or effect of which is to defraud another not a party to such a conveyance, or the intent of which is to avoid some debt or duty due by or incumbent on the party making it. Conveyances of this character are declared invalid by two celebrated English statutes which have been substantially re-enacted throughout the United States with the same provisions. The first of these statutes was passed in the 13th year of the reign of Queen Elizabeth (1571), and commonly referred to as the statute 13 Eliz. ch. 5, and by it all fraudulent conveyances, gifts, or alienations of lands or goods whereby creditors might be in anywise disturbed, hindered, delayed, or defrauded of their just rights, are rendered utterly void; but the statute does not extend to any estate or interest in lands on good consideration, and *bona fide* conveyed to any person not having notice of such fraud. The second statute against fraudulent conveyances is the statute 27 Eliz. ch. 4, which was passed in 1585. It provides that the conveyance of any interest in lands for the intent and purpose to defraud and deceive subsequent *bona fide* purchasers of the lands for a good and sufficient consideration shall be utterly void. This statute differs from the one first mentioned in applying solely to lands, and in protecting the interests of purchasers instead of creditors; but it contains similar provisions declaring the validity of any previous conveyance if it be upon valuable consideration and to a *bona fide* purchaser. It has been held in England, in the interpretation of this statute, that if the previous conveyance be voluntary it is void as to a subsequent purchaser, even if he had notice before he received his deed that such a conveyance had been made. This doctrine has been generally rejected by the courts throughout the United States as unjust, and the principle adopted that the receipt of notice gives a person intending to purchase sufficient opportunity to protect his own interests, and if he is guilty of imprudence in accepting the conveyance he should receive no assistance from the courts. This appears to be the more unobjectionable doctrine. Voluntary conveyances are never set aside under either statute, as between the immediate parties, but only in favor of purchasers or creditors. See FRAUD.

Fraunhofer, Joseph von, yō'sĕf fōn frown'-hō-fĕr, German mathematician: b. Straubing, Bavaria, 6 March 1787; d. Munich 7 June 1826. In 1799 he was placed with a looking-glass maker and glass-grinder at Munich. After various vicissitudes he received an appointment as optician in the mathematical and mechanical institute of Reichenbach at Benedictbeurn, and in 1809 the mechanical part of the optical institute was chiefly under his direction. Ultimately he became one of the members of the firm under which the business was conducted. One of the most difficult operations of practical optics was to polish the spherical surfaces of large object-glasses accurately. Fraunhofer invented a machine which obviated this difficulty, and rendered the surface more accurate than it was left by the grinding. He invented also other grinding and polishing machines, and introduced many improvements into the manufacture of the different kinds of glass used for optical instruments, and which he found to be always injured by flaws and irregularities of various sorts. In 1811 he constructed a new kind of furnace, and on the second occasion when he melted a large quantity found that he could produce flint-glass, which, taken from the bottom of a vessel containing two hundredweight of glass, had the same refractive power as glass taken from the surface. He found that the English crown-glass and the German table-glass both contained defects occasioning irregular refraction. In the thicker and larger glasses there would be more of such defects, so that in larger telescopes this kind of glass would not be fit for object-glasses. Fraunhofer therefore made his own crown-glass. The cause which had hitherto prevented the accurate determination of the power of a given medium to refract the rays of light and separate the different colors which they contain was chiefly the circumstance that the colors of the spectrum have no precise limits, and that the transition from one to another is gradual and not immediate; hence, the angle of refraction cannot in the case of large spectra be measured within 10′ or 15′. To obviate this, Fraunhofer made a series of experiments for the purpose of producing homogeneous light artificially, and unable to effect his object in a direct way, he did so by means of lamps and prisms. In the course of these experiments he discovered that bright fixed line which appears in the orange color of the spectrum when it is produced by the light of fire. This line enabled him afterward to determine the absolute power of refraction in different substances. Experiments to ascertain whether the solar spectrum contains the same bright line in the orange as that produced by the light of fire led him to the discovery of the innumerable dark fixed lines in the solar spectrum, consisting of perfectly homogeneous colors. The importance of this discovery can scarcely be overestimated. It led to the invention and use of the spectroscope, to the science of spectroscopy, and to all our present knowledge of solar and stellar chemistry. Fraunhofer also made a variety of other important discoveries and inventions.

Fraunhofer Lines. See SPECTROSCOPE.

Fraxinus, frăk'sĭ-nŭs. See ASH.

Frazee, Lawrence Fisher, American inventor: b. New Brunswick, N. J., 22 May 1813; d. Jersey City, N. J., 10 Oct. 1896. He became connected with the New Brunswick Steamboat and Transportation Company about 1835; and continued with its successors, the Camden and Amboy, and the Pennsylvania railroad companies till his death. During the Civil War he had command of the transport Massachusetts. He was the inventor of numerous useful appliances.

Frazer, John Fries, American scientist: b. Philadelphia, 8 July 1812; d. there 12 Oct. 1872. Grandson Gen. Persifor Frazer of Revolution. Was graduated with highest honors at the University of Pennsylvania in 1829, and afterward completed courses in both law and medicine. With Professor A. D. Bache he made the first researches on magnetics in the United States. In 1836 he became one of the two assistants on the First Geological Survey of Pennsylvania. After filling for some time a professorship in the Philadelphia High School, in 1844 he succeeded Professor Bache, as professor of natural philosophy and chemistry in the University of Pennsylvania, serving until his death; and from 1855–68 also as vice provost. In 1857 he received the degree of LL.D. from Harvard. He was an active member of the American Philosophical Society (its vice-president in 1855), the Academy of Natural Sciences, and the Franklin Institute (the editor of its journal from 1850 to 1866), and one of the charter members of the National Academy of Sciences.

Frazer, Persifor, American geologist, son of preceding: b. Philadelphia, 24 July 1844. After graduation (1862) from the University of Pennsylvania, served during Civil War in the South Atlantic squadron (1862–63) as aide, United States coast survey; in the cavalry during Gettysburg campaign, and as ensign in the navy to the end. Was mineralogist and metallurgist to the United States geological survey (1869–70), professor of chemistry in the University of Pennsylvania (1870–74), assistant geologist second geological survey of Pennsylvania, 1874–82. He was the first foreigner to receive the degree of Docteur ès-Sciences Naturelles from France, which also gave him the decoration of the golden palms of the Academy. He served as vice-president, representing the

United States in the International Geological Congress of 1888 (London), and of 1897 (St. Petersburg). He has written extensively for scientific periodicals, published five volumes of Reports of the Geological Survey of Pennsylvania; 'Tables for the Determination of Minerals' (1874); and 'Bibliotics, or the Study of Documents' (1894).

Fraziers Farm, Battle of. See GLENDALE, BATTLE OF.

Frear, Walter Francis, American jurist: b. Grass Valley, Cal., 29 Oct. 1863. He was graduated at Yale University in 1885, and at the Yale Law School in 1890; was made second judge of the first circuit court of Hawaii, in January 1893, first associate justice in the supreme court of the Republic of Hawaii in January 1896. He was a member of the commission to recommend to Congress legislation for Hawaii, in August, 1898, became chief-justice of the Supreme Court of Hawaii in July 1900 and governor in 1907. He is the author of 'Evolution of the Hawaiian Judiciary'; etc.

Frechette, Louis Honoré, loo-ē ō-nō-rā frā-shĕt, French Canadian poet: b. Levis, Quebec, 16 Nov. 1839. He has edited several French Canadian journals and in 1889 became clerk of the Legislative Council of Quebec. His lyrics have been much admired both for their form, and sincerity of passion. His published books include: 'Mes Loisirs' (1863); 'La Voix d'un Exilé' (1869); 'Pêle Mele' (1877); 'Les Fleurs Boreales,' crowned by the French Academy (1880); 'Les Oiseaux de Niège' (1880); 'La Legende d'un Peuple' (1887); 'Les Feuilles Volonte' (1891); 'Veronica,' a drama; and in prose 'Lettres à Bastile' (1872); 'Histoire Critique des Rois de France' (1881); 'Originaux et Detraques' (1893); 'Lettres sur l'Education' (1893); 'La Noël au Canada' (1900).

Freckles, brownish-yellow spots of a circular form on the human skin. They are due to excess of pigmentary matter in the cells of the cuticle, immediately above the true skin, and only appear on those exposed surfaces, as the neck, face, hands, and arms. They are sometimes congregated in thick clusters which give to the features an unsightly appearance. Sometimes freckles are hereditary, appearing soon after birth, and continuing through life, or subsiding or vanishing altogether. This affection is most common as well as most persistent in persons of fair complexion and hair, and especially so in those with red hair. There can be no doubt that exposure to the sun increases the disfigurement.

Frederic, Harold, American journalist and novelist: b. Utica, N. Y., 19 Aug. 1856; d. London, England, 19 Oct. 1898. He was for many years London correspondent of the New York *Times*. His writings include: 'Seth's Brother's Wife' (1887); 'The Lawton Girl' (1890); 'In the Valley' (1890); 'The Return of the O'Mahoney' (1892); 'The New Exodus' (1892); 'The Copperhead,' a tale of the Civil War (1895); 'Marsena' (1895); 'The Damnation of Theron Ware' (1896); 'March Hares,' a study of contemporary social life (1896); 'Gloria Mundi' (1898); 'In the Market Place' (1899).

Fredericia, frĕd-ĕ-rĭsh'ē-ă, Denmark, seaport, on the coast of Jutland. It was at one time well fortified, but the forts have not been kept in repair. The chief exports are eggs, meat, fish, cheese, and butter; the chief imports are cotton and woolen goods, fruit, salt, and petroleum. Pop. (1900) 12,700.

Frederick I., king of Denmark and Norway: b. 3 Sept. 1471; d. 10 April 1533. He succeeded his nephew Christiern (or Christian) II., on the deposition of the latter, in 1523, and entered into an alliance with Gustavus I., king of Sweden. After taking Copenhagen, he gained over all the nobility, and introduced Lutheranism into his dominions.

Frederick II., king of Denmark, the son and successor of Christian III.: b. 1534; d. 1588. He ascended the throne in 1559. He was a great friend of learning, and was a patron of Tycho Brahe and other men of science. He waged a long war with Sweden, which ended in 1570.

Frederick III., king of Denmark: b. Hadersleben, Schleswig, 18 March 1609; d. Copenhagen 9 Feb. 1670. He succeeded his father Christian IV., in 1648. The most remarkable event of his reign was his changing of the constitution from an elective to an hereditary monarchy.

Frederick IV., king of Denmark: b. Copenhagen 11 Oct. 1671; d. there 12 Oct. 1730. He ascended the throne on the death of Christian V. in 1699. He leagued against Charles XII. of Sweden, who forced him to make peace; but when Charles fled to Turkey, Frederick drove the Swedes out of Norway, and concluded a favorable peace; retaining possession of the duchy of Schleswig.

Frederick V., king of Denmark: b. Copenhagen 31 March 1723; d. 14 Jan. 1766. He came to the throne in 1746. The character of his reign may be inferred from the following remark, which, on his deathbed, he made to his successor, Christian VII.: "It is a great consolation to me, my son, that I have not injured any person, and that my hands are not stained with one drop of blood."

Frederick VI., king of Denmark: b. Copenhagen 28 Jan. 1768; d. there 3 Dec. 1839. He ascended the throne in 1808, though, from 1784, he was associated in the government with his father, who had lost his reason. On his accession he had to repair the damages done by the English in their bombardment of Copenhagen in 1807, and to wage a war with the Swedes, who attempted to possess themselves of Norway. He succeeded in defeating them, and peace was signed at Jon Kœping, in 1899. Allying himself with Napoleon, Norway was, in 1814, given to Sweden, under Bernadotte; Pomerania and the isle of Rügen falling to Denmark. More tranquil times now arriving, Frederick devoted himself to the extension of the internal resources of his kingdom.

Frederick VII., king of Denmark: b. Copenhagen 6 Oct. 1808; d. Glücksburg 15 Nov. 1863. He ascended the throne in 1848. He was well known as an archæologist, publishing numerous works on the subject. On his death, the elder line of the house of Oldenburg became extinct.

Frederick I., surnamed **Barbarossa,** emperor of the Holy Roman Empire, son of Frederick, Duke of Suabia: b. 1121; d. June 1190. He was chosen to succeed his uncle Conrad III. in 1152. He was crowned at Aix-la-Chapelle a few days after his election. His great ambition was to secure the independence of the empire, and, above all, to be master of Italy. His first expedition to Italy was made in 1154, when, after subduing several towns in Lombardy, he went to Rome, and, after some delays, had himself crowned emperor by Adrian IV. He marched again into Italy in 1158, took Brescia and Milan, and at the celebrated Diet at Roncaglia assumed the sovereignty of the towns and received the homage of the lords. On his return to Germany he triumphed over Bohemia, and made Poland tributary to the empire. After the death of Pope Adrian, Frederick had three anti-popes in succession elected in opposition to Alexander III., who excommunicated him and his pope, Victor. The same year, 1160, he besieged and took Crema, after a most courageous defense. In 1162 he conquered Milan, and had many of the public buildings destroyed, as well as parts of the fortifications; after which the other towns of Lombardy submitted to him. In 1166, he traversed the Romagna, levied contributions on the towns, besieged Ancona, and had himself crowned a second time at Rome by the anti-pope, Pascal. A fresh league being formed against him, he put its members under the ban of the empire and returned to Germany. In 1174 he besieged unsuccessfully the newly founded town of Alessandria, and in the following year was totally defeated by the Milanese at Como. Soon after he made peace with the Pope and the towns of Lombardy. In 1188 he assumed the cross, set out in the following year on the third crusade, was opposed on the march by the Greek emperor and the sultan, arrived in Asia, and was drowned while crossing a river. Frederick was great, not only as a soldier, but as a ruler. His administration was marked by justice, his subordinate officers were chosen for their capacity and probity, he was himself an educated man and promoted education and literature. His memory is still cherished among the peasants of Germany, who dream of the return of Fritz Redbeard, as the Welsh did of King Arthur. Consult: Prutz, ‘Kaiser Friedrich I.’ (1871–3); Fischer, ‘Kreuzzug Friedrichs I.’ (1870).

Frederick I., first king of Prussia (Frederick III. as elector of Brandenburg): b. Königsberg 22 July 1657; d. Berlin 25 Feb. 1713. He succeeded his father in 1688, entered into the alliance against France, and seized Bonn and other towns, sent auxiliaries to the emperor against the Turks, and, after a dispute of some years, sold to the emperor the circle Schwiebus, which the Great Elector had acquired in exchange for the principalities of Liegnitz, Brieg, and Wohlau. He supported the emperor in the war of the Spanish Succession, and in 1701 obtained from him the title of king, which he had long coveted. Frederick gratified his love of pomp in the ceremony of his coronation at Königsberg, the cost of which exhausted his treasury for a time. He placed the crown on his head with his own hands. In 1694 he founded the University of Halle; two years later the Berlin Academy of Painting; and, in 1707, he established the Academy of Sciences, Berlin, and made Leibnitz first president.

Frederick I., William Charles, duke (1797–1803), elector (1803–6), and king (1806–16) of Würtemberg: b. Treptow, Pomerania, 6 Nov. 1754; d. 30 Oct. 1816. He was a son of Sophia Dorothea, niece of Frederick the Great. In 1797 he became duke. His title of king, with a large accession of territory, he gained through an alliance with Napoleon. In 1806 he joined the Confederation of the Rhine; in 1809, 1812, and 1813 fought for Napoleon, but in 1813 took side with the allies.

Frederick I., William Louis, grand-duke of Baden: b. Karlsruhe 9 Sept. 1826; d. Mainau. He was the second son of Grand-duke Leopold. In 1856 he assumed grand-ducal powers. He restored the constitution 28 Sept. 1907; and devoted himself to the promotion of art and science and the spiritual and material interests of his realm. Though he took side with Austria in 1866, he later worked for the admission of Baden to the North German Confederation.

Frederick II., emperor of the Holy Roman Empire: b. Jesi 26 Dec. 1194; d. Viorenzuoli 13 Dec. 1250. He was elected king of the Romans in 1196, again after the death of his father, Henry VI., and a third time on the excommunication of Otho IV., in 1211. He was already king of Sicily and duke of Suabia, under the joint regency of his mother and Pope Innocent II. He made a league with Philip Augustus, king of France, and after the defeat of Otho by the latter at the battle of Bouvines, was crowned at Aix-la-Chapelle in 1215. He received the imperial crown at Rome in 1220, on which occasion he had to renew a vow previously extorted from him to take the cross. In 1225 he married Yolande, daughter of John of Brienne, king of Jerusalem, and in 1227 embarked for the Holy Land. Illness compelled him in a few days to land again, and for this he was excommunicated by Pope Gregory IX. He set out again in 1228, and the Pope exciting opposition to him, and invading his hereditary states, he at once concluded a truce with Kameel, the sultan of Egypt, by which he became master of Jerusalem. He entered the city, crowned himself (no priest daring to do it), and returned to Europe. He recovered his states, made peace with the Pope, and suppressed the revolt of his son Henry, who was then imprisoned for life. In 1235 Frederick began the war with the cities of Lombardy, having for his ally Eccelino, tyrant of Verona. After his victory of Cortenuova, he took Ravenna, Faenza, and Benevento; and, in 1241, his fleet defeated that of the Genoese, and captured the cardinals and bishops who were on their way to attend a council against him. Frederick promoted the election of Innocent IV., who had been his friend, and made a treaty with him; but soon found Innocent a most determined enemy. A new anathema and sentence of deposition, and release of his subjects from their allegiance to him, was published in 1245. The mediation of St. Louis utterly failed to bend the Pope to reconciliation. Rival emperors were set up, the war in Italy continued, Parma was lost in 1248, his son Enzio was defeated and made prisoner in the following year. Frederick was the most accomplished sovereign of the Middle Ages; but his strong sympathies with his Italian motherland, and his unremitting endeavors to establish a compact and all supreme empire in Italy, were the causes not only of his own misfortunes but of the miseries which he brought on the German empire by embroiling him in costly wars abroad, and leading him to neglect the welfare and sacrifice the interests of his German subjects.

Frederick II., landgrave of Hesse-Homburg, called "Prince of Homburg": b. 9 June 1633; d. 24 Jan. 1708. He fought bravely at Copenhagen (January 1659), where his leg was shot away and its silver substitute gained him the sobriquet "mit dem silbernen Bein." In 1670–8 he was a general of cavalry in the army of Frederick William, the great elector of Brandenburg, to whose victory over the Swedes at Fehrbellin (1675) he contributed the chief part. Having succeeded to power in 1681, he renovated the saline springs of Homburg, beautified the city, and made it prominent as a watering-place.

Frederick II., best known as **Frederick the Great**, king of Prussia: b. 21 Jan. 1712; d. Sans Souci 17 Aug. 1786. He was the son of Frederick William I., and the Princess Sophia Dorothea of Hanover. Though, by the direction of his father, he was instructed only in the details of military exercises and service, his taste for poetry and music was early developed by the influence of his first instructress, Madame de Roconles, and his early teacher, Duhan, who, countenanced by the queen, formed a secret opposition to his father's system of education. The prince's inclination led him to adopt entirely the views of his mother. This gave rise to a coolness between him and his father. Indignant at the oppression and hatred which he experienced from his father, Frederick determined to flee to the court of George II., king of England, his mother's brother. His sister Frederica and his friends, Lieuts. Katt and Keith, were the only persons entrusted with the secret of his flight. He was, however, overtaken, was barbarously treated by his father, and obliged to be an eye-witness of the execution of his friend Katt.

While the prince remained in the closest confinement in Küstrin, the king sent a proposal to him to renounce the succession in favor of his younger brother Augustus William, on condition that he should have the liberty of pursuing his own inclinations in regard to his studies, traveling, etc. "I accept the proposal," said the prince, "if my father declares that I am not really his son." On this answer the king, who looked on conjugal fidelity with religious respect, relinquished his plan. That the king was inclined to sentence his son to death is certain. But the provosts Reinbeck and Seckendorf, who had before intrigued against the prince, now saved his life; the latter, in particular, by availing himself of the interference of the emperor.

The prince was not admitted to court till on the occasion of the nuptials of his sister Frederica, and was obliged by his father in 1733 to marry the Princess Elizabeth Christina, daughter of Ferdinand Albert, duke of Brunswick-Bevern. Frederick William gave the castle of Schönhausen to her, and to the prince the county of Ruppin, and in 1734 the town of Rheinsberg, where he lived devoted to study till he ascended the throne. Among his daily visitors were literati, musicians, and painters. He corresponded with foreign scholars, particularly with Voltaire, whom he greatly admired. Several of his writings, in particular his 'Antimacchiavel,' had their origin in the rural tranquillity of Rheinsberg.

The death of his father raised him to the throne 31 May 1740. Frederick on his accession found in his states a population of only 2,240,000. At his decease he left 6,000,000. He raised Prussia to this pitch of greatness by his talents as a legislator and general, assisted in the field and in the cabinet during a reign of 46 years by many distinguished men. Frederick II., who had already excited great expectations, retained for the most part the institutions and laws of his father, but gave to the latter more extent and vigor. The death of the Emperor Charles VI. was a favorable moment, of which Frederick II. took advantage, to revive the claims of the house of Brandenburg with regard to the Silesian principalities, so far as to ask from the queen, Maria Theresa, the duchies of Glogau and Sagan, in return for which he promised her assistance against all her enemies, his vote for the election of her husband as emperor, and 2,000,000 Prussian dollars. These proposals being rejected, he occupied Lower Silesia in December 1740, and defeated the Austrians 10 April 1741, near Molwitz. This victory which was almost decisive of the fate of Silesia, raised new enemies against Austria. France and Bavaria united with Prussia, and the war of the Austrian Succession commenced. The only ally of the queen of Hungary and Bohemia, George II. of England, advised her to make peace with Prussia, because Frederick II. was her most active and formidable enemy. After the victory of Czaslau (Chotusitz), gained by Frederick 17 May 1742, the first Silesian war was terminated by the preliminaries signed at Breslau under British mediation (11 June), and by the peace signed at Berlin 28 July 1742. Frederick obtained Lower and Upper Silesia, and the larger part of the county of Glatz, with full sovereignty. On the other hand he renounced all claims to the other Austrian territories, assumed a debt of 1,700,000 Prussian dollars charged on Silesia, and promised to respect the rights of the Catholics in Silesia. Saxony acceded to this peace, of which England and Russia were the guarantees.

Frederick II. seized the opportunity of a peace to introduce useful institutions into the conquered territories, and to render his army more formidable. In 1743 on the death of the last Count of East Friesland, he took possession of that country, the reversion of which had been granted to his family in 1644 by the emperor. The war of the Austrian Succession continued; the Emperor Charles VII. was driven from his hereditary estates of Bavaria, and the Austrians were everywhere victorious. Frederick, apprehensive that an attempt would be made to recover Silesia, entered into a secret alliance with France (April 1744), and with the emperor, the palatinate, and Hesse-Cassel, in Frankfort (22 May 1744). He promised to support the cause of the emperor by the invasion of Bohemia, on condition that he should receive the circle of Königgrätz. He entered Bohemia suddenly, 10 Aug. 1744, and captured Prague; but the Austrians and Saxons compelled him to evacuate Bohemia before the close of the year. The death of the emperor (18 Jan. 1745), and the defeat of the Bavarians at Pfaffenhofen, obliged Maximilian Joseph, the young elector

FREDERICK THE GREAT,

ONE OF THE STATUES PRESENTED TO HARVARD UNIVERSITY BY EMPEROR WILLIAM II.

of Bavaria, to conclude the Peace of Fuessen with Maria Theresa, and occasioned the dissolution of the Alliance of Frankfort, after Hesse-Cassel had already declared itself neutral. The victory of the Prussians over the Saxons at Kesselsdorf, 15 Dec. 1745, led to the Peace of Dresden (25 December). Frederick retained Silesia, acknowledged the husband of Maria Theresa, Francis I., as emperor, and Saxony promised to pay 1,000,000 Saxon dollars to Prussia.

During the 11 following years of peace Frederick devoted himself with the greatest activity to the domestic administration, to the improvement of the army, and at the same time to the Muses. It was at this time that he wrote his 'Mémoires pour servir à l'Histoire de Brandenbourg,' his poem, 'L'Art de la Guerre,' and other works in prose and verse. He encouraged agriculture, the arts, manufactures, and commerce, reformed the laws, increased the revenues of the state, perfected the organization of his army which was increased to 160,000 men, and thus improved the condition of the state.

Secret information of an alliance between Austria, Russia, and Saxony gave him reason to fear an attack and the loss of Silesia. He hastened to anticipate his enemies by the invasion of Saxony, with which the Seven Years' War, or third Silesian war, commenced. The Peace of Hubertsburg (15 Feb. 1763), terminated this war, without any foreign interference, on the principle that the contracting parties should remain in *statu quo*. Frederick came out of the Seven Years' War with a reputation which promised him in the future a decisive influence in the affairs of Germany and Europe. His next care was the relief of his kingdom, drained and exhausted by the contest. He opened his magazines to furnish his subjects corn for food and for sowing. To the peasants he distributed horses for plowing, rebuilt at his own expense the houses destroyed by fire, established new settlements, built manufactories, and laid out canals. In 1764 Frederick founded the Bank of Berlin, with a capital of 8,000,000 Prussian dollars.

A treaty was concluded with Russia (31 March 1764), in consequence of which Frederick supported the election of the new king of Poland, Stanislaus Poniatowski, and the cause of the oppressed Dissidents in Poland. For the purpose of connecting Prussia with Pomerania and the Mark, and of enlarging and consolidating his territories, Frederick consented to the first partition of Poland proposed at St. Petersburg and concluded 5 Aug. 1772. Frederick received the whole of Polish Prussia (which had been ceded to Poland by the Teutonic Order in 1466) with the part of Great Poland to the river Netz, excepting Dantzic and Thorn. From this time the kingdom of Prussia was divided into East and West Prussia. He declared against the possession of a large part of Bavaria by Austria in 1778, after the death of Maximilian Joseph, elector of Bavaria, without issue, but Austria was not to be diverted from her designs by negotiations. Saxony, therefore, formed an alliance with Prussia and Frederick invaded Bohemia with two armies (July 1778). The Emperor Joseph, in a strongly fortified camp behind the Elbe, could not be induced to give battle. The aged Empress Maria Theresa wished for peace. But Catharine II. having declared her intention of assisting Prussia with 60,000 men, this war of the Bavarian Succession was terminated without a battle by the Peace of Teschen (13 May 1779). Austria consented to the union of the principalities of Franconia with Prussia, and renounced the feudal claims of Bohemia to those countries. In the evening of his active life Frederick concluded, in connection with Saxony and Hanover, the confederation of the German princes, 23 July 1785.

Frederick left to his nephew, Frederick William II., a kingdom increased by 29,000 square miles, more than 70,000,000 Prussian dollars in the treasury, an army of 200,000 men, great credit with all the European powers, and a state distinguished for population, industry, wealth, and science. Improved by severe experience before he ascended the throne, and possessed of rare talents, Frederick shook the political system of Europe when he conceived and established, in accordance with the wants of his time, the confederation of princes, the master-work of his policy. One of his great merits is that in the most difficult circumstances he contracted no public debts, but on the contrary, though he distributed a considerable part of his revenues in different ways among his subjects, he had a richer treasury than any monarch in Europe ever possessed. His contempt for ecclesiastical establishments, which was considered by his contemporaries as a contempt of religion, has been censured, and his writings show that his heart was a stranger to the highest sentiments of piety. Entirely unacquainted with the literature and mental cultivation of Germany, he underrated it, and contributed nothing to its improvement.

Some of Frederick's writings were published during his lifetime, but most of them appeared first in the 'Œuvres Posthumes' (1788–9). In 1846–57 the Berlin Academy published a critical edition of the whole, together with his literary and private correspondence, under the title 'Œuvres de Frédéric le Grand' (31 vols.).

Consult Loryman, 'Frederick the Great and the Seven Years' War' (1881); Carlyle, 'History of Frederick II.' (1858–65); Tuttle, 'History of Prussia under Frederick the Great' (1888); Lavisse, 'La jeunesse du grand Frédéric' (1891); Lavisse, 'Le grand Frédéric avant l'événement' (1893); Koser, 'Friederich der Grosse als Kronprinz' (1901).

Frederick II., landgrave of Hesse-Cassel: b. 14 Aug. 1720; d. Castle Weissenstein, Wilhelmshöhe, 31 Oct. 1785. He ascended the throne in 1760. By the aid of his architect, Du Ruy, he greatly beautified his capital, in which he founded the Collegium Carolinum, the museum, the library, and an academy of painting and sculpture. He sold a corps of 12,000 troops to England for service in America during the Revolution; whence, in the patriot mind, a stigma attached to the name "Hessian."

Frederick III., emperor of the Holy Roman Empire: b. Innsbruck 21 Dec. 1415; d. Linz 19 Aug. 1493. He was elected emperor in 1440 and ruled for 53 years, the longest German reign. His sobriquet was "the Pacific," owing to his plans for the pacification of the empire.

He left it to his son Maximilian to carry out the device inscribed upon his palaces and books, A, E, I, O, U; which characters are generally supposed to represent the motto, *Austriæ est Imperare Orbi Universo* ("Austria is to rule the world").

Frederick III. (the Wise), elector of Saxony: b. Torgau 17 Jan. 1463; d. 5 May 1525. He succeeded his father, Ernest, and is known chiefly as founder of the University of Wittenberg, and as the friend and very cautious protector of Luther, one of the first professors of the new university. It was by his arrangement that Luther, after the Diet of Worms, was seized and carried off to Wartburg. He did not, however, establish the reformed faith in his dominions. He became administrator of the empire in 1519, and was offered the imperial crown, but declined it.

Frederick III., king of Prussia, second emperor of modern Germany: b. Potsdam 8 Oct. 1831; d. 15 June 1888. He married in 1858 the Princess Royal of England, the eldest daughter of Queen Victoria. He early entered the army of Prussia, and when the latter declared war against Austria in 1866 the crown prince, as he was called, became commander of the army of the Oder. By a series of rapid marches from Silesia through the Sudetic mountain passes into Bohemia his army arrived just in time to aid Prince Frederick Charles and snatch the decisive victory of Sadowa. At the outbreak of the Franco-German war he commanded the third German army, which numbered 200,000 men, and with these he advanced to attack the French under MacMahon. The first assault was made at Weissenburg (4 August), and two days later he successfully turned the French defense at Woerth, causing the disorderly retreat of MacMahon's army. He pressed northward closely after MacMahon, and the passage of the Meuse by the Germans under his command greatly contributed to the successful turning of the French advance, and the final surrender at Sedan. This accomplished, he pushed on to Paris, and after surrounding the city established his headquarters at Versailles, where he remained until the capitulation in January 1871. In 1887 he was attacked by a throat disease, and while undergoing treatment for this his father died, and he became emperor in March 1888. The announcement of his own death three months later was received with wide regret, for his renown as a military commander, his liberal views, his large-heartedness, and his resignation under suffering, had touched his personality with the rarest heroic qualities.

Frederick III., elector of Brandenburg. See FREDERICK I. OF PRUSSIA.

Frederick V., elector-palatine and king of Bohemia: b. Amberg 1596; d. Mentz, Germany, 19 Nov. 1632. He succeeded his father, Frederick IV., in 1610. In 1618 he married the Princess Elizabeth, daughter of James I. of England, and in the following year accepted the crown of Bohemia. He made a triumphal entry into Prague, followed in 1620 by his total defeat by the Imperial forces at the battle of Prague, and the loss of his kingdom and hereditary states. He then took refuge in Holland.

Frederick Augustus II., elector of Saxony and king of Poland. See AUGUSTUS II.

Frederick Augustus III., elector of Saxony and king of Poland. See AUGUSTUS III.

Frederick Charles, Prince of Prussia: b. Berlin 20 March 1828; d. Castle of Klein-Ghericke, near Potsdam, 15 June 1885. He was a son of Frederick Charles Alexander and nephew of William I. He was in command of the first Prussian army which made so vigorous a resistance, and, aided by the second army, which arrived opportunely, finally defeated the Austrians at the battle of Sadowa (Königgrätz). In the Franco-German war he commanded the second army, directed the siege-operations against Metz, and 28 Nov. 1870 defeated the army of the Loire.

Frederick, Christian August, duke of Schleswig - Holstein - Sonderburg - Augustenburg: b. Castle Augustenburg, island of Alsen, 6 July 1829; d. Wiesbaden 14 Jan. 1880. He was banished by Denmark in 1851, after having taken part in the insurrection as an officer of the general staff. Upon the conclusion, however, of the war between Denmark and Germany, he was proclaimed duke by a popular assembly at Elmshorn in 1864, and received allegiance at Kiel. But he was not destined to rule. The duchy, by the terms of the Treaty of Vienna, fell to Austria and Prussia for disposal, and Prussia, through Bismarck, imposed upon Frederick conditions which he rejected. After the war with Austria, his domains were incorporated with Prussia. He took part in the Franco-German war as a Bavarian general on the general staff of the Prussian crown prince. His daughter, Augusta Victoria, was married to Prince William of Prussia, later William II., emperor of Germany.

Frederick Louis, Prince of Wales: b. Hanover, Germany, 6 Jan. 1707; d. Leicester House, London, 20 March 1751. He was the eldest son of George II. He became the leader of the Opposition, which was strongly against Walpole and styled itself the Patriot party. In the contest between Handel and Buononcini he was a partisan of the latter. At the outbreak of the rebellion of 1745 he sought, but did not obtain, the command of the royal army. His eldest son became King George III.

Frederick William I., king of Prussia: b. Berlin 15 Aug. 1688; d. Potsdam 31 May 1740. He commenced his reign in 1713, after having married the daughter of the elector of Hanover, afterward George I. of England. In 1715 he declared war against Charles XII. of Sweden, and in conjunction with Denmark took Stralsund; but on the death of Charles, in 1718, he made peace. The habits of this sovereign were entirely military, and he labored unweariedly to promote the discipline of his troops. One of his strongest peculiarities was an extraordinary love for tall soldiers; and in order to procure them had agents employed in all parts of Europe. He held science and literature in profound contempt; but money he worshipped, and men of a military character after his own ideal he respected and encouraged. The consequence was that he left an abundant treasury and a well-appointed army of 66,000 men. He was succeeded by his son Frederick the Great.

Frederick William I., last elector of Hesse: b. Philippsruhe 20 Aug. 1802; d. Prague 6 Jan. 1875. He succeeded to the throne in 1847. His reign was disturbed by conflicts with his people due to his efforts to disregard the constitution of 1831 and to limit popular representation. In 1866 he took sides with Austria in the war with Prussia, was deposed, and for a time imprisoned. In the same year Hesse was annexed to Prussia, in which the larger portion of it is now incorporated with the province of Hesse-Nassau.

Frederick William II., king of Prussia: b. 25 Sept. 1744; d. 16 Nov. 1797. He was the eldest son of Prince August William, brother of Frederick the Great, and ruled from 1786 to 1797. As the result of an interview at Pilnitz in 1791, he arranged with the emperor of Austria to interfere in aid of Louis XVI. of France. The ensuing campaign was an inglorious one, concluded by a retreat to the Rhine in the autumn of 1792. The war was ended in 1795, and Frederick William ceded to France Prussian territory west of the Rhine. From the second (1793) and third (1795) partitions of Poland he acquired large territory.

Frederick William III., king of Prussia: b. 3 Aug. 1770; d. 7 June 1840. He commenced his reign in 1797 by maintaining a strict neutrality in the various alliances with and against France, which resulted from the ambitious designs of Napoleon I. In 1805, however, he yielded to the solicitations of Russia, allying himself with the czar against the French emperor. The rapid campaign of 1806, and the defeat of the Prussians at Jena, opened the gates of Berlin to the enemy, in whose hands it remained till 1809. In 1807 the battle of Friedland led to the humiliating peace of Tilsit. Restored to his capital, the king diligently endeavored to repair the evils of war; but new disasters overtook him, and his kingdom suffered greatly during the struggle from 1812 to 1814. He subsequently joined his troops with those of Russia. The allies having triumphed over the French at Leipsic, Frederick William in 1814, entered Paris with Czar Alexander. On the return of Napoleon from Elba, he once more joined the allies. After the victory of Waterloo, in which the Prussians, under Blücher (q.v.) played an important part, Prussia, once more at peace, gradually recovered the losses she had sustained, under the wise and paternal sway of Frederick, whose constant efforts and moderation contributed greatly to the maintenance of peace. Throughout his life, he was a warm defender of the Protestant religion, and a patron of education. He never redeemed his promise, however, to bestow a representative constitution on his people. The establishment of the provincial estates only affected very slightly the absolute power, which, it is true, he wielded with ability, and with a kind of paternal affection for his people. It may finally be said of him, that, a waverer between the Absolutist party and the Liberal party, he secured, as is the lot of most undecided men, the respect and adherence of neither.

Frederick William IV., king of Prussia: b. 15 Oct. 1795; d. near Potsdam 2 Jan. 1861. On the death of his father Frederick William III. succeeded to the throne in 1840. He evinced, at an early period of his life, a very great love for the arts, which he preserved throughout his career. During the first years of his reign his subjects anxiously demanded the reform of the government, requiring the liberal constitution which had been promised them in 1815, in return for the great sacrifices they had made during the continental war. In 1847, at a general diet of the Prussian states, many of these reforms were granted, and it was thought that the kingdom might escape the troubles of the next year's revolution. In March 1848, however, the king was obliged to change the ministry, to issue a general amnesty, and commence a war in favor of Schleswig against Denmark. In the war between the western powers and Russia, the king preserved a strict neutrality, though earnestly solicited by each party to espouse its side in the conflict. In 1856, in consequence of an attack on Neufchâtel by some Prussian partisans, war was in danger of breaking out between Switzerland and Prussia; but this was avoided, and a treaty concluded, in May 1857, in reference to the king's claims on that place. In the complication relative to the Danubian principalities, Prussia followed the lead of France and Russia as opposed to England and Austria. Toward the end of 1857, a severe illness, resulting in the loss of some of his faculties, caused his brother William to be nominated regent, who succeeded him as king.

Frederick William, duke of Brunswick: b. Brunswick 9 Oct. 1771; d. at Quatre-Bras 16 June 1815. He entered the Prussian military service in 1788, and in 1800 was commissioned major-general. With a Bohemian volunteer corps he invaded Saxony, and with Austrian reinforcements took Dresden and Leipsic. After the armistice of Znaim, he defeated Reubel's corps, 6,000 strong, at Oelger, near Brunswick, finally arrived at Elsfleth and Brake, seized all available shipping, and embarked for England, where he was received with demonstrations of enthusiasm. He participated in the Peninsular war, and returned only after the battle of Leipsic (1813). He was shot while leading an attack at Quatre-Bras.

Frederick William, elector of Brandenburg, called the Great Elector: b. 16 Feb. 1620; d. Potsdam 29 April 1688. He succeeded his father when the unhappy Thirty Years' war was still raging in Germany, and his conduct toward both parties was prudent. In 1641 he concluded a treaty of neutrality with Sweden, notwithstanding the earnest remonstrances of Austria. In 1644 he concluded an armistice with Hesse-Cassel, by which Cleves and the county of Mark were restored to him, and by the Peace of Westphalia in 1648 received Madgeburg, Halberstadt, and Kammin. In the war between Poland and Sweden (in 1655) he was obliged to take part, on account of the duchy of Prussia. He supported both parties in turn, and obtained an acknowledgment of the independence of the duchy of Prussia from Poland, upon whom it was formerly dependent. In 1672 he concluded a treaty with the Dutch Republic, when this state was threatened by Louis XIV. On June 6, 1673, he concluded a treaty with France at Vossem, by which France promised to evacuate Westphalia, and to pay 800,000 livres to the elector, who, in return, broke off his treaty with Holland, and promised not to render any aid to the enemies of France. In 1674 the German empire declared war against France. In the following December a Swedish army, at the instigation of France, entered Pomerania and the Mark. The elector defeated them, 18 June 1675, at Fehrbellin. In 1678 he concluded a separate peace with France, at Nimwegen, as did also Holland and

Spain. France demanded the restoration of all the conquered territories to Sweden. The elector, having refused compliance, formed an alliance with Denmark, and waged a new war against Sweden, but was obliged to submit, by the Peace of St. Germain, 29 June 1679. Louis XIV. having occupied several circles of Alsace by his famous *chambres de réunion,* Frederick William effected an armistice of 20 years between France and Germany (in 1684). But when he renewed (1685) his treaty with Holland, and received into his dominions about 14,000 Protestant refugees from France, new difficulties arose between him and France, which brought him into a closer connection with Austria. He received the circle of Schwiebus in 1686, and in the same year sent 8,000 men to assist the Austrians against Turkey.

The elector paid great attention to the promotion of agriculture and horticulture, and, by affording protection to the French refugees, gained 20,000 industrious manufacturers. A colossal statue of Frederick William in bronze, at Berlin, was cast by Jacobi, in 1700, and is still one of the greatest ornaments of that city. Consult: Hitl, 'Der grosse Kurfürst und seine Zeit' (1893); Philippson, 'Der grosse Kurfürst' (1897–1902).

Frederick, Md., city, county-seat of Frederick County; on Carroll's Creek, and on the Pennsylvania, and the Baltimore & O. R.R.'s; 62 miles northwest of Baltimore. Here are Frederick College, Woman's College of Frederick, and the State institution for the deaf and dumb. The city has manufactories of coaches, leather, shoes, knit goods, shirt-waists, palmetto, fibre brushes, tobacco, etc., and an assessed property valuation of nearly $4,000,000. During the Civil War it was twice occupied by the Confederates, the second time, in 1864, by Gen. Early, who forced the citizens to pay a ransom of $200,000. In 1862 Federal troops under Gen. McClellan occupied the place. Pop. (1900) 9,296.

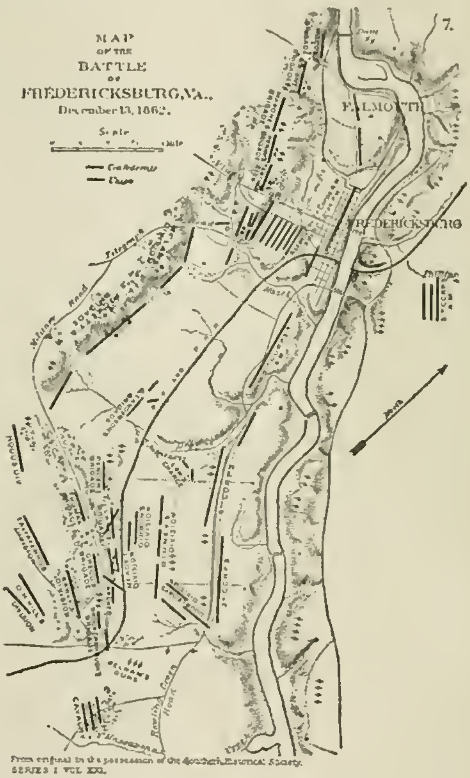
Fredericksburg, Tex., town, county-seat of Gillespie County; on the San Antonio & A. P. R.R.; 80 miles west of Austin. It was founded by a German colony in 1846. Pop. (1900) 1,532.

Fredericksburg, Va., city in Spottsylvania County; on the Rappahannock River, and the Richmond, F. & P., and the Potomac, F. & P. R.R.'s; 61 miles north of Richmond. It has tanneries, iron works, cigars, ice, and shoe factories, and an assessed property valuation of nearly $2,000,000. It was the scene of several battles during the Civil War and 15,300 graves of Confederate dead are in the National cemetery here. Pop. (1900) 5,068.

Fredericksburg, Battle of. At the beginning of December 1862 the Army of the Potomac, under command of Gen. Burnside, held the north bank of the Rappahannock River at Falmouth, Va., while the Confederate army, under Gen. Lee, held the south bank at and below Fredericksburg. The Army of the Potomac "present and equipped for duty" numbered 120,281 men, with 312 guns. Gen. Lee's army, strongly entrenched on a broken range of hills back of Fredericksburg, numbered (10 December) "present for duty" 78,513 men, with 270 guns.

The Army of the Potomac was organized into three grand divisions: The right, under Gen. Sumner, consisted of the Second corps, Gen Couch, the Ninth corps, Gen. Willcox, and Pleasonton's cavalry division; the centre, under Gen. Hooker, of the Third corps, Gen. Stoneman, Fifth corps, Gen. Butterfield, and Gen. Averell's cavalry division; the left, under Gen. Franklin, of the First corps, Gen. Reynolds, Sixth corps, Gen. Smith, and Gen. Bayard's cavalry brigade. Gen. Lee's army was divided into two wings, Gen. Longstreet commanding the left, and Gen. Jackson the right.

Burnside concluded to cross the river at and below Fredericksburg by pontoon-bridges. Under great difficulties, with annoyance from the enemy, the bridges were completed 11 December, troops



rushed over, and by night of the 12th Sumner and Franklin had crossed and taken position. Franklin, who was to open the battle by an attack upon the Confederate right, reinforced by Birney's and Sickles' divisions of the Third corps, and Burns' of the Ninth, had about 60,000 men. At 7.30 A.M. on the 13th, Burnside gave him orders to seize the heights at Hamilton's crossing. One of Franklin's smallest divisions, Meade's, led the attack, moving out at 9 o'clock; but owing to flank attacks and lack of immediate support, it was 1.15 P.M. before Meade drove the Confederates from the Richmond Railroad and, crossing it, charged up a ridge and into the woods, piercing the centre of A. P. Hill's first line; but when he had crossed the road that ran in rear of the crest he was attacked, front and flank, by Hill's second line and the reserves, and was driven back with a loss of over 40 per cent in killed, wounded, and captured. Gibbon, who had been thrown forward to support Meade's right, shared the same fate, being forced back, with a loss of 1,267 men. The Confederates then advanced beyond the railroad but were checked. Franklin made no further attempt to carry the ridge, but directed his attention to protecting his left, which he thought was seriously threatened. At 2.30 P.M., when Sumner was heavily engaged in front of Marye's Heights, Franklin received Burnside's order to attack with his whole force, but the order was not carried out. Franklin put but a small part of his command into the fight.

Sumner was held in position until after 11 A.M. in the expectation that Franklin would make such an impression upon Lee's right as would enable him to carry the line near the Telegraph and Plank roads. Feeling the importance of haste, Burnside now directed Sumner to begin his movement. In rear of the town, and between it and the heights that Sumner was to carry, was a broken plain, traversed about midway by a canal or ditch, running from right to left. Two roads cut the plain nearly at right angles with the canal; the Plank road on the right, the Telegraph road on the left, leading to Richmond. The advance was to be made on and between these two roads, over ground completely covered by artillery on the heights. McLaws' division held the heights to be assaulted, Cobb's and Kershaw's brigades being placed in the sunken Telegraph road, that ran at the base of the hill. On the side of the road next to the town was a stone wall, shoulder high, behind which Cobb's and Kershaw's men were well protected. The Second corps led in the attack. French's division moved out of the town by parallel streets, and at noon, under a severe artillery and musketry fire, had driven in the Confederate skirmishers and gained a rise of ground, within about 120 yards of the stone wall, from which and the top of the hill it received a most deadly fire. Hancock's division followed in support. At 1 P.M. Couch ordered French and Hancock to carry Marye's Heights. French sent in his three brigades in succession, but they were bloodily repulsed by the deadly fire from behind the stone wall. Hancock now ordered in Zook's brigade. It sprang forward, was joined by some shattered regiments of French's division, and when within 25 paces of the stone wall was repulsed with great loss. The Irish brigade and Caldwell's followed in succession, but failed to carry the position and, after losing one-half, fell back, and both French and Hancock continued, with parts of their commands, to hold the rise of ground near the stone wall. While Hancock's men were falling by hundreds, Howard was ordered to move his division to the right of the Telegraph road and turn the Confederate left, but as French and Hancock needed help, Howard was recalled and ordered in on the Telegraph road, and two divisions of the Ninth corps went in on Couch's left. All fought gallantly, but made no impression upon the Confederate line. French's loss was 1,160; Hancock's 2,032; Howard's 900; Sturgis' division of the Ninth corps lost 1,000, and Getty's division 290.

It was 2 P.M. when Hooker, riding in advance of the Fifth corps, came on the ground. After an examination of the position and conference with Couch and other general officers, he concluded that it would be a useless waste of life to make a further attempt and sent an aide to Burnside, giving his opinion. Burnside ordered him to attack. Hooker then rode to Burnside, across the river, and sought to impress upon him the hopelessness of the attempt, but Burnside reiterated the order to attack. Every available battery opened fire upon the Confederate position, and near sunset Humphreys led his division of the Fifth corps against Marye's Heights, Sykes' division moving on his right. Twice Humphreys led his men forward; some of them were killed within 20 yards of the stone wall; but he was repulsed with a loss of 1,000 men. Sykes, on his right, lost over 200, while Griffin's division, on the left, supporting the Ninth corps, lost over 800 men. Night came with the Union army everywhere repulsed. Burnside directed preparations for a renewal of the battle on the morning of the 14th, when he proposed to lead the Ninth corps, his old command, in an assault where the 2d and 5th Corps had failed, but he was dissuaded from the attempt. From the night of the 13th until the night of the 15th the two armies confronted each other, engaged in artillery-firing and angry skirmishing. On the night of the 15th the Army of the Potomac recrossed the river, after one of its most bloody and humiliating defeats. Its loss was 1,284 killed, 9,600 wounded, and 1,769 missing, an aggregate of 12,653. The Confederate loss was 595 killed, 4,061 wounded, and 653 missing. The loss of the Confederate troops defending Marye's Heights was less than 1,000; that of the attacking and supporting Union troops was over 7,300. Consult: 'Official Records,' Vol. XXI.; Allan, 'Army of Northern Virginia'; Swinton, 'History of the Army of the Potomac'; Walker, 'History of the Second Army Corps'; Powell, 'History of the Fifth Army Corps'; The Century Company's 'Battles and Leaders of the Civil War,' Vol. III.

E. A. CARMAN.

Fredericton, Canada, county-seat of York County and capital of New Brunswick, is beautifully situated on the west side of the river St. John, 60 miles north-northwest of St. John. It is on the Canadian P. and Canadian East. Rys., and is the terminus of the Fredericton Ry. It is a port of entry and the seat of a United States consular agent. It has handsome public buildings, and is the seat of New Brunswick University and of the provincial normal school. Fredericton has manufactories of iron castings, machinery, leather, boots and shoes, woolen ware, etc., but its chief trade is in lumber and timber products. The city was founded in 1740, first called Saint Anne, and given its present name by Governor-General Sir Guy Carleton in 1785, two years later becoming the capital of the province. Pop. (1901) 7,117.

Fredonia, N. Y., village, in Chautauqua County; on the Dunkirk, A. V. & P. R.R.: about four miles south of Dunkirk, and about 50 miles southwest of Buffalo. It was settled in 1803 and incorporated as a village in 1829. It was early noted for its good schools, including its free academy. It is a residential village with not a large amount of manufactories. It is situated in an agricultural region, in the Lake Erie grape section, and its chief manufactures are canned and dried fruits, grape baskets, and boxes, and patent medicines. Natural gas was discovered here in the early part of the 19th century and was in use for lighting the village in 1821. The trade is chiefly in fruits, wine, and patent medicines. It has the D. R. Barker free library and one of the State Normal schools. It was for some years the home of William Barker Cushing (q.v.), a United States naval officer. The village owns and operates the waterworks and electric light plant. Pop. (1900) 4,127.

Fredro, frā'drō, Count **Alexander**, Polish dramatist, called "the Molière of Poland": b. Suchorow, Galicia, 1793; d. Lemberg 15 July 1876. He was the founder of Polish comedy, those who preceded him having worked over French plays. 'Mr. Moneybags' (his first piece, 1821); 'Ladies and Hussars'; 'Man and Wife'; and 'Revenge,' are his titles. The scenes are taken from real life.

Free Banking System, the predecessor of and essentially the same as our present national banking system, and on the same principles as the general railroad and corporation laws. Up to 1838 all banks required special charters, with the attendant evils of collusive "blanket" powers, corruption, and an insecurity which was not only a private evil, but seriously affected the state credit and finance. In that year New York State passed a "free" or open banking law, under which anyone could start a bank by depositing with the State an amount of securities equal to its circulating notes. The other States soon followed the precedent.

Free Church, the term applied by British non-conformists to the Christian denominations throughout the British empire, free from state patronage and control. The Free Church of England, a distinct evangelical Protestant denomination founded on the basis of recognizing only two orders, presbyters and deacons, although the first order also comprises bishops, maintains the ecclesiastical parity of presbyters, whether episcopally or otherwise ordained. The governing body is the convocation consisting of all the clergy and laity in the several churches. The denomination originated in the creation of "free churches" in the west of England, as a protest against the Tractarian (q.v.) movement of 1832. The Shore controversy (1843–9), and the Gorham case (1849–50), promoted its development. It was enrolled in chancery by a deed poll in 1863. The bishops are in the Canterbury line of episcopal succession. See Reformed Episcopal Church.

The Free Church of Scotland was the name assumed by the large body of ministers and their adherents who separated from the Established Church of Scotland at the Disruption (q.v.) of 18 May 1843. They seceded in vindication of what they called the "Headship of Christ," that is, to gain liberty to obey what they deemed the will of their Divine Lord in all church arrangements, without the control of the civil power. No new article of faith was adopted, all the forms and rights of the national Church being retained in their integrity. The Church prospered in the face of formidable financial difficulties which were largely overcome by the institution of a sustenation fund, and by the excellent arrangements made for its distribution and employment. After 1867 there was a movement in favor of the union of the Free and United Presbyterian Churches of Scotland, and on 31 Oct. 1900 the union was formally completed by the constitution at Edinburgh of the first assembly of the United Free Church of Scotland. See Presbyterian Church.

The Free Church Association founded in 1866, in English ecclesiology, is a society which has for its main object the abolishment in the Established Church of pew rents and pew ownership, maintaining the equal right of all parishioners to the free use of seats in churches. It has a long list of distinguished patrons, and aids churches with pecuniary grants if "free" and in need. See Institutional Church.

Free Cities, the name applied to various cities of Germany which in the 12th century assisted the emperors in repressing the arrogance of the nobles, and, in return for their services or contributions, received various privileges and immunities and became imperial cities. Free cities existed in Germany from the time of the Romans; they had little in common with the free cities of later times, and in the beginning of the 16th century lost their most essential privileges, and even the name of free cities, through the ignorance and carelessness of their magistrates. The most important of those privileges, as shown in the case of Ratisbon, were, that they should enjoy an independent government; should never swear allegiance to any emperor or king, nor be obliged either to engage in any expedition against the Romans, or to pay for the privilege of exemption; nor to pay any contributions whatsoever to the empire; nor be in any way reckoned among the cities of the empire. Virtually they were independent republics. Commerce and manufactures gradually increased the importance of the imperial cities and they often ventured to resist their masters, the emperors, and could not be reduced to obedience without great difficulty. In the middle of the 13th century two important confederacies were established for common objects — the Hanseatic League (1241), comprising the cities of Frankfort-on-the-Main, Hamburg, Bremen, and Lübeck, and the league of the Rhenish cities (1246), comprising Cologne, Worms, Mainz, Strasburg, Basel and Spires, which are now incorporated in their respective political divisions. The powerful Hanseatic League lasted nearly four centuries, until its dissolution was effected by several causes in 1630. The remnant of this league and of the former *collegium* of cities, which had its representatives in the German Diet, namely the free cities of Hamburg, Bremen, and Lübeck, was incorporated with the French empire in 1810. As these cities co-operated vigorously in the recovery of German independence, they were acknowledged, together with Frankfort-on-the-Main, as free cities by the Congress of Vienna (1814–15). They joined the German Confederacy, and obtained the right of a vote each in the Diet, and one among the four in the narrower council. In conformity with the 12th article of the Constitution of the German Confederacy, they established a common supreme court of appeal in 1830. Frankfort in 1866 was annexed to Prussia. The only free cities now existing are Hamburg, Lübeck, and Bremen, each sending a member to the Bundesrath, and Hamburg three deputies to the Reichstag, the others one each.

Free Congregations (Ger. *Freie Gemeinden*), sometimes called "Protestant Friends," a sect of German Rationalists, who at first professed to be Christians, but now reject the doctrines of miraculous revelation and a personal deity. There are upwards of 120 congregations of them in Germany, and a few in the United States.

Free Negroes, in the United States. At the formation of the Union these numbered about 60,000, nearly half of them in the South; but while there were few slaves in New England, and those dwindling, and less than 50 per cent more than the free colored population north of Maryland, the South had more than 20 times as many slaves as freedmen, and the system was extending. Hence this section began early to dread the free negroes, as an element always making their slaves discontented, and possibly stirring them to revolt; a sentiment deepened into terror after the Santo Domingo massacres. State laws and constitutions were framed or amended to drive them from the States or re-enslave them; one method being to forbid emancipation by will, and provide that free negroes must choose masters or leave the State: and another to punish all penitentiary offenses of negroes with reduction to slavery. The Colonization Society (q.v.) derived its first impetus from this feeling, till it was seen to be a mere reinforcement of slavery. The laws for refusing to allow negro merchant sailors to land, or even imprisoning them if they did, also caused much bad blood with the North. The "Black Laws" reached their acme just before the War, as did the personal-liberty laws in the free States. By the Dred Scott decision, free negroes were not citizens of the United States; which became law and remained so until repealed by the Fourteenth Amendment, though the Thirteenth had abolished slavery.

Free Port, a harbor where ships of all nations may enter and load or unload on payment of harbor dues or charges for accommodation. Goods may be stored at free ports, and may then be either re-shipped for export, or they may be admitted for home consumption on payment of the usual full customs of the country. The bonded warehouse system effects the same end as free ports. See TREATY PORT.

Free Ships, Free Goods. That is, that in time of war, belligerents shall have no right to inquire into anything regarding a vessel and her cargo but whether the former belongs to a neutral, and if so, her cargo must be as free as herself; unless the cargo is agreed contraband of war. This is the doctrine of international law which the countries of predominantly industrial interests have always struggled to have accepted; while those by nature constantly or frequently at war have refused to admit it. In the great wars of France with England, in the Revolutionary and Napoleonic era, the United States was the great champion of this doctrine, while England refused to admit it, claiming the right to confiscate her enemy's goods wherever she found them, and search every neutral for them. The War of 1812 arose partly from this, and did nothing toward settling it; but the close of the war period left it of little practical importance for many years. The Declaration of Paris (q.v.) went farther than this, and proclaimed neutral goods safe even in an enemy's vessels.

Free-soil Party (1848-55). This was the old Liberty party (q.v.) of direct abolition (Birney, Chase, etc.), plus the "Conscience Whigs" of Massachusetts (Sumner, C. F. Adams, etc.), who supported the Wilmot Proviso (q.v.), and the "Barnburners," or Van Buren section of the New York Democrats. The latter as a body adopted their principle of restricting the extension of slavery into the Territories, to punish the Polk administration, ultra-southern, for attempting to build up its own "machine" in New York at the expense of the Albany Regency (q.v.); but a small element of it was really in sympathy with their less extreme purposes. Van Buren had lost the nomination in 1844 by refusing to approve the annexation of Texas; and his co-operation was more than a mere party move. The Liberty party in 1847 nominated John P. Hale of New Hampshire and Leicester King of Ohio for President and Vice-President; but seeing a chance of larger success through the promising split in the Democracy, dropped them and waited. The Barnburners, offered only an even share of the State vote with their rivals the Hunkers in the Baltimore Democratic convention of 1848, withdrew, and after nominating Van Buren at a bolting convention to keep the party together, agreed to join in a fusion "Free-Soil" party. A convention of this at Buffalo in August nominated Van Buren and Adams. The platform declared for "Free Soil, Free Speech, Free Labor, and Free Men"; and that slavery in the States was beyond the control of Congress, but that as Congress could not make slaves it was bound to refuse it admission to the Territories (see WILMOT PROVISO). The party cast 291,263 votes, turned Maine and six western States over to the Democrats (Cass), and would have defeated the Whigs (Taylor) but that the New York defection (120,510) was mainly from the Democrats and gave that State to the Whigs. The New York Democratic delegation to Congress was annihilated all but one; and the two factions at once struck a bargain, which left Van Buren permanently out of public life. The Free-Soilers in the 31st Congress (1849-51) had 2 United States senators (Chase and Hale), and 14 representatives, including J. R. Giddings, George W. Julian, and Horace Mann. Sumner in the Senate and 3 more representatives reinforced them in 1851, and in the 33d Congress (1853-5) they had 5 senators and 17 representatives. Having been abandoned by their casual allies, in 1852 they nominated Hale and Julian; with a platform denouncing the Compromise of 1850 (q.v.), both the great parties for accepting it, and slavery as "a sin against God and a crime against man," and demanding the repeal of the fugitive-slave law. They polled 156,149 votes, of which 25,329 were in New York. They maintained their organization in Congress till the Kansas-Nebraska Bill (q.v.) had created the Republican party, into which they were at once fused.

Free Sons of Israel, Independent Order of, a Jewish fraternal and benevolent society founded 10 Jan. 1849. It has 3 grand lodges and 103 subordinate lodges in the United States. In 1902 it had a total membership of 11,000, and a reserve fund of $860,000.

Free Spirit, Brethren of the, a sect of heretics which originated in Alsace in the 13th century, and quickly became disseminated over Italy, France, and Germany. They claimed "freedom of spirit," and based their claims on Rom. viii. 2–14. Thence they deduced that they could not sin.

Free Stone. See BUILDING STONE; SANDSTONE.

Free Trade, in current use restricted to mean the interchange of commodities between countries politically independent, without obstacles specifically intended to restrict the trade. All taxes on imports, which form a large part of the revenue of most civilized governments to that extent impede the freedom of trade; but the essence of the free-trade system is, that they shall not be arranged to "protect" the correspondent home production, or, as free-traders would put it, to divert capital into otherwise unprofitable channels at the expense of the consumer. This is accomplished by selecting articles not possible to produce at home (as tropical products in a temperate country); by forbidding their production at home (as tobacco in England), foregoing certain new home industries for the sake of sparing existent ones; or by laying corresponding internal taxes.

That free trade was never even formulated as a theory till a few generations ago, nor adopted as a policy till within two generations, that it is even now practised in its fulness by only one country, and nearly so by only two more, and that the former, its chief exponent, is at this moment rent by a fierce struggle to resume its old protective system, indicates something more back of this question than the mere state of economic enlightenment. The truth is, free trade is a matter of business, and all states have prior interests which business only subserves, and to which it is sometimes partially antagonistic. National existence always comes first, national prestige usually, national rivalry and jealousy frequently. In the Middle Ages war was the normal condition of most countries and the constant liability of the rest; hence everything had to be subordinated to diversified resources in war, whence a nation's supplies might be suddenly shut off. As the age of neutrality and the localization of wars has supervened, this danger has practically passed; but masses of capital and of labor in each country, which its rulers cannot politically disregard, can still be injured by the hostile tariffs which are the modern substitutes for fleets and armies of conquest. The problem at issue is, whether these injure the target as much as the marksman: free-traders have one answer, protectionists another. But the protectionist interest is always much more concentrated and effective than the free-trade: it is that of masses of capital embarked in certain enterprises and fighting for life, with all the masses of people behind it whom it maintains, and who would be temporarily injured by a readjustment. Protection is led by those who are interested in terms of millions, free trade mostly by those who are interested relatively in terms of pennies. The contest is so unequal that it is only wonderful that any circumstances have ever given the latter even a temporary victory.

In Europe till the 17th century, and in most parts of that till the 18th, the only way the bounds of free trade were extended was by conquest; and even that did not always effect it, old provinces and feudalities retaining their rights to separate custom-houses — primarily an octroi, but used for "protection." Most countries were cut up by dozens of these vexatious boundary lines, crippling all internal trade, and making each little district a special and self-subsistent world. Under Louis XIV. Colbert (1665–83) swept away many of these old provincial barriers, to the enormous development of French industry and trade, and consequently revenue; but he could not touch the chief portion. Already in 1623 De la Croix had propounded the theory of free trade; and in England it was urged in 1690 by Nicholas Barbon, one of the founders of the life-insurance system. But about the middle of the 18th century it sprung into life at once in two quarters, the lesser influence at the time having been vastly more potent in the end: with the French "Physiocrats" and Adam Smith. The theory of the former — whose founder was Cantillon and the chief heads Quesnay and De Gournay — was enthusiastically taken up by a group of able thinkers and men of affairs, and in 1774 put partially in practice by Turgot, in free trade for grain throughout France. Their method of approach was curious: they held that as commerce does nothing but transfer from hand to hand wealth already existing, without creating new, the gains of the trading class are at the expense of the only real wealth, the products of the earth; it is therefore to the community's interest that they should be as small as possible, and to this end commerce should take the shortest and most natural channels, as this leaves the "net product" of society the highest. Meantime in 1752–63, Adam Smith, a professor of moral philosophy at the University of Glasgow, had been working out a theory of the social progress of nations; and, as one branch of it, he investigated the causes of their material well-being. He was anything but a man of business, but he had a Scotch intellect which reasoned truly, and his society included many keen and able merchants and importers of the day. From them and his own mind he produced and fortified the theory that dams in a stream could never create water, but only force it into other channels. He visited France and met the Physiocrat leaders, and received doubtless new arguments and fresh facts. In 1775 he published his 'Wealth of Nations,' perhaps the most epoch-making single book of all time; for it created political economy as a science and free trade as a practical system. He took separately each kind of protective duty in use or advocated, and proved that each did harm in the very line it was supposed to do good. But he saw no hope of free trade ever coming about in England, so dominating was the influence of invested capital and of "furious and disappointed monopolists." But a curious change in industrial affairs inverted the position of his friends and enemies. His views had been favored by the landed interest and disfavored by the manufacturers; but the course of business made the agriculturists eager to keep up the duties on grain, which gave them immense profits; while the manufacturers began to be irked by the duties on raw material, which checked their coming dominance of the textile market under the splendid English inventions. The ablest statesmen were on the same side: Shelburne and the younger Pitt were convinced free-traders, and the latter tried to put Irish free trade into the act of Union in 1800. Two decades later the adherents were numerous: Ricardo's 'Political Economy' had reinforced Smith's, with greater weight because he was a successful Jewish banker; and London merchants were petitioning to have the shackles taken off trade. The first great success was making William Huskisson president of the board of trade in 1823: he was ignominiously driven from the Cabinet by the Duke of Wellington, but had induced Parliament to free some articles and lighten the duty on others. Thrust aside by more pressing politics, the reform stood still till 1836, when a failure of crops made it once more a burning question. Never was an issue so sharply marked out: the people were sacking the towns for bread while grain was taxed to enrich the landlords. Meantime manufacturers, increasingly the chief reliance of the national revenues, were kept out of foreign markets by having to pay higher for raw materials and more for wages. Local Anti-Corn-Law Associations from 1837 on were fused into the National Anti-Corn-Law League in 1839; at its head were Richard Cobden and John Bright, both partners in Manchester calico-printing works; whence the term "Manchester School" for supposed believers in various doctrines mistakenly attributed to Cobden. The struggle convulsed England, and almost broke the bonds of social order; but the final blow to the old system was the Irish potato famine in 1845. This shortage made food still higher; and Sir Robert Peel, who had taken office expressly to resist the repeal of the Corn Laws, remained in it to repeal them himself, 26 June 1846 — most of the duty at once, the rest by a sliding scale within three years.

The full free-trade policy was not introduced for many years, however: it was Mr. Gladstone in 1869 who framed the present system of absolute freedom from protection, though as Palmerston's chancellor of the exchequer in 1861 he had taken a long step toward it. In 1841 more than 1,000 articles were on the customs list, over half of them large staples; in 1849 they were reduced to 515, and in 1855 to 414, but still 153 main articles of consumption; while in 1861 they were reduced at a blow to 142, of which only 19 were of great importance, and in 1876 to 42, of which 10 were important. They have since been reduced to 12 altogether, in as few classes as possible — seven kinds of drinks, three of sweets, one narcotic and one food; namely, spirits, wine, and beer; tea, coffee, chicory, and cocoa; sugar, molasses, and glucose; tobacco; and dried fruits.

The progress of Great Britain under this system is the very point now in fierce issue, and soon to be passed upon by a fresh election. It may be said here that in the last 30 years of protection, the total increase of British imports and exports was $340,000,000; in the first 30 of free trade it was $2,400,000,000, between seven and eight times as much. In 1816–40 the total increase in British shipping was 80,000 tons; from 1848 to 1858 it was 1,257,000, and thence to 1880 1,917,000 more. The experience of Belgium was even more striking. Under Napoleon prohibitory duties were imposed, and the country became largely depopulated; with the return of the Dutch and low duties, great manufactures at once sprang up; with their expulsion in 1830 high protective duties were again imposed, and in 1851 the prime minister declared that if they were not removed all domestic industry would be ruined; the whole system was swept away in 1855, and Belgium rapidly became, size for size, the foremost industrial and commercial state of the world, the richest per capita, and the manufactory of Europe. Only a few per cent of its revenue is from imports, the rest being from internal duties.

The arguments for free trade cannot be stated without those against protection, being the same. They are not alone industrial, but political and social. Broadly, it is asserted that protection cannot increase the total industrial product to be divided up, and can only enable one class of the community to force the remainder to buy one costly article instead of two cheap ones, thus lessening the volume of trade and production; that its claim, to redistribute the amount in wages is false, as but for the system the same capital would have been employed in other industries and paid as much wages, with lower prices to the consumers; that its claim to ultimately reduce prices is false, because as soon as that object has been achieved, it applies to the government on that very ground to save it from ruin by increasing the duty; that its claim to found industries is false by demonstration; and that it narrows instead of diversifying them; that it extorts high prices from home consumers by squeezing the market of which it is given a monopoly, and then sells its surplus to foreigners at a low price — which Adam Smith sets down as inevitable with a protective system; that it produces trusts, to prevent competition through which the public might secure its alleged benefits; that it produces alternate "feast or famine," inflation and panic, instead of equable business; that it makes orderly public finance impossible, by creating huge random revenues to be spent at random, in place of a calculable budget; that it corrupts politics deeply and hopelessly, by making masses of capital dependent on legislation for its profit, and consequently influencing that legislation for its own ends, stripping the treasury to prevent repeal of duties, inventing extravagant schemes to spend an unnecessary revenue, and buying votes in its favor by enormous permanent burdens on the people, through pensions and the like; that the low tone of American public life, wherein men can remain and be honored after exposures which would drive them into permanent obscurity in any European country, is mainly due to this money power created by legislation. For the opposite side, see PROTECTION.

Free Will. This question is properly divided into two sections, that of the metaphysical basis and the doctrinal application; but the latter has so deeply affected the reasonings on the former, that it is almost impossible to separate them.

The metaphysical problem is unique, from its presenting at the outset an irreconcilable contradiction between the phenomena of consciousness and the operations of reason. In this respect it is different from the insoluble problems of time and space, where the conflict is between opposing conclusions of the reason with regard to the materials furnished by consciousness;

here there is a denial, by reason, of the validity of those materials. Consciousness appears to show us at every moment that we can dictate our actions mostly and our thoughts very largely; reason tells us that each follows on other phenomena, from whose invariable relation of precedence we characterize them as cause and the former as effect. Consciousness tells us that our will is the active agent in producing the phenomena which immediately succeed it; reason tells us that this fancied agency is an illusion and itself a part of the chain of sequences, and that the apparent relation is because, as Hobbes says, the so-called will is the last wish of the mind before determining. But what causes the determination? This involves the problem of the nature of the will as before, as well as of the "coupling-pin" by which, if a reality, it acts on matter; if not a reality, the reason why a mental resolve is invariably followed by a physical movement or mental conception. Of the coupling-pin no acceptable theory has ever been framed; the best explanation of the association of will and act, supposing the former an illusion, is still Spinoza's, that they are twin phases of the same ultimate reality, and of necessity change coincidently. But this leaves it still unexplained why our consciousness makes the will not coincident with the act, but invariably its predecessor: we do not will and act simultaneously, but in succession. The overwhelming weight of reason, however, for 2,500 years, from the Greek predecessors of Aristotle to Jonathan Edwards, has won reluctant acceptance to the doctrine of universal determinism, or in theological phrase, of necessitarianism: a chain of causation extending to all things and back to infinity, since no uncaused first act or idea can be fancied except as part of the First Cause of the universe. It is of course never claimed that all acts are volitional or all volitions deliberate, but only that the mind at will can interject uncaused determinations among the caused. It is evident, however, that to assume the possibility of uncaused acts is to consign the universe to chaos and abolish the reign of law; that only on the theory of strict and unbroken causation (or "invariable sequence") can we reason at all concerning phenomena: that the mind must follow the same law as other entities, and has no power, nor could even be endowed with such by omnipotence, of willing without motive — that is, without a cause itself the resultant of an endless series of other causes. Indeed, as Prof. Huxley puts it, for the mind to cause itself implies that it has anteceded itself, which is absurd: the first mental action must have been part of the chain of causation, which surrenders the whole case, as there is no spot where it can be imagined that it was able to throw down the ladder by which it had climbed, and cut loose from causes into a region of caprice.

To avoid this conclusion, a curious dilemma — usually known as "Buridan's Ass," though Buridan did not devise it — was invented by the mediæval schoolmen. Suppose an ass between two bundles of hay, exactly alike, and with no motive for choosing which to bite first: it is absurd to suppose he would starve in the midst of food, and he must therefore act from free will. To this, however, it was answered that if motiveless he would so starve; and the question remained as before.

Involved with this is the question of God's foreknowledge. It is obvious that this involves his pre-determination of events, as otherwise he would foreknow what was never to happen, or was to happen outside his will; and there can be no change in the predestined order, since any change in a sequence must itself be part of the predestination and foreknowledge.

Alone of all metaphysical questions not incident to the claims of religious founders, this has always been a fierce battle-ground, the dividing line of great religious sects. The reason is that the possibility of sanctions for moral law, and consequently of a decent basis for human society, is believed to depend upon it. Determinism seems to cut the roots of moral obligation, by removing the possibility of obedience to it. If we are without will except as a consciousness of preference resulting from causes outside our control, we are automata; and preaching obligation of any sort to us seems as irrational as preaching it to a doll, for our action will not be influenced by it, nor are we responsible for disobedience. In this extreme form, the fallacy is easily apparent. The will, as Edwards has put it, always follows the greatest seeming good; but its estimate of good is not an unvarying thing, but constantly changing with experience and reason. Now moral rules, apprehended and accepted by the mind, form a part of this good, and therefore become new causes which determine the will; and whatever may have been the causation which has determined the evolving and enforcing of the moral law, it is nevertheless a portion of the environment which acts on the mind. As to responsibility, the question is irrelevant. An automaton which runs into a fire or the sea perishes none the less than if the act were a conscious volition. Punishment waits not on responsibility, but on violation of the laws of its being, and blame as excuse are alike impertinent to the result. We do not blame a child who burns its fingers, but the fingers are in the same condition as if we did.

Back of this, however, lies a contradiction of fact. So far from determinism making moral law impossible, free will makes it impossible. If volition can perpetually nullify the action of motive, there is a fatal breach in the continuity of cause and effect; there can be no calculable sequence of action and therefore no law. The most perverse defiance of natural order is no more independent of cause than the steadiest obedience, for that perversity is itself due to causes precedent. Whence then come the invariable consciousness of freedom to act, its universal recognition, its embodiment into the framework of society, the obvious fact that there can be no society except on this basis? Why, here again, do consciousness and practice oppose themselves unalterably to invincible argument? Edwards explains that though we have not liberty of willing, we have liberty of action; which taken literally would imply that the will has no necessary connection with the act, and that we may voluntarily do a thing we have involuntarily willed not to do. Of course Edwards does not in fact maintain this, but only that God has given a choice of action by furnishing experience and reason and illumination by which to frame correct determinations. Waiving discussion of the difference between these determinations and will, the real explanation probably lies in the confusion between the abstract and concrete will, between its dependence on causes and, as above said, our own power to determine or change those causes. Instruction, example, appeals to self-interest or fear, or vanity, or affection, or honor, etc., produce an evironment and modify the view taken by each of the supreme immediate good, calculably enough to base coherent society upon; where their effect is grossly miscalculated the society goes to pieces. Metaphysics and the general consciousness are both right, each in its own sphere: the will must have motives, but those motives are furnished in great measure externally. Furthermore, subject to the inexorable limitation, it can furnish by its own action motives to change itself; and constantly does so, attributing to its independent action what is really due to the influence of the new causes it has made to operate in altering its estimate of relative good. For the purposes of human life, volition is absolute and there is no injustice in enforcing responsibility.

Freedman. See FREEMAN.

Freedmen's Bank, a savings bank chartered by Congress in the District of Columbia in 1865, at the special instance of Charles Sumner and Charles R. Buckalew, as a means of encouraging thrift among the newly emancipated negroes. It was in fact intended as part of the Freedmen's Bureau work, and had among its corporators Gen. Howard, the chief commissioner, and a host of the most eminent and upright public men and philanthropists; and its investments were restricted to government securities. It started branches in some 30 Southern cities, with doubtful legality, but covered by the elastic ægis of the bureau's power and every one's good will, the South's most of all: and did a large business. But the corporators appointed successors much less disinterested; the restriction on investments was removed in 1870, ostensibly to benefit depositors by a higher rate of interest, against the protest of Simon Cameron in the Senate: the securities were rapidly replaced by "wildcat" stocks, all speculative and mostly worthless, and by mortgages on valueless property; and in 1874 the bank was pronounced insolvent, with practically no assets. The blow to incipient negro thrift was very great; and the scandal discredited the entire system of which the bank was an outcome, and was one cause of the political overturn in 1874.

Freedmen's Bureau, 1865-9. The supervision, temporary maintenance, and employment of the mass of homeless, penniless, and untaught freedmen created by emancipation, was an obvious duty of the government, urged upon it at once after the proclamation of 1 Jan. 1863; and in 1863-4 officials were appointed to lease abandoned lands to them for not exceeding a year. The military officers left much of the care and provision for freedmen in their hands; but a more comprehensive plan was needed, and after various abortive efforts at an acceptable measure, a "Bureau of Refugees, Freedmen, and Abandoned Lands" was established in the War Department 3 March 1865, to continue for a year after the war. It was to be headed by a commissioner, with assistant commissioners in all the seceded States; to issue supplies to destitute freedmen, have charge of abandoned lands to lease and ultimately sell in 40-acre plots, and have "control of all subjects relating to refugees and freedmen"— an elastic provision construed in the most elastic way. Its commissioners — the head being Gen. O. O. Howard (q.v.), a noble-minded and laborious philanthropist — acted as courts of law where there were none, or where negroes were not recognized as free; established the institution of marriage, and kept records; assured the freedmen the right to choose employers, and made fair contracts for them. The "abandoned lands" disappeared under the amnesty acts; but the bureau did excellent work by inaugurating free schools on a large scale. On 6 Feb. 1866 Congress passed a bill to enlarge its powers and make it permanent; Johnson successfully vetoed it, but on 16 July another was passed over his veto, extending the bureau to July 1868, later extended a year in unreconstructed States. Under this its sweeping powers made it largely the government of the South under Reconstruction, especially as the department military commanders were usually made assistant commissioners; and the demoralizing and disastrous struggle of the North to secure negro independence, and of the South to reassert white mastery, is a history of part of the bureau's action — through executive and legislative powers scarcely pretended to be constitutional, and to transfer which to the regular courts the Fifteenth Amendment was passed. Better features of its work were the foundation of the free public schools in the South, and of Fisk, Howard, and Atlanta universities, and Hampton Institute; of the system of negro peasant proprietorship; and the winning of equal rights for all men in the courts. That it failed in its larger hopes, and that its harmful results were so great that many hold them far in excess of its benefits, are facts attributed by the fairest judges to the inevitable conditions of the problem. (See a very lucid and singularly just summary by W. E. B. DuBois — colored — in the 'Atlantic Monthly,' Vol. LXXXVII., p. 354.) The bureau ended its main work in 1869; its educational work continued till 1872, and bounty payments some years longer. It had about 900 agents in 1868; and expended in all some $20,000,000, over $10,000,000 on objects unconnected with soldiers' bounties. Gen. Howard published a report of its work in the House Executive Documents, 41st Congress, 2d session.

Freedom, or Freedom of the City, an English custom occasionally revived in America. The freedom of a city or borough is the right of enjoying the privileges and immunities that belong to the burgesses or freemen, such as electing the council or the parliamentary representative. In certain boroughs there were at one time freemen by birth or marriage not on quite the same footing as burgesses.

Freehold, N. J., town, county-seat of Monmouth County; on the Central R.R. of New Jersey, and the Pennsylvania R.R.; about 32 miles southwest of Jersey City. It was settled in 1734, and for some time it was called Monmouth Court House, because of the county court being held in the village. In 1869 it was incorporated. It is the trade centre for a large agricultural section. Its chief manufactures are bicycles, foundry, and machine-shop products, underwear, and shirts. One of the attractions of the town is the granite monument in memory of the battle of Monmouth (q.v.) which took place here 28 June 1778. Pop. (1900) 2,934.

Freehold, in English and American law, an estate or real property held in fee simple in America, or in England either in fee simple or fee tail; the tenure by which such an estate is held. (See FEE.) Anciently it was one of the two chief tenures known as tenure in free socage, and was the only free method for laymen to hold property. A freehold estate must possess immobility, in other words, must consist either of land or of some interest arising out of land annexed to it. Secondly, it must be of indeterminate duration.

Freeland, Pa., borough in Luzerne County; on the Lehigh Valley R.R.; about 30 miles southwest of Scranton. It is situated in the anthracite coal region, but it is surrounded by a large section of good farming land. The chief manufactures are lumber, mining and farm implements, and foundry products. During the last decade the place has increased rapidly in population and manufacturing. Pop. (1890) 1,730; (1900) 5,254.

Freeman, Alice Elvira. See PALMER, ALICE FREEMAN.

Freeman, Edward Augustus, English historian: b. Harborne, near Birmingham, 1823; d. Alicante, Spain, 16 March 1892. He was educated at Trinity College, Oxford, where he obtained a scholarship in 1841, and after his marriage in 1847 he retired to a small estate at Somerleaze, in Somerset, where he devoted himself to literature. His first publication (1849) was a 'History of Architecture,' a subject in which he maintained interest throughout his life. This work was more especially devoted to Gothic architecture. His architectural researches helped to turn his attention to history, but his earliest historical works were the product of his interest in contemporary burning questions. His 'History and Conquests of the Saracens' (1856) was partly due to the Crimean war; and the American Civil War brought forth his 'History of Federal Government' (1863), which, however, remained a fragment in one volume. Between 1867 and 1879 appeared his *magnum opus*, the 'History of the Norman Conquest of England,' in six volumes, followed in 1882 by two supplementary volumes dealing with 'The Reign of William Rufus and the Accession of Henry I.' In 1884 he was appointed regius professor of modern history at Oxford, and this post he occupied till his death. His last great work was a 'History of Sicily,' which he left unfinished, though three volumes of the work were published. He died in Spain, where he was traveling for the purposes of recreation and research. Other works of his beside those mentioned were: 'Church Restoration' (1849); 'Essay on Window Tracery'; 'The Architecture of Landaff Cathedral'; 'History of Wells Cathedral' (1870); 'Old English History' (1869); 'Growth of the English Constitution' (1872); 'Historical Essays' (three series, 1872–79); 'The Ottoman Power in Europe' (1877); 'Historical Geography of Europe' (1881); 'Sketches from the Subject and Neighbor Lands of Venice' (1881); 'Lectures to American Audiences' (1882); 'English Towns and Districts' (1883); 'Some Impressions of the United States' (1883); 'Exeter' (1887); 'Methods of Historical Study' (1886); 'The Chief Periods of European History' (1887); 'William the Conqueror' (1888). He was a man of strong partisan feeling, with a firm belief in the superiority of the Teuton which sometimes interfered with a judicial weighing of evidence. But he took great pains to verify his facts, indeed was devoted to truth, and had a wide and deep knowledge of history. In spite of his pugnacity and the obstinacy with which he maintained his side in a controversy he was a man of generous and kindly nature. Consult 'Life and Letters,' by Stephen (1895).

