## INDEX TO VOLUME XXVII.

	PAGE.		PAGE.
ABDOMEN, gunshot wounds of the . . . . .	1154	Anthelmintic, an . . . . .	493
Abortion, essential of indictment for attempting to procure . . . . .	879	Anthropology as a positive science . . . . .	1814
consent to, no bar to action for damages . . . . .	1314	Anthropometric measurements of criminals, new apparatus for . . . . .	168
About fevers, referring to natural mechanisms . . . . .	1147	Anti-choleraic inoculations . . . . .	653
Abscess, extra-dural, from mastoid empyema . . . . .	571	Antipyryn eruption, a case of effect of, on the kidneys . . . . .	1158
Abscesses, large pelvic, drainage versus radical operation in the treatment of . . . . .	801	Antiseptics, fragrant . . . . .	603
Academie de Medecine of Paris . . . . .	56	Antitoxin, administration of and intubation, some practical points on the combined effects of . . . . .	19
Accident Insurance, might be entitled to . . . . .	777	another death from . . . . .	113
Accidents from gas or electricity, to report . . . . .	1070	collective investigation (second) American Pediatric Society . . . . .	828
Acetabulotomy . . . . .	1314	improvements in . . . . .	975
Acrocyranosis . . . . .	655	treatment as a cure for diphtheria, the fallacy of . . . . .	17
Actinomycosis, human . . . . .	226	an experience with, with instructive results . . . . .	20
of the lower jaw . . . . .	604	the use of, in diphtheria and membranous croup . . . . .	7
Acute infectious diseases and general paralysis . . . . .	1025	in diphtheria in private practice; report of the American Pediatric Society's collective investigation into the use of . . . . .	27
Addison's disease cured by extirpation of one suprarenal capsule . . . . .	1062	Antivivisection . . . . .	170
disease, operation and cure of . . . . .	1348	Antrum disease, treatment of . . . . .	97
Africa, practice in . . . . .	501	Aphasia of the hand . . . . .	1256
Afrol, physiologic action of . . . . .	506	Apoplexy, preventive medicine in . . . . .	360
Akenside, Dr. Mark (1724-1770) . . . . .	1203	Appendicitis a "dysentery" of the appendix . . . . .	1107
Albany Medical College, Medical Department Union University . . . . .	694	do grape seeds cause . . . . .	1196
Albinism . . . . .	501	etiology of . . . . .	393
Albright, J. D. Catarrhal diseases of the nose and throat . . . . .	906	fruit seeds in . . . . .	557
Albumin, test for . . . . .	385	Helferich on the indications for an operation in . . . . .	157
testing . . . . .	277	massage in . . . . .	418
Albuminuria in pregnancy and parturition, and its relations to eclampsia . . . . .	877	operation for . . . . .	381, 508
physiologic . . . . .	269	report of cases of . . . . .	1156
renipuncture in . . . . .	1247	when and how to operate in . . . . .	1302
Alcohol, cure of carcinoma with injections of . . . . .	1206	Argon in the breath . . . . .	55
in therapeutics, some notes on . . . . .	521	Arkansas Industrial University . . . . .	624
Alcoholic drinks, the abuse of, its relation to public health, and its prevention . . . . .	474	Army medical administration, problems in . . . . .	229
Alcoholism, ammonia in . . . . .	925	Medical Museum, recent additions to the . . . . .	926
and opium habit, the strychnia cure of, in children . . . . .	1070	medical officer, Lord Walseley on the . . . . .	561
the French National League against . . . . .	1356	medical officers, newly appointed . . . . .	1023
Alcohols, toxicity of . . . . .	823	medical school . . . . .	1027
Alder, curious superstition concerning the . . . . .	1171	report of the Surgeon-General of the, for year ending June 30, 1896 . . . . .	911
Alexian Brothers new hospital in Chicago . . . . .	828	surgeons, honors to . . . . .	1261
Allegheny and Pittsburg, Pa., water supply of . . . . .	277	Armenian field, retires from the . . . . .	826
Allen, T. H. Notes on taka-diastase . . . . .	874	Arons, W. C. Practice in Africa . . . . .	501
Allison, H. E. Relations of crime to insanity, and states of mental enfeeblement . . . . .	646	Arsenic in scarlet fever . . . . .	766
Allport, Frank. The relations existing between oculists and ophthalmians . . . . .	35	Artificial respiration for infants . . . . .	877
Alternating personalities; their origin and medico-legal aspects . . . . .	1062	Ashmead, Albert S. The proposed leprosy Congress . . . . .	967
Alvarenga prize of the College of Physicians of Philadelphia . . . . .	925	Albert S. Congress of leprologists . . . . .	387
Amblyopia, central, an early symptom in tumor of the chiasm . . . . .	1202	Albert S. Leprosy . . . . .	219
consequent to chronic endometritis . . . . .	736	Albert S. The Church of Rome and the lepers of Colombia . . . . .	428
Ambulance, the gradual evolution of the . . . . .	1076	Asiatic ant a surgical adjunct . . . . .	557
American birth rate, the decadent . . . . .	969	Aspirator needle, grooved, a new . . . . .	1119
Medical Association, an appeal to the Fellows of the . . . . .	525	Association of American Medical Colleges . . . . .	624
medical college, good showing for . . . . .	449	Athletics with music for the insane . . . . .	1205
Pediatric Society's collective investigation into the use of antitoxin in the treatment of diphtheria in private practice . . . . .	27	Atkinson, Wm. B. Testimonial to Dr. Davis . . . . .	164
tenacity . . . . .	232	Atlanta Medical College . . . . .	626
Analgin in infantile therapeutics . . . . .	1249	Atomizer decision . . . . .	506
Anastomotic buttons, instrument for removing through the mouth . . . . .	270	improved . . . . .	1256
Anastomosis, new method of, without opening organs . . . . .	450	Atresia vagina, operation for . . . . .	1023
Andrews, Edmund. Do grape seeds cause appendicitis? . . . . .	1196	with retention of the menses . . . . .	862
Edmund. In future battles where shall the field hospitals be placed? . . . . .	593	Auditory canal, foreign bodies in the . . . . .	1308
R. R. Chairman's address . . . . .	1327	Authors, give full names of . . . . .	1019
Anemia, pernicious, changes in the cord in injections of salts of iron in the treatment of . . . . .	548	Autumnal fevers of the Southern Atlantic States and their treatment . . . . .	1319
pernicious, fifty cases of . . . . .	709	Ayres, S. C. A case of chloroma . . . . .	985
pernicious, cured with bone marrow . . . . .	924	<b>ASSOCIATION NEWS.</b>	
Anesthetics, are deaths from, due to failure of the respiration or circulation? . . . . .	724	Appointments . . . . .	1169
Angina pectoris in neurasthenia . . . . .	1261	Headquarters of the American Medical Association . . . . .	109
pectoris, on the symptoms and treatment of . . . . .	97	List of Presidents of the Association . . . . .	1353
Angio-neurotic edema . . . . .	904	Philadelphia meeting of the Association . . . . .	1251
Ankles, sprained, new treatment for . . . . .	1303	Philadelphia semicentennial meeting, June 1-4, 1897 . . . . .	1214

## ORIGINAL ARTICLES.

### ORRHOTHERAPY IN DIPHTHERIA.<sup>1</sup>

Read before the Illinois State Medical Society, May, 1896.

BY E. FLETCHER INGALS, A.M., M.D.

CHICAGO.

As a result of the work of Pasteur and the numerous investigations which have followed in the same line, it is now generally believed by bacteriologists that many diseases, especially those which seldom affect individuals more than once, are self-limited by the formation within the blood of a product capable of destroying the toxic material that excites the disease, hence called antitoxin. In such diseases if life be prolonged until a sufficient quantity of the antitoxin has been developed the toxic agent is destroyed and recovery follows if no serious complications have arisen.

In diseases that can be communicated from man to animals and vice versa, such for example as rabies, anthrax and diphtheria, advantage has been taken of this fact by inoculating animals with the attenuated toxic principle in small but steadily increasing quantities until an antitoxin is developed in the blood in sufficient quantity to render the animal immune to the further pernicious effects of the contagium.

Behring enunciated the law that blood serum which had in this manner been rendered immune might be transferred to another individual with the effect of rendering the latter also immune, no matter how susceptible he might be to the disease. Further investigations by Kitasato, Aronson, Roux and Behring have determined what animals have blood serum that produces the least ill effects when introduced into the human system, and how to render a small quantity of blood capable of producing immunity in a second individual. They have also discovered methods of preserving the serum and of measuring its strength and purity.

Diphtheritic poison has been introduced into animals, preferably into the horse, until immunity to its further effects has been obtained. The animal has then been bled, the blood allowed to separate and the serum preserved under the name of antitoxin.

Until recently the serum prepared by Aronson, Behring and the New York Health Department was of strength known as from 60 to 150 antitoxin units to the cubic centimeter, the different preparations being numbered 1, 2 and 3. Stronger preparations are now made; No. 4 representing 200 antitoxin units; No. 5, 300 units, and No. 6, 400 units to the cubic centimeter. These are obtained, not by concentration of weaker solutions, but directly from the animal that has been inoculated. The stronger preparations are considered quite as safe and are preferable on account of their smaller bulk which obviates to a considerable degree the pain caused by the large injections.

One thousand antitoxin units is considered the ordinary curative dose, but in severe cases or those not treated until the third day, 1,500 to 2,000 units are often employed, and sometimes these are repeated until altogether from 4,000 to 6,000 units are administered in a single case. The dose considered necessary for immunizing a healthy individual is about one-fourth the curative dose. The serum is administered by hypodermic injections, preferably in some part of the body where there is an abundance of loose cellular tissue, as at the lower angle of the scapula, in the gluteal region, and upon the abdominal or chest walls. Dr. Chantemesse (*New York Medical Record*, 1896) reports that he has had quite as good results when administering the antitoxin per rectum as by hypodermic injections.

It is generally believed that the earlier the injection is made the better the result; still the classification of cases by days to determine the prognosis and the size of the dose is at fault for there is much difference in individuals in the rapidity with which absorption of toxins takes place and in their resisting power to the poison; therefore, in some, injections made the fourth or fifth day might be quite as advantageous as those in others made on the first day, though the earlier the remedy is used the better the result that would commonly be expected. The rapidity of the accession, the general condition and the age of the patient are of more importance in determining the use of the serum, its dose, and the prognosis to be given than is the number of days since the onset of the disease.

Very little interest was manifested in the antitoxin treatment of diphtheria until 1894, after Roux had presented the subject to the International Congress of Hygiene at Buda-Pesth with the report of five hundred cases treated by this method. Since then many physicians and the health departments of cities and of national governments have employed the serum extensively in the treatment of this disease. Although no crucial experiments have been made to determine the value of diphtheria antitoxin yet the statistics obtained from many sources seem to prove that it is capable of greatly diminishing the mortality of this disease. In studying the literature of this subject I find the majority of reports have been from many physicians who have recorded only one or two cases. From a perusal of these one can not help suspecting that in many instances only the favorable cases have been recorded. The statistics of hospitals are probably more complete and accurate, but the statistics of Health Boards although more extensive are likely to be very inaccurate for many reasons.

In Dr. Foster's report, No. 7, of the accompanying various hospital reports and published records which I have obtained (see Table I), it was noted that all of the cases treated on the first day recovered; of those treated on the second day 9.3 per cent. died; of

<sup>1</sup> See correspondence, page 49.

those treated on the third day 20 per cent. died; of those treated on the fourth day 33 per cent. died.

The following points were noted in the report from the London Hospitals (No. 12): First, that there was a great reduction in mortality in cases treated on the first and second days by antitoxin, second a lowering in mortality in all ages to a point below that of any preceding year, and third a lowering of the mortality of laryngeal cases over the preceding year.

In a personal letter (report No. 13) received from Dr. Wm. M. Welch of Philadelphia regarding the statistics from the Municipal Hospital of that city, I find that the use of antitoxin was mainly limited to cases considered favorable that were admitted in the early stage of the disease, that is, somewhere from the first to the fourth day. In cases that were far advanced, many of which were in a hopeless condition or showed great malignancy when they were admitted to the hospital, the antitoxin was not employed and a large number of the cases which received the antitoxin in the early stages were not severe. Of 302 cases receiving antitoxin 51 or 16.8 per cent. were intubation

reports so obtained were open to the suspicion of not having been accompanied by the unfavorable reports which should have been published at the same time. The observations Nos. 10 and 11 are from the Boards of Health of large cities and are very unreliable for the reason that many physicians do not report cases of diphtheria at all until they fear the patient is going to die, whereas physicians who obtain antitoxin from the Board of Health would necessarily report nearly all cases where it is to be employed. It is therefore not at all improbable that the percentage of mortality as given for cases in which antitoxin was not used is two or three times larger than it should be. There are other reasons, well known to the profession, why statistics obtained from this source are peculiarly unreliable.

In observations Nos. 4, 5, 6 and 9 the mortality among patients treated by antitoxin is compared with that of patients not treated by antitoxin in previous years, and as has already been stated the mortality varies so greatly in different years, whatever the treatment, that very little information can be derived from such statistics. Observation No. 12 is

cases; of the 404 cases which did not receive antitoxin 71 or 17.57 per cent. were intubation cases. Of the 51 intubation cases which received antitoxin 27 or 52.94 per cent. died, while of the 71 cases in which it was not received 40 or 56.33 per cent. died. The difference, therefore, in favor of antitoxin in intubation cases amounted to only 3.39 per cent. notwithstanding the greater malignancy of the disease in some of these. In this series of cases the antitoxin was given to those in which it is claimed to be most beneficial, and was not given to the worst cases. Had the antitoxin been given in alternate cases of this group half of the more serious cases that died without the serum would probably have died with it, or at least they would not have been counted against other methods and this series would therefore have shown a record for antitoxin considerably more unfavorable than it does now.

An analysis of these reports shows that Nos. 1, 2, 3, 4, 5, 6, 7, 9 and 14 are very favorable to the use of antitoxin, but the cases reported in No. 7 were made up from journals and as already stated many of the

favorable to the antitoxin treatment on its face but it will be observed that the cases treated by antitoxin were in 1895 and those not treated were in 1894. Behring's statistics, Observation No. 8, show that in Berlin diphtheria was very much less fatal in 1895 than in the previous years even when antitoxin was not employed, the ratio apparently being about 14 to 40 or 50. If a similar ratio were maintained in London for the two years of observation, No. 12 instead of being favorable to the antitoxin treatment is decidedly unfavorable; the same remark would apply to some of the other observations, where the comparison has been between different years. No. 15 can hardly be considered favorable.

As an immunizing agent it is claimed that one-fourth the curative dose is efficient and that the larger the dose given the longer the immunity, but that repeated small doses are even more effectual. The immunity is said to last from one week to thirty days. Out of ten thousand cases thus treated at Berlin only one contracted diphtheria. As reported in the Annual of the Universal Medical Sciences for

1892 Grancher of Paris stated that in a diphtheritic ward in Paris among 1,741 patients admitted there were 153 children that did not have diphtheria at the time, yet not one of these contracted the disease. This was before the days of antitoxin, and when it is remembered that the children were surrounded in the same ward by diphtheria these facts detract much from the credit given diphtheritic antitoxin as a prophylactic agent.

Several cases have been reported in which this treatment seems to have proven deleterious to the patient and some fatalities have already occurred. In the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION April 4, 1896, a fatal case is recorded in which a healthy child died within five minutes after the injection had been given to protect it from contagion. Another case with serious symptoms in which a prophylactic dose had been given is reported in the same JOURNAL April 18, and still another fatal case has just been reported from Berlin in which Dr. Langerhans lost his little child shortly after an immunizing injection. Nevertheless considering the large number of injections which have been given and the few reports of deleterious effects it must be admitted that there is but slight danger in using the remedy as a prophylactic.

There is some reason to believe that injurious effects follow its use in remedial doses in many instances but as has been claimed by those who favor the remedy, it is possible that the deleterious effects are often observed from the fact that serious cases that would otherwise have died before the development of sequelæ are saved and that naturally in these cases the unfavorable after-effects of the disease would be more numerous. As stated by Mr. Lennox Browne in his book on "Diphtheria and its Associates," 1895, the power of the serum to do good and per contra its capacity for inflicting injury is in proportion to the duration of the disease, in other words, to the degree of toxemia. He claims that a greater number of children have been found liable to attacks of cyanosis, necessitating a demand for the freer use of nervines and stimulants, also that complete recovery is found to be delayed and that unexpected fatal results at a late period are more frequent. In the joint report of the hospitals of London already quoted 3,040 cases treated in 1894 without antitoxin are compared with 2,182 cases treated in 1895 with antitoxin. These show the following complications:

TABLE II.

	Treated in 1894. Without Antitoxin.		Treated in 1895. With antitoxin.	
	Number of Cases.	Per cent.	Number of Cases.	Per cent.
Albuminuria. . . . .	608	24.0	1,081	40.9
Nephritis. . . . .	37	1.2	45	2.0
Paralysis. . . . .	408	13.0	507	23.0
Pneumonia, lobar. . . . .	11	.3	18	.8
Pneumonia, lobular. . . . .	50	1.6	80	3.6
Relapse of diphtheria. . . . .	28	.9	31	1.4

The above figures show a larger percentage of complications after the antitoxin treatment. The experience in these hospitals showed that by far the most frequent complication was a rash, usually urticarial, sometimes erythematous or having the appearance of scarlatina. A rash was observed in 45.9 per cent. of all cases. This was accompanied by fever in many cases, amounting to 29.6 per cent. of the patients

presenting a rash. In some instances the rash persisted for many days, but usually it had run its course by the end of the third or fourth day. There were a few instances of effusion into the joints and abscesses were found at the site of injection in 2.3 per cent. of the cases.

In an abstract from the discussion at the meeting of the British Medical Association 1895, reported in the *Journal of Laryngology*, April, 1896, Dr. Goodale gave the following statistics, based on his observation: Of 105 cases of diphtheria treated with antitoxin, 29 per cent. died; of 136 cases not so treated, 33 per cent. died; albumin was found in the urine of 53.3 per cent. of the cases treated by antitoxin, but only in 49.2 per cent. of the cases not so treated. Nephritis was not noted in any of the cases; paralysis followed diphtheria in 17 per cent. of the cases treated by antitoxin, and in only 14.7 of the cases treated by other methods. Prof. Von Ranke of Munich gave statistics of 163 cases treated by antitoxin in which there was not a single case of laryngeal stenosis. Dr. A. Baginsky of Berlin gave statistics of 525 cases treated by antitoxin in which there had been no laryngeal stenosis. Dr. C. V. Kahlden (JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Oct. 19, 1895) reports that in numerous experiments on guinea pigs and rabbits that have been injected with very large doses of antitoxin for the body weight of the animal he was unable to find any evidence of nephritis in the animals that were killed after one or more injections.

The consensus of opinion of observers as to the symptoms manifested after curative doses of the antitoxin is that the temperature may be either reduced or rendered higher, though it appears that in the majority of cases it is rendered somewhat lower in the next twelve to twenty-four hours; the pulse is strengthened and the general condition appears to be improved in the same time; extension of the diphtheritic membrane to other parts is checked and the membrane commonly begins to loosen within twenty-four hours. The remedy, however, does not prevent suppuration of the cervical glands, does not prevent paralysis and does not favorably modify paralysis when it has once appeared.

Laboratory experiments have undoubtedly proven that antitoxin, when injected into guinea pigs that have been inoculated with large quantities of diphtheria toxin, saves their lives, and also that immunizing doses in these animals are not followed by bad results, but prevent contagion for a certain period.

The reports of clinical investigations taken as a whole are considerably in favor of the antitoxin treatment. There is still, however, much skepticism as to the efficacy of the remedy, based upon the fact that no crucial experiments have been reported. It is well known that the mortality in diphtheria varies from 10 to 75 per cent. in various epidemics or in different portions of the same epidemic, therefore accurate information can not possibly be obtained by comparing the death rate of any year with that of any preceding year, or even by comparing the death rate of one month with that of preceding or succeeding months. Until, in the large hospitals alternate cases are treated by antitoxin alone and by other methods we will have no certain information upon the subject. The report from the Municipal Hospital of Philadelphia approaches nearer a crucial test than any other that I have been able to find. It unfortunately shows a higher death rate with antitoxin than without it; even

though the antitoxin was given mostly to those cases which were considered to be especially favorable for its action and in extreme conditions it was withheld. Until more definite information is obtained conservative physicians may well be excused for declining to experiment upon their patients with this remedy. However, the wide belief that it does much good and the comparatively certain knowledge that it does but little harm suggests that our duty to our patients demands that when diphtheria exists we should administer the antitoxin if it is desired, but that at the same time we should use such other remedies as have been proven of most value in combating this disease; but we should hesitate to recommend it as a prophylactic agent.

Antitoxin certainly has not been proven a specific for diphtheria. In estimating its value it should not be forgotten that the bacteriologic diagnosis of this disease is not perfect; that in a large percentage of cases having diphtheritic membrane the Klebs-Löffler bacillus is not found and also that in a large percentage of perfectly healthy mouths a bacillus morphologically the same is present.

We believe that experimentation in the treatment of diphtheria by serum is in the right direction and we hope that the enthusiastic friends of orrhoterapy may be largely vindicated, yet we can not search far into the history of medicine to find that very many of the remedies now employed have in the beginning been lauded excessively, and that not a few of those that were formerly supposed to be extremely efficacious have been found to be practically worthless.

36 Washington Street.

## THE OUTLOOK IN SERUM THERAPY.

Read before the Michigan State Medical Society, at Mt. Clemens, June 5, 1896.

BY CHARLES T. McCLINTOCK, Ph.D., M.D.

ANN ARBOR, MICH.

A year ago, in a paper read before this Section, I stated that an average of the reports from serum treatment in diphtheria showed a reduction of 50 per cent. in mortality. I repeat this statement to-day with all confidence. Then we had reports from a few thousand cases, to-day from hundreds of thousands. With the profession at large there is no longer any question as to the value of this treatment. Here and there some belated traveler may be heard crying that we are on the wrong road, that trouble and disappointment alone await us. The observer whose opposition has attracted the widest attention in the past year is possibly Dr. Lenox Brown of London. Dr. Brown is a very able man, an authority on many subjects. He attacks the statistics, makes much of the harmful effects of the serum, and enters a general denial against all the claims of good. The best answer to Dr. Lenox Brown's objections is not a review of all the facts and figures, but the recently issued report of the Medical Superintendents of the Metropolitan Asylum's Board of London. This report covers some six thousand cases of diphtheria treated in these hospitals; in round numbers, 3,000 without and 3,000 with the serum treatment. Their conclusion is, that not less than 250 lives were saved in 1895 by the antitoxin that would have been lost under the old methods of treatment.

There have been some improvements in the production of serum that are worthy of note. A year ago,

in a vial of 10 c.c. we thought we had a very good serum, if it contained 1,000 units. Now we have one containing 5,000 units, and I think it altogether probable that by the end of the year we can have a serum of such strength that a 10 c.c. bottle will hold 10,000 units. This is an important advance. To inject 10 c.c. of anything into a child is a heroic procedure. But the injection of 1 or 2 c.c. is quite another matter. Two c.c. of this stronger serum is a full curative dose for an average case; 7 minims is an immunizing dose. There are certain unpleasant complications, urticarias, rheumatic pains, etc., that not uncommonly follow serum injections. In general these are proportional to the amount of serum used. We expect to note a very great diminution in the annoying sequelæ from these stronger serums. Allow me to call your attention to a mistake which I believe many practitioners are making. They argue in this way. "Ten cubic centimeters can be injected without harm. Now if I can get a serum that contains from two to five times the antitoxic power of that I have been using, I will inject the same amount and will get control of the disease in proportion to the strength of the antitoxin." This, I believe, is mistaken reasoning. It is very well established that this serum is not directly antitoxic, *i. e.*, the serum that you give does not of itself destroy the poison. It in some way nourishes or stimulates the cells of the body, and they in turn destroy the toxin. It does not follow, either in theory or in practice, that you will get this needed stimulus better from 5,000 than from 1,000 units. In fact, in so far as I can judge, from a somewhat careful examination of many reports, Behring's original recommendation, 250 units for immunizing, 500 to 600 for mild cases, 1,000 for average, and 1,500 for severe cases, repeated as necessary, still give the best results. On theoretic grounds, I believe that even smaller doses repeated more frequently would give better results. Remember the toxin is not produced all at once, but continuously through the course of the disease, so long as the germs are growing.

The marvelous results obtained in diphtheria very naturally led to enthusiastic work in all microbic diseases. At first it seemed that the same methods could be applied and like results obtained in all of the communicable diseases. And yet, after an enormous amount of work done by careful and skillful investigators, the results obtained are very disappointing. Typhoid and cholera, tuberculosis and smallpox are still unconquered. Why is it that a method applicable to diphtheria will not give as good results when applied to tuberculosis or typhoid? They have similar causes; the germs in these diseases as well as in diphtheria or tetanus can be isolated, pure cultures grown, toxins produced. The chief reason for the failure, I believe, is in this. In an ordinary case of diphtheria there are relatively few germs, confined to a very limited surface. But these germs produce a large amount of a very virulent poison, so much that every tissue of the body may feel its harmful effect. In tetanus this condition is even more pronounced. The germs are confined to the neighborhood of the wound and are so few in number that the skilled bacteriologist must make repeated examinations, or cultures, to find them at all. And yet these few germs will in the average case produce sufficient poison to cause death. How does this compare with tuberculosis, for example? One estimate has it that in the last stages of this disease as many as four billions of the germs

are expectorated in a day. This, I take it, without claiming any exactness for the figures, is a far greater number of germs than is produced in the entire course of a case of diphtheria or tetanus. Yet in pure, unmixed, non-septic tuberculosis, the amount of toxin produced, measured by the temperature curve and general symptoms, is small. To illustrate: Here is a tetanus toxin grown in bouillon from an old and presumably weakened germ, with no attempts to increase its virulence. Of this one five-hundredth c.c. is fatal to guinea pigs. Here is the toxin from the tubercle germ, grown as carefully as can be. This has been concentrated to one-tenth of the original bulk, and yet it requires from 2 to 5 c.c. to kill a guinea pig. At the lowest estimate the tetanus toxin is 10,000 times as strong as that obtained from the tubercle germ. Conversely, it is probably a safe estimate to say that in the average fatal cases of these two diseases, there are a million times as many tubercle germs produced as in the case of tetanus. I believe I am justified in saying that in tetanus it is the toxin that kills, while in tuberculosis it is the germs. The old name consumption is correct, the disease is a literal eating up of the tissues by the germs. Bearing these things in mind, the success of the method in the one case, and its failure in the other can be understood. To cure tetanus we need an antitoxin, while for the cure of tuberculosis we must have a germicide. The antitoxins of tetanus and diphtheria are not germicidal. Such an agent is not needed: free the tissues from the harmful effects of the poisons and they will easily take care of the few germs present. But not so in tuberculosis. Neutralize or destroy all the toxin and you still have left in an advanced case, untold millions of germs, feeding on and literally eating up the tissues in which they are located. I would not say that the toxins in tuberculosis are of no importance, but in an uncomplicated case I think the toxin is relatively unimportant. In the work of the past year these theoretic conclusions have received some experimental proof. Pfeiffer and his assistants in the Berlin laboratory have shown that the blood serum of an animal or man immune to cholera, can help an animal infected with cholera germs, but it does so, not by destroying a toxin, but by killing the germs themselves. Further, that the direct germ-destroying power of this immunized serum is small. But that when injected into the infected animal it so stimulates, or assists the cells, that they or their soluble products can in turn destroy enormous numbers of germs. Pfeiffer illustrates this in the following manner: A drop of the immunized serum is placed in a test tube with a portion of a bouillon culture of the cholera germ. This is left at the body temperature. Exactly similar amounts of serum and culture are injected into the abdominal cavity of a susceptible animal. In another, control animal, an equal quantity of the germ culture is injected without the serum. After a given time the containers, the test tube and the abdominal cavity of the animals, are examined, both microscopically and by the plate method. It is found that a few germs have been killed by the drop of serum in the test tube, while in the animal receiving the mixture the most or all of the germs have been destroyed. In the control animal the germs have increased in number.

Note the exact similarity here, both in theory and in results, to that advocated by Dr. Vaughan and my-

self several years ago in explaining the action of the nucleins in the body. Results corresponding in general to the above have been obtained with typhoid. Results which go far to show that in these diseases at least curative effects are produced by germ-destroying rather than by antitoxic agents.

#### A BRIEF SURVEY OF THE VARIOUS SERUMS.

*Erysipelas Serum for Malignant Tumors.*—There have been a few, apparently well authenticated, cases where an intercurrent attack of erysipelas has markedly benefited, and in a few instances cured malignant neoplasms. Following this indication, several experimenters have inoculated the site of these tumors with the germs of erysipelas, but this procedure proved entirely too dangerous. Whatever the effect on the tumor the patient often died.

Coley then attempted the treatment of these tumors with the toxins of erysipelas. He claimed very favorable results, but in other hands the treatment, although still occasionally used, has not given satisfaction.

Emmerich and Scholl, the former a well-known bacteriologist, conceived the idea of preparing a serum that would antagonize the growth of these tumors. They injected sheep with carefully prepared virulent cultures of the erysipelas germs. These injections were continued for some time. The serum from the sheep was then used for injection into the neoplasms. In theory, they were not attempting to produce an antitoxin, in the sense that we understand that word. Their theory is practically the same that Klebs advances for his antiphthisin. A germ produces both toxic and antitoxic bodies. Although there has been no experimental proof of any such condition, the possibility of its truth seems to have impressed many of the German investigators. Klebs claims that he can take tuberculin and by chemic methods remove the poisonous substances and retain the curative ones. Emmerich and Scholl used the animal body for this purpose. It was to be a separating filter, the poisonous substances eliminated and the anti-poisons or toxins stored in the blood of the injected animal. By repeated injections, a large amount of these curative bodies could be stored in the blood and this in turn used for the treatment of disease in man. These authors believed that they had found a specific cancer (heilserum), and notwithstanding the failure of the remedy in the hands of Bruns, Czerny, Petersen, Reinebroth and others, they persist in asserting that the serum does cure, and in this they are supported by a few clinicians. Bruns thinks it probable that in case there is amelioration, it is not due to any specific action, but results from the fever induced, causing fatty degeneration, and cites numerous instances of neoplasms degenerating in other fevers, as in typhoid, meningitis, etc.

Other experimenters have injected extracts or suspensions of tumors into animals, and then used their serum for injections. There is little promise in this work. For the present, judgment must be suspended. Meanwhile, despite the enormous amount of work done in the past three years attempting to find the cause of these growths, it remains that for the cancerous diseases there is no cure and no palliation save narcotic sleep to the end.

*Cholera.*—Ferran, a pupil of Pasteur, in 1884 showed that guinea pigs could be made immune to cholera by the injection of gradually increasing doses of bouillon

containing cholera germs. He did not follow up this work in a scientific manner but immediately began injecting men. Large numbers submitted to his inoculations. In Spain 25,000 were injected in one year. He even advocated that wells should be infected with the germs, so that those drinking the water should be gradually immunized to the disease. He did not use pure cultures but grew them from foci of cholera patients. This was shortly after Pasteur's notable discoveries on vaccines. Ferran saw that the serum of men who had recovered from cholera had immunizing properties and he used this in treating other individuals. He had discovered the underlying principles in our present methods of serum-therapy. He made the fatal mistake of keeping his methods secret. Ferran's methods were dangerous, his results uncertain and his professional attitude deplorable.

Haffkine, another of Pasteur's pupils, in India, has continued this work of vaccinating against cholera, injecting 40,000 men last year.

Lazarus was the first to demonstrate that the serum of men who had recently recovered from this disease, would confer an immunity on guinea pigs, against the intra-peritoneal injection of cholera germs. Since that time many investigators have busied themselves with the problem of immunity and cure in this disease. There is at present a wordy discussion in progress as to whom belongs the priority for some of the principal discoveries. Pfeiffer of the Koch school in Berlin claims to have discovered a new ground for immunity. He finds it easy to immunize animals so that their serum can be used to protect other animals against the disease. But the interesting and important part of this work is the light thrown on the nature of these anti-bodies contained in the immunized serum. Pfeiffer finds that these anti-bodies have a specific action. For example, when a mixed culture containing the cholera germ along with various other species is subjected to this serum, the cholera germs alone are destroyed. Even when the mixture consists of morphologically related germs, the vibrios, the germs of cholera alone are attacked. He believes that in this we will have an entirely reliable proof of the presence of this germ that can be applied in diagnosis.

This serum can in the test tube destroy a certain number of germs and a far greater number in the body. By heating the serum to 60 degrees its ability to destroy germs in the test tube is taken away; but when injected into the body it still exerts its immunizing power and destroys the germs. His explanation for these facts is, that there is a sort of specific enzyme having two stages, an inactive and an active one. He compares these with glycogen and glucose. The serum does not contain the active substance, but a precursor of it. When this serum is injected into an animal the enzyme-like body becomes active, capable of destroying large number of germs. He finds that this immunized serum has no antitoxic action but is strongly germicidal. As to the chemic position of this body his results are negative. He thinks that he proves that it is not an albumin, as it resists peptic and pancreatic digestion; that it is not a nuclein, that it is not a peptone, albumose or salt, for when freed as far as possible from these substances, it still exerts its specific action.

Here we have a direct experimental proof of artificial immunity due to a germicidal action, not to an

antitoxin, and we are probably justified in concluding that in natural immunity the same principle is true. The body protects itself by an ability to destroy the introduced germs. Pfeiffer does not think that the serum treatment will be of much value in well developed cases of cholera. We are getting nearer and nearer to an understanding of how the body defends itself from the attacks of disease germs. And when once we understand this, the hope is justified that we can lend assistance when there is need.

*Anti-streptococcic Serum.*—Puerperal fever, erysipelas and certain of the septicemias are due to streptococci. This class of germs often attacks the weakened tissues and modify and complicate such diseases as scarlet fever, measles, diphtheria, tuberculosis and broncho-pneumonia.

As soon as it became certain that serum treatment as practiced in diphtheria and tetanus was successful, a number of observers turned their attention to the diseases caused or complicated by the streptococci. It was easy to see that a serum that would successfully check the attacks of these germs would have a wide range of usefulness, far greater, indeed, than that for diphtheria.

To obtain an antitoxic serum was the problem. But there were difficulties in the way. At the outset, here are several varieties, possibly species of the germs. Suppose we obtain a serum antitoxic to the germ found in erysipelas. Will it have any effect on the germ found in puerperal fever? I may say that it has been shown that the serum of an animal made immune by the injection of the germs or toxin obtained from any one of these diseases, is antitoxic to the whole group of streptococci. So far as we know, one serum can be used against this whole class of diseases and complications. Another difficulty: The streptococci did not take kindly to our artificial nutrient media. We would isolate the germs from a case of erysipelas, for example. In the first culture we would have a moderate growth; in the next it would be feeble, and after a short time it would die out altogether. Even in our most recent cultures neither the germs nor their toxins were very virulent. For example, it required something like 15 c.c. of a bouillon culture of the germs to kill a half-grown rabbit. After a careful study of the question Marmorek was able to increase the virulence of the cultures in an almost incredible manner. He claims to have finally obtained cultures, by growing in a mixture of human blood serum and beef bouillon and alternately passing through animals, so virulent that one one-hundredth billion of a c.c. was fatal to rabbits. With these cultures he immunized his animals.

This serum has been extensively used in the hospitals of Paris in treating the streptococcus diseases. Puerperal fever has, fortunately, become so infrequent that it will require some time before sufficient experiments can be made to show the value of the serum. The most striking results obtained with the serum are reported for scarlet fever. While we are wholly ignorant of the organism causing scarlet fever, we are quite sure that many of the complications of the disease, the throat, ear, kidney and heart lesions are, in part at least, due to streptococci. The Paris clinicians report very favorable results from the treatment. Baginsky in Berlin reports on the treatment of fifty-seven cases with the serum supplied by Marmorek and Roux. He says that, owing to the small supply of the serum, he was not able to give in

most of his cases the dose recommended by Marmorek. The death rate was 14.6 per cent., while the average death rate from 1890 to 1895 in this hospital was 24.9 per cent. He believes that but little importance is to be attached to these figures, owing to the great variation in the mortality in this disease, and concludes, that he is unable to draw any conclusion from his experiments, except that the disease was no worse for the treatment and that he intends to continue its trial.

In measles, as in scarlet fever, we believe that the complications are for the most part due to streptococcus infection, and the serum should be equally efficacious here.

It seems to me, although I have seen no suggestions for such application, that the greatest field for usefulness for an anti-streptococcus serum would be in tuberculosis. For some years the belief has been growing that pure, uncomplicated, non-septic tuberculosis is relatively a mild, curable and often self-limited disease. It is the complications that kill in tuberculosis. Most of us will agree that when there is any benefit from the administration of creosote and its allies, it is due to the action on the septic processes and not on the disease itself. And not a few hold that the chief, though not the whole benefit of mountain climates, is the aseptic atmosphere. Most of you are probably familiar with the work published by Prudden last year, where he conclusively showed that for rabbits, at least, cavity formation in tuberculosis was almost entirely due to secondary streptococcus infection. Now, if with this serum we can hold in check the septic processes we will have half conquered the disease. Although the work with this serum is still in the experimental stage, the outlook is very promising.

*Anti-tubercle Serum.*—Maragliano, Boinet, Picq, Babes, Maffucci, Paquin and others have reported work in this line. Most of them claim good clinical results. But tuberculous patients under any treatment, and without any, often improve and occasionally get well. So that, whether with justice or not, the claims of these investigators have met with but little approval. In experimental animals the best results I have seen reported are a prolongation of life in guinea pigs from an average, for untreated animals of some fifty days, to ninety in the treated ones. No treatment yet devised, be it serum or anything else, can save a guinea pig when inoculated with tuberculosis. And while our experimental animals are far more susceptible to the inoculated disease than man, the profession at large will be slow to trust any remedy that can not give demonstrable results in animal experiments.

*Anti-pneumonic Serum.*—The work of the Klemperer brothers on the immunization of rabbits against pneumonia has been followed up by Emmerich and Fowitzky, Redner, and Foa and Carbone. It has been possible to immunize a rabbit so that it would withstand more than three hundred thousand times the fatal dose of the germs for an untreated animal. With serum taken from such highly immunized animals it is possible to save inoculated rabbits if the serum is given five hours or earlier after the infection. In rabbits pneumonia is often fatal in twenty-four hours. The duration of the immunity produced in rabbits is long. After three months they resist fatal doses of the germs. So far as I know, the successful immunization of larger animals capable of producing serum

in quantities sufficient for the treatment of the disease in man has not yet been reported.

*Anti-rabic Serum.*—Following the general lines of procedure in this field, the Italian bacteriologists have produced a serum for the treatment of hydrophobia. Their experimental work seems to be convincing. They claim many advantages for this serum over the Pasteur method of vaccines. The claims are that results are more certain and the dangers of treatment lessened, and of even more importance, the serum keeps well and can be used anywhere by any practitioner.

*Anti-venom.*—Drs. Calamette of Paris and Fraser of Edinburgh seem to have succeeded in producing a very satisfactory serum for antagonizing snake poison. That animals could be immunized to these poisons was shown years ago by Dr. Sewell in Michigan University. It seems that the serum produced from the venom of any one of the serpents is antagonistic to the poison of the whole group.

*Typhoid.*—In general the statements I have made in regard to cholera are true for typhoid. Animals have been immunized and a protective action can be demonstrated, but clinically the results are not convincing. Here, as in cholera, a germicidal instead of antitoxic action is shown. But where in cholera there is a specific action against one germ, it seems that in typhoid the serum antagonizes all related germs, as the coli group. This is as we find it in the streptococci.

*Syphilis.*—It is well known that one attack of this disease confers an almost perfect immunity against subsequent infection. Attempts have been made to borrow this resisting power. The serum of persons who have recovered from the disease has been injected into those who have been recently infected. Again syphilitic nodules have been macerated and this material injected into animals and their serum in turn used for the treatment of the disease. Good results are claimed from the serum of animals that have been treated for some time with mercury and iodids.

*Smallpox.*—Practically the same experiments have been tried with smallpox, the serum of immune individuals being used. Again, the serum from vaccine heifers that have become refractory to the inoculation has been used in treatment. Thus far the results of this treatment in these two diseases have not been noteworthy.

Possibly the best thing I have to report in the line of serum-therapy is the continued growth of the belief that disease can be conquered; that knowing the cause and the methods of many disease processes, we can and will find preventative or curative measures.

## THE USE OF ANTITOXIN IN THE TREATMENT OF DIPHTHERIA AND MEMBRANOUS CROUP.

WITH A COLLECTIVE REPORT OF ONE HUNDRED AND THIRTY-TWO CASES.

Read before the Indiana State Medical Society, May 29, 1896.

BY E. L. LARKINS, M.D.

TERRE HAUTE, IND.

During the year 1894, there were reported to the Board of Health at Terre Haute, Ind., 233 cases diagnosed as *diphtheria*. Of this number 102 were males and 131 females. There were 39 deaths recorded as

due to the disease. During the same period, 19 cases were reported to the Secretary of the County Board of Health, in the county outside of the city, of which number 9 were males and 10 females, with 6 deaths, making a total number of cases reported for the county 252, and the total number of deaths 45.

During the year 1895, there were reported for the city 182 cases, of which number 79 were males and 103 females, with 23 deaths. For the same period in the county outside of the city, 11 cases of which 7 were males and 4 females, with 6 deaths, making the total number for the county of 193 cases and 29 deaths. From Sept. 1, 1894 to April 1, 1895, there were reported 197 cases, of which 92 were males and 105 females. Of this number, 20 were fatal—9 males and 11 females.

From Sept. 1, 1896, to April 1, 1896, there were reported 150 cases, of which 62 were males and 88 females. In this period there were 21 deaths—12 males and 9 females.

Prior to Sept. 1, 1895, antitoxin had not been used except in a few cases. Since that time, it has been used by a majority of physicians in Terre Haute, and with a view of ascertaining as nearly as possible, the exact number of cases treated with it, with results, etc., I sent out a chart and find the total number to be 132, with 18 deaths, or 13.6 per cent., a summary of which is as follows:

SHOWING THE USE OF ANTITOXIN IN DIPHTHERIA AND MEMBRANOUS CROUP.

Number of cases reported, 132. Males, 61; females, 71. Times used: 98 cases, one time; 25 cases, two times; 3 cases, three times; 4 cases, four times; 2 cases, six times.

Day of disease used: 21 cases, first day; 41 cases, second day; 24 cases, third day; 22 cases, fourth day; 8 cases, fifth day; 4 cases, sixth day; 10 cases, seventh day; 1 case, eighth day; 1 case, thirteenth day.

Age of each: 1 case 2 months, 1 case 5 months, 1 case 8 months, 1 case 10 months, 1 case 11 months, 7 cases 2 years, 16 cases 3 years, 13 cases 4 years, 18 cases 5 years, 14 cases 6 years, 13 cases 7 years, 16 cases 8 years, 3 cases 9 years, 10 cases 10 years, 3 cases 11 years, 3 cases 12 years, 1 case 14 years, 1 case 15 years, 2 cases 17 years, 1 case 27 years, 1 case 35 years, 1 case 50 years.

Number of cases of membranous croup, 8; times used in each case, from one to six; result, six recoveries and two deaths.

Number of immunizing injections given, twenty; result, immunity in all. In nearly every case no effort was made at isolation. No unfavorable symptoms reported.

Original location of disease and extension to other parts: Fauces in almost all cases, and tonsils principally; extension to larynx, 29 cases, 5 deaths; intubation 7 times, 3 deaths; extension to nares, 18 cases, 8 deaths; tracheotomy not reported.

Disease extended after injection in only one case, and in that the physician said he was not certain how long the child had been sick before he was called.

Death did not occur in any case where injection was used within the first forty-eight hours of the disease.

Did not notice any unfavorable effect of the injection.

Number of deaths, 18; within the first 24 hours in 14 cases, in 2 days in 2 cases, in 2 and 8 weeks in 2 cases.

Days of disease: 1 case 3 days, 4 cases 4 days, 6 cases 5 days, 3 cases 7 days, 1 case 8 days, 1 case 9 days.

Number of cases followed by sequelae, 9; otorrhea in 1, nasopharyngeal paralysis in 6, aphonia and paralysis of right side of face and neck in 1, and paralysis of all voluntary muscles except of the head in 1. Recovery in all.

Thus we have the following table for the years:

	No. of Cases,	No. of Deaths.	Mortality Per cent.
1894 . . . . .	252	45	17.8
1895 . . . . .	193	29	15
Sept. 1, 1894 to April 1, 1895 . . . . .	197	20	10.1
Sept. 1, 1895 to April 1, 1896 . . . . .	150	21	14

Number treated with antitoxin from Sept. 1, 1895

to April 1, 1896—males 61, females 71; total 132, number of deaths 18, mortality, 13.6 per cent.

In the majority of cases only one injection was given to each patient, but in several it was repeated two or three times, and in two laryngeal cases six injections were administered, the cases being desperate and one eventually recovering.

It would appear from recent experience and a study of the literature upon the subject, that some of the deaths herein reported might possibly have been avoided had the remedy been vigorously pushed to its full therapeutic effect. It is the opinion of all observers that the earlier in an attack of diphtheria antitoxin is used, the better the results and consequently the greater the chances of recovery, and in an analysis of this collection of cases the statement is abundantly verified. In the 132 cases only one death is reported where the remedy was used within the first forty-eight hours of the disease, and in this case, there is doubt about the length of time the child had been sick before the physician was called. One physician reports a series of fifteen and another ten cases without a death, three of the latter being laryngeal, and with nearly all, the remedy was used on the first day, in four or five on the second day and in only three on the third day. In one case it is reported used on the thirteenth day, but upon inquiry the physician states the child had tonsillar diphtheria, from which it apparently recovered, but it subsequently extended to the larynx, for which latter involvement antitoxin was used with favorable results.

According to the reports read, the death rate increases *pari passu* with the length of time the disease had run before the remedy was used. In the 17 of the above 132 cases in which I used antitoxin, the result was favorable, except in two of the three cases where it was administered on the fourth day of the disease. These two proved fatal on the fifth day in twelve and eighteen hours after the injection, from sepsis consequent upon extension of the disease to the nares and laryngeal obstruction from extension to the larynx. I advised the use of antitoxin when I first saw the children on the second day of the disease, but the parents objected. I am still of the opinion that the children would have recovered had the antitoxin been used when I first saw them. On the fourth day of the disease when it became apparent that the children were sinking, request was made to have the antitoxin administered, but it was then my opinion, concurred in by the consulting physician that nothing would avail, as the little sufferers were beyond hope of recovery. In this collection of cases, the ages ranged from two months to seventeen years, but the great majority were from three to eight years of age.

Membranous croup is here classed separately from diphtheria, on account of the uncertain relation of the two diseases. There were eight cases of croup reported with two deaths, neither tracheotomy nor intubation being performed in any of them. These were reported as idiopathic or true croup—croup commencing in the larynx, in contradistinction to secondary croup, or diphtheritic laryngitis, due to extension of the diphtheritic process from the fauces. Of the latter class, twenty cases are given, with five deaths. In two of these the nasal and post-nasal cavities were extensively involved also, and it is difficult to determine which contributed most to a fatal termination—sepsis or laryngeal obstruction. In the

above twenty cases, intubation was performed seven times, with three deaths. No case of tracheotomy was reported.

In eighteen cases, the disease extended to the nares, eight of which died. The time of death in reference to the injection, was within the succeeding twenty-four hours in all but four. Two of these are given as the second day and two in two and eight weeks respectively. The last two cases were evidently due to some secondary effect of the disease.

The time of death in reference to the day of disease (except in the last two cases above mentioned) is given from the fourth to the eighth day. This taken in connection with the time in which death occurred after using the injection, clearly shows that the remedy was not used until after systemic infection had taken place, or laryngeal obstruction had so prostrated the system that the therapeutic effort of the antitoxin could not be obtained. Then, too, the remedy may not have been used as vigorously as it should have been.

There were reported twenty cases in which immunizing injections were given with no development of the disease and no unfavorable symptoms were observed to follow. In only two of the 132 cases is the disease reported to have spread after the injection was used. In one case of diphtheria, the nervous symptoms in a choreic patient, aged 12, appeared aggravated during the next 24 hours and then improved. In this series, six had post-diphtheritic paralysis; one had otorrhea. In one case the paralysis effected the lower limbs and in another case the whole voluntary muscular system, except the head. Aphonia and paralysis of the muscles of the right side of head and neck in one. All recovered.

I will only give the history of a few illustrative cases:

On the morning of Nov. 8, 1895, I was called to see Frank M., age 7 years, and found him recovering from a severe convulsion. The history obtained, was that of some error of diet on the previous day and he had had a light chill a few hours before the spasm. As convulsions were easily provoked in the child there seemed to be no special reason for alarm, but his general condition lead me to suspect some grave disease. Pulse was 110, feeble; temperature 101 degrees, and he had vomited once during the morning. The throat was not examined on account of his general nervous condition.

I prescribed calomel, quinin and bromids, hot mustard foot-bath and hot cloths to the head and over the stomach. In about an hour and a half, I was hurriedly sent for, as the child had another convulsion. I increased the bromids and ordered a general hot pack in blankets. He soon recovered from the spasm and had no more during his sickness. I advised isolation, as I thought it might be diphtheria. Calomel  $\frac{1}{4}$  gr. every hour; quinin  $2\frac{1}{2}$  grs. every three hours and bromids as necessary, were given during the afternoon and night, followed by castor oil the next morning.

November 9, 9 A.M., temperature 100.5, pulse 112, complains of nausea and weakness. Examination of the throat shows the whole fauces deeply congested, tonsils swollen and a gray deposit on each about the size of a split pea. Diagnosis of diphtheria was made. Quinin was continued, mercury bichlorid one-sixteenth gr. in elix. pepsin and bismuth every two hours and teaspoonful of whisky every two hours,

were given. Local applications of Loeffler's solution were made every four hours, and spray of peroxid of hydrogen 50 per cent. with saturated solution potassium chlorid every two hours; 4 P.M., the membrane has covered both tonsils and the uvula, and the child has had nasal hemorrhage.

November 10, 9 A.M., temperature 100, pulse 115. Throat emits a very fetid odor and there is a thin acrid nasal discharge. The whole fauces is completely covered by a thick leathery grayish-white membrane. The membrane is visible in the anterior nares and the child has a coarse croupy cough. I explained to the parents the serious and probably fatal condition and advised that antitoxin be immediately given. The mother dissented. The child's condition continued to grow worse and by the morning of 11th laryngeal obstruction was added to the faucial and nasal involvement. A more serious condition could not be depicted. They now consented to the use of antitoxin and I gave the child a full dose of the Behring No. 2. Now I would give the No. 3, and repeat in six or eight hours, in such a case. The laryngeal obstruction continued to grow worse during the day. In about six hours after giving the injection the child seemed much worse, but rallied some toward evening. About 8:30 P.M. I was sent for hurriedly, as the child was thought to be dying. A severe attack of dyspnea came on and the mother laid him on the lounge, thinking he was dead. When I arrived, he had rallied and was breathing better and improvement was continuous and rapid. I considered the sudden increase of dyspnea the night before, to be due to loosening of large portions of membrane thus producing complete obstruction of the larynx. I now omitted the mercury and gave small and frequently repeated doses of tincture chlorid of iron.

During the whole sickness effort was made to keep the nose and throat clear of septic matter, by the use of syringe and spray. The appetite was irregular and proper feeding was attended with difficulty. Aphonia remained several weeks after recovery.

I have given at length the history of this case in order to show by comparison the probable effect of antitoxin. About two weeks after my last visit to this patient, I was called to see two other children in the same family, one aged 5 years, and one 11 months.

The course of the disease was exactly the same, with the exception of the initial convulsion. I advised the immediate use of antitoxin, but the mother strenuously objected. I could not then conceive, that with such practical demonstration of the efficacy of the remedy in the other child, why objection should be made to its use in these two.

The children continued to grow rapidly worse until the afternoon of the fourth day of the disease, and all hope of recovery was abandoned, when request was made to have the antitoxin administered. My opinion, concurred in by the consulting physician, was that nothing would do any good, as the children were dying. Behring No. 2 was given, but both died in twelve and eighteen hours respectively.

It may be said that if antitoxin saved the first, it should have saved the other two. The inference is not justified, as the latter were profoundly septic, in addition to having laryngeal obstruction. The argument in this is, not that it saved one, but if used not later than the second day it would probably have saved all of them. Subsequent experience in the use of the remedy confirms my belief in this statement.

I will relate one other case of diphtheria, in a girl aged 8 years, who had enlarged tonsils and almost complete nasal obstruction from adenoid growths in the post-nasal cavities. The initial chill, followed by vomiting, occurred in the evening, and I was called the next morning. I found a typical case of diphtheria, the membrane covering the tonsils and extending up the edges of the palate. The characteristic acrid nasal discharge was present, showing extension to that cavity. The breath had a very fetid odor and her general condition showed profound infection. A full dose of Behring No 3 was immediately given, and a No. 2 given the next morning. We could do little with sprays and washes and no effort was made at local application. She immediately began to improve and the recovery was uneventful. I attribute her recovery entirely to the antitoxin.

A marked feature in this case was the very great reduction in size of the tonsils after recovery. An older brother of this girl had diphtheria in November, 1895, to whom two injections of Behring No. 2 were given, and his general health has been better since than ever before. Previous to this sickness, he was subject to frequent attacks of sick-headache, but now seems entirely free from them.

The effect, apparently, of antitoxin in the case of a delicate, nervous girl, 5 years of age, to whom two injections of Behring No. 2 were given, and in whom choreic movements had been frequently noticed and nystagmus was almost constantly present when the child was excited, was that since recovery both have disappeared, and she appears perfectly well.

Diarrhea did not follow the use of antitoxin in my cases, but constipation was of such frequent occurrence that I suspect some causative relation.

In the treatment of membranous croup with antitoxin, I have only one case to relate. I was called in November, 1895, to see a girl aged 5 years. I informed the mother of the serious illness of the child, prescribed the usual remedies and advised that antitoxin be used. Consent was given. Next morning I injected a full dose of Behring No 3. By this time the disease was fully developed. In twelve hours another dose of Behring No. 2 was given. Next morning the child was better. There was considerable dyspnea for two days, but the child recovered without further treatment, except some simple remedies.

In all the cases, except two, in which I used antitoxin, I called another physician to see the case, that it might not be said I used it where no diphtheria existed.

Reliance was placed in all cases upon the clinical picture of the disease for diagnosis. This is partly in accord with the recommendations of the boards of health of New York, St. Louis, Chicago and other cities, as they advise the use of antitoxin in suspicious cases, and especially in those where the physician is satisfied diphtheria exists, and not wait for a bacteriologic examination, as that can be made later. It is in the early use of antitoxin that its specific effect can be obtained.

The Klebs-Löffler bacillus develops upon the false membrane, and in most instances accompanies the local manifestations of the disease. The streptococcus, said to be the most virulent of the supposed pathogenic microorganisms, develops beneath the membrane, is a late product of diseased action, and is found in cases termed mixed infection. They are found (as the Klebs-Löffler bacillus) in the throats

of healthy persons, and even in the substance of the tonsils.

As to medical treatment of these cases, it has been claimed that it in no wise interfered with the use of antitoxin. I believe that large doses of bichlorid of mercury, in some degree at least, counteracts the effect of the antitoxin. Lately, I have confined myself to the use of small and frequently repeated doses of tincture chlorid of iron, and the moderate use of quinin and whisky. The free use of warm salt water or listerin properly diluted, for the purpose of keeping the parts clean, appears to answer every purpose.

This paper deals principally with an analysis of the reported cases.

Antitoxin in the treatment of diphtheria being of comparatively recent introduction, personal experience of the general practitioner must necessarily be limited in its use, and in many instances no opportunity has been afforded to observe its effects. It is from the experience of others that we must learn, and through collective investigation knowledge may be acquired by comparison.

The 132 cases herein given were reported by twenty-five physicians. The report is confined to Vigo County and principally to the city of Terre Haute. It will be observed that more deaths occurred in 1895 than in 1894, presumably on account of the greater severity of the disease. The report represents only the rate per cent. of deaths to the number reported and not to the actual number of cases, as physicians there seldom report more than one case in a family.

No subject could be of more profound interest to the physician, than that of the cure of diphtheria. In using the word *cure*, I refer to its literal meaning and practical application. No discovery since the days of Jenner, when he listened to the story of the milkmaid, and placed the practical banishment of that dreadful scourge, smallpox, within the power of all civilized nations, has been of such great value to mankind.

In antitoxin, I believe we have a true specific for diphtheria. In theory, and probably in fact, it is based upon the principle of vaccination, viz, *to render the human body immune to a virulent disease by introducing artificially into the system, a protective agent developed through modification of its specific product in foreign media.* After successful vaccination, a person may have varioloid, and thereafter, as a rule, be immune to the contagion of smallpox. The immunity conferred by the antidiphtheritic serum in the healthy subject appears to be practically evanescent, but what subsequent effect in this line, a curative dose of antitoxin has upon the human body suffering from a fully developed diphtheria case, has not been observed. So far as I am aware, a second attack of diphtheria has not been recorded as occurring in a patient cured of the first attack by antitoxin. It is well known that one attack of diphtheria confers immunity for a time, and it may be that the introduction of antitoxin into the system in the developed stage of the disease, may so fortify the protective elements that the body will not again become susceptible to the contagion.

The length of time in which antitoxin has been used is not sufficient for extended observation in this direction, but a second attack would be worthy of record.

The exact manner in which antitoxin cures diphtheria, is not definitely settled. According to the law

of Behring, material is developed in the blood which neutralizes the effects of the specific poison of the disease, and confers immunity to those in whom the serum of such blood is artificially introduced. The studies of Pfeiffer have, however, led him to the conclusion that substances are formed which destroy the infectious material and therefore eradicate the cause of the disease. It may be that cell action is so stimulated and the metabolic processes so changed that effectual resistance is offered, through the medium of the blood serum, to the further invasion by the infectious material. This is probable, as experimenters have found that the supposed pathogenic microorganisms may be cultivated in the blood serum of animals immunized for the disease which they produce. Moreover, antitoxins are held in solution in the blood, but do not pass through the coats of the vessels.

### SERUM THERAPY IN DIPHTHERIA.

Read in the Section on Materia Medica, Pharmacy and Therapeutics at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY EDWIN ROSENTHAL, M.D.

PHILADELPHIA, PA.

Since the introduction of the diphtheria antitoxin as a specific remedy in diphtheria, I have used it in 127 cases of diphtheria with a record of five deaths.

As the character of my cases were in many instances of the most dangerous variety, and in nineteen instances necessitated the operation of intubation, I may not be misjudged if I ascribe to the specific action of antitoxin the results obtained.

To briefly summarize my work they are: Tonsillar 67; pharyngeal and tonsillar 14; nasal, pharyngeal and tonsillar 1; pharyngeal 1; laryngeal 12; tonsillar and laryngeal 18; pharyngeal, tonsillar and laryngeal 8; nasal, pharyngeal, tonsillar and laryngeal 4; pharyngeal and laryngeal 2; total 127; number of deaths 5.

The ages were: Under 1 year 4 cases; between 1 and 5 years 55 cases; between 5 and 10 years 30 cases; between 10 and 20 years 13 cases; between 20 and 40 years 25 cases. Nearly 50 per cent. occurred below the age of 5 years and about 25 per cent. between the ages of 5 and 10 years.

1. The deaths occurred below the age of 8 years and were as follows: Age 1 year, 7 months; variety, laryngeal and tonsillar; operation, intubation; time of injection, about seventy-two hours after injection; time of death, forty-nine hours after injection and intubation; cause of death, sepsis.

2. Age, 2 years, 2 months; variety, laryngeal, tonsils, nasal, pharynx; operation, intubation; time of injection, about the fifth day; time of death, thirty-three hours after injection and intubation; cause of death, sepsis and nephritis.

3. Age, 1 year; variety, tonsils, nose, pharynx, lymphatics; time of injection about the fifth day; time of death, three days after injection; cause of death heart failure—a septic case.

4. Age, 8 years; variety, tonsils, nose, pharynx and larynx; time of injection, about the fifth day; time of death, nine days after injection; cause of death, heart failure.

5. Age, 1 year 1 month; variety, tonsils, nose, pharynx and larynx; time of injection, fourth day; time of death, five days after injection; cause of death, heart failure.

They were as regards sex, 51 males, 76 females.

The time in which injections were made: first day, 21 cases; second day, 52 cases; third day, 34 cases with one death; fourth day, 8 cases with one death; fifth day 6 cases with three deaths; sixth day, 3 cases; seventh day, 1 case; eleventh day, 1 case; seventeenth day, 1 case.

Many cases were immunized, using for that purpose antitoxin from several laboratories. In those cases immunized no visual traces of the disease were seen, although the bacteriologic examination frequently revealed the Löffler bacilli. In one case treated for diphtheria of the faucial variety (case 87) a re-infection took place on exposure six months afterward (case 123) the disease manifesting itself in the same way. This proves, that while antitoxin has curative and immunizing virtue, it does not confer lasting or permanent immunity; but the susceptibility to infection remains as in any other form of treatment.

The complications noted: Broncho-pneumonia five cases, only seen by me in the laryngeal variety. Nephritis one case. Albumin was found frequently both before and after injection, antitoxin not increasing the amount. Sepsis four cases. Eruptions noted in about fifteen cases, and was also noticed in several cases that received an immunizing dose.

Sequelæ: Undoubted paralysis of the lower extremities in a female suffering from diphtheria of the laryngeal variety with membranes on the tonsils, complicated broncho-pneumonia, intubated, the tube being worn twelve days, and who received 1,000 units of Behring's antitoxin. The age of this child was 1 year 10 months; the injection was made on the third day, and there was perfect recovery months afterward. Heart failure in two cases, after disappearance of the membranes; in one case three days after the visits ceased. Ozena was noticed in one case.

Method of using the diphtheria antitoxic serum: Antitoxin should be chosen of undoubted reliability. I am persuaded that my results are mainly due, not only to my method, but to the purity and efficacy of the antitoxin used. The technique pursued in the one case is that pursued in all.

Antitoxin is graded as regards strength into what is termed by its originators antitoxic normals or immunity units, which is an amount of antitoxic serum required to save a 500 gramme guinea pig from a minimum fatal dose of the diphtheritic toxin. The number of immunity units per c.cm. gives a standard strength of the serum; for instance: one one-hundredth c.cm. will protect a 500 gramme guinea pig, therefore 1 c.cm. of antitoxic serum, which protects 50,000 grammes of guinea pig, contains 100 immunity units, and would protect an individual weighing one hundred times as much as a guinea pig (about one hundred and twenty pounds, if the susceptibility were the same. The serum, of which 1 c.cm. equals 100 immunity units, is that with which most of my work was done. Serum of greater strength was used. Knowing the strength of the serum makes me have no regard for the quantity used, as I grade my dosage in immunity units and so apply it.

*The technique.* The antitoxin serum is used as a curative or immunizing agent by subcutaneous injection into the tissues of the body. For the purpose of making these injections any hypodermic syringe may be used if of sufficient capacity, as the Pravaes syringe, the Koch bulb syringe; I prefer a special antitoxin syringe, made for this purpose, having a capacity

of 10 c.cm., and which can be measured accurately by a screw, so that the quantity used can be administered in one injection. This syringe is supplied in metal case, with vulcanized rubber packing, thus permitting complete sterilization of both syringe and case. I have discarded asbestos packings since they become soft and pulpy.

The parts chosen by myself are in the back between the scapulae on either side of the vertebral column. Other parts of the body, as the loins, groins or sides of the chest have been selected.

The parts are thoroughly cleansed by means of alcohol soaked upon sublimate cotton or gauze, and after injection are hermetically sealed with iodoform collodion.

The syringe is cleansed by means of very hot water and the whole operation rendered as aseptic as possible. I have yet to record an abscess, or even any inflammatory reaction following at the seat of injection, all of which I ascribe to the rigid cleanliness enforced, in the use of my needles as well as in the parts acted upon.

*The dosage.* The amount of antitoxin used depends upon the time of making the injection, the age and body weight of the individual, and the gravity of the disease, also whether for the purpose of immunization or cure.

Experience has taught me that the method arrived at by the originators of the antitoxin as to the quantity of serum necessary to antagonize the toxins of diphtheria was the correct one; I therefore follow the original method and grade my dose into immunity units.

As an immunizing dose I give an injection of 100 units to perfectly healthy individuals exposed to the contagion—their body weight averaging 120 pounds, basing the dose on these being of equal susceptibility to the guinea pig. This dosage is now the general rule. If there be constant exposure I increase this dosage to 200 units. By constant exposure I mean where the individual to be protected lives in the same room or house, as the tenement system of any large city. In extraordinary instances, as a woman in the last days of pregnancy, about to be confined, I inject a full dose, 600 units, as an immunizing dose. Of such cases I have seen two instances with the most satisfactory results; the accouchement taking place in one instance in the very room occupied by the still affected child, and no symptoms being manifest.

*As a curative dose.* If the case be seen early, within twenty-four to forty-eight hours, and is of the faucial variety, where the infection has not reached the lymphatics, I administer at once 600 units. If the case be seen on the third day, or if at the very beginning the infection is such that leads one to believe in the necessity of prompt heroic treatment, as in the laryngeal cases or where the lymphatics are involved, or where the bacteriologic examinations show mixed infections (streptococcus, staphylococcus, etc.), I immediately inject 1,000 units. I then await results. If in six to twelve hours no change takes place or the symptoms are aggravated, I again inject 1,000 or 1,500 units of the serum, and so on in increasing quantities until there be an amelioration of the symptoms shown by a decline in the pulse rate and temperature and an improvement in the general condition.

The quantity of antitoxin can be increased to

enormous dosage; being harmless, no danger can be apprehended. I have used as high as 13,000 units in one case. Others have used 200 c.cm.—20,000 units, with complete recovery.

*Clinical manifestation of the diphtheria antitoxin serum.*

1. The effects on the pulse and circulation. In faucial diphtheria, within a very short period, about eight hours in the most favorable cases, the pulse rate declines and remains down and the circulation assumes the normal. This, however, may not be permanent, and if the rate increases again it is an indication for the administration of more antitoxin. Especially is this an indication in those cases where the toxemia is so marked that the temperature is only slightly above the normal or is subnormal. In laryngeal cases, however, the pulse rate remains high in the majority of cases, and this is seen especially in those cases intubated. The indication then is not so much for the antitoxin as for judicious collateral medication.

2. Effects on the temperature. In the most favorable cases, by which I mean the pure and simple diphtheria, there is a rapid decline from any elevation of temperature to the normal, and this decline is permanent. Where, however, there may be a recurrence of the fever and no manifestation of any intercurrent complication as pneumonia, and the like, it is an indication for an additional administration of the antitoxin, even if the occurrence should take place in one, two or three days after the injection. An elevation of the temperature later than four days indicates a broncho-pneumonia or some other disease and should be treated accordingly. In laryngeal cases is this especially marked, and in those cases intubated it has been seen by myself even after the tube was withdrawn.

3. Action on the diphtheritic membrane. The action of the antitoxin is visible to the naked eye by the effects on the diphtheritic membrane.

It limits the extension within twenty-four hours and promotes the separation in forty-eight to seventy-two hours.

As an indication for the sufficient use of the serum I have noticed a distinct red line surrounding the membrane, making a line of demarkation between the healthy and diseased mucous membrane. Over this line I have never seen the membrane spread, and when it has formed my experience has taught me to expect a very favorable prognosis in that especial case.

The membranes separate differently; in some cases it comes away in one piece, leaving a healthy mucous membrane beneath. In other cases, especially those in which there is mixed infection the membranes soften and become pultaceous, and seem to dissolve or melt away.

4. Effects in laryngeal diphtheria. When used early enough it prevents the spread of the membranes, thereby averting asphyxia, and avoids the operation of intubation or tracheotomy. The membranes disappear in the same manner as in the faucial variety, stenosis being invariably relieved on the third day. Where the laryngeal diphtheria is complicated with membranes on the tonsils, pharynx or nose, these disappear at the same time as the stenosis.

Intubated cases. Of the forty-four cases of laryngeal diphtheria, sixteen cases necessitated the operation of intubation, three of which were within the twenty-four hours after injection; the others were intubated before or at the time of the injection.

The average reduction in the time the tube was

worn was sixty-nine hours. Previous to the serum period the average time was 185.25; since this period the average time was 116.25 hours. This reduction was noticed and soon recorded by Huebner (*Klinische Studien*, etc.), Von Ranke, Johan Bokni, O'Dwyer and others.

Inasmuch as the indication for tracheotomy was the length of time the tube was worn, with the concurrent symptoms, decubitus, etc., the time being placed above 120 hours. No urgent symptoms were manifested even in the long cases to necessitate tracheotomy. For that reason antitoxin has proven itself of the utmost value and is one of the conspicuous evidences of its effects.

Antitoxin has reduced the mortality in cases of intubation. In my cases so treated the reduction has been from a mortality of 62 per cent. before the serum period, to 10.5 per cent with antitoxin. Nor do I stand alone in this experience. Bokai (Stephanie, Kinder hospital, Buda-Pesth) reports in his hospital work an increase of 17 per cent. in his cures. The reduction in the time the tube was worn in those cases of recovery was eighteen hours, the average being sixty-one hours serum period, against seventy-nine hours before the serum period.

Jos. O'Dwyer of New York, whose work on this especial method of treatment is so well known to you all, has very kindly sent me a short report of his cases, a transcription of which I give here:

"My results up to the present time in 500 cases, in a series of hundreds: First hundred—largely experimental—seventeen recoveries; second hundred, twenty-seven recoveries; third hundred, thirty recoveries; fourth hundred, twenty-six recoveries; fifth hundred, thirty-nine recoveries.

"The marked increase in the last series was due to the antitoxin, in thirty cases, of which there were twenty recoveries. In the seventy preceding cases in which no antitoxin was used, there were only nineteen recoveries, which was about the same percentage as in all the other series."

O'Dwyer's statistics substantiate my own: from a mortality ranging from 83 to 70 per cent. before the serum period his reduction has been to 30 per cent. The average time the tube was worn, serum period, was 80 hours; before this period the time was 147 hours. So the reduction in time in O'Dwyer's cases was 67 hours.

*Its action on the duration of the disease.* Antitoxin limits the duration of the disease to four or five days and shortens the period, which may reach to weeks.

When administered early in simple diphtheria all visual traces of the disease disappear on the third day.

In mixed contagion the diphtheria infection is antagonized and the complications treated without regard to the existence of diphtheria.

In the laryngeal variety the stenosis disappears the third day in those cases not requiring operative interference. In cases intubated, the tube can be withdrawn with a certainty and exactness on the fourth or fifth day, such a rule being unknown before the serum period.

The general condition of the patient in the majority of cases improves at once, and by its early use, even before depression was manifested; thereby preventing complications and sequelæ, the termination of which, even with the antitoxin treatment can not be averted.

*As a prevention of the meddlesome and dangerous method of constant local and systemic treatment in vogue.* As antitoxin acts specifically and the general condition of the patients improve so quickly, no necessity arises for the constant and persistent methods of applying local applications formerly pursued.

It is true that the membranes of the throat are the foci for the invasion of the system by the diphtheria toxin; it is equally true that the injection of the antitoxin antagonizes and prevents further infection. If this be so, and thousands of cases have clinically demonstrated it, the persistent endeavors to remove the membrane by hourly or half-hourly applications are not only superfluous but dangerous, as not only tending to keep the patient awake and in dread, but by weakening the recuperative powers open a way for complications and a dangerous or perhaps fatal sequelæ (paralysis, heart failure and the like).

For this reason when treating a patient with antitoxin, local applications may be made once in four to six hours, and simply for the purpose of cleanliness, or for the specific purpose of ridding the throat of the bacteria, thus preventing the danger of contagion to others.

Poisonous drugs, as corrosive sublimate and the like, are unnecessary, or if administered as indications might require (as ulcerations resulting from the diphtheria, etc., in long cases) may be given at longer intervals.

Nourishment and stimulants are required, but for shorter periods than before, two or three days, and dispensed with when no longer indicated.

While antitoxin is a specific for diphtheria, it is not a "cure all," and complications must receive thorough attention as if diphtheria no longer existed. If the circulation be weak and the case urgent, stimulants, strychnin, digitalis, camphor or ammonia may be indicated. Again if a complication, as pneumonia or nephritis, exists this should be treated without any regard to the diphtheria or intubation, by the wet packs or any method most favored by the operator. But the constant applications to the throat and syringing of the nose at too frequent intervals is to be deplored as tending to a fatal result.

*On the presence of bacilli in the throat.* Antitoxin does not destroy the Klebs-Löffler bacilli in the throat. They persist as long after convalescence as under any other form of treatment.

It is therefore well to make frequent cultures before permitting the patient to mingle with others, thereby spreading the contagion.

I am at present studying what remedies are most useful in destroying these bacilli, and I have the hearty coöperation of Dr. B. Meade Bolton, the director of the bacteriologic laboratory in Philadelphia, who examines these cultures for me.

I have used calomel combined with salol; corrosive sublimate, Löffler's solutions and a solution of nascent chlorin with tincture of the chlorid of iron, which I have used for a long period. The Löffler solutions and the chlorin iron mixture have given me the best results.

The formulæ of the Löffler solutions are as follows:

No. 1.

Menthol . . . . .	10 grms.
Toluol, q. s. . . . .	36 c.c.
Alcohol absol. . . . .	60 c.c.
Liq. ferri sesquichlor . . . . .	4 c.c.

No. 2.	
Menthol. . . . .	10 grms.
Toluol, q. s. . . . .	36 c.c.
Creolin. . . . .	2 c.c.
Alcohol absol. . . . .	65 c.c.

They are used by applying locally to the throat or nose by a mop or spray. Löffler's No. 1 is a painful application and is very much objected to for that reason, and can not be frequently used. The No. 2 is less painful and is applicable to a wider range of use.

The chlorin-iron mixture is administered in teaspoonful doses to a child 5 years of age once in two or three hours, during the day time only.

The formula is:

Potassii chloridi	
Ac. hydrochloric, C. P. . . . .	āā 100
Tinct. ferric chlor. . . . .	500
Syr. simplicis or glycerini . . . . .	12000

The bacilli disappeared under either of these medicaments in two weeks.

Guaiacol has been used by Dr. Martin W. Barr and Dr. Solomon Solis Cohen as a local application. The application is as painful as Löffler's, though Dr. Cohen has obviated this somewhat by the addition of menthol. Their results have been good, though systematic bacteriologic examinations have not demonstrated any superiority over my methods.

As an immunizing agent. That antitoxin produces immunity against an attack of diphtheria has been abundantly verified by a vast number of observers both in hospital experience and in private practice.

The quarantine system in vogue in Philadelphia has given me frequent opportunities to verify the assertion of Behring, Roux and others. This immunity is not lasting. Biggs of New York places it (from careful observation) at thirty days, Behring places it from six to eight weeks. I have seen no case immunized show clinical traces of the disease, though frequently Löffler's bacilli were found in the throat; where such cases existed, they were carefully watched and cultures made from time to time (once in three days). No other treatment except the immunizing dose was used, and cultures made and examined by Dr. B. Meade Bolton or Dr. H. D. Pease evinced the presence of the bacilli even to three weeks, though no visual traces were ever seen.

Antitoxin does not confer permanent or lasting immunity from diphtheria even to those who suffered from an attack of diphtheria and were treated with a curative quantity of the serum. For the susceptibility to a reinfection on exposure still remains with the patient, and therefore it should always be proper to immunize the patient whenever exposed.

The influence of antitoxin on the mortality records. There is no city in the world whose records have been carefully kept that has not shown a marked reduction in the death rates by the antitoxin treatment. I might except Philadelphia, which seems to be behindhand in the method of presenting her records as compared with other cities.

There is no hospital in the world where antitoxin has been used that has not shown a reduction in the death rate. Again I must note exception to this by the records of the Philadelphia Municipal Hospital, where it appears only hopeless or the most serious cases are sent, for this hospital holds the most unique position of recording an increased mortality from this method of treatment.

There is hardly an exception to be noted in the

statistics of private practitioners, which also show a reduction in the death rate.

Still, despite these positive proofs of the utility of the serum treatment; there seems to be a passive antagonism by some to this form of treatment. I can only explain it in the words of Dr. Charles L. Dana, New York (Diphtheritic Palsies and the Use of Antitoxin, *Medical Record*, April 11, 1896), from whose excellent monograph I quote: "While the treatment of diphtheria by antitoxin is a method that has been approved in all parts of the world and is upheld by a volume of statistics whose brute force is almost overwhelming, yet there is still some degree of skepticism about its real value. Most of the skepticism is the result of profound and banal ignorance, coupled, perhaps, with some hysterical obsession in the lines of zoöphilism and antivivisection. There are, however, some conservative physicians whose character and attainments we respect, who still hold a position of reserve, if not of disbelief, as to the value of the method, and they advance some very ingenious explanations of the way in which the statistics that so apparently favor antitoxin are gotten up."

These statistics are supposed to contain in a majority of instances cases whose recognition is simply bacteriologic and where the clinical diagnosis is secondary. Even if this be so, and I for my part have not counted as cases treated those immunized in whom the specific bacilli were found. I think the statistics are superior to the former for this reason: Given a case of diphtheria as formerly treated prognosis was out of the question; a mild case might suddenly become a serious one. A laryngeal case may become tracheal. With antitoxin the disease is aborted and the serious lesions now so commonly noted by different observers as broncho-pneumonia, multiple neuritis, post-diphtheritic palsies, etc., were not noted before because the patients perished long before these complications were noted. Therefore, given a case as now treated with antitoxin, if the serum is used early enough and in a judicious manner, mortality records should be simply to prove exceptions to the rule, and the death rate noted show a lack of careful observance of the earliest symptoms of diphtheria.

### AN INTRODUCTION TO THE DISCUSSION UPON "BLOOD-SERUM THERAPEUTICS."

Read in the Section on Materia Medica, Pharmacy and Therapeutics at the Forty-seventh Annual Meeting of the American Medical Association at Atlanta, Georgia, May 5 8, 1896.

BY HAROLD C. ERNST, A.M., M.D.

PROFESSOR OF BACTERIOLOGY IN HARVARD UNIVERSITY.

Probably the most radical change in the ideas of the causation of disease that has ever occurred has taken place during the last thirty years, its final outcome being the subject of the discussion before this meeting to-day. The steps leading up to the position at present occupied have been taken only after many wanderings and painful experiences, but as a result we seem to have reached a rational standpoint from which further progress may be made. The basis of blood-serum therapeutics is the idea of *immunity*, and the procedure is the result of the investigations made to determine how immunity occurs. It had been known for a long time that after attacks of certain

1 In the preparation of this paper I have received much assistance from the little work of Lachalme, "Blood-Serum Therapeutics, Paris, 1896."

diseases, there was a period during which a second attack of this same disease did not occur. This was, and is, known as *acquired immunity* to the disease in question. Certain races of animals are known to be immune to certain diseases, and this is a *natural immunity*, for which there must be some explanation if only it could be found. This explanation would give a basis for work directed toward the solving of the problem of how this immunity could be produced intentionally, and if this could only be done, we should have made a long step toward the actual and proper treatment of disease.

The securing of artificial immunity has been attempted in several ways; the best known and longest employed is that of vaccination. This method consists in the employment of the virus of a milder disease of the same type, thus, after the attack of the milder disease, and because of it, securing an immunity against the malignant form of disease. Since the introduction of bacteriologic methods, other means have been sought to attain the same end. The protective inoculations against rabies illustrate the use of the actual virus of the disease in an attenuated form, but of gradually increasing strength, to produce an immunity against the full strength of the same virus. Another method makes use of the living cultures of the bacteria producing the disease, as in the protective inoculations against anthrax, and still another of the products of the growth of the bacteria in the test tube, as in the employment of tuberculin. The theory of the action of these various methods is not the same, but their results, so far as they have been explained at all, have been supposed to rest upon some changes produced in the tissue cells or those of the blood, and it is to explain these results that much of the recent work has been carried on.

As to priority in the suggestion of the method under discussion, the position of the *British Medical Journal* seems to be a reasonable one: "The question of who was the originator of the serum treatment is one of interest. It is always difficult to speak with certainty on a point of priority of this kind, for new ideas seldom spring from one man, but we believe that the method had its origin from the observation made in 1887 by Von Fodor, that blood, when drawn from the body, had a distinct bactericidal action. Nuttall and others then pointed out that although this bactericidal action might be connected with the corpuscles of the blood, it was not confined to them, as the serum of freshly coagulated blood was found to contain some proteid substance which undoubtedly exerted a powerful bactericidal effect. In July, 1889, Babes and Lepp recorded a number of experiments in which they had found that the blood of dogs which had been vaccinated against rabies exerted a distinctly protective action when injected into susceptible animals either previous to or along with the virus procured from a rabid animal. Ferran appears to have been the next observer to accentuate this point. He was followed by Bouchard in France, whilst Behring and Kitasato in Germany, and then Roux in Paris, and others in rapid succession pointed out that there was in the serum of the blood of animals vaccinated against diphtheria and tetanus a distinct prophylactic and curative agent which, however, it was difficult to separate from the serum. In 1891 patients were treated in Berlin by the serum prepared by Behring," and the endeavors in this direction are more numerous and widespread to-day than in any other line of medical activity.

So far as the bactericidal properties of an immune body are concerned, all experiments tended to show that they lay especially in the blood, and the main portion of modern endeavor is in the study of the properties of this portion of the body.

The results put it beyond question that the serum of certain animals is so much opposed to some bacteria as not only to hinder their development but actually to destroy them. But this is very far from establishing a general rule as regards immunity, for the refractory condition of an animal and the bactericidal property of its blood are not by any means always, or even most often, present in proportional degree. As for example the bactericidal property of the rabbit's serum, an animal extremely receptive to anthrax, and the absence of bactericidal properties in a dog's blood, who is especially refractory himself to anthrax. So that while the bactericidal property of the serum is a very important matter, it can not be considered as being a factor in the production of immunity. Its existence, however, has served to show that the serum is not an inert material and has been the basis of other important investigations upon the properties of this tissue.

The attenuating power is one to which much attention has been paid by Bouchard, Roger and others, and is probably only a part of its preventive power. This latter factor seems to have been neglected by these observers, and it would seem that the mixtures of serum and bacteria they injected were harmless, not because the bacteria were attenuated but because the serum preserved the tissues from the pathogenic action of the bacteria which accompanied it. From the latest work on this question it appears that the bacteria increase their virulence in the blood of refractory animals, whether in the living body or in the test tube, and that this increase of virulence is the result of a new adaptation, or of a selection among the most resistant bacteria. So that even the existence of an *attenuating* power of the serum seems to be doubtful at present.

The possibility of the *antitoxic* action of the serum first suggested itself to Behring as an explanation of the constantly observed fact of the persistence and development of bacteria at the point of inoculation in refractory animals. The immunity in such cases could not be due to any effect upon the vitality of the bacteria, and the only explanation remaining was that of a neutralizing or destructive action upon their toxic products, this action being carried out by the blood-serum, in preference to the other tissues of the body. Taking up the study of diphtheria and tetanus, two diseases in which the results appeared to be especially due to the action of the products of the bacteria and not of the bacteria themselves, Behring and Kitasato showed that a mixture of the toxins of these bacteria with a small amount of the serum of immune animals could be injected without any results in animals extremely susceptible to the toxin alone. The results were found to be the same whether the mixture was made in the living animal after injection or in the test tube before injection; and also that the injection of the serum in another part of the body, and a little before or a little after that of the toxin could protect the animal from many times the fatal dose of the toxin so far that no effect would be produced by the latter. These observations were of the utmost importance and were asserted to destroy any ground for belief in the theory of phagocytosis. They

were and are believed by many to represent a direct chemical action of the antitoxin upon the toxin, which it either destroys entirely or turns into an harmless product. This antitoxic property is something wholly distinct from a bactericidal power, and is much less easily destroyed, for it resists a temperature of 65 degrees C., the addition of small percentages of antiseptics, and dilution of the serum with water. The antitoxic property has been ascribed to a definite substance contained in the serum, and this substance has been compared to a globulin or a diastase, without as yet ever having been separated, although many efforts to that end have been made. Whatever it may be, its power is enormous, as is shown by the experimental results obtained with serum containing it.

The idea of Behring and Kitasato, of the destruction of the toxin by the serum containing the antitoxin, although simple and easy of comprehension, does not appear to be applicable as a general theory, the more particularly if the observations of Metschnikoff and his followers be correct and taken into account. Metschnikoff has shown in his researches upon the blood of rabbits immunized against hog cholera, that their serum exercised a manifestly curative and preventive effect in fresh animals and without of itself possessing any attenuating or antitoxic property. In other words, that the effect was not merely due to a direct action upon the toxin or bacteria, but that a most important factor was the vitality of the tissues themselves in which the action took place. So that according to Metschnikoff, the action of the serum is especially a stimulation of the tissue resistance, exercised more particularly upon the phagocytes, making them better able to carry out their defensive action. The globucidal power of the serum is another factor that has to be reckoned with. It is closely allied to the bactericidal, and has been studied more especially by Buchner and Daremberg. It is shown upon introducing blood corpuscles of one animal into the serum of another. In such an experiment, the corpuscles are very rapidly disintegrated, and disappear in a very few moments.

This phenomenon occurs in the circulating blood or in the test tube, and Buchner especially has attempted to identify it with the bactericidal property of the blood-serum. They do in fact have characteristics in common, for they are both destroyed at a temperature of about 55 degrees C., upon exposure to light, or upon a modification of the saline constituents of the serum, but the existence of a special albuminoid substance, an alexin, as supposed by Buchner, is not by any means an accepted fact. The coagulating power of the serum is shown by its introduction by intravenous injection in another species of animal. Coagulation very quickly follows because of the precipitation of fibrin, but Richet and Hericourt demonstrated that this was to be avoided by making the injection in the cellular tissue, *not* directly into the blood vessels, so that the injected serum could only enter the blood current after passing through the lymphatics; and it has been recently shown by Hayem that this coagulating power is destroyed by raising to a temperature of 55 degrees C., while Mairot and Bose found that only 52 degrees C. was necessary to accomplish the same purpose. The same authors have demonstrated the toxic properties of serum injected into animals of another species, as manifested by muscular pains, febrile disturbances, respiratory affec-

tions and even fatal convulsions. These properties are somewhat more resistant to heat than those already spoken of and are supposed to be due to certain albuminoid materials. They are extremely variable in different animals and in the same animal toward different species, and they also vary very much in accordance with the condition of health of the animal from which the serum comes. The existence of such properties as these in the serum is of the utmost importance, and that they may exist is unquestionable. At the same time it must be remembered that their effects are only markedly present in intravenous injection and that a wholly different picture is presented as the result of introduction into the subcutaneous cellular tissue. In this situation these toxic effects are so slight as to be inappreciable and may therefore be practically disregarded.

These powers of the serum are apparently closely allied to the physiological characteristics like the "glycolitic" of Lepine and others, and the "peptosaccharizing" of Lepine and Barral.

This paper being merely introductory, the foregoing portion has been devoted to a brief and incomplete summary of the present knowledge of the properties of the serum in general, so far as they are concerned with the present subject.

The production of the antitoxic power has been attempted in the effort to secure immunity or the cure of many diseases, and these efforts are carried out in the same general way. The steps include the production of a toxin immunity first and then an antitoxin immunity. The differences between the two conditions are, that the former is slow in coming, is dangerous during the process, but is lasting and complete when obtained. It is, however, wholly inapplicable to general use. The second is very easy to obtain, is very rapidly reached, is not dangerous, but is not lasting, and sometimes, owing to the uncertainty as to how far it is necessary to go, is not complete. The process of obtaining the first is by the injection into the selected animals of gradually increasing doses of the toxin, either filtered free of the bacteria, or else with them still present, these injections being kept up until they have reached such a point that the animal is not affected by a dose of the toxin or culture sufficiently large to be fatal to untreated controls. This animal has then reached the condition of toxin immunity, and this immunity is a very lasting one. The condition is due to the presence of the antitoxic principle in the blood-serum. This antitoxic property may be used to secure an antitoxic immunity in other animals, and these not necessarily of the same species, provided the serum containing it be injected subcutaneously.

These are the simple bases of the method, the details are of the most varying and, as yet, indefinite character. The remarkable thing is, not that we know so little in regard to these details, but that so much has been accomplished in the time over which the investigations have extended.

A simple list of the diseases in which it has been sought to apply these principles for the production of the antitoxin is a long one, without any attempt being made to give an account of the methods pursued in each. Such a list—and incomplete perhaps—would include the investigations of Richet and Hericourt upon their staphylococcus pyosepticus, and the work upon *anthrax*, *hog cholera*, *avian septicemia* and *symptomatic anthrax*. *Rabies*, *typhoid fever*, *pneu-*

monia and tuberculosis have also been studied, without great success so far as is generally known. In diphtheria certainly, probably in cholera, and possibly in tetanus are to be found the main results that justify us in hoping for further advances in this direction so far as the application to man is concerned. Very possibly, too, results that may be immediately forthcoming will show that we are much nearer to a solution of the problem of the streptococcus antitoxin than at present seems to me to be the case.

### THE FALLACY OF ANTITOXIN TREATMENT AS A CURE FOR DIPHTHERIA.

Read in the Section on Diseases of Children, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY ELMER LEE, A.M., M.D., PH.B.

Vice-President American Academy of Medicine; Chairman Section on State Medicine American Medical Association. Chicago.

Early in my medical career, and at the time that Pasteur declared he had discovered a certain remedy for hydrophobia, it seemed a pity to me that the profound effort could not have been directed to the cure of diphtheria. Hydrophobia is such a rare disease, occurring not oftener than one to the million per annum, whereas diphtheria is universally prevalent, is the reason why regret was felt at the time of his publication. What it was hoped he might have done, is alleged to have been done by other investigators. Pasteur claimed in 1884, that a product made from the culture of the brain of an animal which had been inoculated with the disease of hydrophobia, was able, when injected beneath the skin of the human being, to cure rabies. This prophetic utterance emanated from a man who seemed to me, during this period of medical adolescence, to be utterly irrefutable. The scientific position which was accorded him, made his declaration appear to the world at that time, and to me with almost the same awe inspiring force, as if it had been an inspiration which had directed his mind and his hand. Hundreds and thousands of human beings have turned their faces toward the Pasteur Laboratory since 1884, supposing that they were mortally wounded by the teeth and the virus of mad dogs. There have been many who have presented themselves at his gate who were bitten, but not by a mad dog; hundreds of others who were bitten through the protecting folds of the clothing; many, indeed, who were simply licked by the tongue of a dog, not bitten at all. Still others have submitted to the inoculation through curiosity, having had no injury whatsoever. So great is the influence of the modern press that a scientific proposition, while still in the germinative state, is heralded throughout the civilized world, and is quickly transformed into a perfected science by writers of the press. There were a few who were able to doubt the truth of the allegation as to the curative influence of the Pasteur lymph. Long before cool and scientific inquiry could be made by physicians away from this center of discovery, the die had been cast that hydrophobia was curable by Pasteur lymph. At this present moment there are unmistakable proofs that error in judgment and in practice is the largest element in the hydrophobia cure. During the first few years of the experimental inoculations for rabies, many deaths occurred among the patients; so many, in fact, that Pasteur himself became alarmed at his own work. During a later period the death rate from

hydrophobia, as stated at the Pasteur institute, became less. The lowered death rate was proclaimed to be the result of the natural improvement in the process, and at the time, was accepted by nearly all. In the last few years of the hydrophobia cure the death rate has been materially lessened and is attributed to still further advancement in the understanding of the treatment. Right here is where the point, which is to be drawn from the foregoing statements, appears.

Whatever may be the view of persons who have not personally investigated the treatment of hydrophobia by Pasteur lymph, the real explanation of the reduced mortality since the declaration of the treatment in 1884, is directly due to the dilution of the curative lymph. In so far as the reduction of the virility of the laboratory product is concerned, just so far has there been advancement in the progress; perhaps, if the lymph was indefinitely attenuated, the mortality would be still less. This recital is introduced to show the error which may exist in one of the greatest therapeutic faiths close to the end of the nineteenth century.

Bacteriologic investigators, in Berlin and Paris, sent word to the United States recently, that diphtheria is curable by a specific medicine. This specific cure is produced as follows: A culture of the germs of diphtheria is injected, day after day, in increasing doses for a long time, into a horse, until it is able to withstand the poison of 250 cubic centimeters of the diphtheria virus, whereas one-tenth of a cubic centimeter of the same virus would be fatal to a guinea pig. After a certain period has elapsed a quantity of blood is drawn from the jugular vein of the horse, and the serum, after being further treated in the laboratory, is ready to be injected beneath the skin as a cure for diphtheria.

Ever since the discovery by Tyndall that the atmosphere, as well as the soil and the water, is inhabited by life in invisible form, there has been a prolific series of theories concerning germ organisms. It is generally accepted that a constant state of antagonism exists between minute organic life, and it is supposed that preservation as well as destruction of life, is attributable to these germs which are warring with each other. First came the discovery of germ life in nature, followed in due time by the declaration that all diseases are due to the influence of pathogenic germs. The next step consisted of a conception that pathogenic germs must be antagonized by other germs in the preservation of life and the treatment of disease. The next step in the process is that pathogenic germs, or their ptomaines, are able to be counteracted in their influence upon the life of the human body, by either the same germ or its own ptomaine. It is believed that during the period of inoculation of a horse with the diphtheria culture, a process is going on which is generating a fluid in the animal, that is antagonistic to the disease which it is assumed is caused by the original germ, namely, diphtheria.

Let us now consider diphtheria from a clinical standpoint. There are two varieties of diphtheria which exist to-day, but, one of which did not exist yesterday. One is true clinical diphtheria, the gross symptoms of which are entirely sufficient for practical diagnosis. The other form is the diphtheria of the bacteriologic laboratory. One is diagnosed by the clinician, while the other is discovered by the bacteriologist. These two varieties are made necessary by reason of the claims of bacteriology, by which

discoveries practical medicine has been both aided and retarded. Aided, by helping to a clearer understanding of the pathogenic and bacteriologic changes during the process of disease, and hindered, for the time being, by throwing a cloud across the pathway of natural and practical therapeutics.

Diphtheria is a systemic disease with both general and local manifestations. The local manifestations are located principally in the throat and larynx. By some observers the local symptomatology is considered paramount. It is taught by bacteriology that local microbes develop toxins upon the mucous membrane of the throat, and from this source the entire system is infected, whereas the true explanation regards the pathologic changes in the throat as but local exhibitions of general systemic poisoning. The laboratory declaration that a Klebs-Löffler bacillus found in the secretions of the throat establishes *prima facie* evidence that a disease is diphtheria, need not confuse our judgment and interfere with the conclusion previously stated in the foregoing sentence. It is undoubtedly true, that suitable nourishment for the growth of germs is found in the throats of children whose general system is impaired with diphtheritic sepsis. The so-called specific germ is found upon the tonsil both in health as well as in disease. Is it, therefore, a reliable means of determining the diagnosis of diphtheria?

Is the explanation of the false membrane which forms upon the throat, thus interfering with respiration, to be found by bacteriologic inquiry? When the system is impaired, and a determination of the weakened vital forces results in an inflammation of the fauces, there is thrown out upon the mucous membrane a thick, tenacious, glairy fluid, which dries and thickens into a membrane. The inflammatory state of the mucous membrane keeps adding fresh serous discharges, thus augmenting the deposit and ultimately filling the free space of the throat. In this serum the colonies of a variety of germs find normal food for nourishment and growth. Owing to the occlusion of the breathing space, insufficient air enters the lungs and further embarrassment of the health of the child quickly ensues. Examinations of the blood show an altered relationship among the component parts. Capillary circulation is diminished and congestions arise, both in the structures of the throat and neck, and in other tissues which are adjacent. The physical economy of the vital organs is imperiled and their functions are imperfectly performed. Retention of morbid matter rapidly accumulates throughout the entire system, especially in the capillary and lymphatic vessels. Great efforts are made by the resisting vitality to unload its burden and repair the damage.

At this time of the pathologic processes there are two therapeutic measures which are imperatively demanded: first, the supply of new force to the tissues by fresh nutrition; and secondly, aid to the impaired efforts of the organism to remove the morbid and retained matters. Nature is doing all that it can to carry the effete material produced by the disease, out of the system through the excretory organs. At this moment what is accomplished by forcing into the circulation a substance which has no natural relationship to the structure of a single element composing the entire body? The system is laboring and panting for life, under the oppression of toxins which it is trying to eliminate. At the very crisis of the greatest strain

upon vital resources, a serum which does not belong in the human economy, is strangely added to the fearful load, which is in some cases the last straw that breaks the camel's back. Its use is therefore unphysiologic and absolutely contraindicated. The bacteriologist affirms to the contrary; observe which is the better able to judge, practical clinicians or the ultra-scientist in the laboratory?

The claims that are seductively held out that cases treated early by antitoxin would recover have utterly failed. The claim subsequently that cases treated by antitoxin recover more quickly than those not so treated has utterly failed to be true. The claim that the death rate would be lessened has proved to be a disappointment. The claim that antitoxin was harmless has been proven to the contrary by many fatal terminations. Judging from the facts concerning the use of antitoxin in practice, does there stand on record to-day one single valid reason, from a clinical standpoint, to encourage the hope of better results in the future than have been attained in the past by other methods of treatment? It is not the purpose to impute insincerity, or lack of intelligent industry, on the part of the profession, concerned in experimenting with antitoxin, but the promises of better results through its use have unfortunately failed to be substantiated.

The human system, when laboring under morbid influences, needs rather those elements which can add strength and vigor to the vital resistance. By what law or principle in physiology can augmented vital resistance be maintained by the introduction of antitoxin into the system? Has the explanation of the action of antitoxin been satisfactorily given by those who are its sponsors? It is to be conceded that there are cases of diphtheria which, when treated by antitoxin, have seemingly progressed favorably, while there are other cases which have quickly terminated fatally. The influence of the antitoxin virus is directly dependent upon the condition of the patient at the time of its introduction. If the powers are well maintained, as during the first few days of the disease, naturally the system is stronger and its efforts more effective toward elimination, both of the antitoxin introduced and of the autogenerated toxin. Here is the explanation of the advantage claimed by the early use of antitoxin. It follows, when the system is further impaired its phagocytic action is also impaired, and the chances for recovery by reason of the further introduction of extraneous matter are lessened. What physiologic problem could be more simple? The point is this, that the blood does not need to be further polluted in order to expel the autogenerated products which it already contains. Can any one explain the reaction which takes place in the human living organism when antitoxin is added? There is a reaction, but that the reaction is a curative influence is open to discussion.

A small amount of morbid matter adjacent to living cell structures is dissolved away by the leucocytes and forced out of the body through the escapes provided by nature. This takes place regularly when the cell is aided by forces which contribute to its vigor. If the vitality is diminished by extensive morbid processes, extraneous matter added to the system only further weakens the reconstructive agencies which are at work. The theory that sepsis of any kind, already in the system, is able to be neutralized by the addition of manufactured toxins from without, though freely taught, is utterly inconsistent and

unreasonable. Can the chemic reactions of the laboratory be successfully repeated in the laboratory of the human body?

Has horse serum, plus disease, any natural place in the human blood? And the red corpuscles are dissolved by its presence. No material success has ever been achieved by the transfusion of healthy animal blood into the human body for the cure of disease. Transfusion of salt water accomplishes all that is claimed for the process. Now then, how much the less is likely to be accomplished when an infected animal serum is injected for the cure of diphtheria?

The blood has lost some of its component elementary conditions. It is thereby altered in character, and when acting through inflamed mucous membranes morbid symptoms are produced, such as are seen in diphtheria. The fluid which patrols the entire body should be strengthened rather than further decomposed and disorganized by the addition of extraneous and poisonous matter.

The records of the cases treated in the Willard Parker Hospital of New York City prove that antitoxin is dangerous and even fatal. The statistics of that hospital establish that the further use of antitoxin is unjustifiable. Extreme interest and effort to know the truth has guided the staff of the Willard Parker Hospital. Dr. Joseph E. Winters of New York has sought diligently to establish the value of antitoxin, but the clinical experiences have forced him unwillingly to condemn its use. Is it safe to neglect the warning of such an experienced clinician and medical teacher? Professor Lennox Browne of London, patiently and earnestly sought for clinical reasons to further the interests of antitoxin. His conclusions are emphatic and pronounced against it. Dr. Weeks of Philadelphia also deprecates the use of antitoxin, basing the conclusions upon an extensive experience in the Municipal Hospital of that city.

Health department statistics of New York are cited in Chicago to the advantage of antitoxin, and Chicago statistics are published in the interest of antitoxin in New York. Health department methods of collecting information must be taken with allowance for accuracy. Previous to leaving Chicago a culture was made of the tongue of the office boy and the tube left at the city health office. The answer received stated that the case was one of true diphtheria. In fact, the boy was not ill at all. Provisions were immediately made by the department to fumigate and otherwise annoy the family at the boy's home. Is it not easy to be seen that the enthusiasm and overzealous interest of the medical corps in the employ of cities may bring to the notice of the health departments cases similar to the one cited? Such reports go on the records and contribute toward the statistics which are sent broadcast. The statistics very quickly become confused and their power for usefulness is absolutely *nil*. Unquestionably large numbers of cases which have been reported to be diphtheria and cured by an injection of antitoxin have been of the bacteriologic class.

It was recently stated to me, upon good authority, that the sales were falling off rapidly and an early termination of the demand for antitoxin was not for off; also that offers to purchase antitoxin upon most advantageous figures had been declined because of the fear of pecuniary loss. Thus the straws point the way the wind blows.

103 State Street.

## SOME PRACTICAL POINTS ON THE COMBINED EFFECTS OF ANTITOXIN AND INTUBATION,

WITH SPECIAL REFERENCE TO INFANT FEEDING IN MALIGNANT DIPHThERIA.

Read in the Section on Diseases of Children at the Forty-seventh Annual Meeting of the American Medical Association at Atlanta, Ga., May 5-8, 1896.

BY LOUIS FISCHER, M.D.

Associate Professor Diseases of Children, New York School of Clinical Medicine; Physician to the Messiah Home for Children; Attending Physician Children's Department, German Poliklinik and to the West Side German Dispensary.

Certain factors appeal to us in a severe case of laryngeal diphtheria. The main point to be considered, however, is to afford instantaneous mechanical relief and prevent asphyxia. This, to my mind, is of more importance than the consideration of what the real therapeutics shall be.

If therefore, a child has recovered from the exhaustion following this mechanical relief by intubation, then it is necessary to commence with the real therapeutic management of the case.

If a history of diphtheria exists, and we are positive of the diagnosis, then we should without delay inject our case with either 5 c.cm. of antitoxin of the strength of 500 normal units, and if no relief is afforded in twenty-four hours, then we repeat the injection of the same dose of antitoxin. The choice as to the location of the injection depends on the practitioner. My own preference has been, that seen by me in Berlin with Professor Baginsky, in the interscapular space. It is not the purpose of this paper to detail the technique of intubation, for every one of us, no doubt, knows when and how to place a tube.

The same might be said for the injections of antitoxin. They have become so universally used that the technique is very well understood. It is an important point to lay stress on what I consider of vital importance, especially so, when we hear of sudden deaths occurring within a minute or two after an injection of antitoxin has been given. Any one familiar with the danger of injecting air into a vein will at once recognize the great importance of selecting that part of the body which is least likely to have large veins, and where we would be least apt to puncture them. A thrombus forming in a vein can easily produce death, and we all know that were the barrel of the syringe filled with plain water or milk or with any other ingredient, that death would occur just as quickly if air is injected into a vein, as it does or has done when antitoxin is injected.

We then have reached the two main indications demanded by science of to-day in the treatment of an obstinate case of laryngeal diphtheria: 1. We have satisfied nature's demand for the relief of the stenosis by intubation, and probably avoided asphyxia. 2. We have aimed, by injecting the antitoxin, at the destruction of septic elements or toxins introduced in the system through the agency of the Klebs-Löffler bacilli. The most important part of the treatment of a severe laryngeal diphtheria consists in the after treatment. I insist in every case of laryngeal diphtheria, with a tube in the throat, on feeding per rectum. By this means we can guard against that most dangerous complication, namely, Schluck-pneumonie. This latter is caused by the suction or flowing into the trachea, bronchi and capillaries of liquids, intended for swallowing, and causing pneumonia.

That such a pneumonia is not only a very difficult matter to handle, as a complication, should not be lost sight of, for more than one-half of all fatal cases die of this complication. I therefore advise giving a cleansing enema of soap and water, usually a pint in all, and throw it into the rectum and colon to wash away accumulated feces, and follow this cleansing enema by nutrient enema of peptonized milk, peptonized yolk of egg, peptonized beef juice, and sometimes small quantities of brandy if stimulation is called for. The interval of three hours is usually called for owing to the risk of exciting too active peristaltic movements and having the nutrition emptied out of the bowel.

It is well to bear in mind that the rectum absorbs and does not digest, and therefore that only liquid nourishment should be thrown in. No solid food should be pushed into the rectum. Small quantities will be better borne than large ones; all farinaceous food, like barley, rice and farina, soup made from beef, veal or chicken can be thrown into the rectum in quantities of one to two ounces.

I have frequently tried to resort to forced feeding by pushing a catheter through the nares into the esophagus and pouring small quantities of liquid food directly into the stomach, but this is such a highly objectionable plan in private practice that I have almost completely abandoned it. You will agree with me that while some parents will think it cruel to push a Nelaton catheter through the nose of their beloved infant for feeding purposes, they will not object in any way to using the rectum and colon for this purpose.

A point to remember in connection with dyspnea which sometimes occurs in an intubated child, is that relief is frequently afforded by giving inhalations of oxygen so that as a matter of routine, I invariably advise a cylinder of oxygen to be kept handy, in a malignant case of diphtheria with stenosis and threatened asphyxia.

The wonderful results achieved by me in the treatment of this dreadful disease are due to the rapidity with which I tried to overcome urgent symptoms. Thus I never leave a high temperature, of 105 degrees, without at once giving an antipyretic bath, immersing the child in a temperature of 90 and gradually cooling to 70, the duration of the bath to be in all about five minutes. This is to be continued every three hours until the temperature remains at 102. I do not use antipyretics during the course of treatment of diphtheria. One of the greatest mistakes encountered by physicians is that after an injection of antitoxin has been given, they discontinue all further medication. They do not properly nourish their patients and merely look for miraculous disappearance of the pseudo-membrane and all further symptoms after this one injection, and thus it is that the great many failures in the treatment of diphtheria with antitoxin are not due to the impotency of this most valuable therapeutic agent, but rather to the careless after-treatment, and sometimes the exhaustion of the patient, from lack of proper nourishment.

I insist on a thorough nasal irrigation of warm salt water solution at least twice a day, in every case of diphtheria without nasal complication, merely as a hygienic measure.

*Sustain the Heart.*—This can best be done with nourishment, and the less drugs used, excepting those urgently called for, as for example strychnin in minute

doses, the better. A wise plan is to give most children as little alcohol as possible. It is a good plan to give all medication hypodermically, so, for example, a minute dose of strychnin can be used if required, or alcohol can be injected. A cool, clear temperature of 65 to 70 degrees will add much to the comfort of our patient. If the glands of the neck are very much swollen, then an ice collar will do a great deal toward relieving the swelling. Spartein is sometimes called for, but unusual care must be exercised owing to the irritability of the stomach. Pseudo-membrane should be carefully noted in regard to its size, and every diminution looked upon as favorable progress. *Fetor ex ore* is a usual symptom of necrotic tissue, be it in the form of a pseudo-membrane or otherwise, and is usually found during the course of laryngeal diphtheria. A gradual fall of the temperature, not by crisis, but by lysis, should be looked forward to as a favorable symptom; so also the diminution of the size of the glands of the neck.

Such symptoms as high-colored urine with small traces of albumin, possibly a cast, were now and then found during the ordinary course of a malignant case of diphtheria, long before antitoxin was discovered. It is therefore not surprising to find it now.

I look upon the disappearance of a high color and a freer secretion of urine, and a disappearance of the albumin as favorable symptoms indicating convalescence. The respiration in some of my cases reached as high as one hundred per minute. A diminution in the number of respirations and at the same time decrease in the rapidity of the pulse, with the fall of temperature by lysis, are all favorable symptoms.

Diaphoresis, when commencing after a few days of treatment of a malignant case of diphtheria, I look upon as very favorable symptom, being nature's effort of eliminating toxic elements through the sweat glands.

I have purposely refrained from tiring you with the description of clinical histories of single cases of diphtheria, and furthermore, do not care to give you statistics which can be made to suit the whims of any author, but can assure you that I recognize to-day in diphtheria, not the old foe of former times, but am willing to give a better prognosis to-day, with proper antitoxin treatment, aided by so called supporting treatment, which consists in concentrating nutrition when the body most needs it, than by any old fangled method of treatment known.

## AN EXPERIENCE WITH ANTITOXIN WITH INSTRUCTIVE RESULTS.

Read in the Section on Diseases of Children, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY JOSEPH WM. STICKLER, M.S., M.D.

ORANGE, N. J.

I will quote but two cases, types of others, to call attention to points which seem to me to be of importance in connection with the administration of antitoxin.

*Case 1.*—Some time ago I was asked by Dr. Simmons of Orange, N. J., to see a boy about 7 years of age, who was suffering from some form of laryngeal stenosis. At the time he requested me to consult with him he could not discover by the ordinary method of examining the throat (with tongue depressor) any membrane. When I arrived at the house the child was sitting upon his mother's lap, presenting the appearance of a child in the advanced stage of so-called membranous croup,

*i.e.*, laryngeal diphtheria. The breathing was however fairly easy, at times losing its marked stridulous character. When the respirations were not markedly quickened and labored the skin was normal in appearance and the lips ruddy in color. The pulse was full, strong and regular. Mind clear, urine normal, and body well nourished. An examination with the laryngoscope revealed the presence of quite a large amount of membrane within the larynx. This discovery when coupled with the previous history of the case led me to give a very unfavorable prognosis. I told the Doctor I would be ready to perform tracheotomy any moment he might desire it, fully expecting to be sent for before the following morning. During the interim I advised the use of antitoxin. Three days passed before I heard of the boy's condition. Imagine my surprise when Dr. Simmons told me that the patient began to improve almost immediately after the use of the serum and made a complete recovery in one week. The points presented by this case are: 1. The laryngeal stenosis had been gradually increasing up to the time I saw the patient. 2. The stenosis was due to the presence of membrane which was demonstrable by the use of the laryngoscope. 3. The vital powers of the child had not been markedly depressed by the toxins of the Löffler bacilli, and it is to this latter point I wish to direct special thought.

Case 2.—Dr. Thomas S. Fitch of Orange, N. J., asked me to see a little girl 5 years of age who had diphtheria. The disease had developed three days prior to my first consultation. When I was admitted to the sick room the child was breathing at the rate of thirty to thirty-five times per minute, and the respirations were very labored in character. The pulse was weak and averaged 100. The pupils were somewhat dilated, and the child was very irritable. The skin was mottled and of an ashy hue. The lips were red but somewhat shriveled. The hands trembled and the gait was unsteady. When left alone she would sleep, turning occasionally from one side of the bed to the other. The urine was diminished in quantity and was slightly albuminous. The body was fairly well nourished, but only small quantities of fluid nourishment could be given at comparatively long intervals. The entire pharynx, tonsils, soft palate and a portion of the hard palate presented to view a dense membrane broken only at a few points. The nostrils also contained membrane. Bacteriologic examination showed the presence of myriads of the Klebs-Löffler bacilli. Dr. Fitch felt inclined to use antitoxin. My opinion was that because of the tremendous depression of the vital forces the child must die. It seemed best therefore to support the heart's action, if possible, till nature could rally her spent powers, and to accomplish this result we decided to use active heart stimulants and such nutriment as the patient could and would take. In addition to this line of treatment we thought we would try antitoxin, giving 10 c. c. at twelve-hour intervals. The patient got steadily worse until about twenty-four hours later, when she died. The point presented by this case, which seems to me to be of great moment, is this, the folly of using antitoxin when the whole animal economy has been struck such a tremendous blow by the poison of the diphtheria bacilli.

Judging from these and other cases, I believe that when the heart's action is fairly good, when the system at large has not been seriously impaired in its tone, when the urine shows little or no albumin and indicates no organic nephritic trouble, as in the first case quoted, I care not how much membrane there may be present, antitoxin when judiciously used is likely to benefit the patient. When, on the other hand, conditions obtain such as are mentioned in Case 2, I believe antitoxin to be contraindicated.

DISCUSSION ON PAPERS OF DRs. ELMER LEE, JOS. M. STICKLER AND LOUIS FISCHER.

PROF. EDWIN KLEBS, Citronelle, Ala.—First permit me to speak on the papers read before us. Dr. Elmer Lee stands on the old standpoint of the pathology of diphtheria, which is not tenable. We must, it seems, accept the bacilli as the only cause of diphtheria. That is necessary not only from a bacteriologic or a laboratory view, but of a clinical view also. You know that in diphtheria we first see an affection of the throat, a slight angina, and later a general affection; that is the consequence of the action of the diphtheria bacillus in the throat. The few cases in which we have no local affection are not contrary to this opinion. The local affection may occur in parts we

can not see in the larynx or be a very slight one. But we need not dwell on this point longer. Now the second point he has brought forth, the observation of the diphtheria bacillus in the throat of some healthy people. That part is often discussed. But it seems to me quite clear that the right explanation of it is not given by Dr. Lee.

We see so often in grave diphtheritic epidemics, that the children become sick in a grave manner immediately after having caught cold. In this manner I have lost a child. He was out in a heavy snow storm in Zurich, and upon returning had diphtheria. How was this to be explained? Surely the child had the diphtheria organisms present before, and under the influences of the cold there was made some change in the mucous membranes, probably an obstruction of the circulation that we can see microscopically in fresh cases, so that the tissues become better adapted for the growing of the diphtheria bacilli. And then, if the gentleman does not accept that the diphtheria bacillus is the cause of diphtheria, we would have two different diseases in the same body and we must ask, What is that other disease not differing from the diphtheria bacillus? Now, the other preferred opinions are very difficult to speak upon. He has said the antitoxin can be dangerous. I asked him and he said, yes, he had personally seen such cases. But we will return to that point later.

Dr. Stickler has brought forward two cases, one doing excellently, in such manner as, if I have understood it right, one can not think otherwise than that there has been a very beneficial influence of the antitoxin. In the second he had no effects. But, have we any one treatment that will be efficient in all cases? That is not possible. But I think Dr. Stickler has given us a very important paper. Clear observations are often more valuable than greater statistics.

Now as to the last paper. I have not understood much of it, but I believe the gentleman had good results with the antitoxin. I can not enter into details and return to a more general discussion. From some we hear that the antitoxin serum is inefficacious and may be sometimes dangerous; from others we hear that it seems totally reliable. Now, we must have fair play in this matter. It is enough to now state that numerous observers had good results in a great number of cases. That in farther progressed cases there is noted inefficiency, can not be a ground for rejecting the treatment; a graver objection is the possibility of sudden death after the injection of the antitoxin.

The first point we must regard in this question is the experimental foundation of the whole question. It seems to me there can be no doubt that an anti-poisonous or antitoxic effect of these substances is fairly demonstrated. If Behring and others inject great quantities of it at the same time as poisonous matter from diphtheria cultures, into the abdominal cavity of guinea pigs, and the animal will not die while control animals die in a very short time, we can not say otherwise than that there is a benefiting antitoxic influence. The same observations have been made by all good observers. If we find such a degree of security in animal experiments we can not say there is nothing in it and it is not probable that the same substance is of no use in man, when it is effective in guinea pigs.

But there is another point to discuss. Behring and others have said the antitoxin has alone a healing influence, but it has also a preventive influence. That is another question. We must ask, Can we immunize with the antitoxic serum in a certain quantity susceptible animals? Some physicians have asserted that they have had good preventive results by injecting as small a dose as one cubic centimeter of serum into children. But, gentlemen, that must be a mistake. They may have injected the serum and the children have not become diphtheritic, but that does not prove that the injection prevented the diphtheria. It is very difficult to speak of such a preventive action without proof of infection. But we have other and better ground to say it can not be that there

is given by the injection of so small doses immunity to any animal or human being. The serum has proven a good nourishment substance in which it is possible to cultivate the diphtheria bacillus. Now, can the same substance, in such small quantity, immunize an animal if the diphtheria bacillus can grow upon it? We will remember how great quantities of the strongest diphtheria cultures are necessary for immunizing animals. These must be continued for a long time and the immunity lasts for only a short time. And so I think the antitoxin has not an immunizing power; or, at any rate, such power has not been demonstrated. I must say I have not been able to read the latest German papers, but I think conclusive experiments have not been made. Whether the assertion of R. Pfeiffer that his cholera serum effects degeneration of the cholera vibrio is acceptable or not we can leave undecided.

I think statistics are always a little uncertain. When a new remedy is used, many mild cases are healed in a short time. In Berlin there are two hospitals. The patients in the St. Urban Hospital were treated with the serum whereas in the Bethanien-Hospital the patients were not treated with the antitoxin. The death rate was reduced in the first from 50 to 20 per cent., in the second from 50 to 30 per cent. But in the first the cases were nearly doubled in number, so that more lighter or fresher cases were treated by antitoxin.

Now I come to a point that seems to me to be of the highest importance, the danger of antitoxin. I wish that point would be illustrated in a more extensive manner by publishing all cases in which the injection was shortly followed by death. We have such cases, but a part of them seems to be on account of the disease. But if in one case alone the patient has been killed by antitoxin, we have a great interest to find out the true cause of the death. Such a case is that of Professor Langerhans in Berlin. After a girl in the house became diphtheritic, he thought he would, if possible, prevent the spreading of the disease to his own children, but after the injection the first child died immediately. So it is possible that death may occur after the most cautious injection of antitoxin, a fact that gives a high responsibility to every physician using this remedy. We must search, therefore, to find out, what may have been the cause of such fatal accident.

In this case it is reported that the body of the dead child was quite normal, well nourished. There was no introduction of air into the blood. The danger of introducing air is, by the way, not so great as often accepted. One can inject some centimeters of air in the blood vessels of a rabbit without any bad effect, as the air is resorbed in a very short time. It will be better to inject the fluid in children into the muscles far distant from the lungs, in the dorsal or gluteal region. Then it is convenient to push the needle alone in first and see if bleeding follows or not. If not, one may inject without fear, but always slowly, under no high pressure. If these precautions are followed, I think that no danger can be feared from the injection.

If all these precautions were taken in the Langerhans case, I can not tell, but it is clear that, if the death occurred by the injection into a vein, the antitoxin used must have been in a high degree poisonous.

I do not know, if the consequences of such injections in the blood of animals are studied, or if kymographic designs for measuring the blood pressure and action of the heart before and after the injection of antitoxin are made, certainly they should have been, if they were not.

I think it is not probable that the antitoxic serum itself contains such a formidable heart poison, as very great quantities of it injected into the peritoneal cavity of animals proves harmless. Much more probable it seems to me, that in this and other similar cases observed in Brooklyn, N. Y., an accidental pollution of the antitoxin has combined with intravenous injection to produce the fatal effect.

The sure disinfection of serum is a very difficult matter. Twice I have found microbes in tubercle-serum. On the other side, the best antiseptics, as mercury-bichlorid, phenol and kresol make coagulations in the serum. Therefore, one must search for other disinfectants that will not coagulate albuminous matters. I note that chinisol is proclaimed as such by Emmerich; its antiseptic action is forty times stronger than carbolic acid and does not coagulate albumin. I have proved it a very good disinfectant for external and internal use, and I would recommend it for the disinfection of serum. Certainly we must demand from the manufacturers of antitoxic serum, that they must prepare the serum in an absolutely pure manner, excluding totally the possibility of accidental pollution. It is not a good manner to dispense it in colored bottles. It can be protected against the light by dark coverings.

I am sure that all these precautions can be executed and will be executed, in this land, in which I have seen as good bacteriologic work as anywhere in Europe. I remember with pleasure that in many of our cities are instituted health offices for the preparing of the anti-diphtheric serum (New York, Pittsburg), in which in every case of diphtheria the presence of the diphtheria-bacillus is controlled by bacteriologic examination and the serum is given gratuitously to the profession. In Berlin the magistrate has declined to do the same. I hope that the demands of science will always find here a ready reception.

DR. W. E. CASSELBERRY, Chicago—Having had considerable experience with antitoxin, especially in laryngeal diphtheria, I feel I may at least recite my experience. Previous to the introduction of antitoxin, the results in laryngeal diphtheria and membranous croup were very unsatisfactory. The published results, on the average, only saved about 25 per cent. of all cases that had come to the operating stage. The antitoxin has reversed my statistics, or at any rate my statistics have been reversed, to the saving of about 75 per cent. of cases. I attribute this to the antitoxin, in the first place, because the two epidemics were parallel, and secondly, because of the course of the clinical symptoms. The antitoxin in my hands has, both in laryngeal and pharyngeal diphtheria, within twenty-four hours after its administration, had the result of reducing the intumescence of the parts. I have not observed it caused a rapid falling off of the membrane, but the swelling and intumescence, which is responsible largely for the laryngeal obstruction, within twenty-four hours subsided. The other clinical symptoms also ameliorated under the influence of the remedy. The broncho-pneumonia does not so frequently supervene. The antitoxin appears to limit the disease and prevent its further extension. The tube having been introduced into the larynx, we have to dread much less the extension of the disease in the form of broncho-pneumonia and membranous bronchitis into the respiratory passages not within the reach of the tube. And I feel here the antitoxin has been a very decided help. I do not regard the antitoxin as an innocuous remedy. It has not been my custom to recommend it as a prophylactic measure. I endeavor to make the diagnosis as soon as possible. The microscopic tests I consider of value, but I do not rely wholly upon them. I think the experience of the clinician is of equal value with the bacteriologic examination, and if with that we can find the Löffler bacillus, I think the diagnosis may be made with certainty. But I like to have the clinical experience and the bacteriologic examination both to indicate diphtheria before the serum is used. I think we can conceive that the individual in health might be more affected by the antitoxin than are those affected with diphtheria. Inas-much as cases have been reported of death following the use of the serum as a prophylactic measure, I think it is better to wait until a diagnosis of diphtheria is made.

DR. J. A. LARRABEE, Louisville, Ky.—In the discussion it seems the papers went back far enough to discuss the germs

themselves. There is no such thing as germ *theory* at the present time; it is germ *fact*. So to make progress we must not go back and stir up the germ theory.

It is said of all microorganisms, they are omnipresent, but it is only during the arousing and calling into activity of these germs we have disease. And all those things which put the germs into activity, are causes of disease.

It is surprising we should contemplate immunizing against a disease which does not immunize against itself. The comparison of antitoxin with Jennerian vaccination has fascinated the laity. In one we have a very complete protection continuing for life, ordinarily. This is a molecular change, which remains. It is not and may not be expected the antitoxin, when it fills our greatest expectation, will secure immunity. So, I have not in a single instance attempted immunization in practice. The theory has not appeared tenable to me. I have arrived at this point, there can be no question about toxins and antitoxins. There is no question, even in diphtheria, but that antitoxins, if properly prepared and if they are the real antitoxins, are potent to arrest the disease in its progress. I have seen four children die who I believe would not have died if they had not used antitoxin. I have seen twelve cases of laryngeal stenosis get well, that would have died without the antitoxin.

It is an accepted law, that remedies are capable of doing harm in the absence of disease. It is untenable to suppose sufficient air was injected to produce death. When the jugulars are injected with sufficient air, death may supervene. It is probable a curdling ferment has been introduced, which upon the return of the circulation, in two or three minutes, has produced a thrombus. But I believe the antitoxin does produce an immediate effect on the kidneys. In one poor little fellow, apparently doing well, death occurred within twenty-four hours with complete anuria. Anuria is almost pathognomonic in diphtheria, but this was not the time for it to appear in the case I have mentioned.

Another important point is with reference to pure serum. All who have used antitoxin much have observed the diphtheria rashes. These indicate the heterogenous products formed. I have found the greatest care necessary in color inspection of these bottles before using, and I stopped one just in time, perhaps, to prevent an accident. The fluid was turbid and milky.

We know these cases without intubation died and with intubation we formerly relieved only 25 per cent. of cases. Since the introduction of antitoxin, I have had less fear of laryngeal stenosis, and four cases have gotten well without intubation. I do not believe we can get such good results from anything else. I do not think we should abandon the other treatment. We should take all due pains to remove septic material from the throat. Since I have done this in scarlet fever, I have had less ear trouble and other complications. I believe most of the cases of sepsis have an origin in the throat and not outside of it, and many cases usually supposed to die from diphtheria really die from sepsis. I hoped somebody would bring out the value of the knee-jerk in diphtheria. It is considered by some of my friends in the Windy City as diagnostic of diphtheria.

Now in regard to this treatment, it does not inhibit or prohibit the old well known fortification of the blood. Whatever may be introduced in the form of animal toxins, the invasion of the blood is the principal danger. So I shall not give up the old-fashioned muriated tincture of iron, given internally and applied externally.

DR. W. B. PARKS, Atlanta—The city of Atlanta has just sent in its first order for antitoxin. The only cases we have had here have been cases of follicular tonsillitis, and hence we have not secured the antitoxin sooner.

DR. ROSENTHAL, New York—As to the changes in the blood, due to the injections of the antitoxin, the latest paper was

published April 25, by a gentleman from New York, and was a report made to Professor Biggs, of New York. He had three series of cases: one of pure diphtheria; another, in which the antitoxin was used, and the third, in which the results were given before and after the antitoxin. After the introduction of the antitoxin there was no change in the red blood corpuscles or in the leucocytes. As a curative dose in diphtheria, I have used as high as 13,000 antitoxin units; others have used 20,000 units of the antitoxin, and these patients are walking the streets to-day, well. I have never seen any bad complications following the injections. I give the injections between the scapulae. I prepare the back by washing with corrosive sublimate. I have in my room a chart, which my student and an assistant have made, in which they have taken hourly the temperature and respiration of the patient, and made chemic and microscopic examinations of the urine nearly hourly, and they have found no increase of albumin in the cases with albumin before the injection was made. They only found an increase of the urates and heightening of the specific gravity, no sugar and only a little albumin.

Regarding prophylaxis. The antitoxin does not immunize. Diphtheria is diphtheria, whether you use one c.c. or 1000 c.c. If you treat the diphtheria with a curative dose of antitoxin and expose the patient a month afterward to diphtheria, he will surely get diphtheria. I have in my room the record of the case of a little fellow who was exposed. He was left quite sick, locked up in a house with another case of diphtheria. In this case it had no permanent effect.

I use the Löffler solution, or the guaiacol, or—and it is as good as anything—the tincture of the chlorid of iron.

The post-diphtheritic palsies. We hear more of these than formerly because the patients died, before they had these palsies. We have multiple neuritis, ozena, inflammation of the middle ear, which would have been seen before the use of the diphtheritic antitoxin had the cases lived. But now the toxins have been neutralized by the antitoxins and we have a clearer field to work in. If antitoxin has any virtues it antagonizes the Klebs-Löffler bacillus and nothing else. If we find a mixed infection, then is the time to give the iron.

Another point is the reduction of the time the tube is needed in laryngeal stenosis since the use of antitoxin. In my own cases I have found the reduction has been sixty-nine hours. I could take the tube out on the third or fourth day. Often there is no indication for intubation or tracheotomy.

All my cases have been substantiated by microscopic examination. If we did not have the evidence of diphtheria, we would believe we had been treating follicular affections or something else for diphtheria. We probably all have bacilli in the throat, but when you have set up a chemic or mechanic action in the throat, the disease immediately comes forth and there you have diphtheria which you wonder you did not see before. It is the same thing in pneumonia and other contagions. I have no doubt you could find the pneumococci or the bacilli of diphtheria in my throat. Perfectly healthy gentlemen and phthisical patients have had the secretions examined in the laboratories, and the returns have been made that they were very virulent cases of diphtheria.

I do not stand alone in the matter of intubation. I have here a letter from a doctor who in his last thirty cases has saved twenty. The method we pursue now in Philadelphia, is this: If we have a case with the clinical manifestations of diphtheria, we make the injection first and make the bacteriologic examination afterward.

As to the quotations by Dr. Lee. Dr. Lennox Browne's book is out and has had sufficient criticism. Dr. Winters, I understand, has been entirely crushed and has come out in favor of the antitoxin. Professor Welch has quoted every authority, French, German, Austrian and Russian, who has had anything to do with the antitoxin, in all, 10,000 cases and now

favors antitoxin. Some people have a sort of fever in the antivivisection line, but, he says, it is to the glory and honor of the bacteriologists the antitoxin has come forth. The statistics of Dr. Welch of the Johns Hopkins Hospital are unique. He told me he had to go to other treatment, but with the other treatment his mortality rate has increased from 29 to 33 per cent. Kitasato of Japan, Metschnikoff, Kasmann, Wassermann, Ehrlich and others have given statistics showing a decrease in the death rate. Statistics often lie, but there is certainly great similarity between them; and if they are all liars, I am very glad to be counted among such a class.

Dr. Ross, Kokomo, Ind.—Unfortunately in the little city where I live we have had a good deal of diphtheria. The physicians have in almost every case injected antitoxin early. My partner and myself have probably treated forty-five or fifty cases and have in every case injected the antitoxin. We have sometimes used the Behring preparation and sometimes the preparation made in New York. We have tried to use the utmost antiseptic and aseptic care. We have not had as much irritation about the point of injection as I have seen from a mosquito bite. We have only once seen an erythema, which was slight and disappeared in a few hours. We have not had any trouble from shock or other adverse symptoms. We have never failed to see, within thirty-six hours, the temperature become normal and the membrane begin to disappear. We have not lost a case of diphtheria. No regular physician in our city, of the 200 or more cases treated, has lost a case of diphtheria during this epidemic. Perhaps a dozen cases have died but they were cases treated by irregulars, who refused to use the antitoxin. We have accepted what has been promulgated by the investigators and teachers; we have tried to use suitable precautions, and we have had good results. I shall certainly go on, not at all deterred by the frequency of the word "poison" in the paper by Dr. Elmer Lee, of Chicago. I have not seen nor heard of a case of disease of the kidneys following the injection of antitoxin. Heretofore, in cases treated by the old method, frequently after a patient was discharged and I supposed the disease and my treatment were ended, I have been called back to see the little patient with pulseless wrist and pale countenance, and witness its death in a short time. Such a thing has not occurred in the cases we have treated with the antitoxin.

I was called to see a case of laryngeal diphtheria. The case called for intubation or tracheotomy. The condition of the patient was such I thought neither procedure promised much. We tried intubation without success. We prayed to be permitted to use the antitoxin. The child was apparently almost in the agonies of death. After assuring the mother of the necessity, we were permitted to use the antitoxin. In the evening we made the injection. The next morning, instead of finding the child dead, we found it sitting up in bed, playing, and breathing as if nothing had happened to it.

Dr. GRAY—We have had, during the past year, an epidemic of diphtheria. I have seen from fifty to seventy cases treated with the antitoxin, and have given it personally in twenty-eight cases, of which only one died. In the fatal case death occurred one hour after the administration of the antitoxin. In that case I gave it only at the earnest solicitation of the family, knowing at the time it would be useless.

I found a child 2½ years old suffering from diphtheria. The little patient had been sick about three days and was cyanotic. In the same bed during those three days another child, of 4 or 5 years, had been sleeping. I administered 2,000 units of the antitoxin and in eight hours gave 1,500 units. In a week the child was well. I had cultures made from the throat of the child that slept with him and also from the father and mother, in which the Klebs-Löffler bacillus was found, but they did not develop diphtheria.

At first the doctors were afraid of it and gave small doses. I

have found with the large dose at first we have much better results. I give all my injections into the interscapular region, first washing the back of the child with alcohol. I use an aseptic needle, first soaking it in a weak carbohc acid solution and then washing it with alcohol. I have never had a rash nor the slightest indication of abscess. In the case of a child 4 years of age, sick three days, the larynx, nasal passages and pharynx were involved. The child was cyanotic, with a weak, thready pulse of 140, temperature 103½ degrees, albumin in the urine, and apparently near death. I injected 1,500 units. In eight hours afterward there seemed to be some improvement and I repeated the antitoxin, and again in the course of twenty-four hours, and the child recovered with a subsequent mild nephritis. I have given small doses of brandy to support the heart. Sometimes I have stuck to the iron. Of the twenty-eight cases, I do not think one (except the one that died) did not recover within a week or ten days so it could be on the street.

Dr. THOMASON, Albion, Mich.—I can only give some deductions from my own clinical experience. A year ago, in Washington this same subject was discussed. The antitoxin treatment was then in its infancy. Those of us who defended the antitoxin at that meeting had considerable opposition to meet. The fate of the Koch tuberculin was talked about, and they were all afraid of antitoxin. When the papers were read giving favorable results in a number of cases, and I gave my limited experience of some twenty cases in the same epidemic, in the first few of which (treated before we were able to obtain the antitoxin) there was a mortality of 50 per cent. and in the others, with the antitoxin, 100 per cent. recovered, many thought I was prevaricating. But now we feel antitoxin is very nearly a specific in the treatment of diphtheria. A few cases are reported of death as the result of antitoxin, but it is questionable whether death in those cases was due to antitoxin. But even if it has killed a few, it has saved many. The same applies to cocain. Cocain killed a patient just as he was leaving my office, but for that reason I shall not discard cocain. I take the same aseptic precautions I would take in an abdominal section. I make the injection into the deep muscular tissues of the subscapular region. Prior to the introduction of antitoxin, I operated in twenty cases, every one of which was fatal. Since the introduction of antitoxin I have had four cases and all recovered.

I know I am not in harmony with some of the gentlemen, in regard to it being an immunizing agent. I have used it as an immunizing agent and, rationally or irrationally, I have had justifiable results. In one family of six children, five children had diphtheria and one did not. I gave an immunizing dose to that child and it escaped; and I also gave the parents injections and they escaped. In a family of five children in which three had the disease, I gave immunizing doses to the remaining two and they escaped. I have never had any bad results but an erythema.

The deaths in diphtheria, after the use of antitoxin, I believe to be due to secondary causes. I never neglect the general treatment. The antitoxin arrests the primary trouble, that is all; consequently I stick to the old chlorid of iron treatment as tenaciously as ever.

Dr. J. A. LARRANEE, Louisville, Ky.—I would like to ask one question of Dr. Thomason. The Doctor speaks of results in immunizing. How is it known these cases would have had diphtheria if he had not immunized them?

Dr. THOMASON—I do not know. It may be rational or irrational, but I have used the antitoxin with the results I have given.

Dr. W. J. BELL, Atlanta—In 1894 we had an epidemic in an institution with which I was connected. There I had an occasion to use the antitoxin. The conclusion reached there, by Dr. Parks and Dr. Peck, was conclusive, that antitoxin had an

antitoxic effect. The statistics bear out that conclusion. During my term there I held to the iron treatment, as was insisted upon by our Resident, and it was certainly indicated. I noticed these cases bear iron to an enormous degree of tolerance. I gave at first a small dose, increasing to forty drops in children 18 months to 2 years old. The cases did well. In a great number of those cases I was satisfied I had not only a local effect from the iron but also a good general effect on the system. It seems to me our best result would be obtained if we could use the antitoxin and so saturate the system of those exposed we could render them temporarily immune. I do not think there are any who claim the immunity is permanent, but there is a temporary immunization. Therefore, in those cases where the Klebs-Löffler bacilli are found in the throat, the antitoxin should be used, in smaller doses than for a regular case, but at regular intervals, immunizing the general system. During the first part of the epidemic we had our work done in New York, but afterward we established a laboratory and did the examining for the institution. There were some five hundred children in the institution. We had a regular quarantine and an intermediate quarantine, and we went over the cases as well as possible. We had spots of infection in a number of places through the wards and so could not locate the point of infection. We selected forty cases, where the Klebs-Löffler bacilli were found, and used the usual treatment. Out of this number only two cases developed, which seems conclusive evidence that we obtained an immunizing effect from the antitoxin.

DR. H. E. GARRISON, Dixon, Ill.—In our town we have not found the Klebs-Löffler bacilli, but the antitoxin has been used with wonderful results. We had an examination made by the State Board of Health, of Illinois, and they found the staphylococci only. One or two cases died without the antitoxin and five or six with the antitoxin. There is a population of about 8,000, of which number not less than 1,000 have had a sore throat.

DR. BAKER, Erie, Pa.—I think the cases of infectious diseases may be divided into three classes: 1, cases which are mild and will recover at any rate; 2, cases that may or may not recover; 3, cases that will die. To simply say a case is diphtheria, the antitoxin is given and the case recovered, gives no information whatever. But if you treat a series of cases such as I would include in the third section, and get good results, the statistics are of some value. I saw 150 cases, out of which three or four to me meant something. One boy I remember especially was very sick. We had him early and administered the antitoxin thoroughly, but he died. I do not think, from the observations there, I saw the antitoxin do anything that has not been duplicated without it. In private practice my experience covers some fifteen cases. The theory is seductive. The line of treatment is on a trunk line and it is exceedingly probable it will be worked out in time. Whether that time has arrived is doubtful. I think the question of immunization is answered absolutely by the fact the disease does not immunize itself.

DR. HODGKIS, Connecticut—I had the opportunity of witnessing a number of cases of diphtheria, and being a little distrustful of the results of antitoxin, I allowed one case I considered mild and would get well if left to time, to go on for a period of eighteen days, with a great deal of diphtheritic membrane covering the uvula, soft palate, tonsils and pharyngeal walls, and at the end of that time there was no disappearance of the membrane under the old treatment. Paralysis having resulted, I considered the case going on to the worst and it was a proper time to use the antitoxin. I had previously used it in other cases. After using 10 c.c., on the following day the membrane had disappeared from the uvula and the soft palate. On the next day we used 5 c.c. and on the following day all the membrane had disappeared. This is an illustration showing

positively the disappearance of the membrane after the use of the antitoxin.

DR. D. C. WILSON, Ironton, Ohio—We had a severe epidemic in our town during the past winter. The first few cases I lost. I immediately ordered antitoxin and lost no cases in the some sixty cases treated after that. One child contracted the disease. Inside of eight hours another of the same family contracted diphtheria, and I injected the ten other children and none of them contracted the disease. But the father contracted the disease. In his case I did not use the antitoxin at first and he grew worse until I thought it unjustifiable to wait longer and injected it, with recovery. I was called to a case of laryngeal diphtheria. The child was cyanotic. The consulting physician refused to use antitoxin but I insisted. The next morning the child seemed somewhat better. Later I injected the child again, and the child was soon up and about the house. I have had no bad results. I had in one case an erythema follow. I use the injection in the side. I first thoroughly antisepticize the chest, brush off the skin with alcohol, and use the carbolic solution. I have not sealed up the wounds at all.

DR. KNIPE, Norristown, Pa.—I merely would like the consensus of opinion about this. One man claims antitoxin could not immunize simply because the disease does not immunize itself. Theoretically, my own impression is that ordinarily diphtheria does immunize against another attack. Dr. Garrison has reported a number of cases of diphtheria in which the bacillus was not found. These may have been only cases of tonsillitis. But I believe true diphtheria does immunize as much as smallpox. I believe the statistics from the German army show a good mark of vaccination is a greater security than having had smallpox itself.

DR. EDWIN KLENS, Citronelle, Ala.—Permit me to make a few remarks on this question of immunizing. We have very different qualities of immunity in the different forms of infectious disease. We can not compare, in this point, diphtheria and smallpox. We would be very glad if we had such a high degree of immunity in diphtheria as in smallpox. But some gentlemen have thought they have immunized. Some members of a family have diphtheria and in the other members of the family they found the bacilli, and they injected them with the serum and they did not get diphtheria. In Zurich, for weeks after diphtheria in a family we found in the children who did not have diphtheria the diphtheria bacilli, but they did not have diphtheria although they were not injected. We have two sides to this question of infection; the germ on one side and the body on the other. We must consider, first, sufficient infectionability of the germ; and second, sufficient susceptibility of the body. We know an infectious germ can be in the nose of a healthy child and not cause diphtheria.

DR. ELMER LEE, Chicago—There is not much more to be said. The position taken in the paper read by me, is correct. It is admitted, in that paper, that diphtheria is treated by the use of antitoxin, seemingly with favorable results. If you undertake to say to me or to the world, that that treatment is based upon scientific knowledge, it is my contention that it is an incorrect statement. If you base it upon empiricism, there is nothing more to be said. It is contrary to physiologic law. Physiologic law is the law of our nature and being. That an impurity will secure purity, is not the lesson we learn by watching the bubbling water as it comes out of the side of the hill, that is made muddy by the foot-print of the cattle. The stream will clear itself if we will only let it alone.

There is one weak point in my paper. I know my weak points better than the audience. The weak point is, while criticizing antitoxin, no substitute has been offered to you. The old treatment, as it is called, is not satisfactory.

Here is a letter, that happens to come in, fortunately, to save the day because of the ferocious attack by the gentleman from

Philadelphia. This letter is from Dr. Joseph Winters, Professor of Diseases of Children and head of the staff of the Willard Parker Hospital, New York. The communication is of recent date and is as follows: ". . . It seems to me that one of the main features of this discussion, is the increase of the number of cases of reported diphtheria, as a result of the present method of diagnosis." That method of diagnosis is the one referred to in my paper as the bacteriologic, as distinguished from the clinical diagnosis. Dr. Winters says, further: "I spent three and a half months in the hospitals of Europe, last summer, making a constant study of the results of the antitoxin treatment, and am convinced that there is, absolutely, no value in it." It don't make any difference, gentlemen, Dr. Winters is an experienced man. He is fifty years old, and his judgment is not puerile and it is not to be neglected.

Now, the object of bringing out the paper before you to-day was not to antagonize the profession nor to indulge in any aspersions. It was to call your attention to just exactly what is true. In so much as you have spoken your views, in so much you have delighted me and accomplished that which was intended and expected by the paper. It is not my purpose nor in my power to answer the objections to the paper nor to go into the clinical part of the disease.

In conclusion, it is my purpose to present to you, at the next annual meeting, a substitute for antitoxin, a complete method by which all cases in my practice have recovered quickly and surely, and pleasantly and scientifically.

DR. W. A. DIXON, Ripley, Ohio—I wish to say I admire Dr. Lee for his bold paper yesterday. But if a man has a conviction and is bold enough to state it, he ought to be commended for it. And I expect he is about half right.

THE CHAIRMAN—He certainly put himself in a very trying position.

DR. DIXON—I have never yet had an opportunity to test antitoxin, because we have had no true diphtheria. But every man has his fad and if you start him in the right place he is a "crank," and I have my "cranky" ideas about diphtheria. I believe diphtheria is not primarily a disease of the human family at all, but a disease of animals, obtained from birds, cats, rabbits, rats, etc. I have had occasion to dissect the pet animal of a child seized with true diphtheria. The child was isolated in the country and had no opportunity whatever to be infected from other children. Unless we can devise some theory to explain an autoinfection or the presence of the bacilli in a healthy place in the country, we must look for the contagion in something else. The most noted case I can refer to is the case of a child 3 years old. Not being able to discover how it might have taken diphtheria, and believing as I have stated, I asked if the child had a pet. The mother replied, "O yes, it has a pet cat that it carries in its arms continually and often takes to bed with it." I asked for the cat, and on examination I found it had enlarged glands and discharged at the nose. I took it home, dissected it, examined the membrane microscopically and found it had true diphtheria. Therefore I believed the child obtained its diphtheria from the cat. I have had occasion to report several cases of like kind. In one case the canary bird was sick prior to the child; in one or two cases turkeys were sick prior to the child, etc. I read a paper on this subject at Milwaukee, in the Section of Diseases of Children, but I suppose it must have been a very poor one, for it did not draw out any comments and I have not heard anything from it since. But I am just as firm a believer as ever that the contagion of diphtheria is often derived from an animal or bird. Hence we might have some reason, on that theory, to believe in the virtue of antitoxin, just as we have reason to believe in the value of vaccine as a remedy to prevent smallpox. Those who have read extensively upon the subject of diphtheria, know the first epidemic in this country was brought by the importation of birds, particularly turkeys.

## THEORY OF SERUM THERAPY; CONTRIBUTION FROM THE BACTERIOLOGIC LABORATORY OF THE CITY OF PHILADELPHIA.

Read in the Section on Materia Medica, Pharmacy and Therapeutics at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY B. MEADE BOLTON, M.D.

CHIEF OF DIVISION, PHILADELPHIA, PA.

Some of the theories which have been advanced to explain immunity from infectious diseases have a bearing upon the production of antitoxin; others leave this out of consideration. It is evident that no theory can stand if it offers no explanation of the reason why it is possible to use the blood serum of inoculated animals to protect and cure other animals and human beings. It will be my purpose in this paper to put the various theories, that have been advanced, to this test. Some of the theories merely attempt to explain why the bacteria do not grow in the body of non-susceptible animals and leave out of account the neutralization of the disease producing products, and for this reason fail to be universally applicable.

1. The exhaustion theory of Pasteur claims that the bacteria are unable to grow in the body of an animal that has suffered from an attack of the microorganism in question, because all of the necessary food has been exhausted by the first attack. There are other reasons for discarding this theory, but it is evident that it offers no explanation of the production of substances in the blood which can be used in treating other animals. Even if it should explain the reason why recovery protects the animal itself from subsequent invasion it offers no explanation why the serum of this animal will counteract the poisonous properties of the bacteria in another animal.

2. The accumulation theory of Chauveau comes somewhat nearer an explanation, though not as it was originally conceived. According to the original conception the waste products of the growth of the bacteria in the body simply accumulate till the tissues become so saturated with the effete material that the bacteria are unable to grow. The bacteria, in other words, are poisoned by their own excreta. In order to make this theory fit the facts it would have to be extended so as to mean that not only the bacteria are unable to grow on account of the accumulation of effete products but also that these products neutralize the poisonous products of the bacteria. This enlargement of the theory is practically what has been done in the following:

3. The theory of special organs, Brieger, Kitasato and Wassermann, claims that there are probably two substances in every culture of bacteria, viz., a disease producing substance and a substance tending to counteract this. It is supposed that the disease producing substance is destroyed by certain organs of the body, notably the thymus gland, and that the other substance, the antidote, is liberated.

4. The accommodation theory claims that the tissues of the body gradually become accustomed to the bacteria and their products just as men become habituated to large doses of arsenic, opium or other poisons. But this explanation is not satisfactory because in the production of immunity there is always a crisis observable. The animal undergoing inoculation often more or less suddenly shows a great power of resistance. The process is not gradual enough for it to be accounted for by this theory.

5. Pfeiffer's theory of special enzymes claims that in animals gradually inoculated with the products of the cultures of bacteria two substances are developed: a. A substance capable of being converted into the germicide. b. The germicide itself. The former is converted into the latter by special ferments residing in the animal tissues. The former is called the immunity substance in contradistinction to the latter which is called the germicide. It is contended at least for typhoid fever and cholera that blood serum taken from animals inoculated for a long time with cultures of the bacteria of these diseases contains a certain amount of both these substances, and if an ordinary susceptible animal is inoculated with cultures of typhoid fever or cholera and is given a dose of the protective serum at the same time that the germicide acts at once, and that the immunity substance becomes converted into the germicide, thus furnishing an additional supply. Animals that have been gradually inoculated with the products of typhoid or cholera cultures are supposed to have the immunity substance stored up in their tissues and that this is converted into the germicide when the animal is inoculated with virulent cultures. The action is specific, *i. e.*, animals immunized from cholera have the immunity substance of cholera, and the same with typhoid fever.

6. Under the cellular theory are embraced: a. The phagocyte theory of Metschnikoff. b. The starvation theory of Grawitz. c. The theory of the alexins of Hankin.

a. The phagocyte theory has been more actively advocated and more vigorously assailed than perhaps any other theory. According to this theory, the white corpuscles of the blood destroy the bacteria. The corpuscles concerned are believed to be the polynuclear leucocytes and the large mononuclear; the lymphocytes are not supposed to be concerned. The leucocytes are supposed to actually devour the bacteria at once, or to produce degeneration of the bacteria first and devour them afterward. In the latter case the leucocytes are supposed to break up and liberate a substance which causes the bacteria to degenerate and then fresh leucocytes appear to devour the degenerated bacteria. The breaking up of the leucocytes he calls phagolysis.

b. According to Grawitz's starvation theory the leucocytes deprive the bacteria of nutrition.

c. Hankin's theory, which is advocated by Buchner and others, claims that the neutrophilic leucocytes break up and liberate a substance that destroys the bacteria. Hankin's original statement was that the eosinophilic leucocytes break up and liberate alexins, but he has retracted this statement and his present view is more in accord with Metschnikoff's theory of phagolysis.

7. The humoral theory of Behring claims that there is developed a substance in the humors of the body that neutralizes the poisonous products of the bacteria. It is believed that this substance is generated by the fixed cells of tissues rather than by the leucocytes.

Opinion among bacteriologists is now practically divided between the humoral and the phagocyte theory. Both have been ably supported and both have been vigorously attacked. It is possible that in the production of immunity many of the explanations advanced may play a part. It may be that no one of them is sufficient to explain all the phenomena.

## REPORT OF THE AMERICAN PEDIATRIC SOCIETY'S COLLECTIVE INVESTIGATION INTO THE USE OF ANTITOXIN IN THE TREATMENT OF DIPHTHERIA IN PRIVATE PRACTICE.

REPORTED AT THE EIGHTH ANNUAL MEETING HELD AT MONTREAL, CANADA, MAY 26, 1896.