Freeman, James, American Unitarian clergyman: the first in the United States to assume the name Unitarian: b. Charlestown, Mass., 22 April 1759; d. Newton, Mass., 14 Nov. 1835. He was graduated from Harvard in 1777, in 1782 became lay-reader in King's Chapel, Boston, later proclaimed himself an Unitarian, and, supported by his congregation secured corresponding changes in the Prayer-book. In 1787, his bishop having refused him ordination, he was ordained by his wardens and congregation. Until his death he was rector of the chapel. He published: 'Sermons and Charges' (1832).

Freeman, James Edward, American artist: b. Nova Scotia 1808; d. Rome, Italy, 21 Nov. 1884. He was a pupil of the National Academy of Design, and was elected national academician in 1833. From 1836 his studio was in Rome. His works, largely portraits and genre subjects, are skilful in color and display attention to technical detail. They include: 'Young Italy'; 'Peasants on the Sands of the Sezchio'; 'The Beggars.'

Freeman, James Midwinter, American Methodist clergyman: b. New York 29 Jan. 1827; d. 1900. He was educated at Wesleyan University, and ordained to the ministry of the Methodist Episcopal Church, of whose Sunday-school Union and Tract Society he became secretary and editor in 1872. He was the author of 'Use of Illustration in Sunday-school Teaching' (1867); 'Hand-book of Bible Manners and Customs' (1874); 'Short History of the English Bible' (1879).

Freeman, Mary Eleanor Wilkins, American novelist: b. Randolph, Mass., 1862. She was educated at Mount Holyoke Seminary and after some years spent in Brattleboro, Vt., returned in 1883 to Randolph, which remained her home till her marriage to Charles Freeman in January 1902, when she removed to his home in Metuchen, N. J. She came first into notice about 1886 by her extremely faithful delineations of certain phases of New England life in her short stories contributed to the magazines. After some years she attempted more sustained work, and within the last ten years has published several novels, displaying the same characteristics as her short stories, as well as skill in the handling of plot, and dramatic vigor. Her work has steadily gained in popularity and has been greatly admired by English as well as American critics. A fondness for very short sentences gives her work almost a staccato character at times, and it must be said that while the accuracy of her studies of New England village existence cannot be called into question, her insistence upon the bareness of the life to the exclusion, or almost entire subordination of its happier phases, conveys a not wholly correct impression of the life in its entirety. Her published works include: 'The Adventures of Ann' (1886); 'A Humble Romance and Other Stories' (1887); 'A New England Nun, and Other Stories' (1891); 'Young Lucretia' (1892); 'Giles Corey, Yeoman,' a drama (1893); 'Jane Field,' her first novel (1893); 'Pembroke' (1894); 'The Long Arm,' with J. E. Chamberlin (1895); 'Jerome, a Poor Man'; 'Silence and Other Stories'; 'The People of Our Neighborhood'; 'Understudies'; 'Madelon'; 'The Love of Parson Lord'; 'Evelina's Garden'; 'The Wind in the Rose-Bush'; a series of ghost stories (1903); etc.

Freeman, Nathaniel, American jurist: b. Dennis, Mass., 1741; d. 1827. In 1763 he became resident at Sandwich. He fought in the Revolution, and was brigadier-general of militia forces in 1781–91. In 1795–99 he was a member of the United States Congress, and he also sat in the Massachusetts legislature, and was for many years judge of the court of common pleas. He was also a medical practitioner, and an orator of some distinction.

Freeman, or **Freedman,** is one who has inherited the full privileges and immunities of citizenship; one who has been delivered from the restraints of bondage, but who, usually, is not placed in a position of full social or even political equality with him who was born free. In old Rome, the equivalent for freeman comprehended all classes of those who were not slaves. As the organization of Roman society survived the convulsions of the Middle Ages to a far greater extent in the towns than in the landward districts, where the institutions of feudalism (q.v.) almost entirely superseded it, it is in the borough and other municipal corporations of Europe that we still find freemen, or persons inheriting or acquiring by adoption, purchase, or apprenticeship the rights of citizenship. In the United States the term freemen was used of the colored people emancipated by the Civil War. The duty of caring for those people, finding them work, and preparing them for the privileges of freedom was thrown on the War Department; and in 1865 an act of Congress created in that department the bureau commonly known as the "Freedmen's Bureau" (q.v.), whose duties practically ceased in 1870. The founding of several institutions for colored persons, such as Howard University and Fisk University (q.v.), was a permanent result of its work, out of which have grown other educational achievements of great importance in the advancement of the colored people.

Freemasonry. See MASONIC FRATERNITY.

Freemasons. See MASONIC FRATERNITY.

Freeport, Ill., city, county-seat of Stephenson County, on the Pecatonica River, the Illinois C., the C. & N., and the C., M. & St. P. R.R.'s; about 105 miles northwest of Chicago, and 55 miles southeast of Dubuque. It was settled in 1835 and received its charter in 1855. The "Freeport heresy," a political doctrine much discussed before the Civil War, was that regardless of the Dred Scott case (q.v.) any Territory had the right to reject the slave system by the means of police laws which would be "unfriendly," and would in time stamp out the existence of slavery. This "doctrine" or "heresy" was advanced by Douglas in the famous debate with Lincoln which took place in Freeport in 1858. The chief manufactures are wind-mills, bicycles, organs, wagons, and toys. It has coffee-mills and railroad shops. It contains a free library, St. Francis Hospital, a good system of public and parish schools, and several fine public buildings. Pop. (1900) 13,258.

Freer, Paul Caspar, American chemist: b. Chicago, Ill., 27 March 1862. He was graduated in 1882 at the Rush Medical College of Chicago; at the University of Munich, Germany, in 1887; was assistant in Owens College, Manchester, England, in 1887; and an assistant and instructor in Tufts College in 1887–9. In 1889 he became professor of general chemistry in the University of Michigan. He has published: 'A General Inorganic Descriptive Chemistry' (1895); 'The Elements of Chemistry' (1896); and numerous pamphlets.

Freethinker, a name assumed by those who, disbelieving in revelation, feel themselves free to adopt any opinion in religious or other matters which may result from their own independent thinking. The name was specially claimed by those who in the 17th century took part on the anti-Christian side in the deistic controversy. Voltaire (q.v.) was a well-known French freethinker.

Freetown, Africa, a seaport of West Africa, capital of the British colony of Sierra Leone, on the south side of the river of Sierra Leone. Its principal streets are broad and straight, and have, more especially in the part occupied by Europeans, a very attractive appearance, the houses being generally detached and surrounded by trees. Freetown is a strongly fortified imperial coaling-station. A railway runs from Freetown some distance into the interior. Pop. (1901) 34,463.

Freezing, Congelation, or **Solidification,** the transformation of a liquid into a solid under the influence of cold. Each liquid always solidifies at the same temperature, which is called its freezing point, and the solid also melts again at the same temperature. Thus the freezing point and the melting point, or point of fusion, are the same, and the point is always the same for the same substance. The freezing point of water, or the melting point of ice (32° F.), is taken for one of the fixed points in thermometry. The freezing point of mercury is 39° below zero, of sulphuric ether 46° below zero, of alcohol 203° below zero F. It has been shown that the increase of pressure on water, and on all substances which expand in freezing, will lower the freezing point; and that such substances as wax, spermaceti, sulphur, and paraffin, which contract in freezing, have the freezing point raised by pressure. See MELTING-POINT.

Freezing-mixture, a mixture for the production of artificial cold. For this purpose two substances are mixed, of which one is usually solid, and which tend to form a liquid mixture. In liquefying any solid a certain amount of heat is made latent, and owing to this the temperature of the mixture at the end of the liquefaction is often very low indeed.

Thus on mixing snow and salt together the salt converts the snow into water, or rather tends to form brine; but snow cannot melt without making latent a considerable quantity of heat. Hence the temperature of the brine which is the result of the mixture is very much below that of either the salt or snow. The fact is that salt and water mixed cannot be in the solid condition, except at a temperature very much below that of ordinary snow. The following is a list of freezing-mixtures, and of the lowering temperature obtained by means of them. The substances, with the exception of the ice, mentioned in the second, are supposed to be mixed together at 10° C. (50° F.). Such mixtures are often employed in the making of ice-cream or water-ices, for cooling wine, etc. See ICE, ARTIFICIAL; REFRIGERATING MACHINES.

Substances	Parts by Weight	Reduction of Temperature
Sulphate of sodium..	8	+ 10° C. (+ 50° Fah.) to − 17° C. (+1° Fah.)
Hydrochloric acid....	5	
Powdered ice or snow	2	+ 10° C. to − 18° C. (0° Fah.)
Common salt........	1	
Sulphate of sodium..	3	+ 10° C. to − 19° C. (− 2° Fah.)
Dilute nitric acid....	2	
Sulphate of sodium..	6	+ 10° C. to − 26° C. (− 15° Fah.)
Nitrate of ammonium	5	
Dilute nitric acid....	4	
Phosphate of sodium.	9	+ 10° C. to − 29° C. (− 20° Fah.)
Dilute nitric acid....	4	

Freezing Point, that temperature at which the solid and fluid states of a substance can co-exist in a state of permanent equilibrium. For water, this temperature is 32° F., or 0° C. For the freezing points of other substances, consult the articles in which their general properties are described. See also HEAT; MELTING POINT; SOLUTIONS; THERMODYNAMICS; THERMOMETRY.

Freiberg, frī'bĕrg, Saxony, a mining town 19 miles from Dresden. It is the capital of the mining district of Saxony, and contains a mining academy founded in 1765, with 13 professors, fine scientific collections, among which is the celebrated collection of precious stones amassed by Werner, and a large library. There is a fine relic called the Golden Portal belonging to the ancient Church, which stood on the site of the Gothic cathedral. It is an ancient imperial city, and is still surrounded by the old walls and ditch. The town owes its origin to the discovery of silver mines in the 12th century. Here, on 29 Oct. 1762, Prince Henry of Prussia defeated the allied Austrian and Saxon army. Pop. (1900) 30,175.

Freiburg, frī'boorg, or **Freyburg**, or **Freiburg im Breisgau**, Baden, a town in the circle of the upper Rhine, on the Dreisam, and on the railway from Carlsruhe, in one of the most beautiful and fertile districts of south Germany, at the west foot of the Black Forest. It consists of the town proper, the fortifications of which have now been converted into pleasure-grounds, and of two suburbs, and is the seat of a superior civil and criminal court, and of several public offices. The buildings most deserving of notice are the münster or cathedral, a large and beautiful Gothic structure built of red sandstone, admired for its delicate symmetry and tasteful decorations, with a magnificent portal richly sculptured, and surmounted by a tower, partly of exquisite open work, 380 feet high; the university, founded in 1456; the merchant house, now the chief tax office, a quaint Gothic structure, resting on pointed arches, and decorated externally with fresco portraits of the Emperor Maximilian, his son Philip I., Charles V., and Ferdinand I.; and the grand-ducal palace and government buildings. Freiburg is the see of an archbishop, and the seat of the courts and offices for the circle of the upper Rhine. Pop. (1900) 61,506.

Freiburg. See FRIBOURG.

Freight, formerly a charge paid to the owner of a ship for the carriage and safe delivery of goods; but the term now extends to transportation by land, especially on railroads. In cases of maritime freight, a person chartering a ship pays freight for the goods sent by it, and dead freight in respect of any deficiency of cargo; the terms of the agreement are fixed by the charter party. A person sending goods by a general ship pays freight for them; and the contract takes the form of a bill of lading. So far as the rights of parties are not made the subjects of positive stipulation in the contract of affreightment, they are ascertained with reference to the usage of trade. The carrier's duty is to have the ship ready to start at the time appointed, and to receive the goods and carry them to their destination; having performed these duties, he has a lien on the goods and a right of action in case of non-payment of freight. The shipper's duty is to have his goods forward in time. Freight is not usually payable unless the voyage is completed; but it is sometimes prepaid, in whole or in part, at the risk of the shipper. See BILL OF LADING; CARRIER, COMMON; CHARTER; TRANSPORTATION.

Freiligrath, frī'lig-rät, **Ferdinand**, German poet: b. Detmold 17 June 1810; d. Cannstadt, Würtemberg, 17 March 1876. In 1838 he published at Mainz a volume of his collected poems, and as it proved successful he determined to devote himself entirely to literature. In 1842 he received a small pension from the king of Prussia; but this he retained for only two years, for having embraced views in politics of an advanced liberal stamp which placed him in opposition to the government, he felt bound to resign the benefits of royal favor. At the same time (1844) he published a poem entitled a 'Confession of Faith' (Glaubensbekenntnis), in which he became the champion of the political creed he had adopted. In 1848 other three political poems by him: 'Die Revolution'; 'Februarklänge'; and 'Die Todten an die Lebenden,' saw the light; and the last of these led to his being put on trial for treason. This trial, in which he was acquitted, is memorable for another reason, being the first jury trial ever held in Prussia. From 1851 till 1867 Freiligrath resided in England as manager of the London branch of a Swiss banking establishment. On the failure of the bank a national subscription was got up in his behalf in Germany, and the proceeds of it enabled him to return to private life. The early poems of Freiligrath are distinguished by a wealth of glowing and highly-colored imagery, and by the prevalence of Oriental scenes and subjects. His political poems are too full of the tones of party warfare to live as poetry; but many of his lyrics seem destined to hold an abiding place in German literature. Germany is also indebted to him for many admirable translations from foreign languages, as from Burns, Tannahill, Moore, Hemans, Shakespeare, Longfellow, and Victor Hugo.

Freire, frā'rĕ, **Ramon,** Chilean general: b. Santiago 29 Nov. 1787; d. there 9 Dec. 1851. He was a grandson of Freire de Andrada (q.v.). He fought in the patriot army in the war for independence (1811–20), and defeated Benevides at Concepcion 27 Nov. 1820. He became the leader of the Liberals, and upon the deposition of O'Higgins in 1823, supreme director, with dictatorial powers. In 1826 he ended Spanish rule in Chile by expelling the remaining Spanish forces from Chiloé in 1826. He was re-elected supreme director in 1827, but resigned not long after. The Conservatives having gained control, he led an insurrection against them, was defeated at Lircai (1831), and banished to Peru, whence return was not permitted him until 1842.

Freire de Andrada, dā ān-drä'dä, **Gomes,** Portuguese colonial administrator: b. Coimbra 1684; d. Rio de Janeiro 3 Jan. 1763. He served in the Portuguese army, and became governor and captain-general of Rio de Janeiro in 1733, his authority extending over most of southern Brazil. His administration of almost 30 years was the most successful and prosperous, as well as the longest, in the colonial annals of Brazil. The gold mines were effectively worked, and colonization was greatly furthered. Freire de Andrada was made Count of Bobadilla in 1758.

Frejes, Francisco, frän-sēs'kō frā'hĕs, Mexican historian: b. Guadalajara, Mexico; d. 1845. He was trained for priestly and monastic life, became known as a Franciscan of remarkable eloquence, but retired from publicity in 1838, and eventually became superior of the monastery of Guadaloupe, near Zacatecas, Mexico. His object in his retirement was the prosecution of historical study, and his work: 'Historia Breve de la Conquista de los Estados Independientes del Imperio Mejicana,' is a valuable authority on the subject it treats.

Frelinghuysen, frē'lĭng-hī-zĕn, **Frederick,** American lawyer: b. Somerset County, N. J., 13 April 1753; d. 13 April 1804. He was graduated at the College of New Jersey in 1770; studied law, and was admitted to the bar in 1773. Two years later he was chosen a member of the Provincial Congress of New Jersey. He was a member of the Continental Congress much of the time during the Revolutionary War; served as a captain in the army; filled various State and county offices; led an expedition against the western Indians in 1790; and was United States senator 1793–6.

Frelinghuysen, Frederick Theodore, American statesman: b. Millstone, N. J., 4 Aug. 1817; d. Newark, N. J., 20 May 1885. He was a nephew and adopted son of T. Frelinghuysen (q.v.). He was graduated at Rutgers College in 1836, and became an eminent lawyer. He was attorney-general of New Jersey 1861–6; United States senator in 1868–77; and secretary of state under President Arthur in 1881–5.

Frelinghuysen, Theodore, American lawyer: b. Millstone, N. J., 28 March 1787; d. New Brunswick, N. J., 12 April 1862. He was a son of F. Frelinghuysen (q.v.). He was graduated at the College of New Jersey in 1804; and admitted to the bar in 1808. In the War of 1812 he commanded a company of volunteers, and in 1817 became attorney-general of New Jersey, which office he held till 1829 when elected United States senator. He was chosen chancellor of the University of New York in 1838; was nominated for vice-president of the United States in 1844; and in 1850 became president of Rutgers College.

Fremantle, Australia, the chief seaport of Western Australia, at the mouth of the Swan River, 12 miles from Perth. The manufactures include aërated waters, boots, soap, furniture, confectionery, etc. Pop. of town and suburbs (1901) about 22,200.

Frémont, Jessie Benton, American author: b. Virginia 1824; d. Los Angeles, Cal., Jan. 1903. She was a daughter of Thomas H. Benton (q.v.), and married John C. Frémont (q.v.) in 1841. She published: 'Story of the Guard: a Chronicle of the War,' with a German translation (1863); 'A Year of American Travel'; 'Far West Sketches'; a sketch of her father prefixed to her husband's memoirs (1886); 'Souvenirs of My Time' (1887); 'The Will and the Way Stories.'

Frémont, John Charles, American soldier and politician: b. Savannah, Ga., 31 Jan. 1813; d. New York 13 July 1890. He was of mixed French and Virginian parentage. In 1833 he was appointed teacher of mathematics on board the United States sloop of war Natchez, with which he proceeded on a cruise to South America. On his return he turned his attention to civil engineering, and in 1838–9 undertook the exploration of the country between the Missouri River and the British frontier. Shortly afterward, he proposed to the government to undertake the exploration of the Rocky Mountains — at that day a terra incognita. His plan being approved, he, in 1842, started with a handful of picked men, and reached and explored the South Pass. Not only did he fix the locality of that great defile but he defined the astronomy, geography, botany, geology, and meteorology of that region, described the route since followed, and designated the points upon which a line of United States forts were subsequently erected. In 1845 he cleared the north part of California of Mexican troops, and then, seeking a broader field of activity, planned an expedition to the distant Territory of Oregon. He approached the Rocky Mountains by a new line, scaled the summit south of the South Pass, deflected to the Great Salt Lake, pushed investigations right and left his entire course, and at the same time connected his survey with that of Commodore Wilkes' exploring expedition. Later in the winter, without adequate supplies, or a guide, he traversed the wilderness to the Rocky Mountains. In this daring expedition he crossed 3,500 miles of country in sight of eternal snows, discovering the grand features of Alta California, its great basin, the Sierra Nevada, the valleys of San Joaquin and Sacramento, and determined the geographical position of the west portion of the North American continent. In 1846 he was promoted military commandant and civil governor of the Territory of California, in which capacity he in 1847 concluded those articles of capitulation by which Mexico conceded exclusive possession of that territory to the United States. In 1853 he undertook a fifth expedition across the continent, made new discoveries, and reached California after enduring almost incredible hardships. In 1856 he was the first candidate of the Republican party for the presidency; and in 1861, on the outbreak of the Civil War, was appointed a major-general of volunteers. He then, as commander of the Western Union army, marched into Missouri with the view of encountering Gen. Price's Confederate force then in possession of that State, but an unfortunate dispute with a subordinate officer caused the War Department to relieve him of his command. He was governor of Arizona 1878–81. His publications include: 'Report of the Exploring Expedition to the Rocky Mountains in 1842, and to Oregon and North California in 1843–44'; 'Col. J. C. Frémont's Explorations'; and 'Memoirs of My Life.'

Fremont, Neb., a city and the county-seat of Dodge County, in the central eastern part of the State, on the Fremont, E. & M. V., the Union P., and the Sioux C. & P. R.R.'s, 37 miles northwest of Omaha. The town was settled in 1857 and was incorporated in 1871; it has a telephone system, gas works, and a municipal water supply and electric lighting plant. It is an important market for horses, cattle, sheep, and swine, and has pork-packing establishments, flouring mills, and planing mills. The educational institutions include a normal school and a business college. Pop. (1900) 7,241.

Fremont, Ohio, city, county-seat of Sandusky County; on the Lake Erie & W., the Lake Shore & M. S., and other railroads, and at the head of navigation on the Sandusky River, 30 miles east of Toledo. It occupies the site of a trading post established in 1785, and of Fort Stephenson built in 1812. In 1813 it witnessed the defeat of a body of British and Indian troops under Gen. Proctor, who were repulsed by Maj. George Groghan with 150 men, the British having 94 killed and wounded, and the Americans 1 killed and 7 wounded. In 1850 its former name of Lower Sandusky was changed in honor of J. C. Frémont. It is a busy agricultural and industrial centre with neighboring oil and natural-gas fields, and manufactures machinery, cutlery, agricultural implements, electrocarbons, woolens, beet-sugar, doors, sashes, etc. Steamers connect the city with the principal ports of Lake Erie and carry on a considerable trade. The city has street railways, gas and electric lighting, municipal waterworks and maintains several public parks. The educational institutions include normal and business schools, and the Birchard Public Library, founded by an uncle of ex-President Hayes, whose home here — Spiegel Grove — is occupied by members of the family. Pop. (1900) 8,439.

French, Alice ("Octave Thanet"), American novelist: b. Andover, Mass., 19 March 1850. She was educated at Abbot Academy in her native town and has since lived in Iowa and Arkansas, her works reflecting the local color of both States. She has published: 'Knitters in the Sun: Short Stories' (1877); 'Otto the Knight and Other Trans-Mississippi Stories' (1891); 'Stories of a Western Town' (1893); 'An Adventure in Photography'; 'Expiation' (1890); 'We All' (1891); 'A Book of True Lovers' (1893); 'The Heart of Toil'; 'Man and His Neighbors'; etc.

French, Daniel Chester, American sculptor: b. Exeter, N. H., 20 April 1850. He was educated in Boston and in Florence, Italy; had studios in Boston and Concord, N. H., 1878–87, and in New York city 1887–1900. His principal works include: 'The Minute Man of Concord'; statues of Gen. Cass, Rufus Choate, John Harvard, and Thomas Starr King; 'Dr. Gallaudet and His First Deaf Mute Pupil'; 'Statue of the Republic'; and the Milmore Memorial. He was placed in charge of the sculpture department of the St. Louis exhibition.

French, Henry Willard, American journalist and author: b. Hartford, Conn., 1854. He is known as a war correspondent and lecturer and among his writings may be mentioned: 'Nuna, The Brahmin Girl'; 'Desmonde, M.D.'; 'Art and Artists'; 'Our Boys in China'; 'Our Boys in India'; 'Our Boys in Ireland.'

French, John Denton Pinkstone, English soldier: b. Ripple, Kent, England, 28 Sept. 1852. He served in the navy 1866–7, entered the army 1874 and fought in the Sudan campaign of 1884. In the Boer war in South Africa (1900) he commanded the cavalry division, directed the operations about Colesberg from 10 Nov. 1899 to 31 Jan. 1900, and commanded the cavalry in the movements that led to the relief of Kimberley in February 1900, and the capture of Bloemfontein and Pretoria. His services in South Africa were recognized by his promotion to the command of the First Army Corps at Aldershot, in which he ranks as major-general.

French, L. Virginia (Smith), American poet: b. Maryland 1830; d. McMinnville, Tenn., 31 March 1881. She was associate editor of the 'Southern Lady's Book,' a fashion magazine, published in New Orleans (1852). Her collected works are: 'Wind Whispers,' poems (1856); 'Iztalilxo,' a tragedy (1859); and 'Legends of the South' (1867).

French, Mansfield, American educator: b. Manchester, Vt., 1810; d. 1876. He was educated at Kenyon College, Ohio, and from 1845 to 1848 was president of the Female College, Xenia, Ohio. He was active in the founding of Wilberforce University, the first college for the colored race, as he had been one of the founders of Marietta College. An ardent abolitionist, he laid before President Lincoln his plans for the education of the negroes as preliminary to their emancipation. The National Freedman's Relief Association was the realization of his views, as he had stated them at a mass meeting held in Cooper Union, New York, February 1862.

French, William Henry, American soldier: b. Baltimore, Md., 13 Jan. 1815; d. 20 May 1881. He was graduated from West Point in 1837, served in the Seminole and Mexican wars, was commissioned brigadier-general of volunteers and major of United States artillery, and was mustered out of the volunteer service in 1864 after having for a time commanded the 3d Army Corps. He commanded the 2d Artillery 1865–72, and was retired with rank of colonel in 1880. He commanded the forces which suppressed the Baltimore & Ohio Railroad riots (1887).

French Alliance, The, in American history, an alliance, offensive and defensive, between France and the American colonies, signed in 1778. Three American commissioners, Benjamin Franklin, Silas Deane, and Arthur Lee, sent to the court of France at Versailles, obtained recognition of the independence of the United States, and effected an alliance between the greatest European rival of Great Britain and her revolting colonies in America. The treaty stipulated that should war ensue between France and England it should be made a common cause, that neither France nor America would make peace without the consent of the other, nor should either lay down its arms until the independence of the colonies should be established. The news of the alliance provoked great enthusiasm in the American colonies. See UNITED STATES — AMERICAN REVOLUTION.

French and Indian War. See COLONIAL WARS IN AMERICA.

French Broad River, a river of North Carolina and Tennessee, rising in Henderson County, of the former State, near the foot of the Blue Ridge, flowing northwest into Tennessee, and discharging into Holston River, four miles above Knoxville. It is about 200 miles long. From Asheville to the Tennessee line it is remarkable for its beautiful scenery, flowing through deep mountain gorges, or overhung by high cliffs. In Buncombe County, N. C., are precipices known as the Chimneys and the Painted Rocks. The latter, which are between 200 and 300 feet high, derive their name from some Indian pictures still to be seen on them.

French Chalk, a variety of steatite or talc (q.v.) occurring in fine-granular or scaly masses of milky-white color and pearly lustre. It is extensively used by tailors as a crayon for marking cloth, also as an absorbent in removing grease spots.

French Congo, Africa, a large French territory on the west coast between the Lower Congo and the German Kamerun country, and stretching inland to Lake Chad; total area, about 500,000 square miles. The chief rivers are the Muni, Gabun, Ogowe, and Kuilu, and the stations already founded include Libreville, the capital (pop. 3,000), Brazzaville, Njola, Philippeville, Bonga, Loango, Franceville, and about 20 others. The district is under a commissioner-general, assisted by two lieutenant-governors. Though it is unhealthy even in the more elevated districts for Europeans, considerable trade is carried on, the exports comprising caoutchouc, cocoa, coffee, ivory, ebony, mahogany, palm-oil, gum-copal, etc. Pop. 8,000,000 to 12,000,000, of whom 1,200 are Europeans.

French Creek, N. Y., in the War of 1812. In the course of Wilkinson's invasion of Canada late in 1813 (see CHRYSTLER'S FARM), Gen. Jacob Brown posted himself on the St. Lawrence near the present Clayton, N. Y. On 1 November the British sent two brigs, two schooners, and eight gunboats to dislodge him; but his three-gun battery on a hill at the mouth of French Creek drove them off. They returned the next morning and were again repulsed, with severe loss. The Americans lost two killed, four wounded.

French East India Company. See EAST INDIA COMPANIES.

French Guiana. See GUIANA.

French Guinea, gĭn'ĭ, West Africa, a French colonial possession, between Sierra Leone, Liberia, Senegal, and Portuguese Guinea. The area is about 95,000 square miles and the population (1901) 2,200,000. The centres of population are Konakry, the capital, on the Isle of Tombo, and Boké, Ubrêka, and Timbo. The products are rice, millet, earth-nuts, gum, and rubber. A railroad of 80 miles has been built from Konakry to the Niger. There are 1,060 miles of telegraph line in the colony. In 1900 the imports were $2,755,250, and the exports $1,887,600. The colony is under the administration of a governor, who is under the governor-general of French West Africa. The French colonized the section as early as 1685.

French Indo-China, generally, the French possessions in southeast Asia, which include Cochin-China and the protectorates of Tongking, Laos, Annam, and Cambodia. French Indo-China is bounded by the China Sea, the Gulf of Siam, and the Mekong River. The area and population are given (1901) as follows:

PROTECTORATE	Area Sq. m.	Population
Annam	52,100	6,124,000
Cambodia	37,400	1,103,000
Cochin-China	22,000	2,968,529
Laos	98,000	605,000
Tongking	46,400	7,036,900
	255,900	17,837,429

The military forces of Indo-China consist of 10,901 European troops and 15,000 native soldiers. Over 1,000 miles of railroad were in operation in 1902. Indo-China is under the administration of a governor-general, and lieutenant-governor or resident superiors. The local revenue of the possessions equal the expenditure. See ANNAM; CAMBODIA; COCHIN-CHINA; LAOS; TONGKING.

French Language. See FRANCE.

French Literature. See FRANCE.

French Polishing, a process, generally employed for giving a smooth surface-coating to furniture and cabinet-work. The surface of the wood being finished off with glass-paper and placed opposite the light, the rubber (a ball of wool covered with rag), dipped in the varnish (or polish), is passed quickly and lightly over the surface in the direction of the grain of the wood, and rubbed till dry. This operation must be repeated several times. The most common of the varnishes known under the name of French polish are prepared as follows: Pale shellac, 5½ ounces; finest wood-naphtha, 1 pint; dissolve. Before applying any of these varnishes the rubber must be first slightly moistened with raw linseed oil. See VARNISH.

French Revolution. See FRANCE, *History of.*

French River, Canada, a stream in Ontario. It empties into Lake Huron after a course of 55 miles. For 150 years it was the regular route to the upper lakes.

French Shore. See NEWFOUNDLAND.

French Somaliland, sō-mä'lē-lănd, Africa, a French colonial possession on the west shore of the Gulf of Aden, adjoining Abyssinia. The area is about 46,000 square miles and the population about 200,000. It is administered by a governor and general council. The sea fisheries and interior trade are the only commercial industries. In 1900 the imports were $1,200,000 and the exports $800,000. Among the exports are coffee, ivory, gold, and sheepskins. French and English vessels visit the coast regularly and there are 100 miles of railroad in operation. The principal towns are Jibutil, the capital, Obok, Tagurah, Ambado, Gobad, and Sagallo.

French Spoliation Claims. During the great European wars from 1793 on, French privateers assailed neutral commerce, of which the American was chief, under various pretexts or without any; one was that the United States had violated the treaty of 1778. In the virtual French-American war of 1798–9, their privateers about the West Indies and elsewhere made prize of a great quantity of American shipping, for which our commissioners vainly endeavored to obtain indemnification. Finally, in the treaty of 30 Sept. 1800, as there was no hope of getting the money from Napoleon, the United States for other considerations waived the claim; and in the Louisiana Purchase Treaty of 30 April 1803 a part of the consideration was the assumption by the United States of its citizens' claims against France, then amounting to $3,750,000. Thence till 1885, when the cases were referred to the court of claims, nearly every year saw a bill before Congress to pay these claims, and twice a vote for it was obtained, which was vetoed by the President in each case — Polk and Pierce. The court finally adjudicated several thousand claims, and awarded some $4,800,000.

French Sudan', Africa, the name officially given to a large tract of country in the western Sudan, including the upper basin of the Senegal and the countries watered by the Upper and Middle Niger. It is bounded on the west by Senegal, on the south partly by the French territory of Rivières du Sud, and on the east by independent tribes and by British territory. Officially it is divided into "annexed territories," mostly in the western part, and protectorates. The former have an area of 54,000 square miles and a population of 360,000, while the latter have an extent of 300,000 square miles with a population of about 2,500,000. The control of this region is entrusted to a military commandant subject to the governor of Senegal and residing at Kayes on the Senegal River. A railway has been opened between Kayes and Bafoulabe at the junction of the head-streams of the Senegal.

Frenchman's Bay, Maine, an ocean inlet in Hancock County, extending inland 25 miles with a width of 10 miles. It contains a number of islands, among them Mount Desert, whereon is situated Bar Harbor (q.v.).

Frenchtown, Md., in the War of 1812. As part of the British operations on Chesapeake Bay in 1813, Sir George Cockburn was sent to close its head. Establishing himself first at the mouth of the Susquehanna, then on Elk River, on 28 April he sent 150 marines to destroy the stores at Frenchtown, a small village much used in the land transport between Baltimore and Philadelphia since the closure of the Bay. They drove off the Americans, and burned the stores and five vessels lying near.

Frenchtown, Mich., a township in Monroe County; 22 miles southwest of Detroit. In this vicinity 14 Jan. 1813 an American force of 650 defeated 500 British and Indians. On 20 Jan. the American forces were defeated and taken prisoners. On the 23d the wounded were massacred in what is known as "the massacre of the River Raisin." See WAR OF 1812, THE.

Freneau, Philip, American poet: b. New York 2 Jan. 1752; d. near Freehold, N. J., 18 Dec. 1832. Graduated from Princeton in 1771, he was captured in 1780, during a voyage to the West Indies, by an English cruiser, and his experiences while under detention he later recorded in 'The British Prison-Ship.' Having regained his liberty, he wrote much for the 'Freeman's Journal' of Philadelphia. In 1790 he became editor of the *Daily Advertiser* (New York), and in 1791 of the *National Gazette* (Philadelphia). After an interval at sea he permanently settled in New Jersey. Freneau was the first national poet of America, and a lyrist of real though uneven gifts. His elegy, 'The Battle of Eutaw Springs,' was praised by Scott, who called it "as fine a thing of the kind as there is in the language." During the Revolution he was active in satirical verse. His work attests his extensive culture; and though it conforms in the main to the conventions of the 18th century, it does not lack distinction. He wrote also several volumes of prose, published under the pseudonym "Robert Slender" and of small merit. Until recently his poetry has been strangely neglected; but in 1901 appeared a biography by Austin, and in 1903 an edition of the poems, with a 'Life,' prepared by F. L. Pattee. During Freneau's life there were editions in 1786, 1788, 1809, and 1815. There were reprints of the 1786 edition in 1861 and 1865. Consult further: Tyler, 'Literary History of the American Revolution' (1897); and Wendell, 'Literary History of America' (1900).

Frère, Charles Théodore, shärl tā-ō-dōr frār, French painter: b. Paris 24 June 1815; d. there 25 March 1888. He was a pupil of Cogniet and Roquelan, and made his first exhibit in 1834. He was present at the fall of Constantine, Algeria, in 1837, and from that time chose scenes from eastern life. His pictures illustrating Constantine (1840–8) are among the best he painted.

Frere, frēr, SIR **Henry Bartle Edward,** English statesman and administrator: b. Clydach, Brecknockshire, Wales, 29 March 1815; d. Wimbledon, Surrey, 29 May 1884. He was educated at Haileybury College; entered the East India Company's Civil Service in 1833; introduced improvements into the system of tax collection, and distinguished himself as an administrator. At the outbreak of the Mutiny in 1857 he promptly seized the fortress of Multan, retained command over his own province, and was enabled to assist the neighboring provinces. In 1862 he became governor of Bombay, and in 1867 he was knighted. In 1872, as British commissioner, he negotiated a treaty with the sultan of Zanzibar abolishing the traffic in slaves. In

1877 he was appointed governor of the Cape, and high commissioner in South Africa to settle native and colonial affairs, but the war which he provoked with the Zulus gave so much dissatisfaction to the government that in 1880 he was recalled. See 'Life,' by J. Martineau (1895).

Frere, John Hookham, English poet, translator, and diplomatist: b. London 21 May 1769; d. Malta 7 Jan. 1846. After a career in the diplomatic service, he produced his original 'Prospectus and Specimen of an Intended National Work . . . Relating to King Arthur and His Round Table' (1817), better known as 'The Monks and the Giants'; a literary burlesque, full of charming verse and of excellent character-drawing. It naturalized in English the *ottava rima* afterward used by Byron in 'Beppo' and 'Don Juan.' A version of a large part of Aristophanes succeeded this effort.

Frère, Pierre Edouard, pē-ăr ā-doo-ăr frăr, brother of Charles Théodore Frère (q.v.), French painter: b. Paris 10 Jan. 1819; d. Anvers-sur-Oise June 1886. He studied under Paul Delaroche, and chose sentimental genre as his specialty; many of his delineations of home- and child-life are full of true and simple feeling and have been frequently reproduced. In technique he was remarkable as a colorist, and his 'Little Gourmand'; 'Curiosity'; 'Repose'; 'The Little Cook'; 'First Steps'; 'Going to School' have long been favorites in the print-shop windows.

Fresco, in art, a term applied, originally by the Italian artists, to pictures executed in water-colors upon a freshly-plastered wall. Mineral or earthy pigments are employed which resist the chemical action of lime, and in drying the colors become permanent. On the revival of the arts in Europe it became customary to decorate the walls of churches, palaces, cloisters, and convents with fresco paintings. The Romans found plaster paintings on brick walls at Sparta, cut them out, packed them in wooden cases, and transported them to Rome. Fresco painting was first made of real importance by the Italians in the 16th century. It is a very common error in this country with antiquarians and writers in general to term the ancient paintings frequently found on church walls, etc., frescos; but there is scarcely an instance of a genuine fresco among them. They are distemper paintings on plaster, and quite distinct in their style, durability, and mode of manipulation. The art is very ancient and widely spread, frescos of early date being found in India, Egypt, Mexico, etc., as also in Pompeii and other places. The example of Michelangelo and Raphael shows how worthy it is of the greatest artists. The painter cannot seduce the senses by soft tints and tender harmony of colors; he is, therefore, reduced to depend solely on form, character, expression.

The methods employed in painting frescos is described as follows in a treatise upon painting by the monk known as Theophilus, a work certainly written before the close of the 12th century: "When figures or other objects are drawn on a dry wall, the surface should be first sprinkled with water till it is quite moist. While the wall is in this state, the colors are to be applied, all the tints being mixed with lime, and drying as the wall dries, in order that they may adhere." The method is still in general use in Italy and in Munich, for the production of both exterior and interior decoration. In modern practice lime and fine sand are used for the final coating of plaster, which is allowed to dry thoroughly, and then smoothed by the application of pumice-stone. On the evening before the painter is to begin his work the surface is thoroughly damped with water in which a little lime has been dissolved, and the process is again repeated next morning. The colors are the same as those used in true fresco-painting, which we next describe; but *fresco secco* possesses this advantage over true fresco, that the artist can leave his work at any point, and, having simply redamped the wall, again resume it. The *secco* process is excellently adapted for rough decorative work, and is as durable as true fresco; but it is less suited for delicate and refined artistic productions.

Fresco-painting was accordingly the chosen method by which the greatest Italian masters expressed, upon the walls of cathedral and council-room, their deepest conceptions of religion and polity. Giotto employed it in the Arena Chapel of Padua and the Church of St. Francis at Assisi; Orcagna in the Church of Sta. Maria Novella; Fra Angelico in the Convent of St. Mark; Masaccio in the Brancacci Chapel of the Carmine, Gozzoli in the Riccardi Chapel, at Florence; Perugino in the Sala del Cambio of his native city; Luini in the churches of Milan, Lugano, and Saronno; Pinturicchio in the cathedral library of Siena; Correggio in the Cathedral of Parma; Raphael in the Vatican; and when Michelangelo was directed by Pope Paul III. to paint his 'Last Judgment' in the Sistine Chapel in oils, instead of in fresco as at first agreed on, he protested that oil-painting was an art for women and indolent persons, that fresco was the art for men and painters, and was allowed to have his way. The celebrated 'Last Supper' of Leonardo at Milan is a mural painting in oils, not fresco; and the method used, combined with the fact that the production of the work extended over a period of years, and that the faulty masonry of the wall afforded insufficient protection against damp, accounts for the ruined state in which the subject now exists.

Germany has produced the most distinguished fresco painters in modern times, and Cornelius has established his fame by his grand fresco pictures in the Glyptotheca in Munich. Schnorr is also distinguished in this line, and the Villa Massimi, near Rome, is a fine monument of contemporary German art, as Overbeck, Schnorr, and Feith painted the three rooms in fresco. Fresco painting was long disregarded, when all noble and grand conceptions seemed to have fled from the art; and it is only in recent times that it has been taken up again, chiefly by the Germans. Several works of this kind have been executed in the British Houses of Parliament. See ART; MURAL DECORATION; PAINTING.

Frescos, Boscoreale. See METROPOLITAN MUSEUM OF ART.

Fresh-air Work, a form of benevolence or helpfulness; in this particular the taking of poor children from the tenements and slums of large cities to the country or seashore for recreation. It is said to have originated in 1849, when William A. Muhlenberg of New York sent a large number of poor children and invalids to the country for short vacations. The first general fresh-air societies were organized in

1874, and since then a number of newpapers have inaugurated fresh-air funds. There are now societies in 38 cities and 14 fresh-air organizations in New York. In Europe, Switzerland was the first to take up the movement in 1876. In 1895 there were 73 fresh-air colonies in that country. Nearly all European countries and Argentina in South America have taken up the work. Consult, 'Fresh Air Charity in the United States' (1897).

Fresh-water Insects. Insects are essentially creatures of the air and the land; yet a considerable number pass the whole or the greater part of their lives in rivers, lakes, and ponds. Among insects aquatic in all stages we can distinguish between those which glide or skate over the surface of the water, diving not at all, or only exceptionally, and those which habitually dive and swim through the water after the manner of fishes. The most typical of the surface-dwellers are the bugs of the family Hydrometridæ. See POND-SKATERS.

Among the Coleoptera the whirligig beetles (*Gyrinidæ*) frequent the surface of ponds and brooks where they may be seen in small companies, performing a whirling, mazy dance over the surface-film. These insects, when they dive, carry down with them a small air-bubble; enclosed in a film between the tip of the wing-covers to the hinder end of the abdomen. They are not, like the pond-skaters, completely enveloped in air while under water. The beetles of a nearly related family (*Dyticidæ*), well called "diving-beetles," belong to the group of insects which live habitually submerged. Their contours are admirably adapted for motion through the water, but there is no dense hairy covering to ensure the formation of an air-bubble and the breathing is provided for in quite another way. The abdominal spiracles open on the upper surface of the segments, which are completely covered by the wing-cases when the wings are shut. The wing-cases being convex and the upper surface of the abdomen depressed, a considerable amount of air is enclosed, allowing the insect to remain submerged for some time.

Another mode of adaptation to life in the water is shown by the water-scorpions (*Nepidæ*). They are provided with a pair of long-grooved appendages at the tail-end of the body; these can be closely pressed together and form a tube, the tip of which pierces the surface-film and conveys a supply of air to the spiracles. These insects, like the allied "water-boatmen" (*Notonectidæ*), have well-developed wings, and make excursions by night to new watery dwelling-places.

Many insects lead an aquatic life only during their larval stage. Naturally enough, however, such insects when adult are to be found flying chiefly in the neighborhood of water in which they will lay their eggs — the May-flies and midges for example. The contrast between the conditions of the larval and the imaginal life in such cases is most striking, and can only have been brought about by slow degrees. A certain amount of moisture in the earth is necessary to the well-being of many burrowing larvæ, while some are found in semi-liquid mud, in decaying refuse, or in animal excrement. In such surroundings breathing through the lateral spiracles becomes impossible, and we find that access to the air-tubes takes place only by one or two pairs of spiracles near the head or tail-end of the body, sometimes opening through "respiratory trumpets" whose expanded mouths can be thrust out of the clogging surroundings of the mud or refuse into the fresh air, while the grub remains concealed and continues to feed. A similar suppression of most of the spiracles, with the development of a tubular process at the tail end of the body in connection with the tracheal system, is the adaptation by which many aquatic larvæ breathe — for example, the grub of the mosquito. The families of insects nearly related to these have larvæ which live in mud and damp earth, and this suggests that it was from the shores that the waters were invaded by these insect-hosts.

But there is another division of aquatic larvæ still more perfectly adapted to life in the water. The grub of the gnat or the drone-fly needs to rise to the surface at intervals and pierce the film with its air-tube in order to get a fresh supply of oxygen. But the pupa of the sand-midge, with its tubular gill-filaments, or the larva of a May-fly with its tracheal gill-plates, can remain in the water throughout its life, drawing, as do the fishes, sufficient oxygen from the dissolved air. It is interesting to notice that within the limits of a single and restricted order — the dragon-flies — we find some larvæ breathing by means of tracheal gill-plates, and others taking supplies of water into the hind-gut over whose walls run branching air-tubes; while in the final nymph stage the thoracic spiracles are open, and the insect raising the front part of its body above the surface, breathes through them after the manner of an imago. These various adaptations to an aquatic life within a single group indicate clearly that the habit of living in water is not primitive among insects, but that it has become acquired by different races at different times in the course of the development. It may be presumed that larvæ with the more perfect adaptations for breathing when submerged — leaf-like or thread-like gills — are older inhabitants of the water than those which have to rise periodically to the surface to take in a supply of air.

Fresh-water Mussels, bivalved mollusks that dwell in lakes and rivers; river-mussels, or river-clams. They belong to the family *Unionidæ,* allied to the cockles, which has a large and thick foot, no byssus, siphon short (when present), and a parasitic embryonic growth. The shells are equivalve, varying according from thin and smooth to very thick, rugose and knobbed; the hinge variable (in *Anodonta* having no hinge-teeth); and the interior always thickly nacreous, making it useful in the arts as "mother of pearl," and often producing fine pearls. The family is world-wide in its distribution and includes about a dozen genera, two of which (*Unio* and *Anodonta*) occur in most parts of the world. These mollusks dwell in rivers and ponds, and vary greatly according to the character of their home, whereby a great number of supposed species have been named that are now known to be merely varieties of the same stock resulting from different environment. They stand upright in the sand on the blades of the shell, so that the heavy hinge margin receives any blow from drifting stones, or other harm; and slowly move about, sucking in the minute animal and vegetable organisms upon which they feed. (See PELECYPODA.) The development of their young is most unusual. The eggs when ejected from the ovaries are caught in the gills of the mother and are sustained by a nutritive mucuslike secretion, until they reach a certain degree of age, when they become "glochidia."

They then have a larval shell, provided with strong hooks, and possess a long filament. After a period they are expelled through the exhalent siphon into the water, and this ejection may be timed to the passing of a small fish, to whose body if they touch it the glochidia at once cling by means of the hooks. Should they miss striking against a fish when thrown out the embryos sink and lie upon the bottom with their shells gaping and the filament floating upward. There they remain until a "host" comes within reach; but this must soon happen or they will perish. The glochidia of *Unio* usually become attached to the gills; those of *Anodonta* to the skin or the fins. In this position they become overgrown by the skin or mucous membrane of their host, and are nourished by his juices. This goes on for about 10 weeks, during which time the glochidium has been metamorphosed into a young normal mussel, drops off and begins the ordinary course of life. Their life is probably long.

Mussels abound in all the rivers of the United States and were extremely numerous and varied in those of the Mississippi; and they entered very largely into the fare of the native red men, as is attested by the large refuse-heaps of their shells to be found in all the river courses. It was long ago discovered, however, that these shells yielded pearls of great beauty and price (see PEARL), while the mother-of-pearl of many species was marketable for the manufacture of buttons and similar articles. The result has been a serious depletion of the mussels of many parts of the Middle West, and nearly an extinction of some species.

Fresnel, frā-nĕl, **Augustin Jean**, French physicist: b. Broglie, France, 10 May 1788; d. Ville d'Avray, near Paris, 14 July 1827. He was educated at the Ecole Polytechnique, and early devoted himself to the practice of civil engineering. In 1815 he became distinguished as the discoverer of the polarization of light, and in 1823 was elected a member of the Academy. He made important researches respecting the wave theory of light. The result of his great discovery is shown in the system of lens lighting apparatus, which has changed the mode of lighthouse illumination over the whole world, and is universally known as the "Fresnel system." In 1825 Fresnel was elected F. R. S. of London, and in 1827 received the Rumford medal of the society.

Fresnel's Surface. See LIGHT.

Fresnillo, frĕs-nēl'yō, Mexico, a city in the State of Zacatecas. It has a spacious square, with a costly fountain in the centre, and contains several large churches. In its vicinity are the celebrated mines of Fresnillo, reckoned among the most productive in Mexico. Pop. 13,000.

Fresno, Cal., a city and county-seat of Fresno County, situated on the San Francisco & S. J. V., the Southern P., and Atchison, T. & S. F. R.R.'s. The city is an important fruit-growing centre, the raisin trade alone being valued at $3,000,000 annually. Other important industries are the cultivation and exporting of oranges, grapes, and olives, besides a large live-stock trade.

Fresno was settled in 1872, became the county-seat in 1874, and received a charter as a city in 1885. The government is controlled by a mayor, chosen every four years, a municipal council, and other administrative officials. The assessed property valuation is about $6,000,000. Pop. (1900) 12,470.

Freund, froint, **Herman Ernst**, Danish sculptor: b. Uthlede 15 Oct. 1786; d. 30 June 1840. At first a blacksmith, he studied at the Copenhagen Academy of Fine Arts, won the Academy's large gold medal with allowance for foreign study, and resided in Rome, where he was greatly assisted in artistic progress by Thorwaldsen and executed his 'Mercury' and 'Luke.' His conspicuous successes were produced in the domain of Norse mythology, to which field belongs his Ragnarök frieze, done in 1827 for the Christianborg Palace, where it was nearly destroyed by fire in 1884, and later restored by Ginding. Further works by him are 'Eurydice,' 'Thor,' and 'Mimer and Bolder Consulting the Norns.' See Life by Victor Freund (1883).

Frey, frī, **Albert Romer**, American author: b. N. Y. 17 Feb. 1858. He is secretary of the Shakespeare Society of New York and has written in refutation of Ignatius Donnelly's 'cipher' theory of Shakespearian authorship. Among his other writings are 'William Shakespeare and alleged Spanish Prototypes' (1885); 'Soubriquets and Nicknames' (1887).

Frey, Emil, Swiss president: b. Arlesheim, near Basel, 24 Oct. 1838. While in the United States in 1861 he enlisted as a sergeant in the Federal army, was taken captive at Gettysburg and confined in Libby prison. He returned to Switzerland in 1865, there becoming prominent as a journalist, and was minister from Switzerland to the United States 1882–7. He was elected president of the Swiss Confederation 14 Dec. 1893. He is a noted advocate of educational progress and reform and has been prominent in the furtherance of public works and of army improvement.

Frey, Heinrich, German anatomist and zoologist: b. Frankfort-on-the-Main 15 June 1822; d. Zürich 17 Jan. 1890. He began his studies at Bonn in 1840, and continued them up to 1845 at Berlin and Göttingen, when he took the degree of Doctor in medicine and at the last named university became assistant professor of physiology. In 1848 he was appointed professor of histology and comparative anatomy at Zürich. He was considered one of the first microlepidopterologists of Germany. The range of his published works is wide. He wrote a 'Text-Book of Zootomy' (1847); 'An Introduction to the Study of Invertebrates' (1847); several works on histology, a book on the microscope, and an elaborate account of the lepidoptera of Switzerland.

Freyberg, frī'berg, **Konrad**, German painter: b. Stettin 14 May 1842. He studied at the Art Academy of Berlin and entered the studio of Steffecks, applying himself to the delineation of military subjects, especially cavalry scenes. His canvases are small, but his portraits of the mounted troops are finished and elegant. He has painted in this style many of the principal figures in the Franco-Prussian War. Among his works may be mentioned 'Prince Karl of Prussia with his Staff' (1872); 'Group of Officers of the Guard' (1875); 'Royal Hunt at Letzlingen' (1881); 'Prince Frederick of Hohenzollern at the head of the Second Regiment of Dragoon Guards' (1885).

Freyburg. See FREIBURG.

Freycinet, Charles Louis de Saulces de, shärl loo-ē dė soos dė frā-sē-nā, French statesman: b. Foix (Ariège) 14 Nov. 1828. He was trained as an engineer, and held several important appointments, being associated with Gambetta in the war department in 1871. He was elected to the senate in 1876, and became minister of public works in the following year. He was minister of foreign affairs and president of the council 1879-80, and these posts he held on several subsequent occasions. In 1888 he became minister for war, and continued to hold that office for five years, during two of which (1890-2) he was also premier. In 1893 he had to resign owing to the Panama scandals. As head of the war department he did much to strengthen and develop the French army. He is the author of several important works on engineering and sanitation, and of 'La Guerre en Province pendant le Siège de Paris' (1871). In 1890 he was elected to the French Academy.

Freytag, Gustav, goos'täf frī'täg, German author: b. Kreuzburg, Prussia, 13 July 1816; d. Wiesbaden 30 April 1895. His first dramatic composition was 'The Bridal Tour,' a comedy (1844); it was followed by a little one-act tragedy, 'The Savant' (1844), and by a small volume of poems, 'In Breslau' (1845); after which he produced 'The Valentine' (1846); 'Count Valdemar' (1847), and 'The Journalist' (1853). Among his works outside of the drama may be mentioned his great novel of social life, 'Debit and Credit' (1855; 40th ed. 1893); 'Pictures from the German Past' (1859); 'The Lost MS.' (1864; 23d ed. 1893); 'Die Ahnen' ('Ancestors'), a cycle of six stories portraying the German civilization from the beginning of historic times; and 'Charlemagne' (1894).

Fri'ar, from the French *frère,* Latin *frater,* signifying brother, is a name common to the male members of any religious order. Thus the Capuchins were originally called Friars Hermits Minor, and the Observants Friars Observants. The term, however, is more exclusively applied to those of the mendicant orders; of which the four chief were the Dominicans (Black Friars), Franciscans (Gray), Carmelites (White), and Augustinians.

Friar-bird, a familiar woodland bird of Australia, of moderate size, with brownish-drab plumage, head and neck bare of feathers and a cowl-like neck-ruff. It is an aberrant form of honey-eater (*Meliphagidæ*), some 16 species, all of the Malayan and Australian regions are grouped in the genus *Philemon,* of which the present species is named *P. corniculatus,* in reference to a horny excrescence upon the base of the culmen of the beak. Its loud cries and other peculiarities have given it many local names, such as 'monk,' 'leatherhead,' 'poor soldier,' 'pimlico,' and 'four o'clock.'

Fribourg, or **Freiburg,** Switzerland, a town picturesquely situated on the Saane, which is here crossed by a magnificent suspension bridge, 905 feet long. It is partly surrounded with walls and towers, and among the chief buildings are the Church of St. Nicholas, a handsome Gothic structure, with a spire 240 feet high, and one of the finest organs in Europe; a town-house with a lime-tree near it, which was planted in 1476, on the day of the battle of Morat (Murten), the cantonal university, founded in 1889, and a Jesuit college. A gorge close to the town is crossed by a second suspension bridge, 689 feet in length and 317 feet high. Pop. (1900) 15,794.

Frick, Henry Clay, American manufacturer: b. West Overton, Pa., 19 Dec. 1849. He began commercial life in a small coke business, which grew to be the largest in the country, and is now president of the H. C. Frick Coke Co. He was prominent as instrumental in putting an end to the Homestead Strike (1892) and has been president of the Carnegie Steel Co.

Friction, the resistance which opposes the sliding or slipping of one body relatively to another body with which it is in contact. It is doubtless chiefly due to the minute irregularities that exist upon the surfaces in contact, the motion being opposed by the interlocking of these irregularities. Two kinds of friction may be recognized: (1) "Static friction," between bodies that are relatively at rest, and (2) "Kinetic friction," between bodies that are actually slipping over each other. Static friction is measured by the force that is required to just cause one body to move upon the other, when the two are pressed together by a certain definite pressure; and the ratio of this force to the pressure with which the bodies are held in contact is called the "coefficient of statical friction." Kinetic friction is measured by the force that is required to maintain one of the bodies that are in contact, in a state of uniform motion with respect to the other one; and the ratio of this force to the force with which the bodies are pressed together is called the "coefficient of kinetic friction." The coefficient of static friction between two given substances may be determined by causing a weight composed of one of the substances to rest upon a smooth plane composed of the other substance. If the plane is nearly horizontal, the weight will not slip upon it; but by increasing the angle of inclination, a position will be found for the plane, such that the weight is just on the point of sliding. The angle that the plane then makes with the horizontal is called the "angle of repose" of the pair of substances of which the plane and the weight are composed; and it may be shown by the elementary principles of mechanics that the coefficient of statical friction for these substances is numerically equal to the natural tangent of the angle of repose. Following are a few coefficients of statical friction, as given by Rankine: Wood upon wood, dry, 0.25 to 0.50; leather on metals, dry, 0.56; leather on metals, greasy, 0.23; metals on metals, dry, 0.15 to 0.20. Rennie found somewhat larger values for the coefficient between metals. Thus for statical friction between dry surfaces, he found: Steel on cast iron, 0.33 for ordinary loads; and for similar loads he found 0.22 for brass upon cast iron. Coefficients of kinetic friction are smaller than the coefficients of statical friction between the same substances, and all friction is greatly diminished by introducing oils or other lubricants between the rubbing surfaces. In kinetic friction between surfaces that are smooth and well lubricated, the results depend far more upon the nature of the lubricant than they do upon the nature of the rubbing surfaces; and they are also greatly dependent upon the method by which the lubricant is applied. When a journal is lubricated by means of a pad placed underneath it, the friction may be more than six times as great as when the same journal is run in a bath of the same oil. Speed also has a great influence upon the amount of friction developed. Morin's «laws of friction,» given in 1831, are as follows: (1) The coefficient of kinetic friction is independent of the pressure with which the rubbing surfaces are pressed together; (2) the coefficient of friction, and the total friction, are independent of the areas in contact, so long as the total pressure between the two rubbing bodies is constant; and (3) the coefficient of friction is independent of the velocity, although static friction is greater than kinetic friction. These laws, which are often given in text-books and elsewhere as reliable presentations of the known facts, are now known to be exceedingly imperfect. Morin gave them for ordinary conditions of shafting and journals, where no special care has been taken with the journals, and no artificial means have been provided for the free supply of oil. It is now certain that they cannot be assumed to apply under other conditions, and it has been pointed out that «there are many conditions under which they lead to the wildest kind of error.» The phenomena of friction are in reality quite complicated, and a thorough study of the subject is necessary before the friction that may be expected in any given case can be calculated with even a rough degree of approximation. Consult: Thurston, 'Friction and Lost Work'; Kent, 'Mechanical Engineer's Pocket-Book.'

«Rolling friction,» so called, is not true friction, in the sense in which the word has here been defined. It is due mainly to the fact that a wheel when rolling upon a smooth track or other surface, creates a slight depression by its weight, and is also slightly deformed itself at the same time. The energy which is absorbed in producing these slight deformations is in considerable measure dissipated as heat; but the retardation of the moving body from this cause is seldom comparable with that due to sliding friction. For the internal friction of fluids, see VISCOSITY.

Friday, the sixth day of the week, so named from the Anglo-Saxon *Frigedag,* the day of Friga, the wife of Odin and the Teutonic goddess of love. The Anglo-Saxon is a translation of the Lat. *Veneris dies,* day of Venus, whence the French *Vendredi,* Friday. Its religious associations are varied. According to the Mohammedans it was the day when Adam was created, entered Paradise, was expelled therefrom, the day of his repentance, of his death, and is to be the day of resurrection. It is the Moslem «day of assembly» or sabbath. As the day of Christ's crucifixion it is generally observed in the Greek, Latin, and other Christian episcopal churches as a fast day, and is especially observed on Good Friday (q.v.). From the same cause, also, it is regarded among the superstitious as an unlucky day, and was long associated in the public mind with the execution of criminals sentenced to death, which usually took place on Friday and was commonly called hangman's day.

Friedel, frē'dĕl, **Charles,** French chemist: b. Strasburg 1832; d. 1899. He studied under Pasteur in his native town and continued his scientific education at Paris, entering the laboratory of Wurtz. In 1869 he was graduated with two remarkable theses and in 1876 became professor of mineralogy in the Sorbonne. He eventually succeeded Wurtz (1884) as professor of organic chemistry and director of the research laboratory in the Sorbonne, a position he maintained till his death. His researches are record by him in 254 original memoirs and entitle him to a place among the foremost scientific men of the 19th century. His name is especially connected in association with James Mason Crafts (q.v.) with the synthetic method known as the 'Friedel and Crafts reaction' (q.v.). He published, in addition to text-books on mineralogy and crystallography, 'Cours de Chimie Organique Professé a la Faculté des Sciences de Paris' (1887).

Friedel and Craft's Reaction, in chemistry, a synthetic method discovered by the French chemist, Charles Friedel, in conjunction with James Mason Craft. This discovery revealed the action of various chlorinated compounds on hydrocarbons in the presence of aluminum chloride. A vast number of varying organic compounds may thus be produced in any ordinary quantity, for example, triphenyl methane is a commercial compound, necessary to the production of valuable dyes; by Friedel and Craft's Reaction process it can be produced rapidly and cheaply in any quantity required.

Fried'elite, an acid silicate of manganese, containing some chlorine, and crystallizing in the rhombohedral system, but also occurring massive. It is rose-red in color, and is found in a manganese mine at Aderville, France.

Friedericia, frē-dā-rē'sē-ä, **Julius Albert,** Danish historian: b. Copenhagen 1849. He became assistant librarian of the library of the University of Copenhagen in 1891. He has published 'Danmarks ydre politiske Historie i Tiden fra Freden i Lybek til Freden i Brömsebro' (1876–81); 'Adelsvoeldens sidste Dage Danmarks Historie fra Christians IV.'s Dod til Enevoeldens Indforelse' (1894).

Friedland, frēd'länt, **Valentin,** surnamed Trotzendorf, German educator: b. Trotzendorf, Upper Lusatia, Germany, 14 Feb. 1490; d. Liegnitz, 26 April 1556. He became a teacher at Görlitz in 1515. He was for many years at the head of the gymnasium in Goldberg where the students, at times over 1,000 in number, were organized like a Roman republic, with senate, consuls, censors, and the like, with Friedland as perpetual dictator. See Pinzger, 'Valentin Friedland, gennant Trotzendorf' (1825); Lösche, 'Valentin Trotzendorf' (1856).

Friedland, Prussia, a small town 28 miles southeast of Königsberg, on the river Alle. The Russians under Benningsen were here defeated on 14 June 1807 by the French under Napoleon (q.v.) Pop. (1900) 2,824.

Friedländer, Friedrich, frēd'rĭн frēd'lĕn-dėr, Austrian painter: b. Kohljanowitz, Bohemia, 10 Jan. 1825; d. 1901. Among his works, which are confined to historical or genre themes are 'The Death of Tasso' (1852); 'The War Veterans' (1875); 'News' (1883); 'Distribution of Wine' (1884).

Friedländer, Ludwig, lood'vĭg, German classical scholar: b. Königsberg, Prussia, 24 July 1824. His most representative work is 'Typical Studies in the History of Roman Manners and Morals' (6th ed. 1889), written in popular style. 'The Remains of Nicanor's Emendations of the Punctuation of the Iliad' (1850), and like theses, constitute him an authority in Homeric criticism.

Friedman, frēd'man, **Isaac Kahn**, American journalist and novelist: b. Chicago, Ill., 3 Nov. 1870. He was graduated from the University of Michigan in 1893 and has since been engaged in newspaper work in Chicago. He has published 'The Lucky Number,' a collection of short stories of the Chicago slums (1896); 'Poor People,' a novel (1900).

Friedmann, frēd'män, **Alfred**, German poet and novelist: b. Frankfort-on-the-Main, Prussia, 26 Oct. 1845. Among his poems are: 'Merlin,' 'Orpheus' (1874), two ballads; 'Biblical Stars' (1875), comprising three idylls; 'Love's Fire Test, Angioletta'; 'Lays of the Heart' (1888). He is the author of many novels, including: 'Two Marriages'; 'Suddenly Rich' (1891); 'The Wild Rose' (1893).

Friedrich, Johannes, frēd'rĭн yō-hän'nĕs, German Old Catholic theologian: b. Poxdorf, Bavaria, 5 May 1836. After studying at the universities of Bamberg and Munich he entered the Roman Catholic priesthood in 1859. In 1865 he became professor of theology in the University of Munich. At the Vatican Council, 1869–70, he united with his colleague Döllinger (q.v.) in opposing the dogma of papal infallibility, and when acceptance of the dogma was demanded by the archbishop of Munich of the faculty of the Munich University, he with Döllinger declined and was excommunicated. In 1882, however, he was given another professorship, and in 1882 was transferred to the philosophical faculty. He was one of the leaders in founding the Old Catholic Church, but withdrew from active leadership in 1878 when the Old Catholic Synod voted to allow its priests to marry. Among his many writings are 'Tagebuch während des vaticanischen Concils' (1871); 'Zur Verteidigung meines Tagebuchs' (1872); 'Geschichte des Vaticanischen Concils' (1877–87), and 'Life of Döllinger' (1899–1901).

Friedrich, John, American violin-maker: b. Cassel, Germany, 1858. Having studied violin making under Oswald Möckel, he came to the United States in 1883, and shortly took prominent rank in his calling. In 1893 he obtained the highest award for violins, violas, and violoncellos at the World's Columbian Exposition. He has also made bows of very excellent workmanship, and came to be recognized as an expert in identifying and appraising rare specimens.

Friedrich, Kaspar David, German painter: b. Greifswald 5 Sept. 1774; d. Dresden 7 May 1840. He obtained his training in the Copenhagen Academy of Fine Arts, and in 1795 settled at Dresden, where he became member and professor of the Academy. He excelled in depicting nature as seen through the psychologic medium of transitory human moods. Favorite motifs are the gloom of the forest, night scenes with moonlight, or storms at sea. The Castle of Berlin contains two fine examples: 'Abbey in an Oak Forest on a Winter's Evening,' and 'Pilgrim on the Shore.'

Friedrich, Woldemar, vŏl'dė-mär, German painter: b. Gnadau, Saxony, 20 Aug. 1846. He accompanied the German troops in the Franco-German War, and thence gained material for his illustrations in Daheim and in Hiltl's 'Der französische Krieg von 1870–71' (6th ed. 1891). In 1881 he became professor in the art school at Weimar and in 1885 in the Berlin Academy. He executed decorative paintings in Castle Hummelshain, Weimar; the Weimar gymnasium; and the booksellers' exchange at Leipsic. He also painted a series of aquarelles and numerous genre-works in oils.

Friedrichs, frēd'rĭнs, **Hermann**, German author: b. St. Goar, on the Rhine, Germany, 14 June 1854. He distinguished himself in periodical journalism, and also wrote: 'The Revenge of the Bayadere' (1880), a lyric; 'Love Ordeals' (1888), a volume of stories; and 'Forms and Passions' (1889), a book of poems.

Friendly Islands. See Tonga.

Friendly Societies in America. See Fraternal Societies in America.

Friendly Sons of Saint Patrick, Philadelphia, Pa., organized in 1790 as the Hibernian Society. The first president was Hon. Thomas McKean, a signer of the Declaration of Independence. Among other prominent members of the society have been Gen. Walter Stewart, Commodore John Barry, Gen. Edward Hand, Col. Francis Nichols, Col. Thomas Proctor, Hon. Thomas Fitz Simons, and Gen. Andrew Jackson. The organization still exists, has a membership of over 600, and has in its treasury $75,000 or $80,000. In December 1897 the name Hibernian Society was dropped and that of the Friendly Sons of Saint Patrick adopted. The latter name had been borne by a Philadelphia society which was organized in 1771 and went out of existence sometime after 1805.

Friendly Sons of Saint Patrick, Society of the, New York city; founded in 1784. To-day, as at all times during its long existence, it numbers in its membership a great many of the most eminent merchants and professional men of New York. Among its presidents have been Hon. Richard O'Gorman, Chief Justice Charles P. Daly, Hon. James T. Brady, Eugene Kelly, Hon. Hugh J. Hastings, Joseph J. O'Donohue, David McClure, Samuel Sloan, John D. Crimmins, Hon. Morgan J. O'Brien, Hon. James A. O'Gorman, and Hon. James Fitzgerald. There are no creed or political tests for membership in the organization.

Friends, The Religious Society of. The Religious Society of Friends, commonly called Quakers, had its origin in England about the middle of the 17th century, and was largely the result of the ministry of George Fox, who is often called its founder.

Early History.— George Fox, the son of a weaver, was born at Drayton, in Leicestershire, 1624, and began his public preaching about the year 1648. His spiritual views and practical application of Christian doctrines met a ready response in many pious persons (both Churchmen and Dissenters), and bitter opposition from others whose practices they condemned. His followers increased rapidly, and were known as "Children of Light," "Children of Truth," and "Friends of Truth"; finally adopting the name "Religious Society of Friends." Among them were many itinerant preachers; Fox in his journal (1654) says, above 60 in number. From the first imprisonment of Fox in 1649 to 1687 Friends were the objects of almost continuous persecution. In 1656 Fox computed there were seldom less than 1,000 in prison. Between the years 1661 and 1697, over 13,000 Friends were imprisoned in England, 198 were transported as slaves, and 338 died in prison or of wounds received in assaults while attending meetings. These persecutions were upon various pretexts, as, the refusal to pay tithes, to swear, or to remove the hat; for preaching in public places; as disturbers of public worship, for speaking in "churches" (a practice then not uncommon); and as Sabbath breakers, for traveling to their meetings on the day called the Sabbath. Many were apprehended for keeping an unlawful assembly under the Conventicle Act. Scotland, Ireland, the Continent, and America were early visited by their ministers.

The first to arrive in New England were two women, Ann Austin and Mary Fisher, who came to Massachusetts from Barbadoes in 1656. After five weeks' imprisonment and much cruel treatment they were sent back. Stringent laws were promptly enacted by that colony to prevent others from coming and owners of vessels from bringing them. Regardless of the cruel penalties of these laws, the Quakers continued to arrive and suffer their infliction. In numerous instances delicate women were "stripped naked from the middle up, tied to a cart's tail and whipped through the town" and thence through other towns. Four — one a woman — were hanged on Boston Common. Nevertheless they increased in numbers and spread to adjoining colonies.

The first Friends in New Jersey settled along the Raritan River in 1663. In 1677 over 200 came to this province and founded Burlington. William Penn joined the society in 1667. In 1681 he and several other Friends purchased East New Jersey, and in the same year Penn obtained from the crown the grant of Pennsylvania. A few Friends were in the province before Penn acquired it, and two shiploads came in the fall of 1681. The next year Penn himself came with others, and in less than three years the colony had a population of 7,000. For a period of 70 years, and so long as the influence of Friends predominated, there were no conflicts with the Indians. At an early date the society cleared itself of human slavery. Friends began to protest against it as early as 1688, and for nearly 100 years the agitation was continued, until "in the year 1787 there was not a slave in the possession of an acknowledged Quaker." This was largely due to the labors of John Woolman, a minister in New Jersey, whose journal has a literary reputation.

Organization and Discipline.— Fox and his co-laborers did not have an outward organization as an object. The organization and discipline were progressively developed. The first disciplinary meetings established were held monthly and were in a sense congregational. Some were held as early as 1656, but the practice does not appear to have become general before 1666. The first yearly meeting appears to have been held in 1656, the first in London in 1668, but it was not held there regularly until 1672. The first yearly meeting in America was held in Rhode Island in 1661. Monthly, quarterly and yearly meetings have geographical boundaries: and monthly meetings are subordinate to quarterly, and these to the yearly meeting, which is the source of discipline, and final judge of all questions. At stated periods monthly meetings appoint a few of their number as "Overseers," whose duty it is to have a loving oversight of the members. Men and women hold separate meetings for business, although some subjects are jointly considered. Of late years the practice of separate meetings has largely been discontinued. Elders are men and women chosen out of the body as "Friends of solid judgment, prudence, and experience," to sit with the ministers and to advise, encourage or caution them as seems needful. Persons — men or women — who speak and pray in public to the satisfaction of the members are, in due time, publicly acknowledged as ministers, or those in whom the body recognizes the "true gift." Such recognition does not confer upon them any new powers or authority. All members are embraced in a set of "Queries" which are answered, some quarterly — others annually, by meetings for discipline. These have reference to love and unity; attendance upon meetings; consistency in speech, behavior, and apparel; oaths, military service and fraudulent business; moderation in trade and living, and just payment of debts; encouragement of a stated or paid ministry; care of the poor and education of children; and keeping records of births, deaths and marriages. (The answering of "Queries" has been discontinued in many meetings.) Meetings have no presiding officer. In those for business a clerk is appointed, whose duty is to gather and record the sense or judgment of the meeting as expressed. No question is settled by a majority and no vote is taken. Christ is recognized as "the head over all things to the church."

Distinguishing Views.— In the essential doctrines of the Christian religion Friends were in accord with their fellow Christians. The principal points in which they differed were:

1. Immediate Divine Revelation. Barclay ('Apology') says: "Nothing is less minded and more rejected by all sorts of Christians than immediate divine revelation; insomuch that once to lay claim to it is matter of reproach." Again, "He that affirms himself so led (by the spirit of God) is, by the pretended orthodox of this age, presently proclaimed an heretic." Fox (Journal) says: "I saw that Christ had died for all men, and had enlightened all men and women with his divine and saving light. I was commanded to turn people to that inward light, spirit and grace, by which all might know their salvation and their way to God." Friends believed that this inward saving light of Christ was universal and came to both heathen and Christian.

2. Worship and Ministry. Barclay ('Apology') says: "All true and acceptable worship to God is offered in the inward and immediate moving and drawing of his own spirit. All other worship, praises, prayers, and preachings, which man sets about in his own

will, at his own appointment, and can begin and end at his pleasure are but superstitious will-worship." Again, "As our worship consisteth not in words, so neither in silence as silence; but in an holy dependence of the mind upon God: from which dependence silence necessarily follows in the first place, until words can be brought forth which are from God's spirit." Hence silence is the basis of meetings for worship, which can be, and often are, held without a minister or any vocal service. Neither ministers, nor others, are supposed to break this silence without an immediate opening of a subject, and a sense that the Lord requires the delivery of the message revealed. No special training or educational qualifications are considered necessary for the ministry, and no consistent "Quaker" minister accepts pecuniary compensation for services in that capacity. Accepting literally the command of Christ to his apostles, "Freely ye have received, freely give," Friends refuse to pay tithes or in other ways to contribute to the support of a paid ministry.

3. Sacraments. Sacraments require the services of a priest or minister. Friends denied this necessity, rejecting all types and outward ordinances. They taught that the only saving baptism was that of the Holy Spirit, and that the true communion was not partaking of bread and wine, but the spiritual "eating of the flesh and drinking of the blood" of Christ. They held that marriage was the Lord's joining of man and woman, and therefore was not performed by man — men were but witnesses.

4. War, Oaths, etc. Friends have always maintained that war and oaths were inconsistent with Christianity, being forbidden by Christ and his apostles in the New Testament. Consistent members refuse to perform military service or partake in war-like preparations. They refuse oaths in civil courts or elsewhere as forbidden by Christ's language, "Swear not at all." In their early history they suffered much on this account. They decline the use of complimentary titles and language, believing they proceed from pride and tend to foster it. They refuse the complimentary use of the plural pronoun to a single person, although the "thou" and "thee" to judges and magistrates has often resulted in suffering. They use the numerical language of Scripture instead of the names of months and days in honor of heathen deities. Their plainness of dress is a testimony against pride, and any uniformity the result of a refusal to change its style at the dictates of fashion.

Present Condition and Membership.— With some unimportant exceptions the society maintained a practical unity until the year 1827. At that time a separation occurred in Philadelphia Yearly Meeting and later in others. Since then two distinct bodies have claimed the title "Religious Society of Friends," commonly distinguished by the names "Hicksite" and "Orthodox," although not recognized or officially used by either body. The name "Hicksite" came from Elias Hicks, a talented and popular minister of Long Island, whose ministry was the immediate cause of the schism. The Orthodox party hold that unsound doctrines caused the separations. The followers of Hicks, admitting differences in doctrines, contend that the real cause was not so much these differences, as an arbitrary exercise of authority by the Orthodox party. Quotations from Hicks establish the contention that the divinity of Jesus Christ, the doctrine of atonement, and the inspiration and authority of the Bible were denied or questioned. There were probably some grounds for the charge of an arbitrary spirit on the part of the Orthodox. In the separations, two thirds of Philadelphia and New York Yearly Meetings were of the "Hicksite" party, and in Baltimore four fifths; in Ohio they were about evenly divided, while in Indiana Hicks had comparatively few sympathizers. No separations occurred in New England or North Carolina meetings, they continuing to be identified with the Orthodox bodies, which were officially recognized by London Yearly Meeting.

There are (1903) seven yearly meetings of "Hicksite" Friends: Philadelphia, Baltimore, New York, Genesee (Canada), Ohio, Indiana, and Illinois, numbering about 21,000 members. They are connected by epistolary correspondence. Their principal schools are Swarthmore College, and the George School in Pennsylvania, Friends Central in Philadelphia, and similar schools in New York and Baltimore. 'The Friends Intelligencer,' an ably conducted weekly paper, is published in Philadelphia.

Several of the Orthodox yearly meetings have experienced separations. Joseph John Gurney of England, a wealthy and educated minister and voluminous writer, expressed views which many in England and America regarded as subversive of some always held by the society. Prominent among those in America who opposed his views was John Wilbur, a minister in New England. This resulted in a division in that Yearly Meeting in 1845, which was followed by one in Ohio in 1854. These, and later separations in others, resulted in two distinct bodies of Orthodox Friends within the limits of six yearly meetings, including Canada. They have been distinguished by the respective names, "Gurney" and "Wilbur," and the terms "Progressive" and "Conservative." In Ohio the "Conservative" body was the larger, and in each of the others the smaller. London gave its official recognition to the "Progressive" bodies. There are now 13 of these, connected with each other and with London and Dublin Yearly Meetings by correspondence: New England, New York, Canada, Baltimore, North Carolina, Ohio, Wilmington (Ohio), Western, Indiana, Iowa, Kansas, Oregon, and California. Total membership in America about 88,500.

The six "Conservative" yearly meetings are: New England, Ohio, Canada, Western (Ind.), Iowa, and Kansas. These annually exchange epistles. Their membership is about 4,500.

Philadelphia occupies a unique position, not being connected with either of these groups of related yearly meetings. That its sympathies were with Wilbur against the views of Gurney was shown by the recognition of the "Wilbur" Friends in Ohio. Later, in the interest of peace, Philadelphia ceased correspondence with all yearly meetings, and has never regularly resumed it. The membership is about 4,500. Within most "Progressive" yearly meetings paid pastors, prescribed services, singing, instrumental music and revival methods have been introduced; until, in many localities, the so-called "Friends Churches" more nearly resemble "Methodists" than "Quakers." These yearly meetings have organized "The Five Years Meeting," held periodically as the name indicates, having advisory rather than legislative powers.

Most of them have recently adopted a «Uniform Discipline.» The principal schools of Orthodox Friends in America are: Haverford College, Pennsylvania; Earlham College, Iowa; Guilford College, North Carolina; Pacific College, Oregon; Westtown Boarding School, Pennsylvania; Friends Select School, Philadelphia; Friends Boarding School, Providence, R. I.; Friends Boarding School, Barnesville, Ohio. Their principal periodicals are: 'The Friend,' Philadelphia (weekly), in its 77th year of continuous publication of uniform size and style; 'The American Friend,' Philadelphia (weekly), organ of the Progressive Yearly Meetings.

STATISTICS.

London Yearly Meeting	17,476	
Dublin Yearly Meeting	2,528	
Australasia	550	
Continental: Norway, Denmark, Germany, France, Turkey	247	
Total abroad	20,801	
In America.		
Hicksite Friends	20,773	
Progressive Friends	88,401

Philadelphia Yearly Meeting, about	4,500	
Primitive Friends, about	225	
Total in America		118,399
Total in foreign countries		20,801
Total in the world		139,200

Bibliography.— Barclay, 'Apology' (1678); Evans, 'Exposition of Faith' (1827); 'Friends' Library' (14 vols. 1837–50); Fox, 'Journal' (1694); Gurney, 'Observations on Distinguishing Views and Practices' (1824); Hodgson, 'Society of — in 19th Century' (1876); Janney, 'History of' (1859); 'Life of Thomas Ellwood' (1714); 'Passages from Life and Writings of William Penn'; Sewel, 'History of Rise' (1722); Sharpless, 'Quaker Experiment in Government' (1898); Smith, 'Catalogue of Friends Books' (1867); Thomas, 'History of, in America' (1895); Wilbur, 'Journal' (1859); Woolman, 'Journal.'

Edwin P. Sellew,
Publisher of 'The Friend,' Philadelphia.

Fries, frēs, **Elias Magnus**, Swedish botanist: b. Smaland, Sweden, 15 Aug. 1794; d. Upsala 8 Feb. 1878. In 1834 he was called to the chair of practical economics at Upsala, with which in 1851 that of botany was conjoined. Fries introduced into Sweden the morphological theory in his 'Systems of the Vegetable World' (1825). His work on 'Mycology' (1820–32) was long the standard work on the classification of fungi, of which he gave a relatively complete catalogue in 'Scandinavian Flora' (1846–9). He wrote a series of useful books on the *Hymenomycetæ*, on lichens, and on the flora of Scandinavia, more particularly of Sweden. Among his monographs is one on the 'Hieraciеæ' (1848). In 1851 Fries was appointed director of the botanical museum and garden at Upsala, and in 1853 rector of the university.

Fries, Jakob Friedrich, yä'kōb frēd'rĭн, German philosopher: b. Barby, Prussia, 23 Aug. 1773; d. Wartburg, Germany, 10 Aug. 1843. He is a link between Kant's system and the so-called historical school. 'The New or Anthropological Critique of Reason' (1807) is his most important book. He wrote 'Handbook to Psychical Anthropology' (1820); 'System of Metaphysics' (1824), etc.

Fries, John, American insurgent: b. 1764; d. 1825. When in July 1798, Congress voted a direct tax of $2,000,000 the federal officers who were sent to Pennsylvania to collect the State quota of $237,000, were resisted by a party of opposition which Fries had rallied from among the Germans of Montgomery, Lehigh, Bucks and Berks counties. At Bethlehem, 7 March 1799, the United States marshal was compelled by this party to release 30 prisoners who had been arrested for refusing to obey the law. The «rebellion» was at length put down by the militia which President Adams ordered out, and among those captured was Fries, who was subsequently twice tried and on each occasion sentenced to death. In April 1800 he was pardoned by President Adams, who at the same time proclaimed an amnesty to all concerned in the «rebellion.»

Friese, frē'zė, **Richard**, German painter: b. Gumbinnen, East Prussia, 15 Dec. 1854. He studied at Berlin, and traveled in the East, as well as northward within the Arctic Circle. He is now considered one of the best of German animal painters, and is equally successful in depicting the lion in the desert and the deer in a German forest. In 1886 he was awarded a gold medal by the Berlin Academy, of which body he was elected a member in 1892. His most famous works are: 'Lions Surprising a Sleeping Caravan' (1884), in the Dresden Gallery; 'On the Bredszell Moor' (1895), in the Königsberg Museum.