This subject was chosen by the officers of the Society for its eighth annual meeting, with the belief that a large amount of valuable experience, not otherwise available, might in this way be reached and collated. It was also believed that a more trustworthy estimate of the value of the serum treatment of diphtheria might thus be obtained than by statistics taken from hospital practice. There are very few hospitals in America that receive diphtheria patients, and the conditions under which patients are admitted to hospitals, and the surroundings while there, are so different from those of private practice, that the measure of success in hospital cases can not be taken as an index of the results which have been obtained upon this side of the Atlantic with the new treatment.

In order, therefore, to obtain an expression of opinion from American physicians as to the serum treatment, after what had been, with most of them, their first year's experience, a circular letter was prepared and issued by the Committee early in April. This was distributed through the members of the Society as widely as could be done during the time allowed. An attempt was made to reach as many physicians as possible who had had experience with the remedy.

The first surprise of the Committee was in learning how very widely the serum treatment had been employed, especially in the Eastern and mid-Western States. With more time, the number of cases collected might easily have been doubled and perhaps trebled; but enough reports have come in to enable one to see what opinion was held on the 1st of May, 1896, by American physicians who have used this remedy.

The circular letter asked for information upon the following points: Age; previous condition; duration of disease when the first injection was made; the number of injections; the extent of the membrane—tonsils, nose, pharynx and larynx; whether or not the diagnosis was confirmed by culture; complications or sequelæ, *viz.*, pneumonia, nephritis, sepsis, paralysis; the result; and remarks, including other treatment employed, the preparation of antitoxin used, and general impression drawn from the case.

Reports were returned from 615 different physicians, with 3,628 cases. Of these, 244 cases have been excluded from our statistical tables. These were cases in which the disease was said to have been confined to the tonsils and the diagnosis not confirmed by culture, and therefore open to question. A few cases were reported in such doubtful terms as to leave the diagnosis uncertain. The figures herewith given are therefore made up from cases in which the diagnosis was confirmed by culture (embracing about two-thirds of the whole number) and others giving pretty clear evidence of diphtheria, either in the fact that they had been contracted from other undoubted cases, or where the membrane had invaded other parts besides

the tonsils, such as the palate, pharynx, nose, or larynx. It is possible that among the latter we have admitted some streptococcus cases, but the number of such is certainly very small.

There are left then of these cases, 3,384 for analysis. These have been observed in the practice of 613 physicians, from 114 cities and towns, in fifteen different States, the District of Columbia and the Dominion of Canada.

In the general opinion of the reporters, the type of diphtheria during the past year has not differed materially from that seen in previous years, so that it has been average diphtheria which has been treated. If there is any difference in the severity of the cases included in these reports from those of average diphtheria, it is that they embrace a rather larger proportion of very bad cases than are usually brought together in statistics. The cases according to the extent of the membrane, are grouped as follows: In 593 the tonsils alone were involved. In 1,397 the tonsils and pharynx, the tonsils and nose, the pharynx and nose,

Only two reports embracing a series of over 100 cases have been received, most of the observers having sent in from five to twenty cases, although there are many reports of single cases, particularly of single fatal ones.

In addition to this material which has come in response to the circular, there have been placed at the disposal of the Committee by the courtesy of Dr. H. M. Biggs, 942 cases treated in their homes in the tenements of New York. Of these, 856 were injected by the corps of inspectors of the New York Health Board, upon the request of the attending physician, and eighty-six others were treated by physicians receiving free antitoxin from the Health Board. In the first group the diagnosis of diphtheria was confirmed by culture in every case, and in all of the latter except twenty-six; in these the diagnosis rested upon extensive membranous deposits or laryngeal invasion. The cases of the New York Health Board were of a more than ordinarily severe type, 485 or more than 50 per cent. of these being reported as being in bad

or all three were affected. In 1,256 cases the larynx was affected either alone or with the tonsils, pharynx and nose, one or all. In many instances the statement is made by the reporters, that the serum was resorted to only when the condition of the patient had become alarmingly worse under ordinary methods of treatment. This is shown by the unusually large number of cases in which injections were made late in the disease. Again, many physicians being as yet in some dread of the unfavorable effects of the serum have hesitated to use it in mild cases, and have given it only in those which from the onset gave evidence of being of a severe type. The expense of the serum has unquestionably deterred many from employing it in mild cases. These facts, it is believed, will more than outweigh the bias of any antitoxin enthusiasts by including many mild cases which would have recovered under any treatment. It will, however, be remembered that tonsillar cases not confirmed by culture have not been included.

condition at the time of injection; to mild cases the inspectors were not often called. Further, an unusually large number of them (38 per cent.) were injected on or after the fourth day of the disease. In 182 of these cases only the tonsils were affected; in 466 the tonsils with the pharynx or nose, the pharynx and nose, or all three; in 294 the larynx was invaded with or without disease of the tonsils, nose, or pharynx.

Through the courtesy of Dr. Biggs, the Committee is able to include also a partial report upon 1,468 cases from Chicago, treated in their homes in that city by a corps of inspectors of the Health Department. It was the custom in Chicago to send an inspector to every tenement-house case reported, and to administer the serum unless it was refused by the parents. These cases were therefore treated much earlier, and the results were correspondingly better than were obtained in New York, although the serum used was the same in both cities, viz., that of the New York Health Board.

THE RESULT AS INFLUENCED BY THE TIME OF INJECTION.

In Table I, are given the results obtained in these three different groups of cases, classified according to the day on which they received the first injection of serum antitoxin.

The grand total gives 5,794 cases with 713 deaths, or a mortality of 12.3 per cent., including every case returned; but the reports show that 218 cases were moribund at the time of injection, or died within twenty-four hours of the first injection. Should these be excluded there would remain 5,576 cases (in which the serum may be said to have had a chance) with a mortality of 8.8 per cent.

Of the 4,120 cases injected during the first three days, there were 303 deaths—a mortality of 7.3 per cent., including every case returned. If from these we deduct the cases which were moribund at the time of injection, or which died within twenty-four hours, we have 4,013 cases, with a mortality of 4.8 per cent. Behring's original claim, that if cases were injected on the first or second day the mortality would not be 5 per cent., is more than substantiated by these figures. The good results obtained in third-day injections were a great surprise to your Committee. But after three days have passed the mortality rises rapidly, and does not differ materially from ordinary diphtheria statistics. Our figures emphasize the statement so often made, that relatively little benefit is seen from antitoxin after three days; however, it must be said that striking improvement has in some cases been seen even when the serum has been injected as late as the fifth or sixth day. The duration of the disease, therefore, is no contraindication to its use.

THE INFLUENCE OF BACTERIOLOGIC DIAGNOSIS UPON THE STATISTICS.

This is shown in Table II.

TABLE II.—DIAGNOSIS CONFIRMED BY BACTERIOLOGIC EXAMINATION.

Committee's Reports . . . . .	2,453 cases;	302 deaths;	mortality, 12.3 per cent.
N. Y. Board of Health . . . . .	916 "	160 "	16.9 "

Totals . . . . .	4,837 "	556 "	11.4 "
(Excluding 145 cases which were moribund or which died in twenty-four hours) . . . . .			8.7 "
DIAGNOSIS FROM CLINICAL EVIDENCE ONLY.			
Committee's Reports . . . . .	931 cases;	148 deaths;	mortality, 15.7 per cent.
N. Y. Board of Health . . . . .	26 "	9 "	34.6 "
Totals . . . . .	957 "	157 "	16.3 "
(Excluding 72 cases either moribund or dying in twenty-four hours) . . . . .			9.6 "

In the cases in which the diagnosis was not confirmed by a bacteriologic examination the mortality is thus 5 per cent. higher than in the bacteriologic cases. This difference is to be explained by two facts: first, as already stated, that we have excluded from our reports all tonsillar cases (and hence most of them very mild ones) not confirmed by bacteriologic examinations; and secondly, by the fact that this group of cases comprises those treated in the country where physicians have hesitated to use antitoxin unless the type of the disease was a grave one, and where also a large proportion of the injections were made later than in the cities. However, should we leave out the moribund cases, the mortality is but 9.6 per cent., which differs but slightly from the cases confirmed by bacteriologic diagnosis.

In our subsequent statistics we shall consider together all the cases bacteriologically confirmed and otherwise, as the statistics are not materially altered by this grouping.

THE RESULTS AS MODIFIED BY THE AGE OF THE PATIENTS.

Unfortunately the ages have not been furnished in the report of the Chicago cases, and we have therefore only the cases reported to the Committee, and those from the New York Board of Health for analysis. In Table III, are shown the mortality of the different ages grouped separately.

The highest mortality is seen as in all reports to be in the cases under two years, but including all those returned, even those that were moribund when injected, the death rate was but 23.3 per cent. (21.7 per cent. of the Committee's cases), while if we exclude cases moribund when injected or dying within the first twenty-four hours, it falls to 19.2 per cent.

After the second year there is noticed a steady decline in mortality up to adult life. In many of the reports previously published, the statement has been made that no striking improvement in results was observed in adult cases treated by the serum. Our figures strongly contradict this opinion. Of 359 cases over 15 years old which were returned, there were but thirteen deaths. That the reader may judge for himself how far antitoxin is to be held responsible for the result a brief summary of these thirteen cases is appended:

*Case 1.*—Fifteen years old; injected on the fourth day; membrane covering tonsils and pharynx; profoundly septic, sinking rapidly when injected; died in two hours. "My only death in seventeen cases." (Jones, Gloucester, Mass.)

*Case 2.*—Forty-four years old; injected on the fourth day; membrane on the tonsils and pharynx; in bad condition; died three hours after injection. The tonsils had been previously incised, the early diagnosis having been quinsy.

*Case 3.*—Thirty-one years old; injected on the sixth day; membrane on the tonsils, nose, pharynx, and larynx; intubation; sepsis; in bad condition; lived eight hours after injection.

*Case 4.*—Thirty-five years old; injected on the fifth day; membrane on the pharynx and nose(?); in bad condition; septic; died in twelve hours.

*Case 5.*—Sixty years old; in bad condition; had serious mitral regurgitation; injected on the fourth day; membrane covering tonsils, pharynx, and larynx; died from heart failure on following day.

*Case 6.*—Sixty years old; "kidney trouble for years"; injected on the third day; very extensive membrane, covering tonsils, pharynx, and nose; profound sepsis; in bad condition; dies suddenly on the day after injection.

*Case 7.*—Seventeen years old; in bad condition: convalescing from measles; enormous adenopathy; profound sepsis; exceedingly high temperature; membrane covering tonsils and nose; injected at the end of forty-eight hours; three injections, temporary improvement after each one; duration of life not given.

*Case 8.*—Fifteen years old; in bad condition; injected on the ninth day; membrane covering tonsils, nose pharynx, and larynx; no operation; enormous infiltration of the tissues of the neck; nephritis; sepsis; lived four days and died of sepsis.

*Case 9.*—Twenty years old; injected on the third day; membrane upon the tonsils, nose, pharynx and larynx; "a stubborn patient who got up before he was allowed, and died suddenly after it."

*Case 10.*—Twenty-five years old; injected on the fifth day; membrane covering both tonsils, entire pharynx, and completely occluding nose; nephritis and sepsis; throat cleared off entirely; died suddenly on the fourteenth day from cardiac paralysis.

*Case 11.*—Nineteen years old; injected on the fifth day; membrane upon the tonsils and pharynx; profound sepsis; duration of life unknown.

*Case 12.*—Twenty-two years old; injected on the fourth day; membrane upon the tonsils and gums; sepsis; died on the sixth day.

*Case 13.*—The well-known Brooklyn case, reported in 1895. Girl, 16 years old, who died suddenly ten minutes after injection.

Such are the adult cases which antitoxin failed to cure. Four of them were moribund at the time of injection, no one of them living over twelve hours. Two, both 60 years old, were already crippled by previous organic disease, one of the heart and the other of the kidneys. In the measles case there was undoubted evidence of streptococcus septicemia. Only two of the cases were injected as early as the third day; three of them on the fifth day, and one on the ninth day. Omitting the four moribund cases the mortality of 355 adult cases treated with the serum is 2.5 per cent.

#### PARALYSIS.

Reliable data upon this point and those hereafter to be mentioned are to be had only from the 3,384 reports returned to the committee. Of these paralytic sequelæ appeared in 328 cases, 9.7 per cent. Of the 2,934 cases which recovered, paralysis was present in 276, or 9.4 per cent. Of the 450 cases which died, paralysis was noted in fifty-two, or 11.4 per cent.

The variety of the paralysis and the date of injection is shown in the following table:

TABLE IV.—VARIETY OF PARALYSIS AND THE DAY OF INJECTION.

RECOVERY CASES.	CASES.	DAY OF INJECTION.					Unknown
		1st Day.	2d Day.	3d Day.	4th Day.	5th Day.

Sterno-mastoid	1		1				
<b>FATAL CASES.</b>							
Paralysis mentioned (variety not specified).	9		3	2	1	2	1
1 Cardiac, late after throat clear (In four of them throat also)	32	1	2	8	9	8	4
Throat only	6		2				4
General late	4		1		1	2	
Muscles of respiration	1		1				
Totals	328	28	73	76	43	49	59

Observations of some of the individual cases are interesting, particularly those of cardiac paralysis. It is twice stated that the child had gotten up and walked out of the house, where it was found dead. Twice death occurred after sitting up suddenly; once, on jumping from one bed into another. One patient of 20 years, got up contrary to orders and died soon afterward. Another patient was apparently well until he indulged in a large quantity of cake and candy, soon after which cardiac symptoms developed and he died shortly. One case was that of a woman, 60 years old, who had serious organic cardiac disease.

It is difficult from these statistics to state what protective power the serum may have over the nerve cells and fibers. Apparently this is not great unless the injections are made early in the disease, and even then in severe cases the amount of damage done to these tissues in twenty-four hours may be very great, even irreparable. Time is not the only element in estimating the effect of the diphtheria toxins.

Great discrepancy exists in the statements made regarding the frequency of paralytic sequelæ after diphtheria. In a series of 1,000 cases reported by Lennox Browne, paralytic sequelæ were present in 14 per cent. In 2,448 cases by Sanné, paralysis was

<sup>1</sup> Cases of heart failure occurring at the height of the disease have not been included here; although they are mentioned among the cases of cardiac paralysis in the table of fatal cases.

noted in 11 per cent. In the series of cases here reported, the difference is slightly in favor of the antitoxin treatment, but paralysis is certainly frequent enough to show how extremely susceptible the nervous elements are to the diphtheria toxins. One thing is quite striking from a study of these cases, and that is the proportion that have died from late cardiac paralysis. That many of them would undoubtedly have succumbed earlier in the disease from suffocation (laryngeal cases) or diphtheritic toxemia, had the serum not been employed, is beyond the question. Although the serum is able to rescue even many such desperate cases it can not overcome the effects of the toxins upon the cells which have occurred before it was injected.

#### SEPSIS.

Sepsis is stated to have been present in 362 of the 3,384 cases, or 10.7 per cent. It was present in 145, or 33 per cent. of the fatal cases. Some explanation is necessary for a correct appreciation of these figures. The majority of the reporters, it is plain from their remarks, have not distinguished between diphtheritic toxemia and streptococcus sepsis. The former is certainly meant in the great majority of the cases. There is a very small proportion in which there is evidence of streptococcus sepsis. The six cases complicating measles and the five complicating scarlet fever, however, should possibly be included among this list.

#### NEPHRITIS.

The statements on this point are quite unsatisfactory. The reports state that nephritis was present 350 times, or in 10 per cent. of the cases. On the one hand it must be stated that the diagnosis of nephritis rests in many cases simply upon the presence of albumin in the urine; but, on the other hand, it is true that in a large number of the cases, more than half, no examination of the urine is recorded as having been made, so that it is impossible to state with anything like approximate accuracy, the frequency of nephritis in these cases. Of the 450 fatal cases, the presence of nephritis is mentioned without qualification or explanation in thirty-nine cases, these being usually put down also as septic, dying in the acute stage of the disease. There are fifteen fatal cases, however, in which the renal disease was stated as the cause of death. In no less than nine the nephritis occurred late in the disease, usually during the second or third week. In these fifteen cases the evidence of severe nephritis was conclusive, such symptoms being present as dropsy, suppression of urine, with coma or convulsions.

#### BRONCHO-PNEUMONIA.

Broncho-pneumonia is stated to have been present in 193 of the 3,384 cases, or 5.9 per cent., a remarkably small proportion when compared with hospital statistics. Among the patients that recovered broncho-pneumonia was noted 114 times, or in 3.8 per cent.; among the fatal cases seventy-nine times, or in 17.5 per cent., but in only about one-half of these was the pneumonia the cause of death. Of these, thirty-seven were laryngeal cases operated upon late, ten were septic cases and the pulmonary disease was coincident with the height of the diphtheritic process. In seven pneumonia was independent of both the above conditions, occurring late in the disease in all but two.

#### LARYNGEAL CASES.

Of the 3,384 cases reported to the committee, the

larynx is stated to have been involved in 1,256 cases, or 37.5 per cent. This proportion is somewhat higher than is usual, and is partly explained by the fact that several physicians have sent in the reports only of their laryngeal cases. These laryngeal cases occurred in the practice of 379 physicians.

In 691, or a little more than one-half the number, no operation was done, and in this group there were 128 deaths. In forty-eight of them laryngeal obstruction was responsible for the fatal issue, operation being refused by the parents or no reason for its being neglected having been given. In the eighty remaining fatal cases the patients died of other complications, and not from the laryngeal disease.

In the 563 cases, or 16.9 per cent. of the whole number, there was clinical evidence that the larynx was involved and yet recovery took place without operation. In many of these cases the symptoms of stenosis were severe, and yet disappeared after injection without intubation. No one feature of the cases of diphtheria treated by antitoxin has excited more surprise among the physicians who have reported them than the prompt arrest, by the timely administration of the serum, of membrane which was rapidly spreading downward below the larynx. Such expressions abound in the reports as "wonderful," "marvelous," "prepared to do intubation, but at my next visit the patient was so much better it was unnecessary," "in all my experience with diphtheria have never seen anything like it before," "no unprejudiced mind could see such effects and not be convinced of the value of the serum," etc.

In establishing the value of the serum, nothing has been so convincing as the ability of antitoxin, properly administered, to check the rapid spreading of membrane downward in the respiratory tract, as is attested by the observations of more than three hundred and fifty physicians who have sent in reports.

Turning now to the operative cases we find the same remarkable effects of the antitoxin noticeable. Operations were done in 565 cases, or in 16.7 per cent. of the entire number reported. Intubation was performed 533 times with 138 deaths, or a mortality of 25.9 per cent. In the above are included nine cases in which a secondary tracheotomy was done, with seven deaths. In thirty-two tracheotomy only was done with twelve deaths, a mortality of 37.4 per cent. Of the 565 operative cases, sixty-six were either moribund at the time of operation, or died within twenty-four hours after injection. Should these be deducted, there remain 499 cases operated upon by intubation or tracheotomy, with 84 deaths, a mortality of 16.9 per cent.

Of the 2,819 cases not operated upon, there were 312 deaths, a mortality of 11.3 per cent. Deducting the moribund cases, or those dying within twenty-four hours after injection, the total mortality of all non-operative cases was 9.12 per cent.

Let us compare the results of intubation in cases in which the serum was used, with those obtained with this operation before the serum was introduced. Of 5,546 intubation cases in the practice of 242 physicians, collected by McNaughton and Maddren (1892) the mortality was 69.5 per cent. Since that time statistics have improved materially by the general use (in and about New York, at least) of calomel fumigations. With this addition, the best results published (those of Browne) showed in 279 cases a mortality of 51.6 per cent.

Let us put beside the cases of McNaughton and Maddren the 533 intubations with antitoxin, with 25.9 per cent. mortality. With Browne's personal cases let us compare those of the fourteen observers who have reported to the committee ten or more intubation operations in cases injected with serum. These comprise 280 cases with sixty-five deaths, a mortality of 23.2 per cent. In both comparisons the mortality without the serum is more than twice as great as in the cases in which serum was used.

The reports of some individual observers concerning intubation with the serum are interesting:

Neff, New York, twenty-seven operations, with twenty-seven recoveries.

Rosenthal, Philadelphia, eighteen operations, with sixteen recoveries.

Booker, Baltimore, seventeen operations, with seventeen recoveries, including one aged ten months, and one seven and one-half months.

Seward, New York, eight operations, with eight recoveries.

McNaughton, Brooklyn, "In my last seventy-two operations without serum, mortality 66.6 per cent.; in my first seventy-two operations with serum, mortality 33.3 per cent."

O'Dwyer, New York, "In my last 100 intubations, first seventy, without serum, mortality 73 per cent.; last thirty, with serum, mortality 33.3 per cent."

But even these figures do not adequately express the benefit of antitoxin in laryngeal cases. Witness the fact that over one-half the laryngeal cases did not require the operation at all. Formerly 10 per cent. of recoveries was the record for laryngeal cases not operated upon. Surely, if it does nothing else the serum saves at least double the number of cases of laryngeal diphtheria that has been saved by any other method of treatment.

The great preponderance of intubation over tracheotomy operations shows how much more highly the profession in this country esteems the former operation.

#### A STUDY OF THE FATAL CASES.

Of the 450 fatal cases in the committee's report, 229, or one-half, received their first injection of the serum on or after the fourth day of the disease, and 152, or over one-third of these, on or after the fifth day.

There were fifty-eight cases in which it was stated that the child was moribund at the time of injection, the serum being administered without the slightest expectation of benefit, but at the earnest solicitation of the parents.

There remain 350 cases in which the cause of death could be pretty accurately determined by the reports. These died from the following causes, the most important cause being placed first.

*Sepsis (including diphtheritic toxemia)* was the cause of death in 105 cases, of which sixteen had nephritis, four were intubated or tracheotomized, two were laryngeal cases not operated upon, four had paralysis, one had pneumonia, and in one the fatal sepsis was attributed to a traumatic condition of the left knee.

*Cardiac paralysis* was the cause of death in fifty-three cases. Under this head are included cases of sudden heart failure occurring at the height of the disease (twenty-one in number) as well as those more commonly designated as heart paralysis, where death occurred suddenly after the throat cleared off. Of the latter there were thirty-two examples; four of these had paralysis, nineteen were septic, eight had

nephritis, five were intubated, and one tracheotomized.

*Broncho-pneumonia* was put down as the cause of death in fifty-four cases. In thirty-seven of these it followed laryngeal diphtheria; of these twenty-two were intubated, and four tracheotomized; two had nephritis; nine were septic. Broncho-pneumonia and sepsis was the cause of death in ten cases, of which three had nephritis and one general paralysis. Broncho-pneumonia caused death in seven cases, apart from sepsis or laryngeal diphtheria; of these only one had nephritis; one died from heart failure; and in five, pneumonia came on late in the disease.

*Laryngeal diphtheria without operation* caused death in forty-eight cases. In some of these the operation was refused by the parents, in others it was neglected by the physician, the patients dying of asphyxia; three of these cases had nephritis, four were septic, two had pneumonia, and one had sepsis and nephritis.

*Diphtheritic tracheitis or bronchitis* caused death in eleven cases; all of these were intubated, and in two there was evidence of the existence of membrane in the bronchi before operation. There were thirty-three other cases in which death followed laryngeal diphtheria without the supervention of pneumonia. It is highly probable that in some of these death was due to membranous tracheitis or bronchitis. All of them were operated upon; ten were septic, two had paralysis, and one had nephritis.

*Sudden obstruction of the intubation tube* was the cause of death in three other laryngeal cases.

*The tube was coughed up* in three cases, fatal asphyxia occurring before the physician could be summoned.

*Died on the table during tracheotomy*, one case.

*Nephritis* was the cause of death in fifteen cases; seven of these were septic, and three had been intubated.

*General paralysis* was the cause of death in five cases; in all probably the pneumogastric was involved.

*Paralysis of the respiratory muscles* produced death in one case, one of laryngeal diphtheria, which was intubated, was complicated by broncho-pneumonia.

*Measles associated with diphtheria* produced death in six cases; five of these were laryngeal and were intubated, in two there was pneumonia, and in two sepsis. Diphtheria developed during the height of measles, or immediately followed it.

*Scarlet fever with diphtheria* was the cause of death in six cases; in three of these there was broncho-pneumonia, nephritis and sepsis; in two scarlet fever preceded diphtheria, and in one of these there was sepsis with gangrene of the tonsils. In the sixth case the patient died of scarlet fever, which developed during convalescence from the diphtheria.

*Gangrene of the cervical glands or cellular tissue of the neck* was the cause of death in two cases associated with profound general sepsis.

*Endocarditis* caused death in one case, nineteen days after the diphtheria.

*Diphtheritic inflammation of the tracheal wound with sepsis* caused death in one case.

*General tuberculosis*, five weeks after diphtheria, was assigned as the cause of death in one case.

*Exhaustion* was the cause of death in three cases, one a protracted case; another complicated by pneumonia and sepsis; one by nephritis.

*Convulsions* was the cause of death in three cases

apart from disease of the kidneys. In one, the well-known Brooklyn case, the girl died ten minutes after the injection, in another, twenty-four hours after injection, in the third the particulars were not given.

*Meningitis* was assigned as the cause of death in one case.

#### THE KIND OF ANTITOXIN USED.

They are given in the order of frequency with which they have been used: 1, the serum prepared by the New York Board of Health; 2, Behring's; 3, Gibier's;<sup>2</sup> 4, Mulford's; 5, Aronson's; 6, Roux's. In addition a large number of cases are reported as having been treated by the serum prepared by the Health Boards of different cities—Brooklyn, Newark, Rochester, Pittsburg, etc. The largest number of cases have been treated by the serum prepared by the New York Health Board, a very large number by Behring's serum, all others being relatively in small numbers.

*Dosage and number of injections.* In the great majority of cases but one injection is reported. In very severe ones two and three have been given. The largest amount is in a case by Wiener (Chicago) who gave eighteen injections of Behring's serum to a laryngeal case in a child thirteen years old. Another instance of ten injections is reported with no unfavorable symptoms.

As a rule the dosage has been smaller in antitoxin units than is now considered advisable, particularly in many of the laryngeal cases and others injected later than the second day.

#### CASES INJECTED REASONABLY EARLY (DURING THE FIRST THREE DAYS) IN WHICH ANTITOXIN IS SAID TO HAVE PRODUCED NO EFFECT, THE DISEASE ENDING FATALLY.

These cases are twenty in number. Brief reports are introduced that the reader may judge to what degree they may be regarded as a test of the serum treatment. In our statistical tables all of them have been included among the fatal cases.

In *Cases 1 and 2*, the cultures were reported negative. *Case 1*, by Gallagher, New York: Child eighteen months old; septic; although no eruption was present, the reporter was "inclined on reflection to regard this case as one of scarlatinal sore throat."

*Case 2*, by Potter, Buffalo: Male, fourteen months old; two cultures made, but no Löffler bacilli found; membrane in the nose and pharynx. Injected on the third day one dose of Behring's serum No. 1. No improvement; death from sepsis. "Probably pseudo-diphtheria" (I. H. P.).

In *Cases 3 to 9*, no cultures were made. *Case 3*, by Tefft, New Rochelle: Seven years old; injected after eighteen hours' illness; two injections of Behring's No. 2 serum; membrane on the tonsils, pharynx and nose; no effect observed from injections, patient dying on the third day.

*Case 4*, by Tefft: Male, four years old; membrane on the tonsils and pharynx; injected after thirty-six hours' illness with Behring's No. 2; died on the third day; no noticeable effect from the injection.

*Case 5*, by Tefft: Six years old; membrane on the tonsils, nose and pharynx; septic; injected after thirty-six hours' illness; three injections of Behring's No. 2. "Saw no effect from the injections, the disease going steadily on to a fatal termination."

*Case 6*, by Cameron, Montreal: Two and a half years old; fifty hours ill; membrane on the tonsils, nose and pharynx; septic; no improvement noticed, and child died twenty hours after injection.

*Case 7*, by Baker, Newtonville, Mass.: Three years old; laryngeal diphtheria: injected on the third day 10 c.c. Roux's

<sup>2</sup> It is worthy of note that in the tests made by the State Board of Health of Massachusetts, published under date of April 6, 1896, this serum was found far below the standard as labeled upon the bottle; thus, a package marked to contain 2,500 units, by test was found to contain less than 700. All the other varieties of serum tested were found essentially up to the standard.

serum; cyanosis; intubation; temperature 103 degrees F., and continued high until death in eighteen hours after operation; injections had no effect.

*Case 8*, by Anderson, New York: Three years old; injected after three hours' illness; membrane on the tonsils, nose and pharynx; one injection New York Health Board antitoxin. "A case of malignant diphtheria, full duration twenty-four hours."

*Case 9*, by McLain, Washington: Four years old; twelve hours sick; membrane on the pharynx and the larynx; two injections; no operation; first injection early in the morning, the other early in the afternoon; died the same day; no change in the condition; antitoxin had no apparent effect.

In cases 10 to 13 diphtheria complicated measles, all reported by W. T. Alexander, New York. Disease confined to the larynx in all; in three the stenosis developed during measles, and in one while the patient was convalescing from measles; diagnosis confirmed by culture in every case, and in all intubation performed. Antitoxin seemed to have no effect, the cases going on to a fatal termination; all received their injections within twenty-four hours after the laryngeal symptoms appeared.

In three cases—14 to 16—the type of the disease was malignant from the outset.

*Case 14*, by Lloyd, Philadelphia: Fifteen months old; injected after thirty-six hours' illness; diagnosis confirmed by culture; membrane covered the tonsils, pharynx, nose and larynx; intubation; sepsis; death on the fifth day. Although antitoxin was used as promptly as possible no perceptible effect noticed. One injection, Behring's No. 3, was given.

*Case 15*, by Wert, Mount Vernon, N. Y.: Eighteen months old; injected on the third day; diagnosis confirmed by culture; membrane on the tonsils and pharynx. "Very intense type of the disease." Antitoxin could not be procured before the third day; Gibier's serum used. "Died suddenly in apparent convulsions about ten hours after injection; urine not examined; very little passed."

*Case 16*, by Ingraham: Six years old; membrane covered the tonsils, pharynx, and larynx; diagnosis confirmed by culture; pneumonia present; condition very bad; injected after two and a half days' illness; three injections of Behring's serum; no benefit noticed.

*Case 17*, by Johnson, Buffalo: Three years old; twelve hours ill; case septic from the start; membrane on the tonsils, pharynx, and larynx; diagnosis confirmed by culture. "Antitoxin apparently had very little effect."

*Case 18*, by Baker, Newtonville, Mass.: Two and a half years old; twenty hours ill; disease confined to larynx; diagnosis confirmed by culture; one injection of Gibier's serum; intubation. "Was doing well a few minutes before death when child got up in its crib, changed color and died almost immediately." Death attributed to "sudden heart failure; found no obstruction of the tube."

*Case 19*, by Story, Washington: Five years old; in fair condition; thirty-six hours ill; diagnosis confirmed by culture; membrane on the tonsils, pharynx, and larynx; one injection of United States Marine Hospital antitoxin; injection produced no effect.

#### CASES IN WHICH UNFAVORABLE SYMPTOMS WERE, MIGHT HAVE BEEN, OR WERE BELIEVED TO HAVE BEEN, DUE TO ANTITOXIN INJECTIONS.

Only three cases reported to the committee could by any possibility be placed in this category. All of the details furnished by the reporters are reproduced:

*Case 1*, by Kortright, Brooklyn: Sudden death in convulsions ten minutes after injection. This case is the already well-known Valentine case, occurring in Brooklyn in the spring of 1895. The principal points were as follows: A girl sixteen years old; in good condition; tonsillar diphtheria; diagnosis confirmed by culture; injected on the first day with 10 c.c. Behring's serum; died in convulsions ten minutes later.

*Case 2*, by Kerley, New York: Fairly healthy boy, two and one-half years old; membrane on tonsils, pharynx and in nose. Diagnosis confirmed by culture; injected on the morning of the fourth day with 10 c.c. (1,000 units) New York Health Board serum; temperature at time of injection 100.4 degrees F.; no sepsis, and child apparently not very sick; urine free from albumin. Distinctly worse after injection; in ten hours temperature rose to 103 degrees F.; urine albuminous; throat cleared off rapidly, but marked prostration and great anemia, with irregular fluctuating temperature continued and death from exhaustion with heart failure four days after the use of the serum.

*Case 3*, by Eynon, New York: Male, three and one-half years old; diagnosis confirmed by culture; two days ill; membrane on tonsils and in nose; two injections New York Health Board serum. "A rapid nephritis developed after the second injection, causing coma, convulsions and death twenty hours after the second injection." In response to an inquiry for further particulars the following was received: "The case seemed a mild one, but the injection was given one afternoon and repeated the following afternoon, about 1,500 units in all. The urine up to that time had not been examined. About fourteen or sixteen hours after the second injection unfavorable symptoms began to develop pointing to infection of the kidneys. The urine was found to be loaded with albumin. My impression at the time was that the antitoxin either produced, hastened or intensified nephritis, thereby causing the fatal termination."

In regard to the three fatal cases just cited, Case 1 is wholly unexplained. In Case 2 the query arises, did this sudden change hinge upon the injection of the serum or was it one of those unexplained abrupt changes for the worse in a case apparently progressing favorably, so often observed in diphtheria? As regards Case 3, it will be seen from the letter that the evidence is not at all conclusive. All details available are given and the reader may draw his own conclusions.

#### CLINICAL COMMENTS.

The following are selected from hundreds which have been received and may be taken fairly to represent the sentiments of the physicians who have sent in reports:

Dr. Douglas H. Stewart, New York, sends reports of four cases, all desperate ones, and all "presumably fatal under any other form of treatment." Very extensive membrane in all; larynx involved in three; in one neglected case in a child 3 years old, injected upon the fifth day, the membrane covered the tonsils, nose, pharynx and larynx. Broncho-pneumonia, nephritis and sepsis all present. Temperature 107 degrees F. at the time of the first injection. Prostration so great that he dared not attempt intubation. Believes that this case would certainly have been fatal in a few hours without antitoxin. Perfect recovery.

In another case 3 years old, membrane first discovered in the left ear, next morning seen upon the tonsils, and spread in a few hours over the pharynx into the larynx and trachea. Intubation necessary in a few hours; had never seen membrane spread so rapidly as in this child. Urine albuminous; membrane subsequently expelled from larynx and trachea in large casts with profuse bloody expectoration. Complete recovery on the ninth day. The physician describes this as "the very worst case of diphtheria that has ever come under my notice." Five thousand four hundred antitoxin units were given in four injections. He remarks: "My experiences in the past have been so very unfortunate that the advocates of antiseptics or therapeutics were a constant surprise to me. It has been my fate to have the most desperate cases unloaded upon my shoulders. I had been forced into the belief that the profession was absolutely powerless in the presence of true diphtheria; have lost case after case with tube in the larynx and calomel fumigations at work. Previous to antitoxin my only hope had become centered in nature and stimulants. In two years have not lost a single case, and surely I may be pardoned if I suffer from diphtheria-phobia in a sub-acute form, and use antitoxin sometimes unnecessarily."

Dr. L. L. Danforth, New York, states that during his twenty-two years of practice in New York he has

seen many fatal cases of diphtheria, had used all kinds of remedies, mainly those of the homeopathic school, and while he had as much confidence in the latter as in anything else, he had seen so many deaths during the year past that he "hailed with delight the advent of antitoxin and determined to use it." Reports five cases, all of a severe type. "The result in every case has been marvelous. I would not dare to treat a case now without antitoxin."

Dr. H. W. Berg, New York, reporting fourteen cases, says: "I have not yet ceased to be surprised at the recovery of some of these cases, which, in the light of my former experience with diphtheria treated without antitoxin, seemed to be irretrievably lost."

Dr. George McNaughton, Brooklyn, reports seventy-two laryngeal cases, with twenty-four deaths; sixty-seven of these were intubated, with twenty-one deaths. He states that he has kept no records of cases other than laryngeal ones, as these seemed the best test of the serum treatment. He believes that if the serum is used early, very many cases will not need operation for the relief of stenosis. "I would urge the use of antitoxin in all cases of croup in any patient who has an exudation upon the pharynx; would not wait for bacteriologic confirmation of diagnosis, for in so doing valuable time is lost." Has noticed that the tube is coughed up more frequently in injected cases, and believe this due to the fact that the swelling of the tissues subsides at an early date.

Dr. D. C. Moriarta, Saratoga, reporting four cases, says that the first was a malignant one and "I only used the remedy because I am Health Officer and was urged to do so, as the type of the disease was that from which I have seen recovery but once in eleven years." Boy 5 years old, four days ill when injected; great prostration, rapid breathing, and he was "practically gone." Nares filled and tonsils and pharynx covered; severe nasal hemorrhage; cervical glands greatly swollen; heart's action very frequent and feeble; child unable to lie down. Behring's serum twenty c.c. injected; in six hours evidently more comfortable; in eighteen hours decidedly improved; in twenty-four hours sitting up and feeling much better; in forty-eight hours all urgent symptoms gone and membrane loosening. Subsequently had nephritis which lasted six weeks, and multiple neuritis which persisted for three months, but ultimately recovered perfectly. "I send this report because it converted me. No unbiased person familiar with diphtheria could see such results as this and not feel there must be good in it."

Dr. F. M. Crandall, New York, sends report of a child 7 years old. Membrane on the tonsils and in larynx, with croup for forty hours when antitoxin was injected and intubation done. Progress of the disease had been rapid; semi-stupor and eyes half open; very feeble, rapid pulse; intense toxemia; general cyanosis. Both cyanosis and dyspnea persisted after intubation, showing clearly the presence of membrane below the tube. Case regarded as "absolutely hopeless." The first change was seen in the disappearance of toxemia, with improvement in the pulse, clearness of the mind, etc.; later a change in the local condition; large masses of membrane were expelled from the larynx and trachea, necessitating frequent removals of the tube. Tube finally removed in a week with complete recovery.

Dr. Reynolds, Baltimore, mentions a case showing the danger of relying too implicitly upon the bacte-

riologic diagnosis. Male, 3 years. Culture reported only staphylococcus and streptococcus, consequently injection delayed until the fifth day, when membrane covered tonsils, nose and pharynx. Child died two days later. A sister subsequently contracted the disease, received antitoxin on the third day and recovered. The reporter would not wholly rely upon the culture test for diagnosis.

#### SUMMARY.

1. The report includes returns from 615 physicians. Of this number more than 600 have pronounced themselves as strongly in favor of the serum treatment, the great majority being enthusiastic in its advocacy.

2. The cases included have been drawn from localities widely separated from each other, so that any peculiarity of local conditions to which might be ascribed the favorable reports must be excluded.

3. The report includes the record of every case returned except those in which the evidence of diphtheria was clearly questionable. It will be noted that doubtful cases which recovered have been excluded, while doubtful cases which were fatal have been included.

4. No new cases of sudden death immediately after injection have been returned.

5. The number of cases injected reasonably early in which the serum appeared not to influence the progress of the disease was but nineteen, these being made up of nine cases of somewhat doubtful diagnosis; four cases of diphtheria complicating measles, and three malignant cases in which the progress was so rapid that the cases had passed beyond any reasonable prospect of recovery before the serum was used. In two of these the serum was of uncertain strength and of doubtful value.

6. The number of cases in which the patients appeared to have been made worse by serum were three, and among these there is only one new case in which the result may fairly be attributed to the injection.

7. The general mortality in the 5,794 cases reported was 12.3 per cent.; excluding the cases moribund at the time of injection or dying within twenty-four hours, it was 8.8 per cent.

8. The most striking improvement was seen in the cases injected during the first three days. Of 4,120 such cases the mortality was 7.3 per cent.; excluding cases moribund at the time of the injection or dying within twenty-four hours, it was 4.8 per cent.

9. The mortality of 1,448 cases injected on or after the fourth day was 27 per cent.

10. The most convincing argument, and to the minds of the Committee an absolutely unanswerable one, in favor of serum therapy is found in the results obtained in the 1,256 laryngeal cases (membranous croup). In one-half of these recovery took place without operation, in a large proportion of which the symptoms of stenosis were severe. Of the 533 cases in which intubation was performed the mortality was 25.9 per cent., or less than half as great as has ever been reported by any other method of treatment.

11. The proportion of cases of broncho-pneumonia—5.9 per cent.—is very small and in striking contrast to results published from hospital sources.

12. As against the two or three instances in which the serum is believed to have acted unfavorably upon the heart, might be cited a large number in which

there was a distinct improvement in the heart's action after the serum was injected.

13. There is very little, if any, evidence to show that nephritis was caused in any case by the injection of serum. The number of cases of genuine nephritis is remarkably small, the deaths from that source numbering but fifteen.

14. The effect of the serum on the nervous system is less marked than upon any other part of the body; paralytic sequelæ being recorded in 9.7 per cent. of the cases, the reports going to show that the protection afforded by the serum is not great unless injections are made very early.

The Committee feels that this has been such a responsible task that it has thought best to state the principle which has guided it in making up the returns. While it has endeavored to present the favorable results with judicial fairness, it has also tried to give equal or even greater prominence to cases unfavorable to antitoxin.

In conclusion the Committee desires in behalf of the Society to express its thanks to members of the profession who have cooperated so actively in this investigation, and to Dr. A. R. Guerard for the preparation of the statistical tables.

#### THE ACTION OF THE SOCIETY UPON THE REPORT.

At the close of its presentation, the Society voted to accept the report of the Committee and after a full discussion it was decided to embody its conclusions in the following resolutions:

(1) *Dosage.* For a child over two years old, the dosage of antitoxin should be in all laryngeal cases with stenosis, and in all other severe cases, 1,500 to 2,000 units for the first injection, to be repeated in from eighteen to twenty-four hours if there is no improvement; a third dose after a similar interval if necessary. For severe cases in children under two years, and for mild cases over that age the initial dose should be 1,000 units, to be repeated as above if necessary; a second dose is not usually required. The dosage should always be estimated in antitoxin units and not of the amount of serum.

(2) *Quality of antitoxin.* The most concentrated strength of an absolutely reliable preparation.

(3) *Time of administration.* Antitoxin should be administered as early as possible on a clinical diagnosis, not waiting for a bacteriological culture. However late the first observation is made, an injection should be given unless the progress of the case is favorable and satisfactory.

The Committee was appointed to continue its work for another year and was requested to issue another circular asking for the further cooperation of the profession, this circular to be sent out as soon as possible in order that physicians may record their cases as they occur through the coming year.

**Formalin in Gonorrhœa.**—Dr. George T. Howland reports five cases of gonorrhœa treated with one half per cent. formalin solution. By means of Sterns urethral irrigators, one quart of the warm solution was injected once or twice a day. The discharge ceased in from twelve to twenty-seven days.—*Journal of Cutaneous and Genito-Urinary Diseases*, June, 1896.

## THE RELATIONS EXISTING BETWEEN OCULISTS AND OPTICIANS.

Read before the Tri-State Medical Society, at Chicago, April 8, 1896

BY FRANK ALLPORT, M.D.

PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLGY IN THE MINNESOTA STATE UNIVERSITY; PRESIDENT OF THE MINNESOTA STATE MEDICAL SOCIETY; SECRETARY OF THE OPHTHALMOLOGICAL SECTION OF THE AMERICAN MEDICAL ASSOCIATION, ETC.  
MINNEAPOLIS, MINN.

In presenting this paper before your society, I am impressed with the advisability of an oculist laying before a body of influential general practitioners one of the evils of ophthalmology. It is unnecessary to argue this matter in an ophthalmological society or section, as we clearly appreciate and understand the argument. But it is desirable that our common friend and mother, the general school of medicine and surgery, should listen to our views, and render us that aid and cordial cooperation we so earnestly and righteously desire, and feel we have a right to expect and demand. Many of you, practicing in more general lines of work or separating yourselves into other special fields, do not thoroughly understand and appreciate the importance and gravity of the situation, and often, I fear, nay, I am sure, lend your influence by indifference or positive advice, to the perpetuation and prosperity of an evil striking at the root of essential ophthalmological development. I refer to the alleged correction of errors of refraction by the numerous varieties of opticians.

In discussing this question, no claim of originality is made, for the ground has been quite thoroughly covered by Dr. Pilgrim and others; therefore, what I have to say must appear largely in the light of repetition; I simply desire to awaken in the minds of physicians *not* practicing ophthalmology an interest in the matter similar to that experienced by them (in which they expect us to participate), upon witnessing unqualified and unlicensed men, in the shape of itinerants, residents, or druggists, presuming to boldly practice medicine or surgery. In writing this paper, I am well aware that to little souls, in and out of the profession, it may appear as a narrow and selfish complaint, originating from a diminished income, on my own part and that of my brother oculists. To broad-minded men, however, an entirely different construction will be placed upon my words, and my reasoning will be clear, and understood as an effort to prevent the practice of medicine by improper persons, and to protect the public, by improving the status of our profession. Such reform work has been accomplished in other branches of our science; it should, and will be done in this. With regard to such practices diminishing the incomes of oculists, it is my firm and honest conviction, after years of experience, that this is not the case. Those who primarily patronize the optician, would not usually seek an oculist, and do not except under compulsion, sometimes induced from sad and unfortunate ocular experiences in an optical establishment.

Dr. Gould says, "Every pair of lenses worn by every person in the world has a medical and pathological significance." If this remark is true, and it undoubtedly is, the adjustment of glasses should only be confided to men who have not only some knowledge of optics, etc., but who also possess a broad conception of the anatomy, physiology and pathology of the human body, including the eye. If *properly* adjusted glasses are capable of improving the eye and health, and relieving ocular symptoms and various

reflex neuroses, *improperly* adjusted glasses are capable of *producing* the same pathologic conditions. The average oculist can enumerate scores of instances where this has occurred, by the prescribing of concave for convex glasses, the over-correction of myopia, the improper setting of cylinders and prisms, etc.; but such facts are not so well understood by the general practitioner, and it is hoped that the honest assurance by honest oculists that such instances are of more than frequent occurrence will lead to an establishment of the truth.

Who is the optician? He has a plural existence, the lowest grade of which can be found at the county fair or the street corner. These men, as a rule, do not pretend to much knowledge, and may content themselves with selling their wares, and perhaps aiding their patrons with a few lines of printed matter to select glasses. That they are harmful is certain, but inasmuch as the customer simply purchases whatever glasses he may select, it may be correctly asserted that the circumstance is similar to the sale of a designated variety of patent medicine, and until we can control the sale of the latter, we can not justly demand the abolishment of the former, although the technical argument might be raised, that one is patented and protected by the government and the other is not.

The jeweler or druggist who sells glasses, under practically the same circumstances, with little or no protestation of knowledge, and no tendering of advice, places himself in the same category, an undoubted evil, but nondescript in character and difficult to control. The next grade of optician is he who travels from town to town, announcing himself as Doctor or Professor So-and-So, carrying with him a formidable array of poorly understood instruments, and much seductive literature. He may have "picked up" his fund of knowledge in some optical establishment, or "graduated" at some "Refraction" or "Optical School," whose existence should be at once condemned. His methods of doing business are various and astonishing, but will not be here criticised, as such criticisms are not the aim and object of this paper, which is written for a broader purpose. Suffice it to say that the traveling optician usually does a good and profitable business, and often forms pleasant acquaintances with physicians in small towns, who, it must be regretfully admitted, send them patients who are supposed to need glasses.

Another variety is he who "holds forth" at a department store, or in some room or store of his own, or forms an alliance with a jeweler. He belongs to about the same class as the traveling optician, except that he does not travel, and these two classes have at least one thing in their favor, viz., they do an independent business, and ask no favors of the oculist in the way of prescription work, which can not be said of the highest grade of optician, viz., he who has a store and workshop in a large city, does prescription work for oculists, and all the refraction work he can do besides. He is the evolution of the original optician from whom has sprung all the preceding varieties just mentioned, and consequently the "principal offender" in the present issue. Now permit me to say on the start, that I have no quarrel with opticians as a class; I know many of them personally and take pleasure in testifying to their average honor and integrity. The better class of opticians realize the embarrassments and perplexities of the subject keenly, and would gladly do all in their power toward its rec-

tification; but they are rendered powerless by unprincipled competitors, who are unwilling or unable to see the difference between an oculist and an optician, and who either considers that a superficial knowledge of optics fully equips them to intelligently treat refraction errors, or who know better, but persist in their course in spite of their knowledge. It is chiefly such opticians who come in contact with the oculist, for it is to such shops that his prescriptions are usually sent. This places him in the unfortunate and anomalous position of directing his business to his principle, and not always honorable competitor, which frequently leads to a disintegration of confidence between the oculist and his patient, and an impertinent and presumptuous alteration of a prescription by the optician from time to time to suit the emergencies of the case.

Owing to these and many other abuses, a lack of harmonious relations have necessarily crept in between the oculist and optician, the former feeling that an ocular examination and refractive correction is not a mere mechanical art, but one of the highest and most exacting branches of medical science, and to be dealt with by properly educated physicians only, and the latter, *perhaps*, feeling that he is as competent to "fit glasses" as the oculist, and should consequently be allowed to do so unmolested, and that everybody should strictly "mind his own business." It is strangely true, however, that the optician feels aggrieved when the oculist, in view of the fact that the optician is his active competitor, endeavors to ignore the latter by dispensing his own glasses. There is also a higher motive in such a step, viz., a conviction that he who practices medicine without a license should be discouraged. The optician should remember, that as long as he even *reasonably* adhered to his trade, amicable relations existed between himself and his best friend and patron, the oculist, and not until he endeavored to usurp the latter's position, and inaugurated a series of mutually unfortunate consequences, has the oculist been compelled to resort to measures that the optician views with mingled feelings of hatred and revenge. He has built his own house and should be willing to live in it.

The measures of relief adopted by many oculists, such as purchasing their own glasses, engaging a private office optician, etc., are not as yet wholly desirable, but no one can doubt the evolution of a plan satisfactory to both oculist and patient. Let us hope that the ultimate solution will be the re-establishment of amicable and mutually profitable relations between the oculist and optician, and the determination by the one to adhere to his profession and the other to his trade, and together exterminate pretenders, who are neither one thing nor the other.

In order that errors of refraction may be accurately corrected, it is necessary that the work of both oculist and optician should be properly performed; both are dependent upon each other, and should labor together for their mutual benefit and the good of the public. The optician possesses a high and honorable calling and one of which he need not be ashamed. Why then should he seek to invade the territory of the practice of medicine? The lame and senseless argument is sometimes advanced, that the optician antedates the oculist, who has therefore become the trespasser. The barber might as well claim a right to practice surgery and dentistry, as history places him in the pioneer ranks of both these professions. The

truth of the matter is, that correcting errors of refraction has developed, by inevitable scientific solution, from a mere trade to an important branch of medicine and surgery, and as such should be performed only by properly educated men. If the optician wishes to do such work, he should study medicine and become a licensed physician, when he will be privileged to practice his profession in this or any other line he may select.

I would not be understood as meaning that a medical diploma is an assurance of knowledge, as the occupation of a chair in a medical college for fifteen years, has compelled me to regretfully express an adverse opinion. I am willing to admit that the most intelligent resident opticians possesses a better knowledge of optics and errors of refraction than the average medical man. But two wrongs do not make a right, and no one unpossessed of a medical license should perform such work, and only then when special ophthalmologic training has supplemented a general medical education. I am happy to say that ever-increasing salutary medical laws, combined with efficient postgraduate instruction, have rendered the special practice of ophthalmology untempting to most men not thoroughly equipped for its prosecution. The field would be broadened and deepened, the public benefited, and small towns quite generally supplied with physicians well qualified to work in this department, if only the optician in his various aspects could be prevented from attempting to correct errors of refraction.

The law, as at present interpreted, does not require that an optician shall possess any knowledge whatever in order to follow his important and dangerous calling. A druggist is subject to pharmaceutical laws, a veterinary surgeon to veterinary laws, a dentist to dental laws, but an optician is subject to no laws whatever, and may continue adjusting glasses, and ruining eyes at his own option. One would think that the better class of opticians would take sufficient pride in their own business, profession, or whatever they choose to call it, to precipitate some thoughtful legislation tending toward a purification of their own ranks. It is hoped that the agitation of this question will at least accomplish some result, for a proper eliminating process will leave broader-minded and better educated men to deal with, and it is unquestionably true, that the more intelligent the optician, the more does he comprehend the position of his calling, and the more ready is he to exalt its importance, to distinguish and admit the difference between an oculist and an optician, and to govern his actions accordingly. I am loath to admit that there are many physicians of more than average ability who, either by word or deed, sympathize with the optician in this argument, and do not admit that in attempting to correct errors of refraction the optician is essaying the practice of medicine. Such views are born either of indifference or an ignorant misconception of the facts, and should be easily overcome by the exercise of reason, intelligence and thought. No special field of our profession has made greater advances of late years than ophthalmology, and the most distinguished of its devotees unite in declaring errors of refraction and muscular anomalies its most profound and scientific subject, and one that has taxed without satisfying many of the most powerful intellects of the century. These men declare unhesitatingly that such work can not be separated from general ophthalmology, and surely no one

believes that the latter can be alienated from the practice of medicine.

No intelligent oculist to-day fails to thoroughly examine every patient who seeks his advice, even if only the correction of presbyopia is the object of the visit. Such an examination includes a general review of the physical condition of the patient, and an exacting and systematic investigation of the eye, both intra- and extra-ocularly, not only as to the refraction and muscular balance, but also as to medial opacities, cataract, retinal, choroidal and nerve diseases, and many other pathologic conditions impossible of detection by the inexperienced, and yet frequently of the greatest importance to the applicant when once discovered. It often happens that cases of supposed rapidly advancing presbyopia prove upon careful examination to be glaucoma, amenable to treatment and possible of cure. Diminution of vision is sometimes proven by the ophthalmoscope to be the first evidence of albuminuria in the retina, which serves as an indication for successful therapeutics. Headaches, neuralgias, etc., are daily discovered to be the reflex evidences of hypermetropia, astigmatism, muscular insufficiencies, etc. And so I might proceed in giving instance after instance explaining *why* ocular examinations should be made as frequently as possible and by properly equipped physicians only, but I refrain, as it appears almost an insult to intelligent physicians to urge the claim after once their attention has been diverted in this direction.

Without further specification, then, which I am confident is totally unnecessary, I make the statement boldly, and without fear of contradiction by those having sufficient intellect to judge or breadth of character to concede, that correcting refractive errors is practicing ophthalmology, which, in its turn, is practicing medicine, and that this should be permitted only by medical graduates, and that where State medical practice acts exist, the optician is practicing medicine without a license, and should be restrained from further prosecuting his calling, so far as giving advice and prescribing glasses is concerned. Such work can not be properly performed without a thorough knowledge of anatomy, physiology, pathology, etc., a broad training in ophthalmology and a general comprehension of the different branches of the science of medicine and surgery, as taught in first-class medical colleges and postgraduate institutions.

In presenting this paper I have refrained from casting slurs upon the optician, and from indulging in any personalities or instances whatever; they have pressed in upon my memory, with their aptness and appropriateness, so urgently as to render their repression exceedingly difficult, but I have felt that what was needed was not a display of acrimonious bitterness, inspired by personal quarrels and a sense of wrongdoing and injustice, but a calm, earnest, and unimpassioned presentation of the point at issue, viz., the unlicensed practice of the medical profession by my friend the optician. There is no more reason why an optician should fit glasses, than that a druggist should prescribe medicine, and yet you, my brother general practitioner, would anticipate *our* aid in expelling such an evil, and would not expect us to ask you the reason why. Let us, I beg of you, bespeak *your* assistance in sentiment, influence and action.

What is to be done about it? This is a serious question, and one surrounded with obstacles. Great movements progress slowly, and we can not anticipate

a satisfactory settlement at once. We must primarily awaken a proper comprehension of the subject in the minds of physicians, and through them compel the laity to understand, that "fitting glasses" is not a trifling affair, necessitating only the patient's personal sensations, and the guidance of an optician to correctly consummate; but that it is, on the contrary, an important event, necessitating a thorough examination and possibly entailing serious consequences, and should therefore only be performed by a properly equipped, especially trained, medical practitioner. Until this is reasonably well accomplished, it will be futile to attempt more radical measures. Let this step be well grounded by constant agitation, and a desirable solution of this perplexing question will be rendered comparatively easy.

## SOCIETY PROCEEDINGS

### New Jersey State Medical Society.

*Proceedings of the 130th Annual Session held in Asbury Park, June 23, 1896.*

The usual reports, etc., were presented and acted upon. The committee on the prevention of purulent infection of the eyes of the new born reported that the Board of Health had issued a circular to the profession, etc., detailing the plan of Credé of Leipzig, to prevent this. After the umbilical cord has been divided and the skin cleansed, bathe the eyelids with a cloth wet with pure water, then touch the everted lids with a glass rod dipped into a 2 per cent. solution of nitrate of silver. It was agreed that the State Board of Examiners should be asked to require of each applicant for a license to have a knowledge of this method.

The proposed act to prevent cruelty to animals in the District of Columbia was brought up by Dr. H. Mitchell, the secretary of the State Board of Health and after some discussion it was

*Resolved*, That it is the sense of this Society that the bill entitled a "bill for the further prevention of cruelty to animals in the District of Columbia" now pending before Congress is a menace to medical and surgical progress, a bar to proper scientific investigation and inhumane in that it restricts the possibility of the acquirement of knowledge that will lessen human suffering and prolong life; therefore,

*Resolved*, That the Medical Society of New Jersey respectfully requests the members of Congress from this State to use every proper effort to prevent it from becoming a law.

*Resolved*, That printed copies of this action be forwarded to the New Jersey congressmen and to the chairmen of the committees on the District of Columbia in the Senate and House of Representatives of the United States.

In the afternoon the Standing Committee gave a very valuable resume of the reports of the counties of the epidemics that had prevailed in their localities, the result of the trial of new remedies, of improved sanitation, especially of the results of the employment of antitoxin, mallein and thyroid extract. There was a great want of uniformity in the results as reported. Some appeared to have obtained very great benefit, others had found these remedies useless, while others held them sub judice.

DR. PHILIP MARVEL of Atlantic City, read a valuable paper upon

#### AUTO-INFECTION.

He explained the difference between ptomaines and toxins; the one poisonous, the other harmless. The toxins were the result of decomposition within the body. There is constantly going on a building up and breaking down; so long as the two processes are kept equal, the person is in health. Otherwise, disease results from the alkaloidal products. The channels by which the poisons are eliminated are the blood, lymphatics, the cellular tissue, etc. The putrefaction of foods result in a toxin formed by the action of the bacteria on the proteids.

This is the principal cause of nearly all diseases. The common carriers are the blood and lymphatic systems. When the poison is in excess of the vital fluids, there is impaired function followed by death unless soon relieved. The poisonous substances are formed by the presence in the body of complex substances capable of combining with acids through the action of fermentative bacteria producing salts corresponding to organic and vegetable bases. All animal excretions are poisonous and are eliminated by the skin, the alimentary canal, the pulmonary mucous membrane and the skin. Acute auto-infection is very dangerous and gives rise to symptoms which are alarming, followed by death in a very short time. He quoted several cases where death had followed the ingestion of food already partially decomposed. Also quoted some experiments with animals where the injection of bile produced death in a short time. We must have free elimination constantly going on, or there will be reabsorption. Somewhere in the animal economy there is an unknown means for transforming toxic into inert matter or life could not continue. We find also that there is a different degree of poison for the same toxin in different individuals and under almost the same circumstances. Excess of food will often load the system with these toxins and we also find different types of these troubles. In acute cases we have a development of gas, tympanites, burning stomach, eructations, etc.; with these, headache, depression, fatigue, dizziness, vertigo, etc. In graver attacks there are convulsions, coma, death. These symptoms must be differentiated from ordinary impaired digestion by the suddenness of the onset, within six to twenty hours after taking food. When we can obtain free emesis and relaxed bowels there is more possibility of relief. In some instances we have extensive skin eruptions resembling erythema, scarlatina and the like. Sometimes the absence of vomiting will mask the case. He mentioned cases where the diagnosis had been measles, etc. He carefully analyzed several cases which he detailed showing how to prove the origin. In nearly every case it is the result of food ingested which had already begun to decompose. Some of the results of this trouble may be chronic atony of the stomach, dyspepsia, diarrhea, dysentery, stomach cancer or dilated stomach. 1, we have disarrangement of the structural tissues; 2, consequent interference with the nerve energies; 3, impairment of cellular function, inviting abnormal production; 4, and thus favoring fermentation; 5, prolonging digestion, thus aiding putrefaction. Perhaps in the future we may be enabled to observe these actions by means of skiascopy. He believed that numbers of cases had been diagnosed typhoid fever and when treated by intestinal antiseptics and elimination had been established, got well in ten days or two or three weeks, and thus were quoted as aborted typhoid fever.

DR. G. H. BALLERAY gave the details of a number of cases of fibroids of the uterus obstructing labor, with subsequent disappearance of the tumor. He detailed the symptoms by which the presence of some obstruction was determined, the mode of procedure in delivery, turning, etc. The detail of cases was unique and interesting and elicited much animated discussion. It was agreed by those who participated that the tumors were not ovarian, nor in every case truly fibroids, as these rarely if ever disappear in this manner.

DR. HENRY MITCHELL, the secretary of the State Board of Health, introduced his aid, DR. M. RAVENEL, who gave a very able resume of what was proposed to be done by the bacteriologic department of the Board. It was mainly devoted to the investigation of tuberculosis and diphtheria as these would occupy a central position being most important. The early diagnosis of diphtheria was of great importance and it was only by a bacteriologic investigation that the diagnosis could be made. Then a secondary examination was needed in order to decide when the patient had ceased to be dangerous to others. There is no fixed time when these bacteria disappear

from the throat, even mild cases show them six weeks after the disappearance of the membrane. They often linger in the nose and so long as a nasal discharge continues, it is suspicious and investigation should be made. Cholera also is to be looked after although it is hoped that no such need may arise. The diagnosis here can be made in eighteen to twenty-two hours and in no other way. Water being almost invariably the source of the infection, all water must be examined. It is not possible to be positive as to typhoid fever bacteria in the present state of the science especially in a sample of water, for the time elapsing between the infection and the desire for an investigation of a suspected supply is so long, three to six weeks, that many changes may occur; and then it must be remembered that the bacillus of typhoid is delicate, non-resistant, and temperature and nutrition are not favorable to it, and the common water plants are antagonistic to it. Also we have mechanical precipitation and the disinfection practiced so that there are too many factors entering into the matter. Again we have the constant presence of the colon bacillus and perhaps the formation of ammonia by this bacillus has much to do with this. Diseases of animals must occupy the attention as being of great importance, as in tuberculosis; here tuberculin is an infallible test. Anthrax does not often occur, but the department is prepared to make the diagnosis and this very easy. Glanders can only be diagnosed by the inoculation of animals. Hydrophobia is diagnosed by the injection of brain of the suspected animal rubbed up with sterile water and placed beneath the dura mater of a rabbit. This is the chief use of this animal to allay the fears of those bitten and to check the spread of newspaper hydrophobia. Water examinations are only made when for public use.

The President, DR. WM. ELMER of Trenton, then delivered the annual address. He dwelt upon the need of personal hygiene as it must become a matter of intelligent conviction among all classes. Those who occupy higher positions must help the lower, the wage earners in this point. The physician must work in this line regardless of self to spread the gospel of cleanliness of the person, the house, the surroundings. Thus to stamp out preventable diseases, which are an insult to an enlightened community.

The State and local boards may issue orders, but the people must join to prevent such, as it is a crime greater than many for which men are punished; the greater the nation, the greater the regard for a high grade of sanitation. Public hygiene is now a science, we have a right to demand pure air, pure water, pure soil. Add to these wholesome food and surroundings. The great misery comes not from numbers but from our imperfections and want of control of the conditions in which we live. Sewer waste and filth disease are concomitants in the crowded community, they are forced upon us. The great waste of life is among the children; fully one-half die before they reach the age of 5 years. Cholera infantum is the usual cause, produced by crowded homes, illy ventilated, with bad drainage, bad food and equally bad milk. We are glad to be able to chronicle a great improvement in the last year; not only the poor live better, but the training and education of the young are greatly improved. Munter's "plenty of sleep, milk and flannel" is old but good common sense. We now have physicians on the school boards, we have compulsory vaccination, we have demands for quarantine, and the Health Boards demand a quarantine of not less than forty days for smallpox, scarlet fever, measles and diphtheria. In some places the latter is not regarded safe to release from quarantine until an examination shows the absence of the bacteria. We must teach the young the rudiments of isolation and infection and the laws of living. We demand health of body as well as trained minds. Ventilation of the sick room air without draft needs the attention of the physician; also food well prepared, wholesome, nutritious, daintily served. Baths and sunlight,

with cheerful demeanor and quiet manner are needed for the sick and to prevent getting sick. Another great demand is the filtration of water supplies for the cities. The Cincinnati process of sedimentation and sand filtration appears the best; each bed is independent and there are daily bacteriologic examinations of each. By those means typhoid fever will be greatly lessened. He quoted several cities as showing the value of these methods. The economic value of a life is, say \$780 each, hence a death by typhoid fever is known as destroying that amount of wealth. He also alluded to consumption, its communicability, being the most prevalent disease and with the greatest mortality. It is conveyed by a microscopic parasite, found in the sputum dust. We must rely upon hygiene, not drugs, in this disease. There were many other subjects which demanded our attention, but time would not admit. Preventive, not curative, medicine is the great question of the day.

On the second day DR. ALEXANDER McALLISTER, of Camden, read a paper on the

#### THE THERAPY OF ANTITOXIN SERUM, NUCLEIN SOLUTION AND THYROID EXTRACTS.

Most of the paper was devoted to the first subject. He treated of the discovery of this method and alluded to the work of Roux, Yersin, Klebs, Koch, Löffler, etc. They prove that it is not the mere presence of the bacillus that gives rise to the disease, but the products of it, the ptomaines. Diphtheria is a toxemia and its toxin acts as a ferment, and when injected into living tissues, there results a certain albuminoid body, this isolated, and subjected to alcohol, produces a proto- and dextro-albumose. Rabbits injected with this exhibited the signs of diphtheria. It has also been reduced to a white amorphous powder. Then came the immunizing of animals, next the injecting the serum of blood rendered immune to certain bacteria into animals, thus immunizing them. This is to be carefully distinguished from the Jenner process for smallpox, Pasteur's for hydrophobia, which really produce a milder form of the disease. He described the method of producing antitoxin. The consensus of medical opinion tends to favor this treatment of diphtheria. Of course it has met with opposition. Too sanguine results are expected, a want of understanding of the discovery and its limitations, as where it is used and the patient dies of pneumonia or nephritis, and the prejudices against a new treatment. Since Jan. 4, 1895, he had treated forty-five cases of diphtheria with antitoxin, all of which recovered. Too much attention can not be given to the preservative used in protecting the serum. Carbolic acid is a toxic and dangerous remedy, highly irritating to the kidneys and urethral tracts, hence objectionable. Formalin would be the ideal preservative, except for the fact that it coagulates the serum after a time. Camphor is uncertain, feeble in power, and disguises the signs of decomposition, and putrefaction might be present and not be recognized. The best germicide and preservative is tricresol, a very feebly toxic agent, no irritating effect on the kidneys, and only feebly coagulates albumin. It is for these reasons that we are apt to have strikingly different effects of the different kinds of preparations. Since Jan. 4, 1895, he had treated forty-five cases with the serum; diagnosis confirmed by culture in all but eight. One died of laryngeal diphtheria. There were seventeen of laryngeal form, all recovered. In only five was it necessary to repeat the injection a second time, and a third time in one. Mulford's serum was used. Twenty c.c. were used at each injection. He believed the serum produced in this country was equal in value to that made abroad. No local reaction followed; there was a rise of temperature in some of one or two degrees, and pulse somewhat accelerated. In the mild cases improvement was noticed in ten hours, in others twenty-four to thirty-six hours; membrane changes in color and becomes detached. Had a small abscess in one. Erythema followed in the majority in eight to ten days after the injection; in one it persisted two weeks. Internal treatment was *mistura bashami*, *strychnia*, stimulants, locally *hydrozone*, boric acid solution, etc. Albumin was present in urine of the majority, clearing up as convalescence advanced. Post-paralysis occurred in all to a mild degree. Where paralysis occurs, the results are more favorable where the serum has been used. Only three died of the forty-five; one of heart paralysis, one complicated with abortion, one of sepsis. Beyond a doubt the mortality is lessened. It is not a specific, as vaccination for smallpox. It does not destroy the bacillus, only checks the course of the disease. The mere presence of the Klebs-Löffler bacillus in a case of sore throat does not constitute it diphtheria; it needs other symptoms, as fever, etc. Had immunized twenty-one cases,

two had afterward a mild attack of diphtheria. Immunization takes away the dread of the disease. In intubation the tubes can be removed sooner than without the serum. Pharyngeal cases may be doubtful evidence, but the results in laryngeal cases are conclusive. He quotes 5,794 cases in private practice with 713 deaths, a percentage of 12.3. Injected during the first three days 4,120, with 303 deaths. After the fourth day 1,448, mortality 27 per cent.; 1,256 laryngeal cases, 691 not operated on, 563 recovered, 80 died from other causes, and 48 from laryngeal stenosis; 565 operated on, mortality 25.9 per cent. Intubation in 533, tracheotomy in 32, mortality 37.4 per cent. Cases drawn from the practice of 615 physicians; over 600 express themselves strongly in favor of the serum. We regret that it is impossible to give more at length the details of this interesting and valuable paper. He gave a valuable bibliography, and statistics of American and foreign observers with and without the serum. There have been upward of a million injections and but five deaths were attributed to the serum, and in these no positive conviction can be assigned. With nuclein and thyroid extracts his experience was limited. The masters have given us reason to believe in these remedies, and he believed time would prove them correct. Many able clinicians are using nuclein locally and internally. The minimum dose to begin with is 10 minims, increasing 5 minims daily till the maximum dose is reached, 30 to 80 minims. In delicate or nervous patients you may have shock, fainting; here a stimulant is needed. Sometimes an erysipelatous rash is produced, usually passing in a few hours. A certain elevation of temperature follows. The leucocytosis effect generally lasts fourteen hours. It is claimed as serviceable in tonsillitis, indolent ulcers, incipient phthisis, malaria, diphtheria, etc. The power of nuclein of supplying building material and arresting disease germs make it more applicable than the antitoxins. Thyroid extract is claimed of value in a number of diseases, but specially in Graves' disease, etc.

In the debate which followed there was shown a great difference of opinion, one member having 100 intubations which he had been called to perform. In 20, serum was not used. Here the percentage of deaths was higher. His belief was in favor of its use, as 75 per cent. recovered while the others had 38 per cent. of recovery.

DR. BARKER, of Morristown, regarded it as a double-edged weapon needing care in its use. In one case that he knew 1,000 units were injected, the temperature and pulse reacted; vomiting was stopped by evening, had a comfortable night, in the morning appeared to be doing well. Then 1,500 units were injected, vomiting soon recurred, and death in the evening. Let well enough alone. Here there was no need of the second injection.

DR. DALAND, of Philadelphia, was in favor of the remedy. Many facts must be considered. Formerly many cases were not called diphtheria which are now decided to be such. It is unquestionably the reason of the lessened mortality because of the serum injections. It is difficult to estimate the epidemic influence. Suffocative cases occur less in the hospitals. It is a powerful remedy and needs much care to apply it. He had good results from the thyroid extract in exophthalmic goitre.

Another member had statistics of 5,000 cases and no accident, hence we are justified in employing it. Several others spoke on the subject, and the opinion appeared largely in favor of the serum and the thyroid extracts.

DR. C. R. FISHER read a paper on "Antisepsis." With this we may operate in a farm house with much better hopes of good results. He did not believe it was necessary before delivery to employ antiseptics, but the hands and the canal should be protected by this means at every examination. Puerperal fever was not now epidemic as formerly because of antiseptics. Antiseptic surgery is now simplified, we no longer spray the room, etc.; that was an abuse of it.

DR. McEWAN read a paper on "Chloroform Narcosis." His conclusions were: 1. Chloroform is a dangerous drug. 2. Its dangers can be reduced to a minimum by the most scrupulous attention and conscientious care on the part of the anesthetizer. 3. That the administration of chloroform properly could only be done by one person having charge of it, and it is not a time to assist or to indulge in conversation with a bystander, or to watch an operation in order to familiarize oneself with the steps of scientific procedure.

The officers for the next year are: President, Dr. T. J. Smith, Bridgeton; first vice-president, Dr. D. C. English, New Brunswick; second vice-president, Dr. C. R. P. Fisher, Bound Brook; third vice-president, Dr. Luther S. Halsey, Williams-town.

The next meeting will take place in Atlantic City, fourth Tuesday in June, 1897. It was agreed that the Committee of Arrangements might arrange for a three days' session.

## American Neurological Association.

Annual Meeting held at Philadelphia June 3, 4, 5, 1896.

(Concluded from page 1265.)

DR. N. E. BRILL of New York read a paper on

THE STATUS OF OPERATIVE PROCEDURE AS A REMEDIAL AGENT FOR EPILEPSY.

This paper was a protest against promiscuous operation and surgical treatment in both essential and chronic epilepsy. He favored the removal of depressed bone where there was evidence of depression, as in these cases he had seen good results. In cases due to pathologic conditions, he took the position that craniotomy with excision of the cerebral cortex was unjustifiable, owing to, first, the bad results as far as amelioration is concerned, attending the operation; to our inability as yet to make absolute diagnosis as to the character of the pathologic lesion which occasioned the epilepsy. He cited cases to show that where a positive diagnosis has been made previous to the operation, when the skull was removed, the dura torn back and the brain excised no evidence of cerebral disease or defect was found. He argued further that there was an appreciable risk in the operation even when done with the most careful attention to technique; that fatal cerebritis and meningitis were by no means rare; that death occurred even on the operating table from shock; that we had no right to take even the slightest risk when the chances of amelioration or cure were so problematic unless the civilized world and a legal code endorsed the Spartan doctrine of destroying defective children. With such a purpose in view the thought of operation might possibly be justified. Against indiscriminate surgical interference, he voiced the protest of Lucas, Champonnière and others. As for the operation of craniectomy in epilepsy, he could find no justification whatever, especially when viewed in the light of our ignorance as to the pathology of the disease. He advocated conservatism and demanded that the clinician should hesitate before he ratified surgical measures, as an ameliorating agent in these cases. He regarded the large number of reported cases as a striking result of the clinician's desire to prove his skill in diagnosis by an antimortem operation and concluded by saying that no operation should be recommended unless the diagnostician should satisfy his conscience that the signs of disease were such that there could be no possible doubt as to the absolute presence of a definite pathologic condition, the character and nature of which he had absolutely determined previously.

DR. A. G. GERSTER in discussing the various papers on epilepsy, spoke on the different methods that have been employed in operative procedures. He referred to the fact that the circular saw was considered defective on account of the slowness of its work and the consequent danger of injuring the dura mater and stated that he had found a chisel more desirable than the trephine. In his opinion, the danger of injuring the dura mater is nil. He also considered the V-shaped chisels as too slow and unsatisfactory, as they have a very narrow groove, and penetration of the thinner lamellæ and injury of the dura mater may occur. He referred to Krause's modification of the circular saw and stated that even this did not entirely obviate the possibility of injury to the dura mater. He considered the greatest danger in cranial operations to be that of hemorrhage, and stated that unlike arterial hemorrhages, which could be easily stopped, it was the continual oozing of blood that was difficult to control. He considered any apparatus by which the skull could be opened in ten or fifteen minutes an excellent improvement and he was very glad to see an instrument invented by a Western man which would permit of satisfactory and rapid work. This instrument is built on the principle of the ordinary dental engine; it is very readily sterilized and does not require any expensive apparatus. An incision is made in the usual way and the extent and size of the flap having been defined, drill No. 1 is inserted, the object being to penetrate the entire thickness of the skull, the diameter consequently being a little larger than that of the other two. After outlining with drill No. 1, drill No. 2, which is smaller and sharper, is inserted. This is followed by drill No. 3, which is placed in the aperture made by drill No. 1. As soon as this is finished the flap can be pried up and the section laid open. The first case in which Dr. Gerster used this instrument, the operation took nineteen minutes, while the last took less than four minutes.

DR. M. ALLEN STARR referred to operative interference in epilepsy and stated that there had been a recurrence in every case and none of them had been cured. The first operation was done in October, 1889, and all the operations were performed on carefully selected cases by one of the most skillful operators in the country. No case has been operated on where

there has been very long duration between the trauma and the fit, nor any case of idiopathic epilepsy. With regard to the excision of cysts, Dr. Starr mentioned cases that he had seen die on the table. He referred to a case operated upon by Dr. McCosh, who exposed considerable area, laid back the dura and discovering a clot upon its inner surface, he scraped and thoroughly everted that region. The child had no paralysis and for a time recovered. Concerning abscess of the brain he has seen twelve cases of which eleven were operated upon. In each case an abscess was found either at the operating table or at autopsy. Of these operations three recovered. There are cases of brain abscess where the temperature is very irregular, varying between 98 and 106. There are also many cases which improve without any operation. Concerning the neurologic side of the question he did not think there was any connection with aphasia. He referred to an interesting case of aphasia in which an abscess was found in the temporal lobe. He mentioned another case in which the symptoms pointed to a tumor in the left hemisphere. The patient had epileptiform convulsions with unilateral paralysis. At the operation the tumor was found in the right hemisphere and there was perfectly good decussation of the motor fibers. In his opinion the days of trephining were over and the question now was how to make the flap and what instruments to employ. He stated that Dr. McBurney was doing very rapid work, performing operations in from fourteen to seventeen minutes with chisels and gouges, the gouges being but two mm. in width and the chisel being very sharp and narrow. As to the condition of exophthalmus, he could not understand how this could be caused by brain tumor except it lay behind the eyes.

DR. W. W. KEEN mentioned that paralysis frequently resulted from the injury to the brain caused by the tumor and the surgical interference. In Dr. Thomas' case there was nothing but a moderate paresis of the lower face and a moderate aphasia. After the mechanical interference there was no paralysis, but there was a diminution in the aphasia. He exhibited a tumor removed in December 1889, from a patient who is to-day living and well. In his opinion it seemed as though the removal of large tumors was less dangerous than small ones and if this be true it is doubtless due to the fact that in searching for tumors, one is apt to inflict an amount of injury upon the brain which is incompatible with recovery. During the past ten years the advancement in brain surgery had been very conspicuous and at the present time we are able to draw reasonable conclusions as to the result. He has not reported any of his own cases as he desired sufficient time to elapse to form an opinion as to the ultimate results. Although his experience had been moderately large, he is not able to report a single case cured and by cure he meant that after a reasonable time had elapsed the patient had had no fits. He was not willing to accept one year or even two and thought three should be exacted as the time limit to form an opinion. Although at the end of three years the patient may be still a sufferer, yet there will probably be great amelioration. He considered it worth while in nearly all cases to operate as he thought the results had been sufficiently satisfactory to warrant it and he stated that he would rather run the risk of any operation than go through life with such a frightful disease. As to idiopathic epilepsy he would not operate, but in Jacksonian, he considered operation justifiable judging from a number of cases recently reported. It is his practice to operate whether there are brain symptoms or not, but to refuse operation in cases that have gone on for many years. In his opinion at least twenty years should elapse before this question can be settled to the satisfaction of the profession. He did not think that 50 per cent. of the cases would ever be cured, but that a sufficient number will be benefited to make it worth while to run the risk of operation.

DRS. H. M. THOMAS of Baltimore and W. W. KEEN of Philadelphia reported a case of a large tumor removed from the brain with wide opening of the lateral ventricle. The patient, a young man of 19, with an excellent family and personal history and no history of accident, in December 1895, had an attack of intense headache and vomiting, but without optic neuritis. The latter symptom followed in the middle of January with blindness later in the right eye, slight vision remaining in the left, slight protrusion of the left eye-ball, pupils equal and normal, smell, hearing and taste unaffected, paresis of the lower right face, sensation and the muscles of mastication unaffected, no muscular weakness in either the arms or legs, but there was a good deal of muscular restlessness of the right hand, persisting even during sleep. Reflexes present, mental condition poor. He was dull and apathetic and sometimes slightly wandering mentally. After the early headache and vomiting, neither of these was a marked feature. There was slight aphasia. Drs. Osler and Starr saw the patient with

Dr. Thomas and the conclusion reached that it was a tumor in the left frontal lobe, probably at the base of the second frontal convolution and subcortical. On May 10, Dr. Keen operated. The bone was chiseled from the temporal fossa parallel to the eye-brow and a little above it nearly to the middle line, then backward nearly to the fissure of Rolando, then downward again into the temporal fossa. This large flap was reflected and the dura opened. The tumor presented through a rupture of the cortex at the base of the second frontal convolution as had been diagnosed. After ligating some vessels at its border, the tumor was easily scooped out by the fingers. The lateral ventricle was then seen to be widely open. To prevent blood filling the ventricle and passing into the third and possibly the fourth, the anterior part of the ventricle was packed with a strip of iodoform gauze. This was removed at the end of the second day. After the operation there was no increase whatever in the paralysis. In two weeks the patient had entirely recovered. The tumor was 7.5 cm. long, 5.5 cm. broad and 4 cm. deep and weighed two and a half ounces. It was a hard non-infiltrating sarcoma.

"A Case of Cerebral Abscess Situated in the Posterior Part of the External Capsule (involving the medullary substance of the first temporal convolution, also the posterior part of the lenticular nucleus, and extending into the subthalamic region), with some Considerations in Regard to the Constitution of the External Bundle of Fibers in the Cerebro-Peduncle," by Drs. CHARLES K. MILLS and WM. G. SPILLER.

The authors related the details of the case and stated that at the autopsy an abscess was found in the left hemisphere just above the level of the callosum. Both tympanic membranes were normal and microscopic examination of the pus from the cerebral abscess revealed only the ordinary staphylococcus pyogenes aureus. In view of the frequency of cerebral abscess after suppurative processes in the lungs, it may be added that merely spots of catarrhal pneumonia were found in both lungs. No degeneration was noticed anywhere in the motor tract. The fibers from the first temporal gyrus were almost entirely destroyed as well as those from the upper anterior part of the second temporal convolution. And as no degeneration had been found within the latter bundle of the peduncle by the method of Marchi sixty-eight days after the first attack and twenty-eight days after the second, it was considered that the case demonstrated the fact that no fibers from the first temporal and the upper anterior part of the second temporal gyrus including a portion of the upper middle of this gyrus enter the fasciculus of Turck. In another case of hemiplegia in which death occurred three weeks after the attack the authors were able to show intense degeneration by the method of Marchi.

DR. J. ARTHUR BOOTH of New York, read a paper on and presented a case of

EDEMA OF THE EYELIDS IN GRAVES' DISEASE; THYROIDECTOMY.

After detailing at some length, the circumstances connected with the patient presented, the author drew the following conclusions: 1. Slight decrease of the edema situated in the extremities is a common occurrence in Graves' disease, but this symptom limited to the eyelids is very seldom seen. 2. In distinguishing these various forms of swelling it is necessary to be guided by the position and the degree. If situated only on the face and upper limbs, or if unsymmetrical it is entirely of nervous origin. It may be that it affects the feet, but this will be slight and temporary. 3. These symptoms are evidently of vaso-motor origin and are probably due to a paralysis affecting the constrictor nerves, manifestations of peripheral neuritis. 4. Limited to the eyelids, it may be due to a paresis. If this be true, however, it is strange that we do not meet with it in other palsies of the muscles. 5. Thyroidectomy carefully performed and by one cognizant of the occasional complications, such an operation is not as dangerous as is generally believed. 6. From operative interference in Graves' disease, we may expect an improvement to some extent.

DR. M. ALLEN STARR said that the percentage of death in operations upon the thyroid gland was high and that he knew of several cases operated on in New York where every precaution had been taken, but death had resulted from some unexplained cause, although the ordinary surgical shock was not present.

DR. PHILIP COOMBES KNAPP of Boston read a paper on

THE NATURE OF NEURASTHENIA.

The author's study was based on one hundred cases in hospital and fifty in private practice. The chief symptoms were nervousness and weakness, the "irritable weakness" which is considered an essential symptom of neurasthenia. Next in frequency came headache, indigestion, insomnia and epilepsy. Depression, backache and other symptoms were much less common. Neurasthenia was considered to be apalagous to

chronic fatigue and to be due primarily to exhaustion in the cells of the brain cortex. Mental depression was not infrequent, but it was usually secondary to a neurasthenic condition or the physiologic result of the cause (grief, worry), which had produced the neurasthenic. Among the morbid fears were first those pertaining to the physical welfare of the patient often based upon physical symptoms and having a rational basis, although resting upon false premises and ignorance of the significance of these symptoms. In other cases the fears were of a different character and these cases were not neurasthenia, but true hypochondria, a mental state akin in some degree to paranoia. The second class of morbid fears were the so-called phobias. These fears exist in perfectly healthy people who, under their influence, may be drawn into considerable anxiety and distress. In other cases the morbid fears were secondary to certain unexplained ideas. These fears and unexplained ideas are not uncommon in mild forms in perfectly healthy persons. In the severe forms they exist as independent psychoses. These different psychoses may exist independently without any trace of neurasthenia. It will be found in only a small percentage of neurasthenic cases which is greater among private patients. When found in neurasthenia these fears and unexplained ideas are indicative of the coexistence of another affection.

DR. THEO. DILLER said in his opinion in all such cases it was of primary importance to search for neurasthenia as it is a question whether or not they are the outcome of a neurasthenic disease or a degeneration.

DR. BURT G. WILDER referred to the case of a distinguished etymologist who was made very uncomfortable by the mere presence of a cat even if he could not see it and stated that this fear was greatly intensified if the floor was carpeted.

DR. SPITZKA considered it important to separate the inherent cases from the acquired.

DR. HENRY S. UPSON of Cleveland, read a paper on  
NERVE DISTURBANCES FROM INDIGESTION.

Three cases were cited. While conclusions from so few cases are not warranted, yet the speaker believed that the type of nerve disturbance found in typhoid is found in intestinal indigestion without the intervention of this disorder. It may easily be confounded with mild melancholia or neurasthenia, which presents many points of similarity. It must be carefully differentiated from nerve diseases which are amenable to treatment, which treatment should not consist exclusively in the administration of an antiseptic.

DR. LANGDON—One must not forget that bacteria are of two kinds, the conservative and the pathogenic and there may be a third kind, the indifferent. It is well known that we could not live in our streets except for certain bacteria and it does not follow that because their presence may have a doubtful effect in some cases it will do so in all. He had obtained good results by the administration of mercury given in the form of calomel, which he claimed is converted into bichlorid of mercury by hydrochloric acid.

DR. THOMAS J. MAYS of Philadelphia read a paper on  
TOXICOSIS OF THE NERVOUS SYSTEM AS A CAUSE OF PULMONARY CONSUMPTION.

Dr. Mays said disturbance of the nervous system and especially of the respiratory nerves induces some form of pulmonary disease and frequently pulmonary consumption. That diseases of the pneumogastric nerves leads to these disorders is confirmed by the opinions of Chevan, Holland, Copland, Laycock, Allbutt and Clouston, which are quoted. Besides, clinical proof and post mortem evidence are adduced from cases found in medical literature. Alcohol, syphilis, mercury, lead, typhoid fever, diphtheria, measles, whooping cough, mumps, influenza, cerebro-spinal meningitis, beri-beri, rheumatism, etc., intoxicate the nervous system and become prolific sources of pulmonary mischief. Of all these poisons alcohol is probably most sure to bring about pulmonary diseases through the nervous system, and a number of cases giving post mortem proof of this are cited. Syphilis and most of the other poisons mentioned are treated in the same manner and are shown to have the same effect ultimately in a great many instances. The chronicity or the acuteness of the pulmonary disease which is thus dependent on the nervous system, are governed in a large measure, 1, by the virulence of the poison; 2, by the amount and frequency with which it is introduced; 3, by the persistency of its action, and 4, by the facility or difficulty with which it is excreted by the body. They all vary in this respect. Alcohol is quickly eliminated, but its harmfulness depends on its being taken frequently and continued for a long time. A single infection of syphilis permeates the body and the virus remains for years. Mercury and lead enter the body very gradually, but are excreted very slowly. The poisons of whooping cough, influenza and cerebro-spinal meningitis, having a selective

affinity for the pulmonary nerves, are liable to be followed by a more speedy disease of the lungs. This is the case with those of typhoid fever, diphtheria, measles and mumps. Uric acid being a normal constituent of the blood, only becomes harmful when it accumulates persistently in excessive quantities.

DR. F. W. LANGDON of Cincinnati, presented a paper entitled  
EPILEPSY AND OTHER CONVULSIVE DISEASES; A STUDY IN NEURO-DYNAMICS.

The anatomic digest accepts the neuron of Waldeyer as the anatomic and physiologic unit of the nervous system, especial attention being called to its more complex construction as elucidated by Max Schultze, Schaefer and Gowers. Physiologically, attention is directed to the later views that the cell-processes or their terminal endings are chiefly concerned in dynamo-genesis or conversion as opposed to the older doctrine that the "cell" (neuron-body) was the chief agent of action. Pathologically, objection was raised to the prevalent view that "chemical instability" or "explosion" of cell areas are the main factors in convulsive action. In its place, the view was advanced that definite defects of structure in the neuron-processes, chiefly those of the great pyramidal projection tracts, are responsible for the convulsive phenomena. The foregoing considerations, anatomic, physiologic and pathologic, would appear to justify the following propositions as a working hypothesis: 1. That epilepsy, the choreas and probably most convulsive disorders are the dynamic expression of an inhibitory insufficiency, not indications of over-production of nerve energy nor "explosions" due to a "molecular instability" *per se*; 2, that the cause of this inhibitory insufficiency is to be sought for in the end brushes of the collateral processes of various cortical neurons, the situation varying with the "type" of the disease, whether sensory, psychic, or motor; 3, that the defect consists most probably, in a *structural incompleteness* (small capacity, defective insulation, imperfect contact) or a *numerical deficiency*, or both, in the collateral processes of the neurons referred to; 4, defective collaterals may favor occurrence of convulsions in two days: (a) by impairing connection with other neurons (inhibitory, storage, etc.); (b) by increased resistance to "overflow currents," causing temporary over-charging of motor axis-cylinders. This conception of the anatomico-dynamic basis of convulsive phenomena I would call the "collateral theory." On this basis, cases of epilepsy are classed under three groups, each of which presents important differences as regards prognosis and treatment. 1. *Primary or developmental* type, compromising the "idiopathic." Cases under 20 years of age. In these, the younger the subject and the better the heredity and environment, the better the prognosis under intelligent treatment. Ultimate result depending on the possibility of promoting further and equable development of collateral communications with inhibitory mechanisms. 2. The *accidental* forms. Those due to trauma, syphilis, lead toxins, etc. The prognosis here varying with the longer or shorter duration and the possibility of removal of the cause; being always favorable so long as permanent structural changes in collaterals and inhibitory mechanisms have not occurred. 3. The *degenerative* type. The rare cases of adult life and old age (not accidental) belong in this category. Here palliation only is to be expected as in degenerative changes elsewhere. In all forms the rational indications for treatment are: To lessen the incoming sensory excitation, by diet, hygiene, occupation, medicines; and so lessen the intensity of motor responses which are not provided with suitable overflow and inhibitory mechanisms.

DR. IRVING C. ROSSE read a paper on

NEWSPAPER RABIES.

After referring to the way in which newspapers deal with the subject of hydrophobia and allied affections, Dr. Rosse stated that from bibliographic references and experimental research he felt the following conclusions were warranted: 1, that the notion of a toxico-rabid bite is an old one being mentioned by Homer, but not by Hypocrates; 2, but few physicians have seen a genuine case of this complex and badly elucidated affection; 3, among competent surgeons and neurologists there is a wide difference of opinion, and even irreconcilable diversity as to the existence of genuine hydrophobia in man; 4, there is also considerable diversity of opinion concerning the exact value of the Pasteur method; 5, there is a difference of opinion as to whether pseudo-hydrophobia ever produced death; 6, in view of the uncertain knowledge of the disease and aside from making sensational items of such matters, newspapers are not to blame for publishing statements inconsistent with biologic or medical facts, since they merely reflect current opinion, and holding the mirror up to nature gives us, so to speak, a radiograph of what is going on in the minds of medical men.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, In Advance . . . . . \$3.00  
Single Copies . . . . . 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the Association living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JULY 4, 1896.

PANICKY SANITATION.

It has been published as a fact that a law has been proposed in the British colony of New Zealand prohibiting the admission of all tuberculous individuals and imposing heavy penalties on ship captains and steamship companies which furnish them transportation to the country and permit them to land. If carried out this proposition will be an advance on any sanitary precautions heretofore attempted and will doubtless meet with the approval of some of the more ardent sanitarians. New Zealand is a group of islands, a rather extensive one to be sure, with only comparatively limited means of communication with the rest of the world and it is possible to conceive of a much more perfect isolation there than is practicable in any continental territory. Whether the New Zealanders will be able to keep out the ubiquitous bacillus tuberculosis or do anything more than afford protection from foreign competition to the home produced article is a question, and on the grounds of ordinary humanity, taking this uncertainty into account there are some objections to the proposed enactment. Latent tuberculosis certainly can not be thus excluded, or any other unobtrusive form of the disease unless some tuberculin or other test is applied on passengers and others who reach the country by the ordinary routes of travel, or better through some consular agency before starting. Only in this way can the disorder be excluded; the few pronounced cases will hardly figure among the manifold other

chances of admission of the germs. Then there are to be taken into account the sources of infection already existing in the country and the opportunities it may have of self propagation. Of course the plans must include the extirpation of these. When all is done and the islanders have adapted themselves to the new conditions, supposing these to be possible, is there not yet a possibility that they may be more than ever vulnerable to any accidental introduction of the infection, by reason of their lack of the possible immunity produced by familiarity with and habitual resistance to the microbe. That such an immunity exists in case of many diseases to some extent is highly possible from the fact of the quickness with which they spread in populations hitherto unaccustomed to them. Such immunity can be easily accounted for by the law of natural selection alone, to which there is no reason to believe tuberculosis forms any exception. If New Zealand, or any other country, has the climatic and other local conditions favorable to tubercular disease and if it already exists there as is undoubtedly the case, the exclusion of pronounced cases by the severest legal enactments and penalties will be a very poor method of defense as compared with proper hygienic local regulations. If on the other hand, its climate is such as to make it a desirable sanitarium for consumptives it would be almost a crime against humanity to exclude them from its benefits, by measures that can at best be insufficient for preventing the introduction of the disease and inexcusable in so far as it already existed in the country.

It is true that it is said that tuberculosis has increased among the natives of the Riviera and some other regions resorted to by consumptives, but these localities have nevertheless not lost their climatic advantages and tuberculous invalids still find benefit from residence there. It is not unfair to presume therefore that the natives have not fully availed themselves of their hygienic privileges, or that they have not yet acquired the immunity possessed by residents of less favored localities. There are few disorders that in a general way are more amenable to local sanitary and hygienic measures than is tuberculosis, and there is hardly one that is more generally distributed or harder to control by isolation. There are also probably very few other serious diseases the effective contagion of which is more dependent upon the susceptibility of the individual; it would be hard to find many or indeed any adults in this and most other civilized countries who have not been repeatedly exposed to its germs. Indeed, if what apparently competent observers state is true, that 18 per cent. of domestic cattle are infected with tuberculosis, it might be hard to find a weaned or bottle-fed infant that had not repeatedly imbibed the contagion, and yet the race survives, the average longevity increases and the population question still troubles the Malthusians.

It must not be inferred that it is intended in these remarks to object to or disparage any reasonable attempt to protect the public against so great a scourge as tuberculosis. It is not necessary however for the State, or the public, to treat the consumptive as a leper, and such extreme measures as the one noticed are not only not humane, but can not be said to be in the true line of progress. They obscure and rather tend to the neglect of the less obtrusive but far more efficient local hygiene that is the true defense against the disease. Such measures can be justly characterized as panicky legislation, and cowardice is not an element that favors success in strife with disease, and inhumanity which is its common accessory, is undeserving of it. Tuberculosis does not increase where it is properly managed, and even with the prevalent carelessness in regard to disinfection or destruction of sputa, indiscriminate expectoration, etc., it is no greater a scourge in long settled communities than it has been in years past. With the present enlightenment as to its causes and prevention, there is no reason why it should not decrease with the employment of early rational precautions against infection.

#### THE QUESTION OF PHYSICAL EXAMINATION.

At the recent meeting at Philadelphia of the Association of Military Surgeons of the United States, during the discussion of the paper prepared and read by MAJOR PAUL R. BROWN, Surgeon U. S. Army, on "Modern Methods of Anthropometric Identification, so far as the United States Soldier is Concerned," in which he very earnestly advocated the system based on anatomic and descriptive data devised by BERTILLOX, of whose work he is the translator, COLONEL CHARLES H. ALDEN, the Assistant Surgeon-General of the U. S. Army, and others of that Department, declared their preference for the method now in vogue in the Army of recording prominent marks, scars and peculiarities as proofs of identity, for the reason among others that the French plan proposed was primarily associated with the recognition of criminals. CAPTAIN MYLES STANDISH, Mass. V. M., said that the mere fact that BERTILLOX'S method was employed in connection with criminals would make it difficult or impossible to adopt it in this country, and CAPTAIN ARTHUR R. JARRETT, N. Y. N. G., was also of opinion that in his State the men would feel it an indignity to be measured and inspected by the same procedure as was employed for criminals, which caused MAJOR HAVARD of the Army to remark that this objection reminded him of MARTIN LUTHER'S reply, when he was reproved for playing dance music, that he did not see why the devil should have all the good tunes.

The trend of the discussion illustrated one of the difficulties experienced in this country in enforcing any salutary regulation. The sentimental objection

is alleged that the liberty of the individual is encroached upon by requirements special to one particular occupation or to one class of persons, and resistance is upheld to the point of establishing the license to do as each one pleases without regard to the interests of others or to the better control of public affairs. Only in recent years has the practice obtained of uniforming railroad employes; still later that of requiring letter-carriers to wear a distinctive dress; and only within the past year has COLONEL WARING been able to clothe the force of the New York Street Cleaning Department in a prescribed uniform. The writer recalls the almost rebellious refusal of the female nurses of the Maryland State Hospital for the Insane, of which DR. ROHE was Superintendent, to wear a uniform dress, and he only succeeded by inducing the prettiest of the lot to try on a most becoming and coquettish costume, with which she was so satisfied that she concluded to keep it on, all the others quickly following suit.

Municipal administration in this country is hampered more by this intolerance of restraint, however justifiable, than by any other cause. The same individuals, who in Great Britain, Germany, France, Italy and Russia, conform with no apparent reluctance to the most stringent requirements, are the most defiant of rules of propriety as soon as they fall within the limits of this law-contemning country. It is only necessary to watch the Irish and German drivers of beer-trucks, grocer-wagons and butcher-carts turning the corners of public thoroughfares at full speed without regard for feeble pedestrians, and offensively unclean Italian and Russian laborers crowding into public conveyances to realize how the lax administration of our cities has transformed the alien serf into a very unwholesome variety of American boor. Within a few weeks, the Board of Health of New York nerved itself to issue a regulation that "spitting on the floor of public conveyances is a nuisance, is frequently the means of communicating disease, and is hereby forbidden," which was reinforced by an order of the General Manager of the several street railway lines that "employes of the company are required to call the attention of passengers violating the above order of the Health Department either in the cars, waiting-rooms, or on the stairways and station platforms of the company, to the provisions of the same." The fulmination was printed on cards which have been hung where they can scarcely be seen, employes are supremely indifferent to the injunction and the spitters continue their disgusting practice.

It can not be asserted that indifference and hostility to sanitary and other municipal regulations are inherent to the republican form of government, since both in France and Switzerland, the latter venerable among republics, the citizens render the same prompt obedi-

ence as the Chinaman, who obeys the law because it is the law, in the same spirit as his child who obeys him because it is his duty to obey. During our civil war, an American traveling in Europe became acquainted with a young Swiss merchant who was lamenting that he had been called upon to perform his military service in the field at a time when his business required his presence, and who, when asked by the American, "Why do you not hire a substitute?" as so many thousands of the citizens of the Great Republic were doing at that very time, replied, "Hire a substitute! Why, it is my duty to go"—and he went.

Recurring to the initiatory text, which suggested this article, the alleged objection to the personal indignity and humiliation of a physical examination is really only a pretext, and intended to conceal the very physical defects it is the prime object of the examination to discover. There is no more important duty of the medical officers of the army, navy and marine-hospital service than this of physical examination. Upon its proper performance depends the efficiency of the personnel of the several services. It secures the retention of the fittest—of those least predisposed to disease and most resistant to the morbid influences of climate and occupation—of the most vigorous and best able to perform arduous and exacting labor. The recognition of deserters, convicts and other undesirable recruits is only incidental and based upon information obtained originally with another object. "So far as the indignity and humiliation are concerned," said MAJOR VALERY HAVARD, U. S. A., in supporting MAJOR BROWN'S advocacy of the BERTILLON method, "when a man is stripped and his marks and defects noted he has been subjected to as much indignity as he can be, and therefore I prefer the most scientific system based on anatomic data." MAJOR PHILIP F. HARVEY, of the U. S. Army, goes even farther, in that he proposes to prevent the enlistment of undesirable men by a study and interpretation of the marks of degeneracy, indicating moral defects and criminal tendencies in the individual.

The individual's body is his own most precious possession, but he has no right because of this exclusive ownership to exact concessions from other bodies that may be prejudicial to the general welfare. In some sequestered spot or solitary island, he might go clad or unclothed, and mutilate, disfigure or destroy it without let or hindrance, but where other bodies come within its sphere the inalienable property right has to be restricted. Examinations conducted in privacy by competent and experienced professional examiners, with every regard to decency and delicacy, can be no more objectionable than the diagnostic explorations of the attending physician; and the record of the shape of the nose and other features, the configuration of the body and limbs, and the other points of the congenital conformation of the individual are as

proper as the noting of a scar on the left cheek, a wart on the nose, or an eagle and anchor and the letters A. B. in indelible ink on the left breast. It is gratifying to learn from medical officers of the National Guard of great States like New York, New Jersey and Pennsylvania, that they are aiming to establish the same system of physical examinations as prevail in the national services, and we trust that the recent discussion before the Association of Military Surgeons may have the effect of making the practice general in all the States and Territories, and that the decorous submission to requirements in this instance may lead to a better disposition to recognize the value of law and order in other matters, especially in those concerning the public health. It is not anticipated that any military surgeon will object to the most thorough physical inspection, though hardly to the extent of introducing a rectal speculum or urethral catheter or requiring the subject to urinate under observation as has been done in Europe. Soldiers and sailors of all men should be trained to regard their bodies in a manly spirit. Men bathe together without remark and the familiar exposures of the barracks and bath-deck are neither provocative of libidinousness nor shamefacedness. The cadets at the U. S. Naval Academy are annually subjected to nude inspections, which are made matters of record and are invaluable elements of their physical history. Properly conducted physical examinations of the inmates of girls' schools and colleges would do much in the way of convincing parents and skeptical teachers of the progressive deformation of young women by faulty dress, and now that the injudicious use of the bicycle is distorting the plastic pelvis of immature females, such examinations will be of incalculable benefit. The greater attention paid to the normal development of the body the better for the race, and the general adoption of BERTILLON'S system of physical inspection and registration by the National Guard of the United States will be the indirect means of better acquainting the members of that organization with their bodily selves.

#### THE PUBLIC HEALTH DEPARTMENT.

We have received the following letter from DR. JEROME COCHRAN, State Health Officer of Alabama, Chairman of the Committee on a "Department and Secretary of Public Health" appointed by the ASSOCIATION some years since, of which the late DR. C. G. COMEGYS was the first chairman:

MONTGOMERY, ALA., June 29, 1896.

*To the Editor:* In the JOURNAL of the 27th there is an editorial which has occasioned me no little surprise. It begins on page 1273 and is entitled "An Explanation Is in Order."

The explanation is very simple. After several years of unavailing work the Committee on Department of Public Health presented a report at the Atlanta meeting of the ASSOCIATION proposing a new departure in the effort to obtain

national public health legislation. This report is to be found in the JOURNAL for May 16, beginning on page 988. It was discussed by the ASSOCIATION and unanimously adopted with all of its recommendations. Among these recommendations is one authorizing us to invite the coöperation of the conference of State boards of health.

I accordingly attended the meeting of the conference in Chicago and laid before it the plan for a national health bureau which had been approved by the ASSOCIATION and asked the conference to approve said plan, which it did. I also requested that the conference recommend each State Board of Health to appoint one member of a committee to act with the committee of the AMERICAN MEDICAL ASSOCIATION in securing for the proposed bill the favorable consideration of Congress. This also the conference agreed to.

That is the whole story; and it seems not a little strange to me that the JOURNAL of the ASSOCIATION should begin in such hot haste to oppose the plans and orders of the ASSOCIATION. The United States mail brings Chicago in easy communication with Montgomery, so that it would have been easy for the Editor of the JOURNAL to have obtained all the facts from the chairman of the committee. I will venture to suggest that common justice dictates that you should give this explanation as prominent a place in the columns of the JOURNAL as was occupied by the hasty editorial complained of. I have the honor to remain yours truly,

JEROME COCHRAN, M.D., Chairman of Com.

We only reiterate a demand for what we believe the ASSOCIATION wants and what is expressed in the very name of the committee on a *Department and Secretary of Public Health*. The following extracts from the committee's report (printed in full in the JOURNAL for May 16, 1896) show that we have made no mistake. After reciting the previous failure to obtain a Board of Health, Dr. COCHRAN as chairman on the Committee on a Department of Public Health, says:

"In the meantime, the Marine-Hospital Service, which in 1890 had already been invested with some important health functions, was by the Act of 1893 converted into a National Health Department with very large and far-reaching powers and abundant means. It is not called a department of public health, but is a Department of Public Health in fact.

It seems to us to be a fundamental proposition that we shall have but one National Department of Public Health. This being conceded, one of three courses remain open to us.

1. We may devise and advocate a plan to deprive the Marine-Hospital Service of its public health functions, and for the establishment of an entirely new department; or,

2. We may accept the Marine-Hospital Service just as it stands as a department sufficient for our present use; or,

3. We may endeavor to improve the Marine-Hospital Service and make it a more satisfactory National Health Department than it now is.

It would seem that this last method promises to be the most fruitful of beneficent results; and the question then arises as to the modifications that may be wisely made in the existing law.

Such a scheme as this would probably command the approval and support of the National Conference of State Boards of Health, which Conference is quite as deeply interested in movements of this character as is the AMERICAN MEDICAL ASSOCIATION.

As the conclusion of the whole argument, we recommend that we be authorized to draw up a new bill along the lines we have indicated, and that we be authorized to invite the cooperation of the Conference of State Boards of Health and of the American Public Health Association in our endeavor to have the proposed bill enacted into law."

The following was the discussion thereon.

DR. HIBBERD—I move that the report of the committee be accepted, the plan outlined adopted, the committee continued and enlarged by the appointment of a member from each State. Seconded.

DR. I. N. LOVE—If I understand the proposition rightly, it provides for a Department of Public Health built upon the present foundation of the Marine-Hospital Service. I am therefore in favor of it. It is an elaboration, a building up in a stronger and more definite shape of the public health department and quarantine service which we already have. When we consider that every other department of life is represented in our National Conference Board, or Cabinet, and yet public health is not represented, surely the dignity of medicine and the best interests of the health of the community demand such recognition, and I think the most practical way in which to accomplish this great and good work is by building up that which we already have and crystallizing it in the shape of a more dignified body.

DR. SUMMERS, of St. Louis—I think, sir, it is time for this ASSOCIATION to demand of the United States of America that it should be represented in its Cabinet at Washington. We can learn a great deal from the old Christian mythology, where Gabriel was the Secretary of State, Michael the Archangel or Secretary of War, and Raphael the Secretary of Health, who flew with his wings close to the earth and shed healing in his path. Now, I say, the time has come when this ASSOCIATION in its power and dignity should rise and demand of the government of the United States that it create a department of public health, as has been done in all governments of the world. This is the solution of the question. Twenty-five years ago I joined DR. COCHRAN in his efforts in public health matters in Alabama, and it brought out the fact that it was possible for the State to take hold of medicine and govern it accordingly.

The report was then adopted.

It is entirely clear that the members thought they were supporting a measure to create a *Department of Public Health*. The proposition was understood to be as stated by DOCTOR LOVE, a DEPARTMENT OF PUBLIC HEALTH built upon the present foundation of the Marine-Hospital Service.

That is a very different proposition from the one advocated before the conference. The latter simply provides for a Division of Public Health in the Marine-Hospital Bureau, the chief thereof to be appointed by the SUPERVISING SURGEON GENERAL; that is to say in effect that some subordinate in a bureau, itself subordinate to the Treasury Department, has sufficient power, dignity and authority to represent the important interests which ought to be intrusted to him, with credit to the American Medical Profession.

We do not think the chairman quite understands the sentiment of the ASSOCIATION on that point.

Has he submitted any proposition to make the Marine-Hospital Bureau independent? That would seem a proper move, as by the words of the chairman, "It is not called a Department of Public Health, but is a Department of Public Health in fact." Why then seek to place the chief of the Public Health Service two removes further from departmental independence? The head of the present bureau is not now independent; if it be, as DR. COCHRAN says, the real health service, why not make its chief the chief in fact, instead of merely authorizing him to "appoint" somebody, or employ a new clerk?

There is rarely time to discuss these questions on the floor of the ASSOCIATION, especially when the report is in manuscript, and no one knows what is in it unless fortunate enough to have a front seat. The question then finds its appropriate place for discussion in the columns of the JOURNAL, and we sincerely hope that our esteemed friend, with that courtesy and tolerance that has always distinguished him, will welcome criticism and well-formed opinions from other members of the ASSOCIATION.

In conclusion we might inquire whether or not DOCTOR HIBBERD'S duly seconded motion to appoint one additional member of the committee from each State has been acted upon. That motion was surely wise, and according to the minutes it was adopted.

---

#### THE MEDICAL JOURNAL AND THE "READING NOTICE."

The manager of a medical journal has his troubles quite apart from those of securing leader writers. One of the most annoying and at the same time one of the most unnecessary, is the unceasing demand from those who should know better, that the reading columns of his journal shall frequently present articles descriptive and sometimes eulogistic of some pill, powder or potion. The article thus presented as a "reading notice" is usually written by some impecunious or unknown M.D., who, for a consideration or gratuitously, has furnished our advertiser with this wedge to force the journal.

The thin edge is inserted when the article is written as a scientific one. There is a phase in this matter that is not quite understood. If Editor Jones or Editor Smith shall, as many do, decline to publish the material, then the advertiser may make it a personal matter and withdraw the advertisement. This procedure, we are sorry to say, is growing more and more frequent.

Let us ask advertisers to look this matter squarely in the face. There are two sides. Editor Jones, we may say, has given much thought to this subject, and wishes his esteemed friend C. C., of Selldrugs & Co., a large and prosperous business, but he can not comply with the request of the Messrs. Selldrugs & Co. He tells them in effect that he has only advertising

space for sale in the advertising department. The scientific department of his journal, he explains, is not intended for advertisements, and in fact he has no right to sell any part of it. To do so would be an open violation of an implied contract with his readers.

The editor, as he warms up to his subject, continues: "There is still another point of view; we are carrying your advertisement, my dear friends, and we thank you very much, but our rates are low, and we think we are giving you an equivalent, why should you ask us to insert two advertisements when you pay only for one? If I send my office boy to your drug palace and buy a hundred pills, are you obliged to yield to his demand that having honestly bought the pills, he must now have a pound of bon-bons and a box of cigarettes? You would, my dear Merchant Prince, resent the impudence of the boy. Suppose now that we go ourselves, or write you a note threatening to withdraw our patronage, even to the extent of buying our next box of pills from your hated rival. You would very likely," says Editor Jones, "tell me that you sold the pills at a low price, and if you furnished anything more it would be a gift. You would perhaps say aside to your partner that the editor was coming very close to levying blackmail. I have not put the case to you," said Editor Jones, "on any sentimental grounds, as from the well-known philanthropy and public spirit of your long-established house I might easily do, but I have chosen a simple commercial standpoint and the case is only overdrawn in one particular, that is the dealer has *all* the articles for sale; in the case of the *Medical Journal*, the manager has no right to sell or give away his scientific space; that part of the journal does not belong to him for that purpose; it is actually already paid for by the subscriber."

---

## CORRESPONDENCE.

### Our Journal.

MONTCLAIR, N. J., June 7, 1896.

*To the Editor:*—I have just voted to move the publication office of the JOURNAL to Washington, D. C., and was actuated by the following reasons:

1. The JOURNAL is the organ of a great national Association which should know no local prejudice nor be controlled by any local body of men.

2. Any serial publication must in some measure respond to the influence of its environment, therefore, in the case of a periodical whose aims are so broad and whose spirit must be so catholic as those which the JOURNAL must display, unless it shall fail of its high mission, its seat of publication should be the most cosmopolitan possible.

3. Washington is the most cosmopolitan city in this country. It can have, from the nature of its institutions and government, no strong local prejudices.

4. It is, furthermore, the center of scientific thought as well as the national capital. The fact that it is not a commercial center fosters the scientific and literary spirit, and makes it a delightful place of residence as well as an advantageous literary workshop.

5. It has certain advantages for literary work over any other city in this country, because it contains the Congressional library, the largest general library in America, and the Surgeon-General's library (which has been rendered so available to all scientific readers by the work of Dr. Billings and his assistants). Washington contains also various other libraries, as well as museums and laboratories.

6. These advantages must in the nature of things tend to increase as time goes on, so that it is quite conceivable that, even if the publication of the JOURNAL shall be continued at Chicago for the present, it will be forced to go to Washington finally. Should this prove to be the case, it is obvious that the move had better be made now than later on.

7. The unfortunate defection from the ranks of the AMERICAN MEDICAL ASSOCIATION bids fair to heal in good time. This promise of better things has been brought about greatly through the powerful influence of the JOURNAL. If the JOURNAL shall be moved farther East, a happy outcome of these complications will come more quickly.

8. The JOURNAL is the only prominent medical publication in this country which is not issued from the press of some private publishing firm. Its publishers are, or should be, the entire medical profession of America. It must, therefore, be published in the interests of no set or clique; its opinions must be quite unbiased by any local interest, any spirit of business or any private scheme.

9. There can be no question that the medical profession as well as the laity need in this country one powerful, well edited and liberally supported medical journal, which shall be an acknowledged authority upon scientific medicine, State medicine, hygiene and medical ethics.

10. The high grade of scholarship, the breadth of view and the business sagacity which have been shown of late in the management of the JOURNAL, give every promise that it is bound to become such a publication as has just been described; in short, an American medical journal of which Americans may be justly proud.

11. It will take this high place all the sooner if its seat of publication, its general surroundings and its support shall be as favorable as possible.

12. If the present rate of advance in the character of the JOURNAL shall be maintained the title should become THE AMERICAN MEDICAL JOURNAL, and in smaller type. The words THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION should appear upon the title page.

13. While it is true that the character of a publication is influenced by its environment it is also true that a publication exercises an influence upon the thoughts and action of those in whose midst it may be published, and this influence naturally increases with the growth and power of the publication; it would be well therefore that the JOURNAL should be published in Washington by reason of the restraining and enlightening influence its presence may have upon our legislators.

14. Great questions of national health, national hygiene and physical well-being are now engaging the attention of scientific men the world over, and as intimated above the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION should be in a position to test the alleged discoveries in these lines and to impress what else may be found valuable not only upon the profession but upon our public men as well.

15. The advance of the medical profession in America in learning, dignity, wealth and power has been marvelous during the past two decades. There is no probability that there can be in these respects a retrograde movement. The times are propitious. The future of American medicine is bright with hope. Let the JOURNAL seize the opportunity to place itself at the head of the profession and let each and every one of the members of the ASSOCIATION forgetting all local pride and all sectional prejudice do all that in us lies to advance no particu-

lar sect nor interest, no especial State, county or city but the power and good name of American medicine and the prosperity of its medical association. Let us be broad minded and patriotic and sink all sectional feeling in our common love of our profession and our devotion to the healing art.

RICHARD C. NEWTON, M.D.

#### A Testimonial to Prof. N. S. Davis.

POMFRET, CONN., June 30, 1896.

To the Editor:—D. L.'s letter in the JOURNAL of June 20 in regard to a memorial to Dr. N. S. Davis reminds me that I have in my possession a medal struck in 1846, on its face a medallion and the words "N. S. Davis," and on the reverse the inscription "AMERICAN MEDICAL ASSOCIATION," and the date "1846." This medal was given to me by Mrs. Williams of this town, whose husband, the late Dr. Lewis Williams, was a delegate to the 1846 meeting, which I think met in Louisville, Ky.

S. BURDEN OVERLOCK, M. D.

NOTE.—This convention met in New York in 1846.

#### Treatment of Typhoid Fever.

JUNE 8, 1896.

To the Editor:—I have been much interested in the discussion of the "Woodbridge" treatment of enteric fever, and I am greatly pleased to see that many realize the necessity for fulfilling what I have long considered the essential requirements in not only this, but most, if not all, intestinal disturbances, viz.: Rid the digestive canal, promptly and thoroughly, of all offending or decomposing matter, together with the products of decomposition, thus preventing their absorption; render the contents of the entire tract aseptic as far as possible, and lastly—this and the first being, to my mind, the prime consideration—inducing decided alkalinity, as it is in acid media that most, nearly all, the obnoxious microorganisms thrive best. The degree of alkalinity should be positive and sufficient, and as, within reasonable limits, there is no danger of overdoing the matter, large quantities of alkali, preferably bicarbonate of sodium, should be given with sufficient frequency to maintain the condition.

While practicing in San Diego, Cal., I had many cases of enteric fever to treat, not one of which failed to yield promptly to the course of treatment here indicated, barring two, which were moribund as the result of intestinal hemorrhage when I first saw them.

I had recently on my hands a puny infant to treat, whose surroundings were in the highest degree unfavorable, suffering from entero peritonitis, to which I gave freely sod. bic., 2 drams, and sod. et pot. tart., 1 dram, in milk every two hours. When I first saw the child it was to all appearances nearly dead; thighs flexed upon the abdomen; too weak to even cry; abdomen distended almost to bursting; temperature 106.5, pulse too rapid and weak to accurately count. I promptly got it under the influence of that most reliable and efficient of all stimulants, nitro-glycerin, and then began the administration of alkalies. It began to respond to treatment at once, free evacuations of most offensive material soon taking place, followed by reduction in temperature and tympanites. Ten days later the child had practically recovered. In fact I have found that in all cases of acute intestinal trouble, even when profuse diarrhea is present, brisk cathartics afford the most prompt and certain relief. With them moderate doses of anodynes may be given, but not to the extent of inhibiting catharsis.

While on this subject permit me to invite attention to the great and decided efficacy of large quantities of alkalies in chronic digestive disorders. Particularly in those disturbances from which the users of tobacco and alcohol suffer, will this be found the case. To many such I have frequently given doses of one to two ounces of bicarbonate of sodium, fre-

quently repeated, not only with great and prompt relief to the induced trouble, but, in not a few instances, with at least a temporary overcoming of the causative trouble as well. As in nearly every case of digestive trouble there is a condition of hyperacidity of the gastric juice, is not the giving of alkalis the rational procedure? In fact is not the "requisite degree of acidity of the gastric juice" one of the numerous "bugbears" in the path toward "rational therapeutics"?

H. W. YEMANS, M.D.

### Orrhotherapy in Diphtheria.

To the Editor:—The statistics for my paper on page 1, of this JOURNAL, were collected for me by Dr. Wm. R. Parkes, who had taken everything that could be found in my own journals and in the extensive files at the Newberry Library. It should be kept in mind by the reader that all statistics whether favorable or unfavorable to the use of antitoxin in diphtheria have been used and I have attempted to present an impartial statement. If I have failed to give the credit to antitoxin that many of my readers think is due, it is only because such credit is not borne out by the statistics and I beg the reader to make a careful analysis of the table. It should be specially observed that in nearly all statistics the comparison of the death rate in diphtheria has been made for the latter part of 1894 or for 1895 where antitoxin was used, with *previous* years when antitoxin was not used. As shown in observation 8 of the table Behring's statistics for Berlin prove that the death rate for diphtheria in 1895, whether antitoxin was used or not, was very much less than in previous years, it being only 14 per cent. in 4,479 cases treated in Berlin without antitoxin. If, therefore, statistics of all the patients treated with antitoxin in the latter part of 1894 or in 1895 could have been compared with those treated without antitoxin in the same period, it would appear from these statistics that the death rate in the latter would have been less than in the former.

Yours truly,

J. FETCHER INGALS, M.D.

[Received after the article was in press.]

### The Bracelin Remedy for Diphtheria.

[After all the talk in the newspapers on the subject, and elsewhere, we are sure our readers will gladly know that Dr. Bracelin is still in the ranks of the profession and repudiates the term "secret" as applied to his treatment.]—ED.

CHICAGO, ILL., June 29, 1896.

To the Editor:—Diphtheria, one of the most common and the most fatal of all acute infectious diseases from which the human family suffers, has been the *bête noire* of the medical profession.

For years investigators have been studying the disease so as to learn the cause which produces it, and, if possible, to discover a remedy which would remove the cause or modify or neutralize its effects, but without any satisfactory results. At length, after years of patient study and observation, two German scientists discovered that a certain kind of bacteria was invariably to be found in the diphtheritic deposit. They made known their discovery and now the Klebs-Löffler bacillus is looked upon as the specific cause of the disease. Since the discovery of microbic cause of the disease different antiseptics known to be destructive to bacteria have been used with varying degrees of success, but on the whole with unsatisfactory results.

Medical journals and daily newspapers were filled with reports of wonderful cures effected by the different methods of treatment adopted, yet the average death rate has remained about the same. The last aspirant for professional honors in the treatment of diphtheria, antitoxin, and most generally accepted by the profession as a successful remedy, does not appear to be so useful as it was at first believed it would be.

Clinical tests as reported by some are favorable; as reported by others very unfavorable. According to some reports the death rate has been lowered, but others again show that there has been no appreciable lowering of the rate of mortality. So many authentic records of sudden deaths following immediately after it had been injected, and apparently caused by the remedy, as also the constitutional disturbances undoubtedly produced by it have made many of the profession halt in their advocacy of such a dangerous remedy, even if it had proved more successful in curing the disease than it has been, they feeling that it is not safe nor advisable to use such a dangerous remedy.

In my opinion diphtheria is a self-limited disease of specific origin. If, after the appearance of the disease, auto-infection can be prevented the efforts of nature will, unaided, effect a cure, but if the products of decomposition containing the specific poison of the disease (whether we believe this to be the Klebs-Löffler bacillus or the ptomaines produced by it) are allowed to enter the circulation the disease increases in virulence, the powers of resistance are weakened and the victim dies.

Theoretically, a remedy to be successful in the treatment of diphtheria should be one which would be constitutional as well as local in effect. It should be destructive to the specific cause as found in the diphtheritic deposits, prevent decomposition of the diphtheritic membrane and destroy or prevent formation of the ptomaines which cause auto-infection. But before treatment has been commenced there may have been a greater amount of diphtheritic poison in the system than nature unaided is able to destroy. The remedy must therefore be a constitutional as well as a local one, so that entering the system it may assist nature in her efforts to destroy or neutralize the poison already there. Such a remedy would be an ideal one and should, in my opinion, meet the requirements necessary for the successful treatment of diphtheria.

In January, 1893, I discovered a remedy which appears to meet all the requirements of the ideal remedy. I have been experimenting with, testing clinically and improving on the original idea, until now I believe it is as near a specific for diphtheria as it is possible for a remedy to be for any disease. Since that time I have treated a large number of diphtheria cases in all stages of the disease and have only lost about one per cent., and I believe I have verified my theory that, if chlorin gas, corrected, should prove to be a safe bactericide for diphtheria, it would also be an effective remedy for all diseases of the respiratory organs of a microbic nature. This theory has been fully confirmed by the experience of many physicians beside myself who have used chlorin gas as prepared by me. It is too much to expect that such a small death rate can always be maintained, but I believe that by the use of this remedy the death rate will be less than 5 per cent. Not one who has used it as a prophylactic when exposed to the disease has been attacked by diphtheria. This is the best evidence of its efficiency as a prophylactic. As it is used by inhalation, it not only acts upon the diseased tissue locally, but being a vapor the remedial agent enters the lungs, passes into the circulation with the oxygen and materially aids nature in destroying the systemic poison. It is simple, easy to use, and absolutely safe; there is no danger of any harmful result following its use, or evil being caused by it. The remedy has been successfully used in a number of diseases of the throat and lungs, pneumonia, hay fever, asthma, laryngitis, common colds, bronchitis, whooping-cough, catarrh, consumption, etc. All cases of consumption in the first or second stages where it has been used, have recovered and are now well. Consumptive cases require, in addition to the inhalations, appropriate constitutional and supportive treatment on the usual lines. It has failed to cure in the last stages of the disease, but affords great relief to the sufferer. I have reason

to believe that if used on the first appearance of any symptoms of consumption that comparatively few will die of this much dreaded disease.

Pure drugs and careful manipulation in the process of manufacture are necessary in order to attain an efficient remedy. If made of poor materials, improperly combined, the remedy will prove a failure; but properly made it will prove to be all I claim for it. I have therefore made arrangements with a firm of reliable manufacturing chemists in Chicago to have it made under my personal supervision, and I have removed to this city for that purpose. Every bottle which now goes out will be guaranteed perfectly pure and of full strength. It will be distributed by Mr. J. J. Russell, 167 Dearborn St., Chicago, from whom the genuine remedy can always be procured. On every bottle will be found the formula and none will be genuine without my signature.

The remedy consists essentially of chlorin, deprived of its suffocating, irritating qualities by an emollient corrective. The value of the "corrective" is not so much due to the agents used as to the process of manufacture in making the combination. Properly made the results will be satisfactory, if improperly combined the results will be disappointing. This is the result of my repeated trials and clinical experiments carried on during a period of over three years. Two liquids are used, which are for convenience named "Bracelin Chlorin Bactericide," "No. One" and "No. Two." "B. C. B. No. 1" is set free by the corrected chlorin in "B. C. B. No. 2." "B. C. B. No. 2" is added to "B. C. B. No. 1" in the proportion of one to five parts slightly warmed and the vapor inhaled as directed. Some diseases, such as diphtheria and pneumonia, require its use once each hour, others but four or five times a day. I am now prepared to give my formula to the profession for trial in the treatment of diphtheria and throat and lung diseases, viz:

FORMULA OF BRACELIN'S CHLORIN BACTERICIDE.

Solution No. 1.

Solution Zinc chlorid . . . . .	20 parts.
Solution Arsenic chlorid . . . . .	30 parts.
Hydrochloric acid . . . . .	1 part.
Water . . . . .	49 parts.

Solution No. 2.

Solution chlorinated Soda, Standardized to 2.6 per cent. available.

Chlorin . . . . .	70 parts.
Corrective . . . . .	30 parts.

NOTE:—The corrective consists of menthol, camphor, eucalyptol and salicylate of methyl dissolved in alcohol and water. It will, I think, require no special argument to convince the profession that so chemically unstable a compound can only be prepared satisfactorily by careful and competent hands, and as already stated, I shall hereafter personally supervise its manufacture for the use of physicians.

P. M. BRACELIN, M.D.

## PUBLIC HEALTH.

**Yellow Fever at Rio Janeiro.**—The *Revista de Ciencias Medicas* for May 20 states that there were 451 cases during the first fortnight of March, with 395 deaths.

**An Expensive Investigation.**—It was stated in the House of Commons last week that the total cost of the Vaccination Commission up to March 31 last, had been about \$84,000.

**Cholera in Egypt.**—The *Progrès Médical*, June 6, states that the total number of cases of cholera reported that date is 3,030, of which 2,523 resulted fatally. Malta has announced a seven-day quarantine for ships from Egypt, extending it to twenty-one days if there are passengers on board.

**Board of Health Summer Corps.**—Fifty physicians, who will serve in the summer corps, were appointed by the Board of

Health, of New York city at its meeting June 23. They are employed to attend to the sick in the poorer quarters and teach proper methods of sanitation. The announcement that the President of the Board of Health has selected forty rear tenements to be abated as nuisances shows that reform is at last becoming something more than a mere name in New York.

**Deletio ab Varloia.**—The Berlin correspondent of the *Medical Press and Circular*, in his notes of the recent Jenner centennial celebration in Germany, records that Professor Virchow, who opened the proceedings in the name of the Committee of Honor, said, in his address, that as an ethnologist he was impelled to mention an ethnologic fact in the history of protective vaccination: "All the peoples that had not been reached by vaccination, or that had not accepted it had disappeared from the face of the earth—destroyed by the 'smallpox'—a statement which, if correctly quoted, must be subject to many exceptions.

**Poison in Black Hair Dyes.**—The *Journal D'Hygiène* of June 11, warns the public that several black hair dyes recently analyzed have been found to contain paraphenylenediamin, a derivative of the nitro-analins, which accounts for the serious eye troubles, boils and eczema which have been reported as following occasionally their application. The subject recalls the recent remark of an elderly Paris physician who was being rallied upon his youthful locks: "You young doctors drive us to dye our hair nowadays, as gray hairs no longer command respect."

**The Use of Salts of Copper in the Manufacture of Canned Vegetables.**—Professor Duclaux states that the public should be warned of the dangers of using canned vegetables that have been colored artificially with salts of copper. The natural yellow color of cooked vegetables would be esthetic enough for most people if they knew that there was peril in the bright green ones. He urges hygienists to secure the passage of an ordinance announcing that while the salts of copper are not poisonous enough for the authorities to prohibit their use, still they affect some persons unpleasantly. Consequently the manufacturers must use them at their own risk and be responsible for damages, even when it is proved that the can contained no more copper than others which produced no bad effects.—*Semaine Médicale*, June 6.

**Population of London in 1896.**—The *Lancet*, June 6, has some of the preliminary statistics of the census held in London on March 29, 1896. The population then obtained by count, and since then adopted by the Registrar-General, was 4,435,955, or some 14,000 in excess of the estimate up for the middle of 1896. This error is so small that for statistic purposes it might well be disregarded. In Inner London, it was found that there was an actual decrease in the total population, chiefly caused by the absorption of old residential properties for business purposes and the removal of families to the suburbs. This is the first quinquennial census that has ever been taken in London, all other previous ones having been at intervals of ten years. It was authorized by special legislation matured in 1894.

**Another Shrinkage in "Estimated" Population.**—Even the city of London, it appears, has been over-estimating its population. The recent census shows some 15,000 less than the estimate formed on the basis of 1891. As pointed out by the *St. James Gazette* the difference is small, but important, as it shows that the previous fall in the rate of increase is maintained. The population is growing at a less and less rapid pace. At the beginning of the century it used to increase by more than 20 per cent. in the ten years between successive censuses; in 1881-1891 that rate had fallen to 10.4 per cent., the lowest on record; and now it is still less. The movement is not part of a general decline; it is peculiar to London, and seems to indicate that the huge overgrowth of the metropolis has begun to

cure itself. No town can go on growing indefinitely, and even London—monstrous as it is—has not fulfilled the expectations of earlier statisticians. Two hundred years ago it appeared to be growing so fast that Sir William Petty, one of the earliest pioneers in demographical research, reckoned that by 1840 the population would reach 10,000,000, supposing it to continue at the same rate. He thought however, that a natural limit would be reached before then, and placed it in the year 1890, by which time he calculated London would contain something over 5,000,000 inhabitants and the rest of England only 4,500,000. He was very nearly right about the total, which actually was about 9,000,000, but London accounted for less than one-half. Since then it has nearly reached its maximum, which, curiously enough, seems likely to prove a real natural limit. For the four years 1871-74 the average birth rate was 35.2; for the four years 1891-94 it was only 30.9. There has been a gradual and almost continual fall from year to year, which has not been counterbalanced by the simultaneous but slighter fall in the death rate from 22.7 to 19.9. Fewer people die in proportion to the population, but still fewer are born. This is explained by the increasing disinclination to marry. The marriage rates for the two periods contrasted are 19.6 and 17.3 respectively.

**Bad Plumbing in New York.**—The New York State Board of Health was, on June 15, in receipt of a complaint from the Board of Regents that the health of the 100 clerks, most of whom are young women, was endangered by the vile odors given off by the defective plumbing fixtures of the Capitol building. The Secretary of the Health Office, Dr. Smeltzer, is reported to have said that nothing can be done as there has been no money set aside for sanitary repairs by the late legislature. Incidentally, and in similar vein, complaints have been heard in even higher official circles, regarding the character of the plumbing work done in the government buildings belonging to the navy, at the navy yard and elsewhere. Cheapness of work has for a long time been the order of the day. Second-rate labor has, as a rule, been employed and light weight material has been put in; and there is no expert re-inspection to pass upon the work before the bills are passed.

**July Suicides.**—Commenting upon the fact—again emphasized by a recent "blue book"—that attempted suicides occur in July with far greater frequency than at the beginning or end of the year, *Hospital*, June 20, says it is a well known fact that in July in consequence of the great heat and the stagnant condition of the atmosphere, the physical vitality is generally very low and the depression of the nervous system has reached its deepest. No laboratory experiments are required to prove these contentions. Everybody is aware that in July he is for the most part "played out," and is looking forward to his annual holiday with eagerness. An important question is whether or not anything can be done to combat the natural depression of July. No doubt the earlier taking of the summer holiday would be a step in the right direction; only if this be taken at midsummer a further fortnight will be needed early in the fall, and that is costly in a double sense. The most practicable remedy, according to *Hospital*, July depression is a suitable nerve tonic; and perhaps the best and most easily obtainable of all nerve tonics for summer weather is the sluicing of the head and spine with cold water every day, or even twice a day. If any man who is disposed to commit suicide will give himself a preliminary shower bath, it is highly probable that he will change his mind before the "towel" is finished.

**No Shade for Greater New York.**—At the first meeting in 1873 of the American Public Health Association, the president, Dr. Stephen Smith, read a paper on the "Effects of High Temperature upon the Public Health of New York and Measures of Prevention," in which he advocated the cultivation of shade

trees in the streets, on the ground that they would tend to diminish the mortality caused by excessive heat, by affording protection from the direct rays of the sun; by preventing the paved surfaces from becoming heated; by enveloping the city with an immense evaporating surface which tends powerfully to cool the lower stratum of the air; by equalizing humidity; by the absorption of malarial emanations from the earth; by purifying the air in its absorption of gases deleterious to man and the emission of gases necessary to his existence. Twenty-three years later a society, called the Tree Planting Association of New York, is formed for this very purpose. But that ruthless iconoclast, the *New York Sun*, summarily squelches the project with the assertion that trees once abounded in New York streets "as they still abound in Brooklyn and other semi-rural towns, but they have succumbed to resistless forces, and it is hopeless to try and restore them without a radical remodeling of existing conditions." And so the denizen of the Greater New York, which will, of course, not be a "semi-rural town," may no longer do the Tityrus act—*sub tegmine fagi*—but must go abroad, even unto New Jersey for his shade trees.

**Aftermath of the St. Louis Tornado.**—Already, according to the *Medical Review*, the effects of the great tornado in St. Louis are beginning to show their influence upon the death rate, as foreshadowed in the *JOURNAL* of June 6. The *Review* says a number of deaths have been observed among young as well as old, in healthy and in sick individuals, where death was attributed to fear during and in consequence of the tornado. Several suicides have been reported "which to an extent were undoubtedly due to an intense disturbance of the *psyche* of the unfortunate individuals by the storm and its direct destructive consequences. The impression upon the nervous system of susceptible individuals will probably not be entirely wiped out for months or years, and the study of the nervous phenomena resulting therefrom will be interesting, profitable and instructive. Nor will the subject be exhausted by the resulting affections of the nervous system alone; but the direct effect of the storm upon the course of other ailments and diseases will be equally interesting to note." Dr. W. B. Outten, editor of the *Railway Surgeon*, proposes to study these phenomena and has sent a request to various physicians of the city to relate their experience as to nervous symptoms manifested by their patients in consequence of experiences in the tornado.

**Smallpox in Texas.**—Smallpox has been cropping out here and there in Texas within the recent past, having been introduced in the first place from New Orleans. It must be that there has been a relaxation of the usual vigilance of the health authorities of our sister State; smallpox ought not to get out. Instead of everybody shutting doors against an infection, the infection must be circumscribed and not allowed to escape; the order is reversed from the old days of shotgun; at least that's the way it is done in Texas. As soon as a case appears it is quarantined, and all who have been knowingly exposed are quarantined also. In that way there is usually very few secondary cases. But it got a good start in Smith county before it was discovered; and in all thirty-eight cases occurred. What we wished to call attention to, though, in this connection, was the remarkably small mortality. Only one death occurred out of thirty-eight cases treated, and that was in a man of seventy-five years of age—a case of hemorrhagic variety. Dr. D. H. Connally, the county physician of Smith county, deserves much credit for such successful treatment. The average death rate of smallpox is about 25 per cent.; at Camp Jenner, among the refugee negroes, it was nearly 30 per cent.; a fact attributable, no doubt, to the use of tents with two and three cases in each, and the sides pegged down. The Texas authorities do these things better; treat smallpox as nearly in the open air as possible—weather permitting. The scare is about over, however, now, the last cases reported being in

Liberty county; infection supposed to have been carried from Orange, where, we learn, the county physician employed a negro doctor to do what he ought to have done himself.—*Texas Medical Journal*, June, 1896.

**Health Reports.**—The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Florida: Key West, June 25 to 29, 5 cases, 1 death; Pensacola, June 13 to 20 1 case.

SMALLPOX—FOREIGN.

Bombay, India, May 19 to 26, 17 deaths.  
Calcutta, India, May 9 to 16, 3 deaths.  
Callao, Peru, May 17 to 31, 17 deaths.  
Genoa, Italy, June 6 to 13, 3 cases.  
Licata, Italy, May 31 to June 6, 3 deaths.  
Madras, India, May 9 to 15, 2 deaths.  
Madrid, Spain, June 6 to 13, 19 deaths.  
Montevideo, Uruguay, May 16 to 23, 1 case.  
Moscow, Russia, May 23 to June 6, 2 cases, 2 deaths.  
Odessa, Russia, May 25 to June 6, 2 cases.  
Prague, Bohemia, May 31 to June 6, 3 cases.  
Rio de Janeiro, May 23 to 30, 1 case, 1 death.  
Santiago, Cuba, June 6 to 20, 70 deaths. Smallpox epidemic here—over 900 cases existing on June 20.  
St. Petersburg, Russia, May 31 to June 6, 16 cases, 5 deaths.  
Tuxpan, Mexico, May 31 to June 13, 4 deaths.  
Warsaw, Russia, May 31 to 6, 4 deaths.

CHOLERA.

Alexandria, Egypt, May 29 to June 3, 49 deaths.  
Cairo, May 29 to June 3, 152 deaths. Other Egyptian towns June 3, 338 deaths. From beginning of epidemic to June 3, there have been 3,112 cases and 2,597 deaths in Egypt.  
Bombay, India, May 19 to 26, 22 deaths.  
Calcutta, India, May 9 to 16, 120 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, May 23 to 30, 23 deaths.  
Cuba: Cardenas, June 6 to 13, 3 cases, 1 death; Havana, June 13 to 20, 25 cases, 11 deaths; Sagua la Grande, June 6 to 13, 41 cases, 4 deaths; Santiago, June 6 to 20, 12 deaths.

## NECROLOGY.

A TRIBUTE TO THE MEMORY OF DR. WM. ANDERSON.—At a regular meeting of the Indiana County (Pa.) Medical Society held May 12, 1896, Drs. James McMullen, Luther S. Clagelt and I. P. Klingensmith were appointed a committee to prepare a "Tribute to the Memory of Dr. Wm. Anderson" and forward a copy of the same for publication in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*.

Dr. Wm. Anderson was born June 6, 1825, in Green Township, Pa. His parents immigrated to this country from County Derry, Ireland, in 1817 and settled in the eastern part of Indiana County where he passed his early life, working on the farm and attending at intervals the district schools. A higher course of instruction was entered upon at the Blairsville Academy and finished at a classical academy at Indiana. After two years of office study with Dr. James M. Taylor of Indiana, he entered October, 1850, the Jefferson Medical College, Philadelphia, graduating March 6, 1852, attending however a third course at his alma mater in 1868-69. On graduating he located at Indiana where he continued to reside until his death March 29, 1896, aged 70 years. His practice was general. He had been a member of the Indiana County Medical Society since its organization in 1858, and was its first secretary, its second president, and represented it at different times in the Medical Society of the State of Pennsylvania and in the *AMERICAN MEDICAL ASSOCIATION*. He had been a member of the State Society since 1862, was one of the vice-presidents in 1864 and the president in 1865. Since 1868 he has been a member of the *AMERICAN MEDICAL ASSOCIATION* and was a member of the International Medical Congress that met at Philadelphia in September, 1876; a member of the Ninth International Medical Congress

which met at Washington, D. C., September, 1887, and also of the Pan-American Medical Congress which met at Washington, D. C., September, 1893. Several months before the date of his death, Dr. Anderson was seized with an attack of la grippe, which persistently clung to him and brought about his demise. He was connected with the United Presbyterian Church from youth. Being of a mild genial disposition everybody loved him and he had words of encouragement for all with whom he came in contact. He was noted for his industry in the societies and associations having for their object the free interchange of opinions on medical subjects. He was a frequent contributor to the medical literature of his day. Among his more notable productions are his monographs on Sclerosis of the Nerve Centers, Ozena, Nervous Diseases, Bacteria, Tobacco and Hygiene, in which much original research and thought is shown. The most valuable, perhaps, of Dr. Anderson's literary labors is entitled, "A Brief Biographical Sketch of the Medical Profession of Indiana County, Pa.," published in 1892. It contains 269 biographies.

In Dr. Anderson were happily combined calmness of manner with firmness of character, strictly honest with his patients and honorable with the members of his profession. His strict conscientiousness was one of his most marked characteristics.

THOMAS FERRIS COCK, M.D., of New York City, member of the *AMERICAN MEDICAL ASSOCIATION* since 1848, died June 11, at his country-place at Cold Spring Harbor, Long Island. He was a native of New York City, born there July 1, 1819. His father, Dr. Thomas Cock was for more than thirty years an officer, and part of the time president, of the College of Physicians and Surgeons, N. Y. He was graduated in arts from Haverford College; LL.D. at the same in 1886; M.D., at University of Pennsylvania in 1840. He settled in New York, and made obstetrics his special life-work. He was early a member in the New York County and State Medical Societies, and assisted in the formation of the Academy of Medicine and Pathologic Society. He served for a time at the Northern Dispensary. He was on the Visiting staff at Bellevue Hospital as early as 1849, going thence in 1855 to the city hospital, in whose service he remained at the time of his decease on the consulting staff. He was consulting physician at the asylum for Lying-in Women since 1841, and at the New York Infirmary for Women and Children since 1854, and at the State Hospital for women since 1855, about which year he issued his little manual of obstetrics. For the past ten years he had not been in active practice.

WALTER FISHER, M.D., assistant-surgeon and Captain U. S. A., died at Fort Meade, S. Dakota, June 8. He was at one time stationed at Fort Columbus, Governors Island, N. Y. His remains were interred at Oswego, N. Y.

THOMAS HUN, M.D., at Albany, N. Y., June 18, aged 88 years. In 1827 he entered the medical department of the University of Pennsylvania from which he graduated in 1830. He then returned to Albany and began practice. In 1833 he went to Paris to complete his education and remained six years. He returned in 1839 and accepted the professorship of the institute of medicine in the Albany Medical college.

HENRY SALZER, M.D., at Baltimore, Md., June 19, aged 55 years. He was born in Germany and educated in the Universities of Würzburg and Giessen, graduating at Giessen in 1866. He practiced in Germany about three years and then came to Baltimore, where he had since practiced.

LOUIS OCTAVE HUARD, M.D. (Tulane University Medical Department, New Orleans, La., 1857), at New Orleans, June 17, aged 67 years. He spent ten years in Paris, where he acquitted himself with highest honors, and was one of the few survivors of the famous French medical practitioners in Louisiana. Dr. Huard was honored with the red cross of Geneva for his devotion during the epidemic in France.

FRANK M. TEMPLE, M.D. (Western Reserve University Med-

ical Department, Cleveland, Ohio, 1880 and Department of Medicine of the University of Pennsylvania, Philadelphia, Pa., 1884) at Fairview, Pa., June 17, of pneumonia.—T. D. Kernan, M.D. (Department of Medicine University of Pennsylvania, Philadelphia, Pa., 1853) at Marion, Va., June 18.—George H. Calkins, M.D. (Northwestern University Medical School, Chicago, Ills., 1866) at Waupaca, Wis., June 25, aged 66 years.

PROF. P. STOLTZ. Sixteen years ago he retired from active life as an eminent obstetrician and instructor at Strasburg and Nancy, to the picturesque mountain village where he was born. He was so popular, however, that many patients followed him there, from all parts of the country, till his death last month at the age of 92. One of the addresses at the funeral was by a former pupil, whose father had also been Stoltz's pupil in his day.

## SOCIETY NEWS.

The North Missouri Medical Association at its meeting in Moberly, Mo., June 17, elected the following officers: President, C. A. Jennings; First Vice-President, W. MacAllister; Second Vice-President, J. D. Brummel; Treasurer, Robert Haley; Recording Secretary, George N. Lance; Corresponding Secretary, G. O. Cupaidge; Executive Council, J. H. P. Baker, W. T. Lindley, C. P. Clapp, D. R. Stratton. The next meeting will be held in Moberly in June, 1897.

The Allegany County Medical Society at its annual session, held in Cumberland, Md., June 18, elected the following officers for the ensuing year: President, M. A. R. F. Carr, Cumberland; First Vice-President, C. C. Jacobs, Frostburg; Second Vice-President, E. T. Duke, Cumberland; Third Vice-President, S. A. Boucher, Barton; Secretary, H. W. Hodgson, Cumberland; Treasurer, W. J. Craigen, Cumberland.

The Maryland State Medical Society, at its annual meeting elected officers for the ensuing year as follows: President, N. D. Blake, of Martinsburg, Secretary of State Board of Health; Vice-Presidents, D. C. Louchery, of Clarksburg; W. W. Golden, of Elkins; L. D. Ruppert, of Nuttallsburg, and H. B. Stout, of Parkersburg; Secretary, G. A. Aschman of Wheeling; Treasurer, J. W. Johnston of Davis.

The American Microscopical Society (formerly American Society of Microscopists).—The next meeting of the Society will be held at Pittsburg, Pa., August 18-20, 1896. The Society will be the first National Society to meet in the new Carnegie Library building. A preliminary program will be published on July 15, 1896, and the Society requests communications of anything new or interesting. The officers are: President, A. Clifford Mercer, Syracuse, N. Y.; Secretary, William C. Krauss, Buffalo, N. Y.; Treasurer, Magnus Pflaum, Pittsburg, Pa.

Mississippi Valley Medical Association, meeting at St. Paul, Minn., Oct. 20, 21, 22, 23, 1896. H. O. Walker, President, Detroit, Mich.; Merrill B. Ricketts, First Vice-President, Cincinnati, Ohio; William F. Barclay, Second Vice-President, Pittsburg, Pa.; H. W. Loeb, Secretary, 3559 Olive Street, St. Louis, Mo.; Harold N. Moyer, Treasurer, Chicago, Ill. C. A. Wheaton, Chairman Committee of Arrangements, St. Paul, Minn. Executive Committee: Wm. N. Wishard, Indianapolis; X. C. Scott, Cleveland; Geo. J. Cook, Indianapolis; J. M. Mathews, Louisville; I. N. Love, St. Louis; A. M. Owen, Evansville; Wm. T. Belfield, Chicago; C. S. Cole, New York; C. A. L. Reed, Cincinnati; R. Stansbury Sutton, Pittsburg.

Colorado State Medical Society.—This Society held its annual meeting at Denver, Colo., June 16, 17, 18, I. B. Perkins, President, in the chair. Dr. Perkins in his address spoke briefly of the progress that had been made in bacteriology and of the success that had been met with in the use of antitoxin. The

speaker expressed his regret that more success had not been met with in their efforts to have a national sanitarium established in Colorado and urged the committee to continue their work in that line. Among the papers read were the following: "Bicycle Hernia," Geo. W. Miel; "A Rapid Method of Castration," W. P. Munn; "Radical Operation for Inguinal Hernia," W. W. Grant; "Symphysiotomy," T. Mitchell Burns; "The Management of Puerperal Sepsis," W. A. Jayne; "Supernumerary Oviducts and Typical Hydatid of Morgagni, with a Large Fibroid Uterine Tumor—Hysterectomy," H. G. Wetherill; "The Diagnosis of Tumor of the Brain," J. T. Eskridge. The following officers were elected for the ensuing year: Robert B. Levy, President; H. R. Bull, First Vice-President; Dr. Finney, Second Vice-President; S. D. Van Meter, Third Vice-President; H. R. Whitney, Corresponding Secretary; Laura Liebhardt, Recording Secretary; W. F. McClelland, Treasurer. The various standing committees were reappointed.