Friesland, frēz'lănd, or **Vriesland**, frēs'-länt, a province in the Netherlands, bounded partly by the German Ocean and the Zuyder Zee. It is generally flat, and parts of it are below sea-level, being protected by dykes. Excellent horses, the best in Holland, cattle, and sheep are reared, and cattle and other agricultural produce are sent to England. It is sometimes called West Friesland, to distinguish it from East Friesland, now the district of Aurich in Hanover. It is divided into three districts — Leeuwarden, containing the capital of same name, Sneek, and Heerenveen. Area, 1,281 square miles. Pop. (1901) 345,004. See Netherlands.

Frieze, Henry Simmons, American educator: b. Boston 15 Sept. 1817; d. Ann Arbor, Mich., 7 Dec. 1889. He was graduated from Brown University in 1841, was instructor there from 1841–5, and in the grammar-school connected with the university 1845–54, and from 1854 professor of the Latin language and literature in the University of Michigan, of which in 1869–71 and 1880–1 he was the acting president. He did much to promote the interests of the university, obtaining for it a State appropriation of $75,000 and an important library in political science. He published: an edition (1860) of the 'Æneid,' and (1867) of the 'Ars Rhetorica'; and 'The Story of Giovanni Dupré' (1886).

Frieze, (1) the architectural term for that part of an entablature between architrave and cornice or any similar position, in a work of structural decoration. It is often enriched with figures of animals, etc., in relief, and is sometimes divided into triglyphs and metopes. One of the best known examples is the Panathenaic, frieze around the cella of the Parthenon. (See Architecture.) (2) The name of a thick woolen stuff or cloth with a nap on one side, in use since the 14th century for heavy outer garments. Frieze is largely made in Ireland, whence considerable quantities are exported.

Frigate, the designation in the days of wooden war vessels of a full-rigged ship with two decks, and so distinguished from a ship of the line which had three. Frigates were usually fast sailers, mounted with 28 to 60 guns, and were employed as scouts and as cruisers, to convoy merchantmen, etc. With the introduction of armor-clad war vessels the term frigate has been superseded by that of cruiser, but a large full-rigged merchantman is still sometimes so called. The name originally was used in the Mediterranean to designate a long, swift vessel propelled by oars and sails.

Frigate-bird, or **Frigate Pelican**. See MAN-OF-WAR HAWK.

Frill-lizard, a large Australian lizard (*Chlamydosaurus kingi*) of the family Agamidæ, so called in allusion to the erectile collar or ruff about its neck. This broad membrane is supported on each side of the neck by slender rods from the hyoid bone which extend to its margin like the sticks of a fan; and like a fan it may be folded close against the shoulders or spread until it stands up all around the back part of the head; but this erection can be accomplished only by opening the mouth widely, and always accompanies a stretching apart of the jaws. The exterior of the frill is of the general grayish-brown of the animal's body, but its interior or front is scarlet; and when it is suddenly spread in the face of an enemy behind the open hissing mouth, it is calculated to astonish and frighten the attacker in no small degree, as seems to be the purpose of the structure. These lizards are 6 to 8 inches long plus a long, lash-like tail. They spend their time on trees and logs, searching for the beetles which constitute their principal food; and have an extraordinary manner, when in haste, of rising and running upon their hind legs alone. The species has been extensively described and illustrated by Saville Kent in his books on the natural history of tropical Australia.

Fringe-tree (*Chionanthus virginica*), a beautiful tree of 10 or 20 feet in height, with somewhat oval, smooth, entire leaves, white narrow-petaled flowers in drooping racemes, and oval, purple drupes. Its blossoms are not only suggestive of its English name, but of the generic title of *Chionanthus*, "blossoms of the snow." It is found in the United States from latitude 39° to the Gulf of Mexico, and forms an attractive feature in garden shrubbery. In the southern States it is known as old-man's-beard.

Fringed Dragon, one of the names of the Australian lizards of the genus *Chlamydosaurus*, characterized by an erectile neck-ruff. See FRILL-LIZARD.

Fringillidæ, frĭn-jĭl'ĭ-dē, the finch and sparrow family, an extensive group of oscine birds, regarded as the most highly organized of all birds. The old name *Fringilla*, applied by Linnæus to the whole group, is retained only for the typical genus, represented by the chaffinch (q.v.). All the fringillines are small, compact and active, without eccentricity of form or plumage, and with organs adapted to an omnivorous diet, although seeds form the principal part of the fare. The bill is usually stout and cone-shaped, varying from a greatly swollen size in some of the grosbeaks to the slenderness of that of the goldfinch. The legs are short, and scutellate; the feet strong; and the wings and tail do not vary much from normal, but the wing has a minute outer primary. The plumage is varied, and in many genera the sexes are unlike. These birds mainly frequent fields, roadsides, and woodlands; and build their nests (often elaborate structures) in trees, in bushes or on the ground — never in burrows, or tree-holes, or composed of mud. Their eggs are usually five in number, and usually are spotted. The family includes extremely good singers, and furnishes us not only the canary but many other of the most popular cage-birds; also many whose flesh is considered a delicacy. The group is divided into scores of genera and contains hundreds of species, which predominate in the northern latitudes of the Old World, where many are resident throughout the year: but they also abound in all other parts of the world except Australia. See Evans 'Birds' (1900), and for America the exhaustive monograph by Ridgway in his 'Birds of North and Middle America,' Part I. (1901). See BUNTING, FINCH, GROSBEAK, LINNET, REDPOLL, SPARROW, and names of various species.

Frisian, or **Friesian**, the term applied to a native and to the language of Friesland. The Frisians are descended from a German tribe, who, at the beginning of the Christian era, occupied the territory between the mouths of the Rhine and the Ems, in the modern provinces of Groningen and Friesland. They became tributaries of Rome under Drusus, and lived for some time on friendly terms with their conquerors, but were driven to hostilities by oppression. They were partially subdued in 47 A.D., and rebelled again with the Batavians under Civilis. In the 5th century a host of Frisians joined the Angles and Saxons in invading Britain. About the end of the 7th century the Frisians in the southwest were subdued by the Franks under Pépin d'Héristal, who compelled them to accept Christianity. A century later the eastern branch of the tribe was conquered and Christianized by Charlemagne. Their country was divided into three districts, two of which were annexed on the division of the Carlovingian Empire to the possessions of Louis the German, and the other to those of Charles the Bald. The latter part was called West Frisia (West Friesland), and the two former East Friesia (East Friesland). The distinctive national features were gradually lost by assimilation with their neighbors, and their modern history is chiefly connected with Holland and Hanover.

The *Frisian Language*, a Low German dialect, holds in some respects an intermediate position between Anglo-Saxon and Old Norse. Of all the Teutonic dialects it is the most nearly related to English. Its ancient form exists in some remarkable collections of laws, of which each Gau or district had its own set written in its own language. The Asegabuch (dating from 1200) was a series of laws valid for all Friesland. An almost complete collection of those laws is to be found in Richthofen's 'Friesische Rechtsquellen' (1840). The modern Frisian is mostly confined to the peasantry. It is broken up into three dialects; the North Frisian on the west coast of Schleswig, its islands, and Helgoland; the Batavian comprising the common West Frisian, and those of Mulkweren and of Hindelopen; and the Westphalian, whose varieties are the East Frisian and those of Rustringen, Wursten, and Saterland, each of which is more or less unintelligible beyond the narrow district in which it is spoken. Among specimens of Frisian literature are, 'Waatze Gribberts Brilloft,' a comedy (1712); 'It Libben fen Aagtje Ysbrants,' a novel (1779); the writings of Japicx, Althuysen, the brothers Halbertsma, Dijkstra, Troelstra, and others. Consult: Grimm's 'Deutsche Grammatik'; the 'Altfries'; 'Wörterbuch' of Richthofen; Doornkaat Koolman's 'Wörterbuch der Ostfriesischen Sprache'; Van Helten's 'Altostfriesische Grammatik'; Hewett's 'Frisian Language and Literature.'

Frit. See Fritting Furnace; Glass.

Frith, William Powell, English painter: b. Studley, near Ripon, 9 Jan. 1819. Since 1840, when he exhibited 'Malvolio before Olivia' at the Royal Academy, he has produced a great number of scenes from Shakespeare, Molière, Dickens, Sterne, Goldsmith, etc., besides his immensely popular pictures, 'Coming of Age in the Olden Time' (1849); 'Life at the Sea-Side' (1854); 'The Derby Day' (1858); 'The Railway Station' (1862); 'Before Dinner at Boswell's Lodgings' (1868 — sold in 1875 for £4,567); 'The Private View at the Royal Academy' (1881), etc. He was commissioned by the queen to paint the marriage of the Prince of Wales. He was elected R.A. in 1852, and is a member of several foreign academies. His works do not exhibit the highest qualities of art, but, possibly in part because of this, they have been extremely popular. Large engravings have been produced from a number of his pictures. In 1887–8 he published his autobiography.

Fritillary, in botany, a plant of the genus *Fritillaria,* of the lily family, found in the North Temperate and Arctic zones. The plants are herbaceous, the leaves simple, alternate, though sometimes appearing opposite or verticillate; the flowers terminal and pendent; the perianth campanulate, of six petals; the stamens six; the style trifid. About a dozen species are known, several of which are cultivated in gardens, being hardy and highly ornamental plants. The *F. imperialis,* or crown imperial, supposed to be a native of Persia, has large orange or yellow flowers nodding beneath a terminal tuft of leaves. The bulb is poisonous, as is that of *F. meleagris,* though in a less degree.

Fritting Furnace, in glass-making, a reverberatory furnace in which the materials for making glass are calcined (fritted) as a process preliminary to melting. The object is to effect a partial union of the salicylic acid and alkali, to avoid volatilization in the latter in the subsequent vitrification. The materials (sand, chalk, soda-ash, and cullet) being introduced into the furnace, the temperature is gradually raised for three hours. The pasty mixture is stirred, and the temperature increased to incipient fusion. The frit is then raked out and transferred to the melting pot, or is placed in cast-iron trays, cut into blocks with a spade, and stored away as frit bricks. See Glass.

Fritz, John, American iron and steel expert: b. Londonderry, Pa., 1822. He was at first a machinist in shops at Parkersburg and Norristown, and subsequently was a constructor of rolling-mills, acquiring in the latter capacity an authoritative knowledge of iron and steel manufacture. He equipped the Bethlehem iron and steel works, and was for many years manager of that well-known establishment. Many methods of manufacture now in general use were employed by Fritz among the first in this country, including the Bessemer process. Several manufacturers and scientists established in 1902 the award of the Fritz medal to be given for discovery in the fields of science.

Friuli, frē'oo-lē, **Italy,** a formerly independent duchy, consisting, in its widest extent, of the modern Italian province of Udine, the Austrian county of Görz and Gradiska, and the circle of Idria. It was one of the most important duchies of the Longobard Kingdom, and after the overthrow of that monarchy by Charlemagne, and even up to the 15th century, when it was conquered by Venice and its territories dismembered, it retained a considerable degree of independence. The inhabitants, called Furlani, are Italian for the most part, but speak a peculiar dialect, into which a strong Celtic element has been introduced. See Italy.

Frobisher Bay, an Arctic inlet opening westward near the mouth of Davis Strait, at the southern end of Baffin Land. It is about 200 miles long by above 20 wide, with rugged mountainous shores. It was till Hall's voyage called Frobisher Strait, being erroneously regarded as a passage into Hudson Bay.

Froebel, Friedrich Wilhelm August, frēd'rĭh vĭl'hĕlm ow'goost frē'bĕl, German educationist: b. Oberweissbach, Thuringia, 21 April 1782; d. Marienthal 21 June 1852. It was Froebel who said, "The clearer the thread that runs through our lives backward to our childhood, the clearer will be our onward glance to the goal"; and in the fragment of autobiography he has left us, he illustrates forcibly the truth of his own saying. The motherless baby who plays alone in the village pastor's quiet house, the dreamy child who wanders solitary in the high-walled garden; the thoughtful lad, neglected, misunderstood, who forgets the harsh realities of life in pondering the mysteries of the flowers, the contradictions of existence, and the dogmas of orthodox theology; who decides in early boyhood that the pleasures of the senses are without enduring influence and therefore on no account to be eagerly pursued; — these presentments of himself, which he summons up for us from the past, show the vividness of his early recollections and indicate the course which the stream of his life is to run.

The coldness and injustice of the new mother who assumed control of the household when he was 4 years old, his isolation from other children, the merely casual notice he received from the busy father absorbed in his parish work, all tended to turn inward the tide of his mental and spiritual life. He studied himself, not only because it was the bent of his nature, but because he lacked outside objects of interest; and to this early habit of introspection we owe many of the valuable features of his educational philosophy. Whoever has learned thoroughly to understand one child, has conquered a spot of firm ground on which to rest while he studies the world of children; and because the great teacher realized this truth, because he longed to give to others the means of development denied him, he turns for us the heart-leaves of his boyhood.

It would appear that Froebel's characteristics were strongly marked and unusual from the beginning. Called by every one "a moon-struck child" in Oberweissbach, the village of his birth, he was just as unanimously considered "an old fool," when, crowned with the experience of 70 years, he played with the village children on the green hills of Thuringia. The intensity of his inward life, the white heat of his convictions, his absolute blindness to any selfish idea or aim, his enthusiasm, the exaltation of his spiritual nature, all furnish so many cogent reasons why the people of any day or of any community should have failed to understand him, and scorned what they could not comprehend. It is the old story of the seers and the prophets repeated as many times as they appear; for "these colossal souls," as Emerson said, "require a long focal distance to be seen."

At 10 years old the sensitive boy was fortunately removed from the uncongenial atmosphere of the parental household; and in his uncle's home he spent five free and happy years, being apprenticed at the end of this time to a forester in his native Thuringian woods. Then followed a year's course in the University of Jena, and four years spent in the study of farming, in clerical work of various kinds, and in land-surveying. All these employments, however, Froebel himself felt to be merely provisional; for like the hazel wand in the diviner's hand, his instinct was blindly seeking through these many restless years the well-spring of his life.

In Frankfort, where he had gone intending to study architecture, Destiny touched him on the shoulder, and he turned and knew her. Through a curious combination of circumstances he gained employment in Herr Gruner's Model School, and it was found at once that he was what the Germans love to call "a teacher by the grace of God." The first time he met his class of boys he tells us that he felt inexpressibly happy; the hazel wand had found the waters and was fixed at last. From this time on, all the events of his life were connected with his experience as a teacher. Impelled as soon as he had begun his work by a desire for more effective methods, he visited Yverdon, then the centre of educational thought, and studied with Pestalozzi. He went again in 1808, accompanied by three pupils, and spent two years there, alternately studying and teaching.

There was a year of lectures at Göttingen after this, and one at the University of Berlin, accompanied by unceasing study and research both in literary and scientific lines; but in the fateful year 1813 this quiet student life was broken in upon, for impelled by strong moral conviction, Froebel joined Baron von Lützow's famous volunteer corps, formed to harass the French by constant skirmishes and to encourage the smaller German States to rise against Napoleon.

No thirst for glory prompted this action, but a lofty conception of the office of the educator. How could any young man capable of bearing arms, Froebel says, become a teacher of children whose Fatherland he had refused to defend? how could he in after years incite his pupils to do something noble, something calling for sacrifice and unselfishness, without exposing himself to their derision and contempt? The reasoning was perfect, and he made practice follow upon the heels of theory as closely as he had always done since he became master of his fate.

After the Peace of Paris he settled down for a time to a quiet life in the mineralogical museum at the University of Berlin, his duties being the care, arrangement, and investigation of crystals. Surrounded thus by the exquisite formations whose development according to law is so perfect, whose obedience to the promptings of an inward ideal so complete, he could not but learn from their unconscious ethics to look into the depths of his own nature, and there recognize more clearly the purpose it was intended to work out.

In 1816 he quietly gave up his position, and taking as pupils five of his nephews, three of whom were fatherless, he entered upon his life work, the first step in which was the carrying out of his plan for a "Universal German Educational Institute." He was without money, of course, as he had always been and always would be,—his hands were made for giving not for getting; he slept in a barn on a wisp of straw while arranging for his first school at Griesheim; but outward things were so little real to him in comparison with the life of the spirit, that bodily privations seemed scarcely worth considering. The school at Keilhau, to which he soon removed, the institutions later established in Wartensee and Willisau, the orphanage in Burgdorf, all were most successful educationally, but, it is hardly necessary to say, were never a source of profit to their head and founder.

Through the twenty succeeding years, busy as he was in teaching, in lecturing, in writing, he was constantly shadowed by dissatisfaction with the foundation upon which he was building. A nebulous idea for the betterment of things was floating before him; but it was not until 1836 that it appeared to his eyes as a "definite truth." This definite truth, the discovery of his old age, was of course the kindergarten; and from this time until the end, all other work was laid aside, and his entire strength given to the consummate flower of his educational thought.

The first kindergarten was opened in 1837 at Blankenburg (where a memorial school is now conducted), and in 1850 the institution at Marienthal for the training of kindergartners was founded, Froebel remaining at its head until his death two years after.

With the exception of that remarkable book 'The Education of Man' (1826), his most important literary work was done after 1836; 'Pedagogics of the Kindergarten,' the first great European contribution to the subject of child-study, appearing from 1837 to 1840 in the form of separate essays, and the 'Mutter-und-Kose Lieder' (Mother-Play) in 1843. Many of his educational aphorisms and occasional speeches were preserved by his great disciple the Baroness von Marenholtz-Bülow in her 'Reminiscences of Froebel'; and though two most interesting volumes of his correspondence have been published, there remain a number of letters, as well as essays and educational sketches, not yet rendered into English.

Froebel's literary style is often stiff and involved, its phrases somewhat labored, and its substance exceedingly difficult to translate with spirit and fidelity; yet after all, his mannerisms are of a kind to which one easily becomes accustomed, and the kernel of his thought when reached is found well worth the trouble of removing a layer of husk. He had always an infinitude of things to say, and they were all things of purpose and of meaning; but in writing, as well as in formal speaking, the language to clothe the thought came to him slowly and with difficulty. Yet it appears that in friendly private intercourse he spoke fluently, and one of his students reports that in his classes he was often "overpowering and sublime, the stream of his words pouring forth like fiery rain."

Froebel's educational creed cannot here be cited at length, but some of its fundamental articles are:

The education of the child should begin with its birth, and should be threefold, addressing the mental, spiritual, and physical natures.

It should be continued as it has begun, by appealing to the heart and the emotions as the starting-point of the human soul.

There should be sequence, orderly progression, and one continuous purpose throughout the entire scheme of education, from kindergarten to university.

Education should be conducted according to nature, and should be a free, spontaneous growth,— a development from within, never a prescription from without.

The training of the child should be conducted by means of the activities, needs, desires, and delights, which are the common heritage of childhood.

The child should be led from the beginning to feel that one life thrills through every manifestation of the universe, and that he is a part of all that is.

The object of education is the development of the human being in the totality of his powers as a child of nature, a child of man, and a child of God.

These principles of Froebel's, many of them the products of his own mind, others the pure gold of educational currency upon which he has but stamped his own image, are so true and so far-reaching that they have already begun to modify all education and are destined to work greater magic in the future. The great teacher's place in history may be determined, by-and-by, more by the wonderful uplift and impetus he gave to the whole educational world, than by the particular system of child-culture in connection with which he is best known to-day.

Judged by ordinary worldly standards, his life was an unsuccessful one, full of trials and privations, and empty of reward. His death-blow was doubtless struck by the prohibition of kindergartens in Prussia in 1851, an edict which remained nine years in force. His strength had been too sorely tried to resist this final crushing misfortune, and he passed away the following year. His body was borne to the grave through a heavy storm of wind and rain that seemed to symbolize the vicissitudes of his earthly days, while as a forecast of the future the sun shone out at the last moment, and the train of mourners looked back to see the low mound irradiated with glory.

In Thuringia, where the great child-lover was born, the kindergartens, his best memorials, cluster thickly now; and on the face of the cliffs that overhang the bridle-path across the Glockner Mountain may be seen in great letters the single word *Froebel,* hewn deep into the solid rock. Consult: von Marenholtz-Bülow, 'Reminiscences of Friedrich Froebel'; Barnard, 'Papers on Froebel's Kindergarten' (1881); Hauschmann, 'Froebel's Kindergarten System'; Bowen, 'Froebel' (1897); Quick, 'Educational Reformers.' NORA ARCHIBALD SMITH.

Frog. This familiar animal is the type of the anurous *Amphibia* (order *Anura*). The family *Ranidæ,* to which it belongs, is characterized by having the skin smooth, the hind legs long, and the feet usually completely webbed; teeth are present in the upper jaw and palate, seldom in the lower jaw. The tympanic membrane is situated behind the eyes, and is not concealed. The nostrils are placed at the extremity of the rounded muzzle just above its margin, and open directly into the mouth. When the mouth is filled with air the nostrils are closed, and the animal swallows the bolus of air into the sacculate lungs, there being, in the absence of ribs, no provision for such respiratory movements as take place in the chest of mammals. Frogs are thus air breathers, but they are capable of remaining for a considerable time under water. They swim with great vigor, and on land progress by a series of violent leaps, the long hind limbs being powerful levers. Their food is chiefly insects, which they capture by means of the tongue: this organ is covered with a viscid secretion and is attached in front, its free border being behind; it is rapidly projected from the mouth, the insect adheres to it, and is at once swallowed. The frog does not drink, but its soft skin absorbs fluids rapidly, and thus has a double function both of nutrition and as an aid to respiration. As the frog grows the old outer skin cracks from time to time, and is pulled off and swallowed. The animal retires in winter to the bottom of ponds, from which clusters of frogs may be drawn buried in mud. This hibernation, which is associated with low vital energy, ends in February; in March the spawn is deposited in gelatinous masses of many hundreds of eggs, the males riding for a long period at that season on the backs of the females, and fertilizing the eggs as fast as they are extruded. The eggs soon manifest change, and after a time the young escapes as a "tadpole," a larval animal with short body, circular suctorial mouth, and long tail, compressed from side to side. Gills project on either side of the head from a cleft which answers in position to the gill opening of fishes. The hind limbs first appear as buds, later the fore limbs project, the gills disappear, the lungs becoming more fully developed; the tail gradually shrinks and disappears, and the animal, which was at first fish-like, then closely resembled a newt (or urodele amphibian), finally assumes the adult or anurous form. This is a true process of metamorphosis as complete as that of the butterfly; since there is a change not merely of form and proportion, but also of internal organs. The frog is highest among *Amphibia,* and the successive stages of its development resemble each the adult form of a lower group in its line of ancestry.

Frogs, themselves useful in clearing gardens of slugs and insects, are in turn the prey of birds, especially herons and aquatic birds, of serpents, and fish, the latter destroying large quantities of the spawn. Though exposed to droughts, they can bury themselves in the moist soil and thus live after the ponds are dried up. Though thus tenacious of life, the stories of frogs being found in stone and in trees are for the most part founded on imperfectly noted facts, though it is possible that a frog may now and then get closed into a cavity for which, after entering, it had grown too large; but an aperture must always be present by which water can get access to them. Their fossil history goes back to the early Tertiary days, and probably will be found to extend farther, as Eocene examples differ little from modern forms. See AMPHIBIA.

It is by no means easy to define the word "frog" in classification, as distinguished from "toad" (q.v.), and the safest method here will be to deal only with the aquatic family *Ranidæ*, already defined, accepted as the most highly developed of amphibians. It contains about 280 species and is represented in every part of the world not too cold except southern South America and Australia, where all the so-called frogs belong to a related family, the *Cystignathidæ*, whose members, especially of the sub-family *Cystignathinæ*, may be said to represent the *Ranidæ* in Notogæa. "Some of them," says Gadow, "can be distinguished from the true, typical frogs solely by the arciferous type of the shoulder-girdle and sternum.

The type-genus *Rana* contains more than half the known species, and is scattered all over the northern hemisphere, but is absent from the southern. It is to this genus that the common frogs of Europe and the United States belong — the bull-frog, spring-frog, European grass-frog, etc. The American bull-frog (*R. catesbiana*) is the largest of the whole tribe, occasionally reaching a length of eight inches; and its muffled grunting cry may be heard a mile or more over the water. It is greenish bright upon the head and mottled elsewhere, while the legs are distinctly blotched. This species abounds in all sluggish waters from Kansas eastward, laying its eggs in long strings, and its tadpoles require two years to reach maturity. It is bold and voracious, catching fish, salamanders, other frogs and even ducklings. Its size and the chicken-like daintiness of the flesh in its hind legs, or "saddle," make it the favorite frog for market, and great quantities are eaten in all parts of the country. In the springs, swamps and ditches lives the green frog (*R. clamata*), not half as big, but very similar in color except that it is yellowish or white below. Another green aquatic frog, still smaller, is the leopard frog (*R. virescens*), whose bright coat is marked with irregular blotches of black edged with whitish, in two rows along the back, and the legs are barred. This species is numerous everywhere as far west as the Sierra Nevada. Another checkered frog, confined to the Eastern States, is the pickerel frog (*R. palustris*), which is light-brown with two rows of large oblong square blotches of dark brown on the back, and one or two on the sides. The head is short, and a dark line extends from the nostril to the eye, while the upper jaw is white, spotted with black spots. Another well-known little kind is the wood-frog (*R. sylvatica*), which goes to the water to breed in early spring, but during most of the year lives in the dry woods. It is a variable reddish brown, with the side of the head marked with a dark-brown band. Several other less conspicuous species of frog inhabit North America, including a few representatives of another family (*Engystomidæ*), besides the tree-frogs, elsewhere described.

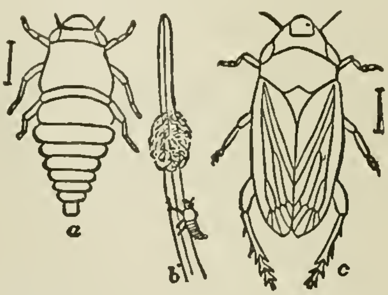
For frogs generally consult Gadow's 'Amphibia and Reptiles' (1901); for those of the United States the writings of Holbrook, C. C. Abbott, O. P. Hay, A. W. Butler, and especially 'North American Batrachia,' by E. D. Cope. See also AMPHIBIA; METACHROSIS.

Frog-mouths, a group of large Australian and Indian nightjars constituting the sub-family *Podarginæ* and remarkable for their huge mouths. The Australian More-pork (q.v.) is an example.

Frog-shell, a small mollusk of the *Triton* family (genus *Ranella*), so called because of its shape and mottled colors.

Frogfish, any of several sea-fishes of low organization, toad-like forms and carnivorous habits, constituting the family *Antennariidæ*, and related to the goosefish (q.v.), itself sometimes called "fishing frog."

Froghoppers, or **Froth-flies**, minute plant-feeding homopterous bugs of the family *Cercopidæ*, which dwell upon plants and may, when very numerous, seriously damage grass-crops. The eggs are laid on the stems of plants in the autumn, and survive in the winter. When the embryos hatch (and these resemble the parents,



a, immature young (enlarged); *b*, froth about eggs, and young froghopper, natural size; *c*, adult (enlarged).

but are wingless) they exude a viscid liquid which is whipped into froth, called in England "cuckoo-spit," by the thrashing of the "tail," an anal appendage probably respiratory in function. The "spittle" is supposed to be a protective disguise, nevertheless the immature insects are preyed upon by wasps, etc. These bugs are called "froghoppers" in double allusion to the froth about their eggs and to their great leaping powers.

Froh'man, Charles, American theatrical manager: b. Sandusky, Ohio, 1858. Having managed several road companies, he took charge of the Empire Theatre, New York, in 1893, and in 1895–6 organized the syndicate which exercises so large a monopoly in American theatrical affairs.

Frohman, Daniel, American theatrical manager: b. Sandusky, Ohio, 1853. He began business life with five years in newspaper offices; he subsequently became manager of a traveling theatrical company, since which he has successfully managed several New York theatres, as well as English and American stars and theatrical companies. He is at present manager of the

Lyceum Theatre, Daly's Theatre, and the Daniel Frohman Stock Company.

Froissart, Jean, zhŏn frä-swä or froi'särt, French chronicler: b. Valenciennes, Hainault, 1333; d. Chimay 1419. He began at 20 to write the history of the wars of the time and made several journeys to examine the theatre of the events he was about to relate. His 'Chronicle' (as the title is usually abbreviated) covering the years 1326–1400, is of capital importance for its period. To a collection of the verses of Wenceslaus of Brabant, Froissart added some of his own, and gave to the whole the title 'Meliador, or the Knight of the Golden Sun.' All his extant poems were published at Brussels (1870–2). His chronicles form a work of permanent value, because of their accurate and impartial account of important events of the 14th century, and of the vivid pictures which they contain of the life of an age so strikingly different from our own. They narrate events connected with France, England, Scotland, Spain, Brittany, etc. See Darmesteter, 'Froissart' (1894).

Fromentin, Eugène, ē-zhān frō-mŏṅ-tăṅ, French painter: b. La Rochelle 24 Oct. 1820; d. St. Maurice, near La Rochelle, 27 Aug. 1876. He began life as a law student, but early turned his attention to landscape painting, working in the studio of Louis Sabat. In 1842 he traveled in Algeria, and it was after this journey that under the guidance of Marilhat, the painter of Oriental scenes, he resolved to work a new vein in the same department by painting the North African deserts. In 1847 he exhibited at the Salon for the first time and visited Algeria twice (1848–52). The fruits of these wanderings were not only numerous pictures, but also two literary works descriptive of his travels. These were: 'A Summer in the Sahara' (1856), and 'A Year in the Sahel' (1858), works distinguished by powerful and richly colored style, and poetic imagination. As a painter his aim was to depict the light and atmosphere of the desert with truth and delicacy, yet imparting to it his own subjective interpretation, and he showed a marked taste for studies in gray and violet. The masterly analysis of ancient painting, which appears in his 'Masters of a Former Day' (1876), embodies the results of his travels in Holland and Belgium (1875), where he made a careful study of the Dutch and Flemish masters.

Frommel, frō'mĕl, **Emil,** German theologian: b. Karlsruhe 5 Jan. 1828. He was an army chaplain, and published several theological works of importance. 'Tales For the People' (1873–86), and similar collections of humorous and realistic compositions, will more surely form his memorials in the future.

Fronde, frŏnd (Fr. frōṅd), the name of a political faction which played a conspicuous part in French history during the minority of Louis XIV., and gave rise to the insurrectionary movement known historically as the War of the Fronde. The members of this party obtained the contemptuous name of Frondeurs (slingers), being compared to boys throwing stones from slings, owing to the pertinacious lampoon warfare which they waged against the powerful minister of that day, Cardinal Mazarin, and the Queen Regent, Anne of Austria. Mazarin, as a foreigner and a parvenu, was detested by the French people — both patrician and proletarian — and especially had incurred the opposition of the Parliament of Paris to his measures. In 1648 Mazarin ventured on the bold step of arresting two of the most popular members of the latter body, and on the next day 27 August (*la journée des barricades*) the Parisians rose in arms, dispersed some of the royal troops sent out against them, and barricaded the approaches to the Louvre, compelling the court party to retire to St. Germain, thus leaving Paris in the hands of the insurgents. Upon the Prince de Condé advancing to besiege the capital, the parliament called the citizens to arms, when the Prince de Conti, the Duc de Beaufort, ("Le Roi des Halles," and son of Henry IV.), and numerous others of the great nobles of the kingdom, came forward to head the insurrection. The famous Cardinal de Retz and the Duchesses de Longueville and de Montbazon also joined the popular cause. The Prince de Condé, too, changed sides and went over to the malcontents, with whom the court party shortly afterward patched up a treaty of peace of but brief duration. Fresh contentions arose, and Mazarin caused the arrest of Condé and Conti. This step excited a revolt in the provinces, and Marshal Turenne hastened to the rescue of the Frondeur princes, but was routed in the battle of Rethel (1650). The cardinal, however, enjoyed but a temporary supremacy; the parliament again agitated against him, and procured his banishment from France, leaving the Prince de Condé master of the situation. Subsequently, the contest degenerated into a war of intrigue and is regarded as one of the most useless conflicts ever waged. The court finally agreeing to dismiss Mazarin a general amnesty was proclaimed. Condé attempted to continue the struggle, but was proscribed, and entered the service of Spain, while Mazarin, after a time, returned to Paris, and again obtained the reins of government.

Front Royal, Engagement at. Front Royal, Va., is 12 miles east of Strasburg, and is the key to Luray Valley. On 23 May 1862 it was held by Col. Kenly with 9 companies of the 1st Maryland infantry, 2 companies of the 29th Pennsylvania, a company of the 28th New York, and a section of Knap's battery, under command of Lieut. Atwell, in all about 900 men. Soon after noon of the 23d "Stonewall" Jackson, moving down the Luray Valley to cut off Bank's retreat from Strasburg to Winchester, pushed through the town, driving in Kenly's pickets and advance-guard. Kenly made a stand on a ridge about a mile north of the town, where he was joined by about 100 men of the 5th New York cavalry, but was soon flanked and pushed across both branches of the Shenandoah, and failed to burn the bridges behind him. When across the river he drew up on its north bank and, with artillery and musketry, resisted for some time all efforts to cross; but Jackson's cavalry forded the stream, both above and below the bridges, thus flanking his position, and Kenly fell back toward the cross-road leading to Middletown, closely followed by Confederate cavalry. He had gone four miles when his cavalry rear-guard was stampeded, and his infantry fiercely attacked, the resistance continuing until his force was cut to pieces and captured, with Atwell's two guns and the entire supply-train. Nearly all the New York cavalry escaped. The Union loss was 18 killed, 56 wounded, and 718 captured; the Confederate loss was 11 killed and 15 wounded. Jackson pushed on after Banks, leaving Col. Conner with the 12th Georgia and a battery at Front Royal. On the 30th the 1st Rhode Island cavalry, the advance of McDowell's corps, dashed into the town, surprised Conner, and captured 156 officers and men and one gun, the loss in the cavalry being 8 killed and 5 wounded.

E. A. Carman.

Frontaura, frōn-tow'rä, **Carlos**, Spanish author: b. Madrid, Spain, 4 Sept. 1834. He published: 'The Philanthropist,' a comedy; 'Fortunes and Misfortunes of Rosita,' a novel.

Frontenac, Louis de Buade, loo-ē dė boo-äd frônt'näk, Comte de, French colonial officer: b. France 1620; d. Quebec 28 Nov. 1698. He entered the army in 1635, and at an early age became brigadier. In 1672 he was appointed governor of the French possessions in North America, to be recalled 10 years later, in consequence of endless quarrels with his intendant and the Jesuits. In spite of his violent temper he gained the confidence of the settlers and the respect of the Indians, and in 1689, when to the horror of constant attacks from the Iroquois the misery of a war with England was added, he was again sent out by the king, as the only man who could rouse the colonists to hope and action. During the next nine years he loosed his savage allies on the defenseless villages of New England, repulsed a British attack on Quebec, and so broke the power of the Iroquois that they were never again a terror to the colony. See Parkman, 'Frontenac and New France Under Louis XIV.' (1877); Winsor, 'Cartier to Frontenac' (1894).

Frontier Posts. See Northwest Territory.

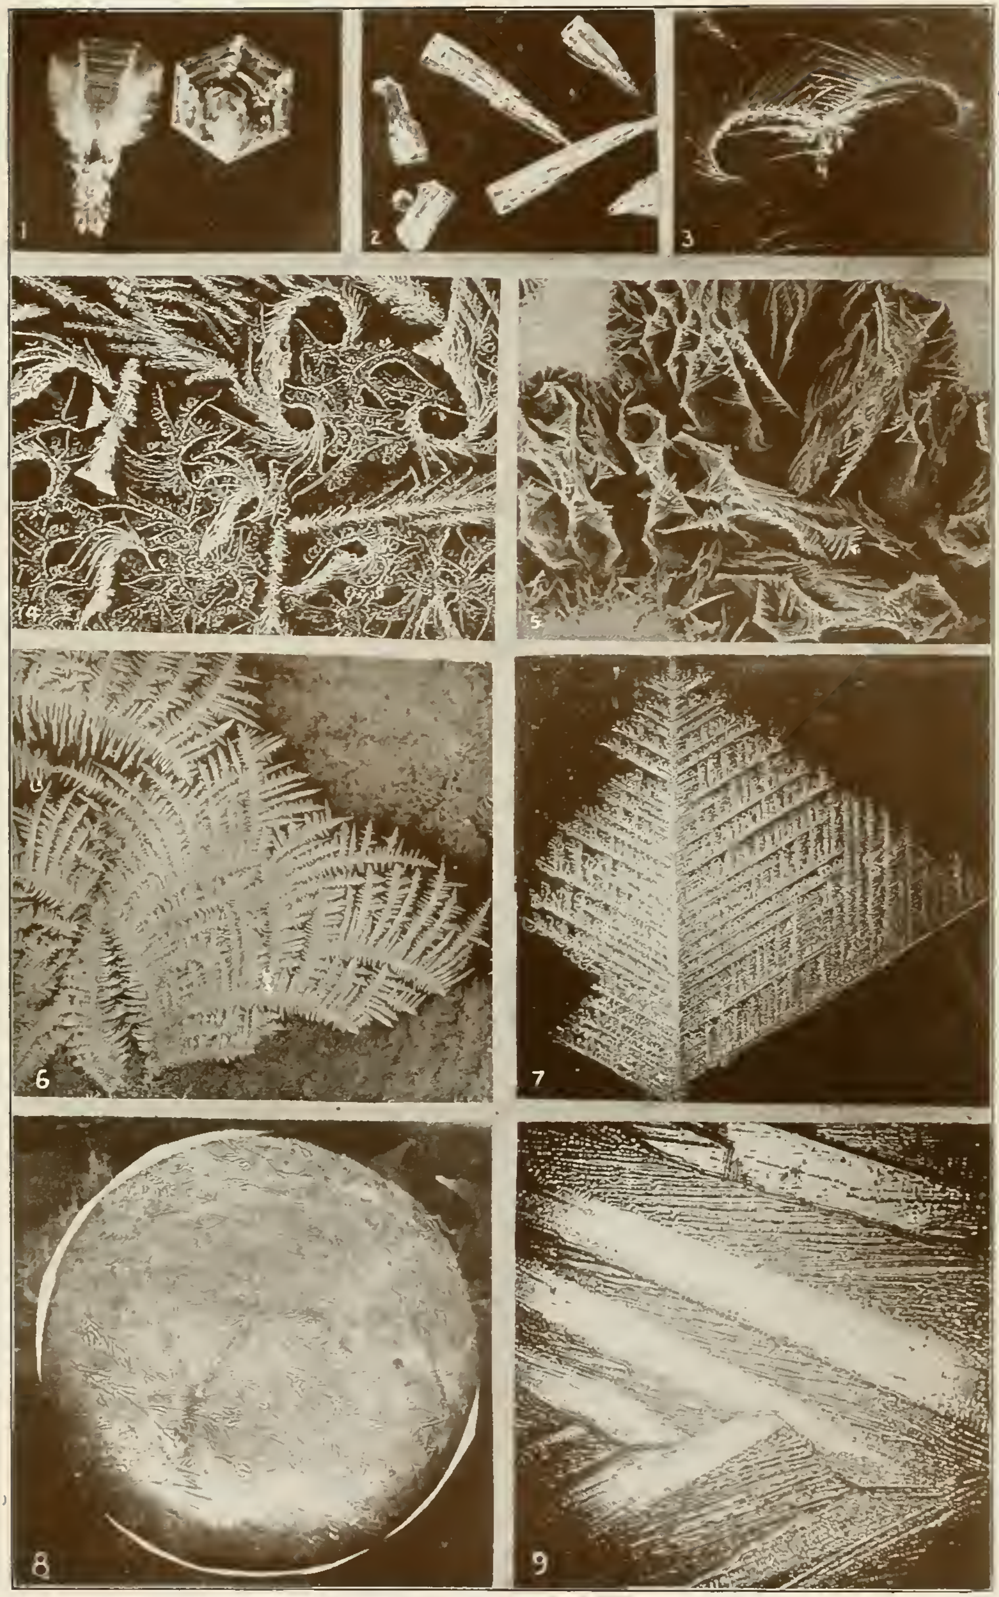
Frontinus, frōn tī'nŭs, **Sextus Julius**, Roman writer, who flourished in the second half of the 1st century after Christ. He was thrice consul, and commanded with reputation in Britain, under Vespasian. He was appointed by Nerva to superintend the aqueducts of Rome, and left an extant work on this subject, 'De Aquis Urbis Romæ,' as well as one dealing with the art of war, 'Strategemata.'

Fron'to, Marcus Cornelius, Roman orator and rhetorician: b. Cirta, a Roman colony in Numidia, about 100 A.D.; d. about 175. He went to Rome during the reign of Hadrian, soon acquired great fame as a speaker and teacher of rhetoric, and was in consequence selected as tutor to M. Annius Verus and L. Commodus, afterward emperors under the names Marcus Aurelius and Lucius Verus. He became a member of the senate, and was a consul in 143 A.D. Till 1814 the only extant writings of Fronto were a worthless tract, 'De Differentiis Vocabulorum' and some fragments; but in that year Angelo Mai recovered many of Fronto's letters from a palimpsest in the Ambrosian library at Milan. These were part of the orator's correspondence with Antoninus Pius, Marcus Aurelius, Lucius Verus, and other distinguished friends, and were published under Mai's editorship in 1815. In 1823 Mai published a new edition of the letters, containing many others which he had discovered in the Vatican library, but the standard edition is that of Naber (Leipsic 1867).

Frost, William Goodell, American educator: b. Le Roy, N. Y., 2 July 1854. He was graduated at Oberlin College in 1876, and afterward studied at Harvard and Göttingen, Germany. He was appointed professor of Greek in Oberlin College in 1879, and president of Berea College 1893. He has published: 'Inductive Studies in Oratory'; 'Greek Primer.'

Frost, the moisture in the atmosphere crystallized or congealed by the cold, upon the earth's surface, or upon various objects and surfaces situated or existing upon it, as grasses, shrubs, trees, window panes, etc. The various phenomena of hoar frost, window frost, etc., grouped under this head, occur over a large portion of the land surface of the earth. In the United States, hoar frosts often occur during the spring and autumn months, over the whole northern portion of the country, and more rarely also in the Southern States, sometimes causing much damage by freezing and injuring the young corn sprouts and early fruits and vegetables. Frosts occur only during calm, cold nights when the temperature falls below 32° F. In the United States the meteorological conditions usually preceding the formation of frosts are northerly winds, accompanied by high barometer, and especially the coincidence of these conditions with the near approach, or passing, of a storm from the west or southwest. The formation of hoar frost depends in some degree upon surface topography and local causes, occurring much more frequently within the deep valleys leading down from mountain heights, than in broader valleys or level regions. In the former, during calm cold nights, the cold air of the hill and mountain tops, by virtue of its greater specific gravity, flows down and mixes with, or flows underneath and replaces, the warmer, lighter air of the valleys, thus furnishing the conditions favorable to frost formation. The cooling of objects by radiation of heat, and by the evaporation of moisture from them, greatly facilitates the formation of frost. Frost crystallizations exhibit a wonderful variety, both of form and structure. The formation of each of the various types seems to depend upon a great number of meteorological and other conditions, some of them obscure. The temperature of the air, its electric condition, humidity, etc., and also the nature of the substances upon which they form, each seem to exert an influence in determining and modifying their form and structure. Two principal types of hoar frost occur,— the columnar, and the tabular. Commonly, both varieties do not occur simultaneously, but on a given night one or the other type will greatly predominate and form the bulk of the crystals. Frost crystallizations in general greatly resemble those of snow, but because their development is usually restricted in one or more directions by the objects or surfaces upon which they form, the resemblance is segmentary, rather than complete. In general, columnar forms vary from similar snow crystallizations, by virtue of their hollow cylindrical, or cup-like character, and by often attaining to much greater dimensions. Sometimes, during extreme cold, such forms attain a length of many inches. Tabular forms rarely attain perfect symmetry, but exhibit within them air tubes and inclusions, assume crystal forms possessing both close and open structure, and develop upon the

WINDOW AND HOAR FROST.



1. Columnar window frost.
2. The same, cup-like.

6. Branching hoar frost.
8, 9. Membranous window frost, highly magnified

same extremely thin plane as do similar snow crystals. As commonly deposited in spring or autumn, they do not usually greatly exceed in size similar snow forms, but during intense and prolonged cold, as in winter, they attain much greater dimensions. A very beautiful effect is sometimes produced by the deposition upon the trees, shrubs, etc., of a heavy coat of hoar frost. Each limb and leaf and delicate twig is transformed and beautified, and presents a white appearance, as though frosted with silver. During zero weather, large and delicately formed branching tabular crystals, and long, icy needles, form in beautiful pendent clusters upon, and depend from, the rafters and timbers of barns, etc., close to where domestic animals are kept; and also upon ferns and similar plants overhanging icy terraces or ice-covered pools. Similar forms also form directly upon or project from icy surfaces. Even the clouds furnish their quota of frost crystallizations. When low-lying clouds enshroud mountain tops covered by forests, they often deposit a portion of their moisture upon the branches of the trees, commonly in the form of long, granular or fibrous needle-shaped crystals. Fogs, when they occur during hoar frost formation, usually deposit moisture upon the forming crystals in granular form. The most beautiful and varied frost crystallizations are those that form upon the window panes of dwelling houses, etc., in arctic or temperate zones. These fairy-like creations, seemingly in imitation of leaves, feathers, ferns, trees, starry firmaments, tropical forest effects, etc., occur as three distinct entities: the granular, the crystalline, and the membraneous. The latter variety forms only in heated rooms, upon window panes covered with an uncongealed film of water, as a dew-like condensation of moisture. It occurs most frequently in the form of long, curving, feather-like forms, or as an exceedingly delicate membranaceous-like network of diverging and coalescing lines. It is due to a process of crystallization that takes place during the conversion of a film of water into ice. The crystalline variety of window frost forms only upon window panes that are free from water in liquid form. Crystals of this class assume branching, star-like forms (often as four- or six-pointed branching stars), curving filaments, fibrous crystallizations, and those resembling sea-moss, long serrated lines, etc. Many of these are very beautiful and interesting. Some of them develop within minute striations in the surface of the glass and will reappear in the same identical positions upon a given pane, with each renewal. When identical meteorological and other conditions recur again and again, the types of frost coexistent with each will, in general, recur simultaneously with them. During zero weather, if conditions are favorable, the formation and growth of these beautiful frost creations takes place very rapidly. A beautiful and absorbingly interesting experiment consists in melting a heavy coat of window frost off a portion of a window pane (by placing an oil lamp close to it). Only the central portion of the pane should be cleared of all moisture; around this a film of water should be left upon the glass. Soon after the lamp is removed the feather-like membraneous frost will form around the outer edges of the film of water, and quickly radiate in beautiful curves toward the centre of the pane. They stop instantly when they reach the clear glass. Soon minute and delicate serrated crystal lines, or tiny crystal stars, appear upon the clear glass space, and slowly develop, and usually coexistent with them, a thin film of granular texture will be laid down upon portions of the clear glass. The latter is not usually deposited in slow progressive order, but in intermittent order. Large spaces of the clear glass are often covered simultaneously, by a succession of auroral-like flashes; each flash, in the twinkling of an eye, spreading a thin granular film upon unoccupied portions of the glass. Singularly enough, the granular deposit does not form near where the true crystalline frost is, the latter repels the former and prevents its formation upon the spaces immediately surrounding it.

The phenomena included under the title frost, as commonly accepted, are understood to include both the processes of freezing and the mechanical effects produced thereby. Considered under this broad definition, frost plays an important part in the economy of nature, both beneficent and otherwise. It enters the crevices and minute cracks in the rocks and rends the rocks apart; and is thus an important agent in aiding and hastening their disintegration, and in converting them and the solid materials of the earth into soil. Its beneficent action in loosening and pulverizing the soil, by entering it and forcing the particles of compacted soil and clods apart through its expansive action upon the particles of moisture disseminated therein, is well known, and is of inestimable value to agriculture and to humanity. The damage sometimes done to vegetation, trees, etc., through the frosts entering them, and rending their fibres, cells, etc., apart, is often very great, and partial failures of crops such as corn, vegetables, fruits, etc., are due to this cause. As any considerable motion of air, the presence of clouds covering the sky, or the placing of a light covering, as of cloth or similar material, over the objects to be protected, greatly reduces or prevents the formation of frost upon them and of injury thereby, artificial preventives are often resorted to. Sometimes smoke-producing fires are built around or within enclosures or fields containing plants, fruits, or vegetables, and light, tent-like coverings are placed over small fruit trees, shrubs, etc., and other tender vegetable or plant growths, and thus the damage by frosts is prevented, or minimized. See also SNOW.

W. A. BENTLEY,
Author of 'Snow and Snow Crystals.'

Frost, Arthur Burdett, American illustrator and author: b. Philadelphia 19 Jan. 1851. He studied under Thomas Eakins in the Academy of Fine Arts, Philadelphia, and coming to New York secured employment on the 'Graphic,' and later entered the studio of Harper and Brothers. In 1877 he went to England, and in 1900 he exhibited at the Paris Exposition. His early work was full of interest and attracted much attention, and his later work showed the spirit of the true artist. He has published: 'Stuff and Nonsense' (1888); 'Bull Calf and Other Tales' (1892); 'Sports and Games in the Open'; and 'Golfers' Alphabet.'

Frost-bird, or **Frost-snipe,** a stilt sandpiper (q.v.).

Frost-bite. See CHILBLAIN; COLD.

Frost-fish, a name given to various fishes, because they appear at the time of early frost, as does the tomcod (q.v.) so called in New England. The frost-fish of New Zealand is one of the scabbard-fishes (q.v.).

Frostburg, Md., a town in Allegany County, picturesquely situated on the Cumberland & P. R.R.; about 2,200 feet above the level of the sea. It has large foundries, planing-mills, and fire-brick works, and an extensive trade in coal. The city controls its own water supply. The government is controlled by a mayor, chosen annually, and a city council, both provided for under the charter of 1870. Pop. (1900) 5,274.

Froth-fly, or **Froth-hopper**. See FROGHOPPER.

Froth'ingham, Arthur Lincoln, American archæologist: b. Boston, Mass., 21 June 1859. He was educated in Rome, Italy, and at Leipsic; lectured on archæology at Johns Hopkins University in 1882–6; and became professor of archæology and the history of art at Princeton University in 1887. He founded the 'American Journal of Archæology' in 1885; and was associate director of the American School of Classical Studies, Rome, in 1895–6. His publications include: 'A History of Sculpture'; 'Mediæval Art Inventories of the Vatican,' and various monographs on Syria.

Frothingham, Ellen, American translator: b. Boston, Mass., 25 March 1835; d. there 11 March 1902. She was a daughter of Rev. N. L. Frothingham (q.v.) and inherited strong literary tastes, particularly in the direction of German literature. Her first published work was a translation of 'Nathan der Weise' (1868), usually ranked as the best English version of Lessing's famous drama. She also published translations of Goethe's 'Hermann und Dorothea' (1870); Lessing's 'Laokoon' (1874); Grillparzer's 'Sappho' (1876); Marie-Herbert's 'Poems of Therese' (1899).

Frothingham, Nathaniel Langdon, American Unitarian clergyman and religous writer: b. Boston, Mass., 23 July 1793; d. there 4 April 1870. He was graduated from Harvard in 1812 and entering the ministry was pastor of the First Church in Boston 1815–50. He was author of: 'Deism or Christianity'; 'Sermons in the Order of a Twelvemonth' (1852); and 'Metrical Pieces' (1855–70). He was one of the earliest American students of German. His writings are marked by grace and refinement.

Frothingham, Octavius Brooks, American clergyman: b. Boston, Mass., 26 Nov. 1822; d. there 27 Nov. 1895. He was a son of N. L. Frothingham (q.v.), and was graduated from Harvard in 1843, and from the Cambridge Divinity School in 1846. His radical views led to the resignation of his pastorate in the North Unitarian Church, Salem, Mass. He was pastor in Jersey City 1855–9; then organized the Third Unitarian Church in New York, where he preached very radical and advanced views till his resignation in 1879. The remainder of his life was devoted to travel and literary pursuits, his home being in Boston. His works were: 'Stories from the Lips of the Teacher'; 'Stories from the Old Testament'; 'The Religion of Humanity'; 'The Cradle of the Christ'; 'Memoir of W. H. Channing'; 'The Safest Creed'; 'Beliefs of the Unbelievers'; 'Creed and Conduct'; 'The Spirit of the New Faith'; 'The Rising and the Setting Faith'; 'Lives of Gerrit Smith, George Ripley, Theodore Parker'; 'Transcendentalism in New England'; 'Recollections and Impressions'; etc.

Frothingham, Richard, American historian: b. Charlestown, Mass., 31 Jan. 1812; d. 1880. He was at various times a member of the State legislature, was mayor of Charlestown 1851–3, and managing editor of the Boston *Post* 1852–65. He published: 'History of Charlestown' (1848); 'History of the Siege of Boston' (1849); 'Life and Times of Gen. Joseph Warren' (1865); 'The Rise of the Republic of the United States' (1871).

Froude, frood, **James Anthony**, English historian: b. Dartington, Devonshire, England, 23 April 1818; d. Salcombe, Devonshire, 20 Oct. 1894. He was the youngest son of Archdeacon R. H. Froude, rector of Dartington, and was educated at Westminster and Oxford. His brother, Hurrell Froude, was one of the leaders in the "Oxford Movement" and both were influenced by Newman, the earliest work of the younger Froude being a contribution to the 'Lives of the Saints,' edited by Newman. He soon emerged from Tractarian influence, however, and for the rest of his life remained indifferent to the Church in which he had been reared. The first two volumes of his history of England appeared in 1856 and at once attracted marked attention, both favorable and adverse, on account of the brilliant style and the audacity of the writer's opinions. The book flatly reversed many historical judgments, and interpreted motives in a manner more common now than then, but very startling to readers in the middle of the 19th century. His attempted vindication of Henry VIII. must be accounted a failure, brilliant and able as it is, and although it is a most striking portrait of Henry that he has painted, it cannot be called a faithful likeness. His treatment of Mary of Scotland is certainly hostile, and has been met with severe criticism. His judgment of Elizabeth, though far from impartial, is more nearly accurate than that of either of the other two personages. He excelled in vigorous, dramatic presentation of men and events, and in the judgment of sober critics appears to have cared much more for picturesque narrative than for absolute historical accuracy. As a historian he will long continue to be read and admired, but his apparent indifference to historical truth at times will not permit of his inclusion in the first rank of historians. He visited the United States in 1872 on a lecture tour, his lectures being afterward published with the title of 'English Misrule in Ireland.' In 1874 he visited South Africa, his impressions being later given to the world in lectures at Edinburgh, and in 1882 made an extended tour through Australia, the West Indies and the United States, the literary outcome of which were: 'Oceana' and 'The English in the West Indies.' He was the friend of Carlyle, whose literary executor he became, and his life of the Sage of Chelsea, his 'Reminiscences of Carlyle' and 'Letters and Memorials of Jane Carlyle' have excited a vast amount of controversy. In 1892 Froude succeeded the historian Freeman as regius professor of history at Oxford, his lectures in that capacity afterward constituting his volume on Erasmus. It may be said that Froude was more distinctly a man of letters than a historian. He is always readable even when one is forced to dissent from him most strongly, but he touched on too many themes to give to the writing of history the devotion toward it so characteristic of such men as the late Samuel Rawson Gardner, Prof. Freeman, or John Richard Green, and he was temperamentally indifferent to the claims of entire truthfulness. He may not have consciously distorted facts, but his selection of certain details and suppression of others for the apparent sake of making the particular hero in question brighter, or the particular villain darker, does not commend itself to the lover of truth for its own sake. His important works include: 'Shadows of the Clouds,' published under the pseudonym "ZETA" (1847); 'The Nemesis of Faith' (1848); 'The Book of Job' (1851); 'The History of England from the Fall of Wolsey to the Death of Elizabeth' (1856–70); 'Short Studies on Great Subjects' (1867); 'Inaugural Address Delivered to the University of St. Andrews' (1869); 'The Cat's Pilgrimage' (1870); 'Short Studies: Second Series' (1871); 'Calvinism' (1871); 'The English in Ireland in the 18th Century' (1872–4); 'Short Studies: Third Series' (1877); 'Life and Times of Thomas Becket' (1878); 'Cæsar: a Sketch' (1879); 'Bunyan' (1880); 'Two Lectures on South Africa' (1880); 'Reminiscences of the High Church Revival' (1881); 'Short Studies: Fourth Series' (1882); 'Reminiscences of Thomas Carlyle' (edited 1881); 'Thomas Carlyle: History of the First Forty Years of his Life' (1882); 'Letters and Memorials of Jane Welsh Carlyle' (edited 1883); 'Thomas Carlyle: History of his Life in London 1831–81' (1884); 'Life of Lord Beaconsfield' (1890); 'The Divorce of Catharine of Aragon' (1891); 'Life and Letters of Erasmus' (1894). The first two volumes named above he attempted to suppress in later life, and succeeded with 'The Shadow of the Clouds,' which cannot now be found anywhere.

Frozen Strait, the passage which connects Repulse Bay and Fox Channel, and separates Melville Peninsula and Southampton Islands. It is from 10 to 20 miles wide and in lat. 65° N. This strait is frozen, as its name indicates, nearly all the year, although some bodies of water farther north are free from ice from two to five months each year.

Fructidor, frük-tē-dōr, signifying the month of fruit and gold, was the name in the French republican calendar of 1792–1806, for the 12th month of the republican year. It commenced on 18 August and ended on 16 September, and was the third summer month.

Fruit, that part of a plant in which the seed or other reproductive element is perfected; in ordinary plants the matured ovary with its pericarp and other parts. This botanical usage is largely extended in popular usage, with the central idea that the fruit is a product of the plant useful to man.

Formation of Fruit.— Starting with those simplest flowers in which all the carpels are separate, we find the stigma and style usually withering back as no longer of service, and the ovary enlarging, as the fertilized ovules grow up into seeds. But in many such simple flowers more ovules are produced than are fertilized, and generally also more fertilized than can be developed up to maturity; hence the reduction of the ovules is exceedingly common, as is simply exemplified in the horse-chestnut.

A second principle of fruit-making is reached through keeping in mind the origin of the ovary from one or more carpellary leaves, of which the individual development has been so greatly checked that they remain closed upon the ovules, and frequently even coalesce with each other from the base upward, so forming a many-celled ovary. Yet the tendency to their individual expansion is not lost; in many monstrosities, and normally a few types, such as the common mignonette, the carpellary leaves early begin to expand, so opening the ovary and exposing the seeds long before ripeness. Far more frequently, however, this final development of the carpellary leaves is delayed until the growth-processes of the seed and fruit have ended, and it is, therefore, accompanied, or even preceded, by their death; the separation often indicating the lines at once of leaf-margin and leaf-fall.

In the best-developed carpellary leaves, such as those of the more floral *Ranunculaceæ*, we naturally find the ovary opening along the line of its united ovule-bearing margins. This is what is termed a follicle.

Since, however, the ovules are on the united margins, the midrib tends to interpose little or no resistance to a tendency to split or tear along its fold. Such "dehiscence by both dorsal and ventral suture" gives us the legume or pod. Another type is the *siliqua* (or when shortened and broadened the *silicula*) of *Cruciferæ*. Here the placental edges of two united carpels develop a transverse septum which divides the fruit; and this is left when the lobes split away, as so familiarly in honesty.

Among united ovaries which readily split open at the united margins (*septicidal*) we may note that of gentian (q.v.), while the more familiar three-celled ovary of a violet, with its parietal placentation, gives a characteristic example of dehiscence along the midribs of the united carpels, so opening the loculi (*loculicidal*). In the five-celled capsule of the geranium (q.v.) the carpellary leaves separate not only at the sides but also at the base, so curling inwards

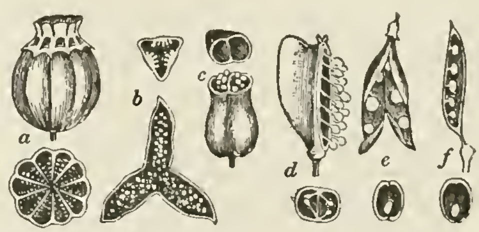

FIG. 1.— *f*, follicle; *e*, legume; *d*. silicula; *c*, capsule of henbane; *b*, of violet; *a*, of poppy.

and projecting the seed. Where, however, the placentæ remain more or less completely upon a central column from which the valves are detached, the dehiscence is said to be septifragal.

In henbane (*Anagallis*), etc., the dehiscence is circular (*circumscissile*). Many-celled capsules are numerous in which the leaf-opening or dehiscence is greatly reduced from completeness; witness the valvular and porous dehiscence of the *Lychnis* and of the poppy respectively. Such cases clearly point us to those of carpels which do not open at all. Such indehiscent fruits, produced from carpels so persistently embryonic, are usually short, few or one-ovuled, and, for the most part, little specialized. Thus the follicle of the *Ranunculaceæ* of more specialized floral character becomes shortened into the one-seeded indehiscent *achene* of the anemone or buttercup. In the achene of the grasses (which similarly represents the capsule of the ancestral lilies) the thin dry pericarp becomes inseparable from the seed-coat (hence the term caryopsis); in many trees (for example, hazel) it becomes hardened and thickened as a nut. In composites, too, the achene is practically a nutlet, although often (on account of its being inferior) superfluously termed a cypsela. Less extremely reduced representatives of the various multicellular ovaries to which such fruits correspond are afforded us by borages or labiates, in which the two-celled ovary of the primitive solanaceous type becomes, as in thorn-apple, etc., subsequently divided into four parts. In *Umbelliferæ* we have another characteristic form of schizocarp, as all such fruits are termed which split up without truly carpellary dehis-

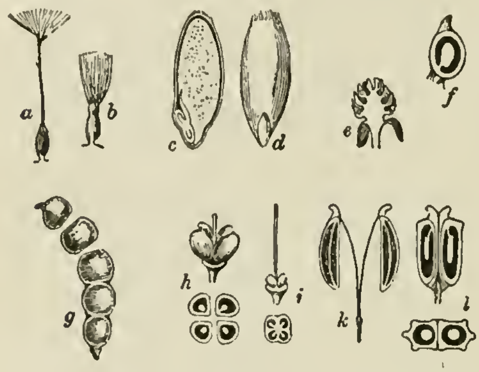

FIG. 2.— *e, f*, achenes of buttercup; *c, d*, caryopsis of oat; *a, b*, achenes with pappus; *g*, "lomentum"; *i, h*, nutlets and ovary of borage; *l, k*, umbelliferous type of schizocarp.

cence, although the tendency to this can be seen still to have some influence. Here the separate portions (or mericarps), each resembling an achene or nut, are two in number, and when ripe swing off upon the ends of a forked carpophore.

So far all our fruits have been dry; but a new physiological "principle of fruit-making" is necessary to comprehend those in which the pericarp is succulent. For, just as the effect of fertilization is seen in many animals to extend beyond the mere ovum to the parent organism, and also in many of the lowest plants, so it is in the case before us. Even in fruits which are dry on ripening we have seen that the ovaries or loculi, on which no demand is made for the growth of fertilized ovules, become reduced or disappear. Sometimes it may be merely the coats of the seed (as in the pomegranate) which undergo the complex histological and chemical changes which we sum up as those of succulence and ripening; at other times largely their placentas, as in the gooseberry and currant. Yet, as in these, the innermost tissue of the ovary may become succulent as well. In the orange also the familiar succulent tissue in which the seeds are immersed are the enlarged succulent cells of the endocarp; the grape, too, gives a characteristic example of soft endocarp. These

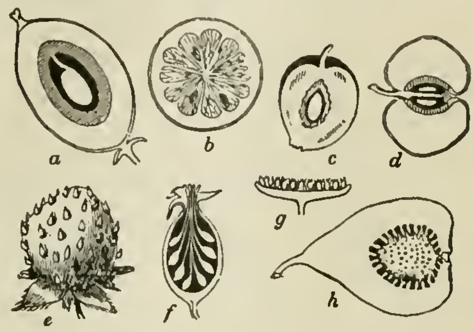

FIG. 3.— *a*, drupe; *b*, orange; *c*, a single drupelet of bramble; *d*, pome; *e*, strawberry; *f*, hip of rose; *g*, capitulum of Dorstenia; *h*, fig.

may all be classed as berries or baccate fruits, for the distinction of the succulent product of an inferior ovary as a berry, from that of a superior one, as a uva or grape, need hardly be allowed to increase our nomenclature. A pepo is merely a berry in which the epicarp is thick and tough (for example, a melon, with which the orange and pomegranate may be reckoned). Where the succulent change, instead of primarily affecting the deeper tissues of the fruit, and so producing a berry, leaves the endocarp hard, we have the drupaceous or stone-fruit. The endocarp here forms a more or less complete "stone" around the kernel or seed, the difference from an ordinary nut being due to the succulence of an outer layer (mesocarp), with a more or less leathery outer skin, the epicarp. The plum, peach, and nectarine are the most obvious examples; but, since we may have many carpels thus transformed, we may have an aggregate fruit or syncarp of tiny drupes. The walnut and even cocoanut are hence not true nuts (see NUT). The immature succulent mesocarp of the former is familiar in pickles, the walnut we crack being merely the stony endocarp (which is exceptionally specialized in being set free by the bursting of the mesocarp on ripening). The familiar cocoanut fibre is the fibro-vascular tissue of the mesocarp, the fruit being thus broadly comparable to a peach which has wizened while still young and stringy. But, as in the kindred grass, the coats of the ovule further unite to the endocarp.

The numerous carpels of the strawberry, although, of course, corresponding to those of the allied raspberry, remain mere nuts; here, however, the subjacent portion of the floral axis or receptacle becomes succulent. In the perigynous or epigynous *Rosaceæ* the same change may take place; hence the rose-hip is a succulent axis, enclosing a multitude of nuts. The apple or "pome" is more akin to the drupe, since the carpels, here deeply sunk in the upgrown floral axis, develop a hard endocarp corresponding to the stone of a drupe.

Fertilization may even be followed by succulent or other thickening of the floral envelopes, or of the floral axis with subjacent bracts — the various cupules, as of acorn, beech, hazel-nut, etc., being of this nature. Or we may have a spurious fruit developed at the expense of an entire inflorescence, as in the pineapple, Dorstenia, and fig.

Chemical Composition of Fruits.— Our knowledge of the chemistry of fruit may be dated from the analyses of Fresenius (1857). But because of the innumerable varieties of almost every cultivated fruit, the effects of different soils and climates upon these, and still more of the fluctuation due to better or worse seasons, the results of any one chemical analysis would tend to convey an idea of undue precision. Thus — for example, while the ratio of sugar to free acid in certain grapes of an ordinary wine-year was found to be 16 to 1, in a very bad year it sank to 12, and in a very good year rose to 24. Hence a broad outline may be of more general use than the statistics of any one analysis.

The percentage of water may be taken as varying from 78 to 80 in the grape and cherry, as from 82 to 85 in plums, peaches, apples, and pears, as 82 to 87 in brambles, currants, etc., and as much as 95 in the watermelon. The proportion of insoluble residue — skin and cellulose, stone and seed — obviously also varies greatly with succulence and ripeness, but may be taken, one fruit with another, at not less than from 4 to 6 per cent. Unripe fruits may contain a notable proportion of starch, but this is fermented on ripening into glucose and other sugars, fruit-sugar, grape-sugar, cane-sugar, or (in *Sorbus*) sorbin. The only fruits which retain starch in important quantity are those of the banana, breadfruit-tree, and baobab; hence the exceptional nutritive value of these. The olive alone yields a notable proportion of oil. The proportion of sugars varies exceedingly, dates, dry figs (48 per cent), and raisins (56 per cent), again very important foods, heading the list. Grapes, of course, stand high, from 12 to 18, indeed sometimes as much as 26 per cent, cherries from 8 to 13, apples 6 to 8, pears 7 to 8, plums 6, red currants 4.75, greengage 3.5, peach and apricot only 1.5. The proportion of pectin bodies is, however, exceedingly notable, especially in fruits such as the three last named. In unripe fruits (as also in roots) we find pectose, a body apparently related to cellulose, but easily transmuted by a natural ferment or by boiling with dilute acid into pectin, $C_4H_6O_4$, and its allies. These are all more or less soluble in water, with which they readily form a jelly (whence the peculiar consistency of our fruit-preserves). The proportion of soluble pectin and gum varies considerably and is of great importance to the blandness and agreeableness of fruit, the harder and more common apples having considerably less than 3 per cent and the best rennets nearly 8. The harsh red currant, indeed, like berries in general, has exceedingly little (0.25 per cent); while the apricot has as much as 9, the greengage 12, and the peach 16 — a circumstance which explains the peculiarly melting quality of these fruits, especially the last-named. The free acid also varies greatly, from 2.4 per cent in the red currant, 1.4 in the raspberry, and nearly as much in the sourest cherries, to 0.5 in sweet cherries and a minimum of 0.1 or less in the sweetest pears. That of apples and of grapes, of course, varies greatly, but both may generally be taken at from 1 to 0.75, while the apricot and peach stand at 0.3 or 0.4. The acid is primarily malic, but citric, acetic, oxalic, tannic, and others may also be present.

The quantity of albuminoids is of course small, in fact, inadequate to render most fruits a staple food. Yet it is by no means inappreciable, ranging from nearly .5 per cent in the majority of fruits to .7 or .8 in the grape (2.7 in raisins), and above 1 in the melon and tomato. Hence to acquire albuminoids equal to those of one egg we must eat 1½ pounds of grapes, 2 pounds strawberries, 2½ pounds apples, or 4 pounds pears. To replace 1 pound starch = 5½ pounds potatoes, we need 5.4 pounds grapes, 6.7 of cherries or apples, or 12.3 of strawberries. See FOOD.

The quality of fruits depends largely upon the proportion of sugar, gum, and pectin to free acid, largely also upon the proportion of soluble to insoluble matters, but in very great measure also upon the aroma. This quality is due to the presence of characteristic ethers, often accompanied by essential oils, although not of course in ponderable percentage. Cultivation and selection operate strongly on all three factors.

Keeping of Fruit.— Many of the finest fruits undergo very speedy decomposition, which, as distinguished from the intrinsic processes of ripening, is due to the attacks of bacteria, molds, or yeasts; and the problem of their preservation is therefore primarily one of preventing these. In damp and stagnant air, especially with considerable or frequent changes of temperature, these fungus pests multiply with special readiness; hence a fruit-room must be cool and shady, yet dry and airy, and the fruit carefully gathered rather before full ripeness, handled so as to avoid in any way bruising or tearing the skin, and laid out and occasionally looked over so that rottenness in one may not affect the rest. Under these conditions apples especially may be kept for many months; indeed many varieties of fruit — for example, winter-pears — require these conditions for satisfactory ripening. On antiseptic principles we see how it is that the dense-skinned and wax-coated grape can be so largely imported in sawdust, or how unripe gooseberries, and even very perishable pears can be kept for months similarly packed in well-sealed jars in a cool place. The process of preserving with sugar in jars promptly covered up is similarly an antiseptic one; but in the systematic application of antiseptic principles we may still look for considerable progress in the preservation and transport of fresh fruit upon a large scale. The method of drying fruit has also been in use from remote times, especially with dates, figs, and raisins.

See CIDER; FRUIT, CULTIVATION OF; FRUIT TRADE, THE AMERICAN; FRUITS, COLD STORAGE OF; GARDEN; and articles on the various fruits, as APPLE, CHERRY, PEACH, etc.

Consult works on fruit-culture by Bailey (1897); Burbidge (1881); Cheal (new ed. 1892); Downing; Du Breuil (1886); Fish (1882); Fuller (1881); Hogg (1885); Roe (1886); Thomson (1881); Wood (1880).

Fruit, Cultivation of, the planting, protecting and ripening of fruit for food. The skilful labor of the cultivator has so greatly improved the original indigenous wild fruit of different zones, that it is worth while to consider from the beginning this gradual process of amelioration. In the tropics, the fruits grow spontaneously with little need for cultivation. The plantain and banana, the guava and sapodilla yield their refreshing fruit without the aid of man. In temperate climates the wild fruits are scarcely edible. Wild cherries, crab-apples, and wild grapes are harsh and sour. By cultivation the crab is changed into the golden pippin, the wild pear into a Bergamotte, and the wild grape into a Concord cluster. There are two or three axioms which underlie all principles of successful fruit culture. The wild fruits if left in their natural state reproduce themselves only. The first step is to domesticate a new generation by sowing their seeds amid new conditions. Take for instance the common wild cherry (*Cerasus avium*). Plant its seed in garden soil and a tree of a different kind appears; each seedling differs from the original plant, and some few will be superior to it. When once this variety appears, selection of the best among many will gradually lead to perfection. This perfection we see in the pears, apples, grapes, and plums of to-day. But only by assiduous care can the present standard be kept up. "There can be no doubt," says Dr. Lindley, "that if the arts of cultivation were abandoned for only a few years, all the annual varieties of plants in our gardens would disappear and be replaced by a few wild forms." Hence the necessity for constant and vigilant cultivation of our present fruits.

Dr. Van Mons, professor at Lourain, was the first to make any great discoveries in ameliorative cultivation. In 1823 his nurseries contained 2,000 seedlings of merit. His theory was that all fine fruits are artificial products. All that wild nature can produce is a healthy, vigorous tree, and a fruit sufficient to protect perfect seeds for continuing the species. The object of cultivation is to enfeeble the tree's excess of vegetation, to diminish the size of the seeds and increase the quantity of flesh or pulp. The older the tree the more likely are its seedlings to return to the wild state. While the seeds of the oldest varieties of good fruit mostly yield inferior sorts, seeds taken from recent varieties of bad fruits, and reproduced uninterruptedly for several generations will certainly produce good fruit. A most important aid in producing the desired varieties is by cross-breeding. This is effected by taking the pollen of one blossom and dusting it upon the pistil of another from which the original stamens have been removed. The development of plums and apples has been much aided by this process, and Mr. Coxe has described an apple which was a cross between a Newton pippin and a russet. It was in appearance half the one and half the other, one end tasting like a pippin, the other like a russet. After a new and choice variety of fruit has been obtained, and of which probably, there is only one tree, it may be propagated by grafting and budding. Grafting is as old as the early Roman Republic; it was also practised by the ancient Greeks. The French orchardists are most expert in it and practice it in more than 50 different ways. The proper time for grafting is in the spring, as soon as the sap stirs, which commences earliest with the cherry and plum, and ends with the apple and pear. Budding differs from a common grafting. Merely a bud, with the smallest possible quantity of the adjoining bark and wood, is inserted in the incised tissues of another tree. All stone fruits are difficult to graft, but can be budded with ease. Fruit trees are also propagated by cuttings, that is, by taking twigs from a good variety and setting them out to take root; or by layers and suckers. A layer is a cutting, part of which is sunk in the ground, while the end is not detached from the parent tree. Suckers are shoots sent up from the root and easily detachable so as to be planted.

The grape vine is almost invariably propagated by cuttings, as are gooseberries and currants. But one of the most important considerations for the fruit cultivator is the soil and its preparation. No good fruit can be produced on dry or barren soil, and fertilizing, watering, and thorough sifting of the orchard or vineyard bed is absolutely necessary for success. Almost equally important is the slope and aspect of the land to be occupied. The warding off of diseases and insect pests from growing fruit also calls for great care on the part of the fruit cultivator.

Fruit-bats, the bats of the family *Pteropodidæ*, called also fox-bats or flying-foxes, because of their fox-like heads and faces. They compose one of the two grand subdivisions of bats, the *Megachiroptera* (see Bat), confined to the tropical parts of the Old World. These are the largest of all bats, and differ from the other bats in that they are entirely frugivorous. There are several genera, the most important being the genus *Pteropus*. The best-known species is the Indian fox-bat (*P. medius*), common in India, Ceylon and neighboring islands. As evening falls these bats fly out of the branches, where they have hung, like great black fruits, all day, and start on their nocturnal depredations, which they continue until dawn, when they return to their homes, — thousands sometimes forming a single colony, wrangling and jostling one another for the most desirable places on the limbs. Once settled they hang, head down, until day is over. They are so numerous and so destructive to crops in certain localities that they are hunted vigorously; but, even when they are shot by thousands, the numbers do not seem to be materially decreased. There are certain species that sometimes feed on flowers as well as fruit; but this is not generally the case. The Indian fruit-bat, Lyddeker says, will greedily drink palm-juice from the pots hung on the trees to collect it, and at times, individuals have been found at the foot of the trees quite helpless from intoxication.

The spread of wing is from 4 to 5 feet in the Indian and Malay species; smaller than these are the ugly-faced *Harpyias*, so named because of the supposition that they were the "harpies" of the old mythology.

Fruit-crows, the somewhat crow-like birds of that section of the South American family *Cotingidæ* called *Gymnoderinæ*. This section contains a number of most unusually ornamented birds, such as the bill-bird, and umbrella-bird (qq.v.), and most of them have bare spaces, or wattles, about the head. They are woodland birds whose habits are little known, but they feed mainly on seeds and berries, and make large nests in trees and bushes.

Fruit-fly, any of the flies of the family *Trypetidæ*, whose eggs are laid and maggots are bred in fruit, for example, the apple-maggot (q.v., under APPLE), or in plant-stems. The Mexican orange-worm (see ORANGE INSECT-PESTS) is another well-known species, while the galls so frequently observable upon the golden-rod are the work of a third (*Trypeta solidaginis*). The maggots remain within the fruit or gall during the winter, then, if not already thrown down, creep out, drop to the ground, and transform into pupa and imago. They vary in color from buff to brownish-black, and are frequently beautifully banded or spotted. See also POMACE-FLY.

Fruit growing. Fruit growing as a distinct phase of agriculture is of comparatively recent development in America. The early settlers, who were located chiefly along the Atlantic Coast, in the Lake Region and the Mississippi Valley, found an abundance of wild fruits of many species similar to those known to them in their European homes, and in many cases superior in size, flavor, and quality, to the wild fruits of Europe. This fact encouraged them to introduce the cultivated forms and varieties of the Old World, so that as soon as regular and reliable means of communication were established with the mother countries, seeds, scions, and young trees of the choice varieties of western Europe and the Mediterranean region were secured for testing in practically all of the colonies from the Saint Lawrence Valley southward to Florida. Naturally these early introductions were made in a desultory way and the larger portion of them failed through inability of the types and varieties developed in Europe and western Asia to endure the more intense climatic conditions that prevailed in similar latitudes on the American continent east of the Rocky Mountains. The art of grafting was evidently known to some of the early colonists for as early as 1647 it is recorded that the apple was grafted on wild stocks in Virginia, where in 1686, one orchard of 2,500 apple trees is known to have existed. In 1647 Governor Stuyvesant planted on Manhattan Island a grafted tree of the Summer Bonchretien pear, said to have been imported from Holland. This tree, which is the earliest recorded grafted tree planted by the colonists, stood at what subsequently became the corner of Third avenue and Thirteenth street, New York city, until it was accidentally broken down by a dray in 1866.

The early efforts with orchard fruits were devoted chiefly to the introduction of such as would yield a supply for the family of the owner, rather than to develop a commercial industry. About the only exception to this was the apple, which was planted quite largely in many sections for cider making. This was especially true from Virginia northward, one Massachusetts village, consisting of forty families, having attained the distinction early in the 18th century of producing «near ten thousand barrels of cider.» The early efforts toward the introduction of wine-grapes are related under GRAPE CULTURE.

Bailey states that there are not less than 150 species of native North American fruits fairly well known, of which not more than 40 are of commercial importance. These cover a very wide climatic range, from the hardy plums and apples of the far north to the figs, oranges, and lemons of California, and the oranges, pineapples, mangoes, guavas, and other tropical fruits of Florida. The great diversity of soil and climate render it possible to produce in the United States, Canada, and Mexico, practically all of the important fruits and nuts known to commerce throughout the world, so that America has become in large degree independent of the Old World in the matter of fruit supply. The chief exceptions until recently have been certain sub-tropical fruits and nuts, such as oranges, lemons, dates, figs, almonds, and walnuts, but production of these has shown such rapid increase during the past few years as to largely displace the former imports of these fruits. For convenience in discussion, the various fruits have been grouped by Prof. L. H. Bailey, ‹Principles of Fruit Growing› (1897), into four classes, which may be summarized as follows:

Class I.— Tree-fruits, comprising about 100 species divided into 13 sub-classes.

Class II.— Vine-fruits, comprising the grapes and passi-floris, divided into two sub-classes.

Class III.— Small-fruits, comprising about 20 species, divided into three sub-classes.

Class IV.— Herb-like fruits, comprising about 10 species, divided into four sub-classes.

While the effort to produce a home supply was evident at a very early day, the development of a large commercial fruit industry can hardly be said to date earlier than 1850. Before then plantings of orchard fruits were limited to the needs of the farmer's family or the nearby village or city, except in a few localities where apples and grapes were grown for the manufacture of cider and wine respectively. Each improvement in transportation has been followed by a marked increase in fruit planting and production, frequently at points remote from those where the product is consumed. This is most noticeable in the case of the more perishable fruits, such as the strawberry and peach. The planting of these for the supply of the cities along the Atlantic seaboard has gradually spread southward and westward until there are large shipments of these fruits each year from points as far south as Florida, and as far west as Texas. The fruits grown in the drier climate of the Pacific coast have been found to endure transportation better than those of more humid regions, and their peaches, plums, apricots, cherries, grapes, and pears, as well as the citrous fruits are marketed with little risk in eastern cities. The perfecting of the refrigerator-car service on land has played an important part in this development, and in conjunction with refrigerated compartments on ocean steamers, has resulted in the beginning of what promises to become a very important export trade in such fruits as peaches, pears, plums, and possibly some other perishable fruits that fail to endure the vicissitudes of ordinary transportation.

Types and methods.— The early efforts at commercial fruit culture in America were mainly based upon European varieties, and the methods of culture were such as were followed in the Old World. The unsatisfactory behavior of a large proportion of the imported varieties gradually led to the substitution of seedlings of American origin, which, in the case of most of the important species, have proved much better adapted to American conditions. Prior to the middle of the 19th century most of the American varieties of orchard fruits that came into prominence were accidental seedlings, which were observed to yield fruit of special value, and were, therefore, named and propagated as commercial sorts by their discoverers, for examples, the Baldwin, Ben Davis, and Winesap apples, and the Catawba grape. In recent years attention has been devoted to the breeding of sorts better suited to special conditions or for specific uses, and rapid progress has been made along this line in strawberries, grapes, plums, and peaches. At first these efforts consisted chiefly of the growing of seedlings from seed of choice varieties without effort to control the male parentage, but more recently much definite work has been done in breeding through the cross-pollination of varieties possessing the characters that are desired in the offspring. Notable work in this line has been done by Munson of Texas, Burbank of California, Webber of the United States Department of Agriculture and others. The result of the tendencies above indicated has been to create a distinctive American pomology, consisting largely of Old-World species but mainly of varieties of American origin. In the case of the strawberry, the raspberry, both black and red, the blackberry, dewberry, and gooseberry, the plums of the Mississippi Valley region and the grapes grown east of the Rocky Mountains, the species as well as the varieties are largely of American origin. (Consult Bailey, 'Evolution of Our Native Fruits.')

The gradual change in varieties cultivated has been accompanied by a radical change in methods of culture. With the development and improvement of agricultural implements, hand labor has largely given way to horse-power methods so that a large acreage is now effectively managed with few hands at comparatively small cost, except during the harvesting and marketing of the crop which, with most of the fruits, is still done by hand labor. The prevention of injury by fungous diseases and injurious insects has necessitated the development of economical and effective means of combating these pests. While radically different treatment is needed for different pests, the last decade has witnessed a very general resort to the use of fungicides and insecticides (qq.v.) applied to the trees or plants in the form of sprays.

Methods of cultivation and pruning differ widely for different fruits and in different sections of the country, but in recent years there has been a marked tendency toward clean cultivation of the soil during the early part of the growing season to insure vigorous growth of wood and foliage, followed by the sowing of some leguminous or other cover crop, which is allowed to grow during fall and winter for plowing under the following spring. This practice, where pursued, aids in maintaining the proper proportion of humus in the soil, and when supplemented by applications of phosphoric acid and potash as needed, promotes a healthy and vigorous growth capable of producing normal crops of well-matured fruit. While the pruning of orchard trees to fixed and arbitrary forms is as yet little practiced in America, more attention is paid each year to pruning for specific purposes, such as the stimulation of growth, the setting of fruit buds or the reshaping of the tree or vine. In most sections the practice of heading trees low is on the increase, such trees being found to endure greater climatic extremes without injury, and the accessibility of their most remote branches greatly facilitates their treatment with sprays and the harvesting of their crops.

The necessity for shipping long distances has resulted in the development of methods of marketing fruits which differ widely from those practiced in the Old World. One of the most marked features is the almost universal use of "gift" packages. For most fruits except the cheaper and lower grades of apples and pears, chiefly used for cider making, evaporating, or canning, special light wooden packages are made of convenient size and form in which to pack the fruit for shipment. In most cases these packages go with the fruit, no effort being made to return them to the shipper or use them a second time. It is noticeably true that the highest type of grading and packing fruit for shipment is found in those regions which are remote from the consuming centers of population, and to a considerable extent the same is true of the methods of cultivation, pruning, thinning, and spraying, the heavy expense of long shipment necessitating the production of a more attractive product, which will command a price sufficiently high to leave a profit to the grower. The increasing tendency to plant large areas under single direction and management has had the effect to still further systematize the operations and render the product more uniform in size, quality, and marketability from year to year, while in certain localities, co-operative grading and packing are accomplishing similar results.

Orchard Trees and Products, Census of 1900, Crop of 1899.

	Trees.	Bushels.
Apple	201,794,764	175,397,626
Apricot	5,010,139	2,642,126
Cherry	11,943,287	2,873,499
Peach and nectarine	99,919,428	15,433,623
Pear	17,716,184	6,625,417
Plum and prune	30,780,892	8,764,032
Unclassified orchard fruits	2,215,267	630,321
Cider	1,754,927 bbls.	
Vinegar	392,497 bbls.	
Dried and evaporated fruit	144,804,638 lbs.	
Value of orchard products	$83,751,840	

Magnitude of fruit industry.— Comprehensive and accurate statistics of fruit culture in North America are unfortunately lacking, but enough is known regarding certain fruits to indicate the large and growing importance of the fruit industry as will be noted below under the discussion of the several fruits mentioned. The Twelfth Census (1900) showed totals as above for the United States, while the known facts regarding the annual production and sale of

FRUIT GROWING

1 Napoleon cherry trees in California. 2. A West Virginia peach orchard.

1. Birdseye view of a well-cultivated peach orchard. 2. Strawberry growing in Wisconsin.

young trees by American nurseries indicate that orchard planting continues with little abatement.

Commercial apples.— The apple is both the most widely grown and generally liked of the fruits of North America. It is grown to a greater or less extent in every state and territory of the Union and Province of Canada. The range of the varieties of this fruit as to date of maturity is so great that with proper attention to their selection planters in many sections can have a continuous supply of this fruit from their own orchards during at least ten months of the year. Since the development of commercial cold storage (q.v.) and the improvement of railroad transportation from the South, the supply of American grown apples in wholesome condition in city markets is practically unbroken. (See APPLES; FRUITS, COLD STORAGE OF; FRUIT-TRADE.)

Pear and quince.—While the pear has never attained in America the relative importance that it holds in England, France, and Germany, it succeeds well. The varieties of best quality are chiefly of the European type (*Pyrus communis*) and several of the most important are of European origin, such as Bartlett, Flemish Beauty, Anjou, Angouleme, Clairgeau, Louise Bonne. The pear requires a somewhat richer soil and more cultural attention than the apple, and is subject to a bacterial "blight" which it is difficult to control in regions where the tree makes a strong and rapid growth, as in the South. In such regions this type is rapidly giving away to the Oriental type (*Pyrus sinensis*), the varieties of which are derived primarily from the Chinese sand pear. The most important of these are Kieffer and Le Conte — sorts of indifferent quality but thriving and producing crops under conditions where the better varieties cannot survive. Kieffer has been more largely planted in recent years outside of California than any other sort, and is largely used for canning. It is also well adapted to the export trade. The most important commercial pear districts are in western New York, western Michigan, central California, New Jersey, and the Chesapeake Peninsula. In the latter two regions the Kieffer predominates; in the others, Bartlett is the leading commercial sort. The quince is but sparingly grown in a commercial way, except in a few localities in western New York, New Jersey, Pennsylvania, Michigan, and California.

Stone-fruits.— Among the stone-fruits the peach ranks first in commercial importance, though its climatic range is narrower than that of the several types of plums. The rapid development and magnitude of the American peach industry constitute one of the striking features of our fruit culture. Although prior to 1870 commercial peach orchards were chiefly confined to New Jersey and Delaware, large and successful plantings are now found in all the warmer and moister states, so that total crop failures of this delicious fruit have become practically unknown. Single orchards of 100,000 trees are no longer rare, and in some instances more than 300,000 trees are under one management. The major portion of the crop is grown for marketing in the fresh state or for canning, except in California where large quantities are sundried in addition to these uses. The standard sorts of widest distribution are probably Early and Late Crawford, Elberta, Oldmixon, Stump, and Smock. The varieties of the Peento and South Chinese groups are grown chiefly in Florida, while the Spanish, Chinese Cling, and Persian groups, respectively, are grown to the northward, with the Chili type of the latter group as the most thoroughly tested as to winter hardiness.

The various types of plums are found under successful culture over a wider climatic range than any other tree fruit in America, but are of less commercial and economic importance than the apple or peach. The European types are considerably planted in the northern states, especially New York and Michigan, and constitute a very important feature of the fruit culture of the Pacific Coast. The yield of prunes is increasing rapidly, having averaged more than 120,000,000 pounds per annum, from 1898 to 1902 in California alone. In the colder portions of the North, especially in the Upper Mississippi Valley, hardy varieties of the native *Prunus Americana* have been developed, which are proving of great value. Among these are Wolf, Stoddard, De Soto, Wyant, etc. The Japanese varieties, now widely planted, are proving useful additions to our lists, though in some cases very susceptible to injury by the fruit rot (*Monilia fructigena*).

Cherries are widely planted as door-yard trees, but their commercial culture is comparatively limited in the eastern states. The sweet varieties are grown to some extent in western New York, but only in California and Oregon are they largely grown with profit. The leading varieties are Napoleon, grown on the Pacific Coast as Royal Ann and Black Tartarian. The sour varieties have a wider commercial range, and Early Richmond, Montmorency Ordinaire, and English Morello are the leading sorts.

Apricots are but sparingly grown outside of California, where there is a large production for drying and canning, as well as for shipment in the fresh state.

Small fruits.— The strawberry is widely and largely planted for commercial shipment, and fruit grown in the open air is obtainable in city markets from January to the middle of July. It is grown in all the northern states, and extensively for shipment in the Gulf States, South and North Carolina, Virginia, Tennessee, Arkansas, and Missouri. Varieties are transient and numerous, but all the varieties grown to any extent are of American origin.

The raspberries — red, black, and purple — blackberries, dewberries, currants, and gooseberries are grown in smaller areas, though in certain localities their culture has assumed distinct importance.

The cranberry, which, as a cultivated fruit, is distinctly an American product, is extensively grown in Massachusetts and New Jersey and somewhat in Wisconsin.

Citrous fruits.— The citrous fruits chiefly grown are the orange, including the mandarin or kid-glove type, the lemon, and the pomelo. The citron and the kumquat are now being commercially planted, the former mainly in California, the latter in Florida. The lime is also grown to some extent in the latter state. Prior to the great freeze of 1894-95, orange culture was the most important branch of horticulture in Florida, the annual yield having exceeded 5,000,000 boxes. Since then the yield has been relatively small, though showing marked increase in 1903. The yield of oranges and lemons in California has steadily increased for several years, having averaged more than 5,000,000 boxes per annum for the past five years.

Nuts.— Of the nuts grown in America only the almond, walnut, and pecan have attained much commercial importance, the two former in California, the latter throughout the Gulf States and lower Mississippi Valley. Chestnuts of European and Japanese types are being planted on a somewhat extensive scale in the Eastern States, and appear well adapted to the existing conditions. Cocoanuts are somewhat planted in southern Florida.

Tropical and sub-tropical fruits.— Of these the most important are the fig, olive, and pineapple, all of which have attained commercial prominence. The two former are more largely grown in California, the latter in Florida. The mango and avacado are now being planted in considerable areas in south Florida, and several other species, including the guavas and anonas, to a less extent. William A. Taylor,

Pomologist, U. S. Department of Agriculture.

Fruit-pigeons, a group (*Trevoninæ*) of pigeons of very brilliant and often curious plumage, and frequently of large size, which are scattered from India to the South Sea islands. They spend their lives in the tops of the forest trees and feed wholly upon fruits, which are swallowed whole. There are about 180 species, chiefly of the genera *Carpophaga* and *Ptilopus.*

Fruit Trade, The American. The American fruit trade, which has now attained such proportions that it is entitled to be regarded as an important factor in our national commerce, had practically no existence one hundred years ago. At the beginning of the 19th century, for example, it is doubtful if there was a merchant in the United States who realized any considerable profit from his transactions in fruit. The extent of the trade at that time was represented by a few of the large importing houses, and their interest in this branch of the provision business was confined to the occasional receipt of a cargo of assorted fruits from some Mediterranean port, a few half-casks of dried prunes, currants, raisins, and figs, with, perhaps, some preserved citron. In fact, it was some years after the birth of the last century before even the New York grocers could see any advantage in trading in the native fruits that were frequently brought to the city by the neighboring farmers, and it was not until many years later, or at sometime about 1830, that any of the Metropolitan business men began to give any serious attention to the importation of foreign fruits.

Of course, this does not imply that foreign fruits were not imported from time to time. As early as 1804, a consignment consisting of about 30 bunches of bananas had been brought into the United States by Captain John N. Chester, of the schooner Reynard, but while, during the next 26 years, similar small lots were imported, it was not until 1830 that John Pearsall, a member of the firm of J. & T. Pearsall, decided that it would pay him to negotiate for cargoes of this fruit at regular intervals. He accordingly chartered the schooner Harriet Smith, and, within a few weeks, unloaded the first large cargo of bananas ever brought to New York. It consisted of 1,500 bunches.

The first cargo of oranges arrived at New York, in a sailing ship from Sicily, in 1832. Within a few months a cargo of lemons followed, and, within a comparatively short time, the importations of fruit from the Mediterranean ports became an established branch of our international trade. For fully 30 years these fruits from Italy, especially in the case of lemons and oranges, held full possession of the American market, and sailing ships, which were chartered expressly for that purpose, sped back and forth across the Atlantic to bring these fruits, the demand for which was constantly increasing. In fact, so eager was the competition in those days that entire shiploads were often purchased by importers and dealers before they had been a day at sea, and while the quality and condition of the goods could be nothing more than a matter of speculation.

Prior to 1865, the market for foreign fruit in this country was largely controlled by the great importing houses, most of whom purchased direct from the Italian producer. Among the houses that were most famous some half a century ago, one may mention the names of such firms as Devlin & Rose; Chamberlain, Phelps & Company; James Robinson & Company, and Lawrence, Giles & Company, all of New York; Daniel Draper & Company, and Conant & Company, of Boston; Dix & Williams, of Baltimore, and S. S. Scattergood & Company, and Isaac Jeanes & Company, of Philadelphia. In 1865, however, the Italian fruitgrowers consented to consign their fruit to the American firms, and this method of transacting business continued unchanged until about 1880, when several of the largest Italian fruit houses sent men to this country to represent their interests in the American market, since which time they have quite generally maintained their control over the importations from Sicily and the mainland, the Italian shippers feeling that it is safer to deal directly with a compatriot than indirectly with a stranger. As the result, Italy is still the largest importer of fruit in America. Spain's attempt to introduce her oranges was unsuccessful, and now, with the exception of her lemons and her Malaga and Almeria grapes, she sends but little of her product to this country.

The great changes in the conditions of the American fruit trade have all occurred since 1865. Prior to that time the importer of foreign fruit had little reason to figure upon any great local competition, but, since the close of the Civil War, the development of American resources has completely altered the situation. In the earlier days, New York, New Jersey, and Delaware were practically the only States in which small fruits were raised in any considerable quantities, but, even in such instances, there was nothing like a systematic trade in these products. If the Delaware peach crop failed, there was no other section of the country that could come

1. Dewberry field in Maryland. 2. Gathering peaches in Georgia.

to the rescue, for California at that time was not what she is to-day, one of the most resourceful fruit-growing States in the Union.

The first consignment of fruit from California came by express to New York, in 1867. Although picked green, and brought through with as much care as possible, considering the primitive methods of shipment then in vogue, the condition of the fruit upon its arrival did not compensate for the expense involved in the experiment. Although financially a failure, however, both the shipper and the transportation company had learned something from the experience, with the result that, in November of the following year, a second shipment of pears and grapes was brought through in such good condition that the pears sold at $3.50 to $5 a box, and the grapes, which were principally Tokays, from $10 to $15 for each 40-pound crate. This fruit, which was consigned to N. R. Doe, came from California in four ventilated cars attached to a passenger train, and, although the transportation charges were heavy, the return was sufficient to prove that the experiment could be made a source of great profit. From this beginning the California overland fruit trade has grown steadily until to-day thousands of carloads of such fruits are shipped from that portion of the country every year, of which upward of 2,000 are consigned to New York alone. Including its canned fruits and nuts, the shipments from California, both by sea and rail, showed an aggregate of nearly 520,000 tons in 1900, and this amount, great as it may seem, has been exceeded every year since the last census figures were published.

The development of the Florida fruit trade dates from early in the seventies, and then, as now, oranges were the staple fruit of that State. Of far better quality than the foreign fruit, they speedily attained a degree of popularity that gave them a most important position in the market. For years, therefore, their sway was uncontested, and it was not until the California growers began to develop their orange industry so extensively that the Florida producer commenced to experience the effect of any rivalry.

One apparent result of the growth of the fruit industry of this country has been the creation of a greater demand for fruit in general, a demand which is now so great that even the foreign fruit trade has profited by it. As in the case of the California fruit, this situation is largely due to the condition of American transportation rates. These are so high that, even in the case of Florida fruit, the Sicilian shipper can box, transport, and pay all charges on his product, including the item of customs duties, and still land the fruit at New York at a smaller total expense than any of the local growers can market their output.

That the local fruit is able to hold its own, however, in spite of such handicaps, is indicated by the fact that the shipment of oranges from California and Florida each year closely approximate 9.000.000 boxes. In addition, there are the other fruits from California, the market for which is constantly widening, to say nothing of the millions of pineapples that are sent to the North from Florida every season, and the annual harvest of olives, which is not far short of $300,000 in value. At the same time our importations of fruit are still eight or nine times greater in value than our exports, nor is there many apparent indications that these figures will undergo much change. At present, as in the past, our exports are confined almost exclusively to our shipments of apples, an item in our commerce that has increased so materially that the exports which amounted to scarcely more than $25,000 in value in 1850, have grown to such an extent that they represented more than $3,500,000 in 1905. England is the greatest receiver of this product, and if her demand for apples continues to increase as it has during the past few years it will not be long before it will require no less than 1,500,000 barrels to meet the requirements of the great auction-houses of London, Liverpool, and Glasgow alone.

The wide development of the fruit trade which has been effected during the past 25 or 30 years has naturally resulted in the organization of many associations which have been planned as safeguards for those who are engaged in such commercial enterprises. To-day there are institutions of this character in all the large cities of the country, but those that are best known are the New York Fruit Exchange, which operates on principles similar to those of other great exchanges; the Fruit Buyers' Union, which aims to systematize the methods of the green-fruit import and auction business, and the National League of Commission Merchants, which purposes to obtain uniformity and integrity of method in the commission business. Through the efforts of these organizations, and the local exchanges and associations in other parts of the country, the dealers in fruit are now able to transact a business which aggregates, including both imports and exports, an amount which will exceed $25.000,000 per annum. In addition to this there is the enormous domestic product, which, while it varies from year to year, and has never been reduced to exact statistics, will undoubtedly represent a sum that is equally as great.

Fruits, Cold-storage of, the preservation of fruits, by keeping them in a refrigerator or ice-box of such a temperature as will neither freeze them nor permit the process of ripening to advance. The problem of cold-storage has at length been solved by experiments recently made (1903) by the government expert, W. H. Ragan of the Department of Agriculture, at Washington. It had been generally supposed that cold-storage fruit quickly rotted, on exposure to the ordinary atmosphere of the dwelling-house in summer or winter. It has, however, been discovered that when fruit is put up in a proper condition, and kept subject to a proper temperature, it remains uninjured by storage for some time. Thirty-two degrees is considered suitable temperature for the cold-storage of fruit. Peaches of good color, yet still hard, if fresh from the tree, have been kept in cold-storage for four weeks, and found at the conclusion of that period in fairly marketable condition. They have maintained this condition for at least four days. It is only when they are in bad condition, imperfect and poorly colored, that they spoil on exposure, after resting in cold-storage.

In order to obtain good results the temperature of a cold-storage warehouse should be kept uniform throughout. Freshly plucked fruit is alone suitable for storage, for a delay of a few days, even of a few hours, will result in serious loss. While pears must be gathered as soon as they reach their full size on the tree, apples may best be stored when well matured and highly colored, though still hard. The storing should be made in small packages, certainly of not over 50 pounds; this is especially the case with regard to quickly fermenting fruits, such as pears and peaches. The careful ventilation of the cases, barrels or boxes, which enclose the fruit, is absolutely indispensable. Nothing is more likely to prolong the preservation of fruit in cold-storage than wrapping them individually. Double-wrappings are even better than single. The inner paper should be porous, like blank newspaper tissue, the outer may be paraffin paper.

Fry, Elizabeth Gurney, English philanthropist and prison reformer: b. Earlham, Norfolk, England, 21 May 1780; d. Ramsgate, Kent, 12 Oct. 1845. Brought up a Quaker by her family she did not adapt her mode of life to that prescribed by the more rigid and orthodox of the sect, till 1798, being then induced to do so by the preaching of William Savery, an American Friend traveling in England on a religious mission. This change was consummated by her marriage in 1800 with Joseph Fry, himself a "plain Friend." In 1810 Mrs. Fry became an occasional preacher and thenceforward devoted herself to offices of the purest benevolence and piety. Owing to her unwearied exertions, important reforms were effected in the prison systems, not only of Great Britain, but also in those of France and Germany. See 'Memoirs' by Tompson (1846); Corter (1853).

Fry, James Barnet, American military officer: b. Carrollton, Green County, Ill., 22 Feb. 1827; d. Newport, R. I., 11 July 1894. He was graduated at the United States Military Academy in 1847, and after serving as assistant instructor at West Point, he was assigned to the 3d Artillery, then in Mexico, where he remained till the close of the War. In 1863 he was appointed provost marshal-general of the United States, with headquarters at Washington, D. C.; and in 1864 was promoted brigadier-general. He was brevetted major-general in the regular army, 13 March 1865, for "faithful, meritorious, and distinguished services," and after the War served in the divisions of the Pacific, the South, the Missouri, and the Atlantic, till 1881, when he was retired. He was the author of: 'The History of Brevets'; 'The Army under Buell.'

Fry, William Henry, American composer and journalist: b. Philadelphia August 1815; d. Santa Cruz, W. I., 21 Dec. 1864. He early showed a singular aptitude for music, and in 1835 produced four overtures which were performed by the Philharmonic Society of Philadelphia, who presented the composer with an honorary medal. He next wrote the operas of 'Aurelia' and the 'Bridal of Dunure.' In 1845 he brought out his opera of 'Leonora,' an Italian version of which was performed in 1858 in New York. In 1846 Fry visited Europe as the correspondent of several American newspapers, and after his return in 1852 gave his attention to music, producing several symphonies of merit. In 1855 appeared his next work, a 'Stabat Mater,' brought out at the New York Academy of Music. He subsequently became attached to the editorial staff of the New York *Tribune*, and attained much popularity as a public lecturer.

Frye, William Pierce, American lawyer, legislator, and statesman: b. Lewiston, Me., 2 Sept. 1831. The son of Col. John M. and Alice M. Frye. He was graduated at Bowdoin College in 1850 and after studying law in the office of William Pitt Fessenden, he began the practice of his profession at Rockland, and later at Lewiston. He was elected to the State legislature from the latter city in 1861, 1862, and 1867. In 1864 he was a presidential elector on the Lincoln ticket. After serving a term as mayor of Lewiston, he was elected attorney-general of the State, on the Republican ticket, holding the office from 1868 to 1870. He was elected to Congress from his home district in 1871, and was re-elected no less than five times.

In 1881 he resigned his seat in the House of Representatives to accept the nomination to the United States Senate, filling the vacancy caused by the resignation of James G. Blaine, who entered Garfield's cabinet as secretary of state. Senator Frye was re-elected to the Senate in 1889, 1895, 1901, and 1907; was elected president pro tem. of the Senate in 1896, and has twice acted as permanent presiding officer of that body — after the death of Vice-President Hobart in 1899, and after the elevation of Vice-President Roosevelt to the Presidency in 1901. After the close of the Spanish-American war Senator Frye was a member of the Peace Commission in Paris. He was chairman of the Commerce Committee in the Senate and has exerted a great influence on national legislation. He has been looked upon as one of the great leaders of the Republican party, and has had much to do with framing legislation on the tariff and as regards American shipping. During the exciting days of the Spanish-American war he acted as chairman of the Senate Committee on Foreign Relations. Senator Frye was given the degree of LL.D. by Bowdoin College in 1889, and also by Bates College in 1881.

Fryer, John, American Orientalist: b. Hythe, Kent, England, 6 Aug. 1839. Educated in London, England, he has occupied several educational posts and acted as government translator in China. He was appointed Agassiz professor of Oriental Literature in the University of California in 1892. Among his writings are: 'Educational Directory for China' (1895); 'Translator's Vade-mecum, or Vocabulary of Scientific Terms in Chinese and English.'

Fteley, Alphonse, American civil engineer: b. Paris, France, April 1837; d. Yonkers, N. Y., 6 Aug. 1903. He was educated at the Ecole Polytechnique, Paris, and came to the United States in 1865. He was resident engineer of the Waterworks Bureau of Boston (1873–80); chief assistant city engineer of Boston (1880–4), and subsequently consulting engineer. He was also chief engineer of the New York Aqueduct Commission (1888–1900). In the last named capacity he planned the Croton dam in 1891, and the Jerome Park reservoir in 1894.

Fu-Kien, foo-kē-ĕn', or **Fokien**, a province of China, bounded north by Che-Kiang, northwest and west by Kiang-Si, south by Kwang-Tung, and southeast by the China Sea; area, 38,500 square miles. The coast is deeply indented by bays and studded with islands, including Amoy, Hai-Tan, and others. The island of Formosa formerly belonged to the province. The interior is generally mountainous; but by cultivating not only the plains and slopes, but terracing the hillsides, often to their summits, the far greater part of the surface is turned to good account. The higher mountains are covered with trees, and the cultivated terraces sometimes number 30 to 40. The Min and its tributaries are the most important rivers. The principal products are rice, wheat, barley, tea of superior quality, silk, sugar, indigo, camphor, and tobacco. The minerals include iron and alum, which, with porcelain, various tissues, and the above products, are the chief exports. The capital is Fu-Chau. Amoy, a treaty port, and other important commercial towns are also included in the province. Pop. 25,790,556.

Fu-Shan, foo-shăn', a town of China, in the province of Kwang-Tung, 21 miles southwest of Canton, on one of the branches of the delta of the Si-Kiang. It has manufactures of silk, iron and steel, etc., and carries on some trade. Pop. (1900) 200,000.

Fuà-Fusinato, foo-ä foo-sē-nä'tō, **Erminia**, Italian poet: b. Rovigo, 5 Oct. 1834; d. Rome 27 Sept. 1876. She was married to the poet Arnaldo Fusinato (q.v.) in 1856. Her spirited appeals to national sentiment in 1848 brought her widely into notice. In 1852 was published her 'Verses and Flowers.' She wrote a series of 'Stornelli,' advocating Florence as the national capital instead of Rome. Her complete poetical works, 'Versi,' were published in 1879; her 'Literary Writings' in 1883.

Fuca, Juan de, hoo-ăn' dā foo'kä (originally APOSTOLOS VALERIANOS), Greek navigator: b. Cephalonia; d. Zante 1602. He was for many years in the Spanish naval service. In 1592, when he discovered the sea-passage separating Vancouver Island from Washington, and connecting the Pacific Ocean with the Gulf of Georgia and with Admiralty Inlet and Puget Sound, he thought he had chanced upon a connection between the Atlantic and Pacific oceans. This straight has been called after his name.

Fuca, Strait of. (See JUAN DE FUCA, STRAIT OF.)

Fuchs, fooks, or **Fuchsius, Leonhard**, German botanist: b. Membdingen, Bavaria, 17 Jan. 1501; d. Tübingen, 10 May 1566. He studied the classics under Reuchlin at Ingolstadt, and was graduated Doctor of Medicine in 1524. He afterward turned his attention to botany, of which science he must be looked upon as one of the fathers. In his 'Historia Stirpium' (1542), he gave a clever description of domestic plants, alphabetically arranged, and laid the foundation of a permanent botanical nomenclature. The fuchsia (q.v.) was named after him.

Fuchsia, fū'shĭ-a or fook'sĭ-a, a genus of plants, the type of the tribe *Fuchsieæ*, natural order *Onagraceæ*, named after the botanist Leonhard Fuchs. The genus contains more than 50 known species, chiefly natives of Mexico, Peru, and Chile. Some have been found in New Zealand. The plants are shrubby or arborescent, sometimes climbing; the flowers are pendent, large, and fine, with brilliant and delicate coloring — purple, rose, and white; the calyx is four-cleft, the corolla four-petaled, the fruit four-celled. The leaves are opposite and verticillate. The flowers are both axillar and terminal, usually one flower springing from the axil, more rarely in racemes at the top of the branches. Fuchsias are much cultivated in conservatories, and are favorite house-plants throughout the United States. Some varieties are hardy enough to bear a northern climate. They are propagated with great facility from cuttings, but the berries, which are preserved and eaten in South America, rarely ripen elsewhere.

Fuchsine, fook'sĭn, an aniline dye prepared by the action of arsenic acid, stannic chloride, or other oxidizing agents upon a mixture of aniline and its homologue toluidine, which yields a mass with a bronze or coppery lustre, called rosaniline. This dissolved in water, precipitated with common salt, and the precipitate washed and crystallized from water, forms fuchsine, which in commerce receives various fancy names, as magenta, aniline or new red, roseine, rubine, etc. It is largely used for dyeing purposes, and wines and even confectionery are sometimes colored with it.

Fuchsius. See FUCHS.

Fuchs' Soluble Glass, so named after its inventor, Johann Nepomuk von Fuchs (1774–1856), who discovered the process in 1823, is a silicate of potassium, made by fusing 15 parts quartz sand, 10 of potassic carbonate, and 1 of charcoal. A similar compound is made from 15 parts sand, 8 carbonate of sodium, and 1 of charcoal. The mixture being made, is heated in a crucible until it is liquefied, care being taken that the materials do not remain too long in contact with the crucible, otherwise alumina, etc., may be dissolved, and the product alter its character. After cooling it forms a hard vitreous mass, tolerably permanent in the air, with conchoidal fracture; and varying in color, passing from pale-green into black. It is soluble in water, with alkaline reaction; the solution is not very stable, being apt to deposit silica on standing, and particularly if carbonic acid gas be absorbed. Soluble glass is employed to render wood uninflammable, and along with a solution of calcium to give stonework a waterproof coating. It is also the fixing agent in fresco coloring according to the art of stereochromy.

Fudge Family in Paris. A satire written by Thomas Moore in 1818, the under-bred English in foreign countries being the subject.

Fuego (fwā'gō) **Island.** See FOGO.

Fuel, Comparative Heating Values of. The effective and economical utilization of the inherent heat energy of fuel in the production of light and power is perhaps the most important industrial question of the times. It is one that plays such a necessary part of modern life, and the cost of the fuel used oftentimes forms so great a part of the conduct of an industrial enterprise on an economical basis, that constant efforts are being directed to improve the present imperfect methods of fuel utilization, and approach the limit of theoretical efficiency.

Kinds of Fuel.—Nature furnishes a great variety of fuel in three general forms— the *solid,* such as wood and coal; the *liquid,* such as petroleum and alcohol and the *gaseous,* such as natural gas. The solid forms of fuel are the most common; the liquid contain the largest amount of heat energy; and the gaseous are the most convenient for use. The fact that any kind of gaseous fuel is the most convenient, and in a great many cases, the most effective for use, has been demonstrated principally through the utilization of natural gas; but as the supply of natural gas is gradually failing, and the cost of oil-firing is much higher, the tendency of the times is to perfect methods for the conversion of solid and liquid fuel into gaseous form. These conditions render the methods of firing employed very important.

Methods of Firing.—In general, the economical and effective utilization of a fuel depends upon the completeness of the combustion thereof. In the combustion of solid fuels by ordinary grate or "direct firing" methods the greater part of the heat liberated is lost in the form of gases which are not combustible at the temperatures attained in grate-fired furnaces. On the other hand, when solid fuel is first converted into gas, and the gas thus obtained utilized by "gas firing" methods, the results accomplished more than compensate the 15 or 20 per cent. loss of heat energy sustained by the process of conversion. As generally applied, gas firing results in more complete combustion, and the attainment of higher combustion temperature, and thereby make possible metallurgical operations which are impracticable with direct firing. There is also less loss of heat through the waste products of combustion, and greater efficiency in transfer of heat. Futhermore, by suitable methods, the heat from the hot waste gases can be recovered and returned to the combustion chamber in preheated air, so that the gas and air supply, and therefore the combustion of the fuel, are placed under easy and complete control.

In practice, the theoretical amount of air necessary for combustion is always exceeded. Direct firing requires at least twice the theoretical amount to even approximate complete combustion, especially in the use of soft coals. With the progress of combustion, the fuel bed becomes more compact, so that with a given draught the amount of air penetrating into the bed decreases with the increase of the depth and compactness of the fuel. Under these conditions, a fresh charge of coal requires a greater amount of air to consume its votatile components, and demands it at a time when its passage is most retarded and the combustion rendered more incomplete by the reduction of temperature accompanying volatilization. As the final result is an irregular air demand, the grates have to be arranged to admit the greater excess of air at all times, otherwise large heat losses will occur from the escape of unconsumed gases.

On the other hand, in gas firing, the air supply is always under control, and therefore can be made to closely approximate the theoretical amount, thus reducing the amount of the products of combustion and insuring more complete combustion. The greater amount of heat then liberated is concentrated in lesser volume, and raises the temperature of combustion, so that the oxygen of the air combines more readily with the combustible constituents of the gas. Futhermore, the smaller the excess of air the lesser the dilution of the gaseous mixture by nitrogen and other inert gases which retard combustion.

The products of combustion being of a higher temperature transfer their heat more readily, and being smaller in quantity carry off less heat by way of the chimney. By suitable arrangements, these products may be intercepted and forced to impart a large amount of their heat to the air supply going to the combustion chamber, thus returning a certain amount of heat to the system, which represents a saving in fuel equivalent to the amount of heat so returned.

Therefore, in considering any fuel the primary question does not relate to the calorific value of the fuel so much as to what percentage of the heat energy represented by its calorific value is actually available for conversion into mechanical energy according to the manner of its utilization.

The latest experience shows, that in the case of a modern steam plant, burning coal by direct firing, the economy lies behind the stop valve, yet this fact does not appear to be clearly recognized by engineers in general, or by those who direct their efforts towards reducing the consumption of steam, rather than its economical generation.

According to the best authorities, the mechanical arrangements and conditions most favorable for the most economical utilization of solid fuel are as follows: the height of the chimney should not be less than 120 feet, nor more than 180 feet, giving a natural draught ranging from 0.50 to 0.83 inches of water, with an average temperature of 300° Fahr. For Lancashire boilers (full size) the chimney area should equal 6 square feet per boiler up to a total of four boilers, and 5 square feet per boiler for every additional boiler. The area of the chimney entrance should be 10 per cent. in excess of this amount, and the flue should enter the chimney with a rising slope of 45 degrees. The area through the economizer should be 20 per cent. greater than the flue area, and the economizer walls should be at least 14 inches thick and exceptionally well built, and the combined area of the boiler side flues should not be less than twice that of the main flue.

As the price of fuel is influenced to a great extent by the convenience with which it can be burned, the general tendency is to use a higher priced fuel even though it may have a lower heating value than a cheaper grade. This tendency can be readily overcome and a large reduction made in the fuel bill by the use of high-class mechanical stokers which will burn coal almost impossible to fire by hand.

Comparative Price of Fuel.—The following table shows the relative prices of fuel, either coal or coke, with different percentages of ash, generally used in furnace practice. The percentage of carbon represent those of carbon and hydrogen combined, and the percentage of ash include less than one per cent. of sulphur. This table will be found very useful not only in connection with the use of solid fuel burned by direct firing, but also in considering the results obtainable in high temperature work by gas firing methods where a high percentage of volatile hydrocarbons is very desirable, and a smaller consumption of coal is needed to do a given amount of work. Under the latter condition, when local coals are inferior and cheap, it is often advantageous to bring from a distance higher-priced coals of better quality.

General Descriptions of Fuel.—For various reasons coal is the most important of all fuels, and in many localities constitutes the only one available; but in some places wood, oil, and gas are abundant, and take the place of coal. In certain industrial and manufacturing plants, their waste products, such as straw, tanbark, sawdust and bagasse are used as fuel more economically than coal, owing to their availability. For general purposes, however, coal is the chief fuel, and the available heating value of all other kinds of fuel are invariably expressed in terms of that of coal. The following limited table gives the weight per cord and equivalent coal values of thoroughly air-dried woods:

COMPARATIVE PRICES OF FUEL.

(Containing different percentages of ash and carbon). The values are given in dollars and cents.

Calorific Values of Fuel.—As stated in the foregoing paragraphs, the calorific value of a fuel does not represent its actual available heating power, and likewise neither does its weight per cubic foot, yet for purposes of comparison an accurate knowledge of both of these values of different kinds of fuel is absolutely necessary. For example, engineers who have compared the value of pine and coal, agree upon the ratio of 2½ to 1 as representing the average. In other words, 2½ pounds of wood are equivalent to a pound of coal, and therefore, the weight of wood which must be burned on each square foot of grate surface will equal 2½ times the weight of coal required to give the same amount of heat as would be derived from burning coal. The introduction of the calorific values of the two kinds of fuel into the problem will serve to still further elucidate such comparisons. As the calorific values of different kinds of fuel, and of different varieties of the same kind vary greatly, the approximate heating values of the principal varieties of coal, and some of the other principal kinds of solid fuel, are given in the following table:

CALORIFIC VALUES OF SOLID FUELS.

KIND OF FUEL.	ASH.	CALORIFIC VALUE.
	Per cent.	B.T.U's per lb.
Pennsylvania anthracite coal	3.49	14,199
Pennsylvania anthracite coal	2.90	14,221
Pennsylvania cannel coal	15.02	13,143
Pennsylvania Connellsville coal	6.50	13,638
Pennsylvania semi-bituminous	10.77	13,155
Pennsylvania brown coal	9.50	12,324
Kentucky caking coal	2.75	14,391
Kentucky cannel coal	2.00	15,198
Kentucky lignite coal	7.00	9,326
Indiana caking coal	5.66	14,164
Indiana cannel coal	6.00	13,097
Maryland Cumberland coal	13.98	12,226
Arkansas lignite coal	5.00	9,215
Colorado lignite coal	9.25	13,562
Texas lignite coal	4.50	12,962
Washington lignite coal	3.40	11,551
Pocahontas coal	4.70	14,100
New River coal	4.60	13,900
Peat, Irish, perfectly dried	4.00	10,200
Peat, air-dried, 25 per cent. moisture	4.00	7,400
Wood, perfectly dry	2.00	7,800
Wood, 25 per cent. moisture	. .	5,800
Tan bark, perfectly dry	15.00	6,100
Tan bark, 30 per cent. moisture	....	4,300
Straw, dry	4.00	6,300
Straw, 10 per cent. moisture	4.00	5,450

KIND OF WOOD.	Pounds Per Cord.	Pounds of Coal.
Hickory or Hard Maple	4,500	1,800
White Oak	3,850	1,540
Birch, Red and Black Oak	3,250	1,300
Poplar, Chestnut and Elm	2,350	940
Pine (average)	2,000	800

Varieties of Coal.—The five most important varieties of coal are anthracite, dry bituminous, caking bituminous, cannel, and lignite.

Anthracite coal is found principally in the Alleghany Mountains, and in the Rocky Mountains region in Colorado. It is a hard, lustrous variety and breaks up easily at a high temperature. It consists almost entirely of carbon, with a small percentage of hydrogen, and burns with very little flame and smoke, unless containing an excess of moisture, and gives an intense heat. There is a variety known as semi-anthracite which contains a larger percentage of hydrocarbon, but is not as hard as true anthracite, and burns with a short flame. Owing to its great brittleness, a large part of anthracite gets broken into small pieces; therefore, in order to obtain the best results it should be fired on grates having small air spaces. The various commercial names and sizes of anthracite coal are given in the following table:

ANTHRACITE COAL SIZES.

SIZE NAME.	Through a Round Hole.	Over a Round Hole.
Chestnut	1½ inches diameter.	⅞ inch diameter
Pea	⅞ inch "	9/16 " "
No. 1, Buckwheat	9/16 " "	⅜ " "
No. 2, Buckwheat or Rice	⅜ " "	7/16 " "
No. 3, Buckwheat or Barley	3/16 " "	3/32 " "
Dust	3/32 " "	

Bituminous coal contains about 80 per cent. carbon, and a large amount of hydro-carbon.

The dry variety is found in Maryland and Virginia, and the caking variety chiefly in the Mississippi Valley. Dry bituminous coal burns freely, without caking and with very little smoke, but the caking coals become pasty, or swell and cake when burning. Caking bituminous coals are largely used for making illuminating gas.

Cannel coal, also known as long-flaming bituminous, contains from 65 to 85 per cent. of carbon. It is found in Pennsylvania, Indiana, and Missouri. All varieties of cannel coal have a strong tendency to smoke, and some of them cake when heated.

Lignite, also known as brown coal, contains from 55 to 75 per cent. of carbon. It is found in the Dakotas, Colorado, Texas, Washington, and Alaska. It is a substance intermediate between peat and coal, and contains some moisture and mineral matter. The poorer varieties have a low fuel value.

Peat consists of decayed roots consolidated with earthy matter. It is cut out of bogs and swamps, and then dried. If it is sufficiently compact it is burned without being previously compressed; otherwise, it is pulverized and compressed into briquetes, and sold as an artificial fuel. The amount of ash varies from 5 to 12 per cent.

Coke is a product obtained from bituminous or semi-bituminous coals by driving off their hydro-carbon constituents by means of heat. As the by-products of gas retorts, commercially known as gas-house coke, it has a low fuel value under direct firing methods; but it will make a very hot fire under forced draught.

Charcoal is made by evaporating the volatile constituents of wood, either by partial combustion or by heating in retorts. By partial combustion, 100 pounds of wood will yield 20 pounds of charcoal, and by heating in a retort about 30 pounds. A cord of wood generally yields about 50 bushels of charcoal.

Wood, considered as fuel, is divided into two classes—hard wood and soft wood. The heating value of different kinds of wood for a given weight, is practically the same; or, in other words, one pound of hickory is not worth any more as fuel than one pound of pine, as the chemical composition of different kinds of wood is nearly the same. The following table shows the average chemical composition of fuel woods:

AVERAGE CHEMICAL COMPOSITION OF FUEL WOODS

CONSTITUENT.	Perfectly Dry Wood.	Ordinary Fire Wood.
	Per Cent.	Per Cent.
Carbon	50	37.5
Hydrogen	6	4.5
Oxygen	41	30.75
Nitrogen	1	.75
Ash	2	1.5
Moisture	..	25.0

Kiln-dried wood has a theoretical calorific value of about 7,800 B. T. U.'s per pound, and wood containing 25 per cent. of moisture, a value of only 5,800 B. T. U.'s per pound. Wood contains a great deal of moisture even after being kept for a considerable length of time in a dry place; and after being thoroughly dried it will absorb as much as 20 per cent. of moisture from the atmosphere.

On account of the large per cent. of moisture in peat or turf, wood, sawdust, and tanbark, these substances, like coke and charcoal, are rarely used for steaming or power-producing purposes, but all of them are available as fuel for gas producers, by the use of which the moisture is readily removed from the constituent gases, which can then be used for power-producing purposes by means of gas engines, or be applied to operations requiring high temperatures, such as those of steel works, rolling mills, smelting furnaces, glass works, and chemical works. In fact, the almost exclusive use of gaseous fuels not only derived from the substances stated, but also from the different varieties of coal, in those and many other fields of industry is only a question of a very short time. The reason for this is now clearly emphasized by two cardinal facts—first, that the supply of natural gas is gradually failing, and second, that the most satisfactory method of using the heat from our most reliable source, coal, is to first convert it into gas and ashes. It is interesting to note in this connection, however, that in the gasification of fuels having a high percentage of moisture, high percentages of carbonic acid and hydrogen occur in the gas. This is probably due to the fact that at a temperature of about 1100° Fahr., water vapor oxidizes carbonic oxide to carbonic acid. Therefore, coke and charcoal, which have a low value as a direct-firing fuel, work more favorably in a gas producer, and yield more gas per pound than any other material. The following table gives the approximate yield of gas per pound of different materials:

YIELD OF GAS FROM DIFFERENT FUELS

MATERIAL.	Yield Per Pound.
Coke or charcoal	104 cubic feet.
Anthracite coal	85 " "
Bituminous coal	75 " "
Lignite or Brown coal	55 " "
Peat or Turf	45 " "
Wood	35 " "

Gaseous Fuel.—The principal kinds of gaseous fuel used at the present time for power-producing purposes are natural gas and producer gas. A certain kind of uncarburetted water gas, made by the decomposition of steam in the presence of incandescent-carbon, is also used to a limited extent, but this gas can never play a very important part as a power producer, on account of the large loss of energy sustained in its production.

The weight and heat value of 1,000 cubic feet of the four types of gases used for power producing and illuminating purposes are given by the table on the following page.

The following table shows natural gas to be the highest in the order of heat energy, its calorific power being 50 per cent. greater than that of coal gas. This is due to the high percentage of marsh gas given to natural gas by a natural process which cannot be duplicated artificially. Producer gas has the lowest heat value, yet it is the cheapest artificial fuel gas per unit of heat, as the oxygen for burning the carbon to carbon monoxide is derived principally from the air. It has only one-fifth the heat energy of good illuminating gas per cubic foot, and it is most successfully applied in operations where a considerable body of gas is burned rather than in

AVERAGE VOLUMETRIC ANALYSES.

CONSTITUENTS.	Nat. Gas.	Coal Gas.	Water Gas.	Producer Gas.	
				Anth.	Bitu.
Hydrogen, H	2.18	46.0	45.0	12.0	12.0
Oxygen, O	0.34	0.5	0.5	0.3	0.3

very small work, where illuminating gas can be used to greater advantage.

Comparison of Gases on a Coal Basis.—The theoretical heat value of average anthracite coal is about 14,200 B. T. U.'s per pound, or the power to evaporate about 14.7 pounds of water per pound of coal burned. This theoretical evaporation is never attained in practice, however, owing to heat losses sustained in various ways—by improper design of boilers, by radiation, by improper firing, etc., so that a boiler rarely gives an efficiency equivalent to the evaporation of 12 pounds of water per pound of coal, or the utilization of 80 per cent. of the theoretical heat energy of the fuel. The efficiency usually attained is about 10 pounds of water, or about 67 per cent. of the theoretical energy, so that only about 9,500 of the 14,200 heat units in a pound of coal are utilized by the average boiler.

As determined by satisfactory experiments, 7½ cubic feet of natural gas burned will evaporate 10 pounds of water; or in other words, about 8,000 heat units in the form of natural gas are equivalent to a pound of good coal burned. Other authorities give the heat value of 1,000 cubic feet of natural gas as equivalent to that of an amount of coal ranging from 80 to 130 pounds.

Comparison of Illuminating Gas and Producer Gas.—First-class coal gas, or carburetted water gas, made with 4½ gallons of Lima oil per 1,000 feet of gas, contains between 730 and 735 heat units per cubic foot, which gives an equivalency of 19 cubic feet of gas to one pound of anthracite coal, or 1,000 cubic feet equal to 59 pounds of coal.

One pound of anthracite coal, composed of carbon 85 per cent., hydro-carbons 5 per cent., and ash 10 per cent., will make 90 cubic feet of producer gas of the following composition: hydrogen 12 per cent., carbon monoxide 27 per cent., marsh gas 1.2 per cent., carbon dioxide 2.5 per cent., and nitrogen 57 per cent., having a heat value of 137 heat units per cubic foot. This gives an equivalency of about 104 cubic feet of gas to one pound of anthracite coal, or 1,000 cubic feet to about 9.5 pounds of coal.

Comparison of Anthracite Gas and Bituminous Gas.—The following tables show the process of conversion, the resulting products, and the value of heat energy computed therefrom, relative to the two principal varieties of producer gas. A comparison of these figures will show at once the much greater energy, both by weight and volume, in the bituminous gas.

Fuel Oils.—The various kinds of fuel oils are all derived from petroleum, which is a liquid hydrocarbon composed of carbon, hydrogen, and oxygen in varying proportions: carbon, 82 to 87 per cent.; hydrogen, 11 to 15 per cent.; oxygen, ½ to 6 per cent. The theoretical average calorific value is about 20,860 B. T. U.'s per pound, corresponding to a theoretical evaporation of 21 pounds of water from and at 212° Fahr.

American crude petroleum carries more of the lighter oils than the European or Peruvian, from which a residuum or fuel oil, consisting largely of the heavy oils, is obtained by distillation. In this work steam atomizers give better results than the air spray, the steam required to atomize being about 4 per cent. of the water evaporated.

«Astatki,» «Mazoot,» «distillate,» «petroleum refuse,» «reduced oil,» etc., are some of the commercial terms used to designate the various kinds of fuel oil.

Approximately, one pound of fuel oil is equal to 1.45 pounds of coal. A test at the Minneapolis Water Works showed that for the same duty 224 gallons of oil, weighing 6.875 pounds per gallon, equalled one ton (2,240 lbs.) of Youghiogheny coal.

Fuel oils have both advantages and disadvantages. The heating value of a fuel oil is nearly twice its weight of coal. Its use is not as injurious to the furnace as the use of coal, on account of the smaller percentage of sulphur. With oil, the fire can be controlled by means of a single valve, and when once regulated to produce a certain heat, it can be maintained at that point with very little trouble. The fire can be started easily, and extinguished instantly. The combustion is complete and smokeless, thus making economy and cleanliness important advantages in its use.

The most important disadvantages are the comparatively high price, danger from explosion, loss by evaporation, and unpleasant odor.

The barrel of crude petroleum of commerce is 42 gallons, weighing 6½ pounds per gallon, and it is customary to consider roughly that 3¾ barrels are equivalent to one ton of coal.

Tests on Fuel.—The most important conclusions of the tests on fuel made by the government and by the laboratories of some of the principal universities, are as follows:

1. Samples of coal from 17 states, tested in steam boiler plants indicate that the high steaming quality of many of the American coals may be improved by washing.

2. Most of the American coals and lignites constitute an available source of power by utilization in gas producer plants.

3. Comparative tests made by the government on 14 bituminous coals from nine states, indicate that when these coals are used in a gas producer plant, their power efficiency is 2½ times greater than when they are directly fired in a steam boiler plant.

4. Some of the lignites found in undeveloped but extensive deposits in the Dakotas and Texas, show very high power producing qualities when gasified in the gas producer and used in the gas engine.

5. Some of the American coals, and the stock produced in mining them can be briquetted on a commercial basis.

6. Under these conditions of attainable fuel economy, it is merely a question of time when the gas engine will supersede any possible type of steam motor.

For relavent information consult articles under the titles GAS; GAS ENGINE; GASES, LAWS OF; and GAS PRODUCER, in this Encyclopedia.

WILLIAM MOREY, JR., C. E.,
Consulting Civil and Mechanical Engineer, New York.

Fuero (from the Latin *forum*), a Spanish word signifying jurisdiction, law, privilege. It is applied to the various written codes and characters of particular districts, towns, etc., and signifies generally those laws, privileges, and immunities founded on usage and sanctioned by the suzerain or supreme authority. Fueros are both civil and ecclesiastical. The earliest, as well as the most universal, is the *fuero juzgo.* This name (a corruption of the Latin *forum judicum*) is given to a 13th century translation of a code of the 17th century. It contains the Gothic laws which, up till this time, gradually superseded the Roman. Each law receives the name of the Gothic sovereign by whom it was promulgated. This code has formed the foundation of Spanish law down even to modern times. The fueros of Leon, known by the name of *fueros bonos,* contain a complete constitution, civil and ecclesiastical, recognize the rights of self-taxation, and of the nobility of all subjects by birth. The constitution of free towns under these fueros is essentially republican, the king having only a right to name the corregidor, who must be confirmed by the junta of the province, an assembly elected by a very liberal suffrage. As the various monarchies became consolidated under a single head, the kings became anxious to evade or withdraw privileges which interfered with the organization of their kingdom, and after 1592 when Philip II. entered Aragon with an army, hanged the grand-justiciary, whose office it was to administer the oath, and abolished the constitution, the fueros as a political institution ceased to exist, although some local and municipal privileges continued to be called by that name. In 1833 a civil war broke out in the Basque provinces, in assertion of the fueros, which were formally recognized in 1844. In 1876, however, the fueros of these northern provinces were superseded by the general laws of the kingdom.

Fuerte Ventura, fwār'tä vĕn-too'rä, one of the Canary Islands, belonging to Spain. It has an area of 650 square miles and numerous extinct volcanoes. Its principal harbor is Cabras on the east coast. Pop. (1900) 11,662.

Fuertes, James Hillhouse, American civil and sanitary engineer: b. Ponce, Porto Rico, 10 Aug. 1863. He was graduated from Cornell University in 1883. He has constructed works for the sewerage, drainage and water supply of various cities in the United States, Canada and Brazil, and is a non-resident lecturer at Cornell. He has published 'Water and Public Health' (1897); 'Water Filtration Works' (1901); etc.

Fuertes, Louis Agassiz, American painter of birds: b. Ithaca, N. Y., 7 Feb. 1874. He was graduated from Cornell University in 1897. He has illustrated 'Birding on a Broncho' (1896); 'Citizen Bird' (1897); 'Song Birds and Water Fowl' (1897); 'Bird Craft' (1897); 'The Woodpeckers' (1901); 'Second Book of Birds' (1901); 'Birds of the Rockies' (1902); 'Handbook of Birds of North America' (1902); 'Coues' Key to North American Birds'; the plates for the 'Report' of the New York State Game, Forest and Fish Commission (1903); 'Upland Game Birds' (1902), and the companion volume, 'Waterfowl' (1903); etc.

Fugger, fook'ĕr or fŭg'gĕr, the name of a wealthy and illustrious German family of Suabia, descended from a weaver, who originally lived in the environs of Augsburg, about 1300. They were at first successful in selling clothes, but afterward extended their dealings, and became merchants, accumulating an immense fortune. Reaching the height of their affluence at the commencement of the 16th century, they rendered considerable services to the Emperors Charles V. and Maximilian, by making them large advances. These princes bestowed titles of nobility on the Fugger family, and they soon became connected with the best blood of Germany. Promoted to the highest dignities of the empire, they did not any the more neglect the pursuits of commerce. Their riches were always forthcoming for the improvement of their birthplace, Augsburg, where they erected some handsome monuments and founded philanthropical institutions. The best known of them are the three brothers, Ulric, James, and George; and afterward Raymond and Antony, both sons of George. Ulric received for his loans to Maximilian the courtship of Kirchberg, and the seigniory of Weissenhorn, which afterward remained in the possession of his family. He was a great encourager of learning. Antony and Raymond bore, to a great extent, the expenses of the expedition of Charles V. against Algeria, obtaining from him the permission to coin money. One day, at an interview with the emperor, Antony, as a mark of his regard and esteem, threw into the fire all the title-deeds and securities which Charles had deposited with him. Toward the close of the 18th century the family withdrew altogether from trade, confining themselves to the management of their landed estates. Count Anselm Maria of Babenhausen, of the Wellenberg line (b. 1776; d. 1821), was raised by the Emperor Francis II. to the dignity of a prince of the empire. The principality of Babenhausen was annexed to Bavaria in 1806, and Leopold Fugger Babenhausen (1827–85), grandson of the first prince, was a hereditary imperial councilor, and lord high-chancelor of Bavaria. He was succeeded by his brother Karl Ludwig Maria Fugger (b. 1829), who in 1891–3 was president of the Bavarian Reichsrat.

Fugio. See CENT.

Fugitive, in law, is a term applied to persons who having violated the laws of a State escape into a foreign territory. As one State cannot pursue criminals into the territories of another, the practice prevails among the more enlightened nations of mutually surrendering such fugitives to the justice of the injured State. This practice is founded on national comity and convenience, or on express compact. The United States recognize the obligation only when it is created by express agreement (see EXTRADITION). As between the States of the American Union, extradition is made compulsory by the Federal Constitution, Art. IV. Sec. 2, which provides that "a person charged in any State with treason, felony, or other crime, who shall fly from justice and be found in another State, shall, on demand of the executive authority of the State from which he fled, be delivered up, to be removed to the State having jurisdiction of the crime." In the several States there are statutory provisions or established usages regulating the procedure in such cases.

Fugitive-slave Laws. In the colonies and under the Confederation, fugitive slaves could only be reclaimed through intercolonial or interstate comity, and in framing the Constitution, one of the chief inducements for the South to join was a fugitive-slave clause. The mandate to deliver them up, however, was only to the States which could not be punished for refusing to comply; and as the free States recognized no obligation of comity on this point, the general government passed the first fugitive-slave law, signed by Washington 12 Feb. 1793. The oral testimony of the alleged owner was all the evidence required, and on this any magistrate, even a town justice, was ordered to surrender the alleged fugitive; $500 fine was imposed for rescue, concealment, or obstruction of arrest. This made kidnapping free blacks a pastime, and it was extensively carried on in the Border States; motions to amend the law and require more evidence were voted down. On the other hand, the Border States complained of increasing escapes, and Congress promptly passed an amendment (30 Jan. 1818), enabling a claimant to make his proof before a judge of his own State, and abolishing the habeas corpus in such cases. The Northern magistrates, however, revolted against the obligation; Pennsylvania passed a law contravening the national act and providing its own methods of reclamation, and made them incumbent on her own magistrates; a Maryland slave-seeker thereupon carried off an alleged slave by force, and on his indictment the Supreme Court decided (Prigg *v.* Pennsylvania) that the execution of Federal laws could not be imposed on State officials. Taney dissented; and on this doubt the Northern States began to pass "personal-liberty laws" to prevent their officials being so employed, or their buildings used as places of detention. This roused the South to demand an effective fugitive-slave law as the price of remaining in the Union; and that of 1850 (see COMPROMISE OF 1850), the death-knell of the Northern-Southern Whig party, was passed, placing the whole course of reclamation in Federal hands. The entire machinery of the United States, from courts to army, was made part of a grand system for this one purpose, and new officials were appointed for it; marshals were liable to $1,000 fine, plus the value of the slave, if he escaped or even was forcibly rescued, and bystanders were held guilty of treason for refusing to assist; the owner's oath was full evidence, that of the alleged fugitive was not to be received, and the habeas corpus was rendered null; obstruction, rescue, or concealment, were punishable by six months' imprisonment and $2,000 damages and fine; if the claimant "apprehended" a rescue, the marshal was to take the fugitive to the claimant's State himself before surrendering him; lastly, an affidavit and general description made in the claimant's own State was to be valid for a reclamation in any other. This atrocious act was met by more stringent personal-liberty laws, which made it hard for the alleged owner or his United States agents to find any State soil to stand on in executing the writs or holding the fugitive; and in 1859 Wisconsin openly threatened to secede if the mandates were executed on her soil. Its political result was an undreamt-of boomerang, each seizure rousing a glare of public notice and hatred, often inflamed still more by the incidents — as riot and bloodshed, the murder of her child by a mother to save it from slavery (see GARNER CASE), the prosecution for treason of two Quakers who refused to join the hunt (see CHRISTIANA CASE), the seizure of long-time free black citizens of towns, etc. The

Free-Soil party demanded its repeal; the Republican party inherited and pressed the claim; and the success of the latter in 1860 was taken by the South as notice that the next administration would repeal it.

Fugue, fūg, a musical term derived from the Latin word *fuga*, — a flight, and signifying a polyphonic composition constructed on one or more short subjects or themes, which are harmonized according to the laws of counterpoint, and introduced from time to time with various contrapuntal devices. The interest in these frequently heard themes is sustained by diminishing the interval of time at which they follow each other, and monotony is avoided by the occasional use of episodes, or passages open to free treatment. The chief elements of a fugue are: (1) the subject; (2) the counter-subject, or contrapuntal harmonization of the answer by the part which has finished the enunciation of the subject; (3) the answer; (4) episodes; (5) the stretto; and (6) the pedal point.

There are three kinds of fugue, the simple, containing one subject; the double, consisting of two subjects, occasionally intermingled and moving together, and the counter fugue, in which the subjects move in a direction contrary to each other. In all the fugues the parts *fly*, as it were, after each other, whence the name. The great masters of fugal form are Johann Sebastian Bach and Handel.

Fuller, Anna, American novelist: b. Cambridge, Mass., 9 Nov. 1853. Her works are: 'Pratt Portraits; Sketched in a New England Suburb' (1892); 'A Literary Courtship' (1893); 'Peak and Prairie' (1894); 'A Venetian June' (1896); 'One of the Pilgrims' (1898); 'Katherine Day' (1901); 'A Bookful of Girls' (1904).

Fuller, Arthur Buckminster, American Unitarian clergyman: b. Cambridgeport, Mass., 1822; d. at the battle of Fredericksburg, Va., 13 Dec. 1862. He was graduated from Harvard in 1843, studied in the Harvard Divinity School, and held pastorates in Manchester, N. H., and Boston and Watertown, Mass. In the Civil War he was chaplain to a Massachusetts regiment. He edited several works of his sister, Sarah Margaret Fuller d'Ossoli (q.v.).

Fuller, George, American artist: b. Deerfield, Mass., 1822; d. Boston 21 March 1884. As early as 1857 his work attracted attention, and during the last years of his life his pictures were warmly admired by many for their richness of tone and peculiar handling, though they never appealed to the popular taste. His best-known works are: 'The Romany Girl' (1879); 'She was a Witch' (1879); 'Winifred Dysart' (1881); 'A Turkey Pasture in Kentucky'; 'Fedalma' (1884).

Fuller, Henry Blake, American author: b. Chicago, Ill., 9 Jan. 1857. He was intended for a mercantile career, but entered literature with 'The Chevalier of Pensieri-Vani' (1891), and 'The Châtelaine of La Trinité' (1892). He next wrote: 'The Cliff Dwellers' (1893), and 'With the Procession' (1895), novels of Chicago life; 'The Puppet-Booth' (1896), dramatic sketches; 'From the Other Side' (1898), short stories; 'The Last Refuge' (1900); 'Under the Skylights.'

Fuller, Melville Weston, eminent American jurist and one of the chief justices of the Supreme Court of the United States. He was born in Augusta, Me., 11 Feb. 1833; graduated at Bowdoin College (A.M.) in 1853, and attended a course of lectures at the Harvard Law School (LL.D.), and was admitted to the bar in his native city in 1855. He began the practice of law, meanwhile becoming the associate editor of the 'Age,' a Democratic newspaper. In 1856 he was elected city attorney and president of the common council. He resigned these offices and removed to Chicago, where he established an extensive law practice.

In 1862 he became a member of the Illinois State Constitutional Convention, and in the following year was elected from Cook County to the lower house of the State legislature. He rose rapidly in State and national politics, and from 1864 to 1880 was regularly a delegate from Illinois to the Democratic national conventions. In 1876 he placed Thomas A. Hendricks in nomination and was himself seriously considered as a candidate for presidential nomination in 1880. The same year he practically retired from politics, but gained additional fame as a lawyer during the next few years. In the famous lake-front case in Chicago he was counsel for the municipality, and in the Cheney ecclesiastical case, he defended Rev. C. E. Cheney, a Protestant Episcopal clergyman, rector of Christ Church, Chicago, against an action brought by an ecclesiastic council.

In April 1888 President Cleveland appointed him chief justice of the United States Supreme Court to succeed R. M. Waite (q.v.), deceased. He was confirmed 20 July 1888, taking the oath of office 8 October. About this time Bowdoin, Harvard College, and the Northwestern University conferred degrees upon him. In the Supreme Court he soon became a prominent figure, and he was largely responsible for the expansion of Federal power, by means of the decision asserting the implied authority of the executive to protect the Federal judge on occasion when there is just reason to believe that, while in the exercise of official duties, they are exposed to personal danger. This was especially applicable to the case of one Nagle, an Arizona cowboy, who was made a United States marshal to protect the person of Chief Justice Field, and who while performing this duty, shot and killed Judge Terry, of California.

In 1899 Justice Fuller was a member of the Arbitration Commission convened at Paris for the adjustment of the Venezuela boundary question.

Fuller, Sarah Margaret. See Ossoli, Sarah Margaret, Marchioness d'.

Fuller, Thomas, English historian and Anglican: b. Aldwinkle, Northamptonshire, June 1608; d. London 16 Aug. 1661. He was graduated from Queen's College, Cambridge. In 1630 took orders and was appointed perpetual curate of St. Benet's parish, Cambridge, and became very popular as a preacher. In 1631 he became prebend in the cathedral of Salisbury. The same year he published a poem entitled 'David's hainous Sin, heartie Repentance, and heavie Punishment.' He gave up his Cambridge curacy in 1633, and next year became rector of Broadwindsor, Dorsetshire. His 'History of the Holy Warre' appeared 1639, soon after the

MELVILLE WESTON FULLER.
CHIEF JUSTICE OF THE UNITED STATES SUPREME COURT, 1888.

publication of which he removed to London, and was chosen lecturer at the Savoy Church in the Strand. In 1642 he published his 'Holy and Profane State' (folio). In 1650 he published 'Pisgah Sight of Palestine and the Confines thereof, with the History of the Old and New Testament acted thereon' (folio), and in 1650 appeared his 'Abel Redivivus,' consisting of lives of religious reformers, martyrs, divines, etc. In 1655 he published the 'Church History of Britain, from the Birth of Jesus Christ to the Year 1648'; to which was subjoined the 'History of the University of Cambridge since the Conquest,' and the 'History of Waltham Abbey.' The year after his death was published his principal literary work, the 'Worthies of England' — a production valuable alike for the solid information it affords relative to the provincial history of the country and for the profusion of biographical anecdote and acute observation on men and manners. Consult 'Life' by Bailey (1874).

Fuller-Maitland, John Alexander, English musical critic: b. 1856. He was graduated from Trinity College, Cambridge, in 1879, and in 1889 became musical critic on the staff of the London *Times*. He contributed to Sir George Grove's 'Dictionary of Music and Musicians,' the appendix to which he edited; translated (with C. Bell 1884) Spetta's 'Johann Sebastian Bach,' wrote a standard 'Life of Robert Schumann' (1884), and further published: 'Masters of German Music' (1894); 'The Musician's Pilgrimage' (1899).

Fullerites, a religious sect near Athol, Mass., known as Fullerites or Howlandites, established 15 Sept. 1855, by Frederick T. Howland, a Quaker, of New Bedford, Mass. Among early converts was Leonard C. Fuller, the present head of the community. Their religious belief resembles somewhat that of the Adventists, but differs in the vital point that the reign of Christ, under the expected new dispensation, is to be spiritual and not personal as held by the Adventists. They believe the judgment day has already begun; the earth is not to be destroyed, but changed; they entirely renounce spiritualism. The community live chiefly upon farinaceous food; they drink principally water and sometimes herb tea. They live on the apostolic plan of having all property in common. They dress very plainly and no jewelry is worn. Sabbath is observed from 6 P.M. Friday until 6 P.M. Saturday. They own a farm of 210 acres.

Fullers' Earth, a pulverulent material formerly much used for fulling cloth and wool, but now more generally employed as a filtering material for the clarification of oils. It is not a substance of definite composition, but consists essentially of clay, mixed with sufficient finely divided silicious matter to destroy its plasticity. The production in the United States in 1902 was $98,144, chiefly from Florida. It also occurs in Georgia, Arkansas, and other States.

Fullerton, George Stuart, American professor of philosophy: b. Fathegarh, India, 18 Aug. 1859. He was graduated from the University of Pennsylvania and in 1887 he was appointed professor of philosophy in the same institution. He is the author of: 'Preliminary Report of Seybert Commission on Spiritualism' (1887); 'The Conception of the Infinite' (1887); 'A Plain Argument for God' (1889); 'The Philosophy of Spinoza' (1894); 'On Spinozistic Immortality' (1899).

Fullerton, Lady Georgiana Charlotte Gower, English novelist: b. Tixall Hall, Staffordshire, England, 23 Sept. 1812; d. Bournemouth, Hampshire, 19 Jan. 1885. She was married to Alexander George Fullerton in 1833, and followed him into the Roman Catholic Church in 1846. Her first novel, 'Ellen Middleton' (1844), was followed by 'Grantley Manor' (1847). Her later stories, after her conversion to the Catholic faith are in a mild way "stories with a purpose," the purpose being to develop the influence of religious belief on life and character; among them are: 'Lady Bird' (1852); 'Too Strange Not to be True' (1864); 'Mrs. Gerald's Niece' (1871); 'A Will and a Way' (1881). She wrote also 'The Gold-Digger, and Other Verses' (1872). See Craven, 'Life of Lady Georgiana Fullerton,' translated from the French by H. J. Coleridge (1888).

Fulling, the act of cleansing, scouring, and pressing woven woolen goods, etc., to render them stronger, firmer, and closer; called also milling, because these cloths are usually scoured by a water-mill. The principal parts of a fulling-mill are the wheel, with its trundle, which gives motion to the tree or spindle, whose teeth communicate that motion to the pestles or stampers, which fall into troughs, wherein the cloth is put, with fullers' earth, to be scoured and thickened by this process of beating it. The operation takes from 48 to 65 hours, and results usually in considerable shrinkage in length and width; it obviates the tendency to unravel and renders the threads of the cloth so firm and close as to be almost imperceptible.

Fulmar, fŭl'mar, an Arctic petrel (*Fulmarus glacialis*), which breeds on rocky coasts of the North Atlantic in enormous colonies, and comes southward in winter. It is about the size of a large duck. The head and neck are pure white; the back and long wings of a pearly gray; breast, belly, and under surface white; bill large, strong and yellow; legs and toes brownish. The young are brownish gray. In the Hebrides, and especially in St. Kilda, where these birds reside in incredible numbers, they are of great value to the people. The fulmars breed on the faces of the highest precipices, on which every grassy shelf over a few inches in extent is covered with their nests, which are slightly excavated in the turf and lined with dry grass and withered tufts of sea-pink. One egg is deposited at a time, which the cliffmen obtain by descending with ropes from the summit of the cliffs. The birds, when seized, vomit a quantity of clear amber-colored oil of a disagreeable odor, which is one of the most valuable products of St. Kilda. The old birds feed the very young with it. The fulmar feeds on animal substances, chiefly fat. It flies buoyantly and rapidly, and withstands heavy gales, skimming the surface of the water. When a whale is caught, though few of the fulmars should be present, they assemble in thousands as soon as the cutting up is commenced; hence the whalers call them "whale-birds" or "mollymauks." They follow in the greasy track of a ship, coming within a few yards of the men engaged in cutting, and devour the morsels of fat voraciously and in great quantity.

Various other large oceanic petrels are called fulmars, as the "Cape pigeon" (*Daption capensis*), giant petrel, "nelly" or "bonebreaker" (*Ossifraga gigantea*) of the Indian and Antarctic seas, and several species in the North and South Pacific. See PETREL.

Fulminates, fŭl'mĭ nāts, compounds of fulminic acid, all of which are violently explosive. The most important of these is mercuric fulminate, which is formed by dissolving 10 parts by weight of mercury in 120 parts of nitric acid (specific gravity 1.4) and, when cooled, pouring this solution into 110 parts of 95 per cent grain alcohol. At the normal temperature a reaction sets in which becomes quite turbulent, dense white fumes being given off and then red fumes, and after this, the mercuric fulminate separates out as a gray, crystalline powder. It has the formula of $HgO_2N_2C_2$, and belongs to the class of chemical substances known as oximes. Its specific gravity is 4.42. When dry, mercuric fulminate explodes violently if struck or compressed or rubbed between hard surfaces, when heated to 186° C., when touched with strong sulphuric or nitric acids, or when in contact with sparks from flint and steel or electric sparks. In all these cases the body undergoes a detonating explosion, and its principal use is to produce detonation in high explosives, though it is also used in percussion caps and primers to ignite gunpowder and other low explosives. Mercuric fulminate should be stored and transported only in the moist condition, yet even in this condition it can be exploded by the explosion of dry fulminate in contact with it. Certain amines like fulminating silver, gold, mercury and copper are frequently confounded with the fulminates because they are also explosive. The best known of these is Berthollet's fulminating silver, which was used in the bomb which killed the Czar of Russia. This body is made by treating freshly precipitated silver oxide with ammonia water. It separates out as a black, crystalline mass, which explodes on the slightest concussion when dry and may even be exploded by rubbing when moist, so that it requires the greatest caution in handling. It has been repeatedly formed accidentally in the ammoniacal silver solutions used in silvering mirrors and in the silver baths used in the wet processes of photography and has given rise to serious explosions. See EXPLOSIVES.

Fulmina'tion, a term used in chemistry to denote the sudden decomposition of a body by heat or percussion, accompanied by a flash of light and a loud report, and differs therefore but little from detonation; except that the latter refers more to the sound, and the former to the flash. See DETONATION; EXPLOSIVES; FULMINATES.

Fulminic Acid. See FULMINATES.

Fulton, Robert, American inventor: b. Little Britain, Lancaster County, Pa., 1765; d. New York 24 Feb. 1815. Early in life he manifested a taste for painting, and purposing to adopt it as a profession, went to England to study under Benjamin West. In that country, however, he became acquainted with the Duke of Bridgewater, the founder of the canal system of Great Britain, who induced Fulton to abandon art, and take to the study of mechanical science. This nobleman was at the time engaged in a scheme of steam navigation, which he imparted to Fulton. The latter visiting Birmingham was brought into communication with the celebrated James Watt, who had just succeeded in his great improvement of the steam-engine, with the construction of which Fulton made himself thoroughly familiar during his stay. About this time he invented a machine for spinning flax, and another for making ropes, for which he obtained patents in England. In 1796 he published a 'Treatise on the Improvement of Canal Navigation.' From 1797 to 1804 he resided in Paris with Joel Barlow, the American representative at the French court. During this period he invented a submarine or plunging boat, called a "torpedo," designed to be used in naval warfare. He invited the attention of the French government to his invention, and Bonaparte, then first consul, appointed Volney, La Place, and Monge as a commission to examine it. Several experiments were made in 1801 in the harbor of Brest. He could easily descend to any depth, or rise to the surface; and where there was no strong current, the boat was quite obedient to her helm while under water. On one occasion, he remained in the torpedo several feet below the surface for more than four hours; but the motion of the boat while submerged was very slow, and it was clearly unequal to the stemming of a strong current. The French government declined to patronize the project, and Fulton accepted an invitation from the English ministry, who also appointed a commission to test the merits of his torpedo. He appears, however, to have received but little encouragement, and in 1806 returned to the United States. Having been supplied with the necessary funds by Robert Livingston (q.v.), who had been American ambassador at Paris, Fulton had the satisfaction of proving, in 1807, that steam could be applied to the propulsion of vessels with entire success. His achievement excited universal admiration, and from that time steamboats were rapidly multiplied on the waters of the United States. His first steamboat, called the Clermont (of 140 feet keel and 16½ feet beam), made a progress on the Hudson of five miles an hour. His second large boat on the Hudson was the Car of Neptune, and was built in 1807. He afterward built other steam vessels, one of them a frigate, which bore his name. His reputation became established, and his fortune was rapidly increasing, when his patent for steam vessels was disputed, and his opponents were in a considerable degree successful. Though an amiable, social, and liberal man, the anxiety and fretfulness occasioned by the lawsuits about his patent rights, together with his enthusiasm, which led him to expose himself too much while directing his workmen, impaired his constitution, and he died at the early age of 49. He was buried in Trinity churchyard, New York, and in 1901 a monument to his memory was placed there by the American Society of Mechanical Engineers. His name is perpetuated in the immediate locality by Fulton Street, Fulton Market and Fulton Ferry. Consult: Colden, 'Life of Fulton' (1817); Preble, 'History of Steam Navigation' (1883).

Fulton, Ill., city in Whiteside County, on the Mississippi River, and on the Chicago, M. & St. P., the Chicago, B. & N. and the Chicago & N. W. R.R.'s; 36 miles northeast of Rock

ROBERT FULTON.

Island. The Northwestern College of Illinois was opened here in 1865, and other prominent educational institutions are located in this vicinity. There are extensive lumber manufactories, clay-mills, sewer-pipe works, stove and metal foundries, and there is a large trade here in grain, lumber, and produce. The municipality is governed by a mayor and council elected every two years by popular vote. Pop. (1900) 2,685.

Fulton, Mo., city and county-seat of Callaway County, on the Chicago & A. R.R., 125 miles west of St. Louis. Here are located the State Institution for the Deaf and Dumb, State Lunatic Asylum No. 1, Westminster College (Presbyterian), founded 1852; the Woods College of the Christian Church of Missouri, and the Synodical College and Conservatory of Music. Fulton is noted for its fire-brick and pottery works, the city having an extensive supply of coal and fire-clay. The town was settled in 1821, and was incorporated as a city in 1859. The charter has never been changed since that date. The mayor and council are elected annually. The city owns and operates its electric light and water plants. Pop. (1900) 4,883.

Fulton, N. Y., city in Oswego County, on the Oswego River and the Oswego Canal, and on the New York C., New York, O. & W., and Delaware & L. R.R.'s, 25 miles northwest of Syracuse. It has a public library, city hall, opera house and other public buildings. It is the centre of the cheese trade of northern New York, and there are manufactures here of paper, woolen goods, flour, fire-arms, tools, water-motors, cutlery, paper-mill machinery, condensed milk, canned goods, etc. Fulton was settled in 1791 and was originally incorporated as a village in 1835. The villages of Fulton and Oswego Falls, with an aggregate population of 8,206, were consolidated and chartered as a city in April 1902. A mayor and common council govern the city, being elected every two years by popular vote. The municipality owns and operates the waterworks.

Fulvia, fŭl'vĭ-a, Roman matron: d. about 40 B.C. After being twice married she became the wife of Mark Antony. Antony divorced her to marry Cleopatra, upon which she attempted to persuade Augustus to take up arms against her husband. When this scheme did not succeed she retired into the East, where Antony received her with great coldness. This broke her heart, and she soon after died.

Fumiga'tion, an attempt at disinfection by gaseous agents. Fumigation is probably a very unsatisfactory mode of bringing about disinfection. The agents that are used most effectively are chlorine gas, sulphur dioxide, and formaldehyde. It has been distinctly demonstrated that chlorine gas as a disinfecting agent is untrustworthy, and that its application is attended with many disadvantages. Sulphur dioxide, in the absence of moisture, gives practically no results, and even when aqueous vapor is generated in a room previous to the use of the gas its bactericidal action is very slight. Moreover, sulphur dioxide in the presence of moisture in the air tarnishes brass and silver, gilt frames, etc., and corrodes fabrics and other stuffs. It is not a satisfactory disinfectant. Formaldehyde gas has been used since 1890 for fumigation. The vapor is extremely pungent, and it has a strong affinity for all organic substances. Its practical value as a disinfectant has been demonstrated to be above that of any other gaseous substance. It cannot, however, be said to give absolute results, and although its power of penetration is greater than in that of any of the others mentioned it is still only a surface disinfectant. The interior of a heap of clothing, for instance, if exposed to the gas, is not affected at all by it. Formaldehyde gas as a fumigant is not sufficiently strong to kill many household pests. This casts suspicion on its value as a room disinfectant. Moreover, it is very costly. In general it may be gathered that gaseous disinfection by fumigants is somewhat of a farce; and although formaldehyde gas approaches more closely the requirements of the ideal, it is far from being perfect. The best disinfectant for rooms is unquestionably sunlight. Short of this, thorough cleansing, rubbing down the walls, etc., should be carried out. As noted in the article on disinfection, it is the effort of hygienists to particularize on the type of disease agents which they desire to eradicate. The general modes of disinfection heretofore much in vogue were largely founded on a lack of knowledge of what the infecting agents have been. See BACTERICIDE; DISINFECTANTS.

Fu'mitory ("smoke of the earth"), a name commonly given to species of the genus *Fumaria.* It is a native European weed which has been naturalized in America. The climbing fumitory or mountain-fringe of the United States grows well under cultivation. To the family *Fumariaceæ* belongs the genus *Corydalis,* found throughout most of the north temperate zone.

Funchal, foon-shäl, Madeira, the capital and seaport of the island in the centre of a large bay on the south coast of Madeira. It is irregularly built; the streets are narrow, winding, ill-paved, and dirty. An old castle, which commands the roads, stands on the top of a steep, black rock, called Loo Rock, surrounded by the sea at high water. The entire produce of the island, consisting mostly of wine and fruit, is exported from Funchal. Pop. (1901) 19,600, among whom are many English, French, Portuguese, and mulatto and negro freedmen. See MADEIRA.

Funck-Brentano, funk brōn-tä-nō, **Théophile,** French philosophical and critical writer: b. Luxembourg 20 Aug. 1830. He became professor at the School of Political Sciences in Paris in 1873. His thorough studies in law and medicine have imparted to his philosophical writings an exactitude of thought and inspired a special stress on method, very apparent in such works of his as: 'New Thoughts and Maxims' (1858); 'Exact Thought in Philosophy' (1869); 'Greek Sophists and Contemporary English Sophists' (1879); and others. As a critic he is esteemed for the happy presentation and careful elaboration of his thought.

Function, (1) In biology, the action proper to tissues, organs, or groups of organs in plant and animal life. The function of respiration is the joint action of lungs and skin; digestion is a very compound function, to which organs and groups of organs contribute. The actions are capable of being grouped in subordination to three leading phenomena of every living thing—namely, sustentation, reproduction, and relation. To the first belong digestion and all the other functions which contribute to the vegetative life; the processes of the second are, as examples of cell transformation, so far identical with those of the other two, but the results are different; the cell changes of the nervous system which regulates the relations of living things, are again identical with those of the other two sets of phenomena. Functional diseases are those due to organs perfect in structure but not performing their functions properly; as opposed to organic or structural diseases, due to defect of structure.

Organs often have more than one function—a *primary*, or that for which it is principally intended, and a *secondary*, some subsidiary purpose which it performs. It sometimes happens that important changes take place in the course of the evolution of a type, or the development of an individual, whereby the primary function disappears and some secondary use becomes pre-eminent or exclusive. Thus "a brilliant speculation," says Carpenter, "has indicated pairs of tracheal gills on the meso- and metathorax as the possible origin of insect wings. The primeval insects forsook, so it is thought, the water for the land; and the plates, becoming useless for breathing, were enlarged and finally changed into organs of flight." Another strong and familiar example is the case so often presented among crustaceans where the mouth parts are largely structures ("foot-jaws") originally ambulatory, but now entirely devoted to the seizing and mastication of food. Change of function results in change of structure. Consult Darwin, 'Origin of Species' (6th ed., London 1882); A. Dohrn, 'Der Ursprung der Wirbelthiere und das Princip des Functionwechsels' (Leipzig 1875); A. M. Marshall, 'Biological Lectures and Addresses' (London 1894); Saint George Mivart, 'Genesis of Species' (New York 1871). See also FUNCTIONALISM.

(2) In mathematics, one quantity is said to be a function of another, or of several others, when its value depends on those of the latter. Thus the area of a triangle is a function of its three sides, and $y=a+bx+cx^2$ is a function of a, b, c, and x. Functions receive distinctive names according to the nature of the dependence above referred to. Thus the function above written is said to be an algebraical function of x, since y is obtainable from x by the performance of a limited and definite number of algebraical operations. Log x, sin x, a^x, on the other hand, are said to be transcendental functions of x, and for obvious reasons receive the distinctive names of logarithmic, trigonometrical, and exponential functions. The term function in its mathematical sense was due to Leibnitz (1692), but in its present sense was first defined by Johann Bernoulli (1718). Lagrange first used the term "theory of functions" in his 'Théorie des fonctions analytiques' (Paris 1797). The object of the theory is the study of functions of one or more variables, in which either the variables or the coefficients, or both, are complex numbers. Lagrange (1772, 1797, 1806) may be said to have been the real founder of this general theory but others before him—Newton, Leibnitz, Bernoulli, Clairaut (1734), D'Alembert (1747), and Euler (1753)—had already worked in its direction. Landen (1775) is usually credited with founding the theory of elliptic functions, though this theory had been suggested by Jakob Bernoulli (1691); Maclaurin (1742), and D'Alembert (1746). The real development of the theory, however, is due to Legendre, who after great labor produced his 'Traité des fonctions elliptiques et des intégrales Euleriennes' (1825-8). Abel, Jacobi, and Cayley also contributed much to this theory. The present form of the general theory of functions is based largely on the works of Cauchy, Riemann, and Weierstrass. For a list of the special functions consult: Müller, 'Mathematische Terminologie,' in 'Bibliotheca Mathematica' (Leipzig 1901), a work in which are given about 200 functions. Brill and Noether, in 'Die Entwickelung der Theorie der algebraischen Functionem in älterer und neuerer Zeit,' in 'Jahresbericht der deutschen Mathematiker Vereingung' (Vol. II, Berlin 1894), give a valuable history of the development of functions. Consult also: Forsyth, 'Theory of Functions' (Cambridge 1893); Harkness and Morley, 'Theory of Functions' (New York 1893); and Merriman and Woodward, 'Higher Mathematics' (New York 1896), in all of which will be found the historical development, bibliography and full discussion of the theory of functions. See also articles in this encyclopedia: COMPLEX VARIABLE, THEORY OF THE FUNCTIONS OF A; REAL VARIABLE, THEORY OF THE FUNCTIONS OF A; MATHEMATICS; TRIGONOMETRY; etc., to which extended bibliographies are appended.

Functionalism (in psychology and philosophy). Functionalism is a term employed by modern writers both in philosophy and psychology. It occurs more commonly in psychological writers and it will be convenient to designate first the meaning which they assign to it. Functional psychology can be considered as dealing with three fairly distinct problems which we may discuss separately.