The Northern "Tri-State" Medical Association will hold its annual session at Algola, Ind., July 21. The following papers will be read: "The Need of Abdominal Section as an Aid to the General Practitioner to Diagnose Obscure Abdominal Troubles," J. H. Carstens, Detroit, Mich.; "Salicylate of Sodium in Septic Conditions," Hugo O. Pantzer, Indianapolis, Ind.; "Modern Brain Operations," Allen DeVilbiss, Toledo, Ohio; "Some Considerations in the Treatment of Acute Otitis Media," E. A. Bulson, Ft. Wayne, Ind.; "Embryonic Miscarriage," J. R. Dodge, Hudson, Mich.; "Management of Vesical Calculus," F. J. Hodges, Anderson, Ind.; "The Cause and Treatment of Color-Blindness," F. C. Mayson, Hillsdale, Mich.; "Purpura Hemorrhagica," Frank M. Guyer, Hillsdale, Mich.; "The Differential Diagnosis of Insanity," C. B. Burr, Flint, Mich.; "Diffuse Cellulitis of Hand and Forearm," W. W. Brand, Toledo, Ohio; "A Case of Brain Tumor, with Exhibition of Specimens," G. W. McCaskey, Ft. Wayne, Ind.; "Asepsis and Antisepsis—Which or Both," J. B. Greene, Mishawaka, Ind.; "Aseptic Technique in Pelvic and Abdominal Operations Outside of Hospitals," C. N. Smith, Toledo, Ohio; "Conservative Surgery in Tuberculosis of the Testicle," J. B. Murphy, Chicago, Ill.; "The Differential Diagnosis of Insanity," C. B. Burr, Flint, Mich.; "A Case of Brain Tumor, with Exhibition of Specimen," G. W. McCaskey, Ft. Wayne, Ind.; "Obstruction of the Bowels," Hal C. Wyman, Detroit, Mich.; "Diagnosis of Typhoid Fever," W. C. Chapman, Toledo, Ohio.

The Minnesota State Medical Society held its twenty-eighth annual meeting at Minneapolis June 17, 18 and 19, Dr. Frank Allport, Minneapolis, President. There was a large attendance and much enthusiasm was evinced. President Allport in his address referred to the present coroner system as a relic and of no use.

The Society adopted the following resolutions concerning anti-vivisection:

WHEREAS, Science within recent years has received untold benefit and has made phenomenal progress from the legitimate practice of vivisection; and

WHEREAS, Humanity has profited and is destined to profit immeasurably by the discoveries in physiology, pathology and bacteriology which have been made possible by the scientific use of living animals; and

WHEREAS, Certain organizations, self-styled anti-vivisectionists, inspired by motives more sentimental than sound, with minds moved by emotional influences and hysterical arguments rather than by scientific facts, are seeking to strike a blow at the interest of science by the introduction into the Congress of the United States a bill restricting or abolishing vivisection in the District of Columbia; and

WHEREAS, The introduction of this measure is but a step preparatory to the presentation of other and similar measures in our State legislatures; therefore, be it

Resolved, That this Society denounces such attempted legislation as mischievous to the medical profession, as suicidal to the interests of society, as destructive to science, and as per-

versive of those moral standards which maintain a true relationship of things;

*Resolved*, That this Society petitions the senators and representatives of this State in Congress to use their utmost efforts for the defeat of this obnoxious measure.

It was decided to hold the next annual meeting at Mankato. Officers were elected as follows: President, W. D. Flynn of Redwood Falls; First Vice-President, David O. Thomas, Minneapolis; Second Vice-President, D. M. Jones, Gaylor; Third Vice-President, Dr. Williams, Lake City; Secretary, Ignatius Donnelly, St. Paul, re-elected; Treasurer, R. J. Hill, Minneapolis, re-elected; Censors, W. W. Mayo, Rochester, and Franklin Staples, Stillwater.

**The Association of Surgeons of the Louisville, New Albany and Chicago Railway System** held a meeting at West Baden Springs, June 4. Seventeen surgeons employed by the company were present. Dr. John G. Davis was elected president, Dr. Dudley S. Reynolds, vice-president and Dr. Samuel L. Easminger, secretary and treasurer. Dr. George F. Beasley of Lafayette reported the case of a youth who had compound fracture of the frontal bone, with loss of bone and extensive injury to soft parts two years ago and recently became epileptic. Pulsation could be felt over the point of injury and pressure caused pain. On making incision and raising the parts covering the opening in the cranium he found the soft parts all intimately connected in a cicatricial mass and adherent to the brain integument. Occipito-frontalis muscle fascia, dura and pia mater firmly united and cicatrized. The bony edges of the opening were irregular and thickened with nodulated growths turned inward pressing on the brain. He carefully separated the brain from the adherent cicatrix, removed the exostoses and used gold foil as a covering for the brain and to prevent union again with the cicatrix. The operation was performed under strict antiseptic rules and succeeded so well that at the time the Doctor reported the case, about two weeks subsequently, there had been no more epilepsy, and the wound had healed without discharge of any kind and the patient was in a manner well.

Dr. Dudley S. Reynolds of Louisville briefly recited the case of a negro boy, 16 years of age, who had frontal headache and was suddenly seized with edema of the eyelids and the left side of the face. The eyes did not seem to protrude from the orbit, although the edema was such as to firmly close the lids. Examination of the left nasal passage showed exudation of pus at the anterior extremity of the middle turbinate. Careful examination of the locality from whence the pus came, with the symptoms already described led him to suspect abscess of the frontal cells. Using a bone drill 4 millimeters in diameter, an opening was made at the external anterior attachment of the middle turbinate, when a large quantity of offensive, cream-colored pus escaped. The cavity was injected with a solution of bichlorid of mercury and chlorid of sodium. The next day the edema had disappeared from the face and the eyelids were opened by the voluntary efforts of the patient, though still somewhat swollen. He had Hutchinson's teeth, and was given 10 grains iodid of potassium every four hours. He appeared at the clinic irregularly for about three weeks and was then lost sight of. Four months later he returned with a tender swelling at the base of the nose. On discovering fluctuation an incision was made, followed by the discharge of a large quantity of cream-colored pus and a sequestrum of bone of irregular outline about one-eighth of an inch thick in its heaviest portion; about three-fourths of an inch in length and between three-eighths and one-half inch wide. This was removed, the incision enlarged and the cavity freely washed with the bichlorid solution. He was cautioned about the necessity of taking the iodid, which had been abandoned. The wound continued to discharge for about six weeks, when a uniform depression of the whole extent of the left half of the frontal bone came on. He has no bony projection of the

brow, owing to the loss of the supra-orbital process; but has recently begun to suffer with epilepsy and it is supposed that cicatricial changes in the meninges at the site of the abscess may account for the epilepsy.

The report and discussion of cases engaged the attention of the Association until the close of the session. The meeting was one of unusual interest and profit to all present. The Association will hold its next meeting at Cedar Lake, July 8-9, 1897.

**The Ohio State Medical Society and Anti-Vivisection Legislation.**—James E. Pilcher, M.D., Ph.D., Captain in the Medical Department of the United States Army, Professor of Military Surgery in the Ohio Medical University, in his remarks before the fifty-first annual meeting of the Ohio State Medical Society, May 27, 1896, said: Humanity is fallible. The most striking example is the existence of the absurd anti-vivisection movement, which has attained an unreasonable prominence through the success of its advocates in getting before the United States Senate a measure directed against vivisection, under the misleading title of "A bill for the further prevention of cruelty to animals in the District of Columbia." This movement of the self-styled anti-vivisectionists has gathered so much momentum in its misdirected career of misrepresentation that the medical profession must, in self-defense, take a decided stand for the preservation of its own liberties and the best interest of suffering humanity. There is no profession in which humanity is so much a part of the daily life of its practitioners as medicine. The absurdity of placing such persons in the attitude of defense against an accusation of cruelty or inhumanity of any kind is evident to every one.

The most rabid anti-vivisectionist will masticate his cutlet of veal or his shoulder of lamb, all regardless of the joyous young life that has been rudely terminated merely to gratify the animal appetite of the alleged defender of our dumb animals. The sportsman inflicts untold agony upon the victims of his prowess, but we hear of no movement looking to the prohibition of hunting. The anti-vivisectionist nestles luxuriously in his furs and his wife waxes gorgeous in her headgear garnished with the plunder of feathered songsters—both the spoil of the rapacity and cruelty of man; while the shoe trade, based entirely upon the products of the death of millions of God's most harmless creatures, is prosperous in the extreme.

When the anti-vivisectionist becomes a strict vegetarian; when he avoids all amusements resulting from animal slavery or suffering; when he clothes himself entirely in garments of vegetable and mineral composition; when he suppresses all practices, sportive and mercenary, by which pain is inflicted upon animals, he may properly begin to inquire into vivisection with a view to ascertaining whether it is humanitarian or cruel. In the war of the rebellion, 3,273 out of 3,717 cases of wounds of the intestines were fatal. It was demonstrated a few years ago by experiments on dogs that abdominal section and intestinal suture in such cases was a feasible and successful operation, and the operative procedure was experimentally elaborated, so that by it the mortality in gunshot wounds of the intestines has been reduced from 90 down to 10 per cent. The brain, which as well as the abdomen, was formerly regarded as forbidden ground to the surgeon, has, by the vivisection experiments of Ferrier and others, been brought within the realm of curative art. The work of Aristotle, Realdus Columbus, Andreas Cæsalpinus, William Harvey, and Marcello Malpighi in discovering the circulation of the blood was entirely conducted by experiments upon lower animals. The experiments of Vesalius, Hooke and Lower gave us artificial respiration. Transfusion of blood was directly the offspring of vivisectional experiment. The entire system of antiseptic and aseptic surgery, the greatest humanitarian triumph in the world's history, is based upon the practice of vivisection. The bacillus of anthrax, the bacterium of tubercle, the micro-

organism of diphtheria, the spirillum of relapsing fever, the streptococcus of erysipelas and puerperal fever, and many other specific agents in disease have been discovered entirely through experiments upon lower animals. The autitoxin treatment of diphtheria, the Pasteur inoculation cure of hydrophobia, the prevention of smallpox by vaccination, and many others of the most important therapeutic procedures of modern medicine are due to vivisection, while still many more are the subjects of observation, which will ultimately result in the discovery of curative procedures.

While vivisection experiments are always beneficial they are never cruel. Even were the medical student the heartless creature represented by the anti-vivisectionists, he would prefer, for his own convenience, to silence the cries and subdue the struggles of his subjects by an anesthetic. All this emphasizes the deceptive and incorrect character of the efforts to embarrass, if not prohibit, the future of these genuinely philanthropic as well as scientific studies. The dangerous movement looking to this end, initiated in the District of Columbia, has met with astounding success, and it behooves all true lovers of scientific progress to unite in the attempt to prevent the enactment of the bill now before the United States Senate for this purpose; for, should this movement be successful in the District, it would not only put an end to most important work in various scientific departments of the government and the medical schools of Washington, but it would be the beginning of a movement jeopardizing scientific study throughout the entire Union.

The Ohio State Medical Society adopted the following resolutions:

*Resolved*, That the Ohio State Medical Society earnestly joins in the protest of the American Medical Association as expressed in the resolutions adopted at the recent meeting of that representative body of American physicians and surgeons held in the city of Atlanta.

*Resolved*, That a copy of these resolutions be sent to the Senators and Representatives of the State of Ohio in the Congress of the United States, and that they are hereby requested to use their influence in opposition to the proposed legislation, "unless it shall first be shown by an impartial investigation that cruel and unnecessary experiments are being performed in the District of Columbia, and that existing laws do not provide suitable punishment for cruelty to domestic animals."

The following amendment, proposed by Dr. L. B. Tuckerman, of Cleveland, was accepted by Dr. Pilcher, and the resolutions as amended were unanimously adopted:

*Resolved*, That a delegate be appointed by this society to go to Washington and interview the Senators and Representatives in person in behalf of these resolutions, and that one hundred dollars be appropriated to pay his expenses.

## MISCELLANY.

**Ivy Poison.**—Recent experiments show that the poison of the ivy is a volatile oil. Hence, water will not remove the poison from the surface as well as alcohol.

**Disturbed Equilibrium.**—"Isn't that too much mustard for so little meat?" exclaimed Charles Lamb as he noted the approach of the plaster.

**Argon in the Breath.**—Kellas concludes from his experiments that exhaled air contains more argon than before inhalation; from this he infers that it is an important element in the animal economy.

**Dr. J. H. Kellogg**, of the Battle Creek Sanitarium, formally opened and dedicated the Workingmen's Home and Medical Sanitarium in Chicago, June 28. Addresses were made by Dr. Bayard Holmes and others.

**Physical Degeneration in Italy.**—A Milanese writer asserts that 45 per cent. of the young men of Italy are unable to enter the military service on account of their lack of the physical requirements.—*Revista de Ciencias Medicas*, May 20.

**His Consolation.**—It is related of the late Professor Sappey, who was far from being an orator, that he used to console himself with the remark that his diffidence in speaking only caused suffering to himself alone, while the fluency of some physicians causes countless others to suffer.—*Journ. de Méd. de Paris*, June 7.

**Not Chemicals.**—The supreme court of Louisiana is of the opinion that soda, seltz and similar drinks are not chemicals, and it holds, in the case of the Crescent City Seltz and Mineral Water Co. v. City of New Orleans, April 6, 1896, that the making of soda, seltz and similar drinks is not the manufacturing of chemicals, within the constitutional exemption of that State of property employed in manufacturing chemicals.

**A Rare Effect of Tobacco.**—J. W. Scott, M.D., reports a case of convulsions, epileptiform in character, due to the use of tobacco. For two months he had one or two convulsions a week and they were growing progressively worse in spite of treatment. With the discontinuance of tobacco the convulsions ceased and have not returned.—*Southwestern Medical Record*.

**Correction.**—In issue of June 20, it was stated that "Dr. Curran Pope will lecture upon Diseases of the Mind and Nervous System; Dr. Pope resigns from the Hospital College of Medicine where he held the same position as the one in the Louisville School." This is an error, as he now holds a regular full professorship in the Louisville Medical College.

**A Cockade and Crests Preferred!**—The subjoined advertisement appears under "special" in the *Glasgow Evening News*. It is too good to be buried in the columns of a daily newspaper: "Doctor's Cockade.—Wanted from Cab Owners, by Doctor who has recently become surgeon in a Volunteer Regiment, estimates for hire of a Brougham three hours a day; driver must wear a Cockade: Brougham with one or two crests on doors preferred. Apply No. 10,737, News Office."

**The Treatment of Cystitis.**—L. Grant Baldwin, M.D., says; "Having excluded in the diagnosis, as causative factors, new growths, foreign bodies and tuberculosis, if the case is an acute one, example an operative case where a catheter has been used in an uncleanly manner, I have found that relief can be obtained in twelve hours and often in a much shorter time by the administration of sandalwood oil, together with benzoic acid, and a cure is practically obtained in from two days to a week."—*Brooklyn Medical Journal*, June, 1896.

**Latent Gonorrhoea.**—Dr. Rosenwasser says of the gonococcus of Neisser: The locations of choice are the urethra and vaginal portion of the cervix. A person may in time become accustomed to his own brood of germs so that they cease giving trouble. Transplant them to new soil and they at once effect the recipient with pristine vigor. Then if these regenerated germs are returned to the original owner they will initiate as vicious action as though they had never been there before. This is his explanation of "latent" and "recurrent" gonorrhoea.—*Cleveland Medical Gazette*, June, 1896.

**International Bacteriologic "Concours."**—As a memorial to Pasteur, the *Circulo Médico Argentino* of Buenos Aires, offers prizes of \$400 and \$200 for the best original and unpublished bacteriologic investigations or studies reported to the President, Senor Gregorio Aroz Alvaro, before May 31, 1897. The reports to be in Spanish or French. For further particulars see the *Crónica Médica* of Lima, April 15.

**Improved Eye Glasses for School Children and Artisans.**—The *Revue Gén. d'Ophthalmologie* for May, describes some spectacles for school children which have a celluloid trap cover for each glass that falls down over them whenever the head droops forward, and springs back into place as soon as the head is held upright. The other is a working glass for cases of excessive myopia. It is a metal plate pierced with stenopeic openings in

the direction of the twelve principal meridians, radiating from around the pupil. It improves the sight to such an extent that myopia of 10 D. is corrected to 1 and -4 D. It also proves useful in irregular astigmatism.

**The Academie de Medecine of Paris.**—At the session of the Academie held June 9, M. Roux was named as a member *vice* M. Pasteur deceased. At the same session Dr. Marcel Baudoin in the name of the Medical Press Association of France, M. Cornil, President, asked the Academie to become represented at the Fête to celebrate the fiftieth anniversary of the discovery of anesthesia. This fête will be held on the occasion of the meeting of the French Congress of Surgery in October next. In response the Academie has designated M. Cornil as its representative on that occasion.

**Serum Treatment of Diphtheria in Cracow.**—Dr. Stapa has presented to the Cracow Medical Society a report of the results obtained by the serum treatment of diphtheria in the Children's Hospital of that city. During the year 1895 the number of children subjected to it was 258. Of these the mortality was 22 per cent. This compares very favorably with the mortality in the ten previous years, which was as high as 56.3 per cent., there being 709 deaths out of a total of 1,354 patients who were treated by other methods. Laryngeal croup occurred in 165 cases, and a rash having the appearance of scarlet fever and lasting from two to sixteen days in fifty-eight cases. It was noticed that certain samples always produced rash. No effect on the occurrence of albuminuria by the serum could be shown.

**Parenchymatous Goitre Treated with Hypodermic Injections of Durante's Solution of Iodo-Iodid.**—Reyes, of Palermo, has treated twenty-eight cases of parenchymatous goitre in this way, and the goitre rapidly subsided in size, the general health visibly improved, the patient gained in weight, while there were none of the unfavorable results that sometimes occur with thyroid medication. The formula used was that proposed by Professor Durante, of Rome, for tuberculosis, "solution iodo-iodurée," given in the *Semaine Médicale*, 1894, p. 252. At first two injections of two to five grams each were made during the week, then one, and later one in two weeks.—*Semaine Médicale*, May 13.

**Substitute for Yellow Phosphorus in the Manufacture of Matches.**—Gurowitz announced at the meeting of the K. K. Ges. der Aerzte of Vienna, May 15, that he had discovered a substitute for the dangerous yellow phosphorus in matches, which is perfectly harmless, is easily applied to wooden and wax matches, lights on any rough surface, and has a very high self-lighting point, 150 to 160 degrees C. It is made by melting together pulverized without danger and the other ingredients are entirely sulphur and red phosphorus; the substance thus formed can be harmless. The members of the board of health were so pleased with their investigation of it that they at once petitioned the government to forbid henceforth the use of the poisonous phosphorus altogether.—*Wiener klin. Rundschau*, May 24.

**Medical Appropriations by the Fifty-Second Congress.**—An act of Congress (No. 213) making appropriation for sundry civil expenses for the year ending June 30, 1897, appropriates the following sums for the purposes named: For preservation and repair of buildings, etc., at U. S. Marine Hospital and Quarantine Stations, \$30,000; special for Marine Hospital at Boston, Mass., \$1,850; at Chicago, Ill., \$8,950; at Cincinnati, Ohio, \$1,000; at Detroit, Mich., \$1,300; at Louisville, Ky., \$1,500; at New Orleans, La., \$2,150; at Port Townsend, Wash., \$6,150; at San Francisco, Cal., \$300; at St. Louis, Mo., \$1,860; at Wilmington, N. C., \$1,200; at Vineyard Haven, Mass., \$1,500. Special Quarantine Stations at Reedy Island, Del., \$1,200; at Brunswick, Ga., \$800; at Gulf, \$350; at South Atlantic, \$15,750; at San Diego, Cal., \$350; at San Francisco, Cal., \$5,000; at Port Townsend, Wash., \$3,500. Ordinary

expenses of the quarantine service, including pay of officers and employes, \$131,000; Government Hospital for the Insane, Washington, D. C., \$293,851; Garfield Memorial Hospital, Washington, D. C., \$19,000; Providence Hospital, Washington, D. C., \$19,000. For pay of surgeons, attendants, and other expenses of the hospitals at the National Homes for Disabled Soldiers at Dayton, Ohio, \$55,000; at Milwaukee, Wis., \$28,000; at Togus, Me., \$25,800; at Hampton, Va., \$30,000; at Leavenworth, Kan., \$30,000; at Santa Monica, Cal., \$20,000; at Marion, Ind., \$24,000. Hospital at Leavenworth (Kansas) prison, \$28,000. Index catalogue of the library of the Surgeon-General's office, \$12,000. The President is also authorized in case of epidemics of cholera, etc., to use the unexpended balance of appropriation of March 2, 1895, in aid of State and local boards of health, or otherwise in suppressing the spread of the same.

**The Harvard Medical Alumni Association** held its sixth annual banquet at Boston, Mass., June 23. The meeting was of unusual interest because of the presence of Theobald Smith, M.D., pathologist of the Massachusetts Board of Health and the new professor of comparative pathology in the Harvard Medical School. Dr. George B. Shattuck, President of the Association presided and opened the post-prandial exercises. He said the Association now numbered 1,321 members, seventy-six having joined since June 1, 1896. He continued: "I can not, as your president, refrain from all mention of this very generous, useful and intelligent endowment in the medical school. Let me read you the text of the donor's deed of gift that you may know just what his wishes and objects were in creating this foundation. 'It is my wish to testify to my deep interest in the advancement of medical science and the higher medical education; an interest originating in the fact that my father was a physician. I therefore offer to the President and Fellows of Harvard college the sum of \$100,000 in cash, payable July 1, 1896, as a fund for the endowment of a professorship of comparative pathology in the medical department of Harvard University. I desire that this fund shall be forever known as the — fund, in memory of my father, — M.D.,<sup>1</sup> and that the professorship shall also bear his name. It is furthermore my wish that the income of the fund shall be applied first to the payment of the salary of the — professor of comparative pathology, who shall also be a member of the medical faculty and appointed to office in the same manner as are other professors in that body, and who shall devote his time to the duties of his professorship, not engaging in private practice without the recommendation of the medical faculty and consent of the President and Fellows.'" Dr. Theobald Smith was introduced. He read a technical paper on "Comparative Pathology in Its Relation to Human Medicine." In conclusion he said he considered it most advisable for the members of the medical profession to take a more active interest in public affairs. The following officers were elected: Dr. Shattuck, President, and Dr. Walter Ela, Secretary, now occupying office for a three years' term; Vice-Presidents, Drs. Gustavus L. Simmons, Sacramento, Cal.; William W. Seymour, Troy, N. Y.; John W. Parsons, Portsmouth, N. H.; Alternate Vice-President, Dr. Thomas W. Huntindon, Sacramento; Secretary, Augustus Thorndike, Boston; Councilors for term ending 1900, Lincoln R. Stone, Newton; J. T. G. Nichols, Cambridge; Robert W. Lovett, Boston.

**Wanted—Improved Pocket Cuspidors.**—The *Journal de Méd. et de Chir.* for May, asks why it is not possible to educate the public until every one with even a catarrhal cold or influenza will no more think of leaving the house without his pocket expectorator than he would go without his handkerchief. Invalids who have learned to use the portable cuspidors of a sanitarium are never content without one afterward. But their

<sup>1</sup> The name of the donor was withheld at his request.

comparatively high price, \$1.60, and the difficulty of procuring them, has prevented their general adoption. Only one store in Paris was found where they were for sale. Something cheap, light and inconspicuous is needed, and there is a fortune waiting for the inventor who will provide something that will find favor in the eyes of an expectorating world, and be the means of saving the lives of thousands yet unborn. The sanitary spit mugs now in use in some hospitals, although ornamental and useful, are scarcely attractive enough for the general public.

**Two New Parasitic Cutaneous Diseases in Russia.**—Recent numbers of *Wratsch* (48, 52, 3) contain descriptions of a skin disease produced by the larva of a fly (*Gastrophilus hemorrhoidalis* L. or *G. pecorum* Fb.) which prevails in the provinces near the Volga. Exposed places, the face, hands and neck, are affected in lines, 15 cm. long, resembling the scratch of a needle, and in each is found the 1 mm. long larva. The hair of the skin is frequently covered with the eggs, which wash off easily, so that only a few of the larvæ find their way under the skin. One writer has found the lesions in the mouth, nose and beneath the conjunctiva. The disease resembles Neumann's "creeping eruption." In the province of Twer there is still another parasite that affects the skin, a still undescribed filaria several inches long. It burrows in the hand, producing a boil, and resulting sometimes in extensive inflammation, ankylosis and even gangrene of separate fingers.—*Centralblatt f. Chirurgie*, May 23.

#### Practical Notes.

**Optic Atrophy.**—Dr. Culbertson recommends glonoin in conjunction with strychnin, in all forms of optic atrophy, retinitis pigmentosa, hereditary atrophy, atrophic choroiditis and all the toxic amblyopias. Dose, 1-50 grain given internally.—*Am. Jour. of Ophthalmology*, June, 1896.

**Erysipelas and Its Treatment.**—Dr. Bedford Brown says (*New England Medical Monthly*, June, 1896) symptoms usually attributed to inflammation of the brain are probably due to blood poisoning from the ptomaines of the streptococcus, after having been rapidly absorbed and transmitted throughout the circulation.

**Treatment of Menstrual Nervous Troubles with Ingestion of Ovarian Tissue.**—Landau stated at the meeting of the Berlin Medical Association, June 3, that he had been administering ovarian tissue from animals to patients suffering from the nervous disturbances caused by the suppression of the menses after extirpation of the uterus or its annexes, or the menopause. In each case it had been followed by the disappearance of the nervous troubles, at least temporarily.—Reported in the *Semaine Médicale* of June 10.

**Pseudo-Erysipelas after the Instillation of 1-120 Grains of Atropia.**—H. McL. Morton, M.D., reports a case: The infiltration of both upper and lower lids was so great that the oculo-orbital and oculo-malar sulci were completely obliterated, and the cheeks were intensely swollen to the angles of the mouth. There was much pain of a severe, burning character. The great amount of infiltration and the redness looked not unlike rhus poisoning. The patient has not been out of the house, however, and the relation of cause and effect was too marked to permit of any doubt as to the cause of the trouble. The trouble disappeared in a few days, under cold compresses, and a solution of lead, water and laudanum.—*Annals of Ophthalmology and Otolaryngology*, June, 1896.

**Pienge's Method of Hardening with Formaldehyde and Making Frozen Sections for Rapid Diagnosis.**—1. A piece of the tissue as thin as possible is hardened in a 4 per cent. solution of formaldehyde for one-half to one hour, or longer if thick. 2. The frozen sections are made with Jung's lever microtome. 3. They are taken up in water which has been boiled to expel the air, or better, in 50 per cent. alcohol. 4. They are stained with

the anilin dyes. 5. They are rinsed with water, alcohol, oil or Canada balsam. This method is used with admirable results at the Heidelberg Path.-Anat. Institute. It is not adapted, however, to normal placenta, pure fatty tissues, solid bones, bone marrow, papillary tumors, normal testes and the small intestines, nor to normal lung tissue which is difficult to treat in this way.—*Centralbl. f. Chir.*, April 25, from *Munch. Med. Woch.*, No. 4.

**Extensive Resections for Tuberculosis of the Foot and Wrist.**—Bardenheuer and Wolff substitute extensive resections for amputations in a large proportion of cases of tuberculosis of the foot and wrist. Their method of resecting the wrist insures a much more solid union between the metacarpal bones and the bone of the forearm than is the case with the usual methods. They cut the upper end of the metacarpal bones in the shape of a wedge, with a wedge-shaped surface to correspond on the end of the bone of the forearm. This secures an exceedingly close and secure junction and a strong bony ankylosis is formed, which is much to be preferred to a movable joint with nothing to support it. They have performed the operation eight times with complete success in each.—From the "Chirurgengcongress," in the *Semaine Médicale*, June 6.

**An Ideal Excipient for Ophthalmic Unguents.**—Dr. Allen Jamieson of Edinburgh reports in the *British Journal of Dermatology*, April, the following combination as an ideal ophthalmic salve: Lanolin (Liebreich), 3 drams; almond oil, ½ dram; distilled water, ½ dram. Mix. If smeared thinly on the lids this occasions no unpleasantness, and it may be employed when it is desirable to use a salve to prevent the lids becoming glued together by an increase of the lachrymal secretion. It is, however, better as a rule to add a couple of grains of boric acid to correct any slight tendency to rancidity, though this is not prone to happen, even if the ointment be kept for a time. In eczema of the lips the salve forms an excellent medium for the yellow oxid of mercury so beneficial in such conditions. Two grains may be added to the half ounce. According to the testimony of patients, the salve gives a pleasant sensation of coolness without trace of smarting or irritation. Its curative influence, the author says, is equal if not superior to that of any other eye salve prepared with other bases.

**Some Common Affections of the Heart and Their Treatment.**—Dr. H. W. Rogers says: In regard to those cases considered purely functional, it may be a question whether many of them do not initiate the more serious lesions found later in life. Usually no murmurs are found on auscultation, but almost invariably a marked accentuation of the second sound at the aortic orifice which means loss of elasticity in the aorta. There are few conditions of the pulse pathognomonic of a particular cardiac lesion. The nervous mechanism plays an important part in its modification. In most cases, however, a rapid pulse means a weak myocardium. A slow pulse, on the contrary, means a heart which is overburdened by some form of resistance in the circulation, but a myocardium which in most instances is essentially strong. Of the diet he says: Limitation of starchy foods and sweets and the employment of rapidly appropriated proteids is the general plan. Digitalis he considers the ideal heart tonic. Strychnin is one of the most potent remedies, but its action is rapid and there is danger if used too frequently or too long. No better combination than morphin, strychnin and nitro-glycerin can be employed in acute attacks, especially those designated as angina pectoris.—*Cleveland Journal of Medicine*, June, 1896.

#### Hospitals.

**METROPOLITAN THROAT HOSPITAL, NEW YORK.**—The 29th annual report shows the number of new patients who received treatment at the hospital during the year was 2,286, and 610

surgical operations were performed. Dr. Clinton Wagner is medical superintendent.

**APPOINTMENT.**—Dr. J. Clement Clark has been appointed by the board of directors first assistant physician of the Maryland Hospital for the Insane at Spring Grove, Md., to succeed Dr. J. Percy Wade, who has been made superintendent.

**INFANTS' SUMMER HOSPITAL.**—The formal opening of the Infants' Summer Hospital at Ontario Beach, Rochester, N. Y., took place June 23. This is its tenth season of beneficent work.

#### Philadelphia.

DR. A. C. ABBOTT has been elected professor of hygiene in the faculty of the University of Pennsylvania, to succeed Dr. John S. Billings, resigned.

DR. JOSEPH McFARLAND has been elected professor of pathology in the Medico-Chirurgical College to the place made vacant by the resignation of Dr. E. B. Sangree.

PROF. WILLIAM THOMSON has resigned the chair of Ophthalmology in the Jefferson Medical College after twenty-four years connection with the school.

THE MEDICAL COUNCIL OF PENNSYLVANIA, which through the State Boards of Examiners, and Licensers, examines all physicians who wish to enter upon medical practice in this State, including graduates of our own schools, has adopted a rule that all students matriculating in medical colleges of the State of Pennsylvania, who intend after graduation to practice medicine in this commonwealth, will be obliged, on and after the term beginning in the fall of 1896, to provide themselves prior to matriculation with a certificate of preliminary examination. The preliminary examination which is now made compulsory and uniform in its application, requires attainment of a satisfactory average in the following branches: Arithmetic, grammar, orthography, American history and English composition. However, the diploma of a college, academy or seminary, normal school or high school, a teacher's permanent certificate, or a student's certificate of examination for admission to the freshman class in any college, shall be accepted in lieu of examination.

AT THE JUNE MEETING of the Philadelphia Chapter of the Alumni Association of the Jefferson Medical College, Dr. Emanuel J. Stout read a paper on "Extra-Genital Chancres;" Dr. J. Abbott Cantrell reported upon the "Clinical Aspects of the Tubercular Syphiloderm." Dr. John Lindsay read a communication on the "Treatment of Syphilis" which led to a general discussion of the subject by Drs. Horwitz, J. M. Barton, Joseph Hearn, L. Wolff, J. Chalmers DaCosta, E. E. Graham, W. S. Jones and H. W. Stelwagon. A reception at the Penn Club and a social entertainment concluded the evening's exercises.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY held its last meeting for the season June 27, when Dr. A. J. Downes exhibited his collapsible and removable bobbins for all forms of intestinal approximation. He also demonstrated a new continuous double-knot intestinal suture and a new abdominal retractor. Dr. Aug. A. Eshner read a communication entitled "Progress in Organotherapy."

THE TRUSTEES OF JEFFERSON MEDICAL COLLEGE on the 29th ult., elected Dr. George E. DeSchweinitz, Professor of Ophthalmology, to succeed Dr. William Thomson. Drs. D. Braden Kyle and W. S. Jones were made Clinical Professors of Laryngology and H. F. Harris, Assistant Professor of Bacteriology and Pathology, at the same meeting.

**MENTAL AUTOMATISM.**—The annals of the Coroner's office contain many interesting and remarkable cases of suicide which may be made to contribute something toward the solution of psychologic problems, and especially that of automatism and the imitative faculty or power of example in influencing human action. A middle-aged woman in this city, becoming disheartened, recently ended her life by the very unusual method

of swallowing hydrochloric acid. A man living in the same neighborhood, after attending the funeral, purchased some of the same corrosive poison in a drug store on his way home and soon after reaching his own house swallowed the poison and soon afterward died. The connection of the two cases seems to have been merely accidental and there is nothing to warrant the idea that there had been any previous agreement between the two.

## THE PUBLIC SERVICES.

**Army Changes.** Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from June 20 to June 26, 1896.

Capt. Walter D. McCaw, Asst. Surgeon (Ft. Ringgold, Texas), is granted leave of absence for one month, to take effect on or about July 5. Major Louis M. Maus, Surgeon (Ft. Sam Houston, Texas), is granted leave of absence for two months, to take effect on or about August 1, 1896.

Major Daniel M. Appel, Surgeon, is relieved from duty at Ft. Porter, N. Y., and ordered to the new post near Little Rock, Ark., for duty.

Capt. Aaron H. Appel, Asst. Surgeon, is relieved from duty as examiner of recruits at Chicago, Ill., and ordered to Ft. Porter, N. Y., for duty.

**Navy Changes.** Changes in the Medical Corps of the U. S. Navy for the week ending June 27, 1896.

Asst. Surgeon S. B. Palmer, detached from the New York laboratory June 29.

P. A. Surgeon George Rothganger, detached from the "Independence," July 15, and ordered to the "Oregon."

**Marine-Hospital Changes.** Official list of changes of station, and duties of Medical Officers of the U. S. Marine-Hospital Service, for the twenty days ended June 20, 1896.

P. A. Surgeon W. P. McIntosh, to proceed from Louisville, Ky., to Cincinnati, Ohio, to inspect unseviceable property; then to rejoin station, June 13, 1896.

P. A. Surgeon J. C. Perry, granted leave of absence for twenty days, June 20, 1896.

Asst. Surgeon C. H. Gardner, order of May 27, 1896, directing him to report for examination, is revoked, June 5, 1896.

Asst. Surgeon Rupert Blue, to proceed from San Francisco, Cal., to Angel Island quarantine station for duty, June 18, 1896.

#### Change of Address.

Altorf, C. D., from Hartford, Conn., to Undercliff, Lake Placid, N. Y. Bussey, S. C., from Washington, D. C., to Atlantic Hotel Narragansett Pier, R. I., until Sept. 1, 1896; Brown, R. A., from Tupelo, Miss., to Paris, Tenn.

Donelson, C. P., from 818 Warren Avenue to 927 Monroe Street, Chicago. Gates, W. S., from 1279 Wolcott St. to 2725 N. Lincoln Street, Chicago.

Henderson, H. C., from Chicago to Milford, Ill. Isbester, R. T., from 696 Washington Boul. to 1223 Indiana Avenue, Chicago, Ill.

Meadows, J. E., from Lisbon to Manghan, La. Polhler, F. T., from Minneapolis to Waseca, Minn.; Packard, J. H., from Devon to 26 So. 18th Street, Philadelphia, Pa.

Rhoden, J. C., from Ponca, Neb., to Elkpoint, S. Dakota. Wilson, A. M., from 27 Union Depot to 229 Park Ave., Kansas City, Mo.

#### LETTERS RECEIVED.

Alport, Frank, (2) Minneapolis, Minn.; Atkinson, W. B., (2) Philadelphia, Pa.; Apollinaris Company, Ltd., The, (2) London, England; Acker, T. J., Croton-on-Hudson, N. Y.

No. 2.

## ORIGINAL ARTICLES.

### CLINICAL NOTES UPON SPASMODIC TORTICOLLIS; WITH SPECIAL REFERENCE TO TREATMENT.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY ASA FLANDERS PATTEE, A.M., M.D.

MEMBER MASSACHUSETTS MEDICAL SOCIETY; PRESIDENT BOSTON THERAPEUTICAL SOCIETY; PROFESSOR EMERITUS OF MATERIA MEDICA, COLLEGE OF PHYSICIANS AND SURGEONS, AND CONSULTING PHYSICIAN TO UNION GENERAL HOSPITAL.  
BOSTON, MASS.

Torticollis (wryneck) is due to a spasmodic condition of the cervical muscles, chiefly those supplied by the spinal accessory nerves. The name is derived from two Latin words, *tortus*, twisted, and *collum*, neck. The terms *tic rotatoire*, *Nickkrampf*, etc., are used as expressive of the spasm, muscles affected, tenacity, etc.

This abnormal contraction of the cervical muscles is directly the result of irritation of the external cervical branch of the spinal accessory nerve, which having two different origins, a spinal and cerebral, has two distinct functions. The spinal or motor branch supplies the motor power to the sterno-cleido-mastoid and trapezius muscles, and communicates with the first, second, third, and fourth cervical nerves, its roots being traced between the anterior and posterior roots of the first five cervical nerves. As we have seen, wryneck proper is an affection of the sterno-cleido-mastoid and trapezius muscles, but in cases of long standing and great severity, especially in bilateral affections, the splenius capitis, scalmi and platysma myoides may become implicated from continuity of nerve fiber, and contiguity of muscle tissue.

This affection presents the objective phenomena peculiar to all spasmodic conditions of the muscles supplied by the peripheral nervous system. The most frequent and simple exhibition of other nervous irritation of the same nature may be seen in the facial spasm of the trigeminus, upper third, in spasmodic closure of the eyelids, with twitching and contortions of the forehead.

To torticollis proper, medical literature has devoted comparatively small space, the sentiment being conveyed that wryneck, being of reflex origin and generally an obscure and complicated one, when it is once well established in the individual, is the condition of a lifetime. Its clinical history is certainly that of permanency.

Wryneck may be divided into three classes, dependent upon the degree of severity, nature of spasm, and muscles involved. The partial or limited contraction of the cervical muscles due to cold, exposure, strain or rheumatism, and which disappears after a period more or less brief, under the administration of heat, liniments, friction, etc., is a condition commonly known as "stiff neck"; a painful state with which all are

familiar, most of us having had personal experience, and does not come within the province of torticollis proper; the former being a condition of the muscle substance itself, while the latter is dependent for its abnormal condition upon the nerve.

In this affection we have the two forms of spasms, the tonic, which is a state of permanent rigidity and immobility of the muscles, and the clonic or tetanic spasm, which consists in alternate contraction and relaxation. The movements are varied and accentuated in accordance with the muscles involved. If it is the trapezius, unilaterally, the head is drawn backward against the shoulder of the affected side, the chin is twisted to the opposite direction, and if the spasm assumes the tonic form, the head is permanently fixed, and can hardly be forced into its normal position; nor will it remain so under any restraint the patient may be able to endure. If the splenius be affected we find the head drawn back against that side, and the enlarged muscle may be felt protruding beyond the cervical edge of the trapezius.

While tetanic spasms are due to the irritability of the peripheral nerves, and may attack any one or part of the superficial muscles of the head or face as well, and their duplicity of action leaves no doubt that all spasms of the external superficial muscles are of the same nature, and are directly due to the same cause, this should by no means warrant us in the conclusion that they may all have the same origin, primal or remote; on the contrary, I think, we may properly make the assertion that irritability of the superficial nerves is the result of causes not always easily ascertained; being sometimes very remote, the nervous irritability being a symptom in the strictest sense of the word. Nerve irritation may be at any point of its course, and the spinal accessory being a complex nerve, having its action in the medulla as well as in the spinal cord, renders it a very difficult matter to locate the exact place of irritation; and owing to the complexity of the nerve branches and their anastomoses with the pneumogastric, we may have a reflex action from gastric disturbances, or by some lesion of the upper cervical vertebræ. In such an event the cause may be sufficiently obvious to enable one to act intelligently in attempting a cure, while in very many other instances we are obliged to grope in the dark. In this, as in all other peripheral neuroses, pathologic proof is absent.

Contraction of any muscle must be recognized as an exhibition of contractile fiber in response to nerve stimulus, and it is only when it ceases to become rhythmic in its action, or refuses to act altogether, that we have what we term a pathologic condition. The only visible result of nerve irritation that we have to go by is change in shape and mobility of muscle as a whole. Wryneck, as with the majority of peripheral nerve affections, is more convincing in its identity than the *raison d'être*.

*Case 1.*—My first case of torticollis was in 1857, the last year of my student life, and occurred in a woman aged 33. Her trouble came on without any apparent cause; first showing itself in merely a tendency to stiff neck at times and without any appreciable provocation. It had continued for about seven years, increasing in severity. At the time I saw her the neck was drawn around with a combination of tonic and clonic form of spasm, being twisted with a jerk and remaining in the tonic condition for a day or two, never assuming the normal state, but would be working back and forth. Her general health was fair; objective symptoms nothing to require attention with the exception of a large ulcer inside the left leg. This ulcer was not of the varicose form, but was what is termed by the laity a "fever sore"; it was two inches by two and one-half, and had been in existence for three years; a non-irritable, chronic ulcer. There were no varicose veins, no history of syphilis, no disease of the periosteum. The best of surgical and medical skill had been employed. As an incentive for me to do my best I was told that if I cured Mrs. B. I should have my room rent free for the next six months.

Without regard to etiology or pathology I began the following treatment: A poultice of pulverized ginger, mustard, capsicum, cloves and cinnamon, mixed with cold water and applied to the spine twice daily, from the first cervical down six inches, for one hour at a time. This was for the purpose of promoting counter-irritation, and also by the absorption of the oils these ingredients contained, to promote stimulation of the deeper nerves, carrying it by reflex action back to the nerve roots.

For internal medication I gave the following:

R. Pulv. capsici,  
 " myrrhæ . . . . . āñ 18 (gr. iij)  
 " cinnamomi . . . . .  
 " asafoetidæ . . . . . āñ 2.00 (grs. xxx)  
 " sapo. . . . .

Mix. Divide into thirty pills. Take ten pills after every meal.

This dose seems almost cruel as we prescribe to-day, but we must remember that this was an incident of thirty-nine years ago, a period very different from the present time of concentrated medicines; but a period too, which had remedies quite as efficient in their action as at the present time of artistic preparations. I dressed the ulcer with an ointment made up of lard and powdered cinnamon, of each half a pound, with sufficient quantity of whale oil to make it of proper consistency. This was applied to the ulcer twice daily. This treatment was kept up for months without change, and the result was a perfect and permanent cure, both of the torticollis and the chronic ulcer of the leg.

While the origin of torticollis may be sometimes as apparent to the physician as the door-plate on his own door, yet I intend to show in the following cases that it may be so swaddled about by the environments of disease obscurely located, that treating for an ordinary cause may result in ignominious failure, as shown in the following:

*Case 2.*—An American woman, aged 35; mother of three healthy children, had been troubled with spasmodic torticollis for three years, or since the birth of her last child. Reckoning from that period as the beginning of her trouble, one would be very liable to attribute the cause to some lesion, more or less important, of the generative organs. Such had been her experience with those whom she had consulted. And her symptoms were typical of such a trouble, only rather more exaggerated than ordinarily met with. Her head would give a sudden and emphatic jerk to the right, then turn as quickly toward the left, where it would remain a minute, then as quickly be jerked back into the normal position. Here it would remain for about ten minutes, generally, though sometimes it would rotate back in a minute or two, and go over the same routine again; keeping up a constant succession of these motions. She was compelled to wear a leather collar buckled tightly around the neck, embracing the face up to the ears, and fastened with a strap under her arms to keep her head in position. But even with this appliance the muscles were in a state of clonic spasm most of the time, unless under the influence of a powerful opiate, which she was compelled to take at night in order to obtain any rest at all. Her treatment had been varied, prompted by all sorts of theories as to the origin of the trouble, but the bene-

fit had been slight, and only temporary at the most. As this period antedated the day of hysterectomy, and ovariectomy was almost unknown, her womb and ovaries were not removed. No definite cause had been assigned. I had the advantages accruing from the experiments of those who had attempted a cure in her case; and it certainly abridged whatever experimenting I might otherwise have done. She had her own teeth, but upon examination it was shown that although few were missing, nearly every one was more or less in a state of decay; still, as they had never troubled her to any great extent it was not surprising that as a cause of her trouble they had been overlooked. Examination then determined me to act upon the decidedly strong suggestion which their appearance seemed to offer. I extracted all of her teeth, gave a mouth-wash of a 1 per cent. solution of potassæ chlorate, and internally, .07 (1 grain) of sulphate of zinc in two ounces of water, after every meal. In less than one week, or as soon as the soreness had subsided, a great improvement became apparent. She continued the treatment for three weeks, at which time the gums had completely healed; the clonic spasms had nearly disappeared, and in three months from the time her teeth were removed she was perfectly well, and there was no relapse. There is no question as to the cause being anything else than reflex irritation from the decayed teeth.

*Case 3.*—Mrs. S., aged 25, had spasmodic torticollis dating from birth of child, six years previous. She had been under treatment of specialists at different times for months together. The patient seemed to be well nourished, and all the organic functions normal. The bowels were regular, no indigestion, no headache, no spinal irritation, no laceration of uterus or perineum, and appetite good. I gave a pill composed of zinc sulphate .07 (1 grain), extract of valerian .12 (2 grains). One to be taken after every meal. A poultice of mustard, ginger, cayenne pepper, cinnamon and cloves was applied to all of the back, behind the ears, over the chest and throat the greater part of the day; keeping it on one spot sufficiently long to irritate the part, then removing it to another, the object being to keep every inch of the skin in a constant state of irritation, from the first dorsal vertebra upward and the same region in front. The poultice was mixed with cold water. Improvement commenced after the treatment had been in operation for two weeks, and at the end of four months the patient was well. There was no assignable cause for this case, and I would not have been surprised to see a relapse, as a result of cold or exposure; but the cure remained complete.

*Case 4.*—At the risk of repetition I now present another case to further illustrate what decayed and decaying teeth will do for a person of nervous temperament (or any other temperament, as for that); as such apparently simple causes are generally overlooked; and, again, to show that it is not always necessary that the process of decay should have advanced to any very perceptible degree in order to produce the mischief. This was a case of trigeminal neuralgia of three years' standing, in a woman of 28, and had resisted every means employed by competent physicians. The teeth were apparently all sound, and she had her full complement; but they were quite crowded, owing to size. From some seemingly trivial indications, but which from previous experience I considered to be fraught with meaning, I ordered their extraction. The mouth was washed with a 1 per cent. solution of potassæ chlorate every two hours. The neuralgic condition began at once to disappear, and in three weeks she was well. No relapse. This shows what may be brought by sound teeth when they press upon the terminal nerves.

*Case 5.*—Another case in the same category will, I trust, be sufficient for my purpose. This was a case of facial paralysis with partial paralysis of the left arm, cured by extraction of all the teeth in both upper and lower jaw. They were nearly all carious. The paralysis was caused by reflex irritation from the carious teeth.

*Case 6.*—Mr. W. S., aged 25; a drummer for a silverware manufactory. Family history good; no symptoms of gout, rheumatism, or tuberculosis on either side of the house. He had never had any illness, and habits were good; organic functions all perfect. After riding several hours on a hot, dusty day, and sneezing a great deal from irritation caused by the dust on the mucous membrane of the nose, he began having slight contraction of the scaleni muscles. He paid little attention to it for several months, when it became very annoying; he then applied to a physician for relief. He was given some sort of stimulating liniment, and anti-rheumatic remedies; these he used for several weeks, but without any appreciable benefit. He then took a two months' course of massage. After this he tried faradic, galvanic, and static electricity for several weeks, but the spasms still continued unabated. When I first saw him he had been experimenting for over a year. It

seemed that as the various new-fangled fads etc., had all been tried: there was little left to be employed but good judgment and common sense. The only treatment I gave—as his general health seemed to be perfect—was a hot shower bath night and morning, fifteen minutes at a time on the neck and shoulders. This treatment brought about the most brilliant results, and at the end of six weeks he was perfectly free from trouble, and there has been no relapse.

Case 7.—Mr. J. L. W., aged 38, a banker, had been ill with spasmodic torticollis for two years. He had been under numerous forms of treatment, and particularly the celebrated mud baths. This was quite a unique case in one respect, viz.: A part of the time the trouble would be confined to one side exclusively for two and three weeks, when it would turn to the other side for the same period, leaving the previously affected side apparently as well as ever it was.

I began treatment by giving hypodermically one drop of the following solution:

R. Aurii et sodii chloridi . . . . .	1 gr.	07
Sodii arsenias . . . . .	1 gr.	07
Sodii bromidi . . . . .	3 grs.	19
Aqua dest. . . . .	1 oz.	3100

Mix.

Injecting five drops of this into the belly of the muscles twice a day in rotation; going over the same muscle on each side, beginning, for instance, at the origin of the muscle and gradually going over its whole length, then taking up another in the same way. The strictest antiseptic precaution was observed. He had considerable brachial neuralgia; otherwise was free from pain. No inflammation or abscess was ever produced by these injections, and but slight pain. This treatment was continued with great regularity for five weeks; the improvement was gradual, but even and permanent, and resulted in a complete cure, without any recurrence at the end of fifteen months.

Case 8.—J. B., a boy aged 9 years, was playing "leap frog" when by accident he was kicked in the neck; but from all appearance he was not particularly injured, and made no complaint until about two weeks afterward, when his head began to twitch backward, yet so slightly that it was hardly noticeable: but in the course of several weeks it became a continual cause of complaint. He was under treatment for six months with various mixtures of liniments, ointments, oils, plasters, electricity, etc., previous to my seeing him; but they had produced no perceptible benefit. Stomach and bowels in good condition, urine normal. I applied the following ointment to his neck:

R. Aurii et sodii chloridi . . . . .	5 grs.	32
Ammonii hydrochloras . . . . .	10 grs.	64
Aqua, well rubbed in . . . . .	1 drm.	400
Adipis benzoas. . . . .	1 oz.	3100

Mix, and apply about ten grains three times daily.

R. Ammonii hydrochloras . . . . . grs. v. 32

To be taken every three hours in a wineglass of water.

This treatment was continued for six weeks with marked improvement. Then ammonia hypophosphite was substituted for the hydrochlorate, in three grain doses for two weeks. Considering the severity of the case his recovery was unusually expeditious, a cure being effected in six weeks.

Case 9.—H. M., a man of 76 years. This man had been employed in a granary for ten years; previous to that he had been in a brewery, and I think there was reason for supposing his blood had become contaminated by micrococci from diseased grain. His face was bloated, and he was always more or less asthmatic. Aside from this, there was a red blotch over his hands and arms. He complained of constant pain in the region of neck and shoulders; the brachial region was the nervous part affected. Soor after first seeing him he was exposed to a severe March storm, and aside from the wetting he was chilled. Driving all day had strained this part of the muscular system, and when I saw him that night I found a condition of acute muscular rheumatism, as one would naturally expect. Proper treatment removed the acute symptoms, but in their place was established, right before my eyes, as it were, a decided case of bilateral torticollis, implicating the whole brachial region (as had the previous attack of rheumatism, which had been removed apparently to give place to this condition). His sufferings were intense; not for one moment during the twenty-four hours was he permitted to rest, save when under the temporary influence of powerful anodynes. In addition to this a persistent cough set in; his breathing became very labored, showing, to my mind, a complication of the phrenic nerve, to which might be traced the spasmodic condition of the cervical plexus. The treatment was the following:

R. Fl. ext. cimicifugæ . . . . .	
Tr. gelsemii . . . . .	
Tr. guaiaci . . . . .	āā gtt. x. 65

Mix.

The above amount to be given every three hours in a wine-glass of milk. Hypodermic injections of hot water, to which .65 (grains x) of salt were added, were made every day into the clavicular origin of the sterno-cleido-mastoid muscles of both sides. This course of treatment was continued every day for two weeks, with marked improvement. After that time the injections were discontinued, but the internal treatment was kept up for three months, and at the end of that time there was no further medicine required for he was perfectly well.

Case 10.—Thomas W., a sober, working man of 45, was suddenly leveled to the ground and rendered unconscious by some means then unknown to him, one night in December, 1894. (It was afterward shown that he was struck by a sandbag.) Consciousness returned after about forty-eight hours, but with it the inability to move his head. Constant pain was felt in the occiput and down the back and sides of the neck, extending by flashes down his arms to the elbows, with numbness of the finger-ends. Upon being lifted in bed he was seized with spasms which twisted his head from one side to the other in quick rotation, then backward over the scapula, with such force that it seemed his neck would be broken. This condition lasted for twenty-four hours, when the patient became unconscious from exhaustion. There must have been some irritating lesion of the spinal cord, extending to the cortical substance of the brain, and the question might be raised whether this was a case of torticollis proper, or of spasms caused by injury to the brain. The pulse and temperature were normal throughout. I gave 4.00 (1 dram) of liquor ammonii acetatis with .65 (10 drops) of tinct. gelsemium every three hours. Hot compresses to the occipital and cervical regions were constantly applied. In about five hours the spasms were very decidedly abated, and in the course of a couple of weeks the pains had all ceased; but there was still to be noticed a tendency to spasmodic contraction of the muscles. I ordered tincture of lobelia be rubbed on the parts, and had him take .32 (5 drops) of the same every three hours. This seemed to act so nicely that in the course of a week the spasmodic tendency had disappeared; but I continued the treatment one week longer, so as to ensure a perfect recovery.

In conclusion, I will copy the following case from one reported in my paper, on "Nerve Vibration and Excitation," as read in the Section on Practical Medicine, Materia Medica and Therapeutics, at the thirty-sixth annual meeting of the AMERICAN MEDICAL ASSOCIATION, held in New Orleans, La., April 29, 1885:

A married woman, aged 29; of extremely nervous temperament, and suffering from mental trouble brought on by death of a child. Electricity had been applied by a competent person, but this seemed only to aggravate the case. The muscles of the right side were affected. This condition had existed for several months. Not only the sterno-mastoid, but the deeper groups of muscles were involved. As the motor filaments of the pharyngeal branches of the pneumogastric are derived from the spinal accessory, I directed my treatment to the base of the occipital bone, across to the upper part of the sterno-mastoid, following the course of the nerve as closely as possible.

The treatments were daily, and of fifteen minutes duration. The percuteur was firmly held against the surface, though not pressed down, so that the whole force of the blow might be obtained. Eight cells of the battery were employed, and I used the olive-pointed hammer, tracing the course of the nerve upward and downward, and over the clavicular portion of the trapezius muscle. At the end of the first sitting the muscles of the neck were a trifle relaxed, the patient being able to turn her head slightly; but the next day found the old condition almost reinstated. However on going over the same treatment I found the improvement still more marked than that of the day previous, and, to cut a long story short, the condition steadily improved under every treatment, the deterioration between times being less noticeable. At the end of three weeks the patient presented no signs

of wryneck, and the corresponding muscles of the other side had regained their normal condition. varied the treatment somewhat, as the case progressed, by passing the hammer down either side of the spinous processes, pausing a moment at each. The entire cerebro spinal nervous system seemed to respond favorably to this treatment, and the result was complete restoration to health, and no inclination to return of the torticollis, so far.

This patient had already gone through the usual list of nerve remedies. I ordered that all accessory treatment should be stopped, save good nourishing food, pleasant surroundings, and all other necessary and proper hygienic conditions.

While it is patent to the practical physician that in the treatment of disease in general there can be no prearranged method which shall be applied with positive certainty to all cases, the routine of treatment fitting the condition as surely as a certain size of glove will fit a correspondingly sized hand, this uncertainty is still yet more apparent when we have to deal with diseases of the peripheral nervous system, and is most plainly illustrated in wryneck. I have seen many cases in which treatment has been a complete failure; cases which had been submitted to braces and various complicated devices; but they were used without accomplishing the desired result. The surgeon's knife has also been powerless to help. Nor am I alone in my experience and consequent conclusions. Physicians of wide repute and acknowledged skill corroborate my opinion. Dr. A. McLane Hamilton says on the subject: Braces and apparatus are often worse than useless, increasing not only the patient's discomfort, but aggravating the malady. This opinion is also expressed by Dr. James Ross, Dr. M. Rosenthal, Dr. Gower, and many other acknowledged authorities. Professor Erb, in speaking of the various devices, and surgical operations says: The division of the nerve is an objectionable proceeding, partly on account of the resulting paralysis, and partly because it has been tried and has failed in effecting a cure, and has increased the spasms with unabated violence.

Dr. C. M. Barr says: Instruments intended to forcibly check the spasms can not be worn any length of time. . . they do no good. I have in my own practice seen ten cases that have had various operations performed on the nerves and muscles, and the result has been the reverse of successful, in fact, disastrous.

I have collected statistics from many sources, amounting to between four hundred and five hundred cases in which surgical operations in one way and another have been performed in torticollis, without deriving the slightest benefit therefrom; in fact the conditions were worse than before the operation.

#### THE FREQUENT DEPENDENCE OF INSOMNIA, MENTAL DEPRESSION AND OTHER NEURASTHENIC SYMPTOMS UPON DISEASE OF THE GASTRO-INTESTINAL TRACT.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY BOARDMAN REED, M.D.

ATLANTIC CITY, N. J.

The group of nerve derangements formerly classed under the terms nervous exhaustion and nervous pros-

tration, and of late more appropriately labeled neurasthenia, is after all a rather vague and indeterminate entity. It has not yet any recognized pathology, and even its etiology is still in dispute. There are not wanting authors, now, who insist that neurasthenia is only another name for toxemia, and that the ptomaines and leucomaines absorbed from an infected or diseased alimentary canal are responsible for all the symptoms which it has so long been the fashion to ascribe to mental overstrain, sexual excesses or other prodigal waste of the vital and nerve forces.

Still others believe that too much food and too little exercise—too much alimentation and not enough oxygenation—cause an overcharging of the blood with uric acid, as well as other products of suboxidation, and that hence arise all or most of these nerve ills which, as is well known, afflict chiefly persons who live a luxurious, or at least a sedentary life, being relatively uncommon among those who use their muscles largely, while they eat and drink abstemiously. Haig,<sup>1</sup> the great exponent of the uric acid theory, believes that butchers' meat, especially when taken in excess, is the most active cause, and he brings forward a very strong array of evidence in proof of his views; but it is probable that he goes too far.

My own belief is, that while any of the various influences just recited may, even singly and alone, produce, under certain conditions, some of the forms or manifestations of neurasthenia, especially in persons who have inherited a tendency thereto, a number of them have usually combined to develop the more aggravated types. Granted, that there are always predisposing conditions, it must now be admitted that the rôle of the indigestions and other morbid states of the alimentary tract, is most important in the causation of these nerve ills. It is an every day observation of physicians who have much to do with nervous patients that their well-being and comfort depend largely upon the condition of their stomachs and bowels.

To give this discussion a more definite and practical character, it will be best to consider here a few of the more marked and familiar symptoms of neurasthenia, rather than that elusive entity as a whole. Let us take, for instance, the mental depression, nervous erethism and insomnia, some one or all of which may always be observed in the severer cases. In the hundreds of neurasthenics who have annually come under my care in that Mecca of American invalids, Atlantic City, the symptoms just named have usually been the most pronounced and troublesome.

They may arise as a result of any of the graver forms of gastro-intestinal disease, such as cancer, gastric ulcer, chronic gastritis and dilatation of the stomach, through the lowered nutrition which such affections induce. Whether this be brought about directly as a result of a starving of the nerve centers, the blood which nourishes them having itself become impoverished, or whether the poisoning primarily of the blood and secondarily of all the tissues, by products of the fermentation, putrefaction and sub-oxidation which such diseases of the alimentary canal greatly promote, is a question which need not be entered upon here. My object in this paper is the more practical one of emphasizing the importance of the part played by stomach and intestinal diseases in a large and most important class of nervous affections.

Cancer and ulcer are apt to be recognized and to receive special attention at a comparatively early stage

of their progress, on account of the pain and frequent vomiting which they usually evoke. Gastric catarrh, however, is unfortunately often allowed to proceed to a late and serious stage before it is diagnosed and the proper treatment begun; while atony and dilatation of the stomach, when only moderate in degree, are very generally overlooked, except by the specialist. This is much to be regretted, since, while generally curable, or at least capable of great amelioration, in the beginning, they are very intractable, as well as sadly afflicting, in their more advanced stages. Moreover, there is no reason now, why every practitioner who is fairly adept in the art of percussion, should not be able to recognize them even without the use of a tube or other intra-gastric instrumentation. A method of establishing the diagnosis in such cases, as well as in the various forms and degrees of gastrop-tosis, or stomach displacement, by external examination, has been described by me in a previous contribution.<sup>2</sup>

Constipation and its immediate sequelæ have disastrous and far reaching effects in causing disturbances of the nervous system, among which the neurasthenic symptoms now under consideration are prominent. This would of itself furnish abundant material for a separate paper, and can only be mentioned here in passing, though it will be referred to again under the head of acid dyspepsia, which is one of the conditions upon which it most frequently depends.

The so-called gastric neuroses, that is, on the one hand, a diminished secretion of hydrochloric acid with or without a decrease of the other constituents of the normal gastric juice, and on the other hand, an excessive secretion of hydrochloric acid, along with usually a hypersecretion of the digestive ferments as well, are also of importance in this connection.

The former condition is admittedly very infrequent in comparison with the latter. Diminished or absent secretion of the gastric juice, especially of its acid constituent, is constantly found as a result of advanced gastric catarrh. It means, then, an organic and virtually incurable disease, though by the proper administration of the acid and pepsin artificially, much can be done in such cases toward compensating for the defect. It is possible that in many cases in which the absence of hydrochloric acid has been observed for short intervals, alternating with periods of excess of the same acid, such absence has been the result of the prolonged and free administration of alkalies, either in substance or in the form of the Carlsbad and other mineral waters which are very rich in the soda salts. These salts, too long given, are known to have such an effect.

It so happens that in a large number of chemie examinations of the stomach contents, I have rarely ever found an absence of free hydrochloric acid, without either a coincident gastric catarrh or cancer. Two notable exceptions were one case of sea-sickness and one of brain tumor.

It was an early observation of mine that neurasthenic patients, while they generally craved nervines and narcotics, and had sometimes taken too much of them before going to the seashore, rarely made any permanent favorable progress as a result of the administration of such drugs, and that, on the other hand, they often gained remarkably in nerve tone and in the ability to obtain sound and refreshing sleep after having been put on a restricted diet together with calomel, even in the smallest doses, to correct a furred

tongue and remove the congeries of symptoms popularly known as biliousness. Hydrochloric acid given with the same purpose, often brought about the same wonderful improvement in their sleep and mental condition. The appetite and digestion were helped at the same time, and following up the treatment with such nerve tonics as iron, strychnin and the phosphates or hypophosphites, often assisted in making very gratifying cures.

A series of such favorable cases, in which insomnia and the associated nervous phenomena were very promptly relieved by the administration of hydrochloric acid, awakened hopes that an unfailing remedy had been discovered for all that class of ailments. Then came a number of cases in which hydrochloric acid not only gave no relief whatever, but even seemed to aggravate the trouble. Not being familiar at that time with the vagaries of the gastric secretion and their intimate connection with deranged intestinal peristalsis, autointoxication, uricacidemia and other abnormalities of digestion and assimilation, I was wholly at a loss to explain these diverse effects of the same drug in the same doses, upon patients suffering from apparently identical symptoms.

But we all know now that very often there is an excess of hydrochloric acid in the gastric juice. This is true not only in many cases of manifest and clearly recognized disturbance of stomach function, especially those in which pains or marked discomfort after eating are the chief symptoms, along with constipation as a rule, but also in the cases of nervous patients who claim to have good digestion and insist that they can eat anything. The latter may have large appetites, often amounting to bulimia, and though they suffer from intestinal flatulence, emphatically object to being considered dyspeptics.

The German writers call this form of disordered secretion hyperacidity, and the French term it hyperchlorhydria. English authors have described it under the name of acid dyspepsia. The administration of hydrochloric acid in the usual manner after meals in this affection, can scarcely fail to increase still further the amount of acid in the already too acid chyme about passing on into the bowel, where it is destined to work all manner of mischief, inhibiting or greatly diminishing the activity of the pancreatic and intestinal ferments, and probably provoking such a spastic condition of the peristaltic apparatus as to bring about the constipation which is so constant an accompaniment of hyperacidity. The interference with intestinal digestion favors the development of the fermentation and putrefaction which are the plague of patients thus afflicted. The poisonous products thus engendered not only absorb directly into the blood, causing anemia, with disastrous effects as well to the nerve centers and many other structures, but also the gaseous portion of them over-distends the intestines, exciting colics, or at least sleep-disturbing pains, besides, when allowed to go on long enough, so paralyzing the muscular coats of the bowel and permanently dilating the tube as to render the constipation very difficult if not impossible to cure.

My note books show that a very large preponderance of the nervous patients who have come under my care and whose cases seemed serious enough to warrant the analysis of their stomach contents, after the usual Ewald test breakfast, were found to have an excess of hydrochloric acid.

By its great relative frequency, its insidiousness

and often unsuspected beginnings, and its serious results when not actively combatted, hyperacidity is probably the cause, directly and indirectly, of more nervous derangements and ill health generally, than any other one disease of the gastro-intestinal tract. Hence this form of indigestion merits here a somewhat more detailed consideration.

When the gastric juice contains an excess of hydrochloric acid, the first symptom ordinarily observed, apart from gastric pain or discomfort, which may or may not be present, is usually constipation. My notes show that this is almost constant and proportioned in degree to the amount of the hyperacidity, though very exceptionally I have observed cases in which the bowel movements were regular or even excessive. In seeking for a rational explanation of the manner in which constipation is caused in these cases, I have been led by a large number of observed facts to infer that in the earlier stages of the affection the superacid stomach contents, as already intimated, often excite contractions of an irregular or spastic character in the muscular coats of the bowels, thus interfering with the normal peristaltic action. By careful palpation one can often feel contracted portions of intestine as hard cords under the fingers. Experienced masseurs sometimes report the same observation to me in these cases of hyperacidity. Such patients usually do not respond well to the ordinary purgatives, and even the milder laxatives, unless combined with alkalis, as in the popular aperient waters, are apt to produce unsatisfactory results with much griping pain. Rough massage with the usual exciting accompaniments of slapping, percussion, etc., often fails to effect any good results, while neutralizing the acidity by substantial doses of alkalis given one or two hours after meals, with the help of mild galvanic treatment and gentle rubbing and kneading of the abdomen, often overcomes the constipation without the administration of any laxative medicines whatever.

Left to itself, or wrongly treated, this constipation of hyperacidity causes intestinal flatulency, retention and absorption of the various products of fermentation and putrefaction, with a resulting endless chain of nervous derangements and other morbid effects. The autointoxication thus originated may provoke not only insomnia, mental depression and many other functional disturbances, but also, according to Bouchard<sup>3</sup> and his followers, various other diseases as well.

Pressure of the fecal masses upon the lower abdominal and pelvic nerve plexuses, as well as, in the case of women, upon the ovaries, probably effects a more direct injury in many cases, and is at least the cause of numerous reflex symptoms. Hyperacidity is the nearly constant accompaniment of gastric ulcer, and is doubtless a factor in its causation. It also tends to develop in time, if severe and uncontrolled by treatment, the serious condition known as Reichmann's disease, or a continuous hypersecretion of the gastric juice, as well as ultimately the still worse state of marked dilatation of the stomach.

Recent experiments by Turck,<sup>4</sup> of Chicago, demonstrate that in at least that form of acute gastritis which can be set up artificially in animals, there is constantly found an excess of hydrochloric acid during the earlier stages of the morbid process. Boas<sup>5</sup> and some of the other recent German authors now admit the existence of an acid gastritis which they look upon as a separate and exceptional form of inflammation of the stomach; but it is a question

whether, in view of Turck's observations and the analogies afforded by catarrhal processes in other organs, this form does not constantly precede the more familiar atrophic type of chronic gastritis.

It might be inferred with considerable plausibility that hyperchlorhydria is only the congestive stage of acid gastritis and the earliest stage of chronic gastritis glandularis; and possibly this may be true. But, unquestionably, such a hyperemic condition of the gastric mucous membrane with excessive secretion, may exist temporarily as a result of the generally hyperesthetic state of the nerve centers and many of the nerve endings so frequently observed in the worst forms of neurasthenia.

Hyperacidity of the gastric juice merits especial consideration in this connection for the further reason that some of the methods of treatment which are most in vogue in cases of insomnia, mental depression, etc., tend directly to increase the secretion of the hydrochloric acid and thus in the end to aggravate the malady. Thus, the tonics and stimulants which are almost universally prescribed as a matter of routine in neurasthenia, are probably all or nearly all excitants of gastric secretion, and therefore when the nervous affection is either dependent upon, or complicated with, hyperacidity, the result must often be disappointing. Mathieu<sup>6</sup> asserts very positively that alcoholic liquors, spices and condiments of all kinds, and such drugs as the iodids, bromids, ferruginous salts and the mineral and organic acids, all excite an increased secretion of hydrochloric acid. It is more than probable that strychnin, phosphorus, arsenic and the other metals in their usual therapeutic doses, have the same effect. In regard to several of these, I have myself noted in numerous cases an increase of hyperacidity while they were being administered.

For the determination of the amount of hydrochloric acid in the gastric juice there has not yet been discovered any reliable method except the quantitative chemic analysis of a definite number of cubic centimeters of a sample of the stomach contents obtained at a certain interval after a test meal, usually one hour after the Ewald test breakfast, which consists of two ounces of bread and a half pint of either water or weak tea. In Germany especially, many elaborate experiments have been made with the view of finding some fixed relation between the acidity of the urine at different times of the day and the proportion of hydrochloric acid in the gastric juice, but so far with only partial success. Both Boas<sup>7</sup> and Riegel<sup>8</sup> quote the experiments of Quincke, Sticker and Hüber in this direction, but do not consider the claim established that the relation is sufficiently constant to be a safe guide. I have tested the matter in a number of cases and found the results too varying to be reliable.

Chemic and microscopic examinations of the stomach contents need to be made also at times during the treatment of hyperchlorhydria to note the results. It is especially important during the administration of large doses of alkalis (which have proved one of the most effective means of relieving as well as curing this affection), to watch the results very carefully. It is well also to test the urine frequently to see that it does not become entirely alkaline, and even to make an occasional microscopic examination of the blood, since a too prolonged or vigorous pushing of even the milder alkaline salts is capable of doing harm.

But the treatment of either neurasthenia or any of

the digestive disorders with which it is so generally associated, forms no part of the scope of this paper. My purpose will have been fully accomplished if the suggestions already offered shall lead to a fuller recognition, in our every day work, of the intimate connection existing between the functional nervous affections and diseased conditions in the alimentary canal, as well as show the great practical importance of a more exact study of the latter by the recent scientific methods.

### THE RELATION OF ASCITES TO DISEASES OF THE KIDNEYS, AND PARACENTESIS ABDOMINALIS AS A REMEDY.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY W. F. McNUTT, M.D.

SAN FRANCISCO, CAL.

The accumulation of fluid in the abdominal cavity with or without dropsy was recognized by the earliest medical writers. Hippocrates was, from his many references to the subject, evidently familiar with dropsy and the accumulation of fluid into the serous sacs. Erasistratus's master, Chrysippus, must have been a contemporary of Hippocrates. According to Galen this famous physician, Erasistratus wrote a work on dropsy and taught that all varieties depended upon obstruction of the liver. Galen himself taught that diseases of other organs might also be responsible for dropsical effusions, and that they not infrequently had their origin in the morbid state of the blood. Aesclepiades, who seems to have been a voluminous writer, according to what can be gathered of his views from Celsus and Galen, divided all dropsies into acute and chronic, not designating the particular viscera whose disease caused the dropsy. Probably Avicenna in his "Canon Medicinæ," is the first to include disease of the kidneys as a cause of dropsy. It is questionable whether he (from postmortem examinations) had a definite knowledge of the connection between pathologic conditions of the kidneys and dropsy. He makes the statement, however, that the kidneys from the induration of their structure fail to separate urine, hence dropsy. We have no knowledge as to what means he had for diagnosing diseases of the kidneys. While many writers since the days of Willis have been particularly interested in dropsy and effusions, it is quite safe to say that before Dr. Bright's time the relation between diseases of the kidneys and dropsy with effusion into the serous cavities was very vague. Scattered through the literature of dropsy one finds a reference here and there to disease of the kidneys as a cause, but from the vague language of the writer it is easy to see he had no definite knowledge of the relations. Hippocrates says: "The most of them [dropsies] commence from the flanks and loins, but some from the liver; in those which derive their ori-

gin from the flanks and loins the feet swell, protracted diarrheas supervene, which neither remove the pains in the flanks and loins nor soften the belly." Adams thinks: "Hippocrates refers one species of dropsy to disease of the parts situated in the loins, by which Galen and Stephanus agree that he means the jejunum, mesaraic veins and kidneys." Ægeneta says: "For the most part it [ascites] arises from hardness and scirrhus about the spleen and liver and from chronic defluxions about the intestines." Aretæus says: "Dropsy is sometimes occasioned suddenly by a copious cold draught, when on account of thirst, much cold water is swallowed and the fluid is transferred to the peritoneum; by which means the innate heat in the cavities is congealed, and then the dropsies which formerly were converted into air and dissipated, flow into the cavities." Aretæus no doubt diagnosed ovarian tumors as ascities. "This other form of dropsy is known. Small and numerous bladders, full of fluid, are contained in the place where ascites is found; but they also float in a copious fluid, of which this is a proof; for if you perforate the abdomen so as to evacuate the fluid, after a small discharge of the fluid, a bladder within will block up the passage; but if you push the instrument farther in, the discharge will be renewed. This species then is not of a mild character, for there is no ready passage by which the bladders might escape. It is said, however, that in certain cases such bladders have come out by the bowels. I have never seen such a case, and therefore write nothing of them; for I am unable to tell whether the discharge be from the colon or the stomach." To Bright, more than to any other writer, are we indebted for the establishment of the relations between the diseases of the kidneys and dropsy. He described the structural lesions of the kidneys that give albuminous urine. Every writer and practitioner now recognizes the important part that diseases of the kidneys play in dropsy and the frequency of effusion into the serous sacs in cases of renal anasarca. No writer, however, seems to have given the proportional frequency of ascites, hydropericardium and hydrothorax in renal dropsy. No one is surprised to find ascites developing in hepatic or right heart obstructions or in peritonitis or cancer of any abdominal organ for instance, but in the absence of any of these conditions, why should ascites occur in renal lesions more frequently than does hydrothorax or hydropericardium; yet the daily experience of every practitioner finds it to be the fact. In renal diseases, barring the inflammations, pleuritis, pericarditis, arachnitis and peritonitis, we find effusions into the abdominal cavities much more often than into any of the other cavities; to be sure, in some cases of ascites with Bright's there may also be an indurated or nutmeg liver or a chronic peritonitis which a postmortem would be necessary to reveal. The heart in the following case is normal and there is not an indication of disturbance of the liver.