First: One of the fundamental problems which psychologists undertake to solve consists in the determination of the number and character of the various materials sensory, ideational, etc., which the mind employs, *e. g.*, the varieties of color, tone, taste, etc. Their effort is directed to analyzing and describing both the elementary and the complex *contents* of consciousness. This field of endeavor is ordinarily entitled structural psychology. As contrasted with this, functional psychology undertakes to discern and portray the typical *operations* of the mind with especial reference to the *actual* life conditions under which consciousness occurs. In describing sensation, for example, it would find its sphere of interest in determining the character of the various sense activities like vision and hearing, as differing in their *modus operandi* from one another and from other mental processes such as thinking and willing.

This branch of functional psychology is found in all important psychological writers from Aristotle to the present day. It is not, however, until the present generation that any essential distinction has been recognized along this line between structural and functional psychology. Indeed, as compared with the remaining forms of functional psychology, the distinction is relatively unimportant. It represents nevertheless a difference in emphasis which is significant. The functionalist is peculiarly resolute in his purpose to describe mental life as it is in the moment of experience. The analyses offered by the structuralist are perhaps apt to dwell too impartially upon details which may be evident to later introspective examination without having constituted noticeable features of the conscious state itself when it was in progress.

Substantially identical with this first conception of functional psychology, but phrasing itself somewhat differently, is the view which regards the functional problem as concerned with discovering *how* and *why* conscious processes are what they are. The structuralist is supposed to be occupied with the problem of determining *what* the conscious elements are and how they are combined. In general it will be seen that functionalism as thus described is roughly analogous to a physiology of mind, whereas structuralism is analogous to a mental anatomy.

Second: A broader conception of functional psychology and one more frequently characteristic of contemporary writers takes its rise from the prevailing interest in the larger formulae of biology and particularly the evolutionary hypotheses within whose majestic sweep is nowadays included the history of the whole stellar universe. From this point of view functional psychology finds its peculiar problem in mental activity as part of a larger stream of biological forces. The psychologist of this stripe is wont to take his cue from the basal conception of the evolutionary movement, *i. e.*, that for the most part organic life possesses its present characteristics by virtue of the efficiency with which they serve to meet the conditions laid down by the environment. With this conception before him he attempts to gain some understanding of the manner in which the psychical contributes to the furtherance of organic activities—not alone the psychical in its entirety, but much more the psychical in its particularities, mind as feeling, mind as judging, as willing, etc. He seeks to discover the exact nature of the accommodatory service represented by the various great modes of conscious expression.

Animal psychology affords a concrete example of the effort to discover these particularistic features of the adaptive service rendered by consciousness to organisms. Modern investigations in this field have thrown a flood of light upon such problems as the mechanism of instincts, the methods of animal topographical orientation, the scope and character of the several sense processes, etc. In a similar manner the studies of human genetic psychology, particularly that branch entitled child study, have contributed to our knowledge of the service rendered to the growing mind by its several different functions, such, for example, as the various sensations, the emotions, etc. Pathological psychology has also contributed in no small measure to our knowledge of the part played by particular portions of our consciousness in the development and organization of our mental life as a whole.

In this connection it is interesting to remark that not a few modern writers hold the view that every accommodation by an organism to a *novel* situation requires and involves consciousness. Such a view rests on the conviction that consciousness is not only of service from time to time in assisting organic adaptation to environment, but also that it is the absolute pre-condition of accommodation to situations which are new.

This broad biological ideal of functional psychology may be considered as issuing in the attempt to discover the fundamental utilities of consciousness. The problem from this point of view has not as yet been satisfactorily solved. It is possible to regard the three great familiar divisions of mental life, *i. e.*, knowing, feeling, and willing, as constituting these basal utilities. There are, however, many subordinate categories which are equally significant; *e. g.*, attending and judging. Moreover, from the strictly utilitarian standpoint it may be urged as practicable to reduce all these manifestations of utility to the basal one, selective accommodation; that is to say, it is because consciousness by its selective action leads to movements which result in the attaining of certain ends, that mind possesses value.

Third: It is sometimes asserted that functional psychology is in reality a form of psychophysics. This means that it finds its major interest in determining the relations to one another of the physical and mental portions of the organism. To be sure all psychology must necessarily entertain some doctrine regarding these relations, but functional psychology is occasionally identified with a peculiar attitude toward this problem which may be described as follows:

The distinction between the mind and the body is not regarded as founded primarily on a difference between two kinds of existence, one physical and the other mental. The two are rather thought of as different modes in which organic life expresses itself, now the one and now the other being more in evidence. Conscious processes are thought of as present whenever novel situations are to be dealt with and the fundamental business of consciousness is conceived to be that of building up efficient habits, or co-ordinations, to meet the necessities of these situations. The purely physical or physiological processes are on the other hand regarded as finding their peculiar sphere of action wherever old and well-formed habits are capable of meeting the requirements of the temporary environment. From this point of view mind and body are not so much two distinct entities as they are stages or aspects of the general process of vital accommodation to environment.

These three conceptions of functional psychology which have been described are obviously supplementary to one another. It is clearly impracticable to carry out a functional psychology which should deal with the problem of mind conceived as engaged in mediating between the environment and the needs of the organism without having some doctrine to offer concerning the connection of the mind and the body, for by common agreement consciousness makes itself effective through the muscular movements to which it leads. Some notion, therefore, of this connection must be involved. Moreover, it is equally certain that no effort to handle either of these problems can go far without some theory as to the basal character of the various mental operations themselves. The three positions must accordingly be regarded as complementary to one another. Their apparent divergence arises chiefly from emphasizing different aspects of a common problem.

The term functionalism, as has been already intimated, is less frequent in philosophy than in psychology. When used, however, it is generally employed as substantially identical with such terms as pragmatism and humanism. It does not represent a definite group of opinions and beliefs, but rather a certain attitude toward philosophical problems. This attitude may be illustrated by the comments in an earlier paragraph upon functional psychology conceived as concerned with the mind-body problem. In general, philosophical functionalism undertakes to discern the exact circumstances out of which the various problems of philosophy have grown, not only in the historical sense in which these problems are connected with the systems of particular movements or philosophers, but in the much more genetic sense in which they may be shown to come to light in the reflective processes of any human being. In a way, therefore, it might be designated a genetic philosophy.

In its purposes at least a philosophy of this kind is peculiarly vital, for it attempts to see the practical living significance of philosophical problems and it finds its solutions in the actual outcome in human life of the multifold factors with which metaphysical speculation finds itself confronted.

(*Journal of Philosophy, Psychology, and Scientific Methods*, 1904, p. 477).

JAMES ROWLAND ANGELL,
Professor of Psychology, University of Chicago.

Fundamental Note, Tone, or Bass. (1) The lowest or gravest note that a string or pipe sounds in generating a series of harmonics. The fundamental note of a stretched string is sounded when the string vibrates as a whole. The fundamental note of an open organ-pipe is sounded when there is one node at the middle of the pipe. In a closed organ-pipe the closed end or stopper acts as the node when sounding the fundamental note.

(2) The fundamental note also signifies the root of a chord, irrespective of the inversions of the chord; thus in the common chord of C, C E G, C is the fundamental note and remains so in the inversions E G C, G C E, E and G being called the bass notes.

Fundamental Units is the term employed in physics for units which constitute the foundation of calculations with regard to other quantities; units used for measuring others. Fundamental units are three, namely, a definite length, a definite mass, and a definite interval of time.

Funded Debt. See DEBT, NATIONAL.

Fundi, or **Fundungi,** a kind of grain *Paspalum exile*, allied to the millets, which is cultivated to a considerable extent in the western part of Africa. It is wholesome and nutritious and is much used by the natives of western Africa as a food.

Funding, in finance, the conversion of floating debt into an interest-bearing obligation with a definite period, on which bonds can be issued. One such operation if of special interest in United States history, as part of the operations by which Hamilton, as leader of the Federalists (q.v.), and then secretary of the treasury, succeeded in setting the government on a firm foundation. The Act of 4 Aug. 1790 funded not only the foreign and domestic debt in full, but the State debts incurred in carrying on the Revolutionary War; the bonds were at 6 per cent., but those for the domestic debt did not bear interest till 1800.

Funds, Public. See DEBT, NATIONAL.

Fundy, Bay of, a huge arm of the Atlantic Ocean extending into the land between New Brunswick and Nova Scotia, and the State of Maine, and terminating in two smaller bays, Chignecto Bay and the Basin of Minas. Its length up to Chignecto Bay is 140 miles, and its extreme breadth 45 miles. It is noted for its high tides, which are influenced by the Gulf Stream, and rise about 30 feet at St. John and 60 feet at the head of Chignecto Bay, rushing into the latter with remarkable force. At Bay Verte, 14 miles distant, the tide rises little more than 4 or 5 feet. Along its northwest side the Bay of Fundy receives the St. John, the largest river in New Brunswick, and also the St. Croix. The tides in the Fundy are perilous to navigation and produce dangerous bores, especially in the upper reaches of the Bay. At low tide there is a long expanse of mud flats, at times over 2 miles in length, and the inreaching estuaries are completely drained. At the entrance to the Bay of Fundy are the Grand Manan and other islands. See TIDES.

Fu'nen, an island of the Danish archipelago, separated from Jutland by the strait called Little Belt; area 1,123 square miles; pop. (1901) 279,501. Its shores are deeply indented; its interior is undulating, and there are numerous lakes, streams, and marshes. The largest stream is the Odense, 36 miles long. It trades principally with Sweden and Norway. It forms with other islands a province of Denmark (q.v.). Chief towns: Odense, Svendborg, and Nyborg.

Funeral Rites, the last religious and ceremonial tribute of friendship and love paid to the remains of the dead. Among the Hindus the corpse is perfumed and adorned with flowers; it is then burned; after many ceremonies the bones are deposited in a casket and buried, but afterward disinterred and thrown into the Ganges. A second series of obsequies commences after the period of mourning has expired, and this is followed by commemorative rites. The voluntary immolation (*suttee*) of the widow of the deceased, now abolished, was the most remarkable part of the ceremony. The Mohammedans bury their dead. The interment takes place as soon as possible, in obedience to the command of the prophet: "Make haste to bury the dead, that, if he have done well, he may go forthwith into blessedness; if evil, into hell-fire." No signs of excessive grief, no tears nor lamentations, are allowed, as it is the duty of a good Mussulman to acquiesce without a murmur in the will of God. On arriving at the burial place the body is committed to the earth with the face turned toward Mecca. Monuments are forbidden by the law, but they are constantly erected. The Egyptians, it is well known, embalmed their dead. Among the Jews the next of kin closed the eyes of the deceased; the corpse was then washed, and, in the case of persons of some consequence at any rate, laid for a time in spices or anointed with spices, swathed in linen bandages, and deposited in the tomb. The mourning customs of the Jews may be collected from various passages of the Scriptures. They went bareheaded and barefoot, covered their mouths and kept silence, put on sackcloth and sat in ashes; funeral songs were sung by persons hired for the purpose. Splendid monuments were sometimes hewn out of the solid rock, with numerous niches: as each niche was filled, its entrance was stopped up by a large stone rolled against it. In the religious creed of the Greeks and Romans sepulture was an act of piety to the dead; without it the spirit had to wander 100 years on the banks of the gloomy Styx. The last breath was generally caught by a near relative, who opened his mouth to receive it; the body was washed and crowned with flowers, a cake of flour and honey placed in the hand, as a bribe for Cerberus, and an obolus in the mouth, as a fee for Charon. Interment and burning were practised indifferently. In interment the body was placed with the face upward and the head toward the west. In burning the pile varied in form and material: it was lighted by the nearest relative; perfumes and wine were poured on it, and the richest clothes of the dead were burned with him. The ashes were then collected and deposited in an urn. This description applies to the Greeks and Romans, whose rites were nearly identical.

In the Roman Catholic Church the body is washed immediately after death, a crucifix is placed in the hands, and a vessel of holy-water at the feet, with which the visitants sprinkle it. The Ritual prescribes that the corpse be borne in procession from the house in which it lies to the church, attended by the parish priest with acolytes and servitors all in cassock and surplice, and one of them bearing the processional cross in the van. Before the procession moves, the priest first sprinkles the coffin with holy-water and recites the *De Profundis* and the *Miserere* while the procession is in movement. Taken into the church, the coffin is laid on trestles in the middle of the nave, the feet to the east or the sanctuary, if the deceased was a layman, the head to the sanctuary if he was a priest; lighted candles surround the coffin. Then follows the Office for the Dead, and after that the Mass for the Dead. After the Mass the priest, attended by the acolytes, pronounces the Absolution and certain prayers, meanwhile sprinkling the coffin with holy-water and fumigating it with frankincense. The procession is now reformed and the body borne to the place of burial. There the *Benedictus* is sung or recited, followed by the Antiphon, *Ego sum resurrectio et vita* ("I am the resurrection and the life"); the corpse is again sprinkled, a final prayer is pronounced, and the body is laid in the grave or tomb. In the funerals of children, the vestments of the clergy are white instead of black, joyous psalms are chanted or recited, there are antiphons of praise and thanksgiving instead of petitions for mercy and forgiveness; and the church bell is not tolled.

In the Greek Church there are distinct services for laymen, monks, and priests severally. The officiant holds a short service at the house of the defunct; service is held at the church, to which the body has been brought, and then at the grave, where the priest takes a shovel and sprinkles dust cross-wise on the body. Finally, before the grave is closed, he casts wax or ashes from his censer upon the coffin. The English Church, followed very closely by the Protestant Episcopal Church in the United States, uses the order for the Burial of the Dead in the Book of Common Prayer. It is a stately and somewhat elaborate service, which is frequently used in part by other Protestant bodies. The first section of the service is recited in church, to which the body has been brought, or at the house of the defunct. It consists of anthem, psalms and a lesson. The second section, sometimes called the committal, is recited at the grave, where dust is scattered on the coffin as it has been lowered.

Fungi, fŭn'jī (singular *Fungus,* Latin name for mushroom), the general name applied to a multitude of lower plants of quite diverse structure, but which agree in not containing chlorophyll, the green coloring matter of the vegetable kingdom. Formerly the fungi were regarded as constituting a natural group (class or order) of plants, but are now recognized by modern botanists as belonging to many natural groups of plants.

The peculiarities of fungi are physiological; they result from their food habits, and are not primarily structural and of profound significance. When we enumerate the physiological changes involved in the change of a plant from an independent life to one of parasitism or saprophytism, we have considered all of the essential differences between the fungi and the green plants from which they have been derived. We may say then, that a fungus is a lower plant which has suffered certain physiological changes on account of the fact that it has become parasitic or saprophytic.

Before going farther it is necessary to define certain terms which must be used in any discussion of the fungi. A plant is a *parasite* when it lives upon or in another living plant, absorbing food from it, and living at its expense. The mere fact of growing upon another plant does not make the first parasitic, for there are many small plants which merely find lodgment upon larger species, not, however, absorbing anything from the plants on which they are lodged. When it is necessary to distinguish such plants, they are called *epiphytes.* In the case of parasites the plant upon which they live is spoken of as the *host.* When a plant lives upon a plant which is no longer living, it is called a *saprophyte.* Thus the toadstools which grow so freely on manure and other decaying vegetable matter are saprophytes. It is sometimes necessary to have a term to apply to plants which are neither parasitic nor saprophytic, and then we use the word *holophyte.* Thus all common green plants are holophytes. When it is desired to contrast holophytes with both parasites and saprophytes, we can use the term *hysterophyte* for the parasitic and saprophytic plants.

Applying the terms we have now defined, we may say that all fungi are hysterophytes, some living parasitically upon their hosts, others living saprophytically.

All holophytes are green in color, and the significance of this is purely physiological. Green plants absorb the gas carbon dioxide, and in green cells this is combined with some of the elements in the ever-present moisture of the plant into a chemical compound allied to starch and sugar, and characterized by consisting of nearly equal amounts of carbon and oxygen, combined with nearly double the amount of hydrogen.

Such compounds are known as carbohydrates and they are made by all holophytes, and then used in the processes of assimilation and growth. It has been demonstrated that plants which are not green cannot make the carbohydrates, and since all plants need these compounds for building up their tissues, it follows that colorless plants must obtain them by taking them from living or dead green plants. Last, it should be borne in mind that even green plants cannot make the carbohydrates in darkness. For this work they need light and in fact the greatest importance of light to a plant is in connection with this process of making carbohydrates. Accordingly plants which are not green, and which as a consequence do not make carbohydrates, often grow in darkness or in feeble light. This is quite characteristic of the fungi, great numbers of which grow as well in darkness as in light, or in some cases grow even much better in the darkness than they do in the light.

The fungi are very numerous, some recent estimates placing the number of species as high as 250,000, of which not more than one third have as yet been described. They occur wherever there is organic matter of any kind upon which they can subsist. Wherever there are living plants or animals there are fungi which obtain food either from the living cells of their hosts, or the dead and cast-off cells and tissues. Some species occur in the lower layers of the air, in all exposed waters, and in the soil. They are the most numerous of living things when we consider individuals alone. They range in size from extremely small to many centimetres in length. The smallest are far too minute to be seen by the naked eye, some being visible only by the aid of the most powerful microscopes. Of some of the smallest species it would require 25,000 to 30,000 placed side by side to measure one inch. On the other hand there are toadstools a foot or so in height and diameter, and puff-balls two to three feet in diameter have been recorded.

The fungi as thus described are found in three of the grand divisions (branches) of the vegetable kingdom.

Branch Protophyta. The Protophytes.— Here are gathered a thousand or so species of microscopic aquatic plants in which the cells have a very low organization. No distinct nucleus is present, and the coloring matter in the typical plants pervades the whole cell, and is of a bluish or brownish-green color instead of a bright green as in higher plants. They reproduce by simple fission, and by the production of spores. There is no hint of any sexual reproductive process. They occur in ponds, pools and streams, to which they give a greenish color by their great numbers. In decaying they usually give off a fetid odor.

While the typical Protophytes are greenish — and are known as green slimes — many have become parasitic or saprophytic, and have lost their green color. These colorless species are known as Bacteria, and are the lowest of the fungi.

Bacteria (Fig. 1) are then to be regarded as colorless green slimes, their lack of color being due to their parasitic or saprophytic habits. Some species are minute rounded cells of remarkable minuteness. To these the generic name *Micrococcus* has been given, and many species have been recognized by botanists.

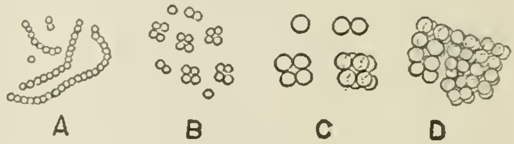

Fig. 1.— Bacteria. A, *Streptococcus pyogenes;* B, *Micracoccus tetragenus;* C D, *Sarcina lutea.* All highly magnified.

Other genera with spherical cells are *Streptococcus, Staphylococcus, Sarcina,* etc. Other bacteria consist of cylindrical cells which tend to adhere end to end in filaments or rods. In the genera *Bacillus* and *Bacterium* the rods are straight or little curved, and short or of moderate length, while in *Vibrio* and *Spirillum* the rods are more or less spirally curved. In still other genera, as *Crenothrix, Leptothrix,* etc., the rods are elongated. See Bacteria.

Branch Phycophyta. The Phycophytes.—These plants, of which there are probably nearly 10,000 species, may very properly be called the seaweeds, since they are typically aquatic, living in the salt and fresh waters of the earth. Typically they are bright green, and the cells of which they are composed have well-formed nuclei. However, the chlorophyll is confined to definite portions of the protoplasm, and is not diffused throughout the cell. Some of the lower species are spherical, rounded cells, but for the most part they consist of filaments of cylindrical cells, or in some instances they are masses of cells constituting leafy-stemmed plants. They reproduce by fission as in the Protophytes, but in addition all, or nearly all, Phycophytes reproduce sexually also. In the simplest cases of sexuality, two equal and similar cells detached from older plants fuse into a new and larger cell, and then this new cell grows into a new plant. Sometimes the new cell becomes covered with a

3. Yellow Cockscomb (Clavaria flava).
4. Early Toadstool (Helvella esculenta).
5. Cantarelle (Cantharellus ciberius).
6 Truffles (Tuber melanosporum .
7. Stubble Fungus (Hydnum repandum.).
8. Butterfly Fungus (Boletus granulatus).
9. Stone-Mushroom (Boletus edulis).
10. Masseron (Agaricus prunulus).
11. Parasol-Mushroom (Agaricus procerus).
12. Champignon, or Cultivated Mushroom Agaricus campestris)
13. Hooded Toadstool (Boletus scaber.

thick wall, and for a time ceases activity as a "resting spore," before it develops into a new plant.

While most Phycophytes are green plants, several hundred species have become parasitic or saprophytic in habit (Figs. 2 and 3) and have therefore lost their color, and become fungi. Among these are the following families, namely:

Fig. 4

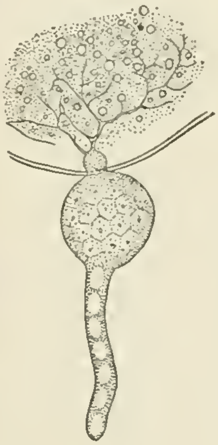

Fig. 3

Fig. 3.— *Rhizidiomyces apophysatus*, another of the lower fungi (*Chytridiaceæ*); the root-like organs are parasitic in a cell of a water mould. Highly magnified.

Fig. 4.— *Saprolegnia thureti*; A, fly with attacking filaments; B, end of a filament forming zoospores. C, zoospores escaping. A, natural size; B and C, highly magnified.

Water Moulds (*Saprolegniaceæ*) which are minute filamentous, colorless plants living in the water on living and dead plants and animals. (Fig 4.) Each plant is a more or less branched thread, some portion of which penetrates the host and thus obtains food, while the other part is external and bears the reproductive organs. The filaments are cylindrical, and are peculiar in having few cross partitions. They are to be regarded as composed of many cells which have not separated themselves by partitions. The nuclei are numerous, and very small.

The more common mode of reproduction is as follows: A terminal portion of a branch forms a partition at some distance from the extremity and the protoplasm in this segment becomes denser, and a little later divides into a great number of small cells, each of which remains naked (that is, no cell wall is formed around it), and soon escapes by a rupture of the end of the segment. (Fig. 4.) These escaped cells are known as zoospores, since they have a very active swimming motion, very like that of some of the lower microscopic animals. The similarity to the lower animals is shown still more by the identity in their locomotive organs, which consists of one or two slender protoplasmic whips (cilia) by whose rapid lashing the zoospores are propelled. After a short period of activity they come to rest, when they cover

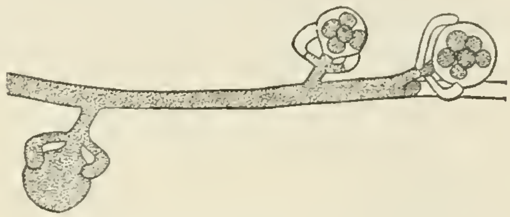

Fig. 5.— *Achlya racemosa*, showing antherids and oögones. Highly magnified.

themselves with a cell wall, and begin to elongate into a filament like that of the plant from which they came. Reproduction by means of zoospores is very rapid, since they are formed in such great numbers when conditions are favorable.

The sexual organs, which are rather rarely formed, consist first of an enlarged and rounded end segment in which the protoplasm is quite dense. From the sides of the branch below the end segment (or from elsewhere on the body of the plant) slender branches grow up and in turn their ends become cut off by cross partitions. (Fig. 5.) The first end segments (the rounded ones) are oögones, or in plainer words they are egg-organs, and in them one or more eggs are produced. The second segments (slender) are male organs called antherids, and the protoplasm they contain has the function of the spermatozoids of many plants (and animals). At the proper time the antherids puncture the egg-organs, and by the inflow of the contents of the former the eggs are fertilized. Later these eggs may germinate and produce new plants like those on which they were borne.

Downy Mildews (*Peronosporaceæ*) are much like the water moulds, but instead of being aquatic, they live in the tissues of land plants. Like the water moulds they are composed of branching, non-septate filaments. The main body of the plant grows in the intercellular spaces of the host, where there is nearly as much moisture as under aquatic conditions. (Fig. 6.)

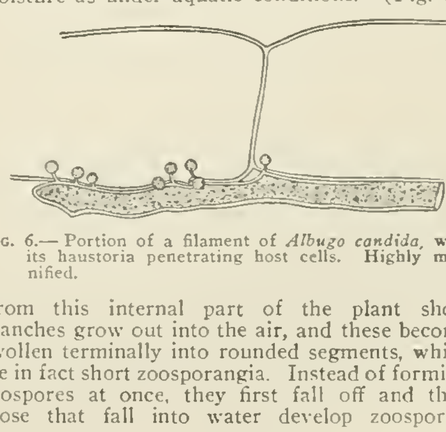

Fig. 6.— Portion of a filament of *Albugo candida*, with its haustoria penetrating host cells. Highly magnified.

From this internal part of the plant short branches grow out into the air, and these become swollen terminally into rounded segments, which are in fact short zoosporangia. Instead of forming zoospores at once, they first fall off and then those that fall into water develop zoospores, much as in the water moulds. As these structures are very minute, a droplet on a leaf is large enough for the germination of hundreds of the detached zoosporangia. Here again, the zoospores, after coming to rest, develop into new plants, which at once penetrate the host. In some species the zoosporangia grow at once into a filament, without forming zoospores.

The sexual organs of downy mildews are much like those of water moulds, the differences being quite immaterial for the present discussion. (Fig. 7.)

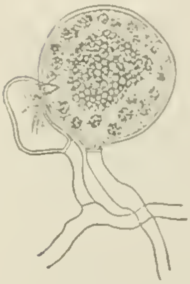

FIG. 7

FIG. 8

FIG. 7.— *Peronospora alsinearum*, showing antherid penetrating the egg-cell. Highly magnified.
FIG. 8.— *Mucor stolonifer*. Highly magnified.

It is evident from a comparison of the structure and reproductive organs of water moulds and downy mildews, that the latter are derived from the former. Just as the water moulds have been derived from the green plants of the green felt family (*Vaucheriaceæ*) by the adoption of parasitic and saprophytic habits, so by the change from strictly aquatic conditions to those found in the intercellular spaces of land plants, water moulds have been changed to downy mildews. Every difference between the two families may be accounted for by this difference in the environment of the plants.

Black Moulds (*Mucoraceæ*) show an additional modification of the water mould type. They are non-aquatic, mostly saprophytes, a few only being parasites. They live for the most part on dead organic matter, animal or vegetable, which is still moist, and but few species can live in the water. The commonest species live on the starchy and sugary substances in pantries, cellars, and other places where these substances are found in the presence of sufficient moisture. Organic substances which are dry are not attacked by black moulds.

Each black mould plant is a branching tubular filament, which has few cross partitions. One part of the plant usually grows in the substance of the organic matter, and another grows upward into the air. (Fig. 8.) The former absorbs food matter, while the latter bears reproductive organs, as in the water moulds. The ends of the aërial branches enlarge as in the two preceding families, but instead of forming zoospores, the protoplasm in the terminal segments forms many small spores, each covered with a cell wall. These spores are the homologues of the zoospores in previous families, but as the plants are not aquatic, these zoospores have ceased to be aquatic also. With a good cell wall to protect their protoplasm, they may be blown about in the air without drying up. It is in this way, in fact, that black moulds are propagated, the air currents carrying the spores sometimes for long distances, and when they fall upon organic matter under favorable conditions they quickly give rise to a new crop of mould plants. On the filaments which penetrate the nutrient substance, or grow over its surface, are to be found (rarely, however, in the common species) sexual organs somewhat resembling those of the two preceding families. (Fig. 9.)

Insect Fungi (*Entomophthoraceæ*) are somewhat similar to black moulds, but are parasitic in the body tissues of insects, and accordingly show considerable structural modifications. (See below.) Fig. 10.

Branch Carpophyta. The Carpophytes.— The plants which constitute this immense group are of much higher structure than those in the two preceding branches. They are still typically aquatic, and so are seaweeds, but this name is not as commonly applied to them as to the Phycophytes. The typical species are green plants, but in one group (the red seaweeds) the chlorophyll is hidden by a red or purple coloring matter. The plant-body is usually composed of an axis, on which are symmetrically arranged branches or leaves. The lower end of the axis is supplied with root-like organs by which it is attached to the soil or other support, and the plant commonly stands upright. Some species show a wonderful beauty of form and color, and on this account are greatly prized by amateur botanists, who collect and preserve them under the name of sea mosses.

All Carpophytes reproduce by two common methods. In the first, certain end cells separate from special branches, and float away to germinate and grow directly into plants like those from which they came. In the second method of reproduction an egg-organ, much like that of

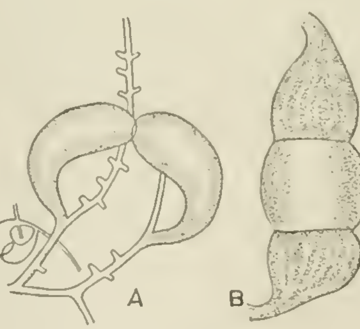

FIG. 9.— *Mucor fusiger;* A, young sexual organs; B, after fertilization. Highly magnified.

the Phycophytes, is fertilized by spermatozoids from an antherid which, again, does not differ in any essential respect from that of the Phycophytes. However, the result of the fertilization is the formation of a more or less compound body which the botanist recognizes as a primitive kind of "fruit." Hence, the aquatic Carpophytes are sometimes known as "Fruit Tangles." In these fruits are spores, and these on escaping and germinating give rise to new plants.

POISONOUS FUNGI

1. Golden Cantarelle (Cantharellus aurantiacus)
2. Puffball (Scleroderma aurantiacum)
3. Green Toadstool (Russula furcata)
4. Devil's Toadstool (Russula emetica)
5. Poisonous Toadstool (Lactarius terminosus)
6. Bulbous-leafed Mushroom (Agaricus phalloides)
7. Thickfoot (Boletes pachypus)
8. Satanic Fungus (Boletus satanas)
9. Antler-Fungus (Calocera viscosa)
10. Fly-Fungus (Agaricus muscarius)
11. Sulphur-Head (Agaricus fascicularis)
12. Witch-Fungus (Boletus luridus)

The chlorophyll-bearing Carpophytes comprise nearly 2,500 species, and are widely distributed in the salt and fresh waters of the globe. From these have sprung an enormous host of parasitic and saprophytic species, which are colorless, and constitute the great bulk of the fungi of the world, aggregating fully 100 times as many species as those from which they sprang.

In changing from the holophytic structure and habits of their ancestral types, these hysterophytes (fungi) have suffered much degeneration of the vegetative plant-body, while the reproductive apparatus has been relatively enlarged and multiplied. This is in accordance with the well-known law that since hysterophytes do not make carbohydrates they have little need of large vegetative bodies, and further, that since they are dependent upon particular hosts or organic matter for their food, they must provide more lavishly for propagation. Many of these fungi are little more than absorbing and reproducing organisms, the vegetative plant-body having almost entirely disappeared through disuse. These fungi are readily separable into two great classes, by characters derived from their reproductive apparatus. The first of these classes is known as the Sac Fungi, and the second as the Club Fungi.

Fig. 10

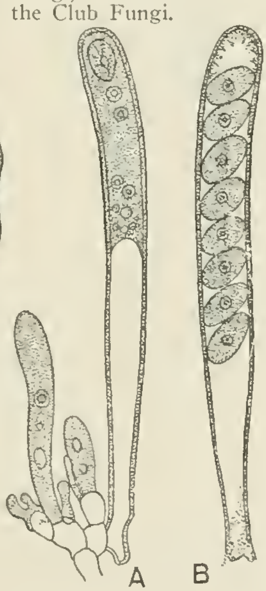

Fig. 11

Fig. 10.— *Empusa muscæ;* filaments from body of fly. Highly magnified.

Fig. 11.— A, several spore-sacs (*asci*) in different stages of development; B, a mature spore-sac. Highly magnified.

Sac Fungi (*Class Ascomycetæ*).— The distinguishing mark of the plants of this class is that the spores which occur in their fruits develop in certain end cells and remain enclosed within the cell wall until matured. (Fig. 11.) These spore-containing cells have been aptly likened to sacs (Latin, *asci;* singular, *ascus*) and from this we derive the name of the class.

There are more species of sac fungi than of all other kinds. They range in size from very minute to many inches in extent. They include some of the most harmfully parasitic plants as well as many which live saprophytically upon refuse organic matter. Among the many families (more than 40) in this class, the following may be noticed:

Powdery Mildews (*Erysiphaceæ*) are to be regarded as primitive sac fungi, but little removed from their aquatic ancestors. The plant body consists of branching filaments which creep over the surfaces of their hosts, from which they obtain food by means of root-like absorbing organs, which penetrate the host cells. Certain branches form spores by the simple process of separating their terminal cells in succession and this is done so abundantly that the spores form powdery masses on the surface of the hosts. These spores float away on wind currents, and those that germinate on similar hosts give rise to new plants.

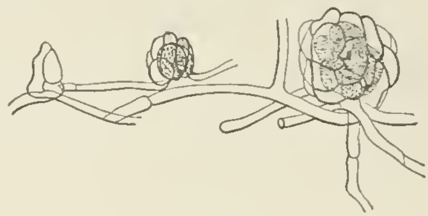

Fig. 12

Fig. 12.— Sexual organs of *Erysiphe* and formation of fruit. Highly magnified.

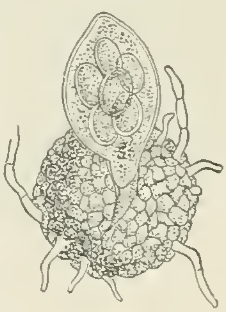

Fig. 13

Fig. 13.— Mature fruit of powdery mildew, with escaping spore-sac. Highly magnified.

The sexual organs (egg-cells and antherids) occur on the creeping filaments, and are short lateral branches, the former somewhat thicker than the slender antherids. (Fig. 12.) The two come in contact with one another, and the protoplasmic contents of the antherid pass into the egg-cell fertilizing it. As a result the egg-cell sends out one or more branches, the end cells of which develop into *asci,* while from below the egg-cell there grows up a cellular, globular covering, constituting the outer wall of the fruit, and enclosing the *asci.* The spores in the *asci* when set free by the rupture of fruit and *ascus* walls, germinate and on similar hosts give rise to new plants. These fruits are usually blackish and may be seen by the naked eye as minute globular bodies on the mass of filaments. (Fig. 13.)

Truffles (*Tuberaceæ*) are evidently related to the powdery mildews, but their life history is not so well known. They are saprophytic, living on the decaying organic matter in the soil in forests. Little is known as to their early life, and the formation of their non-sexual spores, but these are thought to be somewhat like those of the powdery mildews. Their fruits are formed under ground, and may be compared to a mass of compound fruits of the powdery mildews. The sexual organs, which probably precede the development of the fruits, have not yet been discovered. The fruits of the common truffles of Europe are from one to two inches in diameter, and warty and dark colored externally. (Fig. 14.) Internally they consist of a soft, whitish tissue, in which are numerous cavities, each containing several *asci*. Practically nothing is known as to their propagation. A few little known species occur in America, but in Europe they are common. See TRUFFLE.

Black Fungi (*Sphæriaceæ*) are typically parasites which grow in the tissues of higher plants, and whose small black fruits are formed on the surface of the host. Here again we are evidently dealing with plants related to the powdery mildews, but with an increased parasitism. They are known to form non-sexual spores much as in the powdery mildews. Their fruits also resemble the fruits of the powdery mildews, and probably result from a fertilization, but thus far the sexual organs have evaded discovery. (Fig. 15.)

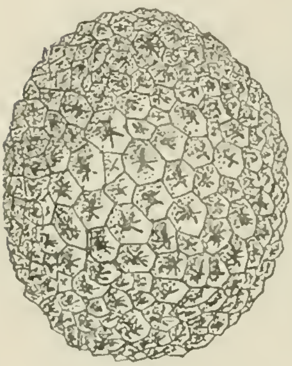

FIG. 14

FIG. 15

FIG. 14.— Truffle; fruit, natural size.
FIG. 15.— *Nectria cinnabarina;* A, bark with enlarged fruits; B, spore-sacs. Highly magnified.

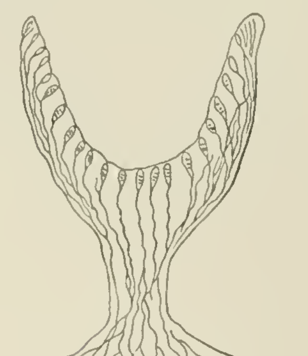

FIG. 16.— Diagrammatic vertical section of a cup fungus.

Cup Fungi (*Pezizaceæ*) are typically saprophytes (Figs. 16 and 17), growing in the tissues of decaying plants, as rotten logs, sticks, etc. In these fungi the plant is filamentous and grows through the decaying tissues as slender white, branching, threads. Non-sexual spores resembling those of the powdery mildews are known for some species. Sexual organs, consisting of a globular egg-cell, and a slender antherid, are found on

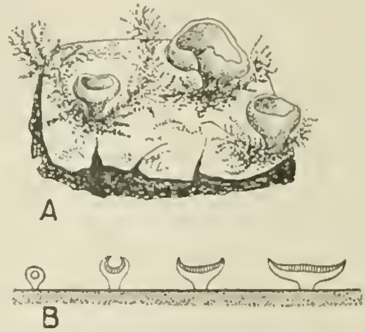

FIG. 17.— *Humaria rutilans;* A, three fruits, natural size; B, vertical sections of fruits of different ages.

the creeping filaments. (Fig. 19.) Fertilization takes place as in powdery mildews, with a similar result, the fruits, however, being at length cup-shaped instead of globular. In many species the fruits (Fig. 17) are globular when young, but as they mature they open out into cup-shaped structures (Fig. 17), in the con-

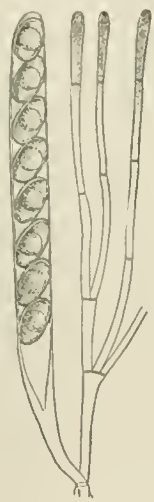

FIG. 18

cave surface of which are found many *asci* (Fig. 18.) It will readily be seen that were these cup-fruits to remain closed, their structure would be closely similar to that of the fruits of the powdery mildews. However, the fruits of the cup fungi are often of considerable size, sometimes being as large as an inch or more in diameter.

Lichens (see article LICHENS) are now regarded as nearly related to the cup fungi and black fungi. (Fig. 20.) In all essentials they agree with those fungi, but they are usually treated separately on account of the peculiar parasitism and

symbiosis which they exhibit. There are several families of the lichen-forming fungi, aggregating between 2,500 and 3,000 species.

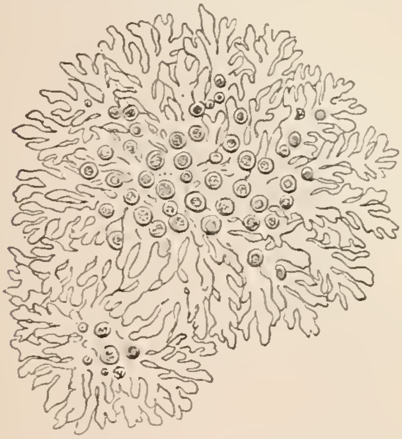

FIG. 20.— *Physcia stellaris*, a common lichen. Natural size.

Yeasts (*Saccharomycetaceæ*) are here briefly referred to in order to call attention to the excessive degradation which they have suffered. Although they consist of single cells, or short chains, they are now regarded as greatly reduced sac fungi. They grow in the watery solutions of sugars, starches, and other carbohydrates, and one result of their activity is the formation of alcohol, while at the same time carbon dioxide is set free. It is for the alcohol that yeasts are used in breweries and distilleries, and it is for the escaping carbon dioxide gas that they are used in the making of bread. See YEAST.

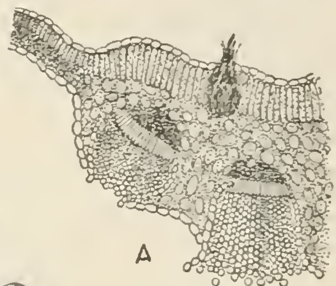
Rusts (*Uredinaceæ*) are minute plants, parasitic in the tissues of higher plants. (Fig 21.)

FIG. 21.— *Puccinia caricis*, a common rust on sedges.

They consist of branching filaments which grow through and live upon the host tissues. Certain branches cluster together and form rows of spores by terminal abstriction (*æcidiospores*) (Fig. 22 A) and later others form single terminal spores (*uredospores*) (Fig. 22 B), and still later other branches form one, two, or several thick walled spores in terminal *asci* (*teleutospores*). (Fig. 22 B.) These all begin within the host tissues, but they eventually break through the epidermis into the air. Lastly, when the teleutospores germinate each produces a short filament (promycelium) on which four minute spores (*sporidia*) develop. There are thus four kinds of spores in a typical rust plant, and these have been taken to characterize as many stages in the plant's life history, namely: 1. Cluster-cup stage (*æcidiospores*); 2. Red Rust (*uredospores*); 3. Black Rust (*teleutospores*); 4. Promycelium (*sporidia*). In most rusts these stages occur on the same host in the order given, but in some the first stage occurs on one host, and the remaining stages on another. The latter is the case with a rust of wheat, in which the cluster-cups occur on Barberry leaves, and the æcidiospores then germinate upon and infect the leaves of the wheat, on which the red rust, black rust and promycelium then follow in succession. No sexual organs have as yet been discovered, but analogy would suggest that they are to be looked for before the development of the teleutospores.

In this account the rusts are considered to be reduced sac fungi, of the cup fungus type, the degeneration being due to their excessive parasitism.

Smuts (*Ustilaginaceæ*) are still more parasitic than the rusts, and as a consequence have suf-



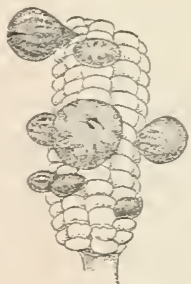


FIG. 23.— Portion of an ear of maize with eight of its kernels attacked by *Ustilago maydis*.

FIG. 22.— *Puccinia graminis*, a common rust of wheat. A, Cluster-cup stag on Barberry leaf; B, three uredospores and one teleutospore from a leaf of wheat. Magnified.

fered still greater degeneration. (Fig. 23.) They grow wholly within their hosts, and do not even bring their spores to the surface. They consist of branching filaments which penetrate the tissues of their hosts, and at last form spores homologous with the teleutospores of the rusts. The latter in germinating produce sporidia. Comparing the rusts with the smuts we note that while there are four stages in the former, there are but two in the latter, the first and second having apparently disappeared.

Imperfect Fungi.—At this point should be mentioned the so-called imperfect fungi, an immense aggregation of many thousand species (12,000 or more) of which we know but one stage (apparently the first) and so are unable to assign them to their proper place in the system. They are minute and mostly parasitic plants, occurring in the tissues of higher plants, and sending their spore-bearing branches out into the air. Some plants formerly placed here have been found to be early stages of certain sac fungi (black fungi, or their relatives) and it is suspected that most, if not all, of them will eventually be so disposed. At present they are grouped under three general kinds, as follows:

Spot Fungi (*Sphæropsideæ*), which produce whitish or discolored spots, and later develop closed, spheroidal cases, containing free spores. *Septoria* and *Phyllosticta* are common genera.

Black-dot Fungi (*Melanconieæ*) are like the spot fungi, but there are no spore cases, the spores developing in masses beneath the epidermis which they eventually rupture. *Gloeosporium* is a common genus.

Moulds (*Hyphomyceteæ*) produce their spores on branches which grow out through the stomata of the host. Here we find the parasitic species of *Ramularia*, *Cercospora*, etc., and the mostly saprophytic species of *Monilia*, *Botrytis*, etc.

Club Fungi (*Class Basidiomyceteæ*).— The distinguishing mark of the club fungi (often spoken of as the higher fungi) is that the spores which develop in certain end cells in their fruits do not remain inside of these cells, but push out into the ends of terminal or lateral protuberances and so come to appear to be external. (Fig. 24.)

Fig. 24.— Spore-clubs in different stages of development; A, when very young; B, with the spore-branches beginning to form at the summit; C, showing the spore-branches with nearly mature spores at their ends. All highly magnified.

These club-shaped, spore-bearing cells are technically known as *basidia* (singular, *basidium*), whence the scientific name of the class. The spore-clubs (*basidia*) of this class are regarded in this discussion as the homologues of the spore-sacs (*asci*) of the preceding class.

Between 10,000 and 12,000 species of fungi of this class are known. Many attain to considerable dimensions, especially their fruits. They are typically saprophytic, but it is now known that many of them are more or less parasitic, also, when the opportunity offers.

About 10 families are commonly recognized, four of which, only, will be noticed here.

Puff-balls (*Lycoperdaceæ*) are saprophytes whose branching filaments penetrate decaying wood or earth rich in organic matter, and finally produce globular fruits which rise above the surface. (Fig. 25.) These fruits are filled with tortuous canals whose walls are studded with spore-clubs (basidia) on which the spores are produced. At maturity the interior tissues of the fruits deliquesce, setting free the spores, which escape into the air a little later as a dusty cloud, by the rupture of the fruit-wall. From these spores new plants are produced, but we do not know the whole life history of these common fungi. Although the sexual organs should precede the formation of the fruits, they have not yet been observed

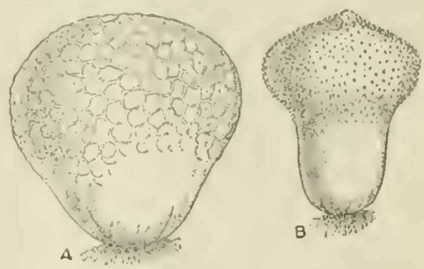

Fig. 25.— Two species of puff-balls; A, *Lycoperdon cœlatum;* B, *Lycoperdon gemmatum.*

Stink-horns (*Phallaceæ*) are closely related to the puff-balls, which they closely resemble in all stages excepting the last. Here the spore-bearing portion of the globular fruit is confined to a vertical, circular layer of tissue about midway between the centre and the circumference. At maturity the spore-bearing tissues deliquesce and at the same time the tissues below rapidly elongate, bursting the fruit-wall and carrying up the spores into the air. (Fig. 26.) These fruits

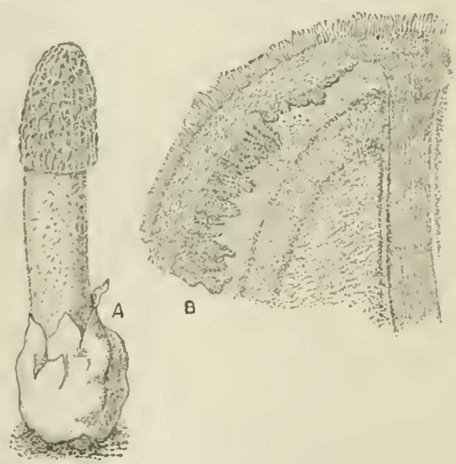

Fig. 26.— A, a stink-horn (*Ithyphallus impudicus*) after the rupture of the volva; B, highly magnified section of the spore-bearing layer.

have very bad odors, which attract insects, and it is thought that these help to distribute the spores. Stink-horns are from an inch or two to six or more inches in height, and grow commonly in lawns and pastures, where their presence is indicated by their intolerable odor.

Toadstools (*Agaricaceæ*) are fungi of the puff-ball kind, consisting of white, branching filaments which creep through the nutrient substance or the host tissues. Most species are saprophytes, but some are parasites. When the fruits are young they resemble those of puff-balls, but as they grow older a circular layer of spore-bearing tissue develops, and this, by the rapid growth of lower lying tissues, is carried up on a stalk, very much as is done in the stink-horns. (Fig. 27.) Here, however, the stalk is

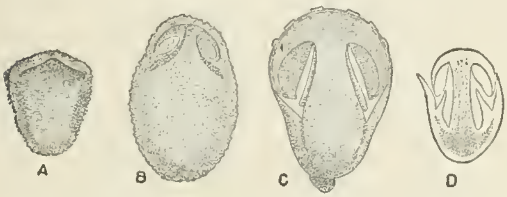

FIG. 27.— Development of a toadstool (*Amanita muscaria*) shown in vertical section. A, very young stage; B and C, later stages; D, after the bursting of the volva.

formed earlier, and the spores are usually developed after the rupture of the fruit-wall.

A typical toadstool fruit has the following structure: There is first at the bottom the cup-shaped remnant of the original fruit-wall (technically, the *volva*); from this rises the cylindrical stem (*stipe*), terminating in an expanded cap (*pileus*). The stem and cap together resemble on expanded umbrella, or a one-legged stool (Fig. 28), from which latter fact the common name "toadstool" was doubtless suggested. The lower surface of the cap is folded into many vertical radiating plates, called gills (*lamellæ*), and these are studded with the spore-clubs, bearing the spores. This gill portion corresponds to the circular spore-bearing layer of the stink-horns, and the gills themselves are to be regarded as devices for increasing the number of spores, by an enlargement of the surface studded with spore-clubs.

FIG. 28.— Two fruits of *Armillaria mellea* attached to the filamentous plant; several young fruits at the left. Considerably reduced.

While in typical toadstools the cap is rounded and centrally attached to the stem, in some species its growth is not uniform, and the stalk is excentric, or even lateral. Lastly, let it be remembered that the toadstool which we see is not the plant itself (that is below the surface) but it is the fruit of the plant which develops in order that it may produce spores.

Pore Fungi (*Polyporaceæ*) are so named because the spore-bearing structure on the under side of the cap of the fruit consists of a mass of small vertical pores, instead of plates, and by this character they may be readily recognized. In typical pore fungi the general structure and development are similar to those of the toadstools, the change from gills to pores being the only important difference. Here, however, many of the species instead of growing into regular umbrella-shaped fruits, have the stalk more or less laterally placed. In others, again, the lateral stalk is very short, and from this the step is a very short one to its complete suppression, when the cap is sessile marginally, as in the bracket fungi, which are so common on decaying logs and other forms of timber.

Some pore fungi are fleshy, but for the most part they are hard and tough, often resisting

FIG. 29.— *Agaricus campestris*, the cultivated mushroom, showing several stages of development.

decay for many years. Some of the species are perennial, adding successive layers of pore tissue to their fruits for some years.

ECONOMIC RELATIONS OF FUNGI.

The economic relations of the fungi are of great importance. Some are edible, and furnish wholesome food to man and other animals, some are used in the arts, some yield medicines, some are the cause of disease in man and other animals, and some again attack and destroy other plants, including many of the cultivated plants of our farms and gardens.

Edible Fungi.—Here perhaps we should include those bacteria which have to do with the flavor of butter and cheese, and those moulds whose presence in cheese adds to its edibility. Of far greater importance, however, are those species which are eaten for the nutriment which they contain. Truffles are collected in Europe, and sold in the markets. Dogs and pigs are trained to search for them, the attendant bagging the truffle when found by the keen scent of the animal. The Morels are sac fungi related closely to the cup fungi; each Morel (fruit) is a hollow-stalked body two to five inches high, with a crinkled and pitted conical cap in whose surface are imbedded the spore-sacs. They grow in fields and thickets, and when fresh are wholesome. Morels are often called mushrooms, although this name should be restricted to the next group.

Mushrooms (Fig. 29) are of the toadstool kind, and popularly any species which is edible is called a mushroom, while those which are poisonous are called toadstools. Many species are collected from the forests and fields by experts who have learned to distinguish them from the poisonous ones, but by far the most commonly used species is the common mushroom (*Agaricus campestris*) which is cultivated by gardeners for this purpose. See MUSHROOMS.

Medicinal Fungi. — The most important species is the Ergot (*Claviceps purpurea*), one of the sac fungi, which is parasitic in the heads of rye.

Pathogenic Fungi (on Animals).—Many bacteria are the direct cause of diseases of animals, including man. See BACTERIA.

Some of the water moulds cause a serious disease of fishes, especially of young fishes in "hatcheries." Occasionally an epidemic, known as the "Salmon Disease," has been known to occur in the streams of Great Britain. Investigation has shown it to be due to a certain species of water mould.

The insect fungi (*Entomophthoraceæ*) annually destroy immense numbers of flies, locusts, caterpillar larvæ, etc. The common house fly is attacked by *Empusa muscæ* in summer and autumn. Every infected insect fastens itself by means of its tongue to some object, and soon perishes miserably, its body walls being pierced by innumerable spore-bearing branches. In the autumn myriads of locusts ("grasshoppers") are destroyed by *Empusa grylli*. When attacked by the fungus the locust climbs a grass or weed stem around which it finally clasps its legs and dies firmly attached. Many other insects, including mosquitoes, are destroyed by these beneficial fungi. Thus far all attempts to artificially apply these fungi in combating insects have been unsuccessful.

Pathogenic Fungi (on Plants). See DISEASES OF PLANTS.

CHARLES E. BESSEY,
University of Nebraska.

Fungicides, fŭn'jĭ-sīd, any agent used to prevent the growth of fungi or their spores. The most important uses of fungicides are in agriculture and horticulture for controlling the fungi that attack crops. These may be divided into two general classes: (1) Fungi which burrow among the tissues of the host plants and expose little more than their fruiting organs to the air. (2) Fungi which expose almost all of their vegetative parts to the air, only the holdfast, absorbing organs (*haustoria*) entering the tissues of the host. From the nature of their growth it is easily seen that members of the second group may be attacked at any time, but that since the vegetative parts of members of the first group are protected by the tissues of the host they cannot be reached effectively by any fungicide without injuring the host. Controlling agencies in such cases must therefore be preventive.

For the control of the exposed fungi the chief agent is sulphur in out-door practice, applied as a powder, which is dusted upon the foliage, preferably with a powder gun. In the greenhouse it is more frequently evaporated, by strewing powdered sulphur upon the heating pipes or upon burlap suspended in warm parts of the greenhouse. This is a slow way, and is mainly preventive. When a considerable quantity must be evaporated in a short time the sulphur is gently heated over an oil stove. It is imperative that the sulphur be kept from igniting, because the fumes are destructive to host as well as fungus. For cleansing a greenhouse of objectionable fungi when the plants are out, the sulphur may be burned and all reachable parts sprayed liberally with Bordeaux mixture.

Various compounds of copper are used as preventives of the attacks of internal feeding fungi and as remedies for the exposed. Chief of these salts is copper sulphate, which may be applied in a pure solution only to dormant wood, walls, etc. It is used at the rate of one pound to the gallon, and will, at this strength, destroy lichens and algæ as well as fungi. For use upon foliage and other actively growing parts it must be mixed with some substance which will counteract its causticity. Lime is most frequently used, and the compound is called Bordeaux mixture from the French city where its usefulness was accidentally discovered about 1882. It is made as follows: A known number of pounds of copper sulphate are dissolved in an equal number of gallons of water, contained in a wooden tank or barrel, the salt being suspended at the surface of the water to ensure quick solution. In another receptacle a known number of pounds of lime, as free from magnesium as possible, are slaked with a little water, and when slaking is complete, enough more water is added to make the proportion one pound of lime to a gallon of water. When needed for use six gallons of the copper sulphate solution and four or five of the lime solution are separately diluted with enough water to make a combined total of 50 gallons. The two diluted solutions are then thoroughly mixed, and afterward tested with ferrocyanide of potash to make sure that there is no uncombined copper sulphate. A brownish discoloration indicates that more lime must be added to neutralize the free copper salt. The mixture is then ready for general use, but for peaches, plums, cherries, and some other plants, another 25 gallons of water must be added because of the susceptibility of the foliage to injury. The stock solution of copper may be kept for weeks, but the lime solution should stand for only a few days and the completed mixture for only a few hours, because the particles tend to flocculate and settle, a process which impairs the usefulness of the mixture.

Copper sulphate is often used as *eau celeste*, a solution of one pound of the salt to two gallons of water plus three half-pints of standard ammonia, and then diluted with water to make 25 gallons. Since the strength of the ammonia varies, this solution often burns the foliage, there being insufficient ammonia to neutralize the free copper sulphate. This fungicide and ammoniacal solution of copper carbonate are used when a non-staining solution is needed, as in spraying ornamental plants and fruit which is nearing maturity. The latter solution is made by dissolving one ounce of copper carbonate in one pint of ammonia and mixing with 10 gallons of water.

The seeds of various cereals are often dipped in hot water formalin solution and copper sulphate solution to destroy fungous spores, and hot water is also used to some extent for destroying exposed fungi, spores, etc.

All solutions must be applied as a mist-like spray, to ensure which a nozzle with a small aperture is essential. The first application to fruit trees should be before the buds begin to swell. This may be a stronger solution than those used after growth starts. The second should be given when the buds begin to swell, the third when the blossoms have fallen. No spray should be given during the blossoming period.

Consult: Lodeman, 'The Spraying of Plants' (1890); Prillieu, 'Maladie des plantes agricoles' (1895); Massee, 'Text-book of Plant Diseases' (New York 1899); various bulletins of the United States Department of Agriculture and of many of the State Agricultural Experiment Stations.

Fungus, fŭn'gŭs. See FUNGI.

Fungus-eaters. The fungi enter largely into the food of the lower animals, and somewhat into the fare of the higher forms. The moulds, slimes, and various aquatic forms are devoured by echinoderms and mollusks, both bivalves and univalves, who take in the minute floating forms, or their spores, or eat the fixed growths from stones and other resting places, and by vegetable-eating fishes and crustacea. Pond-snails will keep the glass sides of an aquarium clean of vegetable growths, a large part of which is fungoid. Worms, slugs, and insects in great variety feed upon the vast array of fungi not aquatic. Beetles are especially fond of the larger forms — the toadstools and tree-borne polypores. A large Javan beetle, known from its shape as the "fiddle-beetle" (*Mormolyce phylloides*), spends its life within and about certain fungi growing on tree-trunks. A whole family of small flies (*Mycetophilidæ*) breed in fungi, including the cultivated mushroom, beds of which are often largely damaged by the work of their maggots bred there; hence the group is termed "fungus-gnats." In the United States the woodland toadstools are eagerly fed upon when ripe in August and September, not only by great numbers of insects, slugs and snails, but by salamanders, tortoises (especially), and by all sorts of squirrels; but they seem to be rarely if ever eaten by birds. For the edibility of fungi by man, see MUSHROOM.

Fungus-gnat. See FUNGUS-EATERS; GNATS.

Funk, fŭnk, **Isaac Kauffman**, American publisher: b. Clifton, Ohio, 10 Sept. 1839. He was graduated at Wittenberg College, Ohio, and after several pastorates, the last of which was in Brooklyn, N. Y., began a publishing business in 1872; founded and published the 'Metropolitan Pulpit' (now the 'Homiletic Review') in 1876, and the 'Literary Digest' in 1890. He has published also the 'Standard Dictionary' of which he was editor-in-chief (1890–4). He is an earnest Prohibitionist, and in 1884 founded the 'Voice,' a prohibition journal, and has been the Prohibition candidate for mayor of New York. In 1901 he began the publication of the important 'Jewish Encyclopedia.'

Funnel-marks, painted designs on the funnels of ocean steamships to designate the ownership of the vessel. American line steamships are thus designated by a black funnel, white band, with black top; Anchor line, black funnel; Cunard line, red funnel, with black rings and black top; French line, red funnel with black top; White Star line, cream funnel with black top; Wilson line, red with black top; North German Lloyd line, cream funnel; Red Star, black funnel, white band, black top; Netherlands line, black, with white band and green borders; Hamburg-American line, buff for express steamers, black for regular steamers; Scandinavian-American line, yellow, with white band and blue star, and black top; Bristol line, black, white band in centre, blue star in centre of white band.

Funston, Frederick, American military officer: b. New Carlisle, Ohio, 9 Nov. 1865. He was educated at the State University, Kansas, and was a commissioner of the Department of Agriculture to explore Alaska 1893–4. He served in the insurgent army in Cuba in 1896–7, and, receiving in 1898 a commission as colonel of the Twentieth Kansas Volunteers, went to the Philippines, where he became brigadier-general of volunteers the next year. In March 1901, he commanded an expedition which succeeded in capturing the Filipino leader, Aguinaldo, and was appointed brigadier-general in the United States army in the same month.

Fur-bearing Animals. In the broader sense any animal which yields a pelt used in the preparation of marketable furs. In a narrower, more zoological sense, the term is restricted to that family of carnivora, the *Mustelidæ*, which contains the weasels, martens, sables, badgers, skunks, wolverines, otters, and sea-otters. The family is not a large one, but is of great economic importance, and many of its genera and species are of very wide distribution, mostly in northern regions. Two groups, the Arctic sea-otter and the skunks, are exclusively American. All are small animals; fierce, and voracious, living in burrows, or holes in trees or rocks, and active in winter. They belong in the arctoid division of carnivores, are most nearly related on the one hand to the bears and on the other to the dogs. For further particulars see FUR-TRADE; and the names of prominent species, as: BADGER; FERRET; MARTEN; OTTER; POLECAT; SABLE; SEA-OTTER; SKUNK; WEASEL; WOLVERINE; etc. Consult: Elliott Coues, 'North American Mustelidæ' (Washington 1877).

Fur Seal, the fur-bear or northern fur-seal (*Otaria*, or *Callorhinus, ursina*), whose pelts form the seal-skins of commerce. (See FUR TRADE.) There is also a southern fur-seal (*O. nigrescens*), dwelling along the southern coast of South America. See SEAL.

Fur Trade, The. The history of the fur trade is so closely interwoven with the early history of America that it is extremely difficult to narrate one without reference to the other. Among all the industries that helped to make this country one of the great commercial nations of the world there was none that exerted such an important influence upon the early prosperity of the colonies as that which was represented by those who took the pelts of animals and prepared them for manufacture into various articles for the use of mankind. It was the rich peltries of North America that were the magnet that attracted the hardy French and British adventurers to the shores of the new world, and it was their brawn that blazed the trail through the wilderness that the more timid agriculturalist might have the courage to follow in their footsteps. In the early days of this country's history it was the hunter and the trapper who explored the unknown regions. To obtain the furs that represented one of the great sources of wealth in the new country they journeyed into the most distant and inaccessible parts of the land, and that they might have havens of safety in which to store their pelts, and, incidentally, rest secure from the attack of savage foe, they established the small settlements, so many of which have since grown into prosperous communities. It was the fur trader, therefore, who was the real pioneer in North America. Always in advance of civilization, his labors in leading the way for the settlement of the country provided a means of advancement that would have been much delayed if it had not been for these preparatory efforts. The Canadian provinces, for example, owed practically all their primary prosperity to their fur trade. In those days there were no mines to stimulate the immigration into that country, and the French pioneers who first made it their home soon discovered that there could be no more profitable source of income than that which was afforded by the possibility of trading in furs, for in Canada, as throughout the English colonies further south, the native Indians were so ignorant of the value of the pelts which they gathered that they were willing to dispose of them upon terms that permitted an enormous profit to the successful trader in such articles.

During the early days in the history of the fur industry in North America there was practically no limit to the percentage of profit that could be made in buying furs. To become a successful trader in pelts the one thing that was necessary was to import a large quantity of cheap and practically worthless trinkets from Europe. For these the Indians would exchange the most valuable peltries without hesitation. In fact, the conditions under which the fur trade with the natives was conducted soon became such a serious scandal that reformatory measures were absolutely necessary, the better class of traders becoming unwilling to sanction the unmitigated dishonesty and unbridled licentiousness of the class of men who were known as *coureurs des bois*, or rangers of the woods. It was to suppress this class that the licensing system was introduced, and, although this too soon became subject to abuse, for a time at least it tended to free the traffic from its most scandalous conditions.

It was during these early days that the feuds between the British merchants of New York and the Canadian traders became a serious factor in the industry. There can be little doubt that the former set out deliberately to encroach upon the business of the fur interests of Canada, and the trouble regarding the infringement of territorial rights had become a most serious situation when the Hudson's Bay Company was formed, in 1670. This company, which was chartered by Charles II., had the exclusive privilege of planting trading stations on the shores of Hudson Bay, and all its tributaries, and when, about a century later, France lost possession of her Canadian colonies, the Britons assumed almost exclusive control over the great fur trade of America. Prior to the beginning of the 19th century this trade was chiefly monopolized by the powerful trading companies.

First in the field, of course, was the Dutch East India Company, with its prosperous trading-posts at New Amsterdam (now New York), Beaverwyck (now Albany), as well as at several points on the Delaware and on the Maine coast. Next came the extensive Hudson Bay Company, which practically monopolized the trade in furs for 200 years, or until the Northwestern Company entered the field and established a somewhat successful rivalry, although its efforts were confined almost entirely to the Pacific coast.

It was in 1808 that John Jacob Astor formed the American Fur Company, establishing a line of trading-posts that extended across the continent, with a depot for furs at the mouth of the Columbia river, from which point he intended to ship direct to China and India. The name of the concern was afterwards changed to the Pacific Fur Company, and Mr. Astor saw his enterprise on the high road to success, when, in 1813, he was treacherously sold out to the Northwest Company by his resident partner, the latter claiming that, as the United States was then at war with Great Britain, the British soldiers would have taken the establishment by force if he had not made other disposition of it. After this incident, Mr. Astor confined his operations to the district east of the Rocky Mountains, where he, with his partner and successor, Ramsay Crooks, transacted a profitable business in furs for many years. The Russian-American Fur Company, which had its main trading post at Sitka, Alaska, with many subordinate posts on the Yukon, carried on an immense traffic in such lines until 1867, when all its rights and properties were transferred to the United States with the purchase of Alaska.

It was somewhat prior to 1809 that John Jacob Astor conceived his great project to make the American fur trade independent of the Hudson's Bay Company. As his scheme was partly based upon the fact that such an enterprise would have a strong tendency to spread the civilization of the East into the far western country, he asked the aid of Congress in carrying it into execution. Briefly described, Mr. Astor's idea was to establish a connected chain of trading posts from the Great Lakes to the Pacific Ocean, with a central depot for packing and shipment at the mouth of the Columbia river; to acquire one of the Sandwich Islands as a provision station, and to establish a line of vessels to sail from the west coast of North America to the most important ports in India and China. Washington Irving, in his "Astoria," presents a graphic description of this gigantic enterprise which met with such a strange disaster when Astoria, the town founded at the mouth of the Columbia river in 1811, was so unnecessarily abandoned during the War of 1812. The balance of Mr. Astor's career, however, was quite as remarkable. Year after year his fur business was extended until its operations surpassed those of any house that had hitherto been established. In addition to its immense American business a gigantic export trade was carried on with many countries, and, when the founder of the company died, he left a fortune that was estimated at $20,000,000. William Backhouse Astor, his son, was interested with him in the fur trade, and when, in 1827, the house of John Jacob Astor & Son was merged in the American Fur Company, he became its president.

The first great establishment founded in St. Louis — one of the principal depots of the fur trade from the middle of the 18th century until 1859 — was that of Laclede, Maxon & Company, in 1763. In the early days of this house the brothers Auguste and Pierre Chouteau were connected with it, and the establishment, which was extremely successful, employed a large number of trappers and voyageurs. In 1808, the Chouteau brothers and a number of their associates in the older firm, withdrew to form the Missouri Fur Company. This prospered until about 1813, when, because of the war with Great Britain, it was dissolved. During the next few years several of its members transacted business independently, but, in 1827, the Rocky Mountain Fur Company of St. Louis was formed to send trappers to the Pacific coast. At this time the perils of the work were so great that fully 40 out of every 100 persons employed in it perished, and yet the life of adventures offered so many fascinations that there was no lack of hardy men eager to take the places of the slain. After several years of varying success the company was dissolved. In 1834, however, Pierre Chouteau, Jr., who had been educated in the fur trade by his father, organized the house of Pierre Chouteau, Jr. & Company, a firm name which was practically a household word among hunters and trappers from the Mississippi and the Lakes to the Pacific during the next 25 years. In 1859, the business was sold to Martin Bates and Francis Bates of St. Louis and New York.

The year 1859 saw the American fur trade more widely diffused than ever before. The passage of the industry into the hands of individuals had commenced to be apparent as early as 1821, and while, by the middle of the century the aggregate amount collected each year was much greater than it had been 40 years previously, the opportunities for making great fortunes in the trade had gone. A writer in 'Silliman's Journal' (1834) gives an interesting description of the situation of the fur trade at that time. He says:

"The Northwest Company did not long enjoy the sway they had acquired over the trading regions of the Columbia. A competition, ruinous in its expenses, which had long existed between them and the Hudson's Bay Company ended in their downfall and the ruin of most of the partners. The relict of the company became merged in the rival association, and the whole business was conducted under the name of the Hudson's Bay Company. This coalition took place in 1821. Almost all the American furs which do not belong to the Hudson's Bay Company find their way to New York and are either distributed thence for home consumption or sent to foreign markets. The Hudson's Bay Company ship their furs from their factories of York Fort and from Moose River, on Hudson Bay; their collection from Grand River, etc., they ship from Canada; and the collection from Canada goes to London. None of their furs come to the United States, except through the Indian market. The export trade of furs from the United States is chiefly to London. A quantity of beaver, otter, etc., is brought annually from Santa Fe. Dressed furs for edgings, linings, caps, muffs, etc., such as squirrel, genet, fitchskins, and blue rabbit, are received from the north of Europe; also cony and hare's fur; but the largest importations are from London, where is concentrated nearly the whole of the North American fur trade."

It was as early as 1834 that those who were interested in this industry began to fear that the American fur trade had commenced to decline and, even at that time, it was quite freely predicted that its downfall would be rapid. By this period there were practically no new lands to be explored. The hunters and trappers in the employ of the great fur trading companies had gone everywhere and had slaughtered so indiscriminately that it seemed almost impossible that the fur-bearing animals should not be exterminated. While in some few cases this prediction has been proved to be only too true in a majority of instances the fear has been shown to be without foundation, for many of the fur-bearing animals, especially the small mammals, actually increased in number. They seemed to thrive better in the neighborhood of small settlements, where they were able to feed upon the farmers' crops. Some of the larger species, like the bear or the beaver, were much reduced in number, although even they did not meet so sad a fate as that of the buffalo, which has now been reduced to a few herds which are being cared for in southern Canada and in the Yellowstone Park. Up to 1875 these animals existed in countless herds on the western plains, where they were of incalculable value, to the Indian as well as to the white man, not only on account of the fact that their skins represented one of the most important commodities in the fur trade, but for the reason that they supplied both the white adventurer and the Red-skin native with food and clothing. Soon after 1870, however, the popular demand for this fur became so great that it is estimated that not less than 4,500,000 of these animals were recklessly killed, merely for the sake of their hides, between the years 1871 and 1874, and it is this ruthless extinction of the buffalo that is responsible for the conditions which now compel the United States Government to supply the Indians with regular meat rations. Of the millions of buffaloes that roamed the plain before the fur companies commenced their campaign of slaughter only a few hundred still remain, and they are so safely guarded that it is hoped that the species may be preserved from absolute extinction.

The table on following page presents a list of the principal fur animals of America, with such descriptive facts concerning them as can be tabulated, and the uses to which their skins are applied.

Among all these fur-bearing creatures the seal is of paramount interest to the trade owing partly to the great demand for such skins and partly to the efforts that are being made to prevent this valuable mammal from following the buffalo into comparative oblivion. There are many varieties of seals, but the four which are most extensively used by the trade are the Alaskan, Victoria or Northwest coast, Copper Island, and Lobos Island. Of these the most extensive fishery is the Alaskan. It was a material element in determining the value of the Alaskan province when it was purchased from Russia at a heavy cost by the United States, and it was one of the principal inducements upon which the purchase was made. That those who engineered the purchase of this territory were not mistaken in their valuation of the seal fisheries has been shown by the fact

PRINCIPAL AMERICAN FUR ANIMALS.

Musk-ox	Ovibos moschatus..	Upper Canada.............	Dark brown.....	Sleigh-robes.
Buffalo	Bison Americanus.	N. W. America............	Drab brown.....	Robes, coats.
Marten	Mustela Canadensis	N. America................	Light brown.....	Coat lining, capes.

that since Alaska became the property of the United States this industry has afforded a very considerable source of revenue to the Government through the lease of the seal fishing privileges, while the furtherance of this industry has not only engaged a large amount of American capital but has provided employment for a large number of American people.

From the early part of the 19th century until 1862 the seal fisheries were leased by the Russian Government to the Russian-American Company, a corporation composed of several wealthy Siberian merchants, but when the United States assumed control of the Alaskan territory these rights reverted to this Government. Even at this early date the question of the possible extinction of the seal had been seriously agitated, and it was not long after American acquisition of the territory that Congress passed a law forbidding the killing of seal upon the islands of St. Paul and St. George except during the months of June, July, September, and October. The laws further prohibited the killing of females, or males under one year of age, and it forbade the use of firearms; the taking of seal in adjacent waters, or on places where they were accustomed to haul up to remain, and limited for a term of twenty years the number to be killed on these islands to 100,000 annually, reserving the right to further restrict the number if at any time it appeared necessary or advisable to do so in order to prevent the serious reduction of the species.

The Alaskan Commercial Company obtained its lease of the seal fisheries in 1870. It continued for a term of 20 years, and gave the corporation the right to take seal, under the regular Government restrictions, in return for a rental of $50,000 per annum, and a further tax of $2 for each seal thus taken. The headquarters of this corporation were in San Francisco, John F. Miller, afterwards senator from California, being its first president. He was soon succeeded by Lewis Gerstle, one of the original stockholders, and the affairs of the company were principally directed by Messrs. Gerstle, Sloss, Niebaum, and Neumann on the Pacific coast, by Mr. Hutchinson at Washington, and by Sir Curtis Lampson (since deceased) at London. As the Government became pretty well persuaded that the amount of revenue received from the fur-seal fisheries had not corresponded with the number of seals taken, the lease was not renewed, but instead, when it expired, 1 May 1890, a lease was granted to the North American Commercial Company for the ensuing twenty years. This lease, which expires 1 May 1910, gave them the exclusive right to take seals in Alaskan territory for an annual rental of $60,000 and a tax of $2 per head upon all seals taken, and an additional bonus of $7.62½ on each skin. Even under such new conditions matters did not turn out satisfactorily, however, and the United States Government finally brought suit against the North American Commercial Company to recover $214,293.37, a sum alleged to be due on the company's contract since April, 1895. The case was fought through the lower courts and was finally settled in the Supreme Court of the United States. This suit has been regarded as one of the utmost importance and is reported in full in the 171 U. S. p. 137. The action, as brought by the Government, was to recover the annual rental of $60,000, as well as the tax and the bonus on each skin. The court found that there was no abatement on account of the tax or bonus, but held that the rental should be reduced in proportion as the whole number of skins allowed to be taken in any one year bore to the maximum allowed by law. As the result, instead of paying a stipulated rental of $60,000 per year, the North American Commercial Company now pays a fixed rental of 60 cents for each skin taken, which, with the tax and bonus, makes a total payment to the Government of $10.22½ per skin taken and shipped.

During the past few years the Government has restricted the lessees of the seal fisheries to a limited catch per year. The following table shows the maximum limit of seals allowed to be killed and the total number taken and shipped from 1859 to 1905 inclusive:

RESTRICTION AND SHIPMENT OF FUR SEALS.

Year	Allowed to be killed	Shipped
1895	15,000	15,000
1896	30,000	19,200
1897	20,000	16,818
1898	30,000	18,032
1899	30,000	16,812
1900	30,000	22,470
1901	30,000	22,672
1902	30,000	22,368
1903	30,000	19,292
1904	15,000	13,128
1905	15,000	14,368

In fact, as the matter now stands, the Government annually fixes a maximum and minimum number of seals that may be killed, and before the opening of the season the approximate number to be taken is fixed upon by the agent stationed at the Alaska fisheries.

The first seals to arrive at the Pribylov Islands each season are the bulls, each one of which immediately proceeds to locate the "homestead" that he and his future harem are to occupy. This "homestead" is about 10 feet square, and, as there is considerable space to be filled, the competition in the beginning — from the 1st to the 5th of May — is not very great. A few days later, however, the breeding grounds become so crowded that late comers find no place to locate their "homestead," with the result that the most terrific combats ensue, some of which are attended with mutilation if not, as is quite frequently the case, by death. The bulls who do not succeed in obtaining a place, or who are unable to oust others from their stronghold, are compelled to live apart from their companions. They are mainly old bulls who have been weakened by age, or young bulls, less than five years of age. The "whites" call them "bachelor seals," while the Aleuts know them as "holluschickie," and they usually number from one-third to one-half of the entire herd.

It is from these bachelor seals that the lessees of the islands are permitted to take the skins that are shipped in batches of 200 to 300 casks to London that they may be sold at auction, the great fur sales being held in that city. Each cask contains from 40 to 45 skins, which are rolled up separately, tied with cord, and packed in salt.

Nearly all the vessels that are employed in the seal fishery are the property of Canadians, but are manned by Indians, the latter making the most successful hunters, and their operations are conducted as follows: When a herd is discovered the natives launch their canoe and steal cautiously towards it. If the animals are asleep, every effort is made to approach them without waking them, for, in that manner, they may easily be speared, when they are almost invariably captured, whereas, when they are shot, they are so liable to sink to the bottom before the canoes can reach them that many valuable skins are lost.

The Victoria seals are captured at an earlier date than the Alaskan seals, and they are chiefly females and old bulls. The Copper Island seals are taken on "Copper Island," one of the islands of the Aleutian group, which is still the property of Russia. Their fur is inferior to Alaskan seal, however, in spite of the fact that it is generally believed that it is the same animal but taken at a different season of the year. It is lighter in color, being of a dark brown hue, and is generally inferior in quality. At the same time from 40,000 to 50,000 of these skins are taken annually.

According to the decision of the Bering Sea Court of Arbitration, announced at Paris, 15 August 1893, a close season was established to begin 1 May and to continue until 31 July, these restrictions to apply both in the north Pacific Ocean and in Bering Sea. A protected zone was also established extending for 60 miles around the islands, Pelagic sealing being allowed in Bering Sea, outside that zone, from 1 August. The use of firearms in sealing was forbidden.

In spite of all the precautionary measures that were adopted it is generally conceded that the Paris Court of Arbitration was a failure, at least so far as the prevention of the extinction of the seals was concerned. In 1901, Governor Sheakley, in a report submitted to the secretary of the interior, insisted that the extinction of the fur-bearing animals in Alaska was almost inevitable. Speaking of the rapidly diminishing seals, he said that the official inspection of skins taken by the pelagic sealers during the previous year showed anywhere from 55 to 80 per cent of female skins, a condition which merely confirmed previous investigations upon that subject, and he explained that so long as buckshot was being picked from the hides of young males killed in the Pribylov Islands, and maimed and wounded seals still limped about the hauling grounds, to say nothing of the fact that female skins predominated in the pelagic catches that arrived in London, it was unnecessary to make any further investigation as to the cause of the demolition of the seals. In his opinion, there was nothing that could be done at the islands to better the situation, for the rehabilitation of the rookeries would be an easy matter if adequate protection could be afforded the females. In 1902, Henry W. Elliott, the Government's fur expert, sounded a similar warning by assuring the Government that better protection was needed than that which was afforded by the finding of the Paris tribunal, and, about two years later, 9 March 1904, he again appeared before Congress to announce that his worst fears were about to be realized as the killings on the islands had run down to the very dregs of the young male life which the law permitted to be killed. In his 1905 report the secretary of commerce and labor considered this subject quite fully, and recommended that strong efforts be made to secure the necessary international regulations to put a stop to pelagic sealing. It was also shown by figures that, as the result of this wanton destruction of seal life, the herd on the Pribylov Islands had been reduced from approximately 2,000,000 animals in 1885, to about

200,000 in 1905, while the ravages of these pelagic sealers had reduced the number of skins taken from 100,000 in 1885, to less than 15,000 during 1905.

It is not for seal-skins alone that the American fur trade is indebted to Alaska, however, for that territory helps to supply the world with many other pelts including those of the sea and land otter, the brown and black bear, the beaver, fox, mink, marten, lynx, wolf, muskrat, and wolverine. An industry pursued incidentally with that of sealing on the Pribylov Islands is that of raising the blue fox for its pelt. This foxing industry, which is conducted by the agents of the lessee, permits of the killing of the fox under proper restrictions, the catch during the winter of 1904 amounting in all the islands to 289 blue fox skins and 13 white fox skins. Efforts have also been made by the agents of the department of commerce and labor, by the careful selection of the best animals for breeders and an insistance upon an adequate quantity of fox food to be furnished by the lessee, to induce an increased birth rate among these animals. What makes this experiment particularly interesting is that the proceeds from the sale of these skins are applied to the support of the native inhabitants of the islands, their services being required in the taking and curing of all kinds of pelts.

The manufacturing of skins into articles of commerce is not only an industry in itself but one that requires considerable knowledge and experience, as both the durability and the appearance of most furs depend much upon the mode in which they are cured, dried, and made up. To prepare most skins for packing and transportation — after they have been stripped from the animal — they are first carefully cleaned of fat and flesh, and are then dried in a cool, dry place. When thoroughly dry they are ready for shipment. This methid, of course, does not apply to the seal-skin, the manner of packing them in salt having already been described.

To present anything like definite figures regarding the consumption of furs is an extremely difficult matter as the demand for the many varieties vary from year to year owing to the fickleness of fashion. It is also due to fashion's foibles that some of the animals having the most beautiful skins are not exterminated, for when the demand for a certain variety of fur ceases for a season or two, with it ceases the destruction of the animals, which leaves them a period of safety in which they may recover their normal status as to numbers.

The American fur industry, like most other business and professions, is divided into departments and few firms now carry on all the branches of the business, as it was formerly done, under one roof. The taxidermist, for example, has one of the collateral branches of the fur trade. The manufacturing furriers and fur dealers represent an enormous investment of capital, especially those who are large exporters and importers of furs, for, in spite of the fact that London and Leipsic still have a firm hold upon the international trade, there are many fur houses in this country that conduct constantly increasing operations with the foreign markets owing to the superiority of American manufactures in furs. In addition to these, however, there are many other branches that are more or less directly connected with the fur industry. Among them one may mention the manufacturers of hats and caps, jobbers of furs, dealers in hatters' furs, proprietors of skunk and other fur farms, fur sewing machine houses, and firms making machinery and materials for the use of furriers, such as muff-blocks, head-forms, skulls, and down muff-beds. According to the 1900 census the aggregate number of establishments handling fur goods in the United States was placed at 994, but these firms paid $5,315,584 in wages to 9,709 employees. The cost of materials used during the census year amounted to $15,742,508, while the value of the product manufactured, including the receipts for custom work and repairing, amounted to more than $27,735,264. The total domestic exports of furs and fur skins during the year 1905, amounted to $6,599,222, while the imports of furs and fur skins, undressed, during 1905, were $10,502,907 The following table gives the value of the imports and exports of furs and the manufacturers of furs in this country from 1880 to 1905, inclusive:

FURS AND MANUFACTURES OF FURS.

Year	Imports	Exports
1880	$ 6,424,112	$5,404,418
1885	5,257,547	4,153,287
1890	7,553,816	4,661,034
1891	9,828,849	3,236,705
1892	10,197,131	3,586,339
1893	10,567,807	3,699,579
1894	7,620,284	4,238,600
1895	10,322,157	3,923,130
1896	9,303,398	3,800,168
1897	6,015,104	3,284,349
1898	7,881,172	2,986,970
1899	10,861,262	3,092,846
1900	12,060,124	4,503,968
1901	11,019,658	4,404,448
1902	15,623,601	5,030,204
1903	15,301,912	6,181,115
1904	14,763,002	5,422,945
1905	18,306,302	6,599,222

Furies, Eumenides, or Erinyes, called by the Romans FURIÆ and DIRÆ, were Greek mythological divinities, the avengers of murder, perjury, and filial ingratitude. They sprang from the drops of blood which fell from Uranus when he was mutilated by his son Kronos or Saturn. Others make them the daughters of Acheron and Night, and of Pluto and Proserpine. Later mythologists reckon three of them, and call them Alecto the unresting, Megæra the jealous, and Tisiphone the avenger. They were supposed to be the ministers of the gods, and to execute their irrevocable decrees; their sphere of action consequently was both in the infernal regions, to punish condemned souls, and on the earth to rack the guilty conscience and chastise by mental torments. Æschylus, in the celebrated tragedy of the Eumenides, introduced 50 furies, and with them Horror, Terror, Paleness, Rage, and Death, upon the stage. These terrible beings were described as clothed in black robes, with serpents instead of hair, with fingers like claws, a whip of scorpions in one hand and a burning torch in the other, an outstretched tongue, and eyes dripping with gore. They were suckers of the blood of men; when they were enraged, a venom oozed from them that spread like a leprosy-spot wherever it fell, and made the ground barren. They were regarded with great dread, and the Athenians hardly dared to speak their names, but called them the *venerable goddesses*, by a similar euphemism the name Eumenides, signifying the soothed or well-pleased goddesses, being introduced. They dwelt in the cave called after them, at the northeast corner of the Areopagus at Athens, below the seats of the judges. Erinyes, the more ancient name, signifies the hunters or persecutors of the criminal, or the angry goddesses. The sculptors represented them as beautiful hunting nymphs, whose character was indicated only by the sternness of their expression, by the torch, dagger, and other similar emblems.

Furman University, a coeducational institution in Greenville, S. C.; founded in 1854 under the auspices of the Baptist Church. Reported in 1905: Professors and instructors, 12; students, 204; volumes in the library, 4,000; productive funds, $90,000; grounds and buildings valued at $80,000; benefactions, $20,000; income, about $40,000; president, E. M. Poteat, D.D., LL.D.

Furnace, a structure wherein a vehement fire and heat may be made and maintained, as for melting ores or metals, heating the boiler of a steam-engine, warming a house, baking pottery or bread, and other such purposes. Furnaces are constructed in a great variety of ways, according to the different purposes to which they are applied. In constructing furnaces the following objects are kept in view: (1) To obtain the greatest quantity of heat from a given quantity of fuel. (See FUEL.) (2) To prevent the dissipation of the heat after it is produced. (3) To concentrate the heat and direct it as much as possible to the substances to be acted on. (4) To be able to regulate at pleasure the necessary degree of heat (see HEAT) and have it wholly under the operator's management. An air furnace is one in which the flames are urged only by the natural draught; a blast furnace, one in which the heat is intensified by the injection of a strong current of air by artificial means; a reverbatory furnace, one in which the flames in passing to the chimney are thrown down by a low-arched roof on the objects which it is intended to expose to their action.

Those furnaces in which gaseous fuel is burned form a class of considerable importance. The gas to be consumed and the air to be used in the combustion are introduced into the combustion-chamber by separate pipes or openings, preferably in parallel streams near to each other, or in opposite directions along one channel so as to mingle before entering the chamber. The fuel may be either some naturally occurring gas, or one specially manufactured for the purpose, or the by-product of some other industrial process, for example, the waste gases of the blast furnace. Four methods of preparing fuel gases are distinguished: dry distillation, as in the case of coal-gas; preparation from oils; the producer method; and the water-gas method. Producer-gas was first introduced by Siemens. Regenerators are furnaces in which the gaseous fuel and the air to be mixed with it are heated before combustion with a view to increasing the working temperature of the furnace. The advantages of gas furnaces may be briefly summarized thus: no ashes or slag, high temperature, certainty of action and capability of exact regulation, simplification of working power, comparative cheapness, and economy. The electric current has been successfully utilized in the production of heat for chemical and metallurgical operations, and in this way temperatures otherwise unattainable have been reached. See ELECTRIC FURNACE; GAS; GAS, NATURAL.

Furnaces, Electric. See ELECTRIC FURNACES.

Furnaces, Metallurgical. See METALLURGY.

Furneaux (fėr nō') **Islands,** a group in the South Pacific off Tasmania, to which colony they belong. The total area is about 1,050 square miles. The principal islands are Flinders, Cape Barren, and Clarke. The inhabitants number about 700, and earn their livelihood by seal-fishing, the capture of sea-fowl, etc. The islands were discovered in 1773 by Tobias Furneaux (q.v.).

Fur'ness, Horace Howard, American Shakespearian scholar and editor; son of William Henry Furness (1802-96) (q.v.): b. Philadelphia 2 Nov. 1833. He was graduated at Harvard in 1854; studied law, and was admitted to the bar in 1859. The honorary degree of Ph.D. was conferred on him by the University of Göttingen in recognition of his services to Shakespearian literature. He is the editor of the exhaustive 'New Variorum Edition' of Shakespeare, the successive volumes of which appearing since 1871, include: 'Romeo and Juliet' (1871); 'Macbeth' (1873); 'Hamlet' (2 vols. 1877); 'Lear' (1880); 'Othello' (1886); 'Merchant of Venice' (1888); 'As You Like It' (1890); 'Tempest' (1892); 'Midsummer Night's Dream' (1895); 'Winter's Tale' (1898); 'Twelfth Night' (1901).

Furness, William Henry, American clergyman and author: b. Boston, Mass., 20 April 1802; d. Philadelphia 30 Jan. 1896. He was educated at Harvard; studied theology at Cambridge, Mass., and was pastor of the First Unitarian Church in Philadelphia in 1825-75. He was an earnest supporter of the anti-slavery movement and was a German scholar of eminence, translating much from the German in both prose and verse. He was a radical in his religious views but made a life study of the character of Jesus, which forms the theme of several of his works. Among his numerous works are: 'Remarks on the Four Gospels' (1836); 'Jesus and His Biographers' (183); 'A History of Jesus' (1850); 'Thoughts on the Life and Character of Jesus of Nazareth' (1859); 'The Veil Partly Lifted' (1864); 'Jesus' (1871); 'Verses and Translations from the German Poets' (1886); 'Pastoral Offices' (1893).

Furness, William Henry, 1828–67, American artist, son of the preceding: b. Philadelphia, Pa., 21 May 1828; d. Cambridge, Mass., 4 March 1867. He very early made a reputation by the excellence of his crayon portraits, and having earned from the sale of these the means for foreign travel, studied art in Europe for two years. On his return to America he established himself as a portrait painter in Philadelphia, and subsequently in Boston, and at the time of his death was one of the foremost portrait painters in the country. Among noted portraits by him are those of his father, Dr. Furness; Charles Sumner, and Lucretia Mott.

Furness, William Henry, 1866, American ethnologist: b. Wallingford, Pa., 1866. He is a son of H. H. Furness (q.v.), and was educated at Harvard and the medical school of the University of Pennsylvania. He has published: 'Folk-Lore in Borneo' (1899); 'Life in the Luchu Islands' (1899); 'Home Life of the Borneo Head Hunters: its Festivals and Folk-Lore' (1902).

Furnishing Goods. See CLOTHING AND FURNISHING TRADE.

Furniture, formerly all the various movable appliances or articles in the interior of a house, now more commonly applied to articles of wood or metal. The ancient Egyptians aimed to variety rather than symmetry in the arrangement of their houses. They had chairs made of the finest woods in great variety of design, covered with rich cloths or skins, and inlaid with gold or ivory. They also used folding stools, sofas, couches, and carpets or rugs. Their tables were of variety of shapes and constructions. Bedsteads were made of wickerwork and sometimes of bronze. The forms of household articles of furniture found in or represented on Assyrian monuments and remains, show great artistic elaboration and a profusion of highly wrought ornament. The Assyrians were especially skilful in the chasing of metals, and they delighted in reproducing natural objects on their ornaments. The Greeks had couches covered with skins or drapery, on which several persons might lie with their bodies half raised; these were used at meal times by the men only, women and children sitting on seats; they had large armchairs with footstools, portable small chairs without arms, and stools with carved legs made to fold up.

Among the Romans, Greek art gained a predominant influence, and the conquerors of the world were at all times glad to employ natives of Greece to design and execute the works intended to display the opulence of their masters. On the ornaments of the *triclinia* or couches on which they repose, immense sums were bestowed. They were often inlaid with precious materials, such as ivory, tortoise shell, gold and silver, and had ivory or metal feet. They consisted of a framework which was strung with girths, on which rested a mattress stuffed with straw, wool, or feathers, and covered with rich drapery. The *lectus cubicularis*, or bed, was higher than the couch, but not unlike it. The tables were generally of costly foreign wood, resting on frames of carved marble or an ivory column. The curule chairs, or seats of state of the patricians and magistrates, were wrought in ivory; and to form an estimate from the number of beautiful utensils in marble and bronze richly chased and inlaid with silver, that have been found in the ruins of a comparatively insignificant city, Pompeii, the wealth of the Romans in movable property of this nature must have been very great. The library first appears as a separate apartment in a Roman house; that discovered at Herculaneum was small, and lined with presses about the height of a man, in which the rolls of papyrus and parchment were kept. Still, according to modern ideas, the Roman rooms would seem rather bare of furniture. They had no writing tables or cabinets; couches, chairs, tables, and candelabra comprised the whole of the furniture with the exception now and then of a water clock, or a chafing dish.

Among European states from 500 A.D. to 1500, the ecclesiastical style prevailed in furniture as in every other species of art, attaining its greatest eminence in the decorated Gothic of the 14th century. Articles of furniture previous to 1500 are very rare. For three centuries after the Conquest domestic furniture was very scanty. The hall was furnished with tables and benches, the furniture of a bedroom consisted of little more than a bed and a chest. Chairs were large and cumbrous, and were usually fixtures; wooden forms, sometimes with black rails, being placed against the walls. The furniture of the dining-room was very limited. Boards on trestles were in general use as tables. In the 14th and 15th centuries remarkable progress was made and a considerable degree of splendor in furniture was attained. Defense began to be not the only object studied in the construction of buildings. The Gothic paneling of the carved bedsteads, chairs, screens, etc., was dazzling with scarlet, blue, and gold, and costly embroidered hangings and curtains heavy with heraldic symbolism, cabinets, reading-desks, prie-dieus, ivory and enameled coffers, fire dogs, or andirons elaborately chased and gilded, began to appear.

The progress of this decorative style was suddenly arrested by the "Renaissance," or revival of ancient classical art and literature, of which Italy was the earliest seat, and from whence the impulse was given that communicated itself speedily to the rest of Europe. A genuine and self-evolved style instantly went out of fashion, and was discarded for an imitation and counterfeit one based on the copying of understood classic models which were applied without consideration to the most incongruous objects. The classical temple was the dominant idea in the manufacture of furniture as well as in the construction of a palace or a cathedral, and columns were considered as necessary in one species of art as in the other. All the architectural details of Roman buildings were then applied to furniture; the lions, griffins, chimeras, etc., of the temple frieze encumbered the stately pillars of the Italian palaces, and caryatides and Roman trophies replaced the patron saint and the crucifix. With all its absurdities, it must be noted that this style was in the hands of great men, and their productions display a boldness and vigor of line, and a mastery over human and animal forms that give dignity to a licentious freedom of design in which all appropriateness is forgotten. Specimens of the Renaissance are still met with, though daily increasing in value. Gothic art never recovered its lost ground.

With various modifications the Renaissance style continued dominant for nearly two centuries. In England it degenerated into positive ugliness, the furniture of the time of Elizabeth and James I. having very little to recommend it in tasteful design. It is distinguished by a mixture of overwrought heavy molding, combined with thin spindly columns, twisted legs, and other inelegant characteristics. Magnificence is sometimes attempted in the value of the material, as in the famous set of chamber furniture in chased silver executed for a royal visit at Knowle Park, the seat of the dukes of Dorset in Kent. It was succeeded by the style named after the French monarch, its patron and encourager, Louis XIV.

The modern predominance of France in the construction of furniture is owing to the minister Colbert. He it was who brought together the best workmen of Europe, and by an edict of the year 1667 established the French royal manufactory of furniture. The new style which the productions of this establishment assumed appears to have been worked out undesignedly, and, like every such successful phase of art, was the genuine product of circumstances. Novelty and magnificence seem to have been the great features aimed at; these were sought by varied treatment of surface in cabinet furniture (as inlays of metals, ivory, enamels, porcelain tablets, tortoise shell, etc.), and by an incrustation of broken scroll panel work, which hid the real constructive forms and frittered away the graceful outlines of the Renaissance into a confused and unsymmetrical mass. Under Louis XV. the same school of art continued, and it received new elaboration under the successors of Boule, Riesner, and Gouthier; their works are known to connoisseurs as articles of vertu by the respective styles of each master, and fine specimens bring almost fabulous prices. Probably more of this class of furniture is to be found in Great Britain than in all the rest of Europe, a great change of owners having been brought about by the French Revolution. While the splendid extravagances of Louis XIV. were holding sway in France, the prevailing taste in England seems rather to have been modified by the fashion introduced from Holland by William III. The native woods, oak or wainscot, chestnut, etc., were about this time superseded for furniture by the dark and heavy West India mahogany, the invariable material of the ill-designed and awkward furniture familiar to us in the immortal designs of Hogarth. A better style based on that of France was introduced by Chippendale, but a severer and more artistic taste was displayed by the designs of Heppelwhite and Sheraton. In the latter part of the reign of Louis XVI. another change is apparent in French furniture. Greece and Rome were looked up to as standards of correctness in furniture as well as in politics. But instead of impressing their own genius on designs inspired by ancient models as did the great artists of the Renaissance, the authors of this revival were too often content with frigid imitation. The classical style did not long hold sway, and since that time the practice of both France and England (and with them the rest of Europe) has been purely eclectic. At present designs after the best work of the older makers are much in favor in both Europe and America. See FURNITURE INDUSTRY IN AMERICA, THE.

Furniture, Colonial. When the Colonists first landed, and during their early struggle for existence, little if any attempt was made to import furniture, and we have nothing now which could be rightfully claimed to have been brought over from Europe before the coming of the Mayflower (1620). The New Englanders were the first to make furniture copying the designs of the original pieces, which were of heavy oak with severe lines and flat carvings. Their puritanical minds apparently abhorred anything of an ecclesiastical cast. As early as 1650 the southern planters imported fine pieces from England, of oak richly carved and inlaid, the designs being influenced by the Renaissance just dawning in France, and the Elizabethan and Jacobean periods in England. The authorities in the South tried to prevent trade with Holland and New England, so a comparison of the English furniture, prior to the Revolutionary War, with that of Maryland and Virginia, shows that the English life of that time was planted there as far as it was possible. Since we find so few of these original pieces, we can only think that the planters becoming wealthy so rapidly, and wishing to keep up to the "prevailing English style," must have discarded the old for the new, as their invoices show large importations of furniture up to the Revolutionary War.

There was a marked difference between the houses of New York and of New England. The Dutch built theirs of brick, while those in New England were mostly of timber, and a striking feature in the living-room of the former was the chimney-piece, which among the wealthy was elaborately carved and tiled and held vessels of brass repoussé and Delft-ware. The fire-place with its colored tiles continued to be a decorative feature, even after coal succeeded wood as fuel and grates took the place of andirons. The floor of the average house was sanded, and rooms had no special character. The ideas which the Dutch brought from the Orient influenced the designs not only around New York but in New England as well, and fast grew into favor. Strange shapes from the East, introducing marqueterie in exotic woods, were eclipsing the old chests of drawers, cupboards, etc., and actual products of the Far East filled many of the Dutch houses. The cabriole legs superseded the severer lines. Other woods beside oak, such as walnut, pine, red cedar, maple, etc., were introduced; ebony was scarce, so the "black egg ornament" was often of white wood stained black.

In the first half of the 18th century New York was an important place, and inventories show that fashions in New York compared favorably with those of London and Amsterdam. The bed was disappearing from the hall; carpets were introduced, and in 1750 they had flowered carpets and "painted floor cloths." The walls, of houses of the better class, were papered before the middle of the 18th century, and for 50 years we have an interesting wallpaper period; their chief designs were large illustrating panels, such as "The Lady of the Lake," "The Four Seasons," etc. Fire-places were growing smaller as wood was harder to obtain, and in 1745 Franklin invented what is now known as the "Franklin stove." Upholstery was taken up and there were many cabinet-makers in New York, Boston, and Philadelphia; skilled workmanship was in demand, and "choice timber and metal furnishings for cabinets" were advertised. Then came the period when mahogany was the favorite wood, and, just as in England, all designs had a tendency toward greater lightness and grace of line, and showed the Chinese influence strongly. In 1776 the home of a wealthy American compared favorably with that of an Englishman in similar circumstances. "Chippendale" was the rage, both imported and domestic. There was a marked difference between the North and South — the Northerners lived more simply, but with a certain amount of fashion and elegance; in the South everything was ease and luxury, and many houses were noted for their costly furnishings. Around Charleston, S. C., at the present time are some excellent examples of typical Southern homes of the 18th century, containing many of the original pieces of furniture. The classic or Greek style adopted by Adam in England, found its way here, and was seen in architecture and interior woodwork, noticeably in mantels and built-in cupboards, but was little used in articles of furniture.

Mt. Vernon — now a museum of relics — is the most interesting colonial house, on account of its associations. It was inherited by George Washington in 1751 from his half-brother Lawrence Washington. Soon after it was almost entirely refurnished, and though by no means palatial was extremely comfortable. There were few of the original Washington pieces left there, as Mrs. Washington bequeathed the furniture to four grandchildren, but now many articles are gradually finding their way back, either through gift, or through purchase by the Mt. Vernon Ladies' Association of the Union. There are many Washington pieces, used by him while in Philadelphia, now in possession of the Historical Society of Pennsylvania. Second in interest is Monticello, the home of Thomas Jefferson. Its architecture and decorations are delightful, and it still contains proofs of the owner's good taste and love of art.

"Colonial designs," as termed in the vocabulary of the dealer of to-day, were not known until the colonies had become States. They are traced in America first through the Dutch, who had taken many points from Spain and the Orient, namely the ball and claw pattern. Chippendale adapted them with more lightness and grace of line, but the French Empire style which came in at that time changed it into the massive mahogany, and gave the rope-carved pillars and lion-claw feet. American makers omitted the elaborate brass and ormolu trimmings used by the French, and depended upon the beautiful grain of the wood, often veneering to obtain handsome effects. The superiority of the old furniture is due to its construction; the old makers worked solidly, dove-tailing, and blocking all drawers, and to-day the age of the wood has greatly added to its value, the stained mahogany loses the beautiful golden shafts of light. The polish was attained by constant rubbing, while to-day most pieces are simply varnished.

Mahogany was brought into England by Sir Walter Raleigh, but was not in general use until about 1725. In New England it was extensively used a little later, being imported from the West Indies. The Honduras and Mexican varieties most commonly used to-day, do not materially improve with age, and are much lighter in weight than the West Indian, therefore a really old piece may often be told by its heaviness. The date of a bureau, chest of drawers, etc., may frequently be ascertained from its handles.

Handles.— The oldest handles, chiefly brass, rarely pewter, were drop-handles, formed like an earring, backed by a small plate. Next in order was a larger plate, usually engraved, with a bail large enough to insert two fingers. The next was a larger plain plate similar to a fleur-de-lis in shape, the bail being much larger, and from now on, held into the drawer by brass nuts instead of wires as formerly, but in reproductions iron nuts are nearly always used. It gradually developed into a thin oval plate embossed with moldings, sometimes with centre design, and the bail, fitted into posts, falls outside the plate, preserving the same curve. Still later came the knob and empire rosette handles, sometimes with ring, usually of brass but also of glass or plain wood.

Chests.— No matter how meagre an inventory, it always included a box, chest, or case. First the ordinary ship's chest of pine with iron handles, which was appraised very low. There are several good examples of these in State historical societies, including one brought over in the Mayflower. Few of these were made after 1725. The oldest carved chests were in low relief with often the date and name of the person for whom it was made; they were afterward made with one drawer, having panel or turned ornaments. This developed into the "chest of drawers," made of oak and more elaborately decorated, which in turn developed into the "chest upon chest," sometimes having as many as nine drawers, and the three-tier "steps" for displaying china was sometimes placed upon these. The "high-boy" is not mentioned until the chest of drawers was placed upon a frame about three feet high, having one or more drawers; it had six legs, and later the part where the centre legs were omitted was finished with "drops." This, in the latter part of the 18th century, became a very handsome article of furniture, with carved top, usually "shell" or "sun" pattern, decorated with gilt torches or balls, and cabriole legs and carved feet.

The Dressing-Table, or "low-boy," came from England in 1716. At first it had but one drawer, afterward it was the same as the frame for the "high-boy," only about three inches lower. The "high-boy" and "low-boy" were often made to match. The Chippendale and Sheraton designs were usually furnished with dressing-boxes and mirror.

The Settle was an evolution of the chest. Handsome examples are rarely found in this country, although there are many varieties of the "fire-side" settle in painted pine and oak found in New England, with a shelf to hold a candle. The settles which appeared in the latter part of the 18th century, following the Chippendale, Sheraton, and Hepplewhite designs, might better be termed sofas, which later took on the Empire designs, with "claw-and-ball" and "wings-and-claw" feet, and "cornucopia" and "swan-neck" ends.

Beds were among the first and most frequently mentioned articles of furniture in wills, being highly prized. In the 17th century the Southern planters owned elaborate European bedsteads, usually of oak. In New England they were very simple affairs, while among the Dutch the bed, at first, was only a sort of bunk. The four-poster soon supplanted all, first of oak, but later of mahogany. Some were most elaborate, with rope-carved, or pineapple and acanthus-leaf posts, and ball-and-claw feet, with

tester drapery, valance, curtains and coverlet to match, of white or bright colored materials, chiefly drugget, lindsey-woolsey, or dimity, though later chintz was popular. In the South, mosquito canopies were prevalent, sometimes colored to match the color scheme of the room. Feather beds were universally used, resting on ropes or sacking pulled taut, and owing to their height, "bed steps" were necessary. We also find mention of turkey feathers and cat-tails being used as fillings, and early in the 18th century hair mattresses appeared.

Cupboards were usually built into the wall, and whether called "livery," "court," "standing," or "press," were all fitted with light movable shelves to hold linen and display china and glass. There are few of these open cupboards to-day. First the upper part was enclosed with doors (later ones show glass doors with lattice work), afterward a drawer was added, then the lower part was enclosed, and when fitted with lock and key was highly prized as an article of furniture. These partly opened cupboards were called "beaufait," afterward contracted to "boufet." Closed-in cupboards show German as well as Dutch origin, and the finest examples were found among the Dutch, usually spoken of as "kasse," carefully carved and painted.

Chairs are scarcely mentioned before 1650, forms or benches being used almost entirely, the chair being considered the seat of honor, but toward the end of the century there was a marked increase in the numbers mentioned in the inventories. They were made of oak, pine, and walnut, turned or paneled, simply carved and with high backs, the seats either rush or cane. About the 17th century we notice leather and "turkey-work" seats with brass nail-heads. The "ball-and-claw" foot, introduced by the Dutch, appeared at the close of the 17th century and remained in favor for nearly a hundred years. Chairs made of wicker and cane were known as early as 1711, and in 1720 came the painted chairs from Holland, usually black, often decorated, with rush or cane seats. The Windsor chair, first made and used in Philadelphia in 1725, was the most popular style up to the 19th century. It was usually of hickory or ash and had a wooden seat, the back was high and either "spindled" or "fan-shaped," sometimes having an extra headpiece. The style known as Chippendale appeared in 1720, the development being apparent before Chippendale worked. Its chief characteristics were the traceried splat, bow-shaped back and cabriole legs, also the "plate-backed," which was a solid splat, usually jar-shaped, and hoof feet. The all-upholstered "wing" chair seemed to be in general use before 1750. Mahogany was now easily procurable and the tendency was toward greater lightness, and most of the designs, from now on, follow the English cabinet-makers; Chippendale, with a strong Chinese influence, then Sheraton and Heppelwhite, some being beautifully decorated with hand-paintings, carvings and inlay. In 1770 we have another style, modeled after the old "splat-back," but with the splats crosswise. About 1800 the style commonly known as "empire" began to be felt, and gave us the "lion" and "bear" claw-feet and rolling backs, copied after old Egyptian designs. The strong empire was partially modified here by the Sheraton influence. There is a style in America, a modification of the empire, with heavy mahogany splat-back, usually jar-shaped, often having the back and back legs in one piece. These were in favor until 1840; they were usually covered with "horse-hair" and are now offered as "Colonial" designs!

Tables.— What has been said of the development of chairs may be applied to tables, as almost every form of chair had its corresponding table. First we had the "table-borde," a board, often 12 feet long by 2 wide, resting on a cross-legged trestle. It gradually became customary to leave the "borde" on the trestle instead of removing it after each meal, and it was then known as a table. Marble and slate-topped tables appeared about 1693, and were considered "the latest thing." Before the 18th century we had imported "chair-top" tables, "drop-leaf," and the "100 legged," which was the first extension table, all with turned posts. About 1735 the Dutch influence was strong, and to-day we have some excellent examples, dating from 1750, of mahogany "pie-crust," "dish-top," etc. The "centre-pillar" table came in with the Empire period. Tea tables were found in every parlor of the 18th century, always ready with complete tea-service, spirit-lamp, kettle, tea-box, tongs, strainer, etc. Among the Dutch the table was frequently of rare or japanned woods, many with adjustable tops. Card tables, of which there were many, usually had a plain surface, though some were covered with green cloth; they had folding tops and corner shallows for counters. Work tables were mostly of Sheraton design, the top lifting up, disclosing compartments for sewing materials. Candle tables were of various heights, with a top only large enough to hold a candlestick.

Desks.— A desk was originally a wooden box with slanting lid, the writing materials, and frequently the Bible, were kept inside under lock and key, and the top served the double purpose of reading and writing desk. The large desk or "secretary" appeared about 1660 and seems to have been another development of the "chest of drawers," usually having two or more drawers in the lower half. The lid on the upper part was either let down on chains or rested on two wooden slides. The interior was fitted with many drawers and pigeon-holes, and they had often secret compartments. Later, a cabinet was placed on top and developed into the "cabinet-top" desk, made in one piece and reaching almost to the ceiling. The "table-topped" desk belonged to a later period, a good example being the one used by Washington while in New York in 1789, now in the City Hall. There are some good specimens of Sheraton and Heppelwhite desks in this country belonging to their respective periods. The later empire or "Colonial" pieces were large and heavy, mostly "bureau-fronts."

Clocks.— There is slight mention of household clocks prior to 1700, but in the 18th century clock-making was quite an art; the Willard Brothers of Massachusetts were the first to become famous. Around New York were found some "Frisian" wall clocks from Holland, run by weights, with elaborate designs of gilded and painted mermaids, cherubs, etc. The English "lantern" clock was on the same order, being of brass with heraldic metal work. This developed into the "bracket" clock, through having a wooden hood placed over it for protection; it was very popular about 1700. The first mention of a tall clock is in the latter part of the 17th century, when long pendulums, also moving figures upon the dial, became fashionable. It was spoken of as "clock and case," and was very plain, of oak or walnut but later of mahogany. Many of them were destroyed during the Revolution, the works being hidden and the cases, in some instances, used for shipping bayonets. Few tall clocks were made after 1815. After the Revolution cheaper time-pieces were in demand, and to meet it, clocks having white enamel dials and wooden works were invented. From then on, there were many styles of cheap clocks for walls and mantels, including the "banjo" clock patented by Willard in 1802; the "lyre" clock, and many "Colonial" designs in wood, some with painted glass covering the pendulum.

Looking-Glasses.— The first record is in an inventory in Maryland 1639. They were rare at that time even in England, being imported from Venice. The frames were of olive-wood, black or gilt, and when the glass exceeded four feet were made of small pieces joined by moldings. Later the frames were heavily carved and inlaid, but always retained the Italian appearance. We find mention of a parlor in a Maryland house in 1732, "set off with pier glasses." In New England it hung over the mantel-piece and was known as the "chimney-glass," usually ornamented at either side with candle sconces. At the end of the 18th century the shield and oval glasses appeared, showing the influence of the English cabinet-makers, followed by the Empire, with rope-carved pillars, acanthus-leaf and lyre carvings, sometimes having the top partitioned off for paintings. What is known as the "Constitution" mirror did not appear until after 1800; most of them bore the eagle at the top.

Mirrors, during the 17th and 18th centuries, were either of convex or concave glass with elaborate frames, and were frequently used for decoration.

Sideboards came into fashion about 1780, taking the place of cupboards and side tables. They were nearly always of mahogany. First after Sheraton, with inlay, noticeably the "bell-flower" design down the slender legs; later "Colonial" of heavy mahogany with the cupboards extending nearly to the floor, ball-and-claw feet and rounded pillars, similar to the bed-posts.

Washstands.— First called a "bason-frame." Few good examples before the latter part of the 18th century, which were influenced by the English cabinet-makers, and later by the Empire.

Warming-Pans were a necessity, especially in New England. The pan was usually of brass with cover, 14 inches in diameter, with a long wooden handle fastened to the pan by an iron socket. Hot coals were placed in it, and when rubbed between the sheets warmed the beds. They were often decorated with open-work carvings and were quite ornamental hanging beside the fire-place.

Screens were used to protect the face from the heat of the fire, were small, made of embroidery or painted wood, with round or square frame, fastened on a post which could be raised or lowered.

Children's Articles.— We find frequent entries of articles of furniture for children. Cradles, the first one brought over in 1620; high-chairs, also "fenders," to keep the children away from the fires.

There were several miscellaneous articles of furniture mentioned after 1750, including "dumb-waiters," now called "butler's trays"; "wine-coolers," "knife-boxes," "sewing-boxes," "clothes-trees," etc.

Collections.— Among the many permanent collections of Colonial furniture may be mentioned the Connecticut Historical Society, Hartford, Conn.; the Pilgrim's Society, Plymouth, Mass.; the Essex Institute, Salem, Mass.; Van Courtlandt Mansion, Van Courtlandt Park, N. Y.; American Antiquarian Society, Worcester, Mass.; Historical Society of Pennsylvania, Philadelphia; Washington's Headquarters, Morristown, N. J.; Independence Hall, Philadelphia, Pa.; and Mt. Vernon, Va.

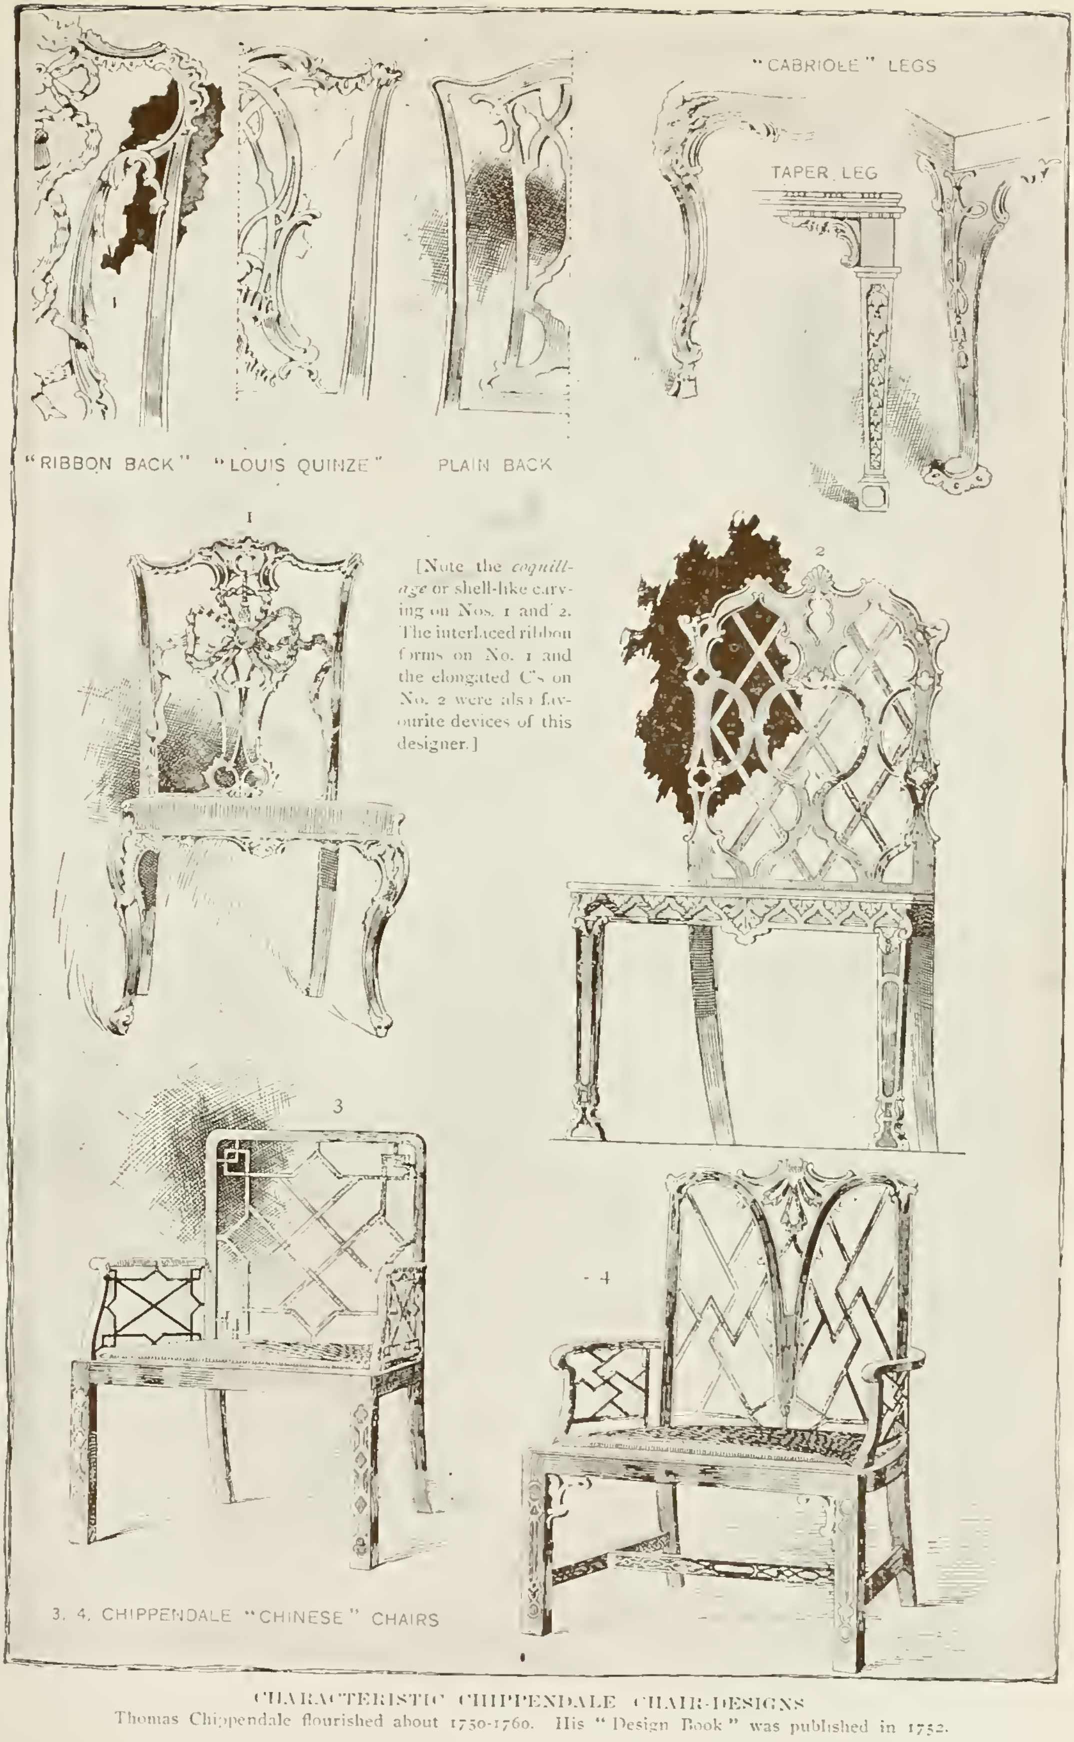
Louise Cowperthwaite,
Of George C. Flint Company, New York.

Furniture Industry in America, The. The early cabinet-shops of America were like the second-hand repair-shops to be seen to-day in New York, Boston, Philadelphia, and other large cities. A great many cabinet-makers made furniture until late in the 1st century of commercial independence on simple Chippendale lines. Gradually the Empire fashions, which were making themselves felt all over Europe, spread to America, and shapes became heavier and more pretentious, mahogany being used almost exclusively. Heads of animals were also used, and claw-feet became a general feature. Common furniture was heavy and unattractive. The general condition of things at this time was unfavorable to the development of art industries. Little thought was given to progress in the manufacture of furniture and for some years there was a decline. Upon a revival of commerce cabinet-makers changed their style, and began producing a debased rococo style, which did not have the elegance or character of the Louis XV., but was covered with a florid ornamentation in which the only consideration was display. The extravagance of curves and lavish ornamentation brought about a reaction, and toward 1830, following the fashion in England and France, an attempt was made to construct furniture in the Gothic style, but with very unsatisfactory results. The lack of artistic training of the manufacturers who were, as a rule, cabinet-makers or carvers by trade, made it very difficult for them to handle a method of decoration and construction so little appropriate in itself to the requirements of home comfort. This Gothic style of furniture, monumental in appearance, was made to a limited extent only, although its influence is to be noticed on other furniture placed on the market at this time and later. The making of rococo furniture was kept up by a large number of cabinet-makers, the cheaper furniture being for many years made in this style. It was also during this period that steam, applied to cabinet-makers' machinery for



CHARACTERISTIC CHIPPENDALE CHAIR-DESIGNS

Thomas Chippendale flourished about 1750-1760. His "Design Book" was published in 1752.

CHARACTERISTIC HEPPELWHITE FURNITURE.

Messrs. A. Heppelwhite & Co., Chippendale's successors, published their "Design Book" in 1789.
The Heppelwhites were designers rather than manufacturers.

the first time in 1815, occasioned a revolution in the manufacture of furniture, bringing labor-saving devices into more general use, and enabling the cabinet-maker to supply the rapidly increasing demand for his product. In 1825, Richardson, of Philadelphia, introduced the circular saw, and Taylor, Rich & Company erected the first mahogany-mill in America, a number of these saws being used there. Ordinary furniture, which until now had been very plain, was covered with endless scroll-work and moldings, produced so easily by the new machines. The manufacturers indulged for a time without restraint in this ornamentation. The use of machinery in shops, and the increased facilities for transportation, wrought a wonderful improvement in the furniture trade; and the cabinet-shop, which had until this time been of small importance and partially engaged in making articles kindred to furniture, suddenly assumed large proportions, and confined itself to furniture only, using in the making of it the new devices which were constantly being brought forth by ingenious inventors. The value of the furniture product in the year 1850 may be estimated at about $15,000,000, and the industry gave employment to 37,000 people, out of a population of a little over 23,000,000. For a long time a great number of hand-shops survived, making to order special high-grade work; and they succeeded in impressing their patrons with the idea of the inferiority of machine-made furniture, which at this early stage in the introduction of machinery was not entirely without foundation. The extensive use of machinery in shops had the immediate effect of again changing the style of furniture. Manufacturers looked for a fashion in which they could use their facilities to the best advantage, and at the same time retain the attractiveness of their earlier work. This they found in the Renaissance, which for a number of years superseded all other styles in the best class of furniture.

Up to this time the furniture industry had been confined to the Eastern States, principally in and around Boston; but a number of factories were now started in the West, where situated in proximity to large forests and regions where population and wealth were rapidly increasing, they soon became important factors in the production of furniture in the United States. These factories, equipped with new machinery and using native timber, produced at first a low grade of furniture in which art seems to have been very little considered. Those who wanted more artistic furniture purchased it from the East. The art revival which had taken place in Boston and New York was fostered by increased travel in Europe, where exhibitions were taking place at short intervals in London and Paris. Moreover, the consideration that old furniture was beginning to receive brought forcibly to the people the inferiority of that then made, and manufacturers gave more attention and study to its appearance than before. Trade kept increasing with the general wealth, and in 1860 the production reached $25,500,000; but the number of workingmen employed in this industry, owing to the improvements in machinery, had fallen to 28,000, although the population had then reached almost 31,500,000.

Industries in general were now to receive another blow, on account of the War of the Rebellion. As soon as this conflict was over, the extraordinary activity which had prevailed in military circles was transferred to the industrial field, and from this time on it is by leaps and bounds that improvements can be noted. The furniture trade was in the hands of two classes of manufacturers, one class of whom, having taken the place of the old hand-shop workers made high-class work to order, continuing the old traditions, but now using machinery extensively. The other class of manufacturers studied the wants of the people, and produced suitable articles at prices which were within the reach of the masses. It is to them that we are indebted for the gigantic development of the industry, as they placed within the reach of all, strong, ornamental, and practical furniture. We have seen that men of taste had recognized for some time that our furniture was inferior to that made at the end of the last century, and had begun to study not only the styles of that period, but also those of the English and French prevailing in the past. As a result we find that a great variety of styles were employed in the productions of the leading firms, who were always striving for novel effects.

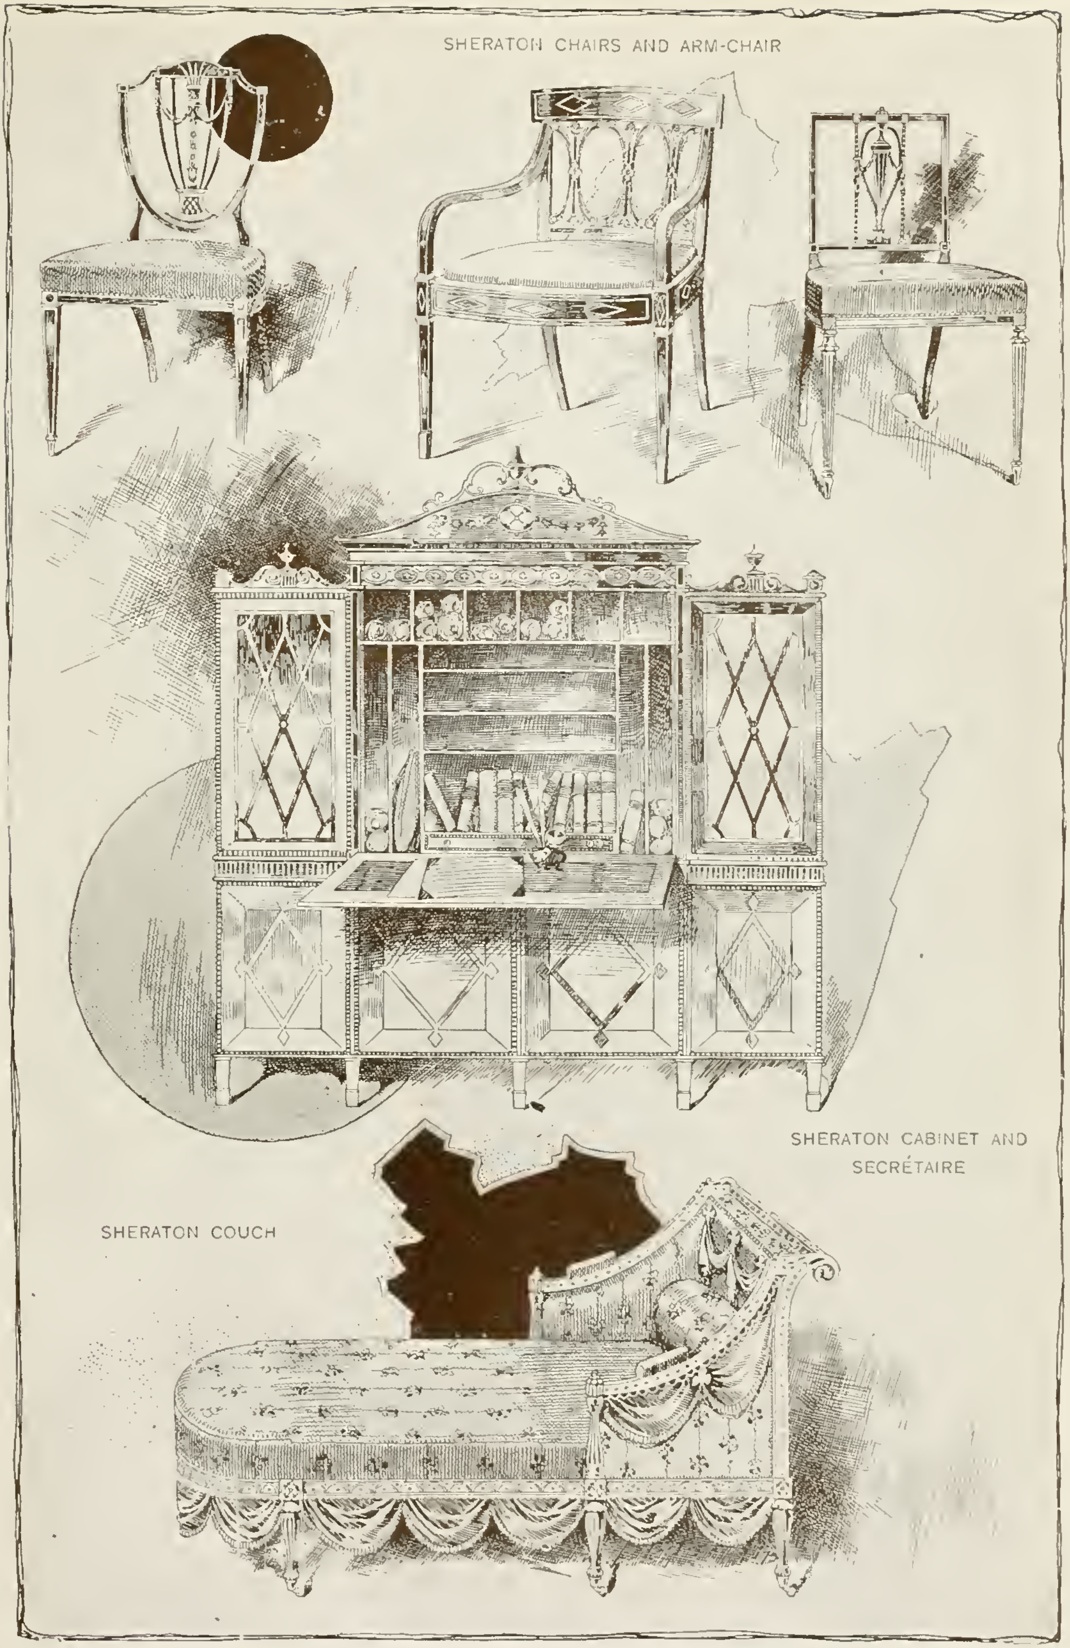
A work published in London, England, in 1868, entitled 'Hints on Household Taste,' by C. Eastlake, waged war on modern work, advocated returning to the primitive principles of Gothic construction; and gave positive instructions as to what was right or wrong, not only in the line of furniture, but in draperies, carpets, and other household decoration, as precisely as if the art had been a science. This book was looked upon as a sort of gospel treatise on furnishing, and however much we may at this time ridicule some of the ideas conveyed, it directed the public mind in its search for more artistic surroundings at home. From that time other styles were discarded, and designs in accordance with the newly developed taste took their places. The movement in favor of more perfect construction and the use of straight lines exclusively became general, the stiff appearance being relieved by an abundant use of arches, spindles, turnings, etc. This style allowed the manufacturers to do the greater part of the work by machinery, for which it seemed specially adapted. The increased interest that the public took in furniture developed the trade in an unprecedented manner, the production for 1870 being $68,500,000, or nearly two and one half times that for 1860. The number of men employed at this time shows a similar increase, being 55,800, out of a population of 38,500,000 people. The Centennial Exhibition in Philadelphia (1876) had a far-reaching influence, especially on western manufacturers, who until this time had not had occasion to compare their products with those of the best manufacturers of America and Europe. This exhibition marks the highest point that the Eastlake or early English was to attain. A number of the most prominent manufacturers of this country had their exhibits made in this particular style. It was quickly taken up by the manufacturers of cheaper furniture, who until then had given very little attention to artistic form, and they are responsible for the enormous quantity of furniture in imitation of this description that can yet be seen in the auction-rooms of large cities. The strife for originality, which was soon to be one of the characteristics of western manufacturers, had now begun to show itself; but an insufficient knowledge of art subjects rendered many of their designs more strange than beautiful, and more noticeably so when they were working on the lines of any given style; but through diligent efforts their designs were steadily improved, and this, in connection with their superior facilities, has secured to them a large part of the eastern trade. The volume of business showed a substantial increase during this decade, although not as large as during the preceding period. The value of the output of furniture for 1880 was $77,845,000 — an increase of 13.5 per cent in value, but a decrease from $1.77 to $1.55 per capita of the population. The wonderful changes which occurred in architecture in the next decade, especially the Romanesque revival due to H. H. Richardson, had a distinct effect on furniture. Richardson himself designed some Romanesque furniture. Furniture manufacturers eagerly welcomed this departure, for the ceaseless demand for new things, as strong then as it is now, obliged them to change their patterns very frequently. Unfortunately, by passing through the hands of manufacturers of cheap furniture, it lost all of its original beauty. During this decade great improvements were made in woodworking machinery, and a large number of new devices were invented. Among them was the carving machine, which enabled manufacturers to ornament even the cheapest kind of furniture. The amount of business done in 1890, large as it was, did not keep up with the increase of population. The value of the product in 1890 was $86,362,685, an increase of 11 per cent over that of 1880; but the amount per capita of population dropped to $1.38, as compared with $1.55 in 1880, and $1.77 in 1870. The International Paris Exposition of 1889 revived a taste for the 18th century furniture, especially of the Louis XV. style, which was quickly taken up by the people of the United States. In spite of the seeming difficulty of using machinery in making such work, American manufacturers made and are still making a large quantity of furniture, in that dainty mode, which certainly equals that of the same class made in Europe, and is generally better constructed. All the 18th century styles, French or English, have been and to a certain extent are now used by American manufacturers:— Louis XV., Chippendale, Louis XVI., Sheraton, Hepplewhite, Empire and the Flemish Renaissance.

Since the decline of the Empire style in the first half of the last century manufacturers have been satisfied to copy the styles of the past, with such modifications as conformed to commercial requirements. The public demand for reproductions of old furniture increased to such an extent as to leave little room for originality in their production. Within recent years a strong feeling has developed that the old styles are not in keeping with present ideals and new styles should be evolved to emphasize simplicity of construction, grace of style, beauty of proportion and harmony of color. The Mission style, at first heavy and shapeless, is acquiring more subtle and refined lines, thereby increasing in public favor. The novelty of the last century is a free natural style called Art Nouveau. Its introduction to this country from France a few years ago was attended by failure. The market was flooded with goods of inferior make in which the vagaries of this style were mistaken for its distinctive features. The meaningless curves and coarse ornaments of the beginning are being discarded and a refined elegance is now taking their place. The extensive adoption of this style in other art industries warrants the belief that it soon will be a distinctive feature in furniture.

Many of the numerous articles of furniture manufactured are distinctly American. The bureau, the rocking-chair, the folding-bed, the chiffonier, as now made with toilet, and in general most of the combination pieces of furniture made with a view of economizing space in apartments in large cities, are of this class. The American bureau is a combination of the old chest of drawers and the dressing-table, having the drawer-room of the one and the swinging mirror and table-top of the other. This has been imitated in Europe to a limited extent, in the production of what is known as the English dressing-table. As made in this country, the bureau is one of the most practical pieces of furniture used. The rocking-chair, almost entirely unknown in Europe, is found in every home in this country, yet it is difficult to ascertain when it was first put in use. We do not find any mention of it in the descriptions of articles of furniture in the 18th century. The first patent issued for improvements in rocking-chairs is dated as far back as 1830. The folding-bed, in the shape of a sofa, with a box-seat for bedding, has been used in Europe for over a hundred years, but America claims the folding-bed in other forms, such as the wardrobe, the cabinet, the mantel, and the combination; some of these were made as early as 1847. The demand for folding-beds, which reached its climax a few years ago, is now showing a material decline.

The woods used in the manufacture of furniture are varied, and subject to frequent changes. Early in the century, mahogany, maple, and black walnut were in favor; then cherry and ash became fashionable; toward 1880, oak, so long forgotten, took a prominent place. At the present time black walnut is almost entirely out of use. Oak has kept its popularity for the hall, the library, and the dining-room. Mahogany, curly birch, and maple are still extensively used; all of them for the bedroom, and mahogany for the dining-room and the drawing-room in the better grades of furniture. The changes in furniture covering have been more frequent and radical than those in the woods. Haircloth and other coverings in use 30 years ago have been superseded by materials more varied in texture and coloring. Their variety is almost endless, and they show, perhaps as much as anything else, the advance that art as applied to furniture has made in this country. The present centres of the furniture industry are, with one exception (Grand Rapids, Mich.), the largest cities, which, with their densely populated suburbs and surroundings, offer large markets. The cities whose productions amount to more than $2,000,000 per annum, in the order of their importance, are: New York, Chicago, Grand Rapids, Philadelphia, Cincinnati, St. Louis, Boston.

The following statistics show the furniture



CHARACTERISTIC SHERATON FURNITURE

Thomas Sheraton (1751-1806) was the last of the famous cabinet-makers of the 18th century. In 1790 he published his first collection of "Designs for Furniture," and this was followed by numerous other publications of a similar class.

factory product of the United States for 1900 according to the twelfth census:

Total	$125,315,986

The furniture industry of the United States has to-day reached a magnitude unknown elsewhere. The perfect equipment and organization of our mammoth factories capable of an enormous production emphasize the necessity for a larger market. Intelligent efforts are now being made in this direction by a number of manufacturers with the hope that eventually a large foreign trade may be secured for our American product. George W. Gay,

Revised by George G. Whitworth, *Berkey & Gay Furniture Co., Grand Rapids, Mich.*

Fur'nivall, Frederick James, English scholar: b. Egham, Surrey, 4 Feb. 1825. He was educated at University College, London, and Trinity Hall, Cambridge, where he graduated B.A. in 1846, and M.A. in 1849, and adopted the study of the law, being called to the bar in 1849. He has, however, devoted his life chiefly to the study of early and middle English literature; and he has been mainly instrumental in establishing the Early English Text Society, the Chaucer Society, the New Shakespeare Society, the Browning Society, the Wickliffe Society, and the Shelley Society. He is also honorary secretary of the Philological Society. The societies named have given a powerful impulse to English scholarship by their publications, and this is in no small measure due to Dr. Furnivall. For them and for the Roxburghe Club and the Rolls Series he has edited numerous works, notably the Six-Text edition of Chaucer's 'Canterbury Tales' (1868–75.) Other works of his are: 'Early English Poems and Lives of the Saints' (1862); 'Early English Meals and Manners' (1867); 'Book of Nurture' (1867); 'Education in Early England' (1867); 'Bibliography of Browning' (1881); and 'The Fifty Earliest English Wills in Court of Probate' (1882).

Furrer, fur'ĕr, Jonas, Swiss statesman: b. Winterthur 1805; d. 1861. After studying at Zurich, Heidelberg, and Göttingen, he became president of the Grand Council of Switzerland in 1839, a position which he again occupied in 1844. In 1845 he received his appointment as president of the Cantonal Diet, and when the new Federal Constitution went into effect he was elected president of the Swiss Confederation. He wrote 'Das Erbrecht der Stadt Winterthur' (1832).

Fursch-Madi, Emma, French opera singer: b. Bayonne, France, 1847; d. Warrenville, N. J., 19 Sept. 1894. After studying at the Paris conservatory, she began to sing in public concerts under the direction of Pasdeloup, and then appeared in opera, first as Marguerite in 'Faust,' and then in Verdi's opera 'Aïda' at the Théâtre de la Monnaie, in Brussels. For three years she sang in Covent Garden, London, and in 1884 came to New York to fill an engagement at the Academy of Music. She then appeared frequently at the Metropolitan Opera House. From 1891 she taught music and singing in the New York College of Music.

Fürst, Julius, German scholar: b. Zerkowo, Posen (Prussian Poland), 12 May 1805; d. Leipsic 9 Feb. 1873. He was of Jewish parentage, and at an early age he had a remarkable knowledge of Hebrew literature, Old Testament Scriptures and Oriental languages. In 1825, after having studied at Berlin, he took a course in Jewish theology at Posen. In 1829, after having abandoned his Jewish orthodoxy, he went to Breslau, and in 1831 to Halle, where he completed his studies in Oriental languages and theology. In 1833 he entered journalism in Leipsic, later securing a position as tutor and lecturer in the university there, from which position he was promoted in 1864 to the chair of Oriental languages and literature, a post he filled with great distinction until his death. His works, especially those on the Semitic languages, are of great value, and among the most important may be mentioned: 'Lehrgebäude der aramäischen Idiome' (1835); 'Concordantiæ librorum Sacrorum veteris Testamenti Hebraicæ et Chaldaicæ' (1837–40); 'Bibliotheca Judaica' (1849–63); 'Hebräisches und Chaldäisches Handwörterbuch' (1851–61); 'Geschichte des Karäerthums' (1862–5); 'Geschichte der biblischen Litteratur und des jüdisch-hellenistischen Schrifttums' (1867–70). From 1840–51 he edited 'Der Orient.'

Furst, William, American composer and conductor: b. Baltimore, Md., 25 March 1852. He studied music in his native town and at the age of 14 was a church organist. His comic opera 'Electric Light' was produced and conducted by him in 1878 and for the five seasons following he received engagements as conductor of opera. He became musical director of the Tivoli Theatre, San Francisco, in 1884. His opera 'She' ran for nine weeks there, and was produced for two seasons in New York His chief productions are: 'Theodora' (1888); 'The Isle of Champagne' (1891); 'Honeymooners' (1893); 'Princess Nicotine' (1893); 'The Little Trooper' (1894); 'Ghismonda' (1894); 'The Merry World' (1895).

Furtado, Francisco José, Brazilian statesman: b. Oeiras (Piauhy) 13 Aug. 1818; d. Rio de Janeiro 23 June 1870. After graduating from the Academy of Law at Caxias and serving for some time as judge, he entered politics and rose to be leader of the Liberals. In 1847 he was elected deputy and re-elected several times. In 1856 he was elected president of the new province of Amazonas, remaining such until 1859, when he was made minister of justice. In 1864 he was elected senator, but held that position for a few months only, and in August 1864 was made premier and minister of state, in which position he did much toward the establishment of a good monetary system. During his term of office as minister of state the dispute with Uruguay was settled and war between Brazil and Paraguay was declared. In 1870 he was again a member of the Senate and as such, being an opponent of slavery, exerted all his influence in behalf of legislation looking toward its final abolition.

Fury and Hecla Strait, in the Arctic region, in lat. 70° N., separates Melville Peninsula from Cockburn Island, and connects Fox Channel with the Gulf of Boothia. It was discovered by Parry (q.v.) in 1822, and named after his ships.

Furze, fèrz, a European genus (*Ulex*) of very branched and thorny shrubs, with linear sharply pointed leaves, solitary flowers, and two-lipped calyx, belonging to the order *Leguminosæ*, sub-order *Papilionaceæ*. The common furze (*U. europæus*), also called whin and gorse, is abundant in many parts of southern Europe and in Great Britain, although not reaching any considerable elevation, and often suffering from the frost of severe winters. It affords a wholesome fodder, especially when young, or when the thorns are artificially bruised, and is grown often on dry and barren hillsides not fitted for other forage crops. A double flowering variety is grown in gardens.

Fusan, foo-sän', or **Pusan,** Korea, a seaport town on the south shore of the peninsula, from the 16th century became more and more under Japanese influence. In 1876 it was formally opened to Japanese trade, and soon after to all nations. At the outbreak of the war between Japan and China (1894–5) the bulk of the population were Japanese, who have the trade in their hands. The imports (chiefly Manchester goods, salt, and Japanese wares) have an annual value of over $1,000,000; the exports (rice, beans, hides, etc.), of $1,300,000. Pop. (1900) 15,000, of which 10,000 are foreigners.

Fuse, a device employed for firing explosives. In mining, quarrying and in military and naval mining operations there is used the "Bickford, safety running" or "tape" fuse which consists of a tubular cord of cotton or hemp that has been rendered slowly combustible, the cavity in the centre of the cord being filled with a slow-burning gunpowder composition. To make the fuse firm and hard, so as to prevent its being cut by the sharp edges of the rock during tamping, the outside of the cord is served with a covering of strong twine, which is wound about it at nearly right angles to the direction of the twist of the cord by the process called countering. To protect the powder from moisture, the wrapped fuse is immersed in a bath of heated varnish composed of glue, soap, and whiting. Finally, to prevent the surfaces of the fuse from sticking together when coiled they are coated with dry whiting, bran, or powdered soapstone. The fuse described is known as "single fuse" and, as the varnish used is not waterproof, this fuse is only suitable for use in dry ground. In wet ground, a fuse is used which is made by coating the countered cord with tar or resin varnish and then, before the varnish is quite set, countering it with tape and again coating it with varnish. This is known as "taped fuse." When the fuse is to be subjected to especially severe treatment, it is provided with a double coat of twine or thread and is known as "double fuse." The varieties in use are: "common hemp fuse"; "common cotton fuse"; "white fuse"; "superior mining fuse"; "single-taped fuse"; "double-taped fuse"; "triple-taped fuse"; "small gutta-percha"; "large gutta-percha"; "small gutta-percha taped," and "large gutta-percha taped." Running fuse comes in lengths of about 50 feet, and, when properly made, is so uniform in quality that it can be depended upon to burn at the rate of 3 feet per minute. This is important, as it is necessary for the safety of the operator. The fuse should be stored in a dry place so that the powder core may not become damp; and, if so treated, it will retain its efficiency until the varnish has lost all its essential oils and become dusty. Care must be taken not to touch the tape with any oily or greasy matter, as this penetrates through the varnish to the powder core and affects the rate of burning. The fuse should not be roughly handled, as pinching and squeezing alter the rate at which the powder burns. Care should be exercised in opening out a coil which has become stiff through age or exposure to cold weather, for the fuse is then brittle, and if the covering is cracked by sudden and violent unrolling the fuse becomes unfit for use. If there be any doubt as to the behavior of a coil of fuse a piece one foot long should be taken and its rate of burning timed.

Although in firing single charges, safety fuse answers admirably, where several charges are to be fired simultaneously, the safety fuses are connected together by "instantaneous fuses." These consist of a strand of quickmatch enclosed in hemp or flax and several layers of gutta-percha and tape, or of a core of guncotton enclosed in a leaden tube. Besides these nitroglycerin compositions have been proposed by Quentin and Nobel, and one containing mercuric fulminate by Philip Hess.

In naval and military operations, and for simultaneous blasts in mining and quarrying, "electric fuses" are preferred to running fuses. These are gunpowder "igniters" or fulminate "detonators," that are fired by electricity. They are classified as "low tension fuses," designed for use with strong currents of low potential, from primary or secondary batteries, or from dynamo-electric machines; "medium tension fuses," for use with magneto-electric machines which generate currents of medium potential, and "high tension fuses," for use with condensed sparks capable of traversing a sensible air space. The use of the word tension is not warranted by the present condition of electrical science, but it has become technical in this art. To-day, only low tension electric fuses are employed and they are described under DETONATORS (q.v.).

Fuses are employed in ordnance for exploding shell and they may consist of a compressed core of gunpowder enclosed in a tube of wood or metal, or of a fulminating composition or of both. They are known as "nose fuses" when put in the front end or "nose" of the conical pointed shell, or "base fuses" when inserted in the lower end or base of the shell. They are known as "time fuses," when they are planned to burn a certain length of time after they have become ignited, before they set fire to the explosive charge in the shell; "percussion fuses" when they are set in operation by the impact of the shell against an object after it has been projected from the gun. They may act instantaneously in firing the charge in the shell, or there may be a column of compressed powder interposed between the charge of explosive in the shell and the fulminating composition which is fired by impact. As sometimes a second or more intervenes between the striking and the bursting of the shell, these are styled "delayed action fuses." They may be used with armor piercing shells designed to penetrate armor and burst within the ship. In time fuses, used with spherical shell, the powder in the fuse used to be ignited from the flame of the burning charge with which the shell was propelled from the gun. In modern time fuses, there is a metal cylinder which serves as a hammer placed within the fuse case and held in place by brittle pegs of metal, or by a number of small balls. When the shell containing such fuses is fired, the inertia causes the hammer to strip from the pegs and set back toward the base of the shell, or, if it be a shell from a rifled gun, the centrifugal force causes the balls to fly outward and release the hammer. When the shell strikes, and is arrested in its flight, the hammer moves forward, strikes a percussion cap and fires the charge.

"Chemical fuses" have been used in firing gunpowder mines and torpedoes. As an example of these we cite the mixture of cane sugar and potassium chlorate used in the Harvey torpedo. Above a column of this mixture was placed a small glass bulb filled with concentrated sulphuric acid, the whole being enclosed by a soft copper cover projecting from the torpedo. When this cap was struck, it collapsed and broke the glass bulb, and, as the sulphuric acid came in contact with the mixture of sugar and chlorate, the latter burst into flame and ignited the powder in the torpedo. Such fuses have been used by anarchists in infernal machines and they have ascertained the rate at which the acid would eat through sheets of bibulous paper so that by interposing a sufficient number of sheets of paper they could set the train in operation and get safely out of the way before the machine exploded. Fuses, consisting of columns of compressed gunpowder composition, are used in pyrotechny by which to ignite the charges in rockets, bombs, roman candles and other devices. By their use the operator is enabled to get to a safe distance after igniting the device before it functions fully.

Fuses are used in "electrical installations," but these are of an entirely different character from the above. They consist of strips of metal of low fusibility which are interposed, in electric lighting and other circuits, between the generator and the lamp, or other device, to prevent damage to the device by an excess of current. When the load is greater than is desired the current heats the fuse to its fusion point, when it melts and cuts out the circuit. See ELECTRIC FUSES; EXPLOSIVES.

CHAS. E. MUNROE,
Columbian University, Washington, D. C.

Fusee, fū-zē', in clock and watch making, is the conical pulley used in connection with the main spring, to equalize the power of the latter, so that the watch may run regularly. The spring coiled within the barrel, when fully wound up and at its greatest tension, draws on the part of the chain wound on the smaller portion of the fusee. The first wheel of the watch or clock is attached to the fusee, and as the latter unwinds by the gearing motion in the watch, the spring also uncoils and loses a part of its tension; as this proceeds, the chain draws on a larger portion of the fusee, and attains an increased leverage on the latter to counterbalance the decreased power of the spring.

Fusel Oil, an injurious and exceedingly objectionable constituent of improperly prepared distilled liquors (q.v.), consisting of an indefinite and variable mixture of amyl alcohol (see AMYL) with certain other alcohols and ethers, and certain organic acids and their esters. Fusel oil always contains amyl alcohol, and usually contains butyl and propyl alcohols also. It comes over in the later parts of the distillate, and may be separated from ethyl alcohol (in large measure at least) by resort to fractional distillation.

Fushimi, foo-shē'mē, Japan, a seaport town in the province of Yamashiro, southern coast of Nippon, on the right bank of the river Uji-gawa, which serves as a trade outlet and depot for Kioto, Otsu, and Nara, and is connected by steam service with Osaka. Pop. (1900) 21,515.

Fusible Metal, any alloy, or metallic mixture, which melts at a comparatively low temperature. (See ALLOY; AMALGAM; BISMUTH; CADMIUM.) Fusible metals are used in the arts for many purposes. Automatic sprinklers, for example, are capped with alloys of this sort, which are chosen so as to have melting points that are higher than any temperature that would normally occur in the room that is to be protected. If a fire breaks out, however, the abnormal rise of temperature so produced causes them to melt, the water in the sprinkler pipes being thereby released, and the fire extinguished. Fusible metals have also been used quite generally in the manufacture of "fusible plugs," for the protection of steam boilers; such plugs being screwed into the boiler at the height which is considered to be the lowest limit to which the water level in the boiler can be allowed to descend with safety. So long as the inner end of the plug is covered with water, the plug itself is thereby kept too cool to melt under the influence of the furnace gases; but when the protecting action of the water is removed by the water level descending below the safety limit, the hot furnace gases melt the material of the plug, and the steam in the boiler escapes. Fusible plugs are excellent appliances, and in fact they are required by law in some of the States. There is no advantage in filling them with an alloy, however, because in any event the alloy must have a melting point higher than that of the steam that the boiler is to generate (365° F., for a gauge pressure of 150 pounds per square inch), and pure tin, with a melting point of 450° F., is entirely satisfactory for the purpose. Indeed, tin is far superior to any alloy for this purpose, because its melting point remains sensibly constant for an indefinite time (so long as oxidation is prevented), while the melting points of alloys that are continuously exposed to heat for considerable periods become quite uncertain, and are often found to be far higher than when the alloy is freshly prepared.

Fusible Plug. See FUSIBLE METAL.

Fusidæ, fū'sĭ-dē, a family of gastropod mollusks, by some conchologists regarded as only a genus (*Fusus*) of the family *Fasciolariidæ*. In either case it is a world-marked group allied to the turban-shells and volutes in structure, but having a long, more or less spindle-shaped, comparatively thin shell, with a very long canal. The animal is closely similar in its soft parts to a whelk or a murex. The family contains the genera *Fasciolaria, Clavella, Latirus*, etc., but interest centres chiefly on the genus *Fusus*, of which many species are known in various parts of the world, and which goes back to Cretaceous time in geological history. North American species are inconspicuous, but some of the several kinds found upon the coast of Great Britain are highly valued by collectors of shells, and constantly sought for by fishermen who bring them up in their dredges from time to time. The "red-whelk" or "roaring buckie" of Scotland is a species (*F. antiquus*) made famous in folklore and by Wordsworth's poem; and it is extensively eaten in various parts of Great Britain and along the continental coast. In Zetland its shell was formerly used by the peasantry as an oil lamp. *F. proboscidialis* is one of the largest of mollusks.

Fusing Point. See MELTING POINT.

Fustel de Coulanges. See COULANGES, NUMA DENIS FUSTEL DE.

Fus'tian, named after Fustat, a suburb of Cairo, where the material originated, is (1) a species of cotton cloth similar to velvet, having, in addition to the warp and weft, a species of pile, consisting of other threads doubled together, which are thrown up in ridges and conceal the groundwork of the fabric. When in the loom, this pile presents the appearance of a set of loops; these are cut in two and sheared down, and when polished and finished, present an evenly ribbed surface on the exterior. The best fustians are known as cotton-velvet and velveteen; besides these there are moleskin, corduroy, and several other kinds. (See WEAVING.) (2) In literature, fustian signifies a forced, bombastic style of writing, abounding with metaphors or other rhetorical figures.

Futa-Jallon, foo'tä zhä-lôṅ', a region of West Africa, in Senegambia. It is extremely mountainous, and remarkable for the romantic beauty of its scenery; and is the source of the rivers Senegal, Gambia, etc. Large herds and flocks are pastured; and the soil produces in abundance bananas and other fruits, besides numerous palm-trees, which furnish dates, wine, and oil. The inhabitants are fanatical Mohammedans. They are governed by an elective chief under French protection. The capital is Timbo. Pop. (1900) 600,000.

Futhark, foo'thôrk, the Runic alphabet which derives its name from the first six letters, *f, u, th, a, r, k*, and is applied to all the systems of phonetic signs of the Teutonic stock, for the same reason as those of classical derivation are called "alphabet" or "abecedarium." They occur in the same order in Old German, Gothic, Anglo-Saxon, and Northern Runes, with a nomenclature in all of them borrowed from trees and other familiar natural objects, suggestive of the derivation of the series of phonetic symbols from a primitive system of pictorial writing. See ALPHABET; RUNIC CHARACTERS.

Fyffe, fīf, **Charles Alan**, English historian: b. Blackheath, Kent, England, December 1845; d. 19 Feb. 1892. He was graduated at Oxford in 1868; and called to the bar in 1876, but never practised. As correspondent of the *Daily News* during the Franco-Prussian war he is said to have sent to that journal the first account of the battle of Sedan that appeared in print. His historical works are distinguished by accuracy and a pleasing, perspicuous style. They include: 'History of Greece' (1875), in a series of 'History Primers'; and the well-known 'History of Modern Europe' (1880, 1886, 1890), covering the period from 1792 to 1878.

Fyles, Franklin, American dramatic critic and author. In 1886 he became dramatic critic of the New York *Sun*. He wrote several successful plays, including the military dramas, 'Cumberland '61,' and 'The Girl I Left Behind Me,' and some works in book form, among them 'The Theatre and Its People,' a popular account of the profession; 'A Ward of France'; 'Drusa Wayne'; etc.

G

G seventh letter of the English alphabet and of other alphabets derived from the Latin. In very early Latin, G stood for the proper g-sound (g hard, as in go) and also for the k-sound of C, as in cup; afterward the k-sound was represented by K, while G continued to represent the sound of G hard; but K did not remain long in the Latin alphabet, being superseded by C (always hard and equivalent to K). Both in Greek and Latin the gamma (Γ, G) was always the hard guttural in whatever situation, and hence *geographia* was pronounced gheographia, *genus* ghenus, etc. The softening of g-hard to j when g precedes e, i, or y, began to prevail in the 6th century of our era, and it persists in the modern languages derived from Latin and in our own. In languages having words derived independently by each from some common stock, for example, the Indo-European languages, the interchange of c-hard, g-hard, k, and the aspirate gutturals ch, gh, is very common; examples: Eng. kin, Lat. *genus,* Gr. *genos;* Gr. *chen,* Ger. *gans,* Eng. goose; Gr. *gnonai,* archaic Lat. *gnosco,* Ger. *kennen,* Eng. ken; Lat. *hesternus,* Gr. *chthes,* Ger. *gestern,* Eng. yester: the same equivalence of g and y is seen in Ger. *gelb,* Eng. yellow; Ger. *gähnen,* Eng. yawn; Ger. *garn,* Eng. yarn. In French words of Teutonic origin an original w is often represented by gu (equal to g-hard), thus Wilhelm becomes *Guillaume;* Ger. *weise,* Fr. *guise;* Teuton *werra,* Eng. war, Fr. *guerre.*

Gabb, William More, American palæontologist: b. Philadelphia 1839; d. 1878. In 1862–5 he was director of the palæontological section of J. D. Whitney's geological survey of California, and later made surveys in Santo Domingo (1868) and Costa Rica (1873). His publications include: Vols. I. and II. of the ‘Geological Survey of California’ (1864); and monographs on the topography and ethnology of Costa Rica and the geology and topography of Santo Domingo in the ‘Transactions’ of the American Philosophical Society and Petermann's ‘Mittheilungen.’

Gabbro, găb'rō, a general name for a large group of evenly crystalline igneous rocks, composed, typically, of plagioclase and pyroxene. Gabbros show by analysis much the same composition as basalts; the silica ranging from 46 to 59 per cent. They may be regarded as plutonic basalts, basalt magmas which have cooled at great depths. Under the general term gabbro, are included anorthosites, abundant in Canada and the Adirondacks, high in silica and composed almost wholly of crystalline labradorite; true gabbros; norites, composed of plagioclase and orthorhombic pyroxene. With decreasing pyroxene and increasing olivine gabbros grade into peridotiles. Gabbros are heavy, dark-colored, usually greenish, rocks. They occur in the Adirondacks, in the neighborhood of Baltimore, Md., and particularly in the highlands along the north shore of Lake Superior, from Duluth to the international boundary. The gabbro near Duluth has this composition: SiO_2 49.15; Al_2O_3 21.90; Fi_2O_3 6.60; FeO 4.54; CaO 8.22; MgO 3.03; Na_2O 3.83; K_2O 1.61. See Basalt.

Gable, the triangular or quadrangular end of a house or other building, from the cornice or eaves to the top, and distinguished from a pediment by this, among other things, that it has no cornices, while a pediment has three. The word is also applied to the highly decorated canopy or screen which in Gothic church architecture rises over some doors or windows. The wall of a house which is surmounted by a gable is called the gable-end. In modern towns the gable-ends of houses are usually at right angles to the line of the street, but in the Middle Ages the reverse was usually the case, the gable-ends being turned toward the street. Many old towns in France, Belgium, and Germany, are still to be seen with this peculiarity, and some even in Britain. In Scotland, a wall separating two houses, and common to both, is called a mutual gable, and according to Scotch law such a gable is the property of the builder, who can therefore prevent the owner of an adjoining property from using the support of his gable, unless he pays half the cost of erecting it.

Gaboriau, Emile, ā-mēl gä-bō-rē-ō, French writer of detective stories: b. Saujon, Charente-Inférieure, France, 9 Nov. 1835; d. Paris 28 Sept. 1873. His early years were a succession of vicissitudes; the army, the law, and even the Church, were in turn the objects of his inconstant attentions till at last when he had already contributed to some of the smaller Parisian papers, he leaped into fame at a single bound with his story ‘L'Affaire Lerouge’ (1866), in the feuilleton to ‘Le Pays.’ It was quickly followed by ‘Le Dossier 113’ (1867); ‘Le Crime d'Orcival’ (1868); ‘Monsieur Lecoq’ (1869); ‘Les Esclaves de Paris’ (1869); ‘La Vie Infernale’ (1870); ‘La Clique Dorée’ (1871); ‘La Corde au Cou’ (1873); ‘L'Argent des Autres’ (1874); and ‘La Dégringolade’ (1876).

Gabriac, Paul Joseph de Cadoine, pōl zhō-zĕf dė kā-dwän gä-brē-äk, Marquis de, French diplomatist: b. Heidelberg, Baden, 1 March 1792; d. Paris 12 June 1865. He was consul-general in New York in 1812-14; appointed minister to Stockholm in 1823; and minister to Brazil in 1826. While in Brazil he induced all the other states in South America to adopt the French maritime law. He was created a peer in 1841, and made a life senator in 1853. His publications include: 'The Question of Brazil' (1829); 'The Republics of South America Considered in Their Future' (1851); 'King Pedro I., Notes and Personal Recollections' (1854).

Ga'briel (Heb. "hero of God"), among the post-exilic Jews, one of the seven archangels (q.v.). In the book of Daniel and in the third gospel he is the messenger and interpreter of God. The rabbins represented him as the angel of death to the Israelites, as Azrael was to the Mohammedans. According to the Talmud he is the prince of fire, who presides over the thunderstorms and the autumnal ripening of fruits. By the command of God he set fire to the temple before it could be burned down by the soldiers of Nebuchadnezzar. According to the teaching of the Koran he is one of the four angels, of which the other three are Michael, Uriel, and Raphael, most highly favored by God, and dictated the Koran to Mohammed.

Gabriel, Brothers of Saint, an order of the Roman Catholic Church in France, founded by the Abbé Deshayes in 1835. Its object was stated as the education of the young, especially deaf-mutes and the blind. In 1880 the order reported 122 elementary schools, 3 boarding schools, 8 schools for deaf-mutes, and 2 for the blind. Its headquarters are at Saint Laurent-sur-Sèvre, La Vendée.

Gabriels, Henry, American Roman Catholic prelate: b. Wannegem-Lede, Belgium, 6 Oct. 1838. He studied classics in the colleges of Audenarde and Saint Nicholas and theology in the Seminary of Ghent, where he was ordained priest, 21 Sept. 1861. He continued his studies at the University of Louvain, from which institution he received the degree of S. T. L. in 1864 and the honorary degree of Doctor in Theology in 1882. When the Theological Seminary of Troy, N. Y., was founded, Dr. Gabriels was one of the four priests sent from Belgium to manage it. He was diocesan examiner for New York and Albany, vicar-general of Ogdensburg and Burlington and one of the secretaries of the Third Plenary Council of Baltimore, the decrees of which he assisted in formulating. For 20 years Dr. Gabriels was rector of Troy Seminary and for nearly 30 years its professor of dogmatic theology, Church history and Hebrew. On 21 Dec. 1891, Pope Leo XIII. appointed him bishop of Ogdensburg and he was consecrated at Albany, N. Y., 5 May 1892. The diocese of Ogdensburg at present (1905) has a Catholic population of about 84,000; 121 priests; 138 churches; 16 parochial schools; 5 hospitals; 2 orphanages, etc. King Leopold of Belgium has recently conferred upon him the decoration of the Royal Order of Leopolds, in recognition of the services he has rendered the Belgium Church and people, particularly by his writings.

Gabriel's Insurrection, an attempted slave rising near Richmond, Va., in 1800, headed by a slave named Gabriel, called also "General Gabriel" and "Jack Bowler." He belonged to a planter named Thomas Prosser, and was about 24; tall, powerful, and noted as a fighter. He drew about a thousand negroes into a plot to attack Richmond by night, massacre the inhabitants, seize the arsenal and arming themselves effectively, rouse a general insurrection. One August night he collected his forces, armed them with scythe blades, and marched toward the city. Meanwhile a negro had disclosed the plot; James Monroe, then governor, had ordered out the militia; a creek in Gabriel's way proved to be unfordable, and hearing that the citizens were in arms, the whole force dispersed to the swamps and woods. They were hunted out, and many hanged, including Gabriel.

Gade, Niels Wilhelm, nēls vĭl'hĕlm gä'dė, Danish composer: b. Copenhagen 22 Feb. 1817; d. there 21 Dec. 1890. In 1841, by his overture entitled, 'Echoes of Ossian,' he gained in Copenhagen the prize of the Musical Union. He was supported during his studies abroad by a royal stipend, and in 1844 was appointed to succeed Mendelssohn in the direction of the Gewandhaus concerts at Leipsic. In 1850 he was appointed musical director to the king of Denmark, and in 1876 received a life pension. His works, which are Mendelssohnian in character, include seven symphonies, several overtures, sonatas, quintets, etc.; a lyrical drama, 'Comala'; a religious cantata, 'The Crusaders'; an opera, 'The Nibelungen'; etc.

Gadfly. See Horsefly.

Gadidæ, găd'ĭ-dē, a family of fishes, the cods, sub-order *Anacanthini* (spineless fishes), with ventral fins attached to the breast or throat. The body is rather long, a little compressed, and covered with small, soft scales; the teeth are in several rows; the gill covers, which are large, have seven rays; the median fins are generally very large, and divided into several portions. They are voracious fishes. They are found chiefly in the depths of the colder seas, and are largely used for the food of man. Fossil remains are rare, but scattered bones have been found as far back as the Eocene. See Cod; Haddock; Ling; etc.

Gadolin, gä'dō-lēn, **John**, Finnish chemist: b. Abo, Finland, 5 June 1760; d. Wirmo, Finland, 15 Aug. 1852. He studied chemistry under Bergman and in 1797 was appointed professor of chemistry in Abo — an office which he held till 1822. He devoted himself to investigations on mineral and metallurgic subjects. But the research for which he is specially remembered was upon a black mineral found in the porcelain feldspar quarry at Ytterby, near Stockholm, by Arhenius, of which an account had been published in 1788. In 1794 he read a paper to the Academy of Sciences, and showed that it contained a new kind of earth. This discovery was subsequently confirmed by Ekeberg, who called the earth yttria, and the mineral gadolinite, after its first investigator. The yttria was afterward shown to be a mixture of several earths.

Gads'den, Christopher, American patriot: b. Charleston, S. C., 1724; d. there 28 Aug. 1805. He was educated in England; returned to the United States in 1741 and later engaged in business in Philadelphia; was a member of the first Colonial Congress which convened in New York in October 1765, and was also a member of the first Continental Congress which assembled in Philadelphia in 1774. He joined the American army as colonel at the beginning of the Revolution, and was promoted brigadier-general in 1776.