The patient, a man of 58, blonde, family history good, rather muscular, temperate habits, but has had a life of exposure, first in the United States army as a young man during the late unpleasant episode in our history, and since as a mining prospector and owner. By the aid of his wife and a friend he was brought to this city, thinking, as he expressed it, there might be another straw to grasp at. When I saw him last, September 30, there was an extreme anasarca, great abdominal distention from ascitic

fluid, the most distressing dyspnea, respiration fifty-five, pulse feeble and very rapid, face cyanosed, headache and vomiting. Urine, twenty-five ounces per day, light colored, 1012 specific gravity and coagulated almost solid in test tube; epithelial and granular casts; he weighed 185 pounds on the hotel scales. It seemed scarcely possible that the man could live many days. I returned to my office and got a trocar, put him on the bed on his side, well braced up, as he could not lie down, put a Kelly pad under him and tapped him. The trocar remained in for several hours and the fluid continued to run from the opening for three days, when it ceased, by which time the anasarca had disappeared and the patient weighed 130 pounds, having lost fifty-five pounds in the three and one-half days. The abdomen soon commenced refilling, and on October 15 he was again tapped, draining off the fluid, eight quarts. It promptly collected again, and on the 20th we obtained six and one-half quarts. From this time he began to improve in strength and the urine increased to forty ounces, and for a few days to seventy. The fluid was again collecting, but more slowly this time, November 19 we again tapped him, this time getting eight and one-half quarts; by the 27th he was again quite distended and was again tapped; the canula was left in thirty-six hours, during which time we collected thirteen quarts of ascitic fluid. December 10, I tapped him again, not leaving the canula in this time, and taking off six and one-half quarts; eight days afterward, viz.: December 8 it was necessary to tap him again; the canula was left in forty-eight hours and fluid escaped from the opening twenty-four hours more, most of it was conducted into a bucket by the Kelly pad; we collected eighteen quarts and the bed clothes were several times saturated. It is safe to say that in those three days twenty quarts of fluid escaped from the abdominal cavity. December 22 we drew off eight quarts. By January 8 it was again necessary to tap him; left the trocar in four days and collected thirteen quarts, and on the 28th we got four quarts; February 10 I drew off four quarts. I have not been able to find an explanation in any of our pathologies of this morbid propensity of the peritoneum in Bright's. In this individual case the peritoneum poured out 506 fluid ounces from December 1 to December 8, eight days; over two and one-half ounces per hour; and no discoverable obstruction to the portal circulation, and no effusion into any of the other serous cavities. It scarcely seems possible that we could have obstructions to the portal circulation sufficient to produce or assist in producing ascites and that the urine should be light in color and of light specific gravity. In order to make ourselves believe that we understood this form of ascites and anasarca we call it hydremic, which conveys about as much exact knowledge of this morbid process as that convenient word, idiopathic, gives us in regard to the real cause of the disease. Never having been able to find any satisfactory explanation of this renal ascites and why it occurs so much more frequently than hydrothorax and hydropericardium, I have watched this case with a great deal of interest. No doubt the hydremic condition of the blood and the nutritive disturbance of the capillaries are factors in renal dropsy, but only secondary factors, the primary factor is mechanical, though not in the same sense as in obstruction of the heart and liver. The peritoneum in Bright's pours out fluid more often than does the pleura or pericardium,

because it is more pendent, it requires more arterial force to drive the blood through the capillaries of the peritoneum into the veins than through the capillaries of the pleura or pericardium. The abdominal veins are numerous and without valves, and edema into the abdominal walls seems to obstruct the venous circulation. When a dropsical patient sits up all day his feet are greatly swollen at night owing to their pendent position; after remaining in bed all night the swelling has disappeared by the morning. The patient is hydremic, but the fact that swelling occurred during the day when the feet were pendent and disappeared when the patient was in a horizontal position shows that this form of dropsy, too, is primarily at least, mechanical. With hydroperitoneum and perhaps with all dropsies there are two mechanical factors, the one as we have seen, pendent—gravity; the other is compression. No sooner has the blood serum escaped from the distended, weakened capillaries and veins than its accumulation in the lymph spaces outside the capillaries faster than it can be taken up by the lymphatics compresses the capillaries and offers mechanical resistance to the passage of the blood into the veins. In this case I noticed that as soon as the abdominal walls would become edematous the accumulation of fluid in the cavity was rapid. After the tapping of January 8 I packed the abdomen with hot applications of alcohol and water and bandaged, making quite a little compression. I thought by supporting the abdominal walls by bandage and stimulating the blood vessels by alcoholic stupes we might prevent the rapid pouring out of fluid by the mural peritoneum. It will be noticed in the next twenty days, only four quarts of fluid were obtained by the tapping of the 28th and from the 28th to February 10 we had only four quarts. During all the time the urine averaged about forty ounces with from 1 to 2 per cent. of albumin, and about two hundred grains of urea daily. The ascitic fluid usually contained about one-half of 1 per cent. of albumin. Since the first tapping, when the patient lost fifty-five pounds in the three and one-half days, we have taken by the various tappings sixty-eight quarts, 136 pounds, which added to the 55 pounds makes 191 pounds. From September 30 to February 10, 132 days, or 3,168 hours, the 191 pounds is 3,058 ounces, almost an ounce an hour. The patient has not been tapped since February 10, is still weak (April 10) but much better than he was before the first tapping. His diet has been largely milk and a prescription of carbonate of iron and sulphur is the only medicine that seems to agree with his stomach or to be of use to him. He always feels better while taking this prescription and the urine falls off when it is stopped. Too frequently, tapping is resorted to by many practitioners as a last resort; to my mind and in my experience it is the most important remedial measure we possess in these cases of renal ascites and anasarca, stimulating stupes and bandaging and gentle friction and massage are remedies for the prevention of the accumulation of ascitic fluids in Bright's disease. In this case the fact that the patient is living is owing entirely to tapping. He could not have lived many days in the condition in which I found him, nor would it have been possible to relieve him by cathartic medicine. There is still nearly 1 per cent. albumin in the urine, but it is not impossible for the kidneys to recover. In one case of cirrhosis of the liver, in which I was called in consultation, with the idea that tapping

ought to be done as a last resort to prolonging life, after repeated tapplings collateral circulation was established and the patient lived three years. Paulus evidently approved of tapping and gives explicit directions as follows: "And it having been there shown that ascites alone falls under the province of surgery, we are now going to give an account of it. Wherefore we must make the patient stand erect, or if that can not be done, we must cause him to be seated, or if he is so weak that this can not be done, we must abandon the operation entirely. If then the man be standing erect we give orders to the assistants standing behind to press with their hands and push downward the swelling to the pubes. Then taking a sharp-pointed knife or lancet, if the dropsy is among the intestines, in the perpendicular line of the navel, and about three fingers' breadth distance from it we divide the hypogastrium as far as the peritoneum. But if the liver be primarily affected we must make our incision on the left side of the navel, or if the spleen, on the right, for we must not make an incision in that part on which the patient is disposed to lie. And having dissected with the point of the instrument the skin that lies over it, we divide the peritoneum a little above the first incision until the instrument comes to an empty space. After this we introduce through the incision of the abdomen and peritoneum a copper tube, having an opening like those of writing pens, and by this we must abstract the fluid in proportion to the strength; feeling the pulse and then removing the tube, we stop the flow of fluid (for it will stop immediately from the alteration of the incision) and, for the sake of security, we introduce a twisted tent into the incision of the abdominal parietes alone; and having placed the man in a recumbent posture and recruited him, we may next day again evacuate through the tube a small quantity of fluid proportionate to his strength; and thus in like manner, until very little be left, avoiding by all means a sudden evacuation, for some ignorant persons having evacuated the vital spirit with the fluid have immediately killed the patient."

## REPORT OF A CASE OF CHRONIC TUBERCULOUS PERITONITIS

WITH REMARKS ON DIAGNOSIS AND TREATMENT OF THE DISEASE.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY H. W. McLAUTHLIN, M.D.

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF COLORADO; ATTENDING PHYSICIAN TO THE ARAPAHOE COUNTY AND ST. LUKE'S HOSPITALS. DENVER, COLO.

A. S., male, age 55, born in the United States, occupation laborer, was admitted to the Arapahoe County Hospital, Denver, Jan. 10, 1896. His father died from violence and his mother from old age. One sister died of tuberculosis. He had been strong and robust up to three years before, having spent much of his life on the Western plains. He contracted syphilis when a young man. For many years he drank whisky more or less continuously. Three years previous to admission he noticed that the abdomen, feet and legs were swollen, and that he was short of breath. Some abdominal swelling had existed off and on since that time.

About a week before admission, while doing some

heavy work, he was taken suddenly with sharp pains in the back and abdomen, especially in the lower part. He was obliged to take to his bed. On admission to the hospital, he still complained of pain, especially in the back. There was considerable ascites but no swelling of the feet and legs. The body was considerably emaciated, the face thin and the eyes sunken; there was no jaundice although the eyes looked muddy. The liver dullness was moderately increased upward. The ascites prevented any satisfactory abdominal examination. The examination of the heart, lungs and urine was negative. The pulse varied between 80 and 100. The temperature was usually below normal, and never rose above 100. The respirations were from 20 to 26. Within ten days after admission, the ascites had increased very considerably, and jaundice was plainly apparent over the whole body. As the ascites and jaundice increased, he grew progressively weaker, and more emaciated. He was inclined to be drowsy. The scrotum, feet and legs became quite edematous. The superficial veins of the abdomen and thorax were enlarged. He vomited occasionally after eating.

A report was requested, but not obtained, on the bacteriologic examination of the contents of the stomach after a test meal. As a rule there was no severe pain excepting in the lower part of the back. One attack of severe abdominal pain occurred, lasting about twenty-four hours and requiring turpentine stupes. The bowels moved regularly under sodium phosphate, which was being administered. The stools were clay colored after jaundice developed. One examination of the urine showed a faint trace of albumin with hyalin casts; the other examinations revealed nothing abnormal but bile pigment. He stated that frequent and difficult urination had troubled him previously at times.

The treatment was palliative. The attending surgeon was asked to withdraw the abdominal fluid in order to give some relief possibly to the patient, and to aid in the differential diagnosis. The surgeon, however, counseled against it. Death occurred February 11 from gradually increasing asthenia.

### AUTOPSY.

The following autopsy was performed twenty-four hours after death by Dr. E. R. Axtell, pathologist to the hospital: The body is that of an adult male, apparent age between 50 and 60 years. The body is well developed, but poorly nourished. The skin shows much jaundice. Postmortem staining, and rigidity well marked.

On opening the abdomen, fully a gallon of serous fluid, deeply stained with bile, escapes, while apparently half that quantity remains behind in the dependent portions. Within the chest, the heart, lungs and pleuræ are found normal, excepting that all the tissues of the chest, especially the aorta, are bile stained.

The intestines are matted together into a mass the size of a child's head and lie in the middle line on the spinal column. They are only slightly distended, and the serous surface is studded with miliary tubercles varying in size from a millet seed to a grain of wheat. This tuberculous infiltration extends over all the abdominal organs as well as over the anterior wall of the abdomen.

The omentum is rolled into an elongated mass, twice as long as it is wide, and lies across the upper part of the abdomen underneath the stomach and just left of the portal fissure. On section this mass shows tuberculous infiltration, but no cheesy areas are found.

The liver is normal except for a large scar, undoubtedly syphilitic, on the upper surface of the right lobe. The spleen is normal. The stomach is normal except that the serous surface shows less tuberculous nodules than the surrounding tissue. The kidneys seem normal to the naked eye. The brain and cord were not examined. Cause of death tuberculous peritonitis.

A positive diagnosis was not made during life. It was supposed to lie between cirrhosis of the liver and cancer accompanied by limited peritonitis. In favor of cirrhosis were the following points: 1, history of steady indulgence in alcohol and of having had syphilis; 2, the development of marked ascites with only slight and slowly developing edema of other parts; 3, gastro-intestinal symptoms and jaundice; 4, the hepatic facies; 5, the increased liver dullness; 6, the length of time from the first symptoms to death.

Opposed to cirrhosis were the following points: 1, the history of swelling of feet and legs occurring simultaneously with the previous attack of ascites three years before; 2, the rapidly increasing jaundice toward the close of life would scarcely be expected excepting with the hypertrophic or biliary cirrhosis, a form not borne out by the other symptoms.

In favor of cancer were the following points: 1, age; 2, marked cachexia and wasting at the last; 3, negatively, the inability to exclude tumor in the gastric region on account of the ascites.

Opposed to cancer were: 1, the slow course of the disease (three years); 2, the absence of tumors in other parts of the body; 3, the extent to which ascites developed, which is usually slight unless associated with cirrhosis.

Had aspiration been resorted to, as it unquestionably should have been, it is more than likely that the omental tumor lying across the upper part of the abdomen, together with the smaller masses, some of which must have been palpable, although such conditions occur in both cancerous and tuberculous peritonitis, would have turned the balance in favor of tuberculous peritonitis as a diagnosis, all the evidence being taken into account, although opposed to it was the fact that no tuberculosis of the lungs or other parts could be demonstrated.

According to Strumpell, tubercle bacilli are not usually present in the exudation of tuberculous peritonitis, so that a bacteriologic examination of the ascitic fluid would probably have been useless as a diagnostic point.

It is interesting to study the probable starting point of the disease in this case. It could not have been part of a general tuberculous process. In such cases the peritoneum is usually affected through the intestines and mesentery. As in women, the disease often extends from the Fallopian tubes, so in man the prostate gland and seminal vesicles may be the starting point. The age, the history of frequent and sometimes difficult urination, and of the pain being especially located in the lower abdomen and back seem to point to the possibility of these structures having been the commencing point of the disease in this case. However, it is not improbable that the peritoneum as a whole may have been the primary seat of the process.

Out of 357 cases collected from literature in Vol. II of Johns Hopkins Hospital reports, only twenty-five were over 50 years of age. The present case was 55 years old.

The absolute covering of all tissue in the abdominal cavity by tubercles was an interesting feature in this case, as well as the tumor-like masses, especially the omental tumor in the upper part of the abdomen. Indeed the condition was not far removed from the one described by Osler where "In rare cases the tumor formations may be due to great retraction or thicken-

ing of the intestinal coils. The small intestine is found shortened, the wall enormously thickened, and the entire coil may form a firm knot close against the spine, giving on examination the idea of a solid mass. Not the small intestine only but the entire bowel, from the duodenum to the rectum, has been found forming such hard nodular tumor." In this case a large solid mass of intestinal coil was removed and exhibited in the lecture room.

Tuberculous peritonitis is of special interest in a diagnostic point of view from the great diversity of symptoms it presents, as well as from its simulation of other diseased conditions. It has repeatedly been found present in abdominal and pelvic operations without having been suspected. On the other hand, the onset may be so sudden and the symptoms so severe as to be considered ordinary acute peritonitis or even hernia. The ascites is usually limited in amount, but when it is large, cirrhosis of the liver may be simulated and suspected particularly if the patient has been an alcoholic. Moreover, cirrhosis often becomes complicated by tuberculous peritonitis before death. Again with moderate continuous fever, slow development, tympany and abdominal pain, typhoid fever, is simulated; while in some cases a peculiar pigmentation of the skin has caused the diagnosis of Addison's disease to be made.

Perhaps the most difficult feature of the diagnosis of tuberculous peritonitis arises from the frequent occurrence of tumors or tumor-like masses in the abdominal cavity. Osler in his text book on medicine speaks particularly of them. The rolled up and hardened omentum which may lie across the upper portion of the abdomen or below this region may simulate cancerous peritonitis although this condition is far more likely to occur in the former disease than the latter. When the fluid is sacculated, it is apt to be located in the middle zone of the abdomen, and in women ovarian tumor is simulated. The similarity must be great, for Osler says that in fully 33 per cent. of the recorded cases of laparotomy in tuberculous peritonitis, the diagnosis of ovarian cyst had been made; moreover tuberculous peritonitis is often associated with tuberculous disease of the tubes. Rotch in his pediatrics says "that most doubtful cases of abdominal tumors in children are tubercular."

Great diagnostic importance is placed on the personal history and on finding evidence in other parts of the body of old tuberculous lesions especially in the pleura, the apex of one lung, the testis in the male and the Fallopian tube in women. No reliance can be placed on the personal appearance, as a patient with this disease may appear well nourished and in good health.

Regarding treatment, the concensus of opinion today seems to be that it should be both medical and surgical; that if after rest and appropriate constitutional treatment, there is no progress and especially if the ascites increases or is already considerable, aspiration or siphonage should be done. If after one or two withdrawals, the fluid tends to return, especially if the case seems to be at all desperate, laparotomy should be resorted to. At times after withdrawing the fluid the cure seems complete, at other times there is temporary improvement, while again it happens that the tuberculous process is arrested in the peritoneum only to break out afresh in some other and probably more dangerous tissue.

## INTESTINAL ANTISEPSIS, DIET AND CASTRATION IN RELATION TO EPILEPSY.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association held at Atlanta, Ga., May 6-8, 1896.

BY EVERETT FLOOD, M.D.

SUPERINTENDENT OF HOSPITAL COTTAGES FOR CHILDREN,  
BALDWINVILLE, MASS.

The effort has been in the present paper to offer as briefly as possible some individual conclusions as to the advisability of employing the three methods enumerated in the title.

Pages have been filled, and can be again filled, with observations and statistics relating to the epileptic symptom. I leave aside now all that class of work and present these three as newer methods and those which to my mind promise, especially in young cases, rather better results than any plan with drugs as usually employed.

The first attack in many instances is after excessive eating, as in the following case: A girl of 14 ate heartily and hastily at dinner, then took a pint of peanuts on her way to school and, soon after the session opened, had a fit. She vomited large chunks of beef and a great quantity of other food. A second fit occurred three months later after another, though less, over-indulgence in food; and they recurred at intervals, always with a similar apparent cause, though after the establishment of the habit the excess required was slight.

The person manifestly, in order to guide against excess and putrefaction as much as possible, ought from the outset of the child's life to have suitable food in right amount at proper intervals.

The gluttony of this class of persons is well known. Unrestricted they nearly all overeat. A sample supper recorded from an actual case, taken at random when no restraint was used was as follows: Boy of 14, six slices of bread and butter; one bowl of hulled corn and milk; three saucers of apple sauce; two cups of cocoa; three cookies.

Many such instances might be cited, though I am fully aware that the initial attack, when not traumatic, is not always traceable to the digestive overbalance.

To regulate and control the food of the child, when there is known to be danger, are rational methods of treatment and have actually proved effective in many instances. I have tested many drugs to a degree and still have observations going on, but I believe more fully in prevention of this trouble than in a possible cure, and the suggestion has many times presented itself as to whether or not the good effects of certain drugs in special cases may be more due to their tendency to correct either putrefactive changes or parasitic influences than to any other quality. With this in view I have a number under various methods of drug treatment, but not as yet conclusive results to record. Auto-intoxication in diseases has received much well merited attention.

We are taught in the main merely a suitable choice of food, cleanliness, right living and to prevent putrefactive changes as far as we can by drugs or other methods. We have merely the same principles to follow when putrefaction takes places instead of wholesome digestion as in the instances where we seek relief from parasitic products and from other sepsis or toxins.

Intestinal parasites are unquestionably common. They are not conducive to the health of the child and

it would be well if all could be removed. Doubtless such forms of life have their place in the economy of nature; but inside the human subject that place should eventually be taken by nutrient solutions, unsapped by even microorganisms, for the strengthening of the surrounding body. Dog breeders well know that all dogs have worms and that vermifuge will prevent or cure fits. The relatively longer intestinal tract in dogs very likely increases the animal's liability to have a fit. Chickens from incubators are apt to be abnormal, to have fits, deformities, etc., but I can not say that they have fewer intestinal parasites than the ordinary chicken. It is claimed that no dog can be reared free from such residents, whatever precaution may be taken with food and care; but I am of the opinion that no case has, as yet, been adequately tested to determine this point.

For purposes of disinfection and for destroying a part of the parasitic life large injections into the bowels, large draughts of water and perhaps the use of the ozone preparations give promise of some favorable results. Keeping the bowels open by suitable food and manner of life, massage of the abdomen, baths to aid digestion, and the measures before outlined, will certainly afford us a better outlook than the over-medication which has hitherto prevailed.

I have twenty-two cases of castration to report, twenty in males and two in females. I was first led to do a castration by my desire to do something to prevent masturbation in certain few boys who were also epileptic, and the habit is not as likely to become offensive in the non-epileptic. Castration as well as circumcision, which, if not God-given rites, are certainly worthy to have come from the mind of Deity conscious of the need of correcting a structural error, have bitter opponents. I would not be so unreasoning as to expect all men to agree even upon the most self-evident proposition. The opponents of vaccination are howling with as much persistency in the face of the most convincing statistics as they did at the beginning of the century when Jenner was promulgating his beliefs. The operation is old. I need not go into its history though a volume might be written thereon.

There is no doubt that the custom prevails in Eastern countries, as formerly, of emasculating certain youths to serve as safe attendants upon the royal women, and among another class for the purpose of keeping the youthful qualities of the voice.

As to the method of operation I may be allowed briefly to suggest that it seems an advantage to make one very small incision in the median line of the scrotum and then squeeze out each testicle successively through the opening. The cut is then easily closed with one stitch and the place being painted with *co. tr. benzoin*, always heals at once. There will be some induration of the stumps beneath the surface but this gradually absorbs and in a very few days the patient is in a safe position. I hardly dare to claim priority of use of this operation, but I certainly originated and used it without knowing of its application in any other quarter.

The effects of castration are, as far as I have observed them, as follows: The masturbation, which is the most important, finally ceases in all cases. Sometimes it persists for months with varying intensity, but it is not obtrusive even in these instances and eventually the habit is dropped. The boy gets plumper and has a clearer complexion. The voice is milder and pleas-

anter and remains so if the case is a young one, at least for a few years, and probably permanently. The boy is less inclined to violence and domineering. The possibility of reproduction is of course eliminated. I consider this a most useful safeguard. I can not understand why any parent having such a son as we are considering should hesitate to have him castrated even if there were no other object than the last one named. No parent understanding the probability of inheritance in such a nervous case, ought to care to run the risk of becoming a grandparent. Sentiment is very wrong on most matters until set right by reason and education. So it is here. There is, however, some hope for spread of intelligence in such a matter as this, but judging from past progress I conclude that a hundred years of deliberation is likely to leave the public in much the same state of intelligence as at the present day. There has always been some fear among medical men that a male masturbator being castrated would fall into lasciviousness or into some other immorality worse than his first state. I do not find this fear substantiated in my cases. We had two boys who were kleptomaniacs as well as epileptic masturbators. For some weeks after the operation this manifestation was exaggerated, but it subsided entirely in a few weeks and only slight and infrequent traces have appeared for a year in one case and two in another. I find that these boys after operation do not entice other boys to masturbate. They have no tendency to think of sexual matters. The smutty story mania disappears and other unpleasant and gross manifestations are happily wanting.

The effect upon the force and frequency of the fits seems in all cases to be noticeable. There have been the same periods of fits and about the same length of period, but each fit has been less in time and milder in type.

Two females have been under my observations both of whom were castrated between the ages of 16 and 20. Certainly no general deductions can be made from so few cases but so far as my experience goes with them, I feel that the operation is not as thoroughly useful as with boys. There are, however, plenty of arguments to show that it is fully justifiable and might even be very desirable. To prevent conception is a very great desideratum, but to encourage the woman to safe and indiscriminate indulgence, which such a case would often be inclined to, would certainly be bad. The first two of these methods cut off in the offspring much of the unintellectualized emotional life which eventuate in the various neurotic disorders. The last is especially adapted to all those instances where we feel certain that marriage would never be proper.

#### DISCUSSION.

DR. G. W. WENSTER, of Chicago—I assume that in the light of the most recent pathology, epilepsy may be said to be a condition of cortical instability. That is its essential underlying condition. It is characterized during the attacks by convulsive seizures, attended by loss of consciousness. If, then, we have, as a basis of the epilepsy, cortical instability, we must further recognize the fact that cortical instability may be influenced in many ways, directly, by the blood circulating in the cortical portion of the brain; and probably by uric acid and other waste products from the blood. This has led Haig and his supporters to hold that a large number of cases of epilepsy are due to uric acid circulating in the blood. The cortical portion of the brain may not only be influenced directly in the manner stated, but also by trauma, producing Jacksonian epi-

lepsy. It may be influenced reflexly, and it is a matter of common knowledge that certain errors of refraction may produce epilepsy, and it was for this reason that a certain gentleman in New York a few years ago offered glasses or division of ocular muscles for the cure of all cases of epilepsy. We also know that in young boys irritation of the penis may result in epileptic seizures. I have seen the case of a child who was having as many as twelve to eighteen attacks in twenty-four hours, that had continued for a year and a half, cured simply by circumcision, we must remember, then, that we may have epilepsy as a reflex condition excited from the genital organs, from the eyes, from the intestines.

DR. LOUIS FAUGERES BISHOP, of New York—It seems to me that in discussing epilepsy as a reflex result of irritation we are going backward. Epilepsy is an essential disease of the cortex of the brain, and the fact that a certain small proportion of cases are aggravated by local irritation is acknowledged by all. But I think the stand taken now in the Vanderbilt clinic, where they have seen many thousand cases of epilepsy, and they have been referred to various specialists for various kinds of treatment. We have had them circumcised, trephined, the nose and eyes treated, and so on. We think that a reflex cause of epilepsy is a very small factor and that it is hardly justifiable even to trephine. Our cures from trephining have all been temporary, and certainly if you trephine in a case where the source of irritation is right at the cortex, and you find that in spite of removal of that area the cure is only temporary, you would feel that anything like castration was hardly justifiable.

DR. WENSTER, of Chicago—The point which I insisted upon in the beginning of my remarks was, that the essential condition in epilepsy is one of cortical instability. That that brain, and the individual of which it forms a part, is what it is from two sources, heredity and environment; and that, given a child with a brain in this condition of cortical instability, treatment of the eye, castration, or anything else, will not change it, and we must recognize this cortical instability to begin with.

### EARLY DIAGNOSIS OF CARCINOMA OF THE STOMACH BY MEANS OF CHEMIC ANALYSIS OF THE GASTRIC CONTENTS.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY W. C. WEBER, M.D.

VISITING PHYSICIAN TO THE GERMAN HOSPITAL, CLEVELAND, OHIO.

The question of how to arrive at an early diagnosis of cancer of the stomach is certainly one which has attracted considerable interest in recent years, and hence concentrated efforts in the study of this peculiarly interesting disease. The reason of this becomes apparent in view of the fact that not infrequently cases come under one's observation which present few and indefinite objective symptoms and a vague sense of disturbance in the digestive process as the only subjective symptom of ailments which in their later stages prove unmistakably to be cancerous.

To proceed in the ordinary way, to palpate, percuss and gather the history of the case, is insufficient and often ends in negative and disappointing results. Such failures can, to a great extent, be obviated by supplementing the usual method of diagnosis with a process of chemic analysis to which the stomach contents are subjected.

The time was, not long since, when the absence of hydrochloric acid from the stomach contents was regarded as a symptom almost pathognomonic of car-

cinoma. This symptom in itself does not now receive the diagnostic prominence it did in the past, for the reason that this acid may be absent in both acute<sup>1</sup> and chronic gastritis in which no neoplasm exists as a causative factor.

At the present time there is a tendency to attribute great diagnostic importance to the existence, in the gastric contents, of lactic acid. It may scarcely seem necessary to say that the presence or absence *per se* of one or the other of these acids is no positive sign of the existence or non-existence of cancer of the stomach. The constant absence of hydrochloric and the constant presence of lactic acid, in connection with certain other symptoms or conditions are of the highest diagnostic import. This point I shall endeavor to emphasize by the citation of a case or two, further on, which at the same time illustrates characteristics of cases most difficult of diagnosis.

Preparatory to the investigation of the gastric juice all medication is to be excluded for a day or two previous to the administration of the test breakfast which consists of a light biscuit or small piece of toast and a cup of weak tea or glass of water (it is well to note here that after the test breakfast the HCl may be absent and may reappear when a meal of steak, potatoes etc., is used); this should be given from one to two hours before the removal of the stomach contents which should be forced, or expressed, through the stomach tube without the addition of water and the stomach may then be lavaged in the usual manner before the tube is withdrawn.

The quantity of the expressed gastric contents is noted, then filtered and the reaction determined; if this be neutral or alkaline no acid tests need be applied; if acid, the total acidity may at once be ascertained by the process of titration; or one or more of the tests for free hydrochloric acid may be used. Those most commonly employed are the aniline dyes of which Günzburg's test dimethylamidoazobenzol, Congo-red and tropeolin are preferred. Tropeolin, an orange-colored powder, is dark yellowish red in saturated aqueous or alcoholic solutions and in the presence of free HCl (1 in 4,000) changes to a dark brown; the acid salts give it a light straw yellow.

Congo-red is changed to a sky blue by the presence of hydrochloric acid. It is more delicate than tropeolin and is not affected by acid salts. A paper has been prepared containing this substance and is used in the same manner as litmus paper.

The first mentioned test, Günzburg's,<sup>2</sup> possesses several important advantages over those just described. This reagent has a pale yellow color and is fairly stable when kept in a dark place. Its superior value chiefly lies in the simplicity of its application, the reliability of its action, which is not interfered with by the presence of albuminates, giving it in this latter respect a distinction accorded to none other of this group: it has no effect on salts or organic acids. To a drop of the reagent in a porcelain dish is added a drop of stomach contents and slowly heated over an alcohol lamp; if free HCl is present, even in so minute a quantity as 1 in 20,000, there is produced a bright red tinge along the edges or delicate stripes through the drop. Overheating, especially when albuminous matter is abundant, produces a brownish or reddish coloration in the center of the drop, which, however, is easily distinguished from the characteris-

tic reaction of HCl. Should there be any doubt as to the character of the reaction it is advisable to make use of a control test which may consist of an indefinitely dilute hydrochloric acid solution. This reaction is always a distinctive one though varying from a bright red to a pale rose color, depending on the degree of hydrochloric acidity. By a little further detail the test can be rendered quantitative by diluting the gastric contents one-third, one-sixth, one-tenth and so on with water, noting between what two successive dilutions the reaction no longer appears the limit of which we know to be in the neighborhood of 1 in 20,000. Another test which has lately come to our notice is the dimethylamidoazobenzol.<sup>3</sup> It consists of the addition of one or two drops of the reagent to one or two drams of the stomach juice, which changes to a red color when HCl is present. The stability of the reagent, its delicacy and extreme simplicity of application, make it one of the most, if not the most preferable of all tests.

As a high degree of acidity of the stomach contents does not in itself indicate the presence of HCl, yet possessing pathologic significance, it becomes important that the total acidity be determined. This is accomplished by the process of titration which is as follows: A deci-normal soda solution is allowed to flow from a burette, drop by drop, into a small glass beaker containing 5 or 10 c.c. of the filtered stomach contents and one or two drops of phenolphthalein solution. When the acid reaction is overcome the contents in the beaker changes to a red color, and the reading from the burette indicates in c.c. or fractions thereof the amount of the standard solution required to neutralize, from which the percentage of acidity can readily be calculated. To illustrate: Suppose it would require 3 c.c. of the deci-normal soda solution to neutralize 10 c.c. of gastric contents; it is thus apparent that the total acidity is 3 or in other words 30 per cent. In place of the phenolphthalein, litmus paper or better the litmus pencil can be used, but these require more labor and care. The normal total acidity ranges from 40 to 65 per cent. and a deviation in either direction from these figures is regarded as abnormal.

As it is not intended in this paper to dilate on the significance of a high or low degree of acidity of the gastric juice, and omitting the citation of the class of diseases occurring in each condition, we come to the consideration of lactic, the principal of the organic acids. The presence of the organic acids in the early stage of gastric digestion may be and usually is normal; it is, on the contrary, when found in the later stage of the digestive process, attributed to morbid influences. This is not difficult to comprehend when it is remembered that the prolonged sojourn of food tends to fermentation in the stomach due to pathologic alterations, notably such as occur in carcinoma of this viscus. But inasmuch as we do not at this time wish to deal with the etiology and pathology of cancer of the stomach, it is perhaps sufficient to state that there is a preponderance of evidence indicating the presence of lactic acid in cancerous diseases of this locality fully as often as the demonstrated absence of the hydrochloric.

Boas, in 1893, was first in calling attention to the value of lactic acid in the diagnosis of the disease under consideration. He further made the observation that this acid is produced in all test meals in which

<sup>1</sup> Ewald, p. 290.

<sup>2</sup> Phloroglucin 2, vanillin 1, and absolute alcohol 30.

<sup>3</sup> Fisher and Phillip, Anal. Pharm. 23, § 434.

bread or meat enters as a constituent; and he therefore resorts to a breakfast of 1 to 2 liters of a thin oat-meal gruel sprinkled with a little sodium chlorid; this is expressed from the stomach an hour later and Uffelmann's test applied. This test is based on the reaction of lactic acid on a diluted neutral ferric chlorid solution. It is a very simple method and the reagent can be freshly prepared for every application in the following manner: To 1 dram of a 5 per cent. aqueous carbolic acid solution add one or two drops tinct. ferri chloridi which turns it to a beautiful amethyst blue. When a solution containing lactic acid is brought in contact with this reagent thus prepared it assumes a canary yellow. The reaction is very characteristic and limited experience will enable the tyro in this line to make the proper distinction between this and various other shades of yellow which may be caused by such substances as sugar, alcohol, and particularly the phosphates. When the stomach juice has a decided yellowish color, the test may be unsatisfactory, necessitating a modification which can be effected by obtaining an ethereal extract, which is then subjected to the usual method. The fatty acids react to Uffelmann's reagent by giving a tawny yellow with a reddish tinge. This is particularly so in the case of butyric acid which can also be demonstrated by the presence of minute oily drops forming in an aqueous solution of the residue of an ethereal extract to which calcium chlorid has been added.

Acetic acid can best be detected by the sense of smell unless present in a very minute quantity. Peptones and propeptones (test applies to both) may be readily demonstrated by the biuret reaction. This consists of the action of a dilute cupric sulphate solution on the peptones or propeptones, producing in an alkaline medium a purple red color, while albumin simply shows a bluish violet.

In this connection it was interesting to note in my work that when the heat and acid tests showed large quantities of albumin, a correspondingly feeble biuret reaction took place, and vice versa, so that by testing for the one the presence or absence of the other could be quite accurately predicted. It seems that peptones are formed whenever pepsin is contained in acid contents, though HCl be absent. Hence no great diagnostic significance attaches to these products.

Examination of the blood will often lend very material aid in differentiating carcinoma of the stomach from the pernicious anemia caused by atrophy of the glandular apparatus of the stomach. In cases of cancer of the stomach that have reached a stage where it may be confounded with the pernicious anemia dependent upon glandular atrophy, there is always a polynuclear leucocytosis of varying degree, poikilocytosis, a considerable loss of hemoglobin, a diminution of the number of red cells, which, however, is not as marked as in cases of pernicious anemia of glandular atrophy.

The practicable application of the foregoing at once becomes apparent when we recall experiences in diagnosis of stomach diseases where, for example, a carcinomatous affection has been called in turn, "a little stomach trouble," "dyspepsia," "chronic catarrh," etc., until the disease has made such progress in its development that longer failure in its recognition would be almost impossible. For, does it not seem reasonable that an organ having undergone structural changes, should first evince that fact by an alteration in its function? If so, we may reasonably expect pathologic changes in the secretions at a compara-

tively early period, the clinical significance of which is now more correctly interpreted.

As before stated, it is common knowledge that for some years too great a value has been placed on the absence of HCl, the hitherto almost certain symptom of gastric carcinoma. Now, it is generally recognized that any morbid process which involves the deeper structures, and especially the peptic glands of the mucous membrane, may be followed by the cessation of the formation of this acid, and therefore can not be regarded with the importance of the past, for it is also a well-known fact that in a great majority of cases of hepatic cirrhosis there is a complete absence of HCl.

It has been stated, too, that the production of lactic acid was caused by stagnation, and Boas and his followers affirm that in no disease in which stagnation of stomach contents occurs is there so much lactic acid ferment developed as in cancer of the stomach. Notwithstanding, this observation has been corroborated by other authority, to unqualifiedly assert that the absence of the mineral and the presence of the organic acid is positively indicative of cancer, would be too strong a statement. In support of this view it is pertinent to call attention to the case of Noorden,<sup>4</sup> of Frankfort. He found HCl absent and lactic acid present in enormous quantity in a case of gastric ulcer that had perforated into the pancreas.

In chronic gastritis and atrophy of the mucosa due to any cause, there may be a diminished or entire absence of HCl; and if the latter acts merely as an antiseptic, as has been suggested, thereby preventing the formation of lactic acid, it may readily be seen that the acid symptoms are insufficient in themselves for positive diagnosis. But when these are associated with any one or two of certain other symptoms, as cachexia, loss in weight, pain or tumor, scarcely a doubt remains as to the nature of the disease. Unfortunately, it often happens that none of the last mentioned symptoms become manifest until the disease has progressed toward its fatal end, the time having long gone by when surgical means might have offered the only avenue of escape from the inevitable doom. When vomiting, great diminution in weight, tumors, etc., have declared themselves, the disease has passed beyond human intervention. In view of the foregoing, the time may not be far distant when tumors (cancers) will be removed from the stomach with far greater frequency than they are at the present time. And to make this possible is, I believe, the province of medicine—to clear and illumine the way on the line indicated.

To give statistics illustrative of what others have accomplished in this field, would no doubt be interesting, but time forbids. We will therefore conclude this paper by citing two cases which quite accurately represent a large proportion of cases in which none of the symptoms formerly relied upon are visible, but whose gastric juice nevertheless, in connection with the conditions before mentioned, bears us a message of great diagnostic value.

*Case 1.*—Mr. E. M., aged 68, normal weight 200, tall and complexion light, married and father of several children. Lived an active out-door life and enjoyed good health until the time of the illness of which we are writing. With the exception of being an excessive smoker, personal habits were good. Heredity, negative. The existing difficulty first manifested itself nine months ago. The first symptom noticed was a disturbance in the digestive process; then sour eructations, loss of appetite

<sup>4</sup> *Medizinische Blätter*, Feb. 7, 1895, No. 6, p. 87.

and constipation; later, diminution in weight, fatigue and antipathy to meats. These symptoms were variously characterized as dyspepsia, catarrh of stomach, etc., and of course empirically treated. At this time, the chief subjective symptoms were anorexia, general weakness, increased flow of saliva, and a vague sense of disturbance in the epigastrium; had vomited a few times. Examination revealed no tumor and no cachexia; the lungs showed no abnormality and the liver occupied its normal relation, but the heart action was weak.

The stomach contents were expressed at intervals of once or twice a week and tested for HCl and lactic acid; the former was always absent, and the latter invariably present. The total acidity averaged 50 per cent. Under the influence of the lavage and carefully directed diet with strychnia, the patient made considerable improvement subjectively, but the circulation continued feeble. A month later, there was vomiting of the characteristic coffee-ground variety. An induration of small size could now be made out in the epigastric region. Left kidney was movable and easily defined. An abundance of uric acid was in the urine.

From this time on the case progressed rapidly in developing tumor and cachexia, reaching its fatal termination on Dec. 21,

in a short time vomiting, fever and thirst supervened, for which large quantities of ice and morphia had been administered, though he had at no time complained of pain. Emaciated rapidly, and soon vomited enormous quantities of a grumous material at frequent intervals.

Examination revealed no tumor, no pain, only tenderness in the epigastrium on pressure.

The circulation had become enfeebled to such an extent that patient died from exhaustion on June 10, 1895. The gastric contents contained neither HCl nor lactic acid, though the tests were applied daily. The following shows<sup>5</sup> both the chemic and microscopic analysis of the stomach fluid:

Hydrochloric acid, Günzburg's was negative, dimethylamidoazobenzol was negative; degree of alkalinity, 36 (Ewald's method); lactic acid, negative; albumin, present; peptones, negative; propeptone, negative; blood, present; bile pigment, negative.

Microscopic examination: White and red blood corpuscles, present; flat and cylindric epithelium, present; several varieties of bacteria, but no *sarcinæ* ventriculi.

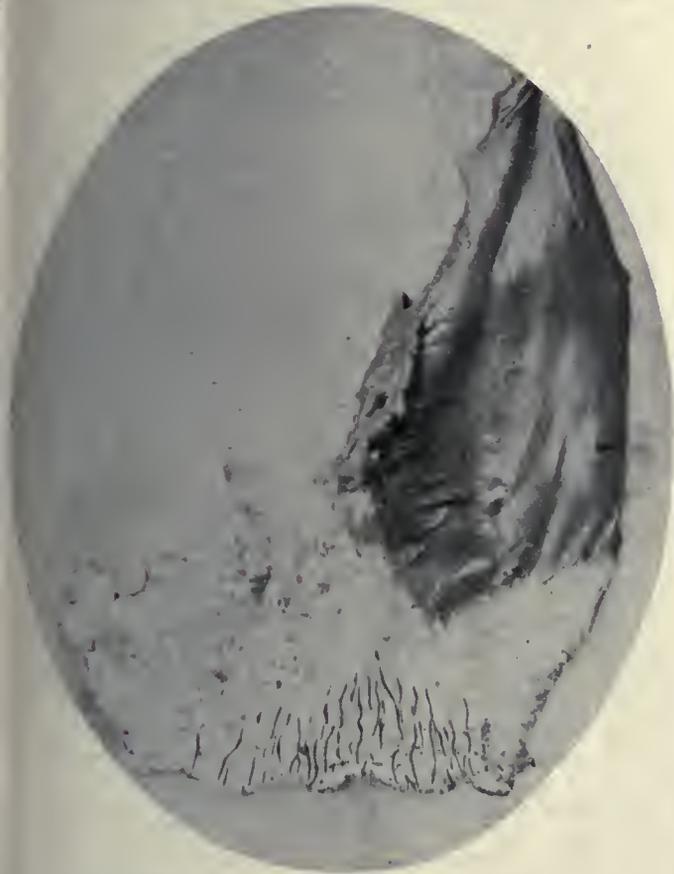

FIGURE 1.

1895. The autopsy revealed carcinoma involving approximately one-third of the stomach from the pyloric end, on the posterior side. The pylorus was a hard mass, and on opening, a concentric tumor became visible which completely filled that end of the stomach. To the posterior surface of the cardiac extremity of the stomach the left kidney was adherent, and on the latter when removed, appeared a cyst one and one half inches in diameter containing a clear fluid. The stomach was considerably dilated.

*Case 2.*—Saw this case first on June 6, 1895, when the following history was furnished: Mr. J. C., aged 40, of slender build and light complexion; married five years and father of one child. Patient has never had any serious illness. During the last two or three years his general appearance was not indicative of good health. For about two months he mildly complained of a stomach difficulty. For this he received treatment and his family the assurance of his early recovery. All this was promised up to within three days of his death, when the case came under my observation. Patient was confined to his bed since the 18th of last May, when he experienced a gnawing sensation in epigastric region and considerable pros-

FIGURE 2.

Autopsy showed three inches of the pyloric extremity of stomach to be a carcinomatous mass with the characteristic blue and gray color and thick gritty hardness. The pylorus was almost closed and the stomach considerably dilated. Photograph No. 1 presents a good anterior view, and No. 2 the interior, the incision being through the posterior surface.

Finally, I will state with confidence that the diagnosis in Case 1 was made on evidence furnished by the chemic analysis of the chyme, in conjunction with the only constitutional symptom present—general weakness which refused to be modified in the least degree by medication. The method crudely outlined necessitates increased labor and the knowledge of certain technique, which will yield results, I believe, that

<sup>5</sup> For the preparation of this table I am indebted to the kindness of Dr. R. J. Wenner.

will amply justify the efforts expended in so fascinating a field as this one.

## DISCUSSION.

DR. JAMES B. HERRICK, of Chicago—I believe it is true that Congo-red has been proven to be a reliable test for free hydrochloric acid, and negative results may be assumed to exclude this acid as well as other mineral acids. I am glad to see that the author does not rely alone upon examination of the contents of the stomach for proof of the existence of carcinoma. He justly calls attention to the value of blood examination and the presence of leucocytosis as confirmatory of the diagnosis of carcinoma. The presence of cachexia and other signs must not be ignored. He calls attention to the fact that free hydrochloric acid is frequently absent in many other affections than carcinoma, and it is also true that some of the later writers have found lactic acid in the stomach contents where no carcinoma was present. For instance, in Professor Osler's clinic there was a case of non-malignant obstruction of the pylorus in which lactic acid was found. So we are forced to look upon examinations of the stomach contents, at least in so far as hydrochloric and lactic acid are concerned, chiefly as confirmatory tests.

DR. WAINWRIGHT, of Kansas City, Mo.—I have had some experience with analysis of the stomach contents the past four or five years in clinic work. Several times I have made an early diagnosis based on a chemic analysis of the contents of the stomach, but I have never yet been able to induce a patient to be operated upon with only such evidence of carcinoma of the stomach. Later when a tumor could be felt and there was cachexia, making the diagnosis very plain to all, the patients were willing to submit to an operation, but it was too late to derive any benefit. The most satisfaction which I have derived from this analysis has been in cases of obscure tumors of the abdomen. During the past winter my attention was called to two or three cases of tumor located in the left hypochondriac region which every physician who examined the patients pronounced tumor connected with the spleen or other organ beside the stomach, yet by analysis of the gastric contents, etc., I was able in each instance to positively locate the tumor in the walls of the stomach, and this diagnosis was afterward confirmed by autopsy. If we are able, as I believe we are, to make a diagnosis of carcinoma of the stomach in the early stage by careful analysis of its contents and functions, I think the time will soon come when surgeons will relieve these cases by operating early.

DR. PAUL PAQUIN, of St. Louis—Although we have many maladies of the stomach, we are yet hardly in a position to make a proper diagnosis. Perhaps the time has not yet arrived for making a positive diagnosis of the diseases of the stomach purely by chemic or bacteriologic analysis; yet in my judgment such analysis is of the greatest importance, especially as giving confirmatory evidence. Such analysis has been a part of my work for some years past, and I am delighted to know that we are progressing in that line. I am, however, of the opinion that we are inclined sometimes to neglect physical symptoms, and to consider too much and too strongly the results obtained by analysis. We must consider that in no other organ except the alimentary canal do we get such chemic changes as are produced by the ingestion of food, beverages, and so on, and we can not depend upon the findings of the chemist and microscopist as a basis for therapeutics. But before this analysis was introduced in the work of the physician for the purpose of diagnosis, he certainly was a great deal more at sea than now, and we have to-day workers like the essayist who are leading up to the ground which we must finally occupy in order to diagnosticate many of the diseases of the alimentary canal.

DR. WEBER—It is gratifying to observe the endorsement of this paper as indicated by the discussion which leaves little or

nothing to be added. It may be emphasized, however, that when you find a well defined tumor, cachexia, and great loss of weight, that patient is past surgical or any other help, and most of us will decline to resort to operative measures at such a stage. The second case which I reported, was most interesting for the reason that no tumor was discoverable by palpation or physical means to within a day of death, and, contrary to the rule, there was absence every day of lactic acid. Another case to which I referred showed enormous quantities of lactic acid, and the autopsy proved it to be an ulcer of the stomach. Hence the conclusion in my paper seemed justifiable—that the acid symptoms in themselves are not always reliable, but when taken in connection with other facts are of the greatest value.

## THE PRACTICE OF PHARMACY AS A LIBERAL PROFESSION.

Delivered in the Section on Materia Medica, Pharmacy and Therapeutics, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY F. E. STEWART, M.D., PH.G.

CHAIRMAN OF SECTION ON MATERIA MEDICA, PHARMACY AND THERAPEUTICS. DETROIT, MICH.

Pharmacy is a branch of medical science and practice. It belongs to that part of medical science formerly known as pharmacology, or the science of drugs. Unfortunately the term pharmacology has been used in a restricted sense, being applied more particularly to experimental vivisection of animals for determining the physiologic effects of drugs. The word pharmacodynamics more properly describes that branch of medical science. Gould defines pharmacology as "A treatise on the nature and properties of substances used as medicines, or those employed in their preparation," and according to the same authority, pharmacodynamics is "The science of the powers and effects of medicines."

H. C. Wood, in the introduction to his classic work on materia medica and therapeutics, clearly defines the meaning of terms used in this connection by saying, "Although pharmacy, or the science of preparing medicine, is entirely distinct from therapeutics, or the science of the application of medicine to the cure of diseases, it is evident that some acquaintance with the former is necessary to the correct appreciation of the latter. Further, as a basis of both studies, must first come a knowledge of materia medica or the substances used as medicine. Pharmacology is the general term employed to embrace these three divisions."

Hermann, professor of physiology in the University of Zurich, and one of the leading authorities in experimental vivisection, in the introduction to his "Experimental Pharmacology," a hand-book of methods for studying the physiologic action of drugs, says: "Pharmacology in its widest scope embraces the study of drugs from all possible points of view, and the information thereby acquired may be useful under the most diverse conditions; to the physician, to enable the recognition and proper treatment of cases of poisoning, or to permit of the use of drugs for therapeutic purposes; to the public, to permit the avoidance of noxious substances; to the physiologist and pathologist, to enable the application of information derived from the study of the action of poisons to the advancement of their sciences. The study of pharmacology can therefore be limited according as one or more of these points of view occupy the first place in the mind of the investigator. The public desires to know only what substances are poisonous, that they may be avoided, while their modus operandi is a matter of

indifference. Those poisons which are suitable for use at the bedside will prove most interesting to clinicians."

"Pure pharmacology is best advanced by the avoidance of any special stand-point, in order that all of its bearings may be equally appreciated, and still more, since the advancement of pure science is always retarded by a search for that only which promises immediately practical results. The history of the progress of the sciences teaches that nearly all the most important discoveries, even those subsequently of the greatest practical value, resulted from investigations untrammelled by a continuous mindfulness of the merely practical. Thus physiology has rendered such inestimable assistance to the progress of practical medicine that she can well be regarded as her handmaid; but, nevertheless, physiology is a pure science, which, like physics and chemistry, should be studied for its worth, without being hampered by doubts as to whether its results are immediately applicable to practical medicine or not. So also pharmacology is growing more and more worthy of occupying a similar position, though it must be acknowledged that as yet, it is not bounded by such sharply drawn lines as to constitute a distinct science. Much, however, can be gained in this direction by constantly bearing in mind that pharmacology has for its object the recognition and study of all changes which a foreign body can undergo or produce, otherwise than traumatically, in the organism, while the questions as to whether the substance under study can be ever likely to prove a poison to man, or whether it has properties which warrant its use as a medicant, should be kept in the background."

"Consequently every substance which possesses any active properties should prove of interest to the investigator in the domain of pharmacology; while naturally those substances will be preferred which are either quite unknown, which show results entirely novel, or whose action admits of predetermination from a theoretic point of view, as from the stand-point of chemical composition. And it should, moreover, be remembered, that even substances which themselves evoke no symptoms in the organism, may form worthy subjects of pharmacologic investigation as throwing possible light, in the changes which they undergo in the system, on the behavior of other more active poisons."

If pharmacy is a department of science, its practice is a medical art. It therefore follows as a natural sequence that pharmacy must be regarded in the light of a medical specialty, and the pharmacist is under the same obligation to science, to the profession, and to suffering humanity as the physician.

Now medicine is a liberal profession. It is distinguished from a mercantile pursuit in that service to humanity (not money-making) is its primary object. What business or profession is there like medicine in this respect, viz., that it seeks to remove the cause for its very existence. And yet we behold such unselfishness and devotion to humanity in preventive medicine, which leaves no stone unturned to ascertain and subdue the causes of disease which the physician gains a livelihood by treating. Indeed, medicine owes its high position among the vocations of men to its philanthropic aim, seeking in every way to relieve and prevent human suffering, devoting itself to original research, and publishing its results for the benefit of science, constantly sacrificing self-interest to aid

others, and neglecting, for philanthropic reasons, to take advantage of many opportunities for gain.

If what I have said is true then pharmacy can never be recognized as a liberal profession, until it becomes part of the medical profession, for it can not, from the very nature of things, become a profession by itself. Pharmacy is directly dependent upon therapeutics, and is like a body without a soul when divorced therefrom.

Pharmacy can find its *higher* advancement, not by catering to an unenlightened public, unfitted to appreciate it either from a scientific or professional stand-point, but by working with physicians to a common end, that end being the promotion of progress in pharmacology as a science, the advancement of pharmacy as a profession, and the study of means to prevent and alleviate human suffering. By serving this end pharmacy will find its true position among the liberal professions.

As a trade pharmacy would seek to create a fictitious demand for drugs by exaggerating their importance as curative agents, thus pandering to the morbid tendency of the public to dose itself for real or imaginary diseases. As a profession it will join with the medical profession in efforts to relieve the public of the necessity of taking medicine. Coöperation between the physician and pharmacist is absolutely indispensable to the advancement of pharmacologic science, for as already said, neither therapeutics or pharmacy as science or practice can exist alone.

The science of medicine professes to exhibit what is actually known, or may be learned, in the forms of exact observation, precise definition, fixed terminology, classified arrangement and rational explanation. To promote the progress of the science of drugs it is therefore necessary for both professions to publish the results of their discoveries for the benefit of science. It is just as reprehensible for physicians to neglect the publication of the results they obtain from the use of drugs, or their preparations, as it is for the pharmacist to restrain the knowledge of the same from general use, by means of secret formulas, protected from legitimate competition by fanciful names, which latter are registered as trade marks, at the Patent office in Washington. How can the demands of science be satisfied unless the knowledge of every substance used in medicine, together with its method of preparation and application to the cure of disease is published, and its manufacture and sale open to legitimate competition?

"In every civilized country<sup>1</sup> there is some recognized official list of drugs and their preparations known as the pharmacopeia. In most places this being prepared with the sanction of the government, partakes of the nature of a law, but in the United States conformity to it depends upon the voluntary action of the professions, of medicine and pharmacy by a representative convention of which it was originally prepared and is decennially revised."

The position and responsibility of the physician and pharmacist in relation to the pharmacopeia is the next point to which I desire to call your attention. On the analysis of 27,000 prescriptions recently made by Prof. Patch, President of the American Pharmaceutical Association, it was shown that the pharma-

<sup>1</sup>A treatise on Therapeutics comprising Materia Medica and Toxicology by H. C. Wood, Jr., M.D. Third Ed., p. 17, Philadelphia, J. & B. Lippincott & Co., 1860.

copeia was sadly neglected by physicians. Only seventeen vegetable drugs were prescribed, and more than one hundred drugs of vegetable origin neglected. Ten metals were honored, but more than ten were left out in the cold. In fact the entire materia medica comprised by these 27,000 prescriptions consisted of the following drugs and preparations, viz:

Acetanilid; antikamnia; antifibrin; antipyrin; aristol; phenacetin; acid arsenious; acid boric; acid carbolic; acid hydrochloric; acid salicylic; acid sulphuric; acids, twenty-five other kinds; aconite and its preparations; ammonium salts, chlorid, carbonate, bromid, etc.; belladonna, its preparations and alkaloids; bismuth salts, principally the subnitrate; brandy; camphor and its preparations; cascara sagrada and its preparations; chloroform, its preparations and combinations; cinchona and its preparations, combinations and alkaloids; digitalis and preparations; gentian and preparations; ginger and preparations; glycyrrhiza and preparations; hyoscyamus and preparations; iodine and preparations; lead salts and preparations; mercury, its salts and preparations; nux vomica, its preparations and alkaloids; potassium salts and preparations; rhubarb, its preparations and combinations.

In this study of 27,000 prescriptions from nineteen drug stores distributed between Chicago, Philadelphia, Bayonne, N. J., Boston, Washington, Baltimore, Denver, San Francisco, New Orleans, Cincinnati and St. Louis, 11.25 per cent. were proprietary articles, not including many elixirs, pills, tablets, fluid extracts, etc., which were of specified manufacture.

An analysis of 10,000 prescriptions, made by the committee on revision of the United States Pharmacopoeia of the Illinois Pharmaceutical Association, shows that in 2,613 prescriptions, or about one-fourth of the whole number, proprietary remedies were prescribed. Many proprietary articles are of the greatest value. They are often the products of manufacturing houses provided with the very best facilities of manufacturing. Many of them represent the researches of the most learned chemists, extended over years of careful investigation. In fact it is fair to assume that some of our proprietary medicines advertised to the medical profession in the medical journals represent the van of progress in pharmacy. To be sure, some of them are of comparatively little value, and should find a place in the lumber room with the trash in company with much of what is now official in the pharmacopoeia. But that is no argument against those that are of value in either case.

Now assuming that the proprietary medicine referred to are valuable pharmaceutical preparations, it is evident that a place should be found for them in the next revision of the pharmacopoeia. It is equally evident that they can not be admitted as proprietary medicines, unless the medical profession shall endorse a system which withholds from general use that entire class of preparations. Such an endorsement on the part of the medical profession would be a complete surrender of the altruistic ideal that distinguishes the practice of medicine as a liberal profession, and an endorsement of a most dangerous form of commercialism.

From what has been said above, it is very evident that affiliation between physicians and pharmacists is of first importance to promoting progress in the knowledge of pharmacology, to improving our pharmacopoeia, and to the rescue of medical and pharmaceutical practice from the grasp of the proprietary

medicine trade, which is now encroaching upon the domain of the pharmacist and the physician. But, you say, there are unsurmountable obstacles to affiliation between the pharmacists and physicians. They are at war with one another everywhere. Physicians charge that pharmacists prescribe over the counter, and that the practice is unjustifiable, as they are not competent to do so either by education or training, and it is an unwarranted interference with the physician's prerogative to treat the sick. But the pharmacist can urge with equal propriety that the physician is not competent, either by education or training to compound and dispense his own medicine, and for him to do so is an unwarranted interference with the prerogative of the pharmacist. But there is a great deal of difference between the deep blue sea and the dry land, though one overlaps the other on the beach. Now it seems to me that this question of interference between the pharmacist and physician is something of the same nature. Both may wade with impunity in the shallow waters along the shore, and do no real harm to each other, or to the public at large. But there are depths in pharmacy capable of drowning the venturesome physician; and the pharmacist who attempts to climb the high mountains of diagnosis and treatment is sure, sooner or later, to fall and break his neck. Yet in some countries these prerogatives are protected by law, and both physician and pharmacist must keep on his own side of the fence.

But, say the physicians, we can never unite with pharmacists until they no longer renew our prescriptions without our authority. It is damaging to our reputation and purse, and a very unfriendly act to say the least about it. But physicians lose sight of the fact that both professions are servants to the public, and if the patient is refused the privilege of having his prescription renewed, he will seek another physician and another pharmacist. Not until the public is educated to appreciate the necessity of consulting the physician before renewing prescriptions will the prescription-renewing nuisance be abated. Pharmacists, to a great extent, are powerless in the matter. And the medical profession has done much to foster the abuse by prescribing ready-made nostrums, so the fault is not entirely with the public either.

Physicians complain bitterly that pharmacists sell "patent" medicines and thus make themselves the agents of the nostrum monger. But the proprietary medicine business owes its present standing in the community more to the medical profession than to the pharmacist. More than ten per cent. of the medicine prescribed by the physicians in the United States are so-called "patent" medicines, and the physician is just as much to blame for prescribing them, as the pharmacist for selling them. I can see no good reason why harmony can not be restored between the pharmacist and physician. Once in touch, and working for a common object, many of the evils now complained of will rectify themselves in time, and the public will soon feel the influence of a united profession, and respect the calling of both physician and pharmacist more highly in consequence.

Two questions naturally present themselves at this juncture, 1, How can coöperation between physicians and pharmacists be secured? 2, What are the best plans for promoting progress in the science of pharmacology, and the useful arts of pharmacy and therapeutics? The answers to these questions merge into each other, so we will consider them together.

First of all, State medical and pharmaceutic societies would do well to imitate the example of the national medical and pharmaceutic societies in the matter of interchange of delegates. Sections on pharmacology should be established in State societies, and physicians and pharmacists should join in debate regarding drugs and their properties. Local pharmaceutic societies should be formed, to meet in conference with the local medical societies at least quarterly. In places where that is impractical, the local pharmacists might be invited to attend the meetings of the county medical societies, and join in debates on subjects of mutual interest. These interesting debates when published in the medical and pharmaceutic journals would benefit the entire profession. Collective investigations of new drugs and preparations both pharmaceutically and therapeutically might be undertaken in which both professions could take part. The manufacturing houses might be invited to join in this work, by establishing scientific departments for original research, and members of these departments invited to join in these conferences. By means of a common object, harmony would be secured between all concerned. The result of such coöperation in promoting progress in our knowledge of drugs upon the next revision of the pharmacopœia can easily be conceived. The next move of importance would be the abolition of the proprietary system as applied to medicine. The existence of the proprietary system as a legal factor seems to be due to a misunderstanding of the patent and trade mark laws, not only by pharmacists and physicians, but by the courts as well. That such a misunderstanding exists will be apparent on considering the verdict of the House Committee on Patents on this important matter.

A few years ago I accompanied a committee from the State Pharmaceutical Society of Delaware to Washington, for the purpose of asking the United States Congress to define a trade mark, and inform us in regard to its application. We were referred to the House Committee on Patents, of which the Hon. Benj. Butterworth was then chairman. After listening to our petition and considering the matter during more than two hours' debate, the following verdict was reached:

1. The registration of an alleged trade mark does not make it valid. Registration is merely to give notice that the thing registered is *claimed* as a trade mark. The validity of the claim can only be settled by the courts.

2. The proper use of a trade mark in no wise restricts the free use by others of the article of merchandise to which it is affixed. It confers on the user no privilege to the exclusive use of an invention of the kind conferred by the patent law, otherwise we should have the anomaly of laws diametrically opposing one another. The patent law grants to the inventor the exclusive use of his invention for a limited time, and then only on the publication of exact knowledge of the invention by a proper application for a patent, whereby the public may manufacture it when the patent expires. The use of a trade mark on the contrary, is unlimited in duration, and no publication is required when it is used on an invention.

3. The public has a perfect right to manufacture and sell any article of commerce not patented, and to do so under its proper or generic name whether a trade mark is used in connection with the article or not. For this reason courts have held that names

describing articles can not be used as trade marks on the articles they describe. Otherwise the use of trade marks would be a hindrance to competition, while the proper use of trade marks promotes competition by distinguishing between one brand of an article and another brand of the same article, thus stimulating manufacturers to improvement in processes and methods of manufacture for the purpose of excelling each other in producing the same articles of a better quality and at a lower price.

4. While not constituting itself an interpreter of law, yet the House Committee on Patents as individuals, did not hesitate to affirm the position above described, and so instructed the Associated Press reporter who was present.

The question why the courts have so frequently made contrary decisions is not a difficult one to answer. There are several reasons to account for it. Judges, as well as doctors, often make mistakes in diagnosis, and one is not more infallible than the other. Again many cases of alleged infringement of trade mark have been decided against the defendants because of the element of fraud involved. It is manifestly unjust for the courts to protect an alleged trade mark when it consists of the only name by which an article (not patented) is known to the market, because, by so doing, the manufacturer is given an unfair advantage over the public in the making and selling of an article to which all have equal right.

On the other hand it would be rank injustice both to the manufacturer and the public to permit the counterfeiting of trade marks, labels and packages, to the injury of all parties concerned. The question that has been decided in most cases brought before the courts, has been whether the goods were counterfeit, not whether the alleged trade mark was a valid trade mark. In the "Syrup of Figs" case the question was decided on its merits, Judge Swan rightly maintaining that the name "Syrup of Figs" was either deceptive or descriptive. If the former the plaintiff had no standing in court, if the latter no infringement of trade mark existed.

The principle that underlies the subject, however, is the copyright or right to copy. The House of Lords, and following the precedent, the Supreme Court of the United States, decided that authors and inventors have no natural right, or right at common law, to prevent others from copying their respective writings and discoveries. The right, when it exists at all, is a creature of statute and of grant, and subject to the terms of the statutes and grants. The other side of the bitter controversy known as the "copyright war," claim that authors and inventors have a natural or common law right to their writings and discoveries, irrespective of the copyright and patent laws. Judges who believe the latter will naturally be influenced in their decisions accordingly, and may grant a protection never intended by our law makers.

But as one learned author truly said, if the right to the exclusive use of writings and discoveries is a natural right, then it exists forever, for who can limit it? Then the inventors of pens, ink, paper, and every article of commerce, ought to have been protected in their alleged "rights" for all time, and the same "rights" should have been continued to their heirs. This would have created an aristocracy that would have owned the entire property of the world in time, and the remainder of mankind would have been the slaves of those great monopolists. Either that or the

remainder of mankind, being in the majority, would have finally revolted, and put an end to the monopoly. And what is the use of a "right" if it can not be maintained?

If we are to have patented medicines, let there be appointed a medical board in connection with the patent office to see to it that the patent law is made to promote progress in science and practice, not to hinder it. Grant no patents except when new and useful articles are really invented, and do not permit patents on mere aggregation of old and well-known drugs, that any pharmacist or physician, with a proper knowledge of his art, would naturally devise in practicing his profession. And let there be an end to the registration as trade marks of the only names by which articles are known, for it creates and maintains perpetual monopoly and such monopoly is contrary to the very spirit of the American constitution.

The latest move by the proprietary medicine manufacturers is to prevent what they call substitution upon the part of the druggists. The recent action of the anilin dye house of Bayer & Co., in relation to phenacetin, illustrates one phase of this. That house is undertaking what the *Chemist and Druggist* (an English drug periodical) calls a "monopoly crusade." Having registered the word "phenacetin" in Germany that house now proposes to force the entire world to recognize it as a trade mark, and to prevent other manufacturers from making and selling the article under the name, phenacetin.

The *Chemist and Druggist* says that "no rights granted to Messrs. Bayer & Co., by the German Imperial Patent Office can effect their claims in this country (England). Strange though it may seem, the British Patent and Trade Marks Act are not yet 'made in Germany,' nor is Britain as yet in the position of a tributary state to the Fatherland." But when one considers that the United States Patent Office granted Bayer & Co., a patent on phenacetin as a product, and recognized the word as a trade mark, it seems strange indeed that we did allow our patent and trade mark laws to be "made in Germany" and actually become tributary to a German anilin dye house.

Now a word about that tribute. Phenacetin can be purchased in England for \$1.25 a pound or thereabouts, but in the United States we are forced to pay \$16.00 a pound for it. In other words we are paying a tribute of over fourteen dollars a pound to a German house or to its American agent for phenacetin, when we can import it, or make it in this country to sell with fair profit at about a dollar a pound.

If any pharmacist attempts to import phenacetin into the United States, he is at once arrested for smuggling. If he makes it for sale he has a law suit on his hands for infringement of patent. He can not offer for sale any phenacetin except that of Bayer & Co., without falling into the clutches of the law. Of what law? Of the law of the United States which ought to protect American citizens, not foreign as against American interests.

Are these our patent and trade mark laws? Either the laws are not clear, or the fault is with the patent office and the courts; or possibly all are at fault. The fact that some of the best judges in America give decisions opposed to any such rendering of the law shows the confusion existing on the subject.

Now, what is substitution? Messrs. Bayer & Co. tell us that it is the use of any other brand of phenacetin in place of their brand of it. The druggist who

protests against this outrageous monopoly, and attempts to furnish our patients with some other brand of phenacetin at a reasonable price, is guilty of substitution, and should be condemned by the profession as a criminal, according to the rendering of the law, and in that rendering every proprietary medicine concern in the world will say, Amen. That is no exaggeration, and before we condemn druggists for substituting where proprietary medicines are prescribed, we ought to understand what is meant by substitution, or we may find ourselves endorsing a scheme of which we may have cause to be ashamed.

Is phenacetin a trade mark? How can it be and yet be the only name by which the article is generally known? Is it not a proper and descriptive appellation of the article? It is an axiom in law that the descriptive name can not be a trade mark. As its proper or descriptive name we have regarded it, not dreaming for a moment that we thereby necessarily specified the brand of Bayer & Co., by using the name phenacetin in our prescriptions, thus endorsing a gigantic monopoly. This is our only excuse as physicians. We have been deceived. But let us be deceived no longer. Let us arise and demand that the true working formula of every medicine we prescribe shall be published, and that phenacetin and every other preparation shall be provided with names free to all pharmacists under which they can be made and sold. Then if each manufacturer chooses to employ a fanciful "coined" word of his own devising as a trade mark thereon it can do no harm, for no monopoly of the product is engendered thereby, and competition will restrain the price within reasonable limits; while at the same time the trade mark will truly be what it was designed to be, viz., a protection to the public against counterfeits and substitutes.

The well-known names of the preparations now on the market have become by use descriptive and should be so regarded. I can see no objection to the use by Bayer & Co., of a fanciful designation as a trade mark on their brand of phenacetin if the true name of the article always appears on the label, and its use is free to all other manufacturers.

Laws against the adulteration of foods and drugs are excellent aids in helping along the common cause, if properly enforced. But they are calculated to do much harm if manipulated by politicians for personal ends. The same applies to a national law to prevent the transit of adulterated products from State to State. The proper enforcement of such laws would finally end in abolishing secrecy in medicine altogether—a most desirable end. The patenting of pharmaceutical machinery, processes and appliances, may not be open to serious objection, but locking up medicinal substances themselves to exclusive monopoly should never be permitted.

In my paper read before the Section of State Medicine last year,<sup>2</sup> I suggested a compromise measure for the purpose of permitting an inventor of a new and useful compound to retain the name and secret of manufacture of his invention for a limited time, provided the true working formula thereof be placed in the hands of a national committee of physicians and pharmacists, and the article marketed only under the sanction of the committee. I suggested that the system remain as it now is, only with the exceptions that a censorship shall be exercised over the market by a committee of

<sup>2</sup> The Proprietary System and Its Remedy. JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Sept. 14, 1895, p. 450.

competent physicians and pharmacists, the monopoly to be limited in time, and the system to be made scientific by providing it with a proper nomenclature and by the final publication of every invention whereby all pharmacists may manufacture the same when the patents expire.

I also suggested that every manufacturing house open a scientific department manned by competent physicians and pharmacists, who can be held responsible to the profession for their utterances, and for the representations made by respective houses in labels, in circulars, in advertisements, and in contribution of these houses to scientific literature.

Now as to the complexion of the committee. I suggested that it consists of one member each of the AMERICAN MEDICAL and American Pharmaceutical Associations, and one member each from the medical department of the Army, Navy and Marine Hospital service, to which might be appropriately added as Chairman the Commissioner or Secretary of Public Health, if such an office is finally created by Congress.

Commenting on this compromise, Dr. Henry D. Holton in his Address on State Medicine, delivered at Baltimore, May, 1895, said: "The question of proprietary medicine which interests every family of the land, is an evil which in spite of the continuous maledictions that have been hurled against it by all scientific medicine, both as organizations and as individuals, has continued to thrive, until at the present time it is entrenched behind millions of money and is held in high esteem by the people because of its ability to hide its worthless character or possible dangerous combination behind a trade mark. If the manufacturers of these nostrums were obliged to deposit with the Public Health Department, under certain restrictions, as suggested by Dr. Stewart, the formula from which they are prepared, it would do more to eradicate this stupendous swindle from the land than all the fulminations that could be hurled at it for centuries; it would have an equally elevating effect upon the science of pharmacy which is so indispensable to our success."

The following excerpt from the President's address, delivered at the annual meeting of the Pharmaceutical Association of the Province of Quebec, held in Montreal, June 11, 1895, contains in a nutshell a great deal of truth in regard to "patent" medicines and also suggests another plan for curtailing their sale:

"Patent medicines are a curse to the physicians, the pharmacists and the public. They are an unjust and direct opposition to the physicians by preventing the sick from obtaining proper advice; they deprive the pharmacist of the sale of his own preparations, and force him to keep in stock a large number of preparations which have only a limited sale, and they are injurious to the public which allowing itself to be cajoled by the certificates of cure which are the compliments of the advertisement, purchases the famous remedy which oftener does more injury than good."

"We should have in this country, as in most European countries, a commission composed of physicians and pharmacists. All demands for copyrights or patents for medicinal preparations should be submitted to this committee, with the formula, and after examination a report should be made to the government recommending or rejecting the demand. This would diminish the number of patent medicines, and the public would know that those the sale of which

was allowed, would be of superior quality and incontestable value."

The introduction of a line of simple household remedies bearing the true formula of each preparation on the label, to be used in place of secret nostrums, would be a step in the right direction. Such a line might be added to the National Formulary. The adoption of the United States Pharmacopeia and the National Formulary as a text-book in all medical and pharmaceutical colleges would certainly do much to elevate medical and pharmaceutical practice and cause all parties to adhere more closely to recognized standards.

In my paper, read before this Section at the Milwaukee meeting, in 1893, I suggested that a laboratory be established in Washington for the purpose of investigating the materia medica of the world under the auspices of the Government. The paper was well received by the AMERICAN MEDICAL ASSOCIATION and a memorial was sent to the U. S. Congress praying that the plan be carried into effect.

It has also been proposed that a National Department of Public Health be created, and a Secretary of Public Health be added to the President's Cabinet.

Now all these suggestions have merits and objections, and the same may be said concerning any plan that can be devised by human ingenuity. In considering these plans it may be well to refer for a moment to the objections and the objectors. One class of objectors own stock in proprietary medicines. They may be divided into three classes, viz., proprietary medicine manufacturers themselves, stockholders in proprietary medicine corporations engaged in the practice of medicine and pharmacy, and professional men who either hold stock in the names of their wives or other members of their families, or whose wives have invested some of their own capital in the business. I have been met with objections from all three classes. Another class of objectors are always looking "for a nigger in the wood pile." No matter who reads a paper on the subject, they always insist that he has "some ax to grind." But it is time for us to rise above the level where self-interest and petty jealousy paralyze endeavor. Something ought to be done to check the demoralizing drift of the times.

This section was originally organized for the purpose of elevating pharmacy and therapeutics, and promoting progress in the science of pharmacology. It represents in delegate capacity the entire medical and pharmaceutical professions of the United States. I hope therefore that my paper may be honored by a full discussion and referred to a committee in which both professions are represented. And I hope this committee will formulate a set of resolutions worded in language that can be endorsed by the entire press of this country, medical, secular and religious, expressing the sense of the ASSOCIATION in regard to the true place pharmacy should occupy in its relation to medicine. It is not my object to attack gentlemen engaged in the patent medicine business or to cast reflections on any one. As business men, physicians, pharmacists, teachers, writers, journalists, we should all condemn the proprietary system because it hinders the progress of medical science and arts.