Gadsden, James, American diplomatist: b. Charleston, S. C., 15 May 1788; d. there 25 Dec. 1858. He was graduated at Yale College in 1806; served with distinction in the War of 1812; and afterward took part in the campaign against the Seminole Indians. He was appointed minister to Mexico in 1853, and on 30 December of that year negotiated the Gadsden Purchase (q.v.), which fixed a new boundary between Mexico and the United States.

Gadsden, Ala., town and county-seat of Etowah County, on the Gadsden and Attalla Union, the Louisville and Nashville, and other railroads, 60 miles northeast of Birmingham. It is dominated by Lookout Mountain, on the north bank of the Coosa River which gives its name to the rich coal and iron mines in the vicinity. There are several steam-mills which manufacture considerable quantities of yellow-pine lumber. Further industries include steel and wire-nail mills, cotton mills, a pipe works, a car and foundry establishment, a pressed-brick plant, a cotton-seed oil mill and ginnery, and coal and iron interests. There are 15 churches, a national and a state bank, and two newspapers, a daily and a semi-weekly. Pop. (1900) 4,282.

Gadsden Purchase, The, a tract of territory, embracing 45,535 square miles, which was purchased by the United States from Mexico in 1854. This region, which is bounded on the north by the Gila River, on the east by the Rio Grande, and on the west by the Colorado, was acquired by treaty and the payment of $10,000,000, and is now included in the southern part of the Territories of Arizona and New Mexico. It is called the Gadsden Purchase after James Gadsden (q.v.), United States minister to Mexico in 1853, by whom, in December of that year, the treaty of sale was negotiated with Santa Anna (q.v.). Issues growing out of the execution of the treaty of Guadalupe-Hidalgo (q.v.) made this negotiation a matter of great importance, as well as a business of much difficulty. Disputes had arisen concerning the boundary line between Chihuahua and New Mexico, involving the possession of the Mesilla Valley, of which, though claimed by the United States, the Mexicans took armed possession. The 11th article of the treaty, imposing upon the United States the obligation to restrain the Indian marauders on the Mexican frontier, had been neglected, and the reclamations in consequence amounted to between $15,000,000 and $30,000,000. By Gadsden's treaty that article was abrogated and a new boundary was agreed upon, while Mexico also agreed to forego all claims against the United States for damages on account of Indian depredations between the years 1848–53. The settlement of the boundary dispute was considered in this country to be of greater moment than the requisition of the land, which was thought to be of little or no value for cultivation; and it was in the minds of enterprising Americans that through this region the Southern Pacific Railroad, already projected, might find an advantageous route, as in fact it did. In Mexico the transaction was vigorously opposed, and on account of his part in the sale Santa Anna, in 1855, was banished from his country as a traitor. On the part of the United States, the Senate made some modifications in the original treaty and then ratified it. On 10 June 1854 it was finally proclaimed. Consult Haswell, 'Treaties and Conventions.'

Gadsden Treaty. See ANNEXATION; GADSDEN PURCHASE.

Gads'hill, England, a hill near Rochester, on the road from London to Gravesend. It is commemorated in Shakespeare's play, 'Henry IV.,' as the place where Falstaff had his encounter with the robbers, and an inn at the place is called Falstaff's Inn. It is interesting in modern times for Gadshill Place, opposite the hill, which was long the residence of Charles Dickens and was the home in which he died.

Gadski, Johanna, yō-hän'nä gädz'kē, German opera singer: b. Anclam, Prussia, 1871. She received her musical training in Stettin, made her début in opera in New York, and appeared as Brünhilde and in numerous other Wagnerian parts. She made a concert-tour in America in 1898–9.

Gad'wall, or Gray Duck, a migratory wild duck (*Chaulelasmus streperus*) found on all the four continents. It is less in size than the mallard, and mainly black, brown, and white in color. It frequents western marshes in small flocks, but is rare east of the Alleghany Mountains. As a table delicacy it is highly prized.

Gæa, jē'ä, or **Ge,** jē, in Greek mythology, the goddess of the earth. She appears in Hesiod as the first-born of Chaos, and the mother of Uranus and Pontus. She also bore the Titans, Cyclops, Erinyes, Giants, etc. As the vapors which were supposed to produce divine inspiration rose from the earth, Gæa came to be regarded as an oracular divinity; the oracles at Delphi and Olympia were believed to have once belonged to her. Her worship extended over all Greece, black female lambs being offered on her altars. She was also the goddess of marriage, and again of death and the lower world. At Rome Gæa was worshipped as Tellus.

Gaedertz, gĕd'ĕrts, **Karl Theodor,** German poet: b. Lübeck 8 Jan. 1855. In 1880 he obtained a post in the Royal Library of Berlin, of which he became chief librarian in 1900. His poems in Low German include 'Julklapp' (1879) and 'Eine Komödie' (2d ed. 1881). He has also written several valuable monographs on German poets and on the history of German drama, his chief works in this field being 'Goethe's Minchen' (2d ed. 1888); 'Aus Fritz Reutersjungen und alten Tagen' (3d ed. 1899); 'Emanuel Geibel. Ein deutsches Dichterleben' (1897); 'Bismarck und Reuter' (1898); 'Bei Goethe zu Gaste' (1900); etc.

Gæl, gāl, the name of a branch of the Celts inhabiting the Highlands of Scotland, Ireland, and the Isle of Man. Gadhel, or Gæl, is the only name by which those who speak the Gælic language are known to themselves. By way of distinction the Highlanders of Scotland call themselves Gæl Albinnich (Gæls of Albin) and the Celtic population of Ireland call themselves Gæl Erinnich (Gæls of Erin). See CELTS.

Gaelic Language. See CELTIC LANGUAGE.

Gaelic Literature. Although the oldest existing MSS. in Gælic are of no earlier date than the 7th century, there is ample evidence that the literature of the Gaels, not only the traditional but the written literature, is of much greater antiquity. The internal evidence furnished by the ancient sagas, songs and chronicles preserved in mediæval manuscripts indicates a regular development extending from a period antedating by many centuries the beginning of the Christian era, down to a time well within the compass of authentic history. And both the internal and external evidence point to the existence of a written as well as a traditional literature long before the Gæl came into close contact with the civilization of the other nations of Western Europe.

The Gaelic, or Gaedhealg, language is an Indo-European tongue, highly inflected, and rich in beautiful forms and euphonious combinations. It is spoken in Ireland, the Highlands of Scotland and the Isle of Man. Being a Celtic tongue it is akin to the Brythonic group of languages, the Welsh, Cornish and Breton, and to the tongues, now extinct, spoken by the Celtic peoples who occupied central Europe before the extension of the Roman power. The isolation of Ireland insured the development of the language along lines peculiarly its own, unaffected by outside influences. This is true not only of those centuries before the dawn of history, when the language was in the making, but is true also of the later period when momentous changes were stirring the rest of Europe and the modern nations were springing into being out of the fragments of the shattered Roman Empire. This isolation made for the development of a unique language and literature and it resulted, too, in the preservation and development of those peculiar social conditions, the record of which is now shedding light on a period which would otherwise be shrouded in darkness. The development of the language is usually assigned by scholars to three periods: Old Gaelic, from the earliest time to about the end of the 10th century, A.D.; Middle Gaelic, from the 11th to the 17th century; and Modern Gaelic, from the 17th century to the present day.

Though much of the old Gaelic literature came down to mediæval times in the form of oral tradition it must not be supposed that it is on that alone that its history is based. The fact that the earliest writing extant can be traced no further back than the 7th century is far from proving that previous to that time writing was unknown in Ireland. During the 8th, 9th and 10th centuries Ireland, like the other nations of Europe, suffered from the incursions of the Danes and Northmen. These marauders landed on the coast, established themselves in seaport towns, set up their own government and raided the interior. Monasteries were sacked and burned and, as in England, almost every existing book and manuscript was burned at their hands. That such manuscripts and books existed before that time, however, is amply proved. Ireland had at that time been long in touch with the rest of Europe and her schools had supplied teachers and missionaries to the western world for centuries. During the Dark Ages, when continental Europe was plunged in almost universal war, Ireland was the home of the monastic schools, where the learning of the ages was preserved and the arts of writing and illuminating were generously fostered.

The present alphabet, which is a modification of the Roman, was introduced, it is believed, by Saint Patrick when he came in the 5th century to preach Christianity. But the art of writing was known before that. Many inscriptions have been found, especially in the southern counties, in Ogam, a system of writing which was peculiar to the early Irish. This script consisted of a series of short lines, drawn either above, below or through a stem-line. Each group of short lines represented a letter, the letter being indicated by the number and position, some being at right angles and some being at acute angles with the stem-line. This stem-line was generally the angle between two sides of a long upright rectangular stone. The vowels were indicated by very small cuts on the angle of the stone, but much larger than points. The use of Ogam was not confined to monumental inscriptions, for some small metal articles have been found inscribed with it, and the old sagas and chronicles contain many allusions to Ogam writings on poets' staves, the shields of warriors and other articles. With the introduction of the modified Roman alphabet the use of Ogam was practically discontinued, although instances of its occasional use have been discovered. In a Saint Gall manuscript of the 9th century eight Ogam sentences were discovered, and others as late have been commented on by Zeuss, Nigra and others. How Ogam was invented is still a profound mystery, but it is certain that it is peculiar to the Irish Gael and only found where he settled.

The literary form in which the primitive Gaelic genius chiefly found expression was the *sgeul*, or *ursgeul*—the saga or song-story—partly in prose, partly in verse, which recited the deeds of gods and demi-gods and heroes in spirited and dramatic fashion. Of drama, strange to say, no trace can be found in ancient Ireland; there is not a record of even a mystery or a miracle play in the early Christian days. But the romance began early and reached a very advanced stage of development, probably long before the art of writing was known. It took the form of prose narrative, interspersed with flights of spirited and highly imaginative poetry. The 'Book of Leinster,' a MS. of the 12th century, enumerates 187 of these romances and the names of many more are given in the 10th or 12th century tales of Mac Coise. Many of these tales show evidence of accretions during subsequent periods. Some of palpably pagan origin, bear traces of Christian additions, such as the legend of Niul, the ancestor of the Milesians, meeting Moses and the Israelites fleeing from Pharaoh, with the miraculous healing of Niul's infant son by the Hebrew prophet; and the tale of the children of Lir, whose enchantment was to be ended by the ringing of the first Mass-bell in Ireland. But in every instance it is an easy matter to separate the accretions from the original tale and so reconstruct the story in its primitive form.

The value to the antiquarian and student of history of the material thus obtained is incalculable. For these old hero-tales give a vivid picture of the social life of the primitive Celts, a history of the early stages of Celtic civilization, that it is impossible to find elsewhere. For although the entire of central Europe, as well as the British Isles, was peopled by Celtic tribes, the records of their civilization have been obliterated everywhere except in Ireland. The Romans, wherever they planted their standards, introduced their own civilization, wiping out of existence whatever antedated their coming, and their historians, writing of the Roman conquests, measured everything by a Roman standard and found nothing worthy of record in the culture of the barbarian. Hence, practically all record of the continental Celt prior to his subjugation by the Roman has been lost. But the Roman legions never secured a foothold in Ireland, and the Gaelic Celt worked out his own destiny without interference. The record of this development is found in his traditional literature and is proving a mine of invaluable material for the investigator of conditions in ancient Celtic Europe. The most important of these sagas resolve themselves into three distinct groups, representing three periods of the history of the race: The Mythological Cycle; the Heroic, or Red Branch Cycle, and the Fenian or Ossianic Cycle.

The Mythological Cycle.—In the oldest Gaelic sagas the confusion of gods and men is baffling. So thoroughly have the ancient deities been euhemerized that later generations came to look upon them simply as earlier races of inhabitants. These romances tell the story of successive settlements of Ireland. They tell of Partholan and his followers who were the earliest settlers; of Nemedh, who followed and possessed himself of the land; of the Fomorians, who conquered the Nemedians and drove them out; of the return some centuries later of the descendants of a part of the Nemedian force, now known as Firbolgs, to dispute with their former conquerors, and the subsequent return of the descendants of another division of the Nemedians, the Tuatha de Danaans, who in turn became masters of the land, holding it until the coming of the conquering Scots, or Gaels, or Milesians as they are variously called. The saga of the 'Battle of North Moytura' tells of the fight between the Tuatha de Danaans and the Firbolgs, which resulted in the utter defeat of the latter, who were driven into the smaller islands. This story and the story of the 'Battle of South Moytura,' between the Tuatha de Danaans and the Fomorians, abound in descriptions of the marvellous achievements of the heroes and ends in the complete defeat of Fomorians. To this period belongs also the pathetic tale of the 'Death of the Children of Tuireann,' included by Hyde in 'The Three Sorrows of Story-Telling.'

The Red Branch, or Heroic Cycle.—This group of tales deals with the history of the Milesians, the warlike race which finally conquered the island and held it until the coming of the English. Unlike the earlier tales, which palpably treat of a fabulous age and purely mythical persons and events, these romances deal with a world which has an apparent basis of reality, despite the legendary character of many of the events there recorded, and of the heroes who participate in them. The people of this cycle, Cuchulain, Conall Cearnach, Deirdre, Naoise, Meve, Conor mac Nessa, Fergus mac Roigh, though of heroic stature, are yet human; their deeds, and the motives for those deeds, are human; and though the marvellous and the preternatural are found there in as marked a proportion as in the 'Iliad' and the 'Odyssey,' they do not dominate as in the tales of the Mythological Cycle. This group of romances is, without question, the finest in all the ancient Irish literature. The period, which is identified by the annalists with the birth of Christ and the beginning of the Christian Era, is associated chiefly with the long war between Connaught and Ulster arising out of the murder of the children of Usnach. This incident is recorded in one of the most beautiful and pathetic tales in the whole range of ancient story-telling, the tale of 'Deirdre, or the Fate of the Children of Usnach.' Cuchulain, the Ultonian champion, is the great hero of this cycle. Conall Cearnach, Ferdiad and Meve, the warrior-queen, are figures hardly less heroic. The most important of the romances of this group is the 'Tain Bo Cuailgne,' or the 'Cattle-Spoil of Cooley,' a tale that has proved a valuable source of information for the antiquarian from the light it throws on early Celtic life and manners. The 'Death of Conlaoch' is a curious parallel of the story of Sohrab and Rustum.

Fenian or Ossianic Period.—Though Cuchulain is the great hero of the heroic age of the Gael, there is another of a later age who comes closer than he to the popular heart. Fionn, or Finn, mac Cumhail, if one may judge by the affectionate reverence with which his name and the records of his deeds are preserved in peasant lore, is without question the most popular of the traditional heroes. While the wonderful achievements of the elder hero are familiar to the scholar, those of Fionn are known to every unlettered peasant and are embalmed in folk songs and folk tales without number. Moreover, the whole body of Fenian story is intimately bound up in the popular interest. Hyde points out that for a period of from 1,200 to 1,500 years these tales showed a most remarkable instance of continuous literary evolution. Century after century saw accretions in the form of stories and poems about Finn and the Fenians, and there are to-day extant in Gaelic-speaking communities numberless stories that have never been reduced to writing in which Finn is the central figure. This was never, at any time, true of Cuchulain and the Red Branch Cycle. Finn is distinctively the popular hero, the hero who stands in the popular imagination for all that is heroic and patriotic.

Like Cuchulain, he is the central figure of a cycle of romance, almost as important as the Red Branch Cycle. The Fenian Cycle, so-called from the fact that it deals largely with the Fianna, or Irish Militia; or the Ossianic Cycle, from Ossian, or more properly Oisin, the son of Finn, who is credited with the authorship of many of the poems, comes nearer than either of the other cycles to the limits of authentic history. These sagas treat of such historical personages as Conn of the Hundred Battles, Ard-Ri (High-King), whom the annalists assign to the 2d century; his son, Art the Lonely; his grandson, Cormac mac Art (A.D. 227, according to the «Four Masters;»

213, according to Keating); and his great-grandson, Cairbre of the Liffey. Finn, himself, is generally accepted as an historical figure, though much of myth and romance has been woven into his history. The earliest, in point of the chronology of the romances of this period, is the tale of the 'Battle of Cnucha,' in which Cumhail, the father of Finn, is killed by Conn of the Hundred Battles. Thence through a long cycle of romances the many adventures of Finn and his redoubtable band of warriors, Oisin, his son, Oscar, his grandson, Caoilte, the poet, Diarmidh and many another, are related until in the 'Battle of Gabhra,' which closes the series, is told how Cairbre of the Liffey broke the power of the Fenians forever.

The most fascinating, and when everything is considered, perhaps the most meritorious of the Fenian sagas is the 'Pursuit of Diarmidh and Grainne.' Like the story of 'Deirdre,' despite its antiquity the human appeal is almost modern, so close does it come to our own manner of thought. It tells of Finn's suit for the hand of Grainne, daughter of Cormac mac Art, the High-King; Grainne's passion, developed while the negotiations for her hand were in progress, for Diarmidh of the Love-Spot, one of Finn's warriors; the flight of the pair and the pursuit of the vengeful Finn.

Miscellaneous Romances.—Besides the stories of the three main groups above enumerated, there is a considerable number of sagas, some as old as those of the Red Branch Cycle, and some more recent, which cannot well be included under any of these headings. The most important is the 'Bruidhean of Da Derga,' a Leinster tale of the Red Branch period; and others that fall under this same heading are: 'The Dream of Mac Conglinne,' a satire full of an irresistible humor; the 'Voyage of Maelduin' and the 'Battle of Moy Rath.'

Early Christian Period.—With the coming of Christianity came a new phase of Gaelic literature. Saint Patrick and his followers found a soil ready to receive the seed of Christianity. Theirs was a bloodless conquest, and although the Bardic Schools struggled long against the innovation of Christianity they at length succumbed and the subsequent literature of Ireland is thoroughly Christian and largely devotional in tone. Saint Patrick himself was a man of works rather than a man of letters, and yet it is to him that the earliest literature of Christian Ireland and, if we except the Ogam inscriptions the earliest authentic writings now in existence can be traced. Of the 'Canon Phaidraig,' or 'Patrick's Testament,' a MS. copy of the late 8th or early 9th century is still in existence, and this, it has been demonstrated, was made from an older copy in the Saint's handwriting. The authenticity of 'Saint Patrick's Confession,' which, strictly speaking, is not a confession but an apology, has been questioned, but it is vouched for by such eminent authorities as Stokes, Todd, and Hyde. These two works, it is true, are in Latin and might be excluded from a consideration of purely Gaelic literature, but as they are the first literary utterance of Christian Ireland, they are worthy of note, despite the alien tongue in which they are written. This objection, however, does not apply to the 'Epistle to Coroticus' and 'The Cry of the Deer,' two compositions in Gaelic which are also attributed to Saint Patrick. Seachnall, a nephew of the great apostle, is looked upon as the first Christian poet in Ireland, although he, too, wrote in Latin.

Biography, chronicle-history and genealogy make up a large part of the remains of Gaelic literature and, as might be expected from the fervor with which the Irish adopted Christianity, the literature of this period is rich in lives of the saints. It is appropriate, too, that among the earliest we should find lives of Saint Patrick. The 'Book of Armagh' contains two very early biographies. There are many others, but the most important is the 'Tripartite Life,' the MS. of which, written in ancient Gaelic, was discovered by O'Clery, one of the «Four Masters,» early in the 17th century. This «Life» might, perhaps, be more fittingly described as a group of three semi-historical homilies on the life of the Saint. Saint Columcille (521-597), after Saint Patrick the most renowned of the early churchmen, contributed generously to the Gaelic literature of this period. His Gaelic poems voice an ardent patriotism, those written after his exile to Iona especially breathing a passionate love for the land of his birth. The same century that knew Saint Columcille boasts of another great churchman and writer, Saint Brendan the Navigator, founder of the famous abbey and school of Clonfert. Saint Brendan is the reputed author of the 'Navigatio Brendani,' a tale of marvellous romance, the influence of which was felt throughout Europe. MS. copies of it may be found in many monasteries on the continent, and it has been edited and annotated in many tongues. Giraldus Cambrensis (1146?-1220?) alludes to it as being well known in his time. The life of Saint Brendan in the 'Book of Lismore' tells of his setting out in three vessels in search of an isle in the west which was to be a land of promise, probably the Moy Mell and Hy Brassil of the ancient pagan legends.

But it must not be supposed that the making of literature in Ireland was confined to the churchmen. The arts of poetry and prose composition flourished after, as before the coming of Christianity and the race of bards did not die out for many centuries. Notable among those who flourished prior to the period of the Danish incursions was Eochaidh, better known as Dallan Forgaill, a contemporary of Saint Columcille. He was Chief Ollamh of Ireland, a dignity which on his death devolved on his pupil, Senchan Torpeist. Others, equally as important, were Cernfaeladh (c. 678) and Angus Céile Dé, or the Culdee. The 'Saltair na Rann,' a collection of 162 poems in Early Middle Gaelic, giving a rather fanciful account of the creation of the world and the fall of Adam and Eve, was long attributed to Angus, but later research by Whitley Stokes has shown that it could not have been written earlier than 1000.

Danish Occupation to Norman Invasion.—Despite the continual warfare and waste of life and property that marked the two or three centuries of Danish occupation of Ireland, literature and learning flourished. Cormac mac Culinan (d. 908), king, and bishop of Cashel; statesman, ecclesiastic, poet and scholar, is the most eminent figure at this stage of Gælic literary development. 'Cormac's Glossary' is the earliest attempt at a comparative vernacular dictionary made in any language of modern Europe. It is valuable not only as an example of early scholarly effort, but also for the light it throws on pagan customs, on law, history and romance. The 'Saltair of Cashel,' also the work of Cormac, has been lost. Others of lesser fame have left examples of their work, the most noted of them being Cinaeth O'Hartigan, Eochaidh O'Flynn and Mac Liag, bard to King Brian Boroimhe, the monarch who in the decisive battle of Clontarf (1014) defeated the Danes and broke forever their power in Ireland. Mac Liag and Errard mac Coise are credited with the joint authorship of the valuable chronicle, 'The Wars of the Gael with the Gaill' (*i. e.* Norsemen), the accuracy of which has withstood some very remarkable tests of modern scholarship. Clontarf saw the end of the Scandinavian power in Ireland, and the 11th and 12th centuries witnessed a great revival of learning. The industrial arts, architecture, letters all flourished, and it is to this period that we are indebted for the three most important relics of Celtic literature now in existence: the 'Leabhar na h-Uidhre,' the 'Book of Leinster' and the 'Book of Hymns.' Tighearnach, Abbot of Clonmacnois, the great annalist, and Flann, head-teacher of the school of Monasterboice, chronologist and poet, are the most eminent individual figures. Irish scholars travelled to the continent and left the impress of their learning on many a European school.

Arrest of Development and Subsequent Revivals.—With the Norman invasion in 1169 came the arrest of development. Hitherto wars, whether between the septs or with foreign invaders, did no lasting injury to the intellectual or aesthetic development of the race, but with the coming of the Normans began a period of decay that lasted for four centuries. The tradition of poetry was kept alive, but no great names illumine the record, and it is not until the beginning of the 17th century that we find a reawakening of the literary spirit. With this period came the last great outburst of classic Gaelic poetry. Teig mac Daire is looked upon as the last of the classic poets and the greatest of his time, although Lughaidh ua Clerigh, with whom he engaged in a notable controversy («The Contention of the Bards»), is also conspicuous for the merit of his poetry. Others whose work has survived were Teig Dall O'Higin and Eochaidh O'Hussey.

This period, too, saw some of the earliest and most notable achievements in the field of antiquarian research and compilation of annals. Chronicle-history and genealogy had been favorite fields of literary effort for the Gael from the earliest time, but this period brought to the ancient labor the resources of mediæval scholarship and the habit of study bred in the monastery. Among the chroniclers of the 17th century we find men of acknowledged learning and skilled in antiquarian research, such men as Brother Michael O'Clery, the learned Franciscan, who compiled the 'Reim Rioghraidhe' («Succession of Kings») and the 'Leabhar Gabhala' («Book of Invasions»); and who, with O'Mulconry, O'Duigenan and Peregrine O'Clery, compiled that greatest of all mediæval Irish chronicles, the 'Annals of the Four Masters.' This work, covering the whole field of Irish history, legendary and authentic, is the most comprehensive and exhaustive record of the kind in the language. Others equally eminent were Duald mac Firbis, the genealogist; and Geoffrey Keating, theologian, poet and historian, whose 'History of Ireland' is a model of Gaelic prose. Keating, in one sense the greatest of these, was the first to depart from the dialect of the learned, the ancient bardic idiom, and write in a popular style. All his predecessors were learned men writing for the learned few; he, a learned man writing for the many. His history was the most popular book ever written in Gaelic. In his poetry, as in his prose, he was an innovator and was the first to depart from the ancient metres.

The metrical systems of the old bardic schools were intricate and elaborate and, technically, had reached an advanced stage of development centuries before. The underlying principle was not alliteration as in Anglo-Saxon and other Teutonic verse; or quantity as in the metres of the Classic tongues, but a consonantal rime, based on a division of the consonants into groups, any consonant in a particular group riming with any other consonant in that group. The syllables, too, were reckoned, but without regard to stress. It was an intricate system and ease of composition according to it could be acquired only after years of arduous labor over its technicalities. But with the breaking up of the bardic schools in the 17th century came the introduction of a new verse-form in which accent and not syllable was the unit of measure and in which vowel rime took the place of consonantal. The change was almost instantaneous and with the introduction of the simpler form the whole nation seemed to burst into song. The new method was elaborated and developed until the rime affected every accented syllable in the line, with a result that was wonderfully melodious. «The Gælic poetry of the last two centuries both in Ireland and in the Highlands,» says Hyde 'Literary History of Ireland,' 1903, p. 542), «is probably the most sensuous attempt to convey music in words, ever made by man. It is absolutely impossible to convey the lusciousness of sound, richness of rhythm, and perfection of harmony, in another language. Scores upon scores of new and brilliant metres made their appearance.»

Eighteenth Century and After.—The 18th century was a period of persecution, and with the means of education and the opportunities for bettering themselves denied them, the Irish people found an outlet for their feeling only in song. The number of poets produced is almost countless, but a few names, such as David O'Bruadar, John O'Neaghtan, Torlogh O'Carolan, Tadhg Gaoloch O'Sullivan, Donough Mac Conmara, and Brian Mac Giolla Meidhre, are worthy of special mention. But with the 18th century the history of Gaelic literature practically ends. Through the early years of the 19th century the struggle to preserve it was kept up, but the famine, coming as the climax of a long series of calamities, put an end to it. Such men as O'Curry, O'Donovan, Petrie, and

Todd; such societies as the Ossianic Society and the Society for the Preservation of the Gaelic Language, labored for the salvation of the tongue, but it was not until the great popular movement of the last two decades of the century that any real progress was made. The Gaelic League has during that time stirred the nation to a sense of its impending loss and as a result the study of the language has been taken up with enthusiasm not only in Ireland but in the United States, South America and Australia. Although this movement, which is purely popular and patriotic and has for its object the restoration of the language and the literature, is distinct from the scholarly interest shown by such scholars as Zeuss, Zimmer, Kuno Meyer, Windisch, D'Arbois de Jubainville, Whitley Stokes, yet its indebtedness to the researches of these investigators is unquestionable. That indebtedness is greater, however, to men like Dr. Douglas Hyde, Dr. Sigerson, Rev. Eugene O'Growney, Rev. P. J. Dineen, Rev. Peter O'Leary and others, who couple with thorough scholarship an enthusiasm that makes their efforts doubly effective. Dr. Hyde is a poet of undoubted gifts, with a command of Gaelic and the intricacies of its metres as sure as is his command of English, and a prose writer of equal fluency in both languages. Father O'Growney's series of text-books is the standard course in most of the classes, and the others have contributed generously to the product of the new school.

THOMAS GAFFNEY TAAFFE,
Instructor in English, College of the City of New York.

Gaeta, gä-ā'tä (Cajeta of the Latins), a city and seaport of Italy and one of the most strongly fortified maritime cities of the country, located in the province of Caserta on the Gulf of Gaeta, 74 miles by rail northwest ot Naples. It is picturesquely situated on an abrupt promontory projecting into the Mediterranean and connected with the mainland by a low and narrow isthmus protected by solid walls. On the summit of the promontory stands the circular tower D'Orlando, said to be the ancient mausoleum of Lucius Munatius Plancus, friend of Augustus. Many interesting classic remains have been found in Gaeta, including a fine marble vase by the Athenian scupltor Salpione, the ancient campanile of the Cathedral of Saint Erasmus and the remains of a Roman theatre and a Roman ampitheatre. The citadel, which is of great strength, contains in its tower the tomb of the Constable Bourbon.

The inhabitants of Gaeta derive their chief profits from the fisheries and their coasting-trade in oil, wine, and fruit—principal productions of the surrounding country. Cajeta, ancient name of Gaeta, derived its origin, according to Virgil, from its being the burial-place of Cajeta, the nurse of Æneas. On the dismemberment of the Roman empire, Gaeta became a centre of civilization and commercial prosperity, and gained still more importance after the decadence of the eastern empire. It successively withstood the invasions of the barbarians and the Lombards and Saracens. Both in ancient and modern times, Gaeta has sustained remarkable sieges, and recently it has been the theatre of several interesting events. In 1134 it fell before Roger II. and was annexed to the Norman Kingdom of Sicily. In 1806 it was defended for six months by Prince Ludwig von Hessen-Philippsthal against the forces of Masséna. From 1848-50 it was the refuge of Pope Pius IX., when the revolution at Rome compelled him to retire. In 1860 after the defeat of the Neapolitans on the Volturno by the forces of Garibaldi, Gaeta was the last stronghold of the Bourbon dynasty of Naples, and after a protracted siege lasting from November 1860 to 13 Feb. 1861 Francis II. of Naples surrendered the city to Gen. Cialdini. Pop. about 6,000.

Gaff, in a ship or boat, spar or a sort of boom to which the head of a fore-and-aft sail is bent, such sail having its foremost side made fast by rings to the mast, and its lower edge, in most instances, held straight by the boom proper. The thick end of the gaff is constructed with «jaws» to pass half round the mast, the other half being inclosed by a rope or wire; this serves to keep it close when the sail is hoisted or lowered. The jaws are usually made by fastening two pieces of wood by means of bolts to the thick end of the gaff, the forward side of these pieces being hollowed out in the form of a semicircle so as to fit snug to the mast but sufficiently loose to allow of free play for the hoisting and shifting of the sail. Lately these jaws have been made entirely of metal, chiefly bronze. The after end of the gaff is called the «peak,» because it is usually raised much higher than the jaws when the sail is set. The ropes used in hoisting and lowering the gaff are called «halyards,» the rope for raising the peak being designated the «peak-halyard» and that near the «jaws» or «throat» the «throat-halyard,» «spankers» and «trysails» are the only ones which have gaffs in square-rigged ships, but these gaffs do not ordinarily lower or hoist and in place of jaws have eyelets holding the forward end to the mast or to a traveler working on a batten to the mast. The latter method, however, is preferable as the gaff may be lowered when the sail is reefed.

Gag-rules, a series of rules adopted 1836-44 by the House of Representatives, to prevent the reception of anti-slavery petitions and check the possibility of debate on the subject. No other measure created more virulent debate. The Constitution forbids Congress to pass any law «abridging the right of the peo-

LYMAN JUDSON GAGE

EX-SECRETARY, U. S. TREASURY

ple to petition the government for a redress of grievances," and impliedly to refuse to receive petitions, as an unheard petition is a nullity. From 1831 on, the abolition societies rained petitions on Congress, urging the abolition of slavery in the District of Columbia, over which it had complete legislative power. They were referred to the committee on the District, which at first reported adversely, then ceased to report at all, despite complaints. The 24th Congress, 1835–6, laid them on the table instead; but in both Houses there soon arose an outcry to bar them from congressional cognizance altogether. In the Senate, Calhoun on 7 Jan. 1836 moved not to receive two such petitions, on the ground that the South must in the end be worn out and degraded by having constantly to justify its institutions, before a body which had no jurisdiction over them anywhere; but after two months' debate, it was voted to receive them and they were immediately rejected, which remained the rule thereafter. In the House, on 8 February, Henry L. Pinckney of South Carolina moved that all the petitions be referred to a select committee, under instructions to report that Congress could not constitutionally interfere with slavery in the States, and ought not to do so in the District; on 18 May the committee so reported, with another resolution that all petitions relating to slavery be laid on the table without action or reference. Under the previous question both resolutions were passed 25–26 May; the last 117 to 68, John Quincy Adams refusing to vote and denouncing them as a violation of the Constitution, the rules of the House, and the rights of his constituents. Thereafter Mr. Adams, as the champion of the right of petition, became involved for years in an endless struggle against the "gag." On 18 Jan. 1837 this struggle was renewed. The furious scenes in which Mr. Adams was pitted against nearly all the rest of the House are among the most picturesque in American history. On 21 Dec. 1837, John M. Patton of Virginia moved and secured the passage (122 to 74) of a resolution to lay on the table without debate, reference, or action, all papers concerning slavery in any State, "District or Territory" of the United States. Adams again denounced it and refused to vote. On 11 Dec. 1838 the "Atherton Gag" was moved by Charles J. Atherton of New Hampshire, and passed 126 to 73; it was the same in essence as the others. On 21 Jan. 1840 the House adopted as its 21st Rule that no paper praying the abolition of slavery or the slave trade should in future be received by the House or entertained in any manner. But this only passed by 114 to 108; the refusal of the right of petition was incensing the North, and forcing even Democratic representatives to protest. Thereafter at every session, in adopting the rules, Mr. Adams moved to strike out the 21st; the violence of the assaults on him increased, but the majorities against him decreased. At the special session of 1841 his motion was carried on a motion to adopt the rules only for 10 days, but reconsidered and defeated. Finally, on 3 Dec. 1844 a motion to lay his motion on the table was lost by 104 to 81, and the 21st Rule was abolished by 108 to 80. Nothing of the kind was again attempted. Since 12 Dec. 1853 petitions are no longer presented in the House, but handed to the clerk.

Gage, Frances Dana Barker, American reformer. b. Marietta, Ohio, 1808; d. 1884. In Ohio, and later at St. Louis, Mo., she appeared as a lecturer on total abstinence, women's rights, and anti-slavery, and underwent the many unpleasant experiences then the lot of abolitionists. She served as a nurse in the Civil War, and wrote over the signature "Aunt Fanny."

Gage, Lyman Judson, American financier: b. De Ruyter, N. Y., 28 June 1836. He removed to Rome, N. Y., in 1848, and was educated at the Rome Academy. He worked in the Oneida Central Bank 1853–5, when he went to Chicago, becoming a clerk, and later, bookkeeper and cashier of a planing-mill company. In 1868 he became cashier and in 1891 president of the First National Bank of Chicago. He was the first president of the Board of Directors of the World's Columbian Exposition, and several times president of the American Bankers' Association and the Civic Federation of Chicago. On 5 March 1897 he was appointed secretary of the treasury, by President McKinley; in 1901 was reappointed; resigning in March 1902. He received the degree of LL.D. from the New York University 4 June 1903. He was the originator of the movement for civic reform which started in Chicago under his inspiration and became a national influence. He wrote the platform of the Economic Conferences, a unique feature of Chicago's social organization, where Republican and Democrat, rich and poor, conservative and anarchist, meet for debate and exchange facts and theories.

Gage, Matilda Joslyn, American woman suffragist: b. Cicero, N. Y., 24 March 1826; d. 18 March 1898. She was secretary to the State Woman Suffrage Society of New York in 1869–70, was later for nine years its president, and in 1875–6 president of the National Woman Suffrage Association. She was president of the Woman's National Liberal Union in 1893, published and edited (1878–81) the 'National Citizen,' and wrote a 'Woman's Rights Catechism' (1870); 'Woman as an Inventor' (1871); 'Woman in Church and State' (1893).

Gage, Thomas, English general: b. 1721; d. 2 April 1787. In 1755 he accompanied Braddock's ill-fated expedition as lieutenant-colonel, and as brigadier-general became in 1760 military governor of Montreal, and in 1763 commander-in-chief of the British forces in America. His inflexible character led the government to regard him as well fitted to end the disturbances in the American colonies. In 1774 he was nominated governor of Massachusetts, a post of peculiar difficulty, and his enforcement of the rigorous decrees of Parliament brought matters to a climax. On the night of 18 April 1775 he despatched an expedition to seize a quantity of arms which had been stored at Concord; and next day took place the memorable encounter of Lexington, which announced that the Revolution had begun. The battle of Bunker Hill (q.v.) made him unpopular. For a short time he was commander-in-chief in America, a post he soon resigned to return to England.

Gahnite, gä'nīt, "zinc spinel," is essentially a zinc-aluminate, $Zn\ Al_2O_4$. The variety automolite has this formula; in kreittonnite the zinc is in part replaced by ferrous iron and magnesium, and the aluminum by ferric iron. The variety dysluite is similar except that manganese is present instead of magnesium. Gahnite usually occurs in octahedrons of a black, gray, dark-green, or brown color, with a hardness of 7.5 to 8. Its most important localities are in Sweden, Bavaria, and Sussex County, New Jersey.

Gail Hamilton. See DODGE, MARY ABIGAIL.

Gaillard, gä-yä, **Claude Ferdinand**, French painter and engraver: b. Paris, France, 7 Jan. 1834; d. there 19 Jan. 1887. He was a pupil of Leon Cogniet, and studied painting and engraving at Ecole des Beaux-Arts. In 1856 he gained the Prix de Rome. Among his pictures are: 'The Education of Achilles' (1863); 'St. Sebastian' (1876); 'Christ at the Tomb' (1877), besides several portraits, and some copies of old masters. His principal engraved portraits are: 'Chateaubriand,' 'Monseigneur Bouvier,' 'Count of Chambord,' 'Monseigneur Merode.' 'The Plates of St. Sebastian,' of one of Botticelli's 'Holy Families,' and of the 'Man With the Pink,' of Van Eyck, rank among the masterpieces of modern engraving. Gaillard gained three medals for engraving and one for painting, and was decorated with the cross of the Legion of Honor in 1876.

Gaillardet, gä-yär-dā, **Théodore Frédéric**, French dramatic author: b. Auxerre 7 April 1808; d. Plessis-Bouchard 12 Aug. 1882. He practised law at Tonnerre. He sent a drama to the Porte Saint-Martin, which partly rewritten by Alexander Dumas, the elder, and signed by him, achieved an enormous success as 'La Tour de Nesle,' 28 May 1832. This led to a duel with Dumas, Gaillardet afterward gaining a lawsuit which permitted him to place his name as one of the authors of the piece. He is the author of two other plays, 'Struensee ou le Medecin de la Reine' (1832), and 'Georges ou le Criminel par Amour' (1833). He also wrote from private papers found at Tonnerre, and the archives of foreign affairs, the 'Memoires du Chevalier d'Eon' (1836, new edition 1866). Coming to New York in 1839 he founded the 'Courrier des Etats Unis,' a French newspaper which he edited until 1848 and which is still published. He returned to France later and served on the editorial staff of the 'Presse.'

Gailor, Thomas Frank, American Protestant Episcopal bishop: b. Jackson, Miss., 17 Sept. 1856. He was graduated from Racine College, Wis., in 1876, and from the General Theological Seminary, New York, in 1879. Entering the ministry he was rector of the Church of the Messiah, Pulaski, Tenn., 1879–82; and in 1882 became professor of ecclesiastical history in the University of the South, Sewanee, Tenn. In 1893 he was consecrated bishop-coadjutor of Tennessee, and in 1898, on the death of Bishop Quintard, became bishop of Tennessee. His writings include: 'A Manual of Devotion'; 'The Apostolical Succession'; 'Things New and Old'; 'The Trust of the Episcopate.'

Gaines, Edmund Pendleton, American army officer: b. Culpeper County, Va., 20 March 1777; d. New Orleans 6 June 1849. He was appointed second lieutenant in the Sixth Regiment, United States Infantry, in 1799, in 1805 became collector of customs of the port of Mobile, Ala., and received the rank of captain 1807. Serving through the War of 1812, he became brigadier-general in 1814, commanding at Fort Erie, in August, until wounded. He afterward became brevet major-general; commanded the Southern Military District during the first war against the Seminoles 1817, the Western District 1821, being wounded in the second war with the Seminoles in 1837, and the Department of the Southwest when war was declared with Mexico.

Gaines, Myra Clark, American claimant: b. New Orleans 1805; d. 1885. She was a daughter of Daniel Clark, who emigrated from Ireland to New Orleans and inherited his uncle's property there in 1799. He was supposed to have lived a bachelor, but it was known that he was the father of two daughters by a French woman of great beauty. He died in 1813; his will gave his property to his mother. In 1830 letters were found detailing the circumstances of Myra's birth; in 1832 one that gave an account of a will made by her father in 1813, in which he acknowledged her as his legitimate daughter and bequeathed her all his property. She then began her remarkable litigation, first to establish her legitimacy, then to secure her father's estate. The supreme court of Louisiana pronounced her legitimate and his lawful heir in 1856. Subsequently, the United States Supreme Court decided that the facts of her father's secret marriage in Philadelphia and her own legitimacy were fully established. Then began the struggle to secure possession of the estate. She filed a bill in equity in the United States Supreme Court in 1856, and a favorable decision was rendered in 1867. In 1861 the property in New Orleans was valued at $35,000,000, and previous to 1874 she obtained $6,000,000. Appeals and counter-suits were in progress at the time of her death in 1885. She married W. W. Whitney in 1832, and at his death Gen. Edmund P. Gaines, in 1839.

Gaines' Mill, Battle of. After the battle of Mechanicsville or Beaver Dam Creek, 26 June 1862, McCall's division was withdrawn from the field of its victory, and Gen. Fitz John Porter, with it and the Fifth corps, took up a defensive position near Gaines' Mill, east of Powhite Creek, a small stream flowing into the Chickahominy. Porter's corps and McCall's division, numbering in all about 20,000 infantry and artillery and 2,500 cavalry, were the only Union troops north of the Chickahominy, the rest of McClellan's army being south of it. Porter's line was formed in the shape of a semicircle, its left resting in the low ground near the Chickahominy, with its right bending around south of Old Cold Harbor. The line was naturally strong, and was strengthened by rifle-pits, by felling trees in front of them, and by piling rails and such other material as was at hand. The east bank of the creek was quite high and the slope to the creek was covered with brush and timber. The line covered several of the bridges over the Chickahominy, and through the centre and right ran the roads from New Cold Harbor and Old Cold Harbor to Dispatch Station. Sykes' division of the Fifth corps was on the right, and Morell's division on the left, with McCall's division in reserve. Gen. Cooke, with three small cavalry regiments, watched the left. The line was somewhat too extended for the number of troops Porter had at his disposal, but these were well posted and his artillery placed in good positions, sweeping the ground in front. On 27 June the Confederates advanced upon Porter's position, A. P. Hill and Longstreet from the west, Jackson and D. H. Hill from the northwest. A. P. Hill led the advance from Mechanicsville, and on reaching Powhite Creek, near Gaines' Mill, at noon, Gregg's South Carolina brigade was so stoutly resisted by the 9th Massachusetts, holding an advanced position, that Hill was checked and compelled to deploy a large force to push the Massachusetts men back, which consumed the time until 2 P.M. Meanwhile the other divisions had come up, Longstreet on A. P. Hill's right, Jackson, Ewell, and D. H. Hill in the order named, on A. P. Hill's left. The main battle began a little after 2 o'clock with an impetuous assault by A. P. Hill on Porter's left division, and resulted in the final repulse of Hill with great loss. Longstreet came to his support, Jackson and D. H. Hill closed in on Porter's right, and for nearly two hours Porter's entire line was successively assailed and pressed at every point, but held firm, so firm that Gen. Lee thought that "the principal part of the Federal army was on the north side of the Chickahominy" and "apparently gaining ground." McCall's division was placed in line; all fought well and were admirably handled; but there were not enough of Porter's men long to withstand the energetic and continued pressure of 57,000 Confederates at all parts of the line. At about 4 P.M. Slocum's division of Franklin's corps came on the field from beyond the Chickahominy; its three brigades were separated and disposed of in weak places on the line, and the general attack was repulsed about 5 P.M. A few minutes later another attempt was repulsed, the Union line holding fast and not yielding a foot. The Confederate forces were now all up; Whiting's division had come to the relief of A. P. Hill; and Stuart, with his cavalry and artillery, opened heavily on Porter's right. Gen. Lee now ordered a general advance, which was responded to in a most gallant manner. Porter's lines were fiercely assaulted; parts remained firm, but other parts gave way, and soon all gave back, losing 22 guns and some 2,800 prisoners. Some of the commands fell back in much confusion; others retired in good order, upon the brigades of French and Meagher, of Sumner's corps, which had crossed the Chickahominy, and now assisted in checking the Confederate pursuit. During the night the Union troops crossed to the south side of the Chickahominy, destroyed the bridges behind them and joined the rest of the army in its retreat to Harrison's Landing on James River. The entire number of Union troops engaged was about 34,000; the loss was 894 killed, 3,107 wounded, and 2,836 missing, an aggregate of 6,837. The number of Confederate troops engaged was about 57,000, of whom 8,751 were killed and wounded. Consult: 'Official Records,' Vol. XI.; Webb, 'The Pininsula'; 'McClellan's Own Story'; the Century Company's 'Battles and Leaders of the Civil War,' Vol. II.

E. A. CARMAN.

Gainesville, Fla., city and county-seat of Alachua County, on the Gainesville and Gulf, the Florida Central and Peninsular, and other railroads, 60 miles southwest of Jacksonville. Owing to its temperate climate it is a favorite invalid winter resort. Its industrial interests are chiefly agricultural; fruit growing, especially oranges, is largely carried on. Pop. (1900) 3,633.

Gainesville, Ga., city and county-seat of Hall County, on the Gainesville, and the Richmond & Danville R.R.'s, 53 miles northeast of Atlanta. From its situation at the summit of the Chattahoochee ridge, and owing to the numerous mineral springs in the vicinity, it is a much-frequented health resort. The educational establishments include Gainesville College and the Georgia Seminary. There are milling industries and manufactures of machinery and cars, and the city owns its electric lighting plant and waterworks. Pop. (1900) 4,382.

Gainesville, Texas, city and county-seat of Cooke County, on the Missouri, K. & T., and the Gulf, C. & S. F. R.R.'s., 65 miles north of Fort Worth. This is the centre of an important agricultural and stock-raising district. It has large meat-packing establishments and manufactures of flour, foodstuffs, cotton-seed oil, carriage works, hide and leather factories, and pressed-brick works. The town was first settled in 1851, and was incorporated in 1873. It was governed under a new charter in 1879 with a mayor and council elected by popular vote every two years. Pop. (1900) 7,874.

Gainsborough, gănz'bŭr-ō, **Thomas,** English painter: b. Sudbury, Suffolk, May 1727; d. London 2 Aug. 1788. He was the son of a wool manufacturer, and was educated under his uncle in the grammar-school of his native town. His artistic genius early displayed itself, and for a time he studied art in London under the French engraver Gravelot, and afterward under Frank Hayman. He married at 19, and in 1760 took up his residence in Bath, where he soon acquired a leading position as a portrait painter. He sent pictures to the exhibitions of the Society of Artists from 1761 to 1768, and in the latter year was elected one of the original members of the Royal Academy. He contributed to the Academy exhibitions during the period 1769–72, and again, after an interval of estrangement from Sir Joshua Reynolds, from 1777 till 1783. The pictures shown during the first of these periods comprised some landscapes and numerous portraits, among them those of Garrick (two), the Duke of Argyll, and Lord Nugent. Owing to a quarrel with his friend and patron, Philip Thicknesse, he left Bath for London in 1774, and in the metropolis his fame rapidly increased. Among the pictures exhibited at the Academy after his arrival in London none is more celebrated than the 'Blue Boy' (1779), said to have been painted to refute a statement made by Sir Joshua Reynolds in one of his discourses. Among portraits painted during this period are those of the Duchess of Devonshire, Duchess of Cumberland, Duke of Argyll, Gen. Conway, Sir Bate Dudley, George III. and his queen, Bishop Hurd, the Prince of Wales, Col. St. Leger, Lord Cornwallis, the Princess Royal, and other members of the royal family. Owing to a quarrel about the hanging of some pictures he never exhibited at the Academy after 1783. Before his death he was reconciled to Sir Joshua Reynolds. Among his other works the following should be mentioned: portraits of Mrs. Siddons, Hon. Mrs. Graham, Pitt, Blackstone, Johnson, Sterne, Richardson, Clive, Burke, Canning, Franklin, besides others; 'The Market Cart'; 'The Watering Place'; 'The Brook'; 'Rustic Children'; 'The Cottage Door'; 'Cows in a Meadow'; 'Gainsborough's Forest'; and other fine landscapes. Both in portrait painting and in landscape painting he is one of the greatest of English masters. A portrait by him of the Duchess of Devonshire was sold in 1876 for £10,605, and was immediately thereafter stolen, not being recovered until 1901 (in the United States). Consult: 'Lives,' by Fulcher (1856); Brock-Arnold (1881); Bell (1897); Wedmore, 'Studies in English Art,' first series (1878); Armstrong, 'Gainsborough and His Place in English Art' (1898); Chamberlain, 'Gainsborough' (1903).

Gairdner, gärd'nėr, **James**, English historian: b. Edinburgh 22 March 1828. At 18 as a clerk he entered the 'Public Record' office in London, where he became assistant keeper in 1859. He has distinguished himself by the rare combination of profound erudition, patient accuracy, and judicial temper which he has shown in the editing of a long series of historical documents: 'Memorials of Henry VII.' (1858); 'Letters and Papers Illustrative of the Reigns of Richard III. and Henry VII.' (1861–3), in the Rolls series; the continuation from Vol. V. onward of the late Prof. Brewer's 'Calendar of Letters and Papers, Foreign and Domestic, of the Reign of Henry VIII.' (9 vols. 1862–86); and 'Historical Collections of a London Citizen' (1876), and 'Three Fifteenth-Century Chronicles' (1880), for the Camden Society series. Equally valuable are the books addressed to a wider audience: an edition of the 'Paston Letters' in Arber's series (1872–5); 'The Houses of Lancaster and York,' in 'Epochs of Modern History' (1874); 'Life and Reign of Richard III.' (1878); 'England' in 'Early Chroniclers of Europe' (1879); 'Studies in English History' (1881), a series of essays written in conjunction with Spedding; and 'Henry VII.,' 'Statesmen' series (1889).

Gairdner, Sir **William Tennant**, Scottish pathologist: b. Edinburgh 8 Nov. 1824. He was graduated M.D. at Edinburgh in 1845, and from 1862 until his retirement in 1900 occupied the chair of practice of medicine in Glasgow University. Among his published books are: 'Pathological Anatomy of Bronchitis and Diseases of the Lungs' (1850); 'Notes on Pericarditis' (1861); 'Clinical Medicine' (1862); 'Public Health in Relation to Air and Water' (1862); 'On Some Modern Aspects of Insanity: Lectures to Practitioners' (1888); 'The Physician as Naturalist' (1889).

Gaisford, Thomas, English scholar and Greek philologist: b. at Ifort, Wiltshire, England, 22 Dec. 1779; d. 2 June 1855. He was educated at Christ Church, Oxford, took orders in the Church, and in 1811 was appointed regius professor of Greek in the University of Oxford. In 1831 he became dean of Christ Church, remaining such till his death, and in 1847 rector of Westwell and curator of the Bodleian Library. He was a prolific writer, his principal works being: 'Hephæstronis Enchiridion de Metres' (Oxford 1810; Leipsic 1832); 'Poetæ Græci Minores' (1814–20, 4 vols.); 'Stobæi Florilegium' (1822, 4 vols.); 'Herodoti Historiæ' (1824); 'Sophoclis Tragædiæ' (Oxford, 1826, 2 vols.; Leipsic 1827, 8 vols.); 'Suidæ Lexicon' (1834, 3 vols.); 'Parænuographi Græci' (1836); 'Scriptores Latini rei Metricæ' (1837); 'Entymologicum Magnum' (1848); and 'Eusebii Demonstratio Evangelica' (1852, 3 vols.). He was elected a member of the Institute of France, and in 1856 the Gaisford prize, for Greek composition, was founded at Oxford in his memory.

Gaius, gā'yŭs, the name of several persons mentioned in history: (1) A Roman general, the son of Marcus Agrippa and Julia, daughter of Augustus Cæsar. He was adopted by Augustus and distinguished himself as a soldier during the 1st century B.C., having reduced Armenia and routed Tigranes. (2) A Roman jurist who lived 130 to 180 A.D. Before the revision of the Roman law and the reform of legal studies by Justinian, the 'Institutes' of Gaius, afterward the groundwork of the 'Institutes' of Justinian, were the received text-books of the schools of law. Almost completely lost until 1816, their discovery at Verona by Niebuhr threw a flood of light on the history of the early development of Roman law. (3) A Christian controversialist of the 3d century. He regarded the Epistle of Saint Paul to the Hebrews as apocryphal, and was the first who wrote against Cerinthus and the Millenarians. (4) Gaius, Saint, bishop of Rome, 283 to 296; d. 21 April 296. A native of Dalmatia and nephew of Diocletian, he suffered many hardships during the first persecution of the Christians by the emperor.

Galabat, gä-lä-bät', or **Kalabat**, Africa, a small district situated near the western frontiers of Abyssinia. The people, some 20,000 in number, and fanatical Mohammedans, trade with Abyssinia in coffee, cotton, hides, and beeswax. The district contains about 1,500 square miles.

Galac'tic Circle, the great circle of the heavens which coincides best with the course of the Galaxy or Milky Way. According to Sir John Herschel, the north pole of this great circle is situated approximately in right ascension 12 hours 47 minutes, and declination $+27°$, the circle crossing the equator at the points whose right ascensions are about 6 hours 47 minutes and 18 hours 47 minutes. See Galaxy.

Galac'tin, or **Galactine**, in chemistry, a nitrogenous substance obtained from milk by first precipitating the casein with acetic acid; coagulating the albumen by boiling, removing the fat by ether, concentration, filtration from earthy phosphates, allowing the milk-sugar to crystallize out, and finally precipitating the galactin by alcohol. Thirty-five parts of dried milk yield one part of galactin, which is soluble in water, insoluble in alcohol and ether. It is precipitated by tannin, but differs from gelatine in redissolving at 60°. Galactin emulsifies fat. It is found in the blood, gastric juice, animal membranes, milk, eggs, and many morbid animal fluids. It also exists in the juices of edible plants and in the fluid of the embryonal cotyledons.

Galago, ga-lā'gō, a genus of African lemurs (q.v.), arboreal and nocturnal in habit, living on fruit and insects. They vary from the size of a rabbit to that of a rat, are covered with soft fawn-gray woolly fur, have somewhat bushy tails longer than the body, and hind legs longer and stronger than the arms, with two of the ankle bones (*calcaneum* and *navicular*) greatly elongated. The head is round like a cat's; the eyes are large with oval pupils contracting in daylight to vertical slits; the ears are naked and very big, expanded during activity, but rolled together when the animal rests. The female is said to bear one young one at a birth, and often carries it about. Soft nests are also made in the branches. The galago proper (*G. senegalensis*) seems to be distributed throughout tropical Africa, and is known in Senegal as "the gum animal" from its frequent habitat in mimosa or gum-acacia forests, and from its alleged habit of gum-chewing. It is said to be eaten there. The largest species (*G. crassicaudatus*) measures a foot in length, not including the bushy tail, which is 15 or 16 inches more. In Zanzibar the komba (*G. agisymbanus*) is said frequently to make itself intoxicated with palm-wine, so that it falls from the tree and gets caught. It is readily tamed and utilized to catch insects and mice in the houses. There are numerous species, and the Madagascar genera *Chirogale, Microcebus* and *Opolemur* are joined with it in the sub-family galaginæ. Consult Beddard, 'Mammalia' (1902).

Gal'ahad, Sir, the noblest of the Knights of the Round Table, of whom he alone was successful in the search for the Holy Grail. He was introduced into the Grail legend by Walter Map (q.v.). See Grail; Round Table, Knights of.

Gal'angal, a dried rhizome obtained from different species of *Alpinia* growing in the East. What is known as the lesser galangal is brought from China. It occurs in small pieces, cylindrical and forked, striated, and diversified with whitish rings; the outside is brown, the inside paler. It has an aromatic taste and odor, and is an agreeable substitute for ginger in dyspepsia. It yields an oil and a soft resin, but its chemical composition is not settled. The larger or Java galangal is coarser, and is not so strongly aromatic. The rhizome of *Alpinia officinarum* has been used in medicine as a stimulant aromatic.

Galan'thus. See Snowdrop.

Galápagos (găl a pā'gŏs) **Archipelago,** a group of volcanic islands in the Pacific Ocean, belonging to the Republic of Ecuador. (For population, etc., see Ecuador.) Features of wholly exceptional interest in the natural history of the archipelago were noted by Charles Darwin in his 'Journal of the Voyages of the Beagle,' which forms the basis of the present description. The archipelago consists of 10 principal islands, of which 5 much exceed the others in size. They are situated under the equatorial line, and between 500 and 600 miles to the westward of the coast of Ecuador, and directly south of Guatemala. The constitution of the whole is volcanic; with the exception of some ejected fragments of granite every part consists of lava, or of sandstone resulting from the attrition of such materials. The higher islands (which attain an elevation of 3,000 to 4,000 feet) generally have one or more principal craters toward their centre, and on their flanks smaller orifices. There are, in all the islands, at least 2,000 craters. Though the islands are placed directly under the equator, the climate is not in all parts of them excessively hot; a circumstance which is owing to the singularly low temperature of the surrounding sea. Very little rain falls, except during one short season, but the clouds generally hang low; therefore the summits, at an elevation of 1,000 feet or more, possess a tolerably luxuriant vegetation, while the lower parts of the islands are extremely arid. On a part of Chatham Island, black cones, the former chimneys of the subterranean heated fluids, are so numerous and in form so regular that they give the country a "workshop" appearance, which strongly reminded Mr. Darwin of the great iron foundries of Staffordshire. All the craters on Chatham are extinct, but on the western islands "the volcanic forces were in frequent activity." Charles Island was frequented by buccaneers and whalers long before Ecuador established a small penal colony there (1829–30). The soil of the elevated portions of that island is fertile black mud; the climate of the same regions is tempered by a cool southerly tradewind; and wild pigs and goats are found in the woods, "but the main article of animal food is derived from the tortoises"— which sometimes weigh 200 pounds each. On both Albemarle and Marlborough islands, eruptions occasionally take place. Of the former, Mr. Darwin writes: "I should think it would be difficult to find in any other part of the world an island situated within the tropics, and of such considerable size (namely, 75 miles long), so sterile and incapable of supporting life." On James Island there is a lake from which salt is procured. The equatorial heat was observed in its effect upon the soil of the lower and sterile parts. There the thermometer placed in sand of a brown color immediately rose to 137°, and black sand was so much hotter that it was disagreeable to walk over, even in thick boots. An acacia, a cactus, and one of the euphorbiaceæ — a bush with minute brown leaves — are common in some parts of these lowlands. Near the summits the vegetation has a very different character; ferns and coarse grasses are abundant; and the commonest tree is one of the Compositæ. There are no members of the palm family. "The natural history of this archipelago," Mr. Darwin says, "is very remarkable. It seems to be a little world within itself; the greater number of its inhabitants, both vegetable and animal, being found nowhere else." And again, "In my collections from these islands there are 26 different species of land birds. With the exception of one, all probably are undescribed kinds, which inhabit this archipelago and no other part of the world." The order of reptiles forms the most striking feature in the zoology of the islands, the species not being numerous, but the number of individuals of each kind extraordinarily great. There is one kind both of the turtle and tortoise; of lizards four; and of snakes about the same number. Of the tortoise (*Testudo Indicus*) some old males have been found so large that it required six or eight men to lift them from the ground. Mr. Darwin says: "I frequently got on their backs, and then, upon giving a few raps on the hinder part of the shell, they would rise up and walk away; but I found it very difficult to keep my balance. The tortoise is very fond of water, drinking large quantities, and wallowing in the mud. The larger islands alone possess springs, and these are always situated toward the central parts, and at a considerable elevation. The tortoises, therefore, which frequent the lower districts, when thirsty, are obliged to travel from a long distance. Hence broad and well-beaten paths radiate off from the wells even down to the seacoast. Near the springs it was a curious spectacle to behold many of these great monsters: one set eagerly traveling onward with outstretched necks, and another set returning, after having drunk their fill." Mr. Darwin inclines to the opinion that the Galápagos islands are the original home of the *Testudo Indicus*, though it is now found in many parts of the world. Also characteristic of this archipelago are the lizards, individuals of the aquatic variety, being 3 or 4 feet long. Many of the islands possess trees, plants, and birds, which do not occur on the others. At the date of Mr. Darwin's visit the birds had not learned to fear man. He writes: "A gun is here almost superfluous; for with the muzzle of one I pushed a hawk off the branch of a tree."

MARRION WILCOX.

Galata, gä'lä-tä, a suburb of Constantinople (q.v.).

Galatea, găl-a-tē'a, in mythology, daughter of Nereus and Doris. The Cyclops Polyphemus persecuted with his love this charming nymph, though he gained nothing but ridicule in return. The handsome shepherd Acis, of Sicily, enjoyed her affection, and suffered death on her account; for Polyphemus, finding them together, and mad with jealousy, hurled a rock at them, which dashed Acis in pieces, while Galatea escaped into the sea. Acis was transformed into a fountain, and hastened to meet his mistress in a safer region.

Galatia, gā-lā'shĭ-a, Asia Minor, the ancient name of an extensive region, so called from its Gallic inhabitants, who were immigrants from Europe. With the Gauls were intermingled a considerable proportion of Greeks; hence the inhabitants were often called Gallo-græci, as well as Galatians.

Gala'tians, Epistle to the, one of the epistles of St. Paul, the genuineness of which has never been questioned by a critic of the first rank. The internal evidence is incontrovertible. No forger would have ventured on the admissions made by the writer; no false Paul would have allowed that Paul's apostleship was doubted and his successes discredited. The occasion of the letter seems to have been as follows: At his first visit St. Paul experienced a most favorable reception from the Galatians, who exhibited a strong personal attachment to him (Gal. iv. 14). After his departure the judaizing teachers commenced their work, and on the Apostle's second visit he found the noxious influence taking effect. During his short sojourn he endeavored, by oral instruction, to meet the evil; but learning after his departure to Ephesus that his converts were again lapsing from the faith, he addressed to them this indignant warning. This epistle has been often commented upon. Consult: Winer (1829), Ruckert (1833), Usteri (1833), Meyer (1851), Ellicott (1867), Lightfoot (1887), Findlay (1889), and Drummond (1893).

Gal'ba, Servius Sulpicius, Roman emperor: b. 3 B.C.; d. 15 Jan. 69 A.D. Caligula appointed him general in Germany. He soon repulsed the Germans who had invaded Gaul, and restored the ancient military discipline. After the death of Caligula he caused his troops to swear allegiance to Claudius, who sent him in 45 A.D. as proconsul to Africa, where great confusion prevailed. In two years Galba restored order, obtained the honors of a triumph, and was received among the priests of Augustus. Nero appointed him in 61 A.D. governor of Hispania Tarraconensis, but soon after became so exasperated against him that he ordered him to be secretly assassinated. Galba then revolted, but when news arrived of the insurrection among the prætorians at Rome, and of the death of Nero, 68 A.D., he himself was chosen emperor by the prætorian cohorts in Rome. Ambassadors from the senate made known to him his elevation. He chose a colleague in the government under the name of an adopted son, but instead of Otho, favored by the soldiery, he selected Piso Licinianus, hated by them on account of his rigid virtue. Otho, offended by this neglect, resolved to get possession of the throne by force of arms. The prætorian cohorts first declared themselves in his favor, and Galba, attempting in vain to restore order, was attacked and slain.

Gal'banum, a gum-resin obtained from *Ferula galbaniflua* and allied plants, used in medicine as a carminative and expectorant, and externally as an irritant.

Gale, a tree. See CANDLEBERRY.

Gale College, a coeducational institution in Galesville, Wis., founded in 1844 under the auspices of the Presbyterian Church. It has 10 professors and instructors; 120 students; volumes in the library, 10,000; productive funds, $20,000; benefactions, $2,000; grounds and buildings valued at $30,000; income, $4,500; number of graduates, 700; president, William D. Thomas.

Ga'len, or Claudius Galenus, Greek physician: b. Pergamus, Mysia, 131 A.D.; d. Sicily about 201 A.D. He began the study of medicine at Pergamus, and afterward studied at Smyrna, Corinth, and Alexandria. On his return to his native city in 158 he was appointed physician to the school of gladiators. Six years later he went to Rome, where he stayed four years, and gained wide reputation. Scarcely had he returned to his native city when he received a summons from the Emperors M. Aurelius and L. Verus to attend them in the Venetian territory, and shortly afterward he accompanied them to Rome. There he remained several years, though how long is not known precisely, and about the end of the 2d century was employed by the Emperor Severus. Galen was a voluminous writer not only on medical, but also on philosophical subjects, such as logic, ethics, and grammar. The works that are still extant under his name consist of 83 treatises, acknowledged to be genuine; 19 whose genuineness has been questioned; 45 undoubtedly spurious; 19 fragments; and 15 commentaries on different works of Hippocrates. His most important anatomical and physiological works are: 'Of Anatomical Administrations' and 'Of the Use of the Parts of the Human Body.' As an anatomist, he combined with patient skill and sober observation as a practical dissecter — of lower animals, not of the human body — accuracy of description and clearness of exposition as a writer. He gathered up all the medical knowledge of his time and fixed it on such a firm foundation of truth that it continued to be, as he left it, the authoritative account of the science for centuries. His physiology does not, according to modern ideas, attain the same level of scientific excellence as his anatomy. He seems to place a more implicit faith in amulets than in medicine, and he is supposed by Cullen to be the originator of the anodyne necklace which was so long famous in England. The best modern edition of Galen's works is by Kühn (1821–33).

Galena, Ill., a city and county-seat of Jo Daviess County, a port of entry on the Galena River, and on the Illinois C.; Chicago, B. & Q., and the Chicago & N. W. R.R.'s, 17 miles from Dubuque. Galena is famous as the home of Gen. U. S. Grant (q.v.) from May 1860 until the opening of the Civil War, and the old Grant homestead still remains one of the attractions of the city. There is here Grant Park, a fine statue of Gen. Grant, a United States customs house, government building, and a public library. The city has an extensive trade by rail and river, and is the centre of large lead and zinc mining interests. There are also smelting works, shoe factories, and other industries. The town, which was named after the galena ore found in the vicinity, was settled in 1827 and incorporated as a city in 1839. The mayor and council are elected every two years. The city owns its electric light plant. Pop. (1900) 5,005.

Galena, Kan., a city in Cherokee County, on the Kansas City, Ft. S. & M., and the St. Louis & S. F. R.R.'s; 7 miles west of Joplin, Mo. It is noted principally for its remarkable growth during 10 years, 1890 to 1900. Like its namesake in Illinois, Galena is engaged largely in lead and zinc mining and smelting. The mining district, about 4 miles square, has 200 concentrating mills, and gives employment to 3,000 men. Over $5,000,000 in ore was mined in 1900. The mayor and council are elected every two years. The deputy marshal and police are appointed by the council. Galena was settled and incorporated in 1877, and its population rapidly increased, as follows: (1880) 1,463; (1890) 2,496; and (1900) 10,155.

Galena, a sulphide of lead (PbS), containing when pure 86.6 per cent lead. It crystallizes in the isometric system, commonly in cubes or cubo-octahedrons, but is often found massive with a well-marked and characteristic cubic cleavage. It has a metallic lustre and lead-gray color. Its hardness is 2.5 and its specific gravity 7.5. Galena is the most important ore of lead, nearly all the world's supply of that metal being obtained from it. As it is always more or less argentiferous the mineral is frequently an important silver ore, the amount of silver present sometimes amounting to over 1 per cent, but galena containing less than 1 per cent silver is often mined as a lead-silver ore. The mineral is widely distributed, frequently being associated with the sulphides of iron, copper, or zinc, and often with native gold. The principal mines working deposits of galena in the United States are in Missouri, Colorado, Idaho, Utah, and Montana. See LEAD; SILVER.

Galenists, gā'lĕn-ĭsts, a religious sect founded by Galen or Galenus Abrahans de Haan. They were a branch of the Mennonites. Galen was a doctor of medicine and a minister among the Mennonites at Amsterdam. He taught freer doctrine in practice and belief than his co-religionists, declaring that the Christian religion was not so much a body of truths to be believed as of principles to be obeyed. His enemies accused him of having Socinian proclivities, a charge from which the States-General acquitted him 14 Sept. 1663.

The term was also in medical controversy during the Renaissance to mean a follower of Galen, whose authority as a physician they maintained against the introduction of new chemical methods into the preparation of medicinal drugs. The new school professed to extract essences, or quintessences, and like modern homœopathists gave doses small in bulk, but alleged to be powerful in effect, as containing a concentrated preparation of the original drug. The Galenists adhered to the ancient tinctures and extracts, which, they maintained, possessed all the virtues necessary.

Galerites, găl-ẹ-rī'tēz, a genus of fossil sea-urchins, peculiar to and abundant in the Cretaceous system. The body in breadth is nearly circular or polygonal. The under surface is entirely flat, and has the mouth placed in its centre, with the vent near the margin. There are five avenues of pores reaching from the mouth to the summit. These fossils are often found silicified. *G. albogalerus* is one of the most abundant; it has received its specific name from its resemblance to the white caps worn by the priests of Jupiter.

Galerius, gă-lē'rĭ-ŭs, or **Galerius Valerius Maximianus**, Roman emperor: b. near Sardica, Dacia; d. 311 A.D. Entering the imperial army, he rose rapidly to the highest ranks. In 292 Diocletian conferred on him the title of Cæsar and gave him his daughter in marriage. On the abdication of Diocletian (305) he and Constantius Chlorus became joint rulers of the Roman empire, Galerius taking the east half. When Constantius died in York (306) the troops in Britain and Gaul immediately transferred their allegiance to his son, Constantine (afterward Constantine the Great). Galerius, however, retained possession of the East till his death.

Gales, Joseph, American journalist: b. Eckington, England, 10 April 1786; d. Washington, D. C., 21 July 1860. He came to the United States with his father in 1793, was educated at the University of North Carolina and learned the printer's trade of his father. In 1807 he was made assistant and later partner of Samuel Harrison Smith in the management of the 'Independent Gazetteer,' which had been removed to Washington and its name changed to the 'National Intelligencer.' He became sole editor of that paper in 1810, and took his brother-in-law, William Winston Seaton, into partnership in 1812. Had it not been for the industry of Gales and Seaton an important part of the proceedings of the Senate and House of Representatives, which they reported, would not have been preserved. Especially is this true of the great debate between Hayne and Webster.

Galesburg, Ill., a city and county-seat of Knox County, on the Atchison, T. & S. F.; the Chicago, B. & Q., and Chicago & N. W. R.R.'s, 43 miles northeast of Burlington, Iowa. This is the seat of Knox College, founded in 1837, where took place the famous Lincoln-Douglass debate in 1859. Lombard University (Universalist) was established here in 1852, and the St. Joseph Academy and the Ryder Divinity School are also located here. There is a public library containing 24,000 volumes. The Burlington railroad shops give employment to many mechanics, and there are extensive stock-yards, brick-making plants, boiler and engine works, farm machinery works, and carriage factories. Under a general State law, passed in 1872, the mayor and city council are elected every two years, and the smaller offices are filled by appointments made by the mayor with consent of the council. The town was settled in 1837 by pioneers from New York State, and named in honor of Rev. George W. Gale, who planned to establish a theological seminary here. During the Kansas-Nebraska struggle Galesburg was a rendezvous and rallying point for the free-soilers. The city was chartered in 1857. The municipality owns and operates its electric light and water plants. Pop. (1900) 18,607.

Galesville, Wis., a village in Trempealeau County, on the Chicago & N. R.R.; 15 miles east of Winona. It is the seat of Gale College (Presbyterian). Pop. (1900) 862.

Gali, Francisco, frän-thēs'kō gä'lē, Spanish navigator: b. Seville 1539; d. Mexico City 1591. He sailed from Acapulco in 1585 with two vessels, under commission of Pedro Moya de Contreras, provisional viceroy of New Spain, to look for a harbor on the coast of California where ships returning from the East Indies might be restocked with provisions. He visited the Philippines, Macao, the Lin-Kins, Japan, and other islands, and on his return (1584) discovered what is now the Bay of San Francisco. The report of the voyage sent by him to the viceroy of the Indies was published by Linschot in a Dutch rendering in 'Track Charts of the Indies' (1596), and an English translation appears in Hakluyt's 'Voyages.' In the National Library, Mexico, are fragments of what is believed to have been a more extended narrative by Gali. He was a skilful navigator and acute observer.

Galicia, gă-lĭsh'ĭ-a, Austria, a crownland or province of Austria, composed of the kingdoms of Galicia and Lodomeria, the duchies of Auschwitz and Zator, and the grand-duchy of Cracow, and formerly including the duchy of Bukowina. It is bounded on the north, northeast and east by Russia, southeast by Bukowina, south by Hungary, and west by Moravia and a small portion of Prussian Silesia; area, 30,307 square miles; pop. (1900) 7,315,939. The physical features of the country are determined by the Carpathians, which form a long and irregular curve on the south, the convexity being toward Galicia. Farther north the hills subside and merge into vast plains. The chief river in the northwest is the Vistula, which partly bounds the province. The Western Bug, a tributary of the Vistula, is partly in Galicia. The chief river is the Dniester. The only part of the surface belonging to the basin of the Danube is in the southeast. It is drained by the Pruth, and is of limited extent. The climate is severe, particularly in the south, where more than one of the Carpathian summits are beyond the limit of perpetual snow. While Galicia is open to the cold north and east winds, these mountains intercept the warm winds from the south. The winters are long and rigorous, and the summers very warm, but comparatively short.

The soil is much diversified. In the more mountainous districts scanty pasture only is obtained, but in general, where the elevation is small, the ground, more especially where resting on a substratum of limestone, is of great fertility, and yields abundant crops of wheat, rye, barley, oats, and maize. Hemp, flax, and tobacco are also extensively grown, and the sugar beet is cultivated. The domestic animals include great numbers of horned cattle, generally of a superior description, and a fine hardy breed of horses, well adapted for cavalry. Sheep are neglected; but goats, swine, and poultry abound. The rearing of bees yields great quantities of wax and honey, and is a lucrative industry. Bears and wolves are frequently met with in the forests, and all the lesser kinds of game are in abundance. The minerals include marble, alabaster, copper, lead, zinc, calamine, coal, iron, and rock-salt. Only the last two are of much importance. Iron occurs in numerous parts of the central Carpathian chain, and bog-iron ore is frequently met with in extensive seams on the plains. They are both worked to a considerable extent. Rock-salt is particularly abundant, stretching in continuous beds for nearly 250 miles along the base of the Carpathians, and of course beyond the limits of Galicia, into Bukowina and Transylvania. The most important mines have their central locality at Wieliczka. Manufactures have not made much progress. The spinning and weaving of flax and hemp prevail to a considerable extent on the confines of Silesia. Distilleries exist in every quarter. Tobacco, sugar, leather, beer, agricultural machinery, etc., are also manufactured. The principal exports are salt, wood, grain, coal, aniseed, linen and spirits. The population is generally of Slavonian origin, and consists of two principal branches — Polish in the west and Russniak in the east. In religion they are divided among Roman Catholics, Greek Catholics, and Armenians. The number of the Jews is considerable. The court of third instance for the country is the superior court at Vienna; there are two courts of second instance, one at Lemberg and the other at Cracow; and there are various district courts of first instance. The government has its headquarters at Lemberg. Educational establishments, both for superior and ordinary instruction, are numerous. At the head of the former stand the University of Cracow, with about 130 instructors and some 1,300 students, and the younger university of Lemberg, with 80 instructors and a similar attendance. The principal towns are Lemberg, the capital, Brody, Cracow, Stanislau, Tarnopol, Przemysl, Sambor, etc.

The nucleus of the modern kingdom of Galicia and Lodomeria was formed by the duchies of Halicz and Vladimir (the original forms of the present names), which were established about the beginning of the 12th century under two princes of the Russian dynasty of Rurik.

After being the field of continuous strife between Russians, Poles, and Hungarians, Galicia continued a Polish dependency from 1382 till the first partition of Poland, in 1772, when it was acquired by Austria. Galicia is now one of the Cis-Leithan provinces of the Austrian empire, and is represented in the Reichsrat by 63 deputies, while the affairs peculiar to itself are deliberated and determined on by its own Landtag or Diet. Polish is the language of official intercourse and of the higher educational institutions.

Galicia, Sp. gä·lē'thē-ä, Spain, an ancient kingdom and province, bounded north and west by the Atlantic, south by Portugal, and east by Leon and Asturias, with an area of 11,340 square miles. It has been divided since 1833 into the minor provinces of Coruña, Lugo, Orense, and Pontevedra, whose joint population in 1900 was 2,073,618. The country is mountainous, being traversed by offsets of the Asturian chain, rising in their highest peaks to about 6,500 feet. The west spurs, Capes Ortegal and Finisterre, project into the Atlantic. The numerous short but rapid rivers form small estuaries which afford secure havens and roads. The principal river is the Minho, which, with its feeder the Sil, is navigable for small vessels on its lower course. Galicia has a mild, nourishing climate, but agriculture is in a backward condition, capital is scarce, roads are bad, and railways are few. Rich meadows and dense forests occur everywhere, but the soil is more suited to the cultivation of garden produce than of corn. Mines of lead, tin, copper, and iron pyrites are worked. The inhabitants, called Gallegos, are a robust, vigorous, industrious race. Great numbers of them annually visit central and southern Spain and Portugal, where they find employment as harvesters, water carriers, porters, etc. Chief exports, live cattle, preserved meat, eggs, minerals, fish, fruits, and grain; imports, coal, oil, hides, spirits, sugar, and tobacco. The principal towns are Santiago di Compostella and the two strongly fortified seaports Coruña and Ferrol. Galicia was a kingdom under the Suevi from 411 to 585, and again from 1060 to 1071, at which date it was finally incorporated with Leon and Castile.

Galignani, gä-lēn-yä'nē, **John Anthony,** English journalist: b. London, England, 13 Oct. 1796; d. Paris 31 Dec. 1873. He was taken by his father to Paris in the latter part of 1798, and succeeded him in publishing the weekly paper 'Galignani's Messenger,' which had become popular among the English residents of Paris. He remained a subject of Great Britain during his life, and was very liberal to the charitable institutions of that country. His brother, WILLIAM (b. London 10 March 1798; d. Paris 12 Dec. 1882) was associated with him in the management of the 'Messenger,' and in the building of a hospital in Neuilly for indigent English people. In his will he provided money and land for the erection in Neuilly of the Galignani Brothers' Retreat for 100 printers, booksellers, etc., or their families.

Galile'an, one of the followers of Judas the Gaulonite, who resisted the payment of the tax imposed by Quirinius, the Cyrenius of St. Luke (Luke ii. 1), and gave the Romans trouble till the capture of Jerusalem by Titus in 70 A.D. Galileans is a name applied to Jesus and his disciples, from the intimate connection they had with Galilee (Matt. xxvi. 69; Mark xiv. 70); hence applied by pagans and Mohammedans, as a term of reproach to Christians generally.

Gal'ilee, Palestine, during the Roman period and at the commencement of the Christian era, a province comprehending the northern part of Palestine, west of the Jordan. In pre-Roman times it was referred to as a district inhabited by the tribe of Naphtali. Its name is derived from the Hebrew *galil,* signifying a circle or circuit. It now forms part of the pashalic of Damascus, in the Turkish province of Syria. Anciently it was divided into Upper and Lower Galilee, and was a fertile region with many towns and villages, thickly inhabited by Syrians, Phœnicians, Arabs, Greeks, and Jews. The Jewish inhabitants, on account of their ignorance, simplicity of manners and less rigid sentiments in regard to religion, were held in contempt by other Jews; but after the destruction of Jerusalem despised Galilee became the refuge of the doctors of Jewish law, and the city of Tiberias the seat of Rabbinical learning. As the cradle of Christianity and the scene at Nazareth, Cana, Capernaum, the Lake of Gennesaret, Mount Tabor, and other localities, of a great deal of Christ's ministry on earth, Galilee has worldwide interest. Consult: Merrill, 'Galilee in the Time of Christ' (1885).

Galilee, Sea of, in biblical history also called the SEA OF CHINNERETH or CINNEROTH, LAKE OF GENNESARET and SEA OF TIBERIAS, is a large pear-shaped lake in the north of ancient Galilee (q.v.), Palestine. It lies 682.5 feet below sea-level; is 13 miles long by 6 broad, and 820 feet deep. It occupies the bottom of a great basin, and is of volcanic origin. The Jordan flows into it red and turbid from the north, and it is fed also by many warm and brackish springs, but its waters are cool, clear, and sweet. Its shores on the east and north sides are bare and rocky; on the west gradually sloping, and luxuriantly covered with vegetation. On its shores are Bethsaida, Capernaum, Magdala, and Tiberias.

Galilei, Galileo, gä-lē-lā'ō gä-lē-lā'ē, Italian astronomer: b. Pisa 14 Feb. 1564; d. Arcetri 8 Jan. 1642. His father, Vincenzo Galilei, a nobleman of Florence, caused him to be instructed in the ancient languages, drawing, and music, and he very early showed a strong inclination to mechanical labors. In 1581 Galileo entered the University of Pisa, to attend lectures on medicine and the Aristotelian philosophy. That spirit of observation for which he was distinguished was early developed. When only 19 the swinging of a lamp suspended from the ceiling of the cathedral in Pisa led him to investigate the laws of the oscillation of the pendulum, which he was the first to apply as a measure of time. He studied mathematics under Ostilio Ricci, soon exhausted Euclid and Archimedes, and was led, by the works of the latter, in 1586, to the invention of the hydrostatic balance.

He now devoted his attention exclusively to mathematics and natural science, and in 1589 was made professor of mathematics in the University of Pisa. In the presence of numerous spectators he went through with his experiments, which he performed on the tower of the cathedral, to show that weight has no influence on the velocity of falling bodies. By this means he excited the opposition of the adherents of Aristotle to such a degree, that after two years he was forced to resign his professorship. Later he became acquainted with Francesco Sagredo, a Venetian, upon whose recommendation the Senate of Venice, in 1592, appointed him professor of mathematics in Padua. He lectured here with unparalleled success. Scholars from the most distant regions of Europe crowded about him. In 1597 he invented the sector.

One of the most important mathematical discoveries which he made at a period subsequent to this is that the spaces through which a body falls, in equal times, increase as the numbers 1, 3, 5, 7; that is, if a body falls 16 feet in the first second, it will fall 48 in the next second, 80 in the third, and so on. Whether the thermometer was his invention it is difficult to determine; perhaps he only improved it. He made some interesting observations on the magnet, and by means of the telescope in a short time made a series of the most important discoveries. He found that the moon, like the earth, has an uneven surface; and he taught his scholars to measure the height of its mountains by their shadow. A particular nebula he resolved into individual stars, and even conjectured that the whole Milky Way, with good instruments, might be resolved in the same manner. His most remarkable discovery was that of Jupiter's satellites, 7 Jan. 1610. He likewise observed Saturn's ring, though he had not a just idea with regard to it. He saw the sun's spots somewhat later, and inferred, from their regular advance from east to west, the rotation of the sun, and the inclination of its axis to the plane of the ecliptic.

Galileo's name, meantime, had grown so celebrated that Cosmo II., grand-duke of Tuscany, appointed him grand-ducal mathematician and philosopher, and invited him to become first instructor in mathematics at Pisa. Here he gained a decisive victory for the Copernican system by the discovery of the varying phases of Mercury, Venus, and Mars; as the motion of these planets about the sun, and their dependence on it for light, were thus established beyond the possibility of doubt. He wrote a work afterward on the floating and sinking of solid bodies in water, and in this, as well as in all his other writings, scattered the seeds of many new doctrines.

While thus employed in enlarging the field of natural philosophy, a tremendous storm was gathering about his own head. He had declared himself in favor of the Copernican system, in his work on the sun's spots, and was therefore denounced as a heretic by his enemies. In 1611 he visited Rome for the first time, where he was honorably received, and where a favorable report was made on his writings by the mathematicians of the Collegio Romano at the instance of Cardinal Bellarmin. On his return to Florence, however, he became more and more involved in controversy, which gradually took a theological turn, and in the course of which he declared the literal understanding of the utterances of Scripture with regard to physical phenomena to lead to absurdities. From Rome he received, in the name of the Cardinal Barberini (afterward Pope Urban VIII.) the warning not to overstep the limits of mathematics and physics, but he paid no heed to the well-meant advice. The monks preached against him, and in 1616 he found himself again obliged to proceed to Rome, where he is said to have pledged himself to abstain for the future from promulgating his system either orally or otherwise. The genuineness of the document on the basis of which this is asserted, has, however, been questioned in modern times, and the controversy regarding this matter is not yet finally settled.

In 1618 the appearance of three comets gave him an opportunity to communicate to his friends some general observations on these bodies. His scholar, Mario Guiducci, wrote a work immediately after, in which he severely condemned the Jesuit Grassi. Supposing Galileo to be the author, Grassi attacked him. Galileo replied in his 'Saggiatore,' a masterpiece of eloquence, pronounced by Algarotti to be the finest controversial work Italy has ever produced, and, notwithstanding the errors contained in it, a work always worthy to be read.

About this time he completed his famous work, in which, without giving his own opinion, he introduces three persons in a dialogue, of whom the first defends the Copernican system, the second the Ptolemaic, while the third appears as a blind and unreasoning supporter of the views of Aristotle. With this work, in which the greatest elegance and accuracy of style is united with the clearest and most concise statements, Galileo went to Rome in 1630, and succeeded in obtaining the privilege to print it. Having obtained the same permission in Florence, he published it there in 1632 — 'Dialogo di Galileo Galilei, dove ne' Congressi di quattro Giornate si discorre de' due massimi Sistemi, Tolemaico et Copernicano.' Scarcely had it appeared when it was attacked by the disciples of Aristotle, and most violently of all by Scipione Chiaramonti, teacher of philosophy at Pisa. A congregation of cardinals, monks, and mathematicians examined his work, condemned it as highly dangerous, and summoned him before the tribunal of the Inquisition. The veteran philosopher was compelled to go to Rome, and in June 1633 was condemned to renounce, in presence of a great assembly, kneeling before them, with his hand upon the Gospel, the great truths he had maintained. "Corde sincero et fide non ficta, abjuro, maledico et detestor supradictos errores et hereses," was the formula which he was compelled to pronounce. Upon this he was sentenced to the dungeons of the Inquisition for an indefinite time, and every week, for three years, was to repeat the seven penitential psalms of David. His 'Dialogo' was prohibited, and his system condemned as contrary to the Bible. His judges were merciful enough to commute his sentence of imprisonment to banishment to the villa of the Grand-duke of Tuscany at Rome, then to the archiepiscopal palace at Sienna, and soon after he was allowed to return to Arcetri, not far from Florence.

He employed his last years here principally in the study of mechanics and projectiles. The results are found in two important works on the laws of motion, the foundation of the present system of physics and astronomy. At the same time he tried to make use of Jupiter's satellites for the calculation of longitudes; and though he brought nothing to perfection in this branch, he was the first who reflected systematically on such a method of fixing geographical longitudes. He was at this time afflicted with a disease in his eyes, one of which was wholly blind, and the other almost useless, when, in 1637, he discovered the libration of the moon. Blindness, deafness, want of sleep, and pain in his limbs united to embitter the last years of Galileo's life. He died in the year Newton was born, and his relics were ultimately deposited in the Church of Sta. Croce, at Florence, where a splendid monument was erected to him near that of Michelangelo.

Galileo was of diminutive size, but strong and healthy. His countenance was agreeable; his conversation lively. He loved music, drawing, and poetry. He knew Ariosto by heart; and in one of his works, first printed in 1793, 'Considerazioni al Tasso,' the product of his leisure hours, he points out the superiority of Ariosto to Tasso, whom he criticises very severely. His style is lively, natural, and fluent. His collected works have been edited by Alberi (16 vols. 1842–56). Consult: Nelli, 'Vita e Commercio Litterario di Galilei' (1821); Brewster, 'Martyrs of Science' (1841); Chasles, 'Galileo Galilei' (1862); L'Epinois, 'Les pièces du procès de Galilée' (1877); L'Epinois, 'La question de Galilée' (1878); 'Galileo Galilei und die Römische Kurie' (1876), Gebler; 'Die Akten des Galileischen Processes' (1877); Favaro, 'Galileo Galilei' (1882); Scarbazzini, 'Galileo Galilei' (1883); Wegg-Prosser, 'Galileo and his Judges' (1889).

Galimberti, Luigi, loo-ē'jē gä-lēm-băr'tē, Italian cardinal and diplomat: b. Rome 1838; d. 1896. He became professor of church history in the College of the Propaganda and of theology in the University of Rome, and was appointed by Pius IX. canon of the Lateran in 1868. From Leo XIII. he received appointment as canon of Saint Peter's, archbishop of Nicæa, and secretary to the Congregation of Extraordinary Ecclesiastical Affairs. He was papal arbiter in the award to Spain, as against Germany, of the Carolines, and in 1880 was sent as ambassador to Germany, where he was successful in adjusting the difficulties of the "Kulturkampf" through the abrogation by the crown of the so-called "May Laws." In 1893 he was made a cardinal and prefect of the papal archives.

Gal'ion, Ohio, a city in Crawford County, on the Erie and the Cleveland, C., C. & St. L. R.R.'s, 81 miles southwest of Cleveland. Galion is an important railroad town, being a connecting point and division terminal. There are railroad shops and round-houses here, brick and tile works, carriage and wagon factories, wheel and gear works, iron foundries, and lumber-mills. The town was originally laid out in 1831, by settlers from western Pennsylvania, and was chartered as a city in 1878. The city owns and operates its electric light and water plants. The government is composed of a mayor, who holds office for two years, and a common council, elected by popular vote. Pop. (1900) 7,482.

Galitzin. See Gallitzin.

Gall, Saint, Irish monk: b. Ireland about 550; d. Saint Gall, Switzerland, about 645. He accompanied Saint Columba to France about 585, and took part with him in all his missionary labors. Banished from France, they went together into the wilder regions of Switzerland, and near the Lake of Constance they founded the monastery which bore the name Saint Gall and gave name to the town and canton of Saint Gall. After a few years Columba retired to Italy, leaving his companion abbot of the new house. The monastery was burnt by Hungarians in the 10th century.

Gall, Franz Joseph, fränts yō'sĕf gäl, German phrenologist: b. Tiefenbronn, Baden, Germany, 9 March 1758; d. Montrouge, near Paris, 22 Aug. 1828. He studied medicine at Strasburg and Vienna, and settled in the latter city in 1785 as a physician. In 1796 he began to give courses of lectures on phrenology (q.v.) in Vienna; but these lectures were prohibited in 1802 by the Austrian government as being subversive of the accepted religion. With Spurzheim, who became his associate in 1804, he quitted Vienna in 1805, and began a lecturing tour through Germany, Holland, Sweden, and Switzerland. He reached the height of his fame when in 1807 he settled as a physician in Paris. On March 14, 1808, he and Spurzheim presented to the Institute of France a memoir of their discoveries, on which a committee of the members of that body (including Pinel, Portal, and Cuvier) drew up an unfavorable report. Thereupon Gall and Spurzheim published their memoir, 'Introduction to Physiology of the Brain'; this was followed by 'Researches on the Nervous System' (1809); and by 'Anatomy and Physiology of the Nervous System' (1810–19) with an atlas of 100 plates. In 1811, in answer to accusations of materialism and fatalism brought against his system, Gall published 'Of the Innate Inclinations of the Soul and Spirit.' He continued to practise medicine and pursue his researches at Montrouge, near Paris, till his death. See Spurzheim, Kaspar.

Gall. See Bile.

Gall-bladder, a pear-shaped bag, attached to the under surface of the liver, the function of which is the storage of bile. It is about four inches long and two inches in diameter at the widest part. It will hold from an ounce to an ounce and a half of fluid. The broad end almost reaches the abdominal wall under the edge of the liver at the border of the ribs, about three inches from the middle line of the body. From a groove on the under surface of the liver two ducts that collect secretion from all parts of the organ join and pass down to the duodenum. The gall-bladder is connected with this common duct by another duct or canal of the same structure. They are all about the size of a quill, but are capable of being distended. Bile is not poured out into the intestine unless the chyme from the stomach passes over the mouth of the duct, but the bile travels down the ducts from the liver, and back through the cystic duct to be stored in the gall-bladder until needed.

Acute catarrhal cholangitis is an acute inflammation of the lining membrane of the ducts, causing swelling of the membrane and obstruction to the outflow of bile. The process is usually an extension of an acute gastritis and duodenitis. Jaundice results from the obstruction to the passage of bile, and aside from this the disease presents the picture of acute gastritis. Three to five weeks usually elapse before the jaundice disappears. Chronic cholangitis is due to the presence of stones, to stricture, to carcinoma, or the pressure on the outside. There is nothing distinctive in its evidences.

Acute cholecystitis is due to infection of the gall-bladder from the intestines by various microbes. It is usually associated with the presence of stones within the bladder. It may be a mere catarrh or may be suppurative, going on to perforation and peritonitis. The symptoms are violent pain, exquisite tenderness on the right side of the abdomen, and a high fluctuating temperature. Operation is usually demanded. Gall-stones, cholelithiasis, a disease attended by the formation of stones within the gall-bladder. These stones are formed chiefly of cholesterin, a normal constituent of the bile. It is held that previous infection and stasis of the bile in the bladder are essential to their formation. Large numbers may be formed and held in the gall-bladder for years without causing disturbance, but there is constant likelihood of inflammation, as well as attempts of the bladder to force out these stones. Stones may be passed directly through the ducts or at any point in the cystic or common duct find lodgment. If stones lodge in the cystic duct no bile can pass into the gall-bladder, but that already there may be added to by a mucous secretion, causing the bladder to distend. This condition is called hydrops of the gall-bladder. A stone lodging in the common duct dams back the bile and causes jaundice of pronounced type.

Hepatic colic is the name given to the intense cramp that accompanies the passage of a gall-stone through the bile-ducts or an attempt at such a passage. There is a sudden excruciating pain in the right side at the free border of ribs or even over the whole abdomen; frequently the pain may shoot up to the right shoulder-blade and arm. The patient rolls and tosses in agony with his face suffused with cold perspiration. Sometimes there is a chill followed by fever. The duration depends on the course of the stone; frequently relief is had in a few hours, only soreness remaining.

D. D. Roberts, M.D.,
Brooklyn, N. Y.

Gall-fly, one of the several minute gall-making insects, as the British ash-fly. See Galls and Gall-makers.

Gall-gnats, a gall-making gnat of the genus *Cecidomyia.* See Galls and Gall-makers.

Gall-stones. See Calculus.

Gal'la. See Nut-galls.

Gallait, Louis, loo-ē gä-lā, Belgian historical painter: b. Tournai, Belgium, 10 May 1810; d. Brussels 20 Nov. 1887. He studied in Tournai, Antwerp, and Paris, where he acquired a name by his portraits as well as his genre and historical paintings. Among his earlier pictures of note were: 'Christ Restoring Sight to a Blind Man'; 'The Strolling Musicians'; 'The Beggars'; 'Montaigne Visiting Tasso in Prison'; 'Abdication of Charles V.' Among his subsequent pictures are: 'Temptation of St. Anthony'; 'The Dead Bodies of Counts Egmont and Hoorn'; 'The Prisoner's Family'; 'The Last Moments of Count Egmont'; 'Alva Signing Death Warrants'; and lastly (1882), 'The Plague at Tournai,' purchased for Brussels Museum at the price of $24,000.

Galland, Antoine, äṅ-twän gä-lōṅ, French Orientalist and archæologist: b. Rollot, France, 4 April 1646; d. Paris 17 Feb. 1715. Attached in 1670 to the French embassy at Constantinople, he three years later accompanied the ambassador to Syria and the Levant. In 1676, and again in 1679, he made other visits to the East. In 1701 he was made a member of the Académie des Inscriptions, and in 1709 professor of Arabic in the Collège de France. The greatest part of his writings relate to archæological subjects, especially to the numismatics of the East; but the work which has secured him the greatest reputation is his translation of the 'Arabian Nights Entertainments' (1704–8), the first translation of these stories made into any language of Christendom. Among his other writings are: 'Remarkable Sayings, Witticisms, and Maxims of the Orientals' (1694), and 'The Indian Tales and Fables of Pilpay and Lokman' (1724).

Gallardo, Aurelio Luis, ō rēl yō loo-ēs' gäl-yär'dō, Mexican poet: b. León, Guanajuato, Mexico, 3 Nov. 1831; d. Napa, Cal., 27 Nov. 1869. He published three volumes of poems: 'Dreams and Visions' (Mexico 1856); 'Clouds and Stars' (Guadalajara 1865); and 'Legends and Romances' (1868); also a collection of poems, 'Home Stories.' He wrote many comedies. The drama, 'Maria Antonieta of Lorena' is regarded as his best work.

Gallas, gäl'läz, an Ethiopian race inhabiting Africa between lat. 9° and 3° S. and lon. 34° and 44° E. Their language is a descendant of the ancient Geez of Abyssinia. They are of average stature, with strong, well-made limbs, skin of a light chocolate brown, hair frizzled but not woolly. Though cruel in war they are frank and faithful to promises and obligations. They are distinguished for their energy, both physical and mental, especially the southern tribes, which pursue pastoral avocations, notably the breeding of horses, asses, sheep, cattle, and camels, and those which live by hunting, especially the elephant. These same tribes are mostly still heathens, though Mohammedanism is rapidly making way among them. The more northerly tribes who dwell about Harar profess a crass form of Christianity, derived from Abyssinia, and for the most part raise cotton, durra, sugar, and coffee. The total Galla population, who call themselves Argatta or Oromo, is estimated at about 3,000,000. Politically they are divided into a great number of separate tribes, which are frequently at war with one another. But their inveterate foes are the Somali, who have gradually driven back the Gallas from the shores of the Red Sea and the extremities of the Somali peninsula, regions which were occupied by them in the 16th century, just as on the other side the Abyssinians and Shoans have beaten them back. The country they now inhabit is a plateau northwest of the Indian Ocean, with a hilly, well-timbered surface.

Gal'latin, Albert, American financier: b. Geneva, Switzerland, 29 Jan. 1761; d. Astoria, N. Y., 12 Aug. 1849. He was graduated at the university there in 1779. In 1780 he went to the United States, and was for a time teacher of French in Harvard College. In 1786 he removed to Pennsylvania, became a member of the State legislature, and in 1793 was elected to the United States Senate, but was declared ineligible. From 1795 to 1801 he served in the House of Representatives, and from 1801 to 1813 was secretary of the treasury, in which post he showed himself one of the first financiers of his day. He took an important part in the negotiations for peace with England in 1814, and signed the Treaty of Ghent. From 1815 to 1823 he was minister at Paris, and in 1826 was sent to London as ambassador extraordinary. On his return in 1827 he settled in New York, and devoted much of his time to literature, being chiefly occupied in historical and ethnological researches. He was one of the founders and the first president of the Ethnological Society of America; and from 1843 to his death was president of the New York Historical Society. His works include publications on finance, politics, and ethnology; among these last are: 'The Indian Tribes East of the Rocky Mountains, etc.' (1836), and 'Notes on the Semi-Civilized Nations of Mexico, Yucatan, and Central America' (1845). Consult Henry Adams, 'Life of Albert Gallatin' (1879).

Gallatin, Mo., city and county-seat of Daviess County, on the Wabash, and the Chicago, R. I. & P. R.R.'s, and on the Grand River, 55 miles northeast of St. Joseph. It is in a farming region and has lumber industries. Pop. (1900) 1,780.

Gallatin, Tenn., town and county-seat of Sumner County, on the Louisville & N., Chesapeake, and Nashville R.R.'s, 26 miles northeast of Nashville, and three miles from the Cumberland River. Its industrial and commercial activities are connected with stock-raising, agricultural products, lumbering, cotton, and woolen manufactures, flour milling, and foundry and machine products. Pop. (1900) 2,409.

Gallaudet, găl-â-dĕt', **Edward Miner,** American educator: b. Hartford, Conn., 5 Feb. 1837. He is a son of Thomas Hopkins Gallaudet (q.v.), and was graduated at Trinity College in 1856. He organized the Columbia Institute for the Deaf, Dumb, and Blind in Washington, D. C., in 1857, and from it developed the Gallaudet College for the Deaf, of which, in 1864, he became president. His publications include: 'Manual of International Law' (1879), and 'Life of Thomas Hopkins Gallaudet' (1888).

Gallaudet, Thomas, American Episcopal clergyman: b. Hartford, Conn., 3 June 1822; d. 27 Aug. 1902. He was a son of T. H. Gallaudet (q.v.); graduated at Trinity College in 1842; was teacher in the New York Institution for Deaf-Mutes 1843-58. He was ordained in 1851; founded and became rector of St. Ann's Church, New York, for deaf-mutes, in 1852; was appointed general manager of the Protestant Episcopal Church Mission to Deaf-Mutes in 1872; and founded the Gallaudet Home for Deaf-Mutes, near Newburg, N. Y., in 1885.

Gallaudet, Thomas Hopkins, American educator: b. Philadelphia 10 Dec. 1787; d. Hartford, Conn., 9 Sept. 1851. In 1817 he founded at Hartford, Conn., the first deaf-mute institution in America, and was president of the same till 1830. In 1838 he became chaplain of the Insane Asylum at Middletown, Conn., where he remained till his death. He was the author of 'Bible Stories for the Young' (1838), and 'The Child's Book of the Soul,' etc. See Lives by Humphrey (1858), and E. M. Gallaudet (1888); Barnard, 'Tribute to Gallaudet.'

Galle, Johann Gottfried, yō'hän gŏt'frēd găl'lĕ, German astronomer: b. in Pabsthaus, Prussia, 9 June 1812. He studied natural sciences and mathematics in Berlin 1830-3; discovered three comets in 1839-40; was the first to observe the planet Neptune (23 Sept. 1846); and in 1851 became director of the observatory in Breslau and professor of astronomy in Breslau University

Gallegos, gäl-yā'gōs, Argentina, a river and city in the extreme southern part. The river rises in the Latorre Mountains and empties into the Atlantic Ocean; length 160 miles. The city is near the mouth of the river in Santa Cruz Territory and has a population of about 5,000.

Gallein, găl'e-ĭn, Pyrogallolphthaleïn. Formula, $C_{20}H_{10}O_7$. Obtained by heating for some hours one part of phthalic anhydride with two parts of pyrogallol from 190° to 200°, then dissolving the fused mass in alcohol, precipitating with water, and recrystallizing from dilute hot alcohol. It is used as a dye.

Gallenga, gäl-lĕn'gä, **Antonio Carlo Napoleon,** Italian publicist and author: b. Parma, Italy, 4 Nov. 1810; d. Llandogo, Wales, 17 Dec. 1895. He left Italy in 1831 by reason of political disturbances, and lived abroad. He represented Piedmont at Frankfort in 1848-9, and was a member of the Italian Parliament 1854-64. He was long the London *Times'* special correspondent in Italy. His works, many of them issued under the name of "L. Mariotti," include: 'Italy, Past and Present' (1841-9); 'Castellamonte, an Autobiography' (1854); 'Mariotti's Italian Grammar,' which went through 12 editions; 'History of Piedmont' (1855-6); 'The Pearl of the Antilles' (1873); and several books of travel.

Gal'leon, a name formerly given to a very large kind of vessel, with three masts and three or four decks, such as those used by the Spaniards in their commerce with South America, to transport the precious metals. They were large, clumsy, square-sterned vessels, having bulwarks three or four feet thick, all of which were so encumbered with tophamper, and so overweighted in proportion to their draft of water, that they could bear very little canvas, even with smooth seas and light winds.

Gallery, in architecture, a long, narrow room, the width of which is at least three times less than its length. Galleries are destined for dancing, music, dining on festival occasions, and are generally decorated with pictures in oil or fresco. Galleries have sometimes been built merely to receive collections of pictures, or to give a painter an opportunity for fresco paintings; hence a large collection of pictures, even if contained in several adjoining rooms, is called a gallery. A celebrated gallery described by Cicero was established by Verres, the well-known spoiler of Sicily. In modern Europe the gallery founded by Cosmo II. in Florence long held the first place; but it has now been eclipsed by several European galleries. The art treasures of Florence now form two collections, that of Uffizi, and that of the Pitti Palace. The Galérie du Louvre in Paris is among the finest in the world, though in 1815 it was stripped of many works of art, reclaimed by the different nations from whom they had been plundered.

Among the other renowned European galleries are those at Versailles and Dresden, the Royal Gallery at Madrid, the Belvedere Gallery at Vienna, the Hermitage at St. Petersburg, the gallery of Berlin, the National Gallery in London, the National Museum at Naples, the Vatican and Borghese collections at Rome, and those in Munich, Brussels, Venice, Antwerp, Milan.

The term gallery is also sometimes applied to what is more properly termed a corridor, or to a platform projecting from the walls of a building supported by piers, pillars, brackets, or consoles, and in churches, theatres, and similar buildings to the upper floors going around the building next the wall. In ship-building, a gallery is a balcony projecting from the stern or quarter of a ship of war, or of a large merchantman; in fortification, a covered walk across the ditch of a town; and in mining to a narrow passage from one part of the mine to another.

Galley, the ancient and mediæval ship of the Mediterranean. The Venetian galleys were about 160 feet long above, and 130 feet by the keel, 30 feet wide, and 20 feet length of stern-post. They were furnished with three masts, and 30 banks of oars, each bank containing two oars, and every oar being managed by six or seven slaves, who were usually chained to it. In the fore part, after the invention of cannon, they had three small batteries of cannon, namely, two 36-pounders, two 24-pounders, and two 2-pounders. They had also three 18-pounders on each quarter, and carried from 1,000 to 1,200 men.

The term galley, as applied to the ships of the ancient Greeks and Romans, refers especially to their war-ships, which were propelled chiefly by oars.

The Greek or Græco-Etruscan vases show many illustrations of biremes, that is, galleys with two banks, or longitudinal rows, of oars. The invention of this form of vessel was a very important advance in naval construction, for it permitted of a large increase in rowing-power, in proportion to the bulk and weight of the vessel. It was the trireme, however, which formed the chief war-ship of Greece during her prime. It had three banks of oars on each side. The seats for the rowers, which were removable, were placed between the sides of the vessel and a series of upright and inclined timbers supporting the main deck. The stem of the vessel was generally curved, and terminated in an ornamental figure-head, and the stern-post was also usually curved upward and finished off ornamentally. At the stern there was an elevated quarter-deck, whence the helmsman and the trierarch or naval captain gave their orders. The latter had full command of the ship; the former acted as navigating officer, having the oarsmen and sailors under his command. The trireme had regularly two masts — a mainmast with one large sail, and a very small foremast.

The rowers formed much the largest portion of the crew, while an Attic trireme carried also 10 marines, 17 sailors, a sort of paymaster, two men in charge of the lines of towers, besides two boatswains, one with a flute, to give the time to the rowers. The total crew would thus be about 220. The total length of a trireme was about 120 feet, of which about 100 was devoted to the rowers; the breadth at the water-line was some 12 feet; and the draught about 5 feet. A speed of 8 or 9 knots was probably about the highest obtainable.

The Romans did not become important as a maritime nation till the period of their struggle with Carthage. They built large numbers of ships, chiefly of higher rates than the trireme. But the triumph of the bireme vessels, known as Liburnian galleys, at Actium led the way for a reversion to lower-rated ships.

Galli, găl'ī, the emasculated priests of the Greek goddess Rhea, afterward identified with the Asiatic Cybele, and worshipped as symbolizing the procreative powers of nature. Cybele was the "Great Mother" and inspired the arts of agriculture. The true home of this cult was Pessinus in Galatia, but it never obtained public recognition in Greece, where the excesses and mendicity of its priests exposed it to contempt. It was introduced into Rome 204 B.C., at the bidding of the Sibylline oracle, and for the purpose of expelling Hannibal from Italy. The Galli were permitted to pass in a procession through the streets of the city, led by an Asiatic priest and priestess, but Roman citizens were forbidden to participate in this service. The cult gained an increasing favor and popularity and in the 2d century A.D. other rites were added, such as baptism in the blood of bulls and rams, by which the devotee was supposed to be cleansed from pollution and regenerated. This baptism was undergone by the Emperor Julian, called the Apostate. The worship of Cybele was checked by Constantine and abolished by Theodosius.

Gallic Acid, $HC_7H_5O_5,H_2O$, is an acid which exists in small quantity in gall-nuts, in valonia (the acorn-cup of *Quercus ægilops*), in dividivi (the pod of *Cæsalpinia coriaria*), in sumach, and other vegetables. It is usually prepared from gall-nuts, which, in addition to gallic acid, contain a large proportion of tannin (tannic acid or gallo-tannic acid). When the gall-nuts are digested with water for some weeks fermentation takes place, and the tannic acid is gradually converted into gallic acid. The same result is obtained more quickly if sulphuric acid be present. To obtain pure gallic acid the gall-nuts are boiled with water, and the hot liquor separated. On cooling gallic acid crystallizes out, and is further purified by solution in hot water and treatment with animal charcoal. It forms delicate, silky, acicular crystals, nearly colorless, and having a sourish taste. It is soluble in three parts of boiling water, but only in 100 of cold water, and on this account it can be readily purified by recrystallization. With solution of iron salts (ferric) it produces a blue-black color, and finally yields a black precipitate on exposure to the air. Hence it may be used in the production of ink, for which purpose it has some advantages over tannin or gall-nuts. When the crystals are strongly heated pyrogallic acid is produced and sublimes over. Gallic acid is a useful astringent. As it does not coagulate albumen it is readily absorbed into the blood, and in this way it is efficacious in Bright's disease. Where a decided local astringent effect is desired tannic acid is much more powerful.

In medicine gallic acid is used as an astringent. In most respects its action is similar to that of tannic acid (q.v.), but it does not coagulate albumen, and therefore does not possess the local action as an astringent. It has been used in excessive sweating, and is useful for sweating feet and as a local spray and gargle in tonsilitis, pharyngitis, and similar affections of the nose and throat.

Gallican Church. See GALLICANISM.

Gallicanism, the tendency to enlarge the prerogatives of a national Church in restriction of the authority of the Roman See. This term more especially describes the manifestation of that spirit in the history of the Church in France, and takes its derivation from the controversies between the French monarchy at various times and the Roman pontiffs in regard to ecclesiastical jurisdiction. It is a mistake to suppose that Gallicanism took its rise in France prior to the 13th century, or that the decrees of Louis IX., including the Pragmatic Sanction, were in any proper sense an attempt to restrict the authority of the Roman pontiffs. So far from this being true, their object was to assure the immunities and franchises accorded to the clergy from the exactions of the royal officers and feudal lords. In his ordinance of April 1228, Louis IX., or rather his mother, Blanche of Castile, the regent, says not a word about the relations of the clergy or the laity with the Roman pontiff, and Pope Innocent IV., in 1250, in a letter to the queen, thanks her for issuing it.

It was not until the time of Philip the Fair that Gallicanism in any proper sense can be said to have manifested itself. That monarch in his contest with the papacy sowed the seeds of the long controversy as to the question of papal jurisdiction, which so long agitated the French Church. As a result of his contest with Boniface VIII., and of the later declarations of the Councils of Constance and Basel, the principles began to be enunciated by the national party; one that the king of France was absolutely independent of the pope in all temporal matters; the other, that the papal power was not absolute, must be exercised within the limits of the canons, and was inferior to that of a general council. By the Pragmatic Sanction passed at Bourges in 1438, the Gallican Church, in union with the king, adopted the decrees of the Council of Basel abolishing papal reservations and expectatives, and restricting appeals to Rome to the *causæ majores.* Against this many popes protested, but it was not until the date of the concordat (1516) between Leo X. and Francis I. that it was abolished.

During the 16th century there were many customs and privileges of more or less ancient date still extant, which the national party delighted to call "Gallican liberties." The crisis came in the 17th century, during the reign of Louis XIV., over the question of the royal right of regalia (q.v.). Two bishops excommunicated the crown nominees to benefices in their dioceses. Their Metropolitans canceled their sentences; whereupon they made appeal to Rome, and the pope annuled the decisions of the Metropolitans. The crown resented the pope's decision as an intrusion upon its rights. Louis XIV. called an assembly of French bishops (1682) to confirm his position. This assembly formulated the famous Four Articles setting forth the "Gallican liberties." The first declared that the jurisdiction of Peter's successor did not extend to civil and temporal affairs, that kings were subject to no ecclesiastical power in temporals, and denied the deposing power of the popes. The second ratifies the third and fourth sessions of the Councils of Constance as regards the respective authority of the pope and general councils, and denies that these sessions refer only to times of schism. The third asserts the validity of the laws, customs, and constitutions of the realm, and of the Gallican Church. The fourth declares that although the pope has the principal share in questions of faith, and that his decrees regard all and particular Churches, still his judgment is not irreformable, unless the consent of the Church be added.

Afterward, at the command of the king, who subsequently realized the radical character of the Four Articles, the bishops who had signed them individually wrote to the pope retracting their *Declaration.* Later Louis himself wrote to Innocent XII., in 1693, stating that he had "given the necessary orders to the effect that the contents of my edict of 22 March 1682, concerning the *Declaration* emitted by the clergy of France, be not observed."

Nevertheless, the spirit of Gallicanism lingered on in France, finding fresh impetus in Jansenism. During the 18th century its strength rapidly waned, and by the time of the French Revolution (1789) it had ceased to have any vital significance.

Gallienus, găl-ĭ-ē'nŭs, **Publius Licinius Valerianus,** Roman emperor: d. 268 A.D. He received the title of Cæsar from the senate at the same time with his father, Valerianus, and associated with the latter in the empire on his accession in 253 A.D. His father having been defeated and taken prisoner by Sapor, king of the Persians, in 260, Gallienus showed complete indifference, and continued to reign alone without making any attempt to deliver his father. With a like indifference he saw his empire dismembered by numerous usurpers, and invaded in all parts by barbarians.

Gallifet, Gaston Alexandre Auguste, gäs-tôṅ äl-ĕks-ändr ō-güst gä-lē-fā, MARQUIS DE, French general: b. Paris, France, 23 Jan. 1830. He joined the army in 1848, serving in the Crimea, Mexico, and Algeria. He took part with the Army of the Rhine during the Franco-German War, being made prisoner at Sedan. During the second siege of Paris he commanded a brigade of the Army of Versailles, and was unenviably distinguished for his frightful severity to the Communard prisoners. Promoted to the rank of general of division 3 May 1875, he obtained the command of the 1st division of cavalry, and in February 1879, that of the 9th regiment. He became minister of war in 1899.

Gallin, in chemistry, gallin, $C_{20}H_{14}O_7$, or $O[C_6H_2(OH)_2]_2.CH.C_6H_4.CO.OH$. Obtained by long boiling gallein and zinc-dust and ammonia, then acidifying with dilute H_2SO_4 and shaking out with ether. It crystallizes out of ether in fine needles, and quickly reddens in the air. It can be used as a dye instead of logwood.

Gallinger, Jacob H., American politician: b. Cornwall, Ont., 28 March 1837. He studied medicine, which he practised from 1858 until his entrance upon public life as a member of the New Hampshire legislature in 1872–3. He was in the State Senate in 1878–80, and its president during the last two years. In 1885–9 he was a representative in the Federal Congress, and in 1891–1903 senator. From 1882 to 1890 he was chairman of the Republican State Committee.

Gallinule. See MUD-HEN.

Gallio, găl'ĭ-ō, **Lucius Junius**, Roman proconsul of Achaia under Claudius when St. Paul was at Corinth, 53 A.D. He was brother of the famous Seneca, and had procured his name by adoption into the family of Gallio the rhetorician. The narrative in the 'Acts of the Apostles' tells how, with regard to the clamor of the Jews against Paul, he was "not minded to be a judge of these matters"; and how "Gallio cared for none of these things"; hence his name has become a synonym for a careless, easy-going, and indifferent man who keeps himself free from trouble and responsibility.

Gallipoli, găl-lĕp'ō-lē, Turkey, a seaport on the peninsula of the same name, at the extremity of the Dardanelles, 130 miles west of Constantinople. The ancient Kallipolis, of which some ruins remain, it was formerly the most important commercial town on the Hellespont, and still retains considerable trade. There are two harbors, extensive bazaars, and some manufactures. The town was taken by the Turks in 1356, and formed their earliest European possession; and here the allies disembarked during the Crimean war. Pop. 20,000.

Gallipoli, Peninsula of, Turkey, a tongue of land separating the Hellespont from the Ægean Sea and the Gulf of Saros, 62 miles long, by a varying breadth of from 4 to 12 miles. Lat. between 40° 3' and 40° 38' N., lon. between 26° 10' and 27° E.

Gallipoli Oil, a coarse olive oil used in Turkey-red dyeing and for other purposes, and prepared from olives grown in Calabria and Apulia, the latter being considered the best. The oil is conveyed in skins to Gallipoli, where it is clarified and shipped in casks.

Gallipolis, găl-ĭ-pō-lēs, Ohio, city and county-seat of Gallia County; on the Ohio River, and on the Columbus, H. V. & Toledo, and the Ohio C. R.R.'s. It contains a United States Marine Hospital, Gallia Academy, the State Hospital for epileptics, Washington High School, and a private epileptic sanitarium. Pop. (1900) 5,432.

Gallitzin, găl-lĕt'sĕn, the name of a noble Russian family whose members have been equally prominent in war and diplomacy from the 16th century downward. VASILI, surnamed the Great (b. 1643; d. 1714); was the councilor and favorite of Sophia, the sister of Peter the Great, and regent during his minority. His great aim was to bring Russia into contact with the west of Europe, and to encourage the arts and sciences in Russia. His design to marry Sophia and plant himself on the Russian throne miscarried. Sophia was placed by her brother in a convent and Vasili banished (1689) to a spot on the Frozen Ocean, where he died. AMALIE, PRINCESS GALLITZIN (1746–1806), daughter of the Prussian general, Count von Schmettau. She was noted for her literary culture, her sympathetic relations with scholars and poets, but, above all, for her ardent piety, which found in Catholicism its most congenial sphere. Having separated from her husband, Prince Dimitri Alexievitch, she took up her residence in Münster, where she gathered round her a circle of learned companions. PRINCE DIMITRI ALEXIEVITCH, diplomat (b. 1738; d. 1803). He was ambassador to the court of France in 1763, and to The Hague in 1773, and was the author of several works relating to geology.

Gallitzin, Demetrius Augustine, PRINCE, American clergyman: b. The Hague 22 Dec. 1770; d. Loretto, Pa., 6 May 1840. He was a son of Prince Dimitri Gallitzin (q.v.), and became a Roman Catholic in his 17th year. He was ordained a priest in the United States in 1795; and betook himself to a bleak region among the Alleghany Mountains in Pennsylvania, where he was known as "Father Smith." Here he laid the foundation of a town called Loretto. He declined to return to Russia on his father's death, and as a Catholic priest was adjudged to have lost his right of inheritance. He was for some years vicar-general of the diocese of Philadelphia. He was austere in his mode of life, but liberal in the highest degree to others, and an affectionate and indefatigable pastor. In 1809 he resumed his original name. He wrote various controversial works, including a 'Defense of Catholic Principles' (1816); 'Letter to a Protestant Friend' (1820), and 'Appeal to the Protestant Public' (1834).

Gal'lium, a metallic element, symbol Ga, atomic weight 69.9. Gallium is a triad element. Specific heat 0.079. It was discovered by the French chemist, Lecoq de Boisbaudran by means of the spectroscope; but the Russian chemist Mendeléeff had shown in his periodic law (q.v.) that an element must exist having intermediate properties between aluminum and indium. He called this supposed element eka-aluminum. The metal is obtained by dissolving the blende in sulphuric acid and placing in the solution plates of zinc. A precipitate containing gallium as a hydrated oxide is thus obtained, and after further solution and precipitation metallic gallium is thrown down by zinc. Gallium is a hard metal, very slightly malleable, and leaves a bluish-gray trace on paper; when melted it adheres to glass; it does not tarnish in the air. Its specific gravity is 5.95. It gives a brilliant violet line in the spectrum. When heated in the air it oxidizes on the surface, and does not volatilize. It dissolves in hydrochloric acid with disengagement of hydrogen. It is scarcely attacked by nitric acid in the cold; when heated it dissolves slowly with evolution of nitrous fumes. It forms salts.

Gallium Chloride, in chemistry, $GaCl_3$ It is colorless, crystalline, and deliquescent.

Gallium Salts, salts precipitated by ammonia. If redissolved by hydrochloric acid, and again precipitated by ammonia, the precipitate is soluble in excess. If zinc is present the gallium is precipitated along with the zinc. Potassium ferrocyanide gives a yellow precipitate with strongly acid solutions of gallium chloride.

Gallon. See WEIGHTS AND MEASURES.

Gallotannic Acid. See TANNIN.

Gal'loway, Beverly Thomas, American horticulturist: b. Millersburg, Mo., 16 Oct. 1863. He was graduated from the University of Missouri, agricultural course, in 1884; was assistant in the horticultural department of the university in 1884–86, and in the United States Department of Agriculture, division of vegetable physiology and pathology, in 1887–8. In 1900 he became director of the office of plant industry. His writings include works on plant diseases, botany, horticulture, and allied subjects.

Galloway, Charles Betts, American bishop of the Methodist Episcopal Church, South: b. Kosciusko, Miss., 1 Sept. 1849. In 1868 he entered the Mississippi conference, and for several years he was pastor of various churches in that State. From 1882 until 1886 he was editor of the New Orleans 'Christian Advocate.' He was also elected president of the board of education of his Church, and published a 'Life of Bishop Linus Parker'; 'Hand-book of Prohibition'; 'Open Letters on Prohibition,' written during his controversy with Jefferson Davis on that subject; 'Modern Missions: Their Evidential Value'; and 'Christianity and the American Commonwealth.'

Galloway, Joseph, American lawyer: b. near West River, Md., about 1729; d. Hertfordshire, England, 29 Aug. 1803. He was admitted to the bar in Philadelphia, and was a member of the Pennsylvania Assembly 1757–74. He held a seat in the Congress of 1774, where he suggested a plan of government headed by a president-general to be appointed by the king and to hold office during the latter's pleasure, and a grand council elected every three years by the assemblies of the several colonies. Before the conclusion of the Revolutionary War he removed to England; and in 1788 was charged with high treason by the Assembly of Pennsylvania, which ordered his estates to be sold. He was the author of: 'A Candid Examination of the Mutual Claims of Great Britain and the Colonies: with a plan of accommodation on Constitutional Principles' (1780); 'History and Political Reflections on the American Rebellion' (1780); etc. Consult: Balch (ed.), 'Examination of Joseph Galloway by a Committee of the House of Commons' (1855); Tyler, 'Literary History of the American Revolution' (1897).

Galls and Gall-makers. Galls are unnatural plant-growths caused by various forms of insects, more particularly by the hymenopterous family of gall-flies (*Cynipidæ*). Gall-gnats (*Cecidornyiidæ*, — minute two-winged midges or flies), many species of mites, some forms of caterpillars, and the larvæ of weevils and other beetles also cause galls. The formation of a gall is due to the puncturing of any portion of a plant, the surface of the leaf, stem, roots, or bark and the deposition of an egg in the cavity formed, or by the presence of the larvæ subsequently hatched from it. Within these excrescences the larvæ feed and grow, and either eat their way out while still grubs or remain till the pupa stage is past and emerge as adolescent insects. A gall may contain a single egg and larva or many, and both external form and internal structure vary widely. Each gall-fly has its favorite or exclusive host, and usually restricts its egg-laying to some special part of the plant. While most produce true galls, some members of the family utilize galls already formed.

Fig. 1.— Bedeguar Gall of Wild Rose.

The reproductive relations of gall-flies are very interesting: in many cases parthenogenesis undoubtedly occurs; in some species, for example, of Rhodites, no males have ever been found; in other forms the males when they occur are very few in proportion to the females. It must be emphasized that many gall-wasps distinguished by entomologists as separate species or even referred to different genera have turned out to be the parthenogenetic and the sexual forms of one species. A common life-history is as follows: (*a*) Out of a summer-gall male and female forms emerge; (*b*) the females lay their fertilized eggs and give origin to winter-galls in so doing; (*c*) from these winter-galls there arise parthenogenetic females which in their egg-laying produce the summer-galls from which we started.

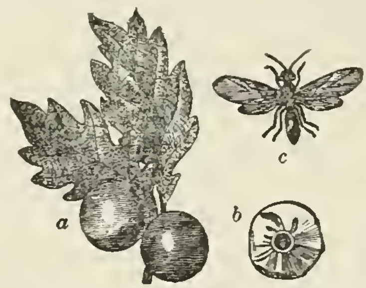

Fig. 2.— *a*, oak gall produced by *Cynips quercus-folii;* *b*, section of gall; *c*, gall-insect (*Cynips quercus-folii*).

Galls vary greatly in shape, and may be solid or spongy, and contain one or several cavities, in each of which a larva is lodged. Though galls are very generally distributed, they occur in commerce chiefly as Levantine articles of trade. The Aleppo nut-galls are spherical and tubercular: blue, black, and white varieties are recognized, the two former being picked before the escape of the larva, the latter after its exit. They are produced by a gall-fly (*Cynips galiæ-tinctoriæ*) on twigs of an oak (*Quercus infectoria*). The galls made on oak by the common British "ash-fly" (*C. quercifolia*), or by the hundred or more American species of Cynips, might serve the purpose of ink making, tanning, etc., just as well; the 70 to 80 per cent of tannin they contain is the principal element of value. Dead Sea Apples, or Mecca or Bussorah galls, or Apples of Sodom (*mala insana*, or *C. q. infectoriæ insana*), are varieties of this vegetable product. The artichoke or strobile galls consist of several pieces, and resemble the fruit (strobilus) of the hop; it is due to the abnormal development of the female involucre before fecundation; its insect is the *C. q. gemmæ*. The hairy galls, or bedeguars, or rose sponges, are chiefly found on *Rosa rubiginosa;* they are produced by *Rhodites rosæ*.

Consult Howard, 'The Insect Book' (New York, 1901), and accompanying bibliography.

Gallus, Caius Cornelius, Roman poet: b. Forum Julii (modern Fréjus), Gaul, about 66 B.C.; d. 26 B.C. He lived at Rome in intimate friendship with Vergil, Asinius Pollio, Varus, and Ovid, and was appointed by Augustus prefect of Egypt, but fell into disfavor and was banished, whereupon he ended his disgrace with his own sword. Gallus was reckoned the founder of the Roman elegy, from his four books of elegies on his mistress Lycoris, of which but a few slight fragments have come down to us. His name was adopted by W. A. Becker as the title of his well-known picture of Roman domestic life: 'Gallus: Roman Scenes from the Time of Augustus' (1838).

Gally, Merritt, American inventor: b. near Rochester, N. Y., 15 Aug. 1838. He was graduated at the University of Rochester in 1863; and later turned his attention to mechanics. His inventions include the "Universal" printing-press; a machine for making linotypes; electric, telegraphic, and philosophical apparatus; musical instruments, including the "Orchestrone," the "Black-Vent System" for tubular church organs; the "Counterpoise Pneumatic System" of the automatic musical instruments, etc.

Galois, Evariste, French mathematician: b. Bourg-la-Reine 1811; d. Paris 1832. He obtained his early education in the Collège de Louis-le-Grand and entered the Ecole Normale in 1830, while there writing a theorem on the solubility of irreducible equations of prime degree by radicals, six articles on the theory of equations and theory of numbers, and with others founded the theories of groups and functions. His works were published in Paris (1897). See EQUATIONS, GALOIS THEORY OF.

Galoparo, gäl-ō-pä'rō, or **Capo di Faro,** kä'pō dē fä'rō, the Charybdis of the ancients. It forms the whirlpool on the outside of the harbor of Messina, in the strait separating Italy from Sicily. Opposite, on the Italian coast, is the rock Scylla.

Galt, gâlt, SIR **Alexander Tilloch,** Canadian statesman: b. London, England, 6 Sept. 1817; d. Montreal 19 Sept. 1893. He was a son of John Galt (q.v.) and went to Canada while still a boy. He made a fortune in the service of the British and American Land Company; was Canadian minister of finance in 1858–62, 1864–6, and in 1867; and Canadian high commissioner to England in 1880–3. He published 'Canada from 1849 to 1859.'

Galt, John, Scottish novelist: b. Irvine, Ayrshire, 2 May 1779; d. Greenock, Scotland, 11 April 1839. In 1804 he went to London, and entered into a mercantile partnership, but the venture soon ended in bankruptcy. He then resolved to try the legal profession, and entered himself at Lincoln's Inn, but made small progress in his studies, and quitted England in 1809. He made a tour of the south of Europe and the Levant, and on his return in 1812 published 'Voyages and Travels in the Years 1809, 1810, and 1811,' and 'Letters from the Levant.' The same year appeared his 'Life of Cardinal Wolsey,' and also a volume of tragedies, which received a rough handling from the 'Quarterly Review.' Among his other literary labors of this period was the tragedy of 'The Witness,' a life of West the painter, and a romance on the legend of the 'Wandering Jew.' In 1820 and 1821 the 'Ayrshire Legatees,' a series of letters descriptive of a supposed visit by a Scottish minister's family to London, appeared in 'Blackwood's Magazine,' and attracted universal attention. Its success induced him to publish immediately afterward his 'Annals of the Parish,' which was received with no less approbation. 'The Provost,' 'The Steamboat,' 'Sir Andrew Wyllie,' and 'The Entail' appeared in rapid succession. These were all extremely popular, but his subsequent novels, 'Ringan Gilhaize,' 'The Spaewife,' and 'Rothelan,' did not sustain the reputation which he had acquired. From 1826–29 he was superintendent to the Canada Company. While in Canada he founded the town of Guelph. He wrote the novel of the 'Last of the Lairds.' After his return to England he set himself resolutely to work, however, at his literary tasks, and produced successively 'Laurie Todd'; 'Southennan'; 'Life of Lord Byron'; 'Autobiography of John Galt'; 'Literary Life and Miscellanies of John Galt,' in three volumes.

Galt, SIR **Thomas,** Canadian jurist: b. London, England, 17 Aug. 1815. He went to Canada 1832 in the employ of the Canadian Land Company, was admitted to the bar 1845 and practised in Toronto. He became Queen's Counsel 1858, Chief Justice of the Court of Common Pleas 1887, retiring in 1894. He was knighted in 1888.

Galt, Canada, town of Waterloo County, Ontario, on the Grand River, the Canadian P. and the Grand T. Rys., 25 miles northwest of Hamilton; named for John Galt (q.v.). The town is picturesquely situated on both sides of the river which is here crossed by several bridges. It is substantially built and lighted by gas and electricity; an important jobbing centre; the seat of a United States consular agent; and has manufactories of flour, axes, paper, woolens, leather, foundry products, wooden-ware, and paper. It has several churches, good schools, a collegiate institute, a public library and reading-room, banks, and daily and weekly newspapers. Pop. (1901) 7,866.

Galton, gâl'tǒn, **Francis,** English scientist: b. Duddeston, England, 1822. He was educated at King Edward's School, Birmingham; studied medicine at the Birmingham Hospital and King's College, London; and graduated from Trinity College, Cambridge, in 1844. Having in 1846 traveled in North Africa, he explored in 1850 lands hitherto unknown in South Africa, publishing his experiences in his 'Narrative of an Explorer in Tropical South Africa' (1853), which obtained the gold medal of the Royal Geographical Society, and in 'Art of Travel' (1855). His investigations in meteorology are recorded in 'Meteorographica' (1863). A member of a Meteorological Committee of the Board of Trade, he was appointed one of the committee entrusted with the parliamentary grant for the Meteorological Office. Later he specially devoted himself to the problem of heredity, publishing: 'Hereditary Genius: its Laws and Consequences' (1869); 'Experiments in Pangenesis' (1871); 'English Men of Science: their Nature and Nurture' (1874); 'Life-History Album' (1884); 'Natural Inheritance' (1889); 'Finger Prints' (1893); 'Fingerprint Directory' (1895), etc. He was general secretary of the British Association in 1863–8; president of the Anthropological Section in 1877 and 1885; and president of the Anthropological Institute in 1885–6.

Galuppi, Baldassare, bäl-däs-sä-rä gä-loo'pē, Italian composer: b. island of Burano, near Venice, 18 Oct. 1706; d. Venice 3 Jan. 1785. He was sometimes called «Il Buranello.» From 1722 he was an organist in Venetian churches, and he early wrote an opera, 'Gli amici rivali.' After study of advanced composition as a pupil of Lotti, he again turned to writing, and achieved notable success with more than 70 comic operas, among them: 'Il mondo della luna,' and 'Il mondo alla rovescia.' He has generally been considered the originator of comic opera (opera buffa) in Italy. From 1741 he was for some time resident and active in London, in 1762 became maestro di capella at St. Mark's and director of the Conservatorie degli Incurabili, and in 1765–8 was in Russia as court composer and director of music. He wrote also some sacred works, but none of his compositions is known to-day save a harpsichord sonata which finds place in Pauer's 'Alte Klaviermusik.' He is apostrophized by Browning in 'A Toccata of Galuppi's.'

Galva, Ill., town in Henry County, on the Chicago, B. & Q. and the Rock I. & P. R.R.'s; 45 miles southeast of Rock Island and 48 miles north-northwest of Peoria. It is in a rich agricultural and coal region, on one of the highest points of the dividing ridge between the Mississippi and Illinois river-basins, and besides coal-mining, has considerable manufacturing interests. It has two banks and two weekly newspapers. Pop. (1900) 2,682.

Galvani, Luigi, loo-ē'jē gäl-vä'nē, Italian physiologist; the discoverer of galvanism: b. Bologna 9 Sept. 1737; d. there 4 Dec. 1798. He studied medicine, and in 1762 entered on the practice of his profession. His favorite studies were anatomy and physiology. He soon received the appointment of professor of anatomy in the celebrated institute of his native city, and published a treatise on the urinary vessels of birds. While engaged in these pursuits he was fortuitously led to the discovery which has immortalized his name. His wife, the daughter of Galeazzi, a medical professor under whom he had studied, and a woman of superior intelligence, having observed that the contact of the inanimate body of a skinned frog with a scalpel lying on the table produced in the frog a series of remarkable muscular convulsions, the knife being in contact with an electric machine, informed her husband of the fact, who instituted a series of experiments, and formed conclusions which led to a controversy with Volta. On a journey to Sinigaglia and Rimini he was so fortunate as to trace the cause of the electric appearances which are observed in the torpedo, and wrote a learned treatise on this subject. The loss of his beloved wife in 1790 rendered him inconsolable. Having refused to take the oaths to the Cis-Alpine Republic, he was deprived of his chair, and refused to resume it, when the government, in consideration of his celebrity, offered to allow him to do so unconditionally. In Rome a medal was struck with his effigy.

Galvanic Batteries. See PRIMARY BATTERIES.

Galvanism. See ELECTRICITY; GALVANIZATION, TREATMENT OF DISEASE BY.

Galvaniza'tion, Treatment of Disease by. Of the different forms of electricity used in medicine the galvanic current is perhaps the most widely employed. It may be administered either locally or centrally; local galvanization is used especially for the relief of pain. It is applied to the brain, eye, ear, sympathetic nervous system, spinal cord, urethra, bladder, and chest, either by what is known as «stabile» application, in which both electrodes are kept in a fixed position, or by «labile» application, in which one or both electrodes are slid over the surface, but not lifted from the skin. It is found that a greater sedative influence is obtained if the galvanic current is not interrupted. Labile and stabile interrupted currents are generally preferred for the galvanization of muscles of the head, spinal cord and nerve-tracts. Stabile continuous currents, either uniform or increasing, give the best results. When the galvanic current is interrupted it causes, as is well known, pronounced muscular contraction. This is of service as a tonic to poorly nourished and atrophied muscles.

By «central» galvanization is meant that mode of treatment by the galvanic current by which the entire central nervous system may be brought under the influence of the electrical fluid. In order to accomplish this, one electrode, usually the negative, is placed over the solar plexus, at the pit of the stomach, while the other is firmly pressed to the top of the head and passed gradually over the back of the head and along the inner border of the strong muscle that pulls the neck to one side, the sternoclidomastoid. From here the electrode is passed down the spine. It is thought to increase the electrical excitability of the central nervous system, inducing sleep and relieving general tire. It is a method, however, that should be used with great caution, as it may do more harm than good. See ELECTRICITY, MEDICAL USES OF.

Galvanized Iron, sheets of iron coated with tin by a galvanic process, and with a second metal, zinc, which is effected by preparing a bath of fluid zinc covered with sal ammoniac mixed with earthy matter. When the tin-coated sheet is plunged into this preparation the zinc is precipitated with a crystal-like diaper upon the tin. The term is sometimes improperly applied to sheets of iron which have been coated with zinc without recourse to the use of galvanism. The iron, after being thoroughly cleaned from all trace of oxydization, by a dilution of sulphuric acid, is then plunged into a bath of melted zinc and other substances such as sal ammoniac, or mercury and potassium.

Galvanocau'tery, the use of a cautery knife, loop, point, or blade heated by the passage of a galvanic current. It is of value wherever a limited cautery action is desired, and particularly valuable in being easy to control.

Galvanometer, an instrument for measuring the intensity, direction or length of duration of an electric current. The many types of indicating instruments such as voltmeters and ammeters, where the pointer is held at zero by some directive force, such as the earth's field, a spring or weight or a permanent magnet, come under this head. With very few exceptions, all galvanometers may be classed under two heads: (1) Those having a magnetized needle suspended so as to move freely in a horizontal plane, the needle being normally held at zero position by means of the earth's field or an external field produced by auxiliary magnets placed to accomplish this result. The needle is suspended on a pivot or a quartz fibre or fibre of silk or other appropriate material. (2) Those having a coil of wire in place of the needle in the first class. This is the type usually called the d'Arsonnal type, and has the coil suspended by means of a fine wire, which provides a way for leading current to the coil, and has another wire underneath the coil for conducting the current from it. The coil, with the conducting wires, is then suspended between the poles of a magnet, its axis being normally at right angles with the lines of the field. The second class of galvanometers, those having a moving coil, are to be preferred for most classes of work, all except those requiring the very greatest delicacy, for the following reasons: The readings are but very slightly affected by the presence of an external field or by magnetic substances in vicinity of the instrument, and are practically independent of the variable influence of the earth's field; this form of instrument may easily be made dead-beat, on account of the strong field in which the coil moves; many forms are portable, and much less affected by vibrations than those of the first class.

The figure of merit of a galvanometer may be expressed either as the current necessary to cause a deflection of one scale division, or as the resistance through which one volt will cause a deflection of one scale division when such resistance is inserted in the circuit. Such an expression of the delicacy of a galvanometer should be accompanied with the following data: The resistance of the instrument, the scale distance and size of one division of the scale. The sensitiveness of a galvanometer is expressed as the difference of potential across the galvanometer terminals necessary to cause a deflection of one scale division; and to be exact, should be accompanied with the same data as for the figure of merit. Of the moving needle class of galvanometers the tangent galvanometer and the Thomson astatic galvanometers are probably in most general use. The tangent galvanometer is constructed so that the inside diameter of the coil which surrounds the needle is at least 12 times the length of the needle. Under these conditions, the needle being held at zero by the earth's field, the current strength will vary directly as the tangents of the angle of deflection; hence the name of the instrument. Although at one time much used for the absolute determination of current strengths, it has of late been replaced by other types, on account of its many correction factors, some of which are of uncertain magnitude, a prolific cause of error being the necessity of knowing the exact value of the horizontal component of the earth's magnetism, which quantity is subject to continual change and is affected by large masses of iron or heavy electric currents in the vicinity.

The Thomson Galvanometer.— This type was designed by Lord Kelvin, and to him we are indebted for the most sensitive instruments as yet made. The moving system consists of a slender quartz rod to the centre of which is fastened a small mirror of glass. Above and below the mirror at each end of the quartz rod is fastened a complex of carefully selected magnetized needles, minute in size, placed parallel to the plane of the mirror. In the upper complex the north poles of the needles are all placed in one direction, and in the lower complex the north poles of the needles are placed in the opposite direction, the combination forming an astatic system, on which the earth's field exerts a very slight directive force. This directive force exerted by the earth's field would be zero if the two complexes could be made exactly equal in magnetic strength. Each complex of needles is enclosed by two coils, thus making four coils in an instrument. These coils are provided with binding posts for series or parallel connection, and are connected so that the current flowing through them will cause the magnetized needles to be deflected in the same direction in each complex. An adjustable magnet mounted on top of the instrument provides a directive action on the needles which may be modified to any extent, a weak directive force increasing the sensitiveness greatly, and also increases the period of oscillation, so that in the best instruments the sensitiveness is limited largely to the patience of the observer.

Moving Coil Galvanometers.— This type is most familiar in the d'Arsonnal galvanometers, and is to be preferred for most purposes within the limits of its sensitiveness. Its preference lies in the fact that it may easily be made dead-beat, and the readings are practically independent of the earth's field or magnetic substances in its vicinity. The construction also adapts itself to a portable type of instrument, and it may be so constructed as to be very slightly affected by vibrations. The sensitiveness of this class of galvanometers may be further increased by substituting an electro-magnetic field for that produced by permanent magnets. Consult: Nichols, 'The Galvanometer.'

J. E. Taylor,
Western Electric Company, Philadelphia.

Galveston, Texas, city, port of entry and county-seat of Galveston County, on Galveston Island, at the mouth of Galveston Bay. It is on the Southern Pacific, the Missouri, K. & T., the Gulf, C., & S. Fe, the International and Grtat Northern, the Galveston, Houston & Henderson, and the Gulf & Interstate Railroads. The city, which includes Pelican Island, has a total area of 13 square miles.

Trade and Commerce.— Galveston is the natural entry port for the great Southwest. The trade year beginning 1 September, showed for the year of 1902–03 the breaking of many records. Comparative figures are as follows: Cotton receipts (1902–03) 2,093,070 bales; (1901–02) 2,090,710 bales. Bank clearings $413,185,000, an increase of $40,946,200. Galveston has advanced from fourth to third place in its rank among exporting ports of the United States. The total value of foreign exports and imports for the trade year (1902–03) was $105,632,087; (1901–02) $97,691,312. Total value of goods handled over the Galveston wharves (1902–03), $447,910,707; (1901–02) $246,567,246. Cash receipts at the custom-house from all sources (1902–03), $448,519; (1901–02) $220,321. The total value of foreign exports (1902–03) $104,121,087; (1901–02), $96,181,423. The foreign imports for 1902–03, were $1,511,334; (1901–02), $1,192,758. The total value of foreign goods imported over the Galveston wharves during 1902 was $3,233,039. A statement of the total tonnage entered or cleared at the port for 1902 shows 1,340 vessels with a tonnage of 3,094,903, compared with a total of 1,042 vessels, with a tonnage of 2,222,928 for 1901. The coastwise trade during the year 1902–03 more than doubled that of the previous year. Galveston has 53 lines of steamships to foreign ports. There are two regular lines of coastwise vessels to New York and 9 lines of coastwise vessels to points in the gulf. During 1902–03 over 90,591 loaded cars were handled in the yards of the Galveston wharf company by the various railroads, compared with a total of 77,139 loaded cars handled during 1901–02. The domestic exports are cotton, wool, hides, oil cake and oil meal, cottonseed oil, fish oil, cement, and poultry. The domestic imports are drugs, boots and shoes, hats, dry goods, chemicals and like commodities. The foreign exports are cotton, cottonseed oil, oil cake and meal, wheat, corn, flour, copper and iron ores, cattle, lumber and timber, and provisions. The foreign imports include fire brick, tiles, chemicals, cement, liquors, earthenware, prepared vegetables, and fancy woods. There are four export grain elevators, with a storage capacity of 4,000,000 bushels and one clearing and conditioning elevator. There are six miles of completed wharfage covered with sheds and a complete railroad trackage system which covers about 50 miles.

Public Buildings.—Galveston has 31 churches for white people and 12 churches for colored people, two orphan asylums, a home for homeless children and a home for aged women; the School of Medicine of the State University, 12 private or sectarian schools, a Roman Catholic university, two Roman Catholic academies, a business college and public high school and five graded schools for white children. One high and two graded schools for colored children; a library building which cost $150,000 endowed with a fund of $400,000; a Masonic temple and a Scottish rite cathedral.

Finances and Industries.— The city has eight private and two national banks, 21 building, loan, abstract and real estate corporations. The waterworks, fire department, sewer system and street electric-light plants are owned by the city. The waterworks plant is valued at $1,550,000. The supply of water comes from artesian wells on the mainland and is piped under the bay. Two daily papers and eight weekly papers are published here. The city has two thoroughly equipped hospitals; 12 hotels; a large jobbing trade; bagging mills, rope mills, brewery, cement and pipe works, ice plants, iron works, sash, door and blind manufactories, cotton presses, clothing, cotton oil, flour, meal, coffee, baking powder, spices, extracts, pickles, preserves, macaroni and mineral water manufactories, and rice-mills.

Here is the recognized finest beach in the world, 30 miles long, sea-bathing, fishing, boating, driving and riding facilities unsurpassed and semi-tropical winters and balmy summer breezes offer a delightful climate the year round. Annual average temperature 69 degrees. Average temperature for July 84 degrees. Average temperature for January 53 degrees. Average annual rainfall 46 inches. The rate of taxation for the city is $1.70 on the $100 and for the State and county $1.44⅔. Total tax rate $3.14⅔ on the $100. The assessments of the city for 1903 were $20,574,000 and for the county $21,895,950.

Government.— The State legislature in 1901 placed the city under a commission. This government has proved most satisfactory and is being run on a basis of about $100,000 a year cheaper than the previous municipal administration. The State legislature also provided for the refunding of the bonded floating indebtedness of the county and for grade raising bonds. Authority was also granted to issue bonds on the approval of two thirds of the tax-paying citizens for breakwater purposes. The city commission appointed a board of engineers and plans for protection calling for an expenditure of $3,505,000 were adopted. The bonds were voted almost unanimously and more than $1,000,000 of the $1,500,000 voted for breakwater purposes were subscribed for by Galveston people. The State legislature granted Galveston for a period of 17 years the State's portion of taxes on city property. This amounts to about $80,000 per year. The money thus derived is to be used for the purpose of raising the grade of the city.

The Sea Wall.— Work on the Galveston sea wall was begun in October, 1902. Half the work on the structure was completed in September 1903. The wall will be 17,593 feet long, 16 feet wide at the base and 17 feet high. (See GALVESTON SEA-WALL.)

History.—About the year 1782 a Spanish fleet made an examination of the coast of the Gulf of Mexico west of the Mississippi River, and named Galveston Bay and island in honor of Conde de Galvez, then governor of Louisiana. The explorers found on the island one white man who subsisted by hunting and fishing. Galvez was governor of Louisiana from 1780 to 1785. Until the year 1816 Galveston island remained in its primeval state, a low island formed in process of time by the sea throwing up sand and shells. The conjecture that La Salle visited Galveston island during his brief stay in Texas is without reasonable foundation. The island was long a favorite hunting ground for the Caroñkawas, the once powerful and warlike tribe which inhabited so much of the coast of Texas. Francisco Zavier Mina, a young Spanish soldier, resolved to lend the patriotic cause in Mexico his sword and aid the people of that country in their struggle for liberty. He determined to make Galveston island his base of operations. He worked in co-operation with Don Luis Aury, a naval officer. His plan was approved by Herrara, commissioner of the Mexican revolutionary or Morelos government to the United States. Herrera, with Aury, landed on Galveston island with an expedition in September 1816. A government was organized, Aury was made civil and military governor of Texas and Galveston island and took the oath of fealty to the Republic of Mexico. In November 1816, Mina arrived at Galveston with a few small vessels and about 200 men. Mina and Aury abandoned the island in March 1817. Just about the time they left Galveston island we have the first account of Lafitte coming to the island. The pirate is supposed to have reached Galveston late in 1816. He held letters of marque from the revolutionary government of Venezuela authorizing him to prey upon the commerce of Spain. He had a number of vessels and quite a force of adventurers. He also assumed to be governor of Texas under the revolutionary government of Mexico, probably having received some such authority from Herrera, the Mexican commissioner in New Orleans. Lafitte's purpose was to capture Spanish vessels sailing under the flag of the Mexican republic. By the close of the year 1817 the population of Galveston had increased to nearly 1,000. The United States and Spain found cause for complaint against the pirates, but Spain feared the United States would claim the island if the pirates were dispersed by the American naval establishment, and the United States did not feel called upon to take action, owing to the attitude assumed by Spain, consequently Lafitte was left undisturbed. In 1820 an American vessel was taken by Lafitte's men. The United States government then dispatched an armed vessel under Lieut. Kearney to break up the establishment at Galveston. Lafitte left Galveston for good, but continued his depredations upon Spanish shipping until 1826. In 1820 Dr. James Long visited Galveston island to induce Lafitte, who was about leaving Galveston, to co-operate with him in the establishment of a government at Nacogdoches. Lafitte referred to the failure of all previous attempts to invade Texas and refused to join Long. Before Long left Bolivar Point a French sloop freighted with wine stranded on Galveston island. Caroñkawas to the number of 200 were encamped in the vicinity. They attacked and butchered the crew, plundered the sloop and engaged in a drunken jollification. Long determined to chastise them. After nightfall with 30 men he passed over to the island in small boats. In the fight the Caroñkawas outnumbered the whites seven to one. Long was compelled to retreat. Three of his men were killed; 32 Indians were left dead on the field.

Little is heard of Galveston island after Long's expedition until just previous to the battle of San Jacinto. The island was practically abandoned from 1820 until along in the thirties, when the Mexican government established a custom-house on the island. On the occasion of the preliminary meeting at Brazoria to declare the independence of Texas in 1835 there was no representative present from Galveston. The same is true of the more formal declaration of independence which was made on 2 March 1836, at Washington on the Brazos. Just prior to the battle of San Jacinto the new Texas government retreated from Washington to Harrisburg. As Santa Anna and his army approached Harrisburg, President Burnet and his cabinet sailed down to Galveston island, narrowly escaping capture. The news of the victory at San Jacinto reached President Burnet on Galveston island 26 April 1836. The provisional government of Texas under Governor Smith in 1835 had granted letters of marque and reprisal and had provided for the establishment of a small navy. The Liberty, one of the vessels of this navy, was at Galveston at the time of the battle of San Jacinto. Several prizes were taken by the Texas navy and brought into Galveston Bay. During the hostile period following the battle of San Jacinto the Mexican government proclaimed a blockade against the ports of Texas and in attempting to enforce it interfered with vessels of the United States. In 1837 the Texas navy was increased and several vessels were stationed at Galveston. The third congress of the Texas republic assembled at Houston in November, 1838. The County of Galveston was represented for the first time in the third house of representatives by Moseley Baker. After the annexation of Texas and the outbreak of the Mexican War the first Texas regiment to join General Taylor was composed of six months' men raised and organized in Galveston, commanded by Albert Sydney Johnston. Galveston County was created 15 May 1838. The battle of Galveston during the Civil War, occurred 1 January 1863. The first railroad begun in Texas was at Harrisburg in 1852. The Galveston, Houston and Henderson road was begun at Virginia Point in 1855. Trains were first run from Virginia Point to Houston in 1859 and in that year a contract was let for the first Galveston bay bridge, which was completed and trains were run into Galveston in 1860.

The jetties at Galveston were completed in 1896, since which time the water at the point where the bar existed has been slowly deepening. (See Galveston, Jetties at.) Galveston wharves are only one hour from the deep sea for a laden steamer. Galveston wharf and terminal facilities, as a system, have few equals in the country, being excelled in no particular except size.

In December, 1836, Colonel Michaël B. Menard purchased of the Republic of Texas for the sum of $50,000 one league and labor of land on the east end of Galveston island. He associated with him a number of persons and they formed a joint stock company known as the Galveston City Company, which was incorporated in 1841. This company is still in existence, although its present holdings of real estate are not large. The city of Galveston was incorporated in 1839. The first mayor was John M. Allen.

Galveston has had three noted philanthropists. George Ball gave the city the Ball High School, which cost $100,000 and has been added to since his death by his widow and son. He also left $50,000, the interest of which is to be used for the poor and deserving of the city. John Sealy presented the city with the Sealy hospital, which has cost over $100,000. Henry Rosenberg left $30,000 for an orphans' home, $30,000 for Grace church, $30,000 for a home for aged women, $65,000 for a Y. M. C. A. building, $50,000 for a monument to the heroes of the Texas revolution of 1836, $30,000 for drinking fountains, $150,000 for a library and $400,000 with which to endow the same. He also presented the city before his death with a $100,000 school building, which is known as the Rosenberg school.

The property loss at Galveston occasioned by the storm of 8 Sept. 1900, was $17,058,275. The loss of life on the island is estimated at 6,000. The total cash receipts of donations made to flood sufferers amounted to $1,243,495.

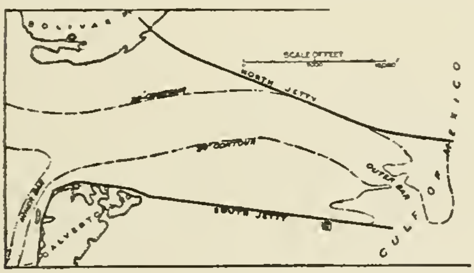
Population.— (1880) 22,248; (1890) 29,084; (1900) 37,789. The population of Galveston,

according to the City Directory for 1903-04 is 32,745.
R. G. Lowe,
Vice-President of the Galveston News.

Galveston Bay, an inlet of the Gulf of Mexico, extending northward from Galveston about 35 miles.

Galveston Island, an island off the coast of Texas on the northeastern end of which is Galveston. Length, about 28 miles.

Galveston, Texas, Jetties at. The entrance to Galveston harbor was originally obstructed by an inner bar upon which the depth of water was 9½ feet and an outer bar with a depth of 12 feet. The Federal government adopted the jetty system for improving the entrance to this harbor. Two jetties have been constructed of sandstone riprap and are covered with granite blocks weighing from 5 to 12 tons each. The south jetty is 35,603 feet in length and the north jetty 25,907 feet in length. They are to be built to a height of 5 feet above mean low tide and are from 12 to 15 feet in width at the top with a slope of about 1½ feet to each vertical foot in depth. The distance between the shore ends



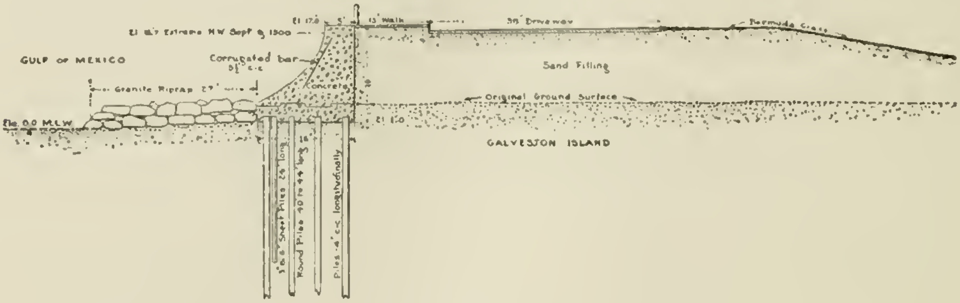
of the jetties is about two miles, they converge until their sea ends are about 7,000 feet apart. There had been expended to 30 June 1902 on this work $8,519,684.42. The jetties, by confining the water, has increased the tidal scour and secured a depth of over 26 feet at mean low tide on both bars. These works were damaged by the hurricane of 8 Sept. 1900, but have been repaired with granite blocks of ten tons weight. There is every assurance of securing, when this work is completed, not less than 30 feet of water at mean low tide.
Walter Gresham.

Galveston, Military and Naval Operations at. In the summer of 1862 Farragut sent several light squadrons to cruise along the coast of Texas, and a blockade was maintained against Galveston, which was abandoned by the Confederate military forces, and 8 October surrendered by its civil authorities to Commander Renshaw of the United States Navy. Six United States vessels lay in the bay, commanding the city. 7 November Lieut. Jouen, with two launches, captured and burned the privateer Royal Yacht, carrying one heavy gun, and took 13 prisoners, with a Union loss of two killed and seven wounded. On 24 December, 260 men of the 42d Massachusetts regiment were landed and encamped on the city wharf. At daybreak, 1 Jan. 1863, Gen. Magruder, the Confederate commander in that department, made a combined naval and land attack upon the Union fleet in the bay and the military in the city. He secured four steamers from the adjacent rivers, used cotton-bales for armor, mounted them with guns and filled them with sharpshooters, and attacked the six United States vessels. The Westfield was blown up and destroyed by her officers to prevent capture; the Harriet Lane was boarded, and surrendered after her captain and executive officer had been killed. One of Magruder's boats went to the bottom in its encounter with the Harriet Lane. The land force was attacked by a largely superior force and, after a stout resistance, in which it had 20 men killed and wounded, surrendered. Magruder reported his loss as 26 killed and 117 wounded. The other United States vessels then abandoned the blockade, but Farragut quickly restored it, soon after which, 11 January, a strange vessel was seen outside and the Hatteras was sent to overhaul her. She proved to be the noted Alabama, and after a short and hot fight she sunk the Hatteras, saving her crew. Ten days later the Union gunboats Velocity and Morning Light, blockading Sabine Pass, were attacked by Confederate steamers, driven out to sea, and captured, with guns, prisoners, and a large amount of stores. Galveston remained in Confederate possession until the close of the war. Consult: 'Official Records,' Vol. XV.; Mahan, 'The Gulf and Inland Waters'; Maclay, 'History of the Navy,' Vol. II.; Lossing, 'Field Book of the Civil War,' Vol. II.; the Century Company's 'Battles and Leaders of the Civil War,' Vol. III.
E. A. Carman.

Galveston Sea-wall. The date 8 Sept. 1900, in Galveston, Texas, will be referred to by its inhabitants for generations to come. The appalling loss of life and the destruction of property on that date, due to the terrific West Indian hurricane which drove the waters of the Gulf of Mexico over the oleander city, shocked the civilized world. Over 6,000 lives were sacrificed to satisfy the storm king's anger, and over $17,000,000 worth of property was completely destroyed. The city of Galveston is located on the east end of an island about 30 miles in length and from one to three miles in width. The entire south side of the island fronts on the Gulf of Mexico, while the north side fronts on Galveston Bay. As to the frequency of hurricanes, and the probability of Galveston being visited again, is a matter of mere conjecture. This city was settled in 1847, and since that time has been visited by six storms, none of which, however, caused the loss of exceeding three lives. In September 1875 a hurricane swept over the island, causing considerable damage to property. At this time the convention was in session which framed the present Constitution of the State of Texas. The impression produced by this hurricane led to the insertion of Sections 7 and 8, in Article XI. of the Constitution, granting all counties and cities bordering on the coast of Mexico the right to issue bonds and construct sea-walls, or breakwaters. Judge Wm. P. Ballinger, one of Galveston's most honored citizens and a lawyer of marked ability, was a member of this constitutional convention, and the author of the sections before named. On 28 Aug. 1886, having in mind a storm which swept the city on the 20th day of that month, Judge Ballinger addressed an open letter to the citizens of Galveston, calling to their attention this constitutional provision and warning them of the great necessity for the construction of a sea-wall as a means of protection. This letter was a strong appeal, and while it provoked much newspaper discussion, no active steps were taken to carry out the plan offered. When the people of Galveston awoke from their night of death in September 1900, Judge Ballinger's plan was again brought to light, and, although the author had long since passed away, it required no new appeal to spur the then thoroughly aroused people to the point of action.

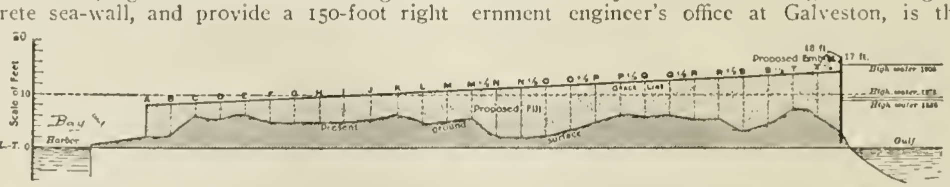
On 22 Nov. 1901, the Board of Commissioners of the city of Galveston appointed a Board of Engineers, consisting of Brig.-Gen. H. M. Robert, U. S. Army (retired), Alfred Noble, and H. C. Ripley, engineers of national renown, to devise a plan for the protection of Galveston against destructive overflows. On 25 Jan. 1902 this board submitted a plan calling for the construction of a solid concrete sea-wall and the raising of the city's grade. The raising of the grade was not only intended to furnish a solid backing for the sea-wall, but also to prevent the water from the Gulf, in the severest storms, from ever reaching a depth in the city dangerous to life or property. The plan for protection submitted by this engineering board was accepted as the best that could possibly be devised. The county of Galveston, through the commissioners' court, agreed to construct the granite concrete sea-wall, and provide a 150-foot right of way and filling for the same, with the understanding that the city proper, with aid from the State of Texas, would undertake the task of raising the grade.

Construction of the Sea-Wall.— This wall is now nearing completion. Its total cost, including the 150 foot right of way, will be $1,500,000. Its top is seven and one half feet above the extreme high water mark of September 1875, the highest ever known, excepting on 8 Sept. 1900, and it is one and three tenths feet higher than on that unprecedented occasion. The sea-wall, when completed, will be 17,593 feet in length, and is constructed on a piling foundation driven 43 feet in the ground, below mean low water, with a double thickness of sheet piling on the Gulf side. The wall is 16 feet at the base, 16 feet high, and 5 feet wide at the top, curving from the top to the base, as shown in sketch. The concrete is composed of one part of cement, three parts of sand and six parts of crushed granite. At intervals of three and one half feet, there is placed in the wall one and one half inch square, corrugated steel reinforcing rods 10 feet long. The rip rap in front of, or on the Gulf side of the wall is 27 feet wide, and from three to seven feet in thickness, and is composed of granite. The contract for constructing the wall was let to J. M. O'Rourke & Company, of Denver, Colo., on 9 Sept. 1902, with the provision that the work be completed in 15 months from date of contract.



CROSS SECTION OF GALVESTON SEAWALL & FILLING..

Raising the Grade.— In order to carry out the plan for raising the grade, the legislature of the State has authorized the city to issue bonds to the amount of $2,000,000 at a rate not to exceed five per cent. In order to aid the city in caring for these bonds the State has granted it $70,000 per annum for a period of 17 years. The management, control and direction of this work is in the hands of three commissioners appointed by the Governor, and known as the "Grade Raising Board of the City of Galveston." This board is composed of Capt. J. P. Alvey, chairman; John Sealy, and E. R. Cheesborough. Capt. C. S. Riche, U. S. Army, of Chicago, who for six years was in charge of the government engineer's office at Galveston, is the consulting engineer. The grade is to extend from the Bay eight feet above mean tide to seventeen feet at the sea-wall, thus forming a rise of one foot in 1,500 from the Bay to the Gulf. With this protection carried out, the city so protected will not be exposed to any danger from the waters of the Gulf.



Geo. W. Boschke,
Engineer in Charge of Sea-Wall Construction.

Galvez, gäl'vāth, **Bernardo**, Count de, Spanish colonial administrator: b. near Malaga 1755; d. Mexico City 30 Nov. 1786. He entered the Spanish army in the Walloon guards, served also in the Cantabrian regiment of France (1772–5), and later fought with distinction under Gen. O'Reilly in the war against Algiers. In 1776 he became lieutenant-governor of Louisiana, in the same year governor; and during the Revolutionary War, particularly after the Spanish declaration of hostilities against England in 1779, was of much service to the American cause. His capture of Pensacola and with it the Florida west coast (19 May 1781) was celebrated in verse by de Poydras. In 1783-5 he was captain-general of Cuba, and in 1785 was appointed viceroy of Mexico. His construction of a fortress-palace on the site of the castle of Montezuma at Chapultepec caused him to be misrepresented to the Spanish government as plotting the establishment of an independent Mexican kingdom. He improved the mines, increased the revenue, and alleviated the famine of 1785. He was one of the ablest of Spanish officials in the New World.

Galway, Ireland, a municipal and parliamentary borough, a seaport, and county of itself at the mouth of the river Corrib, on the north shore of Galway Bay, 50 miles north-northwest of Limerick. The old town is poorly built and irregular. The new town consists of well-planned and spacious streets, and is built on a rising ground which slopes gradually toward the sea and the river. Galway is the see of a Roman Catholic bishop, but is in the Protestant Episcopal diocese of Tuam. The principal buildings are the cruciform church (Episcopal) of Saint Nicholas (1320); St. Augustine's Roman Catholic church (1859), monasteries, nunneries, the county court-house, barracks, prison, infirmary, and Queen's College (1849). Galway has flour-mills, a distillery, a foundry, extensive salmon and sea fishing, a good harbor, with docks that admit vessels of 500 tons, and a lighthouse. During 1858-64 a line of steamers plied between Galway and the United States, but the service was abandoned in the last named year. The exports consist mainly of agricultural produce, wool, and black marble. It was taken by Richard de Burgh in 1232. From the 13th till the middle of the 17th century it continued to rise in commercial importance. In 1652 it was taken by Sir Charles Coote, after a blockade of several months; and in July 1691 it was compelled to surrender to General Ginkell. Pop. (1901) 13,244.

Galway Bay, a large bay on the west coast of Ireland, between County Galway on the north and County Clare on the south, about 30 miles in length and from 20 to 7 miles in breadth. Across its entrance lie the Aran Islands, and there are numerous small islands in the bay itself.

Gáma, gä'mä, **Antonio Leon de,** a Mexican scientist: b. City of Mexico 1735; d. 12 Sept. 1802. He was secretary to the supreme court for a number of years, and subsequently was a professor at the School of Mines. He is best known for his study of the celebrated Aztec calendar stone which was discovered in his time.

Gama, José, Basilio da, Brazilian poet: b. in the district of Rio-dos-Mortes, Brazil, 1740; d. Lisbon, Portugal, 31 July 1795. Educated by the Jesuits, he joined their order; but about 1786 renounced his allegiance to it, and published the poem 'Uruguay' to expose the alleged Jesuit design of forming an independent state among the Uruguay Indians. He was elected a member of the Academy of Lisbon. He also published 'Lenitivo da Sandade do Principe D. José' (1788), and 'Quitubia' (1791).