A series of resolutions formulated in the spirit of devotion to humanity which we are supposed to possess, as members of a learned and liberal profession, could not fail to meet the approval of all right-thinking men everywhere. Such a set of resolutions officially sent to the State and local medical and pharm-

ceutic associations would be of value in guiding physicians and pharmacists in their relation to each other and to the public at large, and if written in a spirit of fairness to all would do much in the education of the public to a higher appreciation of medical science and practice in both departments, pharmaceutical and therapeutic.

## THE METHODIC DESCRIPTION OF A SURGICAL DISEASE.

BY EDMOND SOUCHON, M.D.

PROFESSOR OF ANATOMY AND CLINICAL SURGERY, TULANE UNIVERSITY,  
NEW ORLEANS, LA.

No art, no study has ever become a science until it had evolved its methods and its laws. The great effect and the use of these are to cover and govern a multitude of details which otherwise have to be remembered separately; also to facilitate the understanding between writers and readers.

Students sorely need a methodical guide to lead them in the intricate labyrinths of surgical descriptions, and yet those labyrinths are really only so because we lack the knowledge or the charts of their construction, or an Ariadne's thread which will be a sure guide in, through and out of the apparently innumerable turns and meanders. Upon close study it is found that in the diseased as in the healthy state nature's laws are less numerous, less complicated, more simple than we think, after we have succeeded in recognizing them, reading them, understanding them and remembering them.

Another object of this method is to assist students in remembering thoroughly, easily and intelligently; also how it is done and should be done. Although most likely and truly imperfect to the mind of many readers, the following description can not fail to assist the student of surgery; the thread may be coarse, may be made up of pieces, different materials tied together, but it is a thread none the less and as such most precious if constantly held in hand. The best of all methods or guides would be the one which all would agree to follow, however susceptible of improvement it might be.

The innumerable and complicated facts of surgical diseases can be better learned and remembered by adopting a uniform and rigorous method in their description. The guide should be inexorably systematic and always the same for each and every surgical disease. This may be dry, monotonous and hard but it will be of the greatest assistance to those who have to learn and to remember. Indeed all text-books on surgical diseases have almost the same great divisions and headings in describing a disease, but it is in the details and smaller things under those headings that the students need systematic and uniform assistance. It is to be borne in mind that the students of surgery who read a text book are to remember for ever all he reads; therefore, all superfluous words, remarks and dissertations had better be omitted so as to leave the facts as simple and prominent as possible; but the guide must not interfere with extensive descriptions when deemed desirable. Students of ordinary intelligence can readily supply in their own minds connecting words and even sentences.

The guide describing a surgical disease should be followed more or less closely, according to the importance of the disease or of the facts connected with it. If some facts are of no importance they should be

skipped and stress should be laid up on those facts only which present a practical bearing or scientific interest. It is essential to follow the guide systematically, as one fact is so intimately connected with the following one that the place where to say it can not very well be altered without disturbing the harmony of the whole. There is a place for everything and everything should be said in its place. We should say at the beginning what belongs there and not say it in the middle of the description. Again, we must say in the middle of it what belongs there and not say it at the end. It is most discouraging to read a fact concerning the prognosis, for instance here, then another a few lines further and a third one a few lines further again, separated by facts relating to symptoms, cause, etc.; instead of saying together all that pertains to prognosis where it should be said.

It may seem difficult and complicated at first, but after the guide has been committed thoroughly to memory, so as to have it at the tongue's end without hesitating to think, it will be seen how smoothly it works and how much it will assist. It is impossible to forget or skip anything as every few words almost in the guide call for an answer at its proper place, which answer is easily remembered by one who has studied the disease two or three times with this severe system and training. Students in surgery must learn how to spell, read, write and remember surgery as children learn how to spell, read, write and remember the language they speak.

According to cases, the course of the whole description or of a part of it only may be changed or inverted, but this should be done as seldom as possible so as to preserve the general application and utility of the method, even at the cost of a little apparent awkwardness, which will disappear with time and custom.

The order of description may jar against the present accepted ideas and some just objections will be made, some facts may seem to be forced in, but on the whole they are few and are fully compensated by other gains.

### GUIDE TO DESCRIBE METHODICALLY A SURGICAL DISEASE.

(An ordinary or typical and uncomplicated case.)

We will first describe the guide or course to be followed in describing methodically a general surgical disease. The type adopted should be an ordinary or uncomplicated case. This means that all points and features which are not observed frequently in the disease should be left out, to be described with all other rare or exceptional points and features, with the forms, varieties and complications of the disease. This is very important as it relieves the description of many confusing and apparently contradicting statements which so harass and perplex students. Yet these points being often of importance must be studied, but by themselves and where the attention is laid on them with all profit.

The description should begin by the *synonyms* or various names of the disease and their *etymology*.

The History is often most interesting as showing the efforts required to bring the knowledge of the disease to the present state. When possible it should be divided into periods marked by, and named after, the great steps which have characterized positive progress. The names of the investigators and writers must be given with the date of their contributions and the points or features they have specially investigated and

cleared. It is but sheer justice to the pioneers who have contributed to build the knowledge from which we are now deriving reputation and profit. This teaches the reader and student that by thus profiting by the labors of their predecessors they are incurring the obligation to make efforts to contribute themselves to the common stock for those who follow.

The definition of a disease is described after its cause or its pathology, its symptoms, course, duration, termination, prognosis, or after several of these features combined.

The frequency should be described here in a general way, only, as this feature will often return in describing the causes, lesions, symptoms, etc. The division of the disease or subject into various parts is important if it is at all complicated. A general description should be made of all the points common to the various diseases and then each division should be described separately as a separate disease.

#### ETIOLOGY OR CAUSES.

The etiology or causes of diseases should be divided into the two great divisions, the external and the internal causes.

The external causes are all those originating outside of the patient. They comprise the following headings. The geographic, meteorologic and atmospheric causes include the mention of the effects of latitude, longitude, altitude, climate, seasons, rains, storms, changes, sudden or slow, of the effects of the thermometer, barometer, hygrometer; of the influence of day and night air, etc., as a cause of the disease. Telluric causes call for the description of the action of dry soil, damp soil, wet soil, marshy soil, defective drainage, sandy soil, clay soil, calcareous soil. Zymotic, microbic, infectious, contagious, epidemic, endemic, sporadic causes should be mentioned specially; also the presence or absence of parasites as causes. The physical causes or agents may be traumatic (blow or fall), or may be the action of direct heat or cold, or of dampness or of wet on the part diseased. Chemical causes or agents call for the statement of the action of the various gases, fluids, solids, metals or metalloids, organic substances susceptible of producing the disease. Hygienic causes or agents comprise the description of the effects of the various characters and conditions of the air we breathe, the water we drink, the food we eat, the clothing, the housing, and all such. Therapeutic causes or agents are those which cause serious disorders or real diseases by their action in overdoses, or in normal doses, but on subjects of peculiar susceptibility.

The internal causes include all those which are inherent to the patient himself. They comprise the following headings: Sex. Age: Congenitality, infancy, childhood, youth, maturity or manhood, middle age, old age and decrepit age. Races. Nationalities. Anatomic causes or peculiar conditions of the part as a cause of the disease; of the skin, connective tissue, adipose tissue, tendons, muscles, fasciæ, periosteum, bones, medulla, arteries, veins, capillaries, lymphatic vessels, lymphatic glands, nerves, organs special to the region. The side most commonly affected must be mentioned. The weight, the height, the breadth of neck, shoulders, chest at inspiration and at expiration, the abdomen, the hip. Physiologic causes include the effects of the constitution, temperament, idiosyncrasies, heredity (ascending, descending,

collateral), trades, professions, habits, social condition, mental and psychic conditions (such as emotions, fright, antipathy, suggestion, grief, anger). Pathologic causes form the group of symptomatic diseases or diseases due to other diseases, directly or indirectly, *i. e.*, due to previous diseases, medical or surgical, of which the actual disease may be a sequel or a consequence, or to traumatism, or injuries, or surgical operations. These diseases may be of some of the organs or of the blood or fluids of the body (hematologic causes); each organ and fluid and its diseases should be reviewed and its effects noted as a cause of the present disease. Metastatic causes must be here mentioned.

All the above causes may be predisposing or determining; exciting, or instrumental, or controlling, or final, or ultimate; efficient or not; or primary, or idiopathic; or secondary, or symptomatic.

For each cause we must state its frequency and degree of importance.

#### PATHOLOGY OR PATHOLOGIC ANATOMY.

The lesions of each stage should be described as those of a separate disease.

The lesions are macroscopic or microscopic.

The lesions of the main diseased organ must be first described; they comprise the following: 1, the description of the alterations of the normal physical characters, *i. e.*, of the size, situation, direction, mobility, shape; the alterations of the normal structure, *i. e.*, of the color, consistency, envelopes or coats, stroma, proper tissue (cells, fibers, tubes), capillaries; the alterations of the normal chemic composition of the parts (inorganics, organics). All these may be decreased, increased, perverted. 2, the alterations due to new pathologic products. These may be gaseous (traumatic emphysema in fractures without lesions of the air passages); they may be fluid, serous (edema, dropsy) or due to blood or pus; they may be solid or semi-solid (exudations or deposits of fibrin, fibrino-plastic lymph or matter, or false membranes); they may be new envelopes (where none existed before), new stroma, new cells and arrangement, new fibers and arrangement, new deposits (granular, fatty, calcareous, pigmentary, melanotic; germs; parasites), finally new capillaries and new nerve fibrils. 3, alterations due to new chemical elements, inorganics, organics; gases, fluids, solids, metals, metalloids, etc.

The lesions of the region, *i. e.*, of the neighboring organs, comprise the lesions of the skin, connective tissue, adipose tissue, tendons, muscles, fasciæ, periosteum, bones, medulla, arteries, veins, capillaries, lymphatic vessels, lymphatic glands, nerves, of the organ special to the region, if any. These we must describe as above, lesions of each stage, of the normal physical characters, etc. The lesions of the distant organs, or the organs at large, comprise those of the organs of circulation (blood and lymphatic system), respiration, innervation, urination, digestion, generation of special sense (eye, ear, nose, taste, skin). In each we must describe the lesions of each stage, of the normal physical characters, etc. For each pathologic feature we must state the frequency and the importance.

#### PATHOLOGIC PHYSIOLOGY.

Diseased organs have altered functions. The physiologic alterations of each stage should be described as a separate disease. The possible lesions are the

following: 1, the alterations in the normal characters of the physical or mechanical phenomena of the functions of the organ; these usually affect the movements or contractions of the muscular fibers; they are decreased, increased or perverted; 2, the alterations in the characters of the chemical and vital phenomena, or action of the peculiar secretions and excretions, which will be more fully described further; 3, the alterations by new or abnormal phenomena, which may be physical, chemical or vital; 4, the alterations in the functions of the region, *i.e.*, of the neighboring organs, which may also be physical, mechanical, chemical or vital; 5, the alterations of the functions of the organs at large, *i.e.*, organs of circulation, respiration, etc.; 6, the mode of repair or of reproduction of injured and lost parts.

For each phenomenon, state the frequency and importance.

#### SYMPTOMS.

The symptoms to be described are local, regional and general.

The local symptoms may be subjective, physical, functional.

The subjective symptoms are those felt by the patient only and which can not be detected by the surgeon; they consist in pain, sensations of heaviness, of heat, of cold, of pricking.

The physical symptoms are those detected by the sight, touch, hearing, smell, taste.

By the sight we detect and describe the general appearance of the part, its attitude, the muscular movements, the color, transparency, shape (form or deformity of the parts); the sphygmographic tracing of the part, of the pulse, of the heart; we make the comparison with other side.

By the touch and by palpation we detect and describe the temperature, the consistency, the presence of emphysema, crepitus, crepitation, fluctuation, mobility of the part, of pulsations with or without expansion, of displacement. By mensuration we determine and describe the changes in the normal length or breadth or circumference of the parts. By probing, the course, depth and bottom of a sinus and the presence of a foreign body. By percussion we detect and describe the presence or absence of resonance, the dullness, the absence of elasticity. By the exploring needle we determine the presence of a liquid, and of its nature by its macroscopic and microscopic examinations.

By the hearing or auscultation, we detect and describe the alterations in the character of the normal sounds of the diseased part, and the alterations due to new or pathologic sounds.

By the smell we may detect the alcoholic breath, the fetid breath of diseases of the mouth, throat and lungs, the fetid sputum, the odor of suppuration under a dressing, the odor of blood, of incontinence of urine, of fecal matter, of gangrene, of peculiar remedies.

The fluids or secretions, normal or abnormal, presented by the diseased parts, must be described (see description of a fluid, further), also the microscopic examination of the secretions or of particles of tissues (as described in pathologic anatomy). In some cases the condition of the blood must be described (as a fluid).

Tests with inoculations, with hypodermic injections, and graftings, with fluids or particles, before or after cultures, on the same subject or other subjects, or the lower animals, must be described as parts of symptomatology.

The functional symptoms are produced by the impairment of the functions of the diseased parts; they are physical or mechanical, chemical or vital. They are decreased, increased or perverted (as above). For each symptom state the frequency and importance.

The regional symptoms or symptoms presented by the neighboring organs are subjective, physical, functional, and should be described after the same method as explained above.

For each of these symptoms state the frequency and the importance.

The general symptoms are those presented by the facial expression, the general attitude of the patient; by the organs at large, organs of circulation, respiration, etc. They may be subjective, physical, functional; they must be described as above explained. For each of these symptoms also state the frequency and importance.

The symptoms of each stage of the disease must be described; they are also local, regional, general; and in each of these cases subjective, physical, functional. For each also we must state the frequency and importance.

The stages are the premonitory, the prodromic, the incipient or *début*; the developed or established state (as described above), the terminal stage, whose symptoms vary with the termination.

#### COURSE.

The course of the disease must be stated as subacute, acute, subacute, subchronic, chronic or long chronic, stationary. State the frequency and importance of each.

#### DURATION.

The duration must be described in considering the disease as a whole and then of each stage; state the most frequent duration and the duration of each stage.

#### TERMINATION.

The termination must be described as cure, stationary, chronic state, death. State also the frequency of each.

#### DIAGNOSIS.

The diagnosis presents the following parts to describe:

1. Enumerate the diagnostic signs by which the disease may be recognized; these are derived from frequency, causes, symptoms, course, duration; also from the effects of the treatment. State the frequency and importance of each. Pathognomonic signs must always be given precedence above the others.

2. Enumerate the other diseases resembling the disease under study.

3. Make the differential diagnosis between these diseases by comparing and weighing the importance and value of each sign in each disease (frequency, intensity, peculiarity).

4. Diagnose or establish the stage, the course, the duration, the tendency to termination without or with proper line of treatment, the form and variety, the complications.

5. The diagnosis may be a diagnosis by anticipation when animals are inoculated to determine the true nature of the supposed case and determine what is to be expected in the case of the patient who has been subjected to the same cause, as for inoculations in rabies and in tuberculosis with tuberculin.

6. The retrospective diagnosis, that is the diagnosis of the true nature of the disease with which a patient

has been affected, is based upon the clinical history and the sequelæ or consequences of the disease: spots, cicatrices, impairment of the functions, etc.

#### PROGNOSIS.

The prognosis must state the general prognosis of the final termination of the disease; of its duration; the possibility of relapses and of sequelæ; for each we must state the frequency and importance of each point.

#### TREATMENT.

The description of the treatment of the disease embraces the following points: The prophylactic and preventive treatment, the abortive treatment, the removal of the offending cause, the specific treatment, the curative, the palliative, the symptomatic treatment or the treatment of the symptoms, or treatment on general principles.

In each case state the means employed. These may be hygienic (diet, rest, etc.); they may be medical and remedial (medicines of all kinds); they may be surgical (topical or operative, of a minor or a major nature). The treatment may be by the mouth, by the rectum, by enema, by hypodermic injections, by intravenous injections. State the efficacy of each. The description of the treatment of each stage is indicated above.

#### RELAPSES, SEQUELÆ, CONSEQUENCES, RECURRENCES.

The description of relapses, sequelæ and consequences must be stated carefully; state also the frequency, causes, symptoms, course, duration, termination, diagnosis, prognosis, treatment, sequelæ and consequences of sequelæ, forms and varieties, complications of sequelæ, recurrences; in a word, describe them like separate diseases.

(To be continued.)

## MEDICAL LONDON.

### NOTES FROM MY SKETCH BOOK.

BY L. HARRISON METTLER, A.M., M.D.

CHICAGO, ILL.

It is demonstrably true that distance lends enchantment, for three thousand miles of ocean does increase one's transatlantic veneration. Europe and America are veritable El Dorados when viewed respectively from the opposing shores. The philosopher of Chelsea would have been less of a hero-worshiper had he been more of a traveler. Plato's Republic was a beautiful thing to dream of in the groves of the Academy, but out here in America it seems to have drawbacks that reveal many imperfections. A medical code of ethics is "a thing of beauty and a joy forever" until—well, until you discover your high-code neighbors underbidding for your patients. Medical matters are strictly scientific abroad, you fondly imagine, until you plant your feet upon foreign soil. London with its hundred and thirty or more hospitals is far from being the medical Elysium for everybody there, as we had foolishly fancied. The wail of our insular brother against *hospitalism* is quite as loud and lugubrious as our own. "Too many hospitals and too many dispensaries" is the first response of the unhappy practitioner, when asked to tell us something of medical London. And yet with all this hospital material, post-graduate education is

not what it might be. Absence of governmental control and encouragement, over-intense individualism, and want of proper centralization are given as a few of the causes of the inferiority of London as a post-graduate medical center. As compared with Germany, laboratory teaching in England is sadly deficient. There are no endowments; there is no university teaching. There is abundance of hospital material, but it is not made use of as it should be. In the Poor-law infirmaries there are no less than 12,000 beds unused for the clinical teaching of the students. The same is true of many of the fever hospitals. All of which goes to show that medical matters in London are as much in need of readjustment as they are with us. The particular attraction for an American physician in the metropolis is the large number of special and general hospitals and the abundance and variety of clinical material that may be observed.

Every tourist, upon first arriving in London, sets out at once to visit Westminster Abbey and the Parliament buildings. As he approaches the end of Westminster Bridge, the view from which inspired Wordsworth to exclaim, "Earth has not anything to show more fair," he looks away across the river and immediately inquires about the magnificent row of buildings rising from the Albert Embankment, directly opposite the Parliament Houses. If he is a physician his interest will be quickened upon being told that those seven elegant, modern-looking structures constitute the famous St. Thomas's Hospital, an ancient Foundation by Richard, Prior of Bermondsey, in the year 1213, for Converts and Poor Children. In 1215 it was remodeled by Peter de Rupibus, Bishop of Winchester, for canons regular. Like other religious houses, it was surrendered to Henry VIII. in the thirtieth year of his reign, purchased by the citizens of London in 1544, and opened for the reception of patients in November, 1552, under a charter from the Crown. The ancient site of the hospital was in the borough of Southwark, at the southern extremity of the famous old London Bridge, near Guy's Hospital. In 1862 a railroad corporation bought the site and the hospital removed temporarily to Newington in Surrey. It was in 1868 that the foundation stone of the present magnificent edifice or edifices was laid with royal ceremony by the Queen. Her Majesty opened the hospital June 21, 1871. It contains about 600 beds and is prepared for the reception of all kinds of cases. Surgery receives special attention under its roof. The income of the hospital, derived largely from rents and donations, is about £45,000, but from this a large deduction has to be made, leaving about £33,000 for hospital purposes. The lover of the historical will find much to entertain him within a few steps of the hospital. Lambeth Palace, for six centuries and a half the city residence of the Archbishops of Canterbury, the famous Lollards' Tower and Prison full of sad memories, the Chapel, the gay and notorious Vauxhall, Bedlam, Astley's Amphitheater, Lambeth Ferry made famous by Macaulay in his description of the midnight flight from Whitehall of the Queen of James II and her infant son, and Vauxhall Bridge, erroneously associated with the name of Guy Vaux or Fawkes of the notorious Gunpowder Plot, are all in the immediate vicinity.

A few steps to the southwest of St. Thomas's stands the famous Bethlehem or Bethlem Hospital, vulgarly

called Bedlam. Even the general physician will visit this institution, if for no other reason than its remarkable history. Its name is derived from a priory of canons belonging to the Order of the Star of Bethlehem, established in a monastery near Bethlehem, and caring especially for the sick and the insane. The badge of the order was a star worn on the mantle. The hospital was founded at the Dissolution, by Henry VIII., upon the endowments of a priory established by Simon Fitz-Mary, a sheriff of London in 1246, who gave to it all the land he owned in Bishopsgate Without, and there in Liverpool Street erected the first Bethlehem Hospital. More correctly speaking it was a "dungeon house" for furious lunatics, whence it became popularly known as Bedlam. It was only large enough to contain sixty patients and it was the first institution devoted to the insane in England of which there is any record. In 1675 it was removed

171 patients were discharged as benefited and 139 as actually cured. Such results were never obtained by the old restraining and torturing methods of treatment. The income of the hospital in 1888 was over £25,000. A small number of male and female patients are now admitted on a uniform payment of £2, 2s per week. The name of Bedlam used to be synonymous with all the horrors and tortures of the Inquisition. The complete change in the modern method of treating the wretched inmates, the employment of gentleness, kindness and persuasion with all the corresponding better results, have hardly yet sufficed to remove the odium attached to the name, Bedlam. The earliest legislation in regard to the insane poor was in 1744, George the Second's time, when any two justices were given the power to arrest pauper lunatics found at large and to chain and incarcerate in "some secure place" within their parish

ST. THOMAS' HOSPITAL, LONDON.

to Moorfields, where a building was erected to accommodate one hundred and fifty-two inmates. After many additions had been made to it from time to time, it was thought best in 1814 to change its site again and to erect the buildings which it now occupies in St. George's Fields, Southwark. The architecture of the main structure is imposing. Its cupola resembles that of St. Paul's Cathedral. The hospital now accommodates about 400 patients of both sexes, and it receives *gratis*, all poor lunatics who are likely to be cured within one year and who are not fit applicants for a county lunatic asylum. The better class of educated patients are preferred, and the treatment is along the lines of kindness and consideration. The women are provided with pianos, needlework, embroidery and knitting; the men with bagatelle and billiard tables, newspapers and periodicals. In 1888,

of settlement. Up to this time enactments were made only for the custodial care of the insane considered too dangerous to be at large. They were allowed to overrun the country much to the annoyance oftentimes of the people and to the distressing neglect of themselves. Shakespeare avails himself of this state of affairs to enable Edgar in King Lear to assume a disguise:

"Whiles I may 'scape,  
I will preserve myself; and am bethought  
To take the basest and most poorest shape,  
That ever penury, in contempt of man,  
Brought near to beast; my face I'll grime with filth;  
Blanket my loins; elf all my hair in knots;  
And with presented nakedness out-face  
The winds and persecutions of the sky.  
The country gives me proof and precedent  
Of bedlam beggars, who, with warring voices,  
Strike in their numb'd and mortified bare arms

Pins, wooden pricks, nails, sprigs of rosemary;  
And with this horrible object, from low farms,  
Poor pelting villages, sheep-cotes and mills,  
Sometime with lunatic bans, sometime with prayers,  
Enforce their charity."

Until a very few years ago the lunatics of Bedlam were one of the exhibitions of the metropolis. In Hogarth's "Rake's Progress" the last scene represents a number of fine ladies screening with affected prudery by means of their fans, a half-naked, fettered madman whom they have come to see. Henry Carey, an author who lived a century earlier and who wrote "Sally in our Alley," speaks of Bedlam as one of the most popular resorts. Once he followed, out of curiosity, a gay young cockney couple—such as Sally and her lover—through their day's festivities and noticed that the latter treated his sweetheart *seriatim*, to the following amusements, namely, "a sight of Bedlam, the puppet shows, the flying chairs (? swings) and all the elegancies of Moorfields." This exhibition of the insane, heavily manacled and chained, or kept in cages of iron, afforded Bethlem Hospital a considerable revenue in fees, down to the year 1770. To further add to the funds of the hospital in the olden time, partially convalescent patients, with badges affixed to their arms and known as "Tom-o'-Bedlams" or "Bedlam Beggars," were turned out to wander and beg in the streets. The practice was stopped, however, before 1675.

A short walk northeastward from Bethlehem Hospital brings one to the southern extremity of old London Bridge and the famous old Borough of Southwark. Who does not recall with dear old Chaucer

"That, in that seson on a day,  
In Southwerk at the Tabard as I lay,  
Redy to wenden on my pilgrimage  
To Canterbury with devoute corage,  
At night was come into that hostelrye  
Wel nine and twenty in a compaignie."

and who does not remember Tooley Street where dwelt the three tailors who began their petition to Parliament with "We the people of England?" In this Borough the immortal Sam Weller was first discovered to the world officiating as "boots" at the White Hart Inn; here also stood the church of St. George's and the Marshalsea Prison so familiar to poor Little Dorrit. Not far away rises the church of St. Mary Overy, second in interest only to Westminster and containing the graves of the poet John Gower, of Edmund Shakespeare brother of the dramatist, of Fletcher, of Henslow and of Philip Massinger. Ah! but this is a famous old district and the medical tourist who is fond of historical memories and literary anecdotes will be sorely tempted to divide his attentions between Guy's Hospital, which lies in the heart of old Southwark and the other sights of the borough. Passing down St. Thomas's Street (named from St. Thomas's hospital that used to stand here) one soon comes in front of an old-fashioned archway and a row of old-time buildings. The hospital forms a hollow square in the midst of a noisy, odoriferous, bustling part of London and surrounds a quiet, well-shaded courtyard. It was founded in 1721 by Thomas Guy, the son of a lighterman at Horselydown, who became a bookseller in Lombard street and made a large fortune by printing and selling Bibles and by speculation in the South Sea Company. At first Guy gave much money to St. Thomas's hospital but he afterward bought (at a rental of £30 a year) of the gov-

ernment of that Hospital a lease for 999 years of the land on which he built Guy's Hospital at a cost of nearly £20,000. At his death he bequeathed to it £210,499. The testator's benefactions constituted the largest sum that had ever been given up to that time by any one person for charitable purposes. A very pretty way to ease one's conscience in the disposal of wealth obtained by the discreditable practice of purchasing the prize tickets of seamen at a large discount and subsequently investing them in South Sea stock! Soon after Guy's death, the executors procured an act of parliament, incorporating themselves and 51 other gentlemen, named by the founder, as president and governors of the hospital. At first the number of patients amounted to 402. In 1829 a further endowment was made to the hospital of nearly £200,000 by a Mr. Hunt of Petersham, thus making accommodation for 100 additional inmates. Other benefactors have bestowed about £10,000 more. Until quite recently the annual income of the hospital amounted to £40,000, but through the depreciated values of property and landed estates it is now scarcely £25,000. Nevertheless the expenditure for hospital purposes is £34,500. The wards contain some 600 beds. The out-patient departments are especially rich in clinical material and owing to the location of the hospital a large number of accident cases are received daily. The yearly average of patients received in the hospital is 3,000, while the out-patients that are relieved amount almost to 50,000.

Situated in the heart of an old, malodorous, thickly populated district of London, the dispensary work of this famous hospital interested me exceedingly. The hospital building consists of two quadrangles, with two wings extending from the front to the street. The west wing is quite elegant and uniform in its architecture but the rest of the edifice while regular is rather ancient looking. The courtyard might be kept in a little more attractive state with flowers and lawns, though the noble old trees give it an agreeable shade. The medical school associated with the hospital is one of the best in London and contains about 400 students. The anatomical museum especially awakened my admiration. It is unusually rich in specimens and its arrangement is unique, affording the greatest amount of facility for the study and examination of its contents. In the Chapel of the Hospital is an admirable statue of Thomas Guy in marble and the grave of Sir Astley Cooper.

St. George's Hospital, near the gay and fashionable Hyde Park Corner, was founded in 1733, contains 350 beds, has associated with it a very good medical school, and is chiefly interesting to visitors as the place where the renowned John Hunter practiced and died (1793). The London Hospital dates from 1740 and expends about £51,000 per annum in the relief of suffering. It contains 790 beds. There are many other hospitals deserving more than a passing notice, but those I have already mentioned are the most renowned and must suffice.

The practitioners of London have their offices in their residences, and usually upon the ground floor. They make less effort than we Americans do to adorn them with attractive hangings and luxurious furnishings. With crowded desks, piles of journals, charts, scientific apparatuses and other paraphernalia lying about, the offices of our London confreres have a distinctively professional and business-like appearance. The London medical man dislikes exceedingly

to talk "shop" outside of his office, whereas within his sanctum I have invariably found him full of medical chat and medical opinions. Certain parts of the city, notably in and around Cavendish Square, seem to be the favorite haunts of the medical fraternity. Here are to be seen many modern as well as old-time residences, upon whose doors hang many an old-fashioned brass knocker and ample brass plate bearing the legend "Mr. A." or "Dr. B." to indicate the home of the surgeon or physician. With proper introductions one will find the medical profession of London a most hospitable set of men. A morning call will be equivalent to staying and taking lunch with the whole family; an invitation to accompany your host to an operation will probably mean a drive to several hospitals with your generous host as guide and informant; a polite request to "drop in" upon a certain evening is an indication that you are expected to come in full dress and participate in a reception. The cordiality of our English cousins is shown by the invitations, programs, announcements of social events and society meetings that are poured in upon you during your stay in the capital. Many London physicians make a habit of keeping open house upon a special evening of each week. A table is set and the ladies of the household assist in entertaining. There is a fine *esprit de corps* amongst the London medical men, as is shown in many ways, but especially in the matter of fees. There is very little if any underbidding. Consultants are extremely considerate of those by whom they are called. An unusual courtesy is extended to one another, both in public and in private. Professional etiquette and gentlemanly demeanor are never lost sight of, as I had frequent opportunity to observe in the various medical society meetings and social relaxations.

At one of the meetings of the Royal Medical and Chirurgical Society which I attended, I was impressed with the comfortable furnishing of the apartment on Berners Street, the dignity and appropriate ceremoniousness of conduct, the courteousness yet freedom of debate, and the friendly sociability after the meeting had adjourned. In the middle of the well carpeted and heavily-draped room stood a great tall, old-fashioned stove in which blazed and crackled a cheering log fire. At the head of the room stood the throne-like president's desk, having above it a large shield ornamented with the royal arms. On either side were the desks of the secretary and treasurer. The readers of the papers and most of the audience, which numbered about fifty, were in full evening dress suits. Sir E. H. Sieveking occupied the chair, presiding in a most courtly and dignified manner. One of the papers was upon gastro-enterostomy, and as an American I was naturally much gratified to hear the author pay a high compliment to our American surgeons, especially to our fellow citizen, Dr. Nicholas Senn. He said that the latter had now made the operation so perfect that scarcely any more could be desired or suggested. The second paper was upon cicatricial transplantations and was most liberally illustrated with photographs and patients. After adjournment we all assembled in a neighboring room and partook of the light collation of sandwiches and coffee, which served to banish any stiff formality. This is a fair illustration of the average medical society meeting in London. One of the most active and interesting societies to attend is the British Gynecological Society, which holds its meetings fort-

nightly in a building in Chandos Street, near Cavendish Square. The gynecologists I found to be a pugnacious set of men and to be an observer of one of their fortnightly tilts is as exhilarating as to have been present, I presume, at a medieval tourney. What with the Clinical Society of London, the Medical Society of London, the Obstetrical Society of London, the Hunterian Society, the Harveian Society and a host of others, one need never be at a loss for a battle field whenever he may feel medically pugnacious while staying in London. He will always find there able combatants and strong bulwarks ready to entertain him.

4544 Lake Avenue.

## REPORT OF A CASE OF PERIHEPATITIS AND PLEURISY RESULTING FROM INJURY.

Read by Title in the Section on Practice of Medicine at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY J. M. G. CARTER, M.D., Sc.D., Ph.D.

PROFESSOR OF PREVENTIVE AND CLINICAL MEDICINE IN THE COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO; FELLOW OF THE AMERICAN ACADEMY OF MEDICINE, ETC.  
WAUKEGAN, ILL.

The case which is the subject of this paper was that of a farmer's daughter of German descent, aged 15 years. She was in good health although rather under weight as compared with girls of her age, and had passed the period of puberty. Her parents were strong robust people.

On Sept. 15, 1895, she fell from a tree a few feet, 10 or 12, and struck her right side against a stone, receiving an injury which stunned her. At the time I saw the patient, two hours after the accident, the pulse was 130, respirations 40, temperature normal. The seventh and eighth ribs on the right side were fractured.

A bandage was put around the thorax, and remedies administered to secure rest. On the following day the pulse was 120, temperature 102 and respiration 30. Considerable tenderness was manifested over the liver and injury of that organ was suspected. The succeeding day all the symptoms were increased in severity. Perihepatitis was diagnosed. In a week icterus occurred. The symptoms were those of perihepatitis with disturbances of respiration especially marked. No points of peculiar interest presented and it was hoped that two weeks would see the case fully convalescent.

At the end of two weeks the temperature had not subsided; the pulse was 130, respiration 30. The skin was clear, bowels in good condition, but the urine was high-colored and contained indican in excess with some increase of urates. The ribs seemed to be united and the perihepatitis had apparently subsided. What could account for the continued elevation of temperature and rapidity of pulse and respiration? Careful examination of the right thoracic region had been made frequently but no marked evidence of pleurisy had appeared. Could it be inflammation deeply seated in or about the liver or an obscure pleurisy? A thorough examination was instituted to determine this point. Finally, I thought I could detect that there was a slight reduction of the clearness of the respiratory murmur. Believing I had to deal with secondary pleurisy, I placed the patient on appropriate treatment. The pulse, respiration and temperature remained high. In two days from time of

diagnosing pleurisy, the symptoms and physical signs were well marked, and the patient passed along as in an ordinary case of secondary pleurisy, the only peculiarity being a gradual increase in the rapidity of the pulse. At the end of ten days, October 11, nearly four weeks from the time of the accident I decided that it was necessary to remove the effusion. The family, objected. Tuesday she had a chill; the family consented to let me perform paracentesis. Wednesday, October 16, I operated removing two quarts of pus. All the symptoms abated and the chills ceased. The temperature fell to 99.5. The pulse, which had reached 160, dropped to 120 in the minute. Nov. 2, 1895, the temperature was 102.5, respirations 40, the pulse 150. I decided to operate the second time. I plunged a trocar and canula between the sixth and seventh ribs, just posterior to the axillary line. The first operation was performed with an aspirator; but as I wished to introduce a drainage tube, the second operation was performed as described. The trocar was withdrawn and the canula left in place. Three pints of pus were removed and a No. 7 (Am.) soft rubber catheter passed through the canula into the pleural cavity, under proper aseptic precautions. The canula was withdrawn leaving the tube in place. A safety pin was passed through one wall of the catheter, a string tied to each end of this and the strings held in place by strips of adhesive plaster. The temperature and rapid respirations abated at once and within two or three weeks both were normal and the pulse had fallen to 120.

Malt, cod liver oil and iron tonics were administered and she gradually improved. It was not until Jan. 2, 1896, that the pus ceased flowing and only one inch of the tube remained within the chest wall; the tube was removed and the opening closed antiseptically. The patient has remained well, but the adhesion of the pleural walls has left the right side smaller than the left and cause the right shoulder to fall considerably below the level of the left; improvement is noticeable however, and at the present writing (April) she has very little deformity.

### GUNSHOT WOUND OF THE CHEST; REPORT OF A CASE; RECOVERY.

BY J. LUE SUTHERLAND, M.D.

GRAND ISLAND, NEB.

Fritz Thavenet, aged 9 years, by the accidental discharge of a small target rifle in his own hands, consequently at close range, was shot through the chest from front to back. The ball, a 22-caliber, conical, entered one inch below and one-half inch to the left of the tip of the ensiform cartilage and almost touching the costal arch at a point exactly opposite the costo-cartilaginous articulation of the seventh rib. It ranged upward, backward and a very little outward, emerged between the ribs, at the point shown in photograph, and lodged in the trapezius muscle from which it was easily extracted. A line drawn horizontally around the chest at this point is just four and one-half inches above the entrance wound. His condition one hour after receiving the wound was, pulse 84, respiration 26 and rather shallow; temperature not taken, but seemed to be slightly subnormal and there was a general pallor of the skin, but no vomiting; and when asked if he felt sick at the stomach replied, "not much." Hemorrhage was slight. Air escaped with

a bubbling sound when the ball was cut down upon and removed. The first dressing consisted in rendering both wounds as aseptic as possible, loosely plugging them with iodoform gauze, covering with large thick pads of gauze and absorbent cotton and the application of a roller bandage around the chest sufficiently firm to slightly restrict respiratory movement. This dressing was not disturbed for twenty hours, during which time, and for forty-eight hours after, he was given nothing but liquids in very limited quantities, and he was kept in a recumbent position with

head and shoulders elevated. At the second dressing, the wound in the back was covered with fresh pads and allowed to close, but the entrance wound was cleansed and plugged at each dressing for eight days. His recovery was rapid and without event; the temperature at no time was above 100 F. and at the present writing, sixteen days from the receipt of the injury, he says he feels as well as ever, there being no pain or discomfort. The wound in the back is completely healed and the one in front, having been burned with the powder, suppurred a little and is not yet closed. He was permitted to be up on the fourth day, was out of the house the greater part of the time after the sixth day, came to town, a distance of over a mile, on the tenth day.

A study of the anatomy of the parts will show that it is possible that the stomach was not wounded, but the question naturally arises, where was the left border of the liver at this time? If either of these organs were wounded, notwithstanding the smallness of the missile, there certainly would have been symptoms indicative of the fact.

The apparent miraculous escape of the stomach from injury can be accounted for by an anatomical fact and a physical condition, viz: The patient being only 9 years old the natural position of the stomach approaches more nearly the perpendicular than it does in adult life; consequently instead of the supe-

rior curvature we have an irregular oblique line, the upper third of which lies to the left of the median line. In harmony with this in this particular case is the fact that his breakfast that morning was small, consisting wholly of wheaten pancakes, and as full four hours had elapsed before the shooting, stomach digestion had advanced to such a degree as to leave that organ almost empty, but whatever of its contents there was yet remaining, it was in the most dependent part and by its weight would thus aid in dragging the stomach downward, diminishing the size at the cardiac extremity, increasing its perpendicularity and carrying the entire organ toward the

left, as the boy was standing at the time of the accident.

Taken in all its bearings it was a narrow escape between the stomach on one side and the left border of the liver upon the other. The descending aorta must have been uncomfortably near the track of the bullet also, not to mention other minor but none the less vital organs in the immediate region of the wound.

## THE SILK LIGATURE IN URETHRAL STRICTURE.

BY J. D. THOMAS, M.D.

Professor Genito-Urinary and Venereal Diseases Western Pennsylvania Medical College, Medical Department Western University; and Genito-Urinary Surgeon to South Side Hospital.  
PITTSBURG, PA.

Recently in operating upon a case of urethral strictures in conjunction with my colleague, Dr. H. R. O'Conner, at the South Side Hospital, we met with a difficulty somewhat out of the ordinary. The case was one of urinary fistula—the fistula opening upon the left side of the scrotum and due to the strictures. Beginning two inches from the meatus and involving the urethra from this point backward for the distance of another inch was a stricture that would admit nothing larger than a filiform (“a filiform stricture”). After the filiform was passed through this and into the bladder an opening was made in the perineum. An effort was now made to pass a tunneled Maisonneuve urethratome (No. 6 F.) over the filiform in order to cut the anterior stricture internally, but the stricture tissue was found so rigid that the shaft of the urethratome could not be made enter the lumen of the stricture with ordinary pressure. As a *dernier ressort* an attempt was then made to divulse the stricture by pushing the instrument with sufficient force to accomplish the object in view, but this proved a failure, for, instead of the Maisonneuve entering the stricture the penis (rather a small one) was simply crowded backward into the perineum. The filiform was now withdrawn and after the removal of the tunneled tip from the urethratome the regular screw guide was attached, thus giving the entering part of the instrument more of the wedge form, but with this change no better success was met with. This instrument again was removed, a filiform passed and the smallest tunneled instrument in our possession used, hoping to divulse or dilate sufficiently to allow the cutting instrument to pass. This, again, was a failure. It now suggested itself to me that to pass a silk ligature through the urethra the stricture might be sawed (Abbe's method for the esophagus) sufficiently to permit the urethratome to pass. This proved a success and was accomplished by tying a small-sized ligature around the bulbous end of the filiform, already in the urethra, and drawing the filiform with the thread out through the perineal opening. This left one end of the string projecting from the meatus, the other from the perineal wound, and by taking hold of these two ends and resorting to a sawing motion while an assistant made pressure on the under surface of the penis at the location of the stricture, we were soon able to secure sufficient room for the introduction of the Maisonneuve urethratome. The ligature was threaded through the tunneled end of the urethratome and utilized as a guide.

77 and 79 South Thirteenth Street.

## SOCIETY PROCEEDINGS.

## Twenty-Fifth Annual Congress of the Surgeons of Germany.

The quadricentennial "Chirurgencongress" was celebrated at Berlin in May with great festivities; among them we note a series of tableaux in the Opera House, representing the history of surgery in Germany. The Association formally adopted the proposition to coöperate in the formation of an International Congress of Surgery. The six opening addresses were all on subjects that have been created or revolutionized in the last two decades, and presented by the men who have contributed most, perhaps, to their development.

PROFESSOR BRUNS reviewed the

## EVOLUTION OF THE MODERN SURGICAL TREATMENT OF GOITRE

from the time only twenty years ago when Lücke wrote that "Surgeons generally dread and avoid an operation" and the first tedious process of extirpation, requiring sometimes 200 ligatures, to the popular Billroth-Kocher total extirpation, an absolutely certain, bloodless and artistic operation. Then came the loss of life from cachexia strumipriva after these supposed successful operations. Bruns himself was the first to become convinced that the insignificant thyroid gland was after all an important secreting organ, and that the organism suffered severely when its secretions were withdrawn. In the revulsion that followed this discovery, an old method was revived, producing atrophy of the thyroid gland by ligating the thyroid arteries. This method not proving satisfactory, enucleation, attempted by Porta in 1840, was improved by Socin, and now comprises with resection and partial extirpation, the modern surgical treatment of goitre, varied or combined to suit individual cases, and no longer considered dangerous. In Bruns' 400 cases since 1883, the fatalities have only been 1½ per cent. with none in his last 150 cases. Partial extirpation is very frequently followed by a return of the goitre, but seldom to such an extent as to necessitate a second operation. Only a dozen cases are known in 800 operations (Socin, Krönlein, Kappeler, &c.). He considers therefore the present surgical treatment of goitre as eminently successful, but still more valuable is the thyroid medication, which has proved a prompt and certain cure for hyperplastic goitre. In 300 cases of goitre of various kinds, 100 were effectively relieved and the growth materially diminished. In another 100 cases the growth was only relatively diminished, but the accompanying troubles were relieved until an operation became unnecessary. Thyroid medication is also an invaluable preliminary to an operation, especially to enucleations and resections. It decreases the amount of blood in the region and effectively prevents hemorrhage. As was stated in an article in the *JOURNAL*, April 4, page 662, Bruns considers that the success of enucleations depends upon finding and enucleating the capsule without injury to the surrounding tissue. It is the standard operation in well developed cystic and nodular goitre, and it is indispensable in double goitre, where the remaining tissue must be carefully preserved. But it must be strictly avoided if the nodules are not distinctly separate from the surrounding tissue, or if there are extensive adhesions. In such cases there is sure to be profuse and almost uncontrollable bleeding, and it is often impossible to complete the operation. Bruns' experience in 200 cases of enucleations was that the bleeding was scarcely noticeable in 70 per cent.; considerable in 20 per cent. and so profuse in 10 per cent. that the operation had to be abandoned. Post-operative hemorrhage followed in 8 per cent. Enucleation may also seriously affect the functions of the gland if the nodules are very numerous, requiring many ligatures. Resection is to be preferred in such cases. Hemorrhages can be controlled with it and sound tissue preserved, while the operation can be varied and modi-

fied in many ways to suit each case, leaving the hilus, the isthmus or the upper or lower pole as may be required, and combined with enucleations if necessary. Bruns concluded with the statement that the experiments he had been making on goitrous animals with Baumann have thrown some light on the finer processes which occur during thyroid medication.

PROFESSOR ESMARCH of Kiel, announced that his amputations of limbs and external genital organs were absolutely bloodless, owing to his

## METHOD OF DRIVING THE BLOOD OUT OF THE LIMB AND PREVENTING ITS RETURN UNTIL THE OPERATION IS COMPLETE,

and the final bandage applied. He uses a thin bandage of pure brown rubber, winding from below upward, although linen or cotton bandages wound on dry, and afterward wet, will answer the purpose. If there is any inflammation or thrombosis, he first holds the limb in a perpendicular position until it grows pale. He arrests the arterial blood with a woven rubber bandage 5 cm. wide and 140 cm. long, strong enough to compress the femoral artery in the most muscular man to such a degree that no blood can flow into the limb, fastening it with a buckle. He restricts the use of the rubber tube he invented for this purpose to operations on the scrotum and penis, and to exarticulations of the hip and shoulder joints or amputations below them. After an amputation the larger blood vessels are seized with the torsion forceps and ligated. After the wound is closed and a well-fitting, firmly compressing bandage applied, the limb is held perpendicularly and the elastic bandage rapidly removed. The patient is then placed in bed with the limb still held in this position for fifteen minutes longer, when it is lowered to a horizontal position, and there is usually no question of hemorrhage. If the bandage over the wound has not been properly applied it may be stained by blood trickling through, but this can almost always be stopped by a pad of cotton laid over the place, held firm with a rubber bandage if necessary. In the majority of cases the blood that exudes is found later when the permanent bandage is removed, in the form of a thin narrow red strip lying over the healed wound. No knowledge of anatomy is required to wind up a limb with an elastic bandage like this, while considerable skill is required to apply a tourniquet so as to do good and not harm, which is the great advantage of the former in cases of traumatism when unskilled hands render the first aid. Many lives have already been saved by them, and especially with the elastic suspenders Esmarch invented and described at the time the Czar Alexander II. died from this cause. Many operations on the internal organs, the uterus and rectum, have been much facilitated by this method of driving the blood from part of the body to another, and it is in itself a cure for certain aneurysms (W. Reid), for pseudoarthrosis (Helferich, Dumreicher), for local tuberculosis (Bier), for snake bites (Fayrer) and it prevents death from excessive hemorrhage by autotransfusion, sending the blood back to the heart (P. Muller).

PROFESSOR WÖLFLER reviewed the history and achievements of

## SURGERY OF THE STOMACH AND INTESTINES

in a comprehensive address. He said of the Murphy button that it would certainly be exclusively used if it were not for the objection that the side anastomosis can not be made deep enough on account of the swell of the button, and that there is danger to the organism from the presence of an unresolvable foreign body. He consequently advises Winiwarter's method of side apposition of the separated and closed ends of the intestine, as his own experience with it has been very favorable. The union secured is the strongest and most perfect we have. He recommends Madelung's needle for suturing and adds that all agree that as broad spaces as possible should be left, the stitches taken in sound tissue, and the mucous membrane included in the suture, while the special resistance of the submucosa must be borne in mind. The statistics of resec-

tion of the intestines are 39.5 per cent. mortality in total of cases; or 42 per cent. in 85 resections during 1875 to 1888, and 36 per cent in 161 resections during 1888 to 1895, which shows an improvement of 6 per cent. during the latter period. Examining these statistics we find that out of 221 resections, 84 were of the small intestine, with a mortality of 30 per cent.; 69 were ileo-cecal resections, with a mortality of 42 per cent., and 81 resections of the colon, with a mortality of 49 per cent.—the proportion of successes diminishing with the length of the mesenterium. Beside these figures Körte has had no fatality in 9 cecum resections and Czerny only one in 8 cases. The figures of resection with artificial anus are 78 cases, with 78 recoveries. Goetz reports 68.2 per cent. recoveries in 71 cases, and another report mentions 63 per cent. cures in 127 cases. Resection for tuberculosis of the intestines shows 73 per cent. recoveries in 34 cases, 65 per cent. cured in 20 cases of cicatricial stricture, and 46 recoveries in 114 resections for neoplasms of the intestine. The mortality was greatest, 54 per cent. cases of carcinoma, and least with artificial anus. Rydygier reports a mortality of 23 per cent. in 17 resections for chronic intussusception. The favorable results obtained in local or subserous tuberculosis of the cecum are worthy of note, the operative mortality being only 8 to 10 per cent. Many surgeons report the permanency of the cure effected, some of their successful operations dating from one to seventeen years, most of them cases of carcinoma. Equally promising are the reports of recovery without relapses in tuberculosis of the cecum, dating from one to five years. The classic method of resectio pylori is practiced with increasing success by the most experienced surgeons. Some prefer the Kocher modification, which implants the duodenum in the stomach, instead of the circular union of the open ends. It is still to be seen whether this is a permanent improvement over the old method. The operative results of resectio pylori have improved so much lately that there is no longer any discussion as to the relative merits of this operation and gastroenterostomy. The indications for each are entirely different, but resectio pylori lengthens life more than the other, even when a relapse occurs. Wölfler's statistics include the experience of fifteen operators beside himself. In a total of 92 cases of resectio pylori the mortality was 56.4 per cent. From 1888 to 1896 the percentage was only 21.2 per cent in 173 operations. This favorable showing is due to the fact that some of the operators, Kocher, Krönlein, Gersuny and Mikulicz secured immediate recovery in 84.75 per cent. of their cases. Resectio pylori on account of cicatricial formations has a more favorable showing than the cases of carcinoma—10 per cent. The proportion between them is as 25 per cent. to 31.9 per cent. It is interesting to know that the cicatrix formed at the pylorus after resection assumes the function of the physiologic pylorus, as Rosenheim has demonstrated. Also that the motor function is improved in carcinoma, while the secreting function of the mucous membrane is not improved. It would be of great service in forming a final opinion on this subject to learn the experience of those patients whose digestion has continued good for years after resection of the stomach. As to the permanent results, it is established that patients operated upon for carcinoma of the pylorus have survived many years in undisturbed good health. I find twenty-four cases on record where patients have lived from two to eight years afterward. Time has restricted the indications for resectio pylori and enlarged the scope of gastroenterostomy. All are in accord in regard to the suture in the latter; the only question is the entering point. Some, like König, Hahn, Lauenstein, cling to the original method, gastroenterostomia retrocolica (Hacker's). The immediate results of each are about equal, 45 to 42 per cent. If in gastroenterostomia antecolica a loop of the small intestine with a long mesenterium is taken, the colon is not compressed and the contents of the stomach will not escape. This also prevents the formation of the dreaded spur. When the front

wall of the stomach is diseased, or the mesenterium of the small intestine is too thin, the Hacker or Brenner method is to be preferred. It is impossible to decide at present which is to be the operation of the future, the retrocolica or the antecolica. The results of gastroenterostomy reported up to 1888 show a mortality of 55.6 per cent. in the 45 operations (against 56.4 per cent. in resectio pylori). Since 1888 the mortality in the 219 operations has been 36 per cent. (against 31.2 in resectio pylori). The mortality in 195 cases of carcinoma was 30 per cent. Without cicatricial formations 20.9 per cent. in the last eight years. But single operators have secured much more favorable results than this.

Cases of carcinoma in which the stenosis appears early and death is imminent, call for a prompt operation, and Wölfler described several cases where he had relieved patients actually at the point of death from starvation, and restored them to their usual occupations for 1½ and 2¼ years afterward. Any one who has witnessed the gratitude of such a patient will never abandon gastroenterostomy. As is generally known it produces a normal chemic action of the stomach in cases of benign stenosis, and conduces to permanent recovery. The results of entero-anastomosis (Maisonvieu-Hacker operation of incomplete scraping out of the intestine), stand in the same proportion to those obtained in resection of the intestine, as the results of gastroenterostomy to resection of the pylorus. The most conservative treatment of stenosis of the pylorus or intestines is evidently plastic surgery. In Wölfler's collection of 50 cases the mortality is only 26 per cent. There are no reports on record of relapses. Unfortunately its application is limited, as the rule is inevitable here too, that the stitches must be taken in sound tissue. The last ten years have also seen much improvement in the lesser operations on the stomach and intestines. A better and more easily closed fistula is produced now in gastrotomy, partly because we make it smaller, but principally because we have transformed it into a canal opening upward and easily closed. (Witzel, Frank). As a consequence there can be no question now of opening the stomach a second time. The immediate results have also become much more favorable. Mannaberg states that the mortality from 1849 to 1883 was 66.7 per cent. in 162 cases. From 1883 to 1886 36.9 per cent. in 111 cases. The mortality from cicatricial stenosis of the cardiac orifice of the stomach is much less, and Wölfler's own experience has been that these figures are too high, and he believes that the next few years will see them very much reduced. In regard to colostomy the progress has been that now, instead of the tedious lumbar colostomy we make colostomia iliaca, and divide the intestine obliquely (Madeling and Schinzinger, 1881), or in some other way ensure that the part leading to it is separated from the part leading away from it, while we keep the opening of the latter open (Maydl) by scraping and draining the rectum in the modern sense of the term. The part leading to it must be continent of course. There does not seem to be much difference between the results of intra or extra peritoneal colostomy. Both show less operative infection as methods improve with time. Up to 1877 the mortality was 42 per cent; to 1887 29 per cent. and to 1895 27 per cent. The experience of 120 years with colostomy in cases of carcinoma shows that 18 persons survived three to six years; 28 lived three years, 43 lived two years, and 36 died within eleven months of the operation, out of 120 cases collected by Bryant. The farther down and nearer the rectum that the carcinoma is located the longer the patient survives. Wölfler dismissed jejunostomy with the remark that it was yet too untried for a final judgment, but that it was indicated in certain forms of stenosis of the pylorus and cardia.

PROFESSOR LANGENBUCH, "the inventor of cholecystectomy," terminated his sketch of

SURGERY OF THE BILE SYSTEM,

with the suggestion that the arteria mesenterica superior should

be ligated in operations on the liver, as ligating the portal vein produces a congestion of the intestinal walls that may lead to collapse and death. It is easy to find the strongly pulsating artery by lifting the colon and pushing the small intestine to the left, when it will protrude between the pancreas and the small intestine. It is also advisable to ligate this artery as a preliminary measure to ligating the artery and veins of the liver.

Among the numerous other speakers was König, "Tuberculosis of the Joints;" Sonnenburg, "Appendicitis" (with a record of 200 operations); Kehr, "Surgery on the Gall Bladder" (record of 200 cases operated); "Jürgens on his discovery of the "Sporozoa of Certain Kinds of Sarcoma," with which he has successfully inoculated animals, in spite of the difficulty that sporozoa will not develop on the usual mediums, and Angerer on the "After-results of Thiersch's Extirpation of the Trigemini; twenty-six cases." In sixteen cases, four years have passed since the operation, seven have been permanently freed from pain, there were seven relapses, while three required a second operation. Krause's intracranial operation is indicated if the pain continues after the trigemini is extirpated. Angerer recommends extirpating the sound branches also as a preventive measure. Helferich advises extirpating the nerve as far in as possible, as the central end is the one affected, and warns against allowing the nerve to escape from the forceps. He mentioned a desperate case in which he had performed a Krause operation on the Gasserian ganglion with success. Krause added that more than half of the cases of nerves extracted terminated in a relapse, and he believed that fully as good results were attained by simple section or resection as with the Thiersch operation. It can also be resorted to later if necessary.

PROFESSOR HASSE described his successful treatment of inoperable carcinoma with parenchymatous injections of alcohol. In four cases declared inoperable by eminent surgeons he had extirpated the breast and then prevented relapses with his injections of alcohol, securing complete recovery.

#### Mitchell District Medical Society.

*Meeting held at Shelbyville, Ind., June 29 and 30, 1896.*

DR. EDMUND ANDREWS of Chicago, the President, in the chair. In the absence of the Secretary, Dr. Geo. W. Burton of Mitchell, Dr. J. W. RUCKER of Shelbyville, was made Secretary *pro tem*.

The first three papers on the program were read and discussed together. The first by Dr. J. A. Thompson of Cincinnati, was a scientific but clear and practical paper on "The Diagnosis and Treatment of Acute Purulent Otitis Media." The writer opposed the use of leeches and the ordinary methods of irrigating the ear, favoring incisions in the tympanic membrane and packing the canal with iodoform gauze.

The next paper, by DR. F. C. HEATH of Indianapolis, was a brief statement of the peculiarities of "Influenza Otitis" and some remarks upon its treatment. DR. MAX THORNER of Cincinnati, then followed with an instructive paper on "Serious Complications of Suppuration of the Middle Ear." He showed that from one-third to one-half of all brain abscesses are of otitic origin. Among the other complications mentioned were sinus thrombosis, meningitis, caries, necrosis, hemorrhage and the general cachexia from a protracted suppuration.

The discussion was opened by Dr. Dudley Reynolds of Louisville, who opposed the use of water, leeches, hot or cold applications, favoring peroxid of hydrogen, paracentesis, politzeration and the internal use of the salicylates.

DR. THOMPSON in closing defended his method of incising the membrane. Dr. Heath held that the satisfactory results obtained more than justified the use of water, leeches, hot and cold applications and other measures advocated in his paper

His position was endorsed by Dr. Thorner, who also showed that incising the membrane may carry infection into the middle ear, an epidermal surface being extremely difficult to disinfect.

DR. J. G. SHERRILL of Louisville, presented the subject of "Intestinal Anastomosis." He favored lateral anastomosis by means of the clamp devised by Dr. H. H. Grant. Its advantages are: 1, no change in the direction of the fecal circulation; 2, no foreign body; 3, less danger of contraction of the gut; 4, nearest to the natural method of repair; 5, means of performance always at hand.

DR. EASTMAN of Indianapolis, expressed his preference for end to end anastomosis, using iron-dyed silk in the Czerny-Lembert suture.

DR. HALL of Cincinnati, thought the method advocated by the essayist better than the Murphy button in emergency work and less likely to cause impaction. As to suture he would use catgut, running stitch.

DR. RANSOHOFF of Cincinnati, had lost several cases with the Murphy button and while they were bad cases and might have died under any method, he believed the button was a foreign body and likely to cause obstruction.

DR. MATTHEWS of Louisville, believed the tendency was now toward lateral anastomosis and that Dr. Grant's method was sure, clean and easily learned.

DR. KATTO of Decatur, Ill., spoke of a method of end to end anastomosis by invagination.

"The Necessity for Opening the Cranium after Injuries Producing Coma and Convulsions," was the subject of a paper by DR. W. B. FLETCHER of Indianapolis. He exhibited a number of calves' brains and skulls, showing lesions principally at the base of the brain from blows on the top of the head and marked shattering of the inner tables of the skull where there was little evidence of injury outside. The paper was discussed by Drs. Reynolds, Parsons, Sherrill and Ransohoff, who cited cases confirming the writer's statements.

DR. S. C. AYRES of Cincinnati, presented a thoughtful paper on "Artificial Ripening of Cataract." His method is trituration of the cornea with the smooth-rounded handle of a Graefe knife, previously moistened with Pavy's solution.

DR. REYNOLDS feared injury to cornea by this method and preferred applying a needle directly to the lens. He claimed good results however in extracting immature cataracts.

DR. RICE of Indianapolis, objected to the method of Dr. Reynolds as liable to cause sympathetic ophthalmia. He said that Fuchs had shown that contact was all that was necessary, the essential thing being separation of fibers of the lens to allow infiltration of aqueous or vitreous. Dr. Ayres in closing said that there need be no fear of injuring the cornea if the method he advocated was carefully carried out.

A case of gallstones was reported by DR. EDWIN RICKETTS of Cincinnati. The main point in the discussion was as to their location, Dr. Eastman contending that they were always in the cystic duct while Dr. Ricketts held that they were found, occasionally at least, in the common duct.

In the evening a very enjoyable reception was given by the Shelby County Medical Society. It was attended by a large number of the citizens.

At the morning session, second day, PRESIDENT ANDREWS read his address on the

#### NEW WEAPONS IN WAR AND THEIR EFFECTS ON MILITARY SURGERY.

He showed that the new smokeless powder is effective at greater distance than the old. The guns are far more destructive. All open ground can now be swept with a storm of bullets. The famous old charges of cavalry and infantry can never occur again. The new tactics require thinner and longer lines. Each company has men trained in first aid to the wounded. The surgeons' camps and field hospitals must be

in gorges, hollows and behind hills to avoid the long range guns.

There are new difficulties in bringing up ammunition as well as disposing of the wounded. The question of antiseptics and asepsis is a grave one. The dependence must be on hot water, granite pans, rubber pouches, sublimated gauze, etc. The paper was briefly discussed by Dr. A. W. Brayton of Indianapolis. Following this, DR. JOSEPH RANSOHOFF of Cincinnati read an essay on "The Radical Cure of Umbilical Hernia by Omphalectomy." Four cases were reported operated on within the year without recurrence, up to date. The salient features of the operation proposed are excision of the ring, suture of the recti and buried metallic sutures. This paper was brief, clear and well received.

Under the title "Credulity and Skepticism in Medicine," DR. W. G. MCFADDEN of Shelbyville vigorously opposed the general use of new remedies until their true qualities were proven by those using them in hospitals, and censured the over-zealous gynecologists. In the discussion by Drs. Culbertson, Ricketts, Sterne, Reamy, Reynolds and Hall, issue was taken with the author, especially by the gynecologists.

In the afternoon session DR. W. M. CATTO of Decatur, Ill., reported twelve cases of "Puerperal Eclampsia" seen in fifteen years, about one to every 150 confinements. Most of these recovered. The treatment advocated was elimination by bleeding, purging, diuresis and diaphoresis.

DR. REAMY opposed bleeding as dangerous treatment and advocated veratrum viride assafer and as effective. DR. C. K. BRUNER of Greenfield reported his experience with veratrum, confirming Dr. Reamy. In closing, DR. CATTO said he feared the drug more than the lance. The following paper was also read: "The Value of Certain Therapeutics in Functional and Organic Diseases of the Nervous System," by DR. CURRAN POPE of Louisville; "Cerebral Arterio-Sclerosis and Its Relation to Apoplexies," by DR. A. E. STERNE of Indianapolis; "Treatment of Typhoid Fever," by DR. J. C. CULBERTSON of Cincinnati; "The Similarities between Albuminuria and Glycosuria" by DR. GUIDO BELL of Indianapolis, and "Nicotin Amblyopia," by DR. R. C. HEFLEBOWER of Cincinnati.

The election of officers resulted as follows: President, Dr. Samuel Kennedy, Shelbyville, Ind.; vice-president, Dr. J. Garland Sherrill, Louisville; corresponding secretary, Dr. J. W. Rucker, Shelbyville; permanent secretary, Dr. Geo. W. Burton, Mitchell; chairman program committee, Dr. F. C. Heath, Indianapolis; executive committee, Dr. S. C. Ayres, Cincinnati, Dr. Thomas J. Whiting, Nokomis, Dr. Dudley S. Reynolds, Louisville, Dr. F. C. Heath, Indianapolis, and Dr. A. J. Banker, Columbus, Ind.

#### British Orthopedic Society.

This society met at Birmingham, Eng., on May 30, 1896. The New General Hospital, the General, the Children's and the Royal Orthopedic Hospitals were visited by the members.

MR. WM. THOMAS showed cases of congenital torticollis, severe lateral curvature in a male adult, congenital absence of metacarpus and phalanges, double congenital displacement of the hip and talipes treated by tarsectomy.

DR. WARDEN showed a case of partial absence of the fibula, marked lateral bending of the tibia, associated with congenital talipes valgus.

MR. E. LUKE FREER brought before the meeting a case of double congenital talipes equino-varus which was successfully treated by tenotomy, wrenching and manipulation. He also showed a case of rhachitis adolescentium. The girl was aged 16 years and had been under his care for severe genu valgum when 4 years of age, and had worn instruments for four years with no material improvement. A double osteotomy was then done and she continued to wear supports for three years more.

Mr. Freer then lost sight of her for eight years and a few months since she was brought to him again in a condition of pronounced genua vara. He also showed a case of knock-knee which had been treated by osteotomy, and another case of very severe congenital talipes equino-varus.

The above cases were discussed by Mr. Keetley, who stated that in his opinion Mr. Thomas' case of lateral curvature in the male adult was probably due to sciatica. Mr. Openshaw referred to cases of congenital dislocation which had been under his care in which he had operated by Lorenz's method with success, except in one instance, in which he carried out Hoffa's procedure, the patient dying from shock.

MR. ROBERT JONES brought forward a case of recrudescing rickets and gave the following history. The patient, a girl of 16 years, was admitted into the Southern Hospital, Liverpool; the family history was good. She was the second of four daughters and her sisters were of moderate physique, strong and free from deformity. She passed an uneventful childhood and there was never any suspicion of rickets. At the age of 7 she felt rather poorly and was ordered change of air. On her return, twelve months later, it was noted she had developed knock-knee. She had no fever and no particular ailment when first attacked, but since the genu valgum appeared her back had been painful. Up to two years ago she was able to walk comfortably, but since then her symptoms had been much aggravated and she had been quite unable to stand or walk. She had always been a dainty feeder and was said never to have made a good meal. On examination it was found that the left parietal bone was slightly flattened, so that the head was asymmetrical. The sutures were closed but the sulci were well marked, especially that between the frontal and parietal bones. The palate was arched and all the teeth except the wisdoms were present. The lower jaw was thickened at the angles and pointed at the chin. The circumference of the head was twenty and one-half inches. The chest was somewhat barrel-shaped, the ribs were beaded, and Harrison's sulcus was marked. The heart and lungs were normal. There was also some rib deformity, due to a slight lateral curvature. The abdomen was large and prominent; the abdominal muscles were flabby. In addition to a lateral curve to the left, there was very marked lordosis, accompanied by rigidity. The angles of the scapulae were prominent. There was nothing very noticeable about the clavicles or humeri. The radii were enormously thickened at the lower end so that the appearance was somewhat that of a very bad Colles' fracture. Supination was much interfered with, pronation to a slighter degree. The arms were very thin and poorly developed, but she had a fairly good grasp. The pelvis appeared to be normal; there was considerable enlargement of the lower end of the femora, and the internal condyles were very prominent and elongated so that on extension of the limbs, there was an exceptional knock-knee, the leg forming an obtuse angle of 135 degrees with the thigh. This deformity was more marked on the left than on the right side. There was also flexion deformity of the knees and it was impossible to get the legs perfectly extended. Flexion perfect and the knock-knee disappeared. Further, there was flexion deformity of 25 degrees at the hips. The feet were in varus position, and this was due to an acute bend at the lower end of the tibia just above the ankle joint, and also to a great thickening at the lower ends of the fibula. The sacrum was curved and prominent. The child was very stunted in growth and small for her age, and ill nourished. She was fairly intelligent, but could not walk or stand at all. There was one ninth albumin in the urine.

MR. JONES—Attention has been drawn in this country to either late or recrudescing rickets by Dremitt, Clutton, Lucas and others, and the rarity of the condition has been generally admitted. I am convinced, however that its rarity is overstated. Without being able to verify the precise number I

have certainly seen between twenty and thirty cases. In most of these the lower extremities are alone affected. In some, as in the present case, the head, chest and upper extremities participate in the deformities. In all, the enlargements are more or less shared by the epiphysial ends of bone. They therefore differ from the cases of Clement Lucas in the fact that the deformities are not confined to the shafts of the bones. Clutton, in the description of his case, draws attention to the fact that the shafts of the bones of the forearm were not bent and that this was another confirmation of the fact that the upper limbs bend in infantile rickets from the inability of the little patients to assume the erect position. In the case I report, the forearms are characteristically bent; the deformities starting long after the patient had ceased to crawl. This bears out several observations I have made with regard to the etiology of knock-knee; the deformity characteristic of rickets arising and developing while the patient remained in bed. In none of the reported cases do I note any reference to flexion deformities at the hip and knee, symptoms which I have frequently observed. From my experience I should conclude that: 1, late rickets is generally recrudescient; 2, that epiphysal enlargements are an essential feature; 3, that while static influences bear an important part in the production of the limb deformities they are not essential factors; 4, that in addition to the common deformities of rickets, flexion deformities are found in the hip and knee and frequently limitations of movement in other joints; 5, that contrary to the experience gained from the cases of Clutton, Pitts and others, the skull and face may exhibit rachitic deformities; 6, that the sacrum generally presents an angular projection about its middle.

MR. A. H. TUBBY remarked that although late rickets was accepted by many authors as a veritable disease, yet he had not come across any microscopic examination of the epiphyses of bones proving its identity with rickets of infancy.

After votes of thanks were passed to the Birmingham members for their hospitable reception and to the Birmingham Medical Institute for allowing the use of the rooms, the proceedings terminated.

## SELECTIONS.

**Exploration of the Duodenum by Intubation.**—In the *Bulletin of the Johns Hopkins Hospital*, April, Dr. J. C. Hemmeter reports that he has been engaged in working out a new diagnostic procedure, which he calls "Intubation of the Duodenum." This is not an analogous procedure to the passage of a rigid tube into the larynx in occlusion of the lumen of that passage by pseudo-membrane or edema. It is possible that intubation of the duodenum may be interpreted as meaning the insertion of a rigid tube through the pylorus, to secure permeability in the duodenum in cases of stenosis resulting from cicatricial contraction or of stenosis resulting from neoplasm. The intubation referred to in this report, however, is simply the passage under normal conditions of a tube through the mouth, esophagus, stomach and pylorus into the duodenum. Dr. Hemmeter's explanation is as follows:

"The possibility of this procedure occurred to me during a long series of experiments in the biologic laboratory, in which it was attempted to get a method of registering the peristalsis of the stomach upon the kymograph. We use a deglutible apparatus which consisted of a very soft rubber bag having the shape of the stomach kymograph, which was passed into the stomach in the collapsed state and then blown up so that it applied closely to the walls of the organ. In this manner the muscular contraction of the stomach, the impulse of the aorta and the respiratory movements were registered through a writing apparatus connected with a manometer to which the esophageal tube leading into the intragastric bag was attached.

In one or two cases it was discovered beyond a doubt that this intragastric bag had slipped the duodenum, which was evidenced not only by the length of the tube, but also by the fact that when the bag was blown up the stomach was not distended, the patient complaining of pain in the region of the gall bladder by the distension. From a large number of very accurate measurements on living and dead subjects, male and female, it has been found that the average length of the esophagus, or rather the length from the incisors to the deepest part of the stomach, is 59 centimeters. The average length of the stomach in its longest direction is 18 to 22 centimeters. The greatest width is 7 to 8 centimeters. Under normal conditions, therefore, there is no physical reason why a tube can not be passed into the duodenum, presuming that the tube does not kink or turn in the stomach, which it will unfortunately do. The esophagus takes a nearly perpendicular course until near the bifurcation of the bronchi it begins its spiral turn, which brings it to the left of the aorta. In that region it has a very gradual swelling, so that it there assumes a spindle shape. About the level of the tenth thoracic vertebra the esophagus begins to narrow down until its narrowest portion is reached, at what is called the hiatus. The foramen esophagum is about 8 centimeters behind the articulation which the sternal end of the tenth rib makes with the base of the ensiform cartilage. From this point the subphrenic portion of the esophagus passes decidedly to the left, expanding in a funnel-shaped manner. This deviation causes a deflection of the tube. To avoid this deflection it occurred to me to fill the stomach with a rubber bag, the superior surface of which contains a groove running longitudinally. After the bag is inflated the tube is passed down and finds its way along the groove and enters the pylorus. Now the sphincter of the pylorus is not an absolute sphincter. The sphincter of the bladder will retain water; not so the pyloric sphincter."

In the discussion that followed in the Hospital Medical Society, Dr. Howard A. Kelly briefly referred to his two diagnostic intestinal instruments, the sigmoidoscope and the proctoscope. He said, "My practical interest is entirely in endoscopic progress at the other end of the body. As I have had some questions to discuss relative to priority lately, I realize how important it is to get on record in time, so I will show you what I have done to meet Dr. Hemmeter. Those of you who have been in my clinic have seen my proctoscope and sigmoidoscope in use. They have been very successfully employed in a number of cases in diagnosing and treating diseases of the whole of the rectum and a large part of the sigmoid. The following case illustrates their use: A doctor in New York swallowed his teeth one night. They stayed in his stomach quite a while and then he felt them pass the pylorus; then they rested at the ileo-cecal valve for a long time. Then they were traced from the ileo-cecal valve to the sigmoid flexure, where they lodged. Here they could be felt by the doctor himself as well as by Dr. Wyeth. He came down to Baltimore to me one evening for an examination by my method, but as the rectum was too full of fecal matter for an examination at that time I ordered an active purge. The next day he came and I passed a long coloscope into the rectum, while he was in the knee-breast position; he felt the instrument strike his ribs and was well satisfied that he had passed the teeth during the night on account of the purge. I certainly found nothing abnormal. The difficulty usually is that the expansion of the bowel ceases in the sigmoid. I now have an instrument in my operating room which is made to reach from the anus to the splenic flexure. The plan of construction is this: A long metal tube with a piece of glass in the proximal end has set in one side a small electric lamp which is connected with a storage battery. On the other side is an opening attached to a Davidson syringe with which the bowel can be inflated; under inflation we can follow the bowel up to the splenic flexure, and

sometimes with a prism we can see around into the transverse colon."

**The Recent Serum Tragedy at Berlin; Official Report.**—Professor Ehrlich's official report on the serum used in the sad Langerhans case has been published by the Prussian *Cultus-minister*. Ehrlich comes to the conclusion that the serum was entirely normal in its constitution. He says: "In the Langerhans case No. 216 of the Höchst works was used. This No. 216 had been officially tested on December 16, 1895, and passed on for sale on December 18, the examination having demonstrated the required 100 immunizing units per cubic centimeter, perfect sterility, and the prescribed admixture of carbolic acid. Immediately after the announcement of the death this serum was subjected to a careful reëxamination. As the legal authorities had disposed of the remainder of the bottle used for the injection, samples of the same pass number that had remained at the station were taken, and also bottles of the same number from the stock of the Charité Dispensary, where Professor Langerhans's bottle had come from. The serum again showed the required 100 units per cubic centimeter, and bacteriologic examination proved it to be free from germs, so that there can be no question of any subsequent formation of poisonous bacterial products. By a number of experiments on animals the admixture of carbolic acid was shown to be no higher than permitted. Thus, on reëxamination too, the serum answered to the tests exacted. Nevertheless, it seemed important to ascertain whether, perhaps, toxic effects produced by this number had been noticed anywhere else. About 1,300 portions of this serum had been brought on the market, and if it really contained toxic substances it seemed extraordinary that no one had drawn attention to the dangerous qualities of this particular number. Researches were made in the hospitals that had received No. 216 serum from the Höchst works (serum depôt of the Royal Charité Dispensary, Julius Hospital in Würzburg, General Hospital in Hamburg, sick club of the Royal Dockyards in Kiel, Municipal Hospital in Magdeburg, Krefeld Hospital); in none of these places had any special, much less any toxic, effect of the serum been observed. According to the statement of the director of one of these hospitals, a child of 18 months had been given a dose of 16 c. cm. without showing any alarming symptoms. This is at least ten times the dose used for Professor Langerhans's child. The director of the Hamburg Hospital gave an account of immunizing experiments on children. He says that four bottles of the No. 216 serum were used for immunizing children in the eye department; not only were no ill effects observed, but it might be confidently asserted that none existed. Thus the clinical communications also contradict the assumption that substances of strong toxic action were contained in the serum. On the contrary, the No. 216 serum has shown itself to be a preparation answering to all the tests at present exacted, and perfectly normal in its constitution."—*British Medical Journal*.

**Orphol.**—Dr. Edmond Chaumier, physician to the Sanatorium of Touraine, and director of the Animal Vaccine Establishment of Tours, France, has written an article on the use of orphol for intestinal antiseptics, and in surgery, of which the following is a summary:

All the various substances employed for the purposes of intestinal antiseptics, calomel, carbolic acid, creosote, boric acid, carbon, iodoform, etc., are useful; but all have their disadvantages. Thus calomel, whilst it has an antiseptic action and cleans out the putrefying matter, may lead to a catharsis and an absorption of mercury that may be dangerous.

Naphthol has none of these drawbacks, and possesses certain important advantages of its own. In typhoid fever it keeps the tongue moist, lessens the stupor, delirium, subsultus, and all the ataxo-dynamic symptoms of auto-intoxication. Its use diminishes the number of microbes in the intestinal tract.

Together with naphthol, Dr. Bouchard employed the salicylate of bismuth. This causes ringing of the ears, on account of the absorption of the salicylic acid into which it is decomposed in the intestines. The caustic taste of the naphthol renders it necessary to administer it in capsules; given otherwise it is vomited.

These inconveniences have led me to try another naphthol compound, orphol, which is a naphthalate of bismuth. It is a grey powder that has neither the penetrating odor nor the burning taste of naphthol. Jasenski's experiments have shown that orphol is decomposed in the intestinal canal into naphthol and bismuth. The naphthol acts as an antiseptic, and, if there is a diarrhoea at the time, the bismuth set at liberty controls, but does not cause the obstinate constipation that the other bismuth salts do. Orphol stops the development of microbic life in the intestines, yet is perfectly harmless; 10 gms. (150 grains) given daily to dogs, and 5 gms. (75 grains) daily in the human subject have done no harm, even when continued for weeks. Jasenski recommends the drug in all maladies, acute or chronic, of the digestive tube. Hugo Engel regards it as the best intestinal antiseptic, and has given it in large doses both to children and to adults.

Orphol contains 26.5 per cent. of naphthol, and 73.5 per cent. of oxid of bismuth. Bouchard having demonstrated that to obtain intestinal antiseptics in the adult, 2.5 gms. (37½ grains) of naphthol daily are required. Ten gms. (150 grains) of orphol would be the quantity necessary to obtain a like result. This dose can be given without difficulty; but experience has shown that 5 gms. (75 grains) daily has almost always been sufficient.

In cancer of the stomach antiseptics necessarily plays a large part in the treatment; and orphol is to be employed in preference to all other drugs, from the fact that it in no way irritates the diseased tissues. It may be given in half gm. (7½ grains) doses dry in capsules or with syrup. It may also be employed in suspension for lavage of the stomach. Ten gms. (150 grains) in suspension in a liter (1 quart) of water used after washing with plain water and repeated twice a day. In gastric ulcer it has been highly recommended by Wilcox, and may be used in capsules, or in suspension, as in cancer.

As an antiseptic and germicide it is commended in all morbid conditions of the stomach and intestines due to fermentation, putrefaction, or the infection by special germs.

Wilcox has found great benefit from the use of orphol in typhoid fever. Dr. Hueppe recommends orphol in cholera, he having treated a large number of cases with it in the hospitals of Hamburg. Nencki, Schubenko, Blackstein, and Petkevitch have administered it with success in the choleric diarrheas. Jasenski, in six cases of intestinal catarrh, effected cures in two to five days. It was successful even in old chronic cases.

For surgical antiseptic applications orphol would seem to be especially indicated, in the place of iodoform, salol, etc. The accidents so common with iodoform would certainly not occur. It should be very useful also in burns. Being antiseptic, it is as efficacious and more useful than bismuth. I have used it as a powder in the treatment of the ulcerations of the thighs and genitals in children, either pure or mixed with talcum. In impetigo I use orphol with vaselin, 1 to 10, with much success.

**The Dangers of Diphtheria Antitoxin.**—At a meeting of the Société Médicale des Hôpitaux (*Semaine Médicale*, April 29, 1896) held on April 24, M. Variot made a brief communication concerning a case of death following the use of antitoxic serum. A child aged 18 months had a slight attack of pharyngeal diphtheria, followed by croup, with spasm of the glottis. Intubation was resorted to, and 20 c.cm. of antidiphtherial serum was introduced in two doses; the child died in forty-eight hours, with a temperature of 104.9 F. On *postmortem* exam-

ination no special cause for the death was found in the pharynx or larynx, from which the membrane had disappeared. Without affirming that the antidiphtherial serum was the cause of death in this case M. Variot suggests that it may possibly have had something to do with the production of the high temperature, and throws out the suggestion that there may be, in certain serums, a fever-producing body which can not, however, be recognized by chemical analysis. Fully recognizing, as he does, the enormous value of this serum, he desires to have this point settled at once. A colleague, M. Sevestre, who has had very extended experience of the use of serum, has never observed any such accident among his cases, and he thought that this must be looked upon as quite an exceptional case: he therefore did not think it right, until the proof of the nexus between the serum and the high temperature could be more fully demonstrated, that the serum should get the blame. There can be little doubt that with some serums, and in the hands of some physicians, a larger percentage of high temperatures have been observed than in others. This statement does not apply to the slight initial rise of temperature which frequently follows the introduction of antitoxic serum and precedes the fall which is now by most people looked upon as a somewhat favorable sign, indicating as it does that the serum is exerting its specific effect on those cells that have been overstimulated and paralyzed by the toxin. It applies rather to the secondary fever which is usually associated with the rashes, the joint pains, and the other sequelæ, which are said to be associated with the use of this substance, and which appears to be due to the fact that the skin may be stimulated to excrete the products formed by the tissue cells under the influence of the antitoxic serum, and perhaps also of the toxin. The second possibility is that there may be some irritant matter in the serum, under certain conditions, which may determine these results. In view, however, of the fact that only one patient in every two or three ever has the slightest symptoms which could in any way be ascribed to the serum, and as some physicians treat case after case without the occurrence of any such symptoms, only one occurring here and there, may it not be that idiosyncrasy plays an important part in determining the effects mentioned? Coming, however, to the special cases in which death has been ascribed to the injection of antitoxin, it must be borne in mind that diphtheria has always been looked upon as one of the most treacherous diseases with which a physician ever has to deal. Patients who appear to be on the high road to recovery have succumbed with symptoms of heart failure, of pyrexia, and various forms of paralysis. It is too much to hope that antitoxin, especially when administered in the later stages of the disease, can prevent the fatal issue of a number of such cases of diphtheria that come up for treatment. The death rate will be and has been diminished by the use of the remedy in the early stages of the disease even in severe cases, but when not given until the later stages we must always expect a certain proportion of accidents similar to those with which we have hitherto been only too familiar before the introduction of antitoxic serum.—*British Med. Jour.*

**The "Open air" Treatment of Phthisis.**—At a recent meeting of the South Eastern Branch of the British Medical Association, Dr. Arkle read a paper on this subject, with special reference to *Heilanstalten* or sanatoria. He drew attention to the great number of cured phthisical cases which were observed by persons who made a large series of postmortem examinations on old town dwellers, male and female, and remarked that it was almost usual at such necropsies to find, either from old cicatrices, calcareous nodules or old caseous foci, evidences of an attack of tubercle in early life. Probably the majority of these patients had thrown off the attack without any special treatment. Could anything be learnt from observations on the life-history of the tubercle bacillus in the laboratory or

from a study of the disease as it was seen clinically? Points of importance seemed to be the somewhat limited range of temperature at which this particular organism flourished in the laboratory, the dangers which arose from the dissemination of the bacillus or its dried spores in every day life, and the ease with which these latter could be counteracted. Clinically, the very considerable amount of digestive disturbance which was so common in cases of phthisis was referred to, and the great repugnance these patients had to fatty foods. From the observation of these two points, in the natural history of the disease, the author urged that treatment in a sanatorium offered the best prospects of success. The essentials of a good sanatorium were then enumerated, special reference being made to the facilities for keeping the patients in the open air, in the construction of such an establishment, and to the care which must be taken to disinfect all sputa and other dejecta. Attention was also called to the system of "hardening" patients which was carried on in these institutions. In the climatic treatment of phthisis the sea, the dry land, mountains and valleys, hot dry air, cold dry air, all varieties of elevation, temperature, and situation had their advocates, but without doubt the most important quality must be the purity of the air in the locality where the patient was treated. The author considered that with proper care and selection suitable places could be found in the British Isles. In the matter of diet and medicinal treatment the digestive functions were kept active and vigorous, as much milk taken as possible in addition to a good full diet, the patient being kept as long as possible in the open air in the day and with the windows of his sleeping room open at night; little then remained to be done except to prevent him contaminating his surroundings with sputa or other tuberculous dejecta. Inasmuch as pure air, antisepticism and nourishment were the chief potent factors which were offered (under certain restrictions) by any health resort, due thought ought to be given to every individual case before it was decided to banish such patients from our shores.—*Brit. Med. Journal.*

#### Practical Notes.

**Rubella.**—One of the most interesting features of rubella is the constant presence of glandular enlargements. So constant is the occurrence of this symptom that the diagnosis should be made with caution when it is not present. The glands most frequently involved are the cervical, the post-cervical, and the sub-occipital. A nest of small glands found low in the neck behind the sterno-mastoid is especially characteristic of this disease. Although rubella is an extremely mild disease, the peculiar glandular enlargements, the marked eruption, and its close simulation of other more serious diseases render it of considerable interest.—*Arch. Pediatrics*, June 1896.

**Cystin.**—Dr. E. Cutler says of cystin: It is not as rare as thought and is of clinical importance. Cystinic rheumatism is so called because cystin predominates in the blood. It is probably a normal body if kept in solution in the blood by sufficient water supplied to the system. Cases where cystin is found oftenest are those in which sulphur has largely entered into the food *i.e.*, yolks of eggs. Treatment of the condition consists in removing sulphur foods as far as possible from the diet. Supply menstruum in abundance; distilled water is best. Give lemon juice as a solvent.—*Med. Bulletin*, June 6.

**Sponge Grafting in the Orbit for Support of Artificial Eye.**—Dr. E. Oliver Belt has performed the operation in five cases with fairly good results. He says: The operation is a simple one, and is performed as follows: The eyeball is removed by the ordinary method under strict asepsis. After all hemorrhage is arrested, the socket is washed out with formalin solution, 1 in 1,000, followed by sterilized salt solution. A globe of fine, soft, sponge about three-fourths the size of the eyeball (previ-

ously sterilized in 5 per cent. formalin solution and rinsed in the salt solution) is then inserted into the socket, or capsule of Tenon. The conjunctiva is brought together and sewed with rat-tail sutures. The eyelids are then closed with compress and bandage. In a few weeks the sponge is filled with new tissue, which in time becomes firm, solid flesh, making a full orbit and a fine support for the artificial eye. The sponge fibers are apparently absorbed.—*Medical News*, June 27.

**Transient Bulbar Paralysis Caused by Malaria.**—Orlandi describes in the *Riforma Medica*, several cases of apparently severe progressive bulbar paralysis, following an attack of pernicious malaria, all cured by large hypodermic injections of quinin.

**Treatment of Acute Infectious Diarrhea in Infants.**—Dr. H. M. McClanahan says: Stop the food supply. Remove the products of imperfect digestion from the intestinal tract by irrigation, continued until the water returns free from admixture of fecal matter. Inject solution of 20 grains of tannic acid in a pint or more of sterilized water and have it retained in the bowel about an hour. When vomiting persists the stomach should be washed out also. To neutralize the toxins calomel in 1-10 grain doses hourly for the first twenty-four hours is recommended. First among antipyretics is the cooled bath. When watery discharges continue after the irrigation, hypodermics of 1-100 grain of morphin and 1-800 grain of atropia can be given. Stimulants are indicated in the severe cases and whisky is the best that can be given. After the urgent symptoms have subsided the child can be nourished with the white of an egg stirred in cold water, or the mixture recommended by Jacobi: Five ounces of barley water; the white of one egg; one or two teaspoonfuls of brandy or whisky; some salt and sugar. A teaspoonful every five or ten minutes as indicated. No milk should be given for several days.—*Am. Jour. of Obstetrics and Diseases of Women and Children*, June 1896.

**The Differential Diagnosis of Vascular and Muscular Tinnitus Aurium.**—One variety is caused by the flow of blood through the irregular-calibered blood vessels of the internal ear and those in the neighborhood, producing vibrations by the passage of the blood. This I have named vascular tinnitus aurium. The other variety is produced by the action of diseased muscles of the middle ear, producing vibrations by alternate contractions and relaxations. This I have named muscular tinnitus aurium. Many persons, who are partially deaf and experience excessive noise in their ears, will hear a conversation in a moving railroad coach better than in a quiet room. This is positive proof that all such persons are afflicted with muscular tinnitus aurium. The sound or sounds that are formed in the internal ear and its neighborhood, *i. e.*, vascular tinnitus aurium, will not be decreased in any degree by extrinsic noises of any kind. It is often of the utmost importance to be able to differentiate between the two kinds of tinnitus, for a treatment or procedure that would be of great value to a patient suffering from the muscular variety would be decidedly injurious, if not disastrous, to one suffering from the vascular variety, and vice versa.—THOS. F. RUMBOLD, M. D., in *St. Louis Medical and Surgical Journal*, June, 1896.

**Rapid Cure of Soft Chancres by Electric Heat (Not Caution).**—The Paris correspondent of the London *Lancet* sends the following note to the issue for June 6, under the title of a new treatment of soft chancres by heat:

Dr. Audry, of the Toulouse Faculty, has devised a modification for the heat treatment of soft chancres introduced three years ago by Dr. Welander, of Stockholm. Dr. Audry employs radiant heat supplied by the thermo-cautery, the button of which is held for a few seconds at a distance of three or four millimeters from the sore previously washed and dried. Should the point of the thermo-cautery be fine it must be brought to a white heat; if larger, to a dull red heat. Exposure to this radiated heat for the period indicated has the effect of thoroughly drying the ulcer, on the edges of which there now appear sanguinolent striæ. Too long exposure determines a

raising of the surrounding epidermis and a reddening of the skin. A single seance is stated to be usually sufficient to transform the chancre into a simple ulcer, which soon cicatrizes under the influence of any antiseptic powder. The rapidity of the healing is due to the absence of the scab that always follows the direct application of actual or chemic heat. The pain is said to be quite endurable, being less than when the actual cautery is employed.

**Symptoms of Incipient Exophthalmic Goitre.**—It is very important to be able to distinguish this disease from the first, instead of waiting for the exophthalmus and goitre to appear. An article in the *Journ. des Pract.* for May describes several early signs by which it may be recognized. Principal among them is a series of ocular troubles, a lack of synergic action in the lid and brow when the ball is turned abruptly upward, incomplete occlusion of the palpebral fissure, pulsation in the lids, muscular paralyses and sometimes diplopia or photophobia. There are also disturbances in the nervous system; beside a general irritability; there are often cramps, neuralgias, hyperesthesias, insomnia, choreic movements and sensations of excessive heat. The tremor, which is rarely absent from the first, has a specific character in its rapid vibrations. If there are no accompanying symptoms of hysteria, this tremor is of great diagnostic value. The general symptoms that may occur are numerous and various, from dyspepsia, bulimia, gastric and diarrhetic crises to genital troubles and edema resembling myxedema. Other disturbances indicate the participation of the medulla oblongata, suffering from lack of the normal secretions of the thyroid gland, polyuria, albuminuria and dyspnea. Pregnancy is one of the most important predisposing causes of this disease, and it may also appear as a complication of neurasthenia, chorea, epilepsy, paralysis agitans, syringomyelia, general paralysis and various psychoses, especially tabes and hysteria. It is also a possible complication of diabetes, sclerodermia, acromegalia, mollities ossium and chlorosis.—*Revue Int. de Méd. et de Chir.*, June 10.

**The Limits of Vaginal as Compared with Abdominal Exploratory Section.**—Dr. Henry C. Coe says his experience leads him to select the abdominal method of exploration in the following conditions: "1. In the case of neoplasms or obscure enlargements which are situated in the abdominal cavity, or have risen above the pelvic brim, especially if they are more or less adherent. 2. In ascites of doubtful origin, more particularly when tuberculous or malignant disease is suspected. 3. In cases of disease of the adnexa in which the latter are situated near or above the pelvic brim, as established by bimanual palpation. 4. In cases in which the history and symptoms point to general intestinal adhesions, and above all, when appendical complications are suspected. 5. In ectopic gestation before rupture, when the sac is high up, at the side or in front of the uterus, instead of in Douglas's pouch. 6. In case of intractable pelvic and abdominal pain of obscure origin, including the so-called neuroses. On the other hand, explorative vaginal section should be preferred: 1. In all cases in which the presence of pus within the pelvis is suspected, as in pyosalpinx, pelvic abscess proper, suppurating dermoids and cysto-adenomata, and hemocele. 2. In the case of small intra-pelvic tumors situated in the pouch of Douglas, or at least readily accessible from below. Impacted ovarian cysts, dermoids, and fibroids belong to this category. 3. Adherent adnexa situated in the true pelvis. 4. Unruptured ectopic sacs in the same locality. 5. Circumscribed exudates and indurations in the broad ligaments or behind the uterus, especially when associated with displacement and fixation of the lateral organ."—*N. Y. Polyclinic*, June, 1896.

**Epiphysal Separation of Lower End of Femur.**—Dr. Richard H. Harte says in regard to diagnosis: There are two forms of injury with which it is likely to be confounded, *i. e.*, dislocation of the knee joint and fracture of the femur above the con-

dyle. Traumatic luxations of the knee are a rare injury in early life. If the separation is compound there is little difficulty in diagnosis; when simple the abnormal mobility will serve to distinguish it from dislocation in which the movements of the leg on the thigh are restricted in a marked degree. Fractures in this part of the bone are rare at any time of life and especially so in persons under maturity. The age of the individual and the character of the crepitus will assist in determining the position of the injury. If the crepitus is of the dry, grating character, it can be easily distinguished from the soft moist crepitus caused by rubbing the diaphysis against the cartilaginous head of the tibia.—*American Journal of Medical Sciences*, June, 1896.

**Artificial Ear Drum Membranes.**—Dr. Vincent Gometz says: The artificial drum membrane was first used by the laity in 1640 and afterward by the profession. It has been made of a variety of materials. Tearsley, in 1841, selected a cotton pellet for the purpose. It is first slightly moistened and placed in the same position where it will best improve the hearing. This will be found by experiments. Toynebee, in 1853, introduced an artificial membrane, consisting of a thin rubber disc attached to a fine wire. Lucas has covered the wire with rubber tubing to prevent the unpleasant rattling in the ear. Gruber uses a similar piece of rubber as that of Toynebee but attaches to it a piece of silk thread to withdraw it from the ear. Artificial drums are sometimes made of tin foil, used in the same manner as cotton. Ordinary blotting paper answers the purpose very well. The indications for the use of the artificial drum membrane are as follows: 1, when a drum cavity needs protecting from the air; 2, whenever the ossicula are detached from each other, the result of destruction of their ligaments or from failure of the membrane to keep them in proper contact, or even a severance of continuity consequent on relaxation of the ligaments or absence of the incus, with a gap existing between the membranes and the stapes (the latter also may be in a state of subluxation from relaxation of its annular ligament), the artificial membrane keeps it properly in position.—*New Polyclinic*, June, 1896.

**Treatment of Antrum Disease.**—Dr. John E. Bacon describes his method of operation. It consists in cleansing and medicating the cavity through a small puncture in its inner wall in the inferior meatus of the nose, which can be made without general anesthesia and without pain. The instruments are a steel trocar and canula, two silver tubes, a silver wash tube, and a hard rubber syringe with rubber tube connections made to fit the canula and wash tubes. Cleanse the nares with the antiseptic spray, cocaineize the inferior turbinal and floor on the side to be operated upon, insert a rubber operating speculum well into the nostril and place the trocar beneath the inferior turbinal about one and one-fourth inches from the skin margin; by bending the septum to the opposite side the point of the trocar will point obliquely into the cavity of the antrum. A slight tap with a leaden or rawhide mallet will cause the trocar to penetrate the thin bone which constitutes the inner wall of the cavity. Care must be taken not to penetrate too deeply and so wound the opposite side of the antrum, as serious hemorrhage might result. In most cases the trocar can be pushed through the thin bony wall with the fingers alone, and this should be done, when possible, to avoid the mental shock which the blow with the mallet sometimes gives. The trocar may now be withdrawn, leaving the canula in place, and the rubber tube may be attached to the canula and the cavity syringed out with warm sterilized normal salt solution. The fluid will escape into the nose through the ostium maxillare and bring with it pus if any be present. After the cleansing, the trocar may be replaced and the nut removed, when the canula may be withdrawn over the trocar; now a silver tube is slipped over the trocar and the latter is withdrawn, leaving

the silver tube in place, and this may remain as long as required without any irritation. This tube is exactly fitted by the silver wash tube, and the cleansing may be repeated without inconvenience. A solution of menthol and camphor in liquid alboline may be easily sprayed through the tube and aristol or other non-irritant powder may be blown into the antrum by the same means. It is imperative to thoroughly sterilize all instruments used, and to use only warm sterilized fluid in each case, to prevent infection.—*The Am. Therapist*, June, 1896.

**Clinical Experience with Benzosol.**—Concerning this remedy, which is a benzoate of guaiacol, the June issue of the *American Therapist* has a clinical report by Dr. J. V. Kofron of Cleveland, Ohio, which states that he has found the following favorable features: 1, the avoidance of the unpleasant eructations which so frequently occur after the administration of pure creosote or guaiacol, and 2, the liberation of the antiseptic guaiacol in the intestine where its action is especially desired in the treatment of septic conditions of the intestinal tract attended with fermentation. In the treatment of tubercular affections, the administration of benzosol affords a most pleasant and efficient method of obtaining the constitutional effects of creosote without the many unpleasant features of the latter drug. As it is entirely free from unpleasant taste or odor and is almost invariably retained by even a sensitive stomach, one can by this remedy push the dose much higher than when creosote itself is employed. In cases of incipient tubercular phthisis with considerable cough and expectoration, slight evening elevation of temperature, loss of appetite, furred tongue, etc., the administration of benzosol gr. iv four times a day serves to relieve the cough, reduces the amount of expectoration, brings down the hectic temperature, clears the tongue and increases the appetite. Similar results have been observed in cases of chronic bronchitis in which severe cough, profuse expectoration and dyspeptic symptoms have been predominant features. Very surprising to me have been the results obtained from the use of benzosol in the treatment of cases of tubercular diarrhea, in which the remedies usually administered proved of little value. In intestinal catarrh with flatulency, benzosol speedily and effectually checks undue fermentation, and it also affords a valuable intestinal antiseptic in cases of typhoid fever. In three cases of this latter disease in which this remedy was used exclusively, the following satisfactory results were noted: Temperature never rose above 103, tongue quite clean and usually moist, none of the patients exhibited tympanites or suffered from diarrhea, and none of them suffered from a relapse. "I have been desirous to test the efficiency of benzosol in the treatment of diabetes mellitus, as advocated by von Jaksch, Piatkowski and J. Blake White of New York city, but have not as yet had the desired opportunity. In conclusion, I wish to express my belief that we have in benzosol a valuable substitute for creosote in pulmonary affections, a safe and efficient intestinal antiseptic for the treatment of gastro-intestinal disorders attended with fermentation, and a useful remedy in sterilizing the bowel in typhoid fever."

**On the Symptoms and Treatment of Angina Pectoris.**—Sir Benjamin Richardson, in his *Asclepiad*, describes this affection as a disease of the sympathetic system rather than as a specific organic change in the heart or its vessels. He says, first, regarding the symptoms, that in the paroxysm the condition is simply terrible. It is in the chest that suffering seems to be concentrated. The chest is, as it were, pierced or transfixated through and through. The breath is held, and, as more than one of the sufferers has expressed it, it is as if the chest were in a vise, one blade of which was on the center of the back and the other on the sternum at its center. The chest feels as if it were filled and dilated with air which it is impossible to expel. The chest, in fact, can not be emptied, neither can it be

dilated or filled; and the coldness of the surface of the body, the whiteness and the fixity of the features, the condensation of water on the brow and running down the cheeks and the apparently rigid state of the limbs, all testify that there is no true breathing power. Yet it is not asphyxia that presents itself; it is rather syncopal unrest; and, indeed, there appears to be no exhaustion of air or any change for the better until there is a certain degree of relaxation of the diaphragm and of the muscles of the intercostal spaces. As to the treatment, nitroglycerin and nitrate of amyl, made into a mixture, so that it could be taken by the stomach slowly, he thinks, gives better effects than when it is inhaled, because when it is swallowed it seems to act favorably on the whole course of the sympathetic nervous system. As a mixture he has usually combined it with glycerin, putting 3 minims to a dram of glycerin, adding 3 drams of water and ordering that quantity, diluted further with an agreeable quantity of water, to be taken at intervals in the course of an hour. The effect of either of the remedies described above is, he says, often strikingly beneficial. Their action is to take off blood pressure and relax the arterial system, so that blood can flow more readily through the lungs, through the heart and through the general circulation. He fears neither remedy exerts a true curative action, for if it did we should really cure, whereas, as a rule, we only give relief.

**Roentgen Photographs of Vesical and Renal Calculi.**—D'Arsonval presented at the meeting of the Académie de Médecine, June 2, some Röntgen photographs of calculi taken by GaiFFE for Dr. Lavanx. In their experiments reported last February, they announced that it was possible to distinguish between the silhouette cast by a calculus and that cast by a rib, which was confirmed later by Chappuis and Chauvel. But these latest photographs possess an importance which will be readily recognized as they demonstrate that it will soon be possible to diagnose calculi in the urinary passages with absolute exactness. They not only show the existence of a calculus in the bladder, kidney or ureter, but it is possible to distinguish the substances of which it is composed, whether it is homogeneous or formed of different layers, whether the kernel is small or large and of what it is composed. The most interesting photograph from this point of view showed: 1, the silhouette cast by a calculus of pure uric acid; 2, that of a calculus the same size as the first, but composed exclusively of phosphate of ammonia and magnesia; 3, that of a calculus much larger than the others, formed of several distinct layers of uric acid in the center, with an outer layer, 4 mm. thick, entirely different in color, and composed exclusively of the triple phosphate; 4, the silhouette of a bone 1 cm. thick, and another of the index finger of one of the experimenters. The differences in the depth of shadow in this photograph are so marked that it is impossible to mistake the characteristics and kinds of the calculi. The tiny kernel of uric acid is distinctly visible, while the outer layers of the large calculus are represented by clearly defined rings. A second photograph showed another calculus with a kernel formed of urate of soda, inclosed in an outer layer of the triple phosphate, both very clearly defined in the photograph. A third represented a number of uric acid calculi lodged in the parenchyma of a kidney, one-half of which was 5 cm. thick. The rays passed through this thick layer of tough tissue and the calculi alone showed in the photograph. It will be a very simple matter, therefore, preliminary to an operation, to take the photograph of similar calculi, and then compare them with the results of photographs taken through the patient. This will provide most important points of comparison, as the results differ with each Crookes' tube. A recent special publication states that the indications for an operation vary according as the calculus is of primary or secondary formation. An exact diagnosis thus made preliminary to the operation, will be of great value, especially in the case of

elderly persons and "prostatics," to determine beforehand the exact location and composition of the calculi. The progress accomplished in the last few months promises a speedy solution to the entire problem.—*Bulletin de l'Académie de Médecine*, June 2.

**Actinomycosis Treated by Iodid of Potassium.**—A well-written and laborious essay is one on the above subject in the *London Lancet* for June 6, by Mr. Malcolm Morris. The author is not only the editor of the *Practitioner*, but surgeon to St. Mary's Hospital, and his paper appears as a model of its kind in its care of preparation, in its judicial attitude and its utility to students. By one thing, it may be added, it has a bibliography extending beyond seventy numbers. The case, in brief, which responded favorably to the treatment, had the following salient points: "A single woman aged 59 years came under my care at St. Mary's Hospital on Nov. 18, 1895, with a large swelling over the lower jaw on the left side. About October 10 she first noticed a small nodule behind the ramus; it was just underneath the skin, and in about seven days began to discharge. It was very painful and continued to increase until she came to the hospital. The patient had for the greater part of her life been in service as a housemaid, but for about a year she had made her living as a needlewoman. She stated that she had never had to do with horses, cows or other animals nor with grain, hay or straw. There was no history of a blow or other injury and she could throw no light on the origin of the disease. Her record of previous illnesses showed nothing that could be interpreted as having any bearing on her condition, nor was there anything of significance in her family history. She had a large, dark red, nodular tumor with a sharply circumscribed edge on the left side of the face. It extended from the angle of the lower jaw forward to the corner of the mouth, upward to the zygomatic arch, and downward over the sterno-mastoid for about two inches. On the most prominent part, in the temporo-maxillary region, the surface of the mass was irregularly raised into nodules varying in size from a split pea to a small bean, each having a small opening at the top, the position of which was marked by a yellow bead of pus. On squeezing the nodules a little sero-purulent matter escaped. In this discharge were found firm yellowish-gray granules which microscopic examination showed to be masses of actinomycetes or ray fungus. The skin over the whole mass was brown and reddened. To the touch the swelling at first gave the impression of cartilaginous hardness, but on firm pressure between the fingers it was felt to be elastic. There was no fluctuation. Narrow spurs of infiltration also extended upward behind the lobe of the ear and backward to the posterior border of the sterno-mastoid. A hard lump of the size of a large hazel nut could be felt under the buccal mucous membrane. The structures forming the cheek were infiltrated and firmly fixed to the jaw, especially toward the angle, but the bone itself was not implicated. There were no teeth in either jaw except the left superior external incisor and canine. No enlargement of glands, either concatenate or supra-clavicular, could be felt on the left side of the neck, and there was no evidence of secondary growth. There was no trismus, but the patient complained of great pain, particularly on mastication, and the nodules were tender on pressure. She had a poor appetite and slept badly, but otherwise there was no disorder of the general health. The microscopic examination was conclusive; apart from this, however, the situation and appearances of the swelling were characteristic. The internal administration of iodid of potassium was begun on November 21, when the following mixture was ordered to be taken three times a day: Potassii iodidi, 15 gr.; spiritus ammonia aromati, 20 minims; decoct. cinchonae ad ʒj. For the first three days after the commencement of the treatment the pain was worse and the discharge was profuse, but after that the good effect was soon manifest. The pain abated, the swelling became paler and softer and began to shrink. After ten days of the treatment only slight traces of the fungus could be discovered in the discharge, which was very scanty. On December 16 the dose of iodid of potassium was increased to 20 gr., and on Jan. 27, 1896, to 30 gr. three times a day. The improvement continued, and, in short, the history of the case from the time the patient was brought under the influence of the iodid was a record of uninterrupted progress toward a cure. Together with the retrocession of the local process appetite and sleep returned and the woman felt better than she had done for a considerable time. At the beginning of February the swelling had nearly disappeared, the sinuses had healed up and only a trace of the disease was left." When last seen (May 28) the patient was well, but was still taking the iodid.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance . . . . . \$5.00  
Single Copies . . . . . 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the Association living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JULY 11, 1896.

THE CELLAR IN ITS HYGIENIC ASPECT.

The Legislature of the State of New York has for some time been considering the subject of bake-shops and bakers, the remedial enactments effected having had primarily the interests of the employes in view, with which as physicians we have no especial concern; but incidental to the investigation as to the hours they were required to work (one hundred to one hundred and thirty-two a week, the limit now fixed by law being sixty), it was discovered that one thousand and forty-nine of the one thousand and fifty-nine bake-shops investigated were in cellars, and that in seven hundred and thirteen of these the height from floor to ceiling was less than eight feet; and when it is further stated that six hundred and twenty-three of the number were found to be absolutely unhealthy and *only five positively clean*, it does become a matter with which physicians have most especial concern.

The word microbe has become domestic as well as professional, and parents and children discuss their deadly tiny enemies as glibly as learned professors describe their cultures and death-points. It is the age of the Lilliput and the terror inspired by these diminutive foes makes them indifferent to the visible presence of lusty Brobdingnagians. Theoretical speculations concerning germicides and blind dependence upon disinfectants cause people to forget the simple precautions of common sense hygiene and lose sight of the abundant store of health-preservers and

germ-destroyers at hand with no other cost than the trifling labor of admitting them in the shape of air and sunlight.

The ingenuity of civilized man has been but little exercised in the direction of habitable homes for the intelligent product of centuries of education. The masses are gathered into buildings, where everything that can be is being done to enfeeble the inmates and dwarf their offspring, and to this end it seems to matter little what system of house-building prevails or in what locality.

Of all the abominations of modern residences, the cellar or underground basement, which characterizes our old cities, is the vilest. The city of Philadelphia, for instance, is completely undermined by these subterranean, dark, damp, moldy, foul-smelling receptacles for all kinds of household refuse, as well as coal, probably stowed wet, wood in the same condition and perishable provisions. The atmosphere of these murky underground apartments has a characteristic nauseous odor. Excepting a minority in first-class residences, they have either rotting wooden floors or none at all and the walls are the rough, untrimmed foundations of the house, seldom whitewashed or calcimined, and affording myriads of angles for the deposit of dust and molds. Many of these cellars are further contaminated by imperfectly closed and leaking drains and soil-pipes. The writer has in the course of many a sanitary inspection, to which the tenant was abusively hostile, discovered a condition of things, which while cement and whitewash might temporarily relieve, only a heavy fine could permanently remedy.

To the professional man, who is acquainted with the willful blindness of the many to their sanitary interests and their insane dependence upon drugs to nullify the mischief their neglect invites, it is not surprising that they not only allow their own homes to be endangered by a foul cellar, but are indifferent to the existence of other unhealthy cellars with which they have more or less direct relation. The underground bake-shop is an instance. Any passer-by can get a glimpse of the dirty, low-ceilinged hole in the ground, in which bread, cakes, pâtisserie and confectionery are prepared, from materials which have been stored there indefinitely, by unclean men from whose unwashed rags drops the sweat of heat and fatigue into the mixture they are molding. The official announcement that there were *only five positively clean* in over one thousand (1,049) investigated ought to provoke a revolt against any form of underground bakery or confectionery. PROFESSOR VAUGHAN rendered inestimable service to the community by showing some of the unclean ways by which ice-cream becomes poisonous, but is it not really a matter of surprise that any ice-cream manufactured in a cellar daily wet from melting ice and soiled by spilled flour, starch, eggs, sugar, gelatin, milk and other uncertain

ingredients, can be anything but poisonous? It was a wise sanitary advance which placed the kitchen in the uppermost stories of certain hotels and restaurants, but these are few beside the numerous sub-basement kitchens where weary cooks compound their culinary mysteries. The ordeal of fire is assumed to settle the mischief-making power of the ordinary microbe, but his coadjutor ptomaine is not so easily disposed of, and many a savory mess has endangered life, when the abused oyster, clam, lobster, prawn or frog had no prior claim to toxicity.

The investigation referred to showed another source of dirt and disease in the over-crowded underground sleeping-quarters of employes, which they further shared with dogs, cats and other domestic animals and noxious vermin—a state of things repulsively nasty if not positively dangerous. It is bad enough to have your morning roll and loaf of bread delivered by the dirty-handed driver of the baker's cart, but this is trivial beside the possible contaminations during the foul stages of their concoction.

The list of cellar nuisances can be greatly extended. It is the chosen home of the rag-picker and bone-gatherer. The corner grocer keeps his vegetables there which are unsold from day to day. The writer has encountered under-ground meat and game shops; and since the advent of the Italian fruit-peddler, he has made it his storage-place for bananas, grapes and the like, from which he wipes, in his own filthy fashion, the street dust of the day and the mold and mildew of the night to tempt unwary buyers on the morrow.

The alert modern sanitary inspector has no sinecure. Upon the proper housing of the population of a great city depends its vital condition. A local newspaper reporting a young witness in a great murder trial described her as "a typical New York flat-house child. Her face is slender and her limbs fragile. Although she is eleven years old, she could easily pass for eight or nine. Her voice was such a mere shred of articulation that it could not be heard a few feet away," and she was the daughter of a family of the better class, but she slept in a little cell dimly lighted from a shaft or well like others in which so many hundred thousand little children are being slowly smothered. The "apartment" has no cellar, but the same culpable defiance of common sense sanitation develops the typical flat-house child, and health authorities should wage war both upon the contracted windowless bedroom in which little Mary Cunningham was murdered and upon the dark damp cellar of the dwelling-house. An old medical officer of one of the national services, inspecting a large Government Hospital, astonished the junior officers by giving scant attention to the wards on which they had devoted so much time of preparation, while he pried into every corner of the basement and every cranny in the attic, and when they expressed

their disappointment that he had only glanced at the especial objects of their pride, he said to them, "when the cellar and garret are in good condition, there need be no doubt about the rest of the building." Garrets are as apt to be neglected as cellars, but the greater inconvenience of access in a measure protects them from becoming receptacles of perishable articles and their very elevation secures better hygienic conditions. The cellar is the chief pestiferous site and the health officer should see that decayed flooring is replaced by cement, that the walls and ceilings are scraped and then thoroughly and repeatedly white-washed, that all leaking drains, soil and water pipes are repaired, that every destructible accumulation is removed, that the cellar-doors and other apertures are wildly opened in clear weather, and that when industrial occupations are permitted in them by law (and the effort should be made to reduce these to a minimum) they should be subjected to the most thorough weekly inspection, and the rigorous imposition of penalties upon landlords and tenants for neglect to remedy the nuisances reported. Perhaps the most effective way of having sanitary defects properly removed is for the health department to do the work required as it should be done by its own employes, the cost being charged to the delinquent owner or occupant.

#### THE HEMATOZOA OF MALARIAL FEVERS.

When LAVERAN in 1881 announced the discovery of a malarial hematozoon which in its full development was as large or larger than a red corpuscle, decorated with pigment granules often arranged in the form of a corona, and provided with flagella which stirred the neighboring blood discs by their oscillations, the medical world was probably more amused with the announcement than impressed with its value. Beside the perfected micro-parasite this French army surgeon described and figured a crescentic or banana shaped form which he considered an imperfect development, and oval or spherical, non-fillamented, degenerative or cadaveric forms, all containing pigment granules loosely scattered or variously aggregated. When it is remembered that HESCHL in 1850, and PLANER and FRERICHS in 1854, described pigment granules in the blood of malarial cases and noted their aggregation in cells or in small masses bound together by a hyaline connective it seems surprising that so little effort was made to verify LAVERAN'S observations. At the time, however, every trained microscopist was looking for the *bacillus malarie*. KLEBS and TOMASSI-CRUDELI were credited with having found it, and as the likelihood was considered to be all in this direction, LAVERAN'S work was undervalued. He was credited with having mistaken degenerative characters in the blood corpuscles for phases in the life history of a hematozoon. In 1882 RICHARD came to his support

with observations on Algerian remittents, and three years later MARCHIAFAVA and CELLI in Italy, and COUNCILMAN and ABBOTT in this country, verified many of the observations. About the same time GOLGI, in studying quartan agues, discovered in the red corpuscles colorless plasmic bodies which as they grew larger became dotted with melanotic particles. He found that in a short time the normal constitution of the invaded red corpuscle became lost in its transformation into a colorless globule containing pigment. The dark particles became aggregated in the center and the colorless plasmic substance underwent fission in lines radiating to the circumference. The resulting segments or cellules, together with the central pigment, were then liberated into the current of the blood, and when this stage was reached a febrile paroxysm was imminent. After GOLGI'S announcement the subject attracted general attention and the existence of LAVERAN'S organism was acknowledged.

The latest study of the *Plasmodium* comes from the Medical Clinic of the Johns Hopkins Hospital as "an analysis of 616 cases of malarial fever with special reference to the relations existing between different types of hematozoa and different types of fever, by WILLIAM SIDNEY THAYER, M.D., and JOHN HEWETSON, M.D." These investigators describe and figure three types of micro-parasite, one associated with tertians, a second with quartans, the third with estivo-autumnal fevers. In their observations a clean cover-slip was brought lightly in contact with a drop of blood from the lobe of the ear. It was then placed on a perfectly clean slide and pressed gently to have the corpuscles spread side by side between the two surfaces.

In tertian ague a small hyaline body is found in the interior of the red corpuscle. It is actively ameboid, changing from a disc to a cross or star and sometimes to a ring by the fusing of pseudopodia. In a short time pigment granules, also having an active motion, appear in its substance, and the latter continues to increase until it fills and distends the shell of the red corpuscle. The pigment meanwhile collects in the center and segmentation by striation of the protoplasm takes place, the segments apparently becoming the small hyaline bodies which invade the red corpuscles for a new cycle of growth. Often the plasmic mass escapes from a ruptured cell before the segmentation is perfected. This parasite requires about forty-eight hours to complete its development, and is associated with relatively regular tertian paroxysms lasting ten or twelve hours, and usually presenting the classic stages of chill, fever and perspiration. Infection with two groups of tertian organisms maturing on different days gives rise to quotidian paroxysms.

In quartans the hyaline bodies are smaller than in tertians, but they are more refractive, the ameboid movements slower, and the pigment granules larger,

darker, motionless and generally peripheral, but sometimes star-shaped and central. Ultimately the red corpuscles become filled, but not enlarged as by the tertian organism, and segmentation follows as described by GOLGI. A period of about seventy-two hours is required for this development. Infection with two groups causes a double quartan with intermission on the third day; with three groups a quotidian. In both of these forms some of the full grown organisms become flagellate or vacuolated as described by LAVERAN. The nature of the flagella has not yet been determined. Their discoverer considered them appendages of the perfected organism; later observers regard them as degenerative.

The organism of estivo-autumnal fevers when fully developed is rarely half the size of the red corpuscle. During its growth crenation of the corpuscle, brassy color, retraction of hemoglobin, and sometimes central aggregation of pigment are found; but probably the greater part of the development, including the segmentation, is carried on in the spleen and other internal organs. The cycle of development lasts from less than twenty-four to more than forty-eight hours. After the infection is five to seven days old the ovoid and crescentic bodies observed by LAVERAN in the remittents of Algeria are discovered. Quinin has less power over these than over the other forms. The Johns Hopkins investigators are satisfied that the crescents represent a very resisting form of the organism and that they may develop into the flagellate forms. Further observation is needful to determine their significance.

The presence of the plasmic bodies in the blood has been generally acknowledged, but occasionally there arises an investigator who questions their accepted meaning and denies their parasitic nature. The latest of these objectors is Surgeon Lieutenant-Colonel E. LAWRIE, who has been studying the subject at Hyderabad. From similarity of appearance, he considers the white blood cell of the frog to be the escaped nucleus of its red blood corpuscle, and he therefore concludes that the leucocytes of human blood are the nuclei of red cells liberated in the spleen by its blood forming action. The theory which he builds on this assumption, is that the spleen in its disabled condition in malarial disease is unable to turn out perfected non-nucleated red blood corpuscles, and that the plasmic bodies are merely the embryonic, or nucleated, corpuscles which escape from it into the general circulation; the plasmodium being, therefore, not a cause but a consequence of malarial fever.

The form in which these organisms exist outside the body, as in malarious soils, water or air, and the mode or modes of their entrance into the human system are wholly unknown. LANCIANI and McCULLOUGH explained the causation of malarial diseases on the theory of a miasmatic exhalation which disorganized the blood. Our modern researches recognize the disorganization of the blood, but call for a specific

entity as the cause. Investigation into the influence of the ameboid forms, so common in marsh waters on the corpuscles of living blood, appears to be now in order.

#### SIR HENRY HALFORD AND THE REVIEWER.

Noticing DR. WILLIAM M. MUNK'S "Life of SIR HENRY HALFORD," who was by his enemies dubbed the "Eel-backed Baronet" on account of his deep and oft-repeated bows, the *Saturday Review* (June 13) recalls the story told by MR. BRANSBY COOPER, in his "Life of SIR ASTLEY COOPER," of SIR HENRY'S three profound formal bows to LORD LIVERPOOL when he entered the room in which his lordship was lying on a sofa, utterly insensible, under the attack of apoplexy, from the effects of which he eventually died. The *Review* says that he seems to have contributed nothing to the science which, after all, lies behind the practice of medicine; he relied chiefly on his soothing manners and on what he delighted to call the *vis medicatrix naturee*, and, in nearly every respect, he might be taken as the "glorified example of the successful medical tradesman." On the other hand, in one respect his profession remains indebted to him; during the long period that he served as President of the College of Physicians he labored hard and successfully to further the dignity and advantages of that great corporation. He was physician to four successive sovereigns, GEORGE III., GEORGE IV., WILLIAM IV., and QUEEN VICTORIA. For twenty-four years he was President of the Royal College of Physicians. In the first year of his practice his professional receipts amounted to £220. They increased annually, and in 1809, his eighteenth year of practice, they reached £9,850, thereafter always exceeding ten thousand a year.

We presume the *Saturday Review* has some good authority for the assertion that SIR HENRY HALFORD was the court physician mentioned by BRANSBY COOPER, but that writer does not say so. The exact quotation is as follows: "He had been seized with a fit of apoplexy while at breakfast. I felt his pulse, and was at once convinced of the necessity for bleeding, and I immediately bled him. He seemed somewhat relieved, for the pulse was less labored, but he did not speak. Shortly after this operation had been performed, one of the court physicians entered the room. He at once made three profound formal bows to LORD LIVERPOOL as he lay senseless on the sofa, to which we had now removed him, and then, turning to me, asked if I were aware of the grave responsibility I had taken upon myself in bleeding the Prime Minister of England before his arrival. I replied that I thought I should have incurred a far greater had I hesitated in doing that which was evidently necessary, and further that I had the sanction and support of DR. DREVER<sup>1</sup>

for my conduct. He seemed, however, but ill pleased at what he considered a want of proper courtesy toward himself."<sup>2</sup> The action of the court physician toward MR. COOPER, which was evidently the occasion of his record of the bows, is easily explained when we recall that SIR ASTLEY COOPER had been summoned, and being absent, his nephew, BRANSBY COOPER, then an unknown young man, responded. It must have been a shock to one so long accustomed to the punctilio of the court. It is by no means clear from the record that SIR HENRY, if indeed the court physician mentioned was SIR HENRY HALFORD, was aware, on entering the room, of the comatose condition of the Premier. At any rate, it is a curious instance of the democratic tendency of the times, when we see a tory publication make bold to pillory a man seventy years after his death for an observance of the ordinary etiquette of the earlier half of the century.

SIR HENRY HALFORD was one of a very distinguished family of brothers, the sons of DR. JAMES VAUGHAN, a physician of Leicester. This gentleman had his sons educated with peculiar judgment, and expended his entire income in so doing. It is mentioned that not one of them asked or received further pecuniary assistance from the father after finishing their education and commencing their efforts in providing for themselves. HENRY VAUGHAN was graduated B.A. at Oxford in 1788 and M.D. in 1791. He had acquaintances and friends enough to borrow £1,000 on coming to London, and in 1793 was appointed physician to Middlesex Hospital, and was elected a Fellow of the College of Physicians in 1794. Such were his talents and abilities that at twenty-seven he was appointed Physician Extraordinary to the King. Having inherited a large property on the death of the widow of SIR CHARLES HALFORD, his name was changed from VAUGHAN to HALFORD. His skill in practice was acknowledged by his contemporaries, although no one ever claimed for him the merit of original discoveries. There are many physicians of exceeding skill and learning who are not discoverers, and few of large practice have the time to devote to path-finding. As an orator, he may without question be given the highest rank of any British physician, and in elegant literature he has had few superiors. His orations were models of elegant Latin, particularly the Harverian oration, delivered October, 1800, showing the connection between literature and medicine, and touching with pleasing reference the most illustrious characters of British medicine from LINACRE to WARREN. The stately oration in dedication of the new building of the Royal College of Physicians has the stamp of genius, and no one can read the scholarly essay "On the influence of some of the diseases of the body on the mind" without becoming deeply im-

<sup>1</sup> Lord Liverpool's family physician.

<sup>2</sup> Life of Sir Astley Cooper, Bart., by Bransby Blake Cooper. Vol. II., p. 222.

pressed with the innate goodness of the man and his amiability.

The sneer of the modern reviewer can not now seriously disturb the record of the life of one whose long and useful career was so many years connected with that of the Royal College, and to whom, if for nothing else, the modern medical man is indebted for a type of medical man distinguished above his fellows for deep learning, eloquence, wisdom and that politeness which comes from natural amiability and sweetness of temper.

#### COMMITMENT OF THE INSANE IN THE STATE OF NEW YORK.

On July 1, the new law, or codification of laws on the above subject, that was enacted by the Legislature of 1896, went into effect. It has generally been felt that that law handed the insane over bodily to the politicians; but the enactment is apparently thought by the Commissioner in Lunacy to be less malign in its probable future operation than has appeared at first sight. He hopes for the best; but it is probable that he will soon feel "the clutch of the ring." Under the new law, the procedure for commitments will be, in brief, as follows:

Application for the commitment of an alleged insane person may be made by any person with whom such insane person may reside or at whose house he or she may be, or by his or her father, mother, husband, wife, brother, sister or child or other next of kin, or by the superintendent of the poor of the county, the commissioners of charities of the counties of New York and Kings, or the overseer of the poor of the town or city wherein such insane person may be. The proceedings are to be initiated by a petition of the applicant containing a statement of the facts upon which the allegation of insanity is based, signed and verified by him, to which must be annexed the certificate of lunacy executed by two legally qualified medical examiners. Such papers must then be presented to a judge of a court of record, *i. e.*, a justice of the supreme court, a county judge, a surrogate, or certain judges of city courts which are declared by statute to be courts of record.

Notice of the application should be served personally upon the alleged insane person, and if made by a county or municipal officer, upon the husband or wife, father or mother, or next of kin, if there be any residing within the county, of said person. *The judge may dispense with such personal service, or direct substituted service upon some person named by him.* In such case the judge is to attach to such petition a certificate, stating his reasons for dispensing with personal service, or if substituted service is directed, the name of the person to be served. The commissioner says:

"It is not expected that the examiners will do more than properly fill out the certificate of lunacy,

as has been the custom heretofore, and the new form of certificate is substantially the same as has heretofore been in use. The examination must be made by two qualified medical examiners, jointly, and the certificate must be executed and dated upon the day of such joint examination. *The order of commitment must be granted within ten days from the date of the certificate.*

"The petition, the certificate of lunacy, and the various necessary orders, are printed as one form, and will be known as form 472 of the forms of the State Commission in Lunacy, and in ordering blanks it will only be necessary to refer to this form number. The parts of this form, five in number, while they are bound together, are so arranged as to permit of the insertion of additional papers of reference when required, and care should be taken that the page and line where matter is to be inserted are carefully indicated.

"It should be noted that the law requires that the petition and all the papers relating to the commitment of an insane person must be made *only* upon forms prescribed and furnished by the commission.

"It is respectfully suggested that in proceeding under the new statute it should be carefully read and its contents understood before final action is taken, and attention is particularly called to Section 60, of Chapter 545, Laws of 1896, which among other things provides as follows: No idiot shall be committed to or confined in a State hospital."

#### AN IMPERFECT LIST.

In the May-June issue of the *Bulletin* of the Johns Hopkins Hospital there is given what should be a very useful list of the scientific medical journals in public and private libraries in Baltimore. It includes besides medical journals a large number of scientific publications which are, as the compiler says, "somewhat remote from scientific medicine and biology," and omits many medical journals. In fact it is much fuller as regards foreign than American journals, and here it is open to criticism. A list purporting to be that of the "scientific medical journals," by wilful or inadvertent omission of certain journals that ought to be available in series in Baltimore libraries, while including others no better entitled to the term scientific, is open to the accusation of making invidious distinctions. Certainly some of the less than thirty existing American medical journals here included are no better entitled to be designated as scientific than a large number of those omitted of the series ought to be found in Baltimore libraries.

The phrase "somewhat remote from scientific medicine" covers the astronomic and mathematic publications included in the list, though the adjective "altogether" would have been more appropriate. The numerous natural history and physical publications may have a remote relation to medicine or may contain articles of some medical interest, and their appearance here is less objectionable.

The list is interesting, not only for its omissions of American medical journals, but also on account of

some of the European deficiencies. There is, aside from transactions, etc., a notable dearth of Italian and Scandinavian literature, and some special and general journals of note among the German and French publications are lacking. Such deficiencies are of course of less consequence in Baltimore, only forty miles away from the great medical library of the Surgeon-General's Office, but one can not help noticing them, if they occur in a city that has so many claims to be considered a center of medical learning and progress. It is probable, however, that the list is incomplete and will very soon need thorough revision; but as an experiment it is useful and suggestive. It would be well could it be followed by other similar publications of the resources of other centers in medical literature, more carefully and discriminatingly prepared and covering a wider field, including not only the foreign periodicals but a full series of those published in this country. There are undoubtedly some American medical publications of only moderate scientific interest, but there are many more than seems to be recognized at Baltimore that are indispensable to a reference library with any claims to completeness.

## CORRESPONDENCE.

### The Pan-American Medical Congress.

TOPEKA, KAN., June 27, 1896.

To the Editor:—Only yesterday my attention was called to the very invective letter under caption of the "Second Pan-American Congress," written by David Cerna, M.D., Ph.D., and published in the JOURNAL May 30. I have been a reader of the JOURNAL for a number of years, but by some coincidence I failed to notice this strange correspondence and was in blissful ignorance of all that had been written about me and my paper. One would suppose that I was guilty of some awful crime committed over two years since from reading this unkindly letter. The editor of the *Kansas Medical Journal*, published in this city, had requested me to write an editorial regarding the Pan-American Medical Congress, and when I handed the copy to the editor he kindly referred to the Cerna letter and asked if I had seen it. Had it not been for this coincidence I would probably not have seen it.

This is my first experience in public notoriety and I do not take very kindly to this method of getting my name before the public, but when a man, claiming to hold important positions in the profession, writes for publication such an article of unkind innuendoes without quoting a single word that I had written regarding my friends in Mexico, it is certainly my duty to at least acknowledge having carefully perused said letter, and perhaps ought not to give it any further consideration. However, when such grave charges as are found in this verbose letter, are made against a member of the profession, and not a word of information relative to the alleged crime, what answer can one give? The excuse made that space would not permit him to quote any part of my paper is the most unkind hit of all. Justice to myself would demand that the entire paper referred to be republished and furnished the profession, that they might judge for themselves regarding the enormity of the crime committed, but I will only briefly refer to some of the most emphatically incorrect points. Before doing this, however, I wish to preface this by saying that I have been appointed by Dr. Liceaga, and also by Dr. C. A. L. Reed, to

act as vice-president for Kansas for the Second Pan-American Medical Congress. I accepted the appointment and this explains the editorial which I will again refer to in this letter.

I spent nearly three years in the Republic of Mexico, and I wish to say they were three years of great pleasure. During most of this time I held an official position, which brought me prominently in contact with the best people of Northern Mexico, and I have never had cause to complain of the constantly courteous, and I might say universally considerate, treatment of the rich as well as the poor people of that country. More than this, I have never, by written or spoken word, desired to convey to any one, that the Mexican people are not the most courteous and kindly in the human family, not even excepting our Southern neighbors. In this paper so kindly (?) referred to by Dr. Cerna, I had only the highest praise for the Mexican physicians as gentlemen and as scholars, and only spoke of their methods in the treatment of patients as being in many respects entirely different from our way of doing and jocularly referred to their easy-going habits and, perhaps, careless customs, but in every instance only brought out these facts to illustrate some thought. What I said was true, David Cerna, M.D., Ph.D. to the contrary notwithstanding. Having on several other occasions spoken in public of the kindness of their people, it was but fair to history and fair to the profession of that country and ours, to speak of some features of the practice on that side of the Rio Grande which had not been before mentioned by any one, and I can assure my Mexican friends that it never occurred to me that I was not treating them in all respects fairly. I took that particular aspect of the subject which, perhaps, was not the most pleasing one, but with no intention of doing any one harm.

I have never had the pleasure of the acquaintance of David Cerna, M.D., Ph.D., but trust that I will meet him in Mexico, and feel assured from my slight knowledge of men and things, that he will fail to find me quite the wild and woolly animal that he has so invectively pictured me to be. Dr. Cerna's tactics in dragging Dr. Warfield into the controversy regarding the Pan-American Medical Congress, because the doctor found it served his purpose in writing a paper on "Typhus Fever of Northern Mexico," to speak of the habits of some of the people of that country, is absolutely reprehensible. Dr. Warfield can defend himself, if he should need any defense, but I do not think he does, as he told the truth, and any one doubting his statements may satisfy himself by a personal contact with the lower class of Mexican people. What has this fact to do with the success of the coming Congress? What has been said of Mexico may truthfully be said of other peoples, and of our own, under some circumstances.

In an article published in a monthly periodical which has an extensive circulation in Mexico and the United States, writing under the caption of "Mexico as a Field for Physicians and Surgeons," I had this to say of the country and people; "Never before in the history of this country have such opportunities been offered for the investment of money and the building of permanent homes by foreigners, as at the present time. Much may be said in explanation of this statement. Suffice it to say, that there are two special reasons for this happy condition of affairs: First, nearly every part of the republic has most magnificent railroad accommodations and telegraphic facilities, making the country completely civilized, and giving its inhabitants every modern accommodation for travel and communication; secondly, the government of Mexico, with that magnificent statesman and philanthropist, President Porfirio Diaz, and his loyal cabinet, who so ably manage the general government, together with the judiciary, among the most scholarly to be found anywhere on the continent, to say nothing of the governors and other officers who are loyal to their country, make this one of the most stable and law-abiding republics under the sun.

"The Mexican people are extremely confiding in their natural disposition, and at the same time they must be entirely satisfied regarding the sincerity of people who are strangers before complete confidence can be secured. In other words, they are very sagacious and discreet, making it necessary for physicians locating in any part of their republic to so conduct themselves that the poor as well as the rich may have no cause to question their good intentions. *In all the cities and larger towns may be found a sufficient number of native physicians to meet every ordinary demand. Many of these physicians are very scholarly and in every way competent to treat successfully the diseases prevalent in that country.* The requirements in their colleges are far in advance of American colleges, so far as the number of years of attendance is concerned. There is, however, an inexplicable fascination which takes possession of the people of that country in favor of foreign physicians, who have established a reputation for unusual skill, both in the practice of medicine and surgery. There has been a very serious prejudice on the part of the more educated against American physicians, but it is rapidly disappearing, the result of the marked advancement on the part of our medical colleges in the past few years."

The foregoing does not sound much like the "bear" Dr. Cerna would make you believe that I am. In the editorial, written before I saw Dr. Cerna's correspondence, and which will be published next week, I have the following to say:

"Dr. Milo Buel Ward of Topeka has received the appointment by both the American and Mexican authorities of the Pan-American Medical Congress, of vice-president for Kansas, and has been furnished a liberal supply of literature to be distributed to any who desire to contribute a paper or attend the meeting, which will be held in the City of Mexico, November 16 to 19, of this year. This literature includes special and general regulations and appointment blanks, and will be of value and interest to all who intend to contribute or attend the meeting. Dr. Ward will gladly supply these papers to all who desire them. This Congress will be a meeting of medical men of great renown from all parts of America and should be attended by every lover of his profession who can possibly go. The extremely polite and ever courteous Mexican insures to all who attend this great meeting a most delightful entertainment and an ever to be remembered pleasant occasion. No one can appreciate the painstaking courtesy of the Mexican people and their ability to make the stay of their friends pleasant and highly enjoyable, unless they visit that country and learn these facts from personal intercourse with them.

"There is no doubt whatever but the second Pan-American Medical Congress will be one of the most enjoyable and profitable meetings of the medical profession which has ever been held on this continent. Kansas should certainly have a liberal number of representatives at this meeting, and the *Kansas Medical Journal* urges the members of the profession throughout the State to at once notify Dr. Ward if they will furnish a paper or attend the meeting. It is desirous on the part of the General Executive Committee that all who are planning to go shall notify them through their local vice-president, in order that the Executive Committee in Mexico may plan to entertain their visitors. Let us again urge our readers to act promptly and decisively regarding this important matter, that our great State with its large number of prominent and active workers in the medical profession may have honorable representation at the second Pan-American Medical Congress."

No further reply to the unkind accusations of David Cerna, M.D., Ph.D., seems to me necessary. I am very fond of that country and admire the intelligent, educated Mexican very much and expect to attend the Congress, and feel assured that my time will be pleasantly and profitably spent, and that all the members of the profession who can find it possible to attend will be repaid for the time and money spent.

Respectfully,  
MIL0 B. WARD.

### Location of Journal.

CHICAGO, ILL., July 1, 1896.

*To the Editor:*—I wish to change my vote to Washington, D. C., for the reason that, having maturely considered the subject, I am of impression that the JOURNAL would gain a great deal by being published where its editorial rooms might be in close proximity to the Army Medical Museum, the great Army Medical Library, and the Smithsonian Institution. Financially, as I notice from the advertising columns, the principal support of the JOURNAL comes from east of the Alleghanies, I do not see that the ASSOCIATION would be any worse off; beside that, the editor might have the advantage for the ASSOCIATION of the bright writers of the many scientific departments of the Government, in addition to those now upon the staff; beside that, the power and influence of the ASSOCIATION in the matter of medical legislation would be very much greater with the JOURNAL published at the Capitol, where copies could be sent to members of committees of the House and of the Senate. It seems probable that but a short time will elapse before the ASSOCIATION will be compelled to have a standing committee on Congressional bills, like the British Medical Association, which now has a standing committee on Parliamentary bills. It must be obvious that in the neutral ground of the Capitol the JOURNAL could develop its greatest strength easier and more conspicuously than in any other city. As it can never be a local journal owing to its very nature, and as it is not in competition with local journals, it is all the more necessary that a neutral place of publication be selected. For these reasons, I wish my vote changed from Chicago to Washington.

E. J. DOERING, M.D.

### Apply the Baconian Method.

DENVER, COLO., July 3, 1896.

*To the Editor:*—In the name of scientific medicine I feel it to be a duty to protest against the promulgation of such ideas as those advanced under the heading "Lycopersicum Cardio-pathia" in the issue of the JOURNAL for June 27. In this article three pages of theory are offered us without, so far as I am able to find by careful examination, any facts whatever as a basis. In the first place, the substance which produces such dire results, acidum lycopersicum, is not mentioned by either Gould, Dunglison, Fowne, Roscoe and Schorlemmer or any authority that I have consulted, while the article itself gives no further proof of its existence than the bare statement that it has been found in the tomato.

I submit that a single case, carefully observed and recorded, of any disturbance of any kind, if such ever existed, from the ingestion of this universally used article of food, would be worth infinitely more than pages of mere theoretic twaddle as to the effect of the acid with the long name. I doubt if any ill effects have ever been noted, by any competent observer, from the use of the tomato, other than may be accounted for by ordinary indigestion, fermentation, or personal idiosyncrasy. It is time for some one to call attention most vigorously to the point that we will make of medicine more nearly an exact science only by collecting facts and reasoning from them, or, in other words, by following the methods pointed out by Bacon, adherence to which methods has been the *sine qua non* of progress in all branches of scientific knowledge since his time.

If I speak warmly, it is only because I feel that the occasion calls for vigorous denunciation of such pseudo-science.

Yours very truly,

J. N. HALL, M.D.

**Multum in Parvo.**—Dr. J. P. Crozer Griffith reports a case of varicella gangrenosa, diphtheria, rubeola and varicella existing at the same time in a child aged 22 months, admitted to the Children's hospital of Philadelphia.—*Med. and Surg. Reporter*, June 27, 1896.

## PUBLIC HEALTH.

**Health in Michigan.**—Consumption was reported present in June at 208 places; measles at 78 places; scarlet fever at 49 places; typhoid fever at 43 places, and whooping-cough at 36 places.

**Street Noises Injurious to Health.**—It is stated on the authority of prominent physicians that nervous disorders in New York City are on the increase. Unnecessary street noises are believed to be responsible in a great measure for this condition.

**Medical Examiners Appointed.**—Gov. Lippitt of Rhode Island has appointed new medical examiners as follows: Dr. Jay Perkins for Providence, Dr. R. G. Reed at Woonsocket, Dr. Charles H. French at Pawtucket, Dr. Nelson Reed at Warren, Dr. John Winsor at Anthony.

**Health of New York State.**—The monthly bulletin of the State board of health shows the total number of deaths for the month was 9,541, which is an average of about 308 a day. The prevalence of diphtheria has slightly increased, but is confined to the maritime districts. But one death from smallpox was recorded and that was from New York city.

**Wisconsin State Board of Health.**—The semi-annual meeting of the State board of health was held June 24, at Milwaukee. Dr. Solon Marks is president, and U. O. B. Wingate, secretary. An analysis of the water at Ashland is being made every day by the health officers for the purpose of showing the efficiency of a new method of filtering and the results show a steady improvement.

**Typhoid Fever in Plymouth, Pa.**—The number of typhoid fever cases in Plymouth is growing alarmingly large, and fears of another epidemic, such as visited the town in 1885, are being entertained by a number of people. The memories of that time are still fresh in the people's mind, and it is no wonder that they dread another such visitation—a visitation that made a hospital of the school house and brought weeks of suffering and death to many homes. There are now in that town upward of twenty-five typhoid cases.

**Smallpox and Yellow Fever in Cuba.**—The report to the Surgeon-General of the Marine-Hospital service from the United States Sanitary Inspector at Santiago, Cuba, is that smallpox is raging epidemically, and the cases, which can be counted by the hundreds, are increasing daily. "Malarial affections of the most deadly character are very common, especially the remittent and pernicious form." From Sagua la Grande the report is that yellow fever is on the increase among the troops at that point. Cienfuegos reports forty deaths from smallpox and increasing yellow fever for the week.

**Ireland's Unapproached Record for Legitimacy.**—The *Scalpel* for May refers to the low birth rate of Ireland as being partly due to the large emigration of able-bodied adults. Of the children born in 1894, 53,922 were boys, and 51,433 were girls; the predominance of the male sex being thus equal to nearly 2½ per cent. "The chief feather in Ireland's cap is the comparative infrequency of illegitimate births. So great, indeed, is this distinction that the Registrar-General draws special attention to the fact by remarking, somewhat inconsequentially, that 'it is unnecessary to say the proportion compares very favorably with the returns from most other countries.' The illegitimate birth rate for the entire country was 2.7 per cent. of the total, but it varied greatly in different provinces. In Ulster 39 children in each 1,000 were born out of wedlock; in Leinster, 27, in Munster 22; while in Connaught the number fell to one. We are certainly of opinion that, instead of *most*, the official dictum might well have been *all* other countries."

**Hygiene Pays.**—That public parks in cities are good investments from a sanitary standpoint goes without saying. That they are also profitable as a pecuniary investment is shown in

a recent report by J. Clyde Power, landscape engineer, recommending extensions of the park system of Indianapolis. He cites New York as a notable instance of the great increase of value accruing to land in the vicinity of parks. In 1856 the assessed valuation of the three wards adjoining Central Park was \$20,429,565; in 1873 it was \$236,081,515, a gain in seventeen years of \$215,651,950. The natural average increase of three other wards in the city, taken from all the wards, except the ones adjoining the park, showed only \$53,000,000, making the earning capacity of the park \$183,081,515. In Brooklyn, in 1864, Prospect Park, 515 acres, was acquired and the increase in valuation in three years was 38 per cent.

**Annual Quarantine Orders.**—In accordance with the quarantine laws authorizing the Surgeon-General to promulgate such additional regulations as may be necessary for the disinfection and detention of vessels from ports suspected but not positively known to be infected with yellow fever, the usual order has been issued. It provides that during the active quarantine season, continuing until November 1, all vessels from ports in the West Indies, on the east coast of Mexico, Central and South America, as far south and including ports in the Rio Platte; ports in Peru, Ecuador, Columbia and on the west coast of Central America and Mexico, arriving at the national quarantine stations, shall be detained and treated in accordance with the provisions of the quarantine regulations for domestic ports.

**Dangers from Sewage Farms.**—An outbreak of typhoid fever in the village of Wycombe Marsh, Eng., which seems directly traceable to the pollution of a river by the effluent from a sewage farm, leads *Hospital*, June 20, to conclude, first, that sewage farming demands a high degree of skill and care in order that non-poisonous effluents only may be turned into running streams; and, second, that village wells which are in any close contiguity to sewage farms should, if possible, be closed, and an adequate supply of water obtained elsewhere. Civilization must get rid of its sewage; and sewage farms, when scientifically and conscientiously managed, are excellent methods of sewage disposal. But it is probable that in no long time they will have to be submitted to competent periodical inspection by a sanitary authority in order that such calamities as that which has overtaken Wycombe Marsh may, as they ought to, become impossible.

**A Scottish Sanitarian's View of the English Disregard for Jenner.**—The *Glasgow Sanitary Journal*, for May, says editorially:

"It is a trite saying that the world knows little of its great men, and in a very considerable degree that the world has only a short memory for its chief benefactors. The reason is not far to seek. A century after a great danger to public health has been removed, it is difficult to realize the greatness of the danger when it did exist, and the very success of the preventive means is apt to cause forgetfulness of the value of the original benefaction. In Germany, in the present day, vaccination and revaccination are compulsory and smallpox is unknown. How can a German housewife be expected to feel acutely her indebtedness to Jenner when smallpox, to her, is merely a name, and the sore place on her baby's arm is for a day or two a troublesome reality? But in Germany there is a different legislative system from ours. There is an autocracy, not a democracy, and the result is that vaccination continues to be enforced independently of universal knowledge of its benefits. In this country we are under the democracy, and the democracy is apt to have a short memory. Thus it is that within recent years there has been a tendency to deery and neglect the protection against smallpox which was given to us by Jenner. But the very neglect is already resulting in a fresh acquaintance with smallpox, and a fresh appreciation of the value of cowpox. Nowhere in this country has the neglect been so great as in Gloucester, and nowhere in this country has there been recently such a return to the Jennerian practice as in that city, whose cathedral contains a statue of the Berkeley village doctor. He is fortunate in his wisdom who is wise through the experience of others, and in some defaulting districts the Gloucester experience is causing a return to vaccination. A year or two ago in Bristol there was an exhibition of

Jenner relies, and in some important centers of population in both the new world and the old the centenary day of Jenner's first vaccination has been suitably celebrated. It is a curious example of human folly that in the city of Gloucester the celebration should have to take the form of a smallpox epidemic."

Those of us who behold the "celebration" from a safe distance are moved to add: It is a form of poetic justice, the like of which we do not often see!

**On the Management of the Tuberculous at Hotels.**—The Pennsylvania Society for the Prevention of Tuberculosis, under the presidency of Dr. Lawrence F. Flick, has published some circulars of information for gratuitous distribution. The third tract of the series treats of the duties of hotel-keepers in relation to their infected and non-infected guests. Among the points brought out are the following: The linen, etc., of consumptives should be washed separately and should always be well boiled before being washed. The persons to whom such articles are given to wash should be properly instructed as to what to do in order that they too may be protected. As far as practicable, consumptives in the advanced stage of the disease should be assigned to separate tables, in order that their tableware and linen can be kept apart from those of the other tables and washed separately. All such tableware should be boiled before washing.

"All parts of a hotel or boarding house which are likely to be frequented by consumptive guests should be well supplied with cuspidors in which there should be at all times a germicidal fluid. This fluid should be changed once a day and the cuspidors should be thoroughly scalded with boiling water. In conspicuous places throughout the house and especially in the rooms assigned to consumptive guests there should be notices requesting guests never to eject sputa into any place other than the cuspidor, and suggesting that a handkerchief should never under any circumstances be used for the reception of such sputa where a spittoon is at hand. When out upon the lawn or in any place where a cuspidor is not of convenient access, the sputa should be ejected into paper handkerchiefs, these to be placed, upon returning to the room, in a receptacle furnished for that purpose; such handkerchiefs should not be thrown into the ash bin but burned by the chambermaid. After a room has been occupied by a consumptive, it should be carefully cleansed before another guest is assigned. Where the rules already laid down have been observed, wiping the walls, floor and furniture with a sponge dampened with a germicide solution, whisking the rugs with the same solution and sending the sheets, blankets and pillow cases and counterpanes to the laundry, will be all that is necessary. Where, however, no care has been observed and the consumptive has been careless about spitting on the floor or into linen, silk or muslin handkerchiefs, or where the bed clothing has been visibly soiled with broken down tubercular tissue, it will be necessary to carefully rub the walls with fresh bread and then wash them with a strong germicide solution, to wash the floors and furniture with the same strong solution, to have all the bed linen and blankets thoroughly boiled and to have the rugs and other articles which can neither be subjected to strong germicide solution nor boiled, sent to a renovating place and steamed."

**Sensational Statements Regarding Consumption.**—In a paper prepared for the recent meeting of the American Climatologic Association and published in the *Boston Medical and Surgical Journal* (June 25), Dr. V. Y. Bowdich earnestly protests against the sweeping statements made as to the contagiousness of consumption and the barbarism and brutality which the laity are thus led into showing in their treatment of the consumptive. He considers the physician who asserts that consumption is "as contagious as smallpox" and that "hospitals for consumptives are a source of danger to the whole surrounding community" is making perfectly unwarrantable statements which can not be borne out by facts; and cites observations made in the communities near two of the largest sanatoria for consumptives in the world, namely, Görbersdorf in Silesia and Falkenstein near Frankfort, to prove that consumption has lessened in amount in the entire population since the introduction of the sanatoria there, largely due to the strict

hygienic rules which are used at the sanatoria for the disposition of sputa and which are taught to the inhabitants in the surrounding villages. He admits that it is, doubtless, perfectly true on the other hand, that in various "open resorts" for consumptives where strict methods for the disinfection of the hotels and boarding houses are not enforced the death rate among the inmates from consumption has increased greatly, the most striking cases being those of Mentone and Nice where according to statistics consumption has greatly increased since the places have become such a common resort for phthisical patients, many of whom through carelessness or ignorance become sources of contagion to others. Referring to the experiments of Delepin and Ransome (*JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, Vol. XXIV, page 450. *British Medical Journal*, Feb. 16, 1895) with reference to the germicidal effects of various agents upon the bacilli of tuberculosis, exposure to the direct rays of the sun for a comparatively short time prove to be the most effective. As a result of these experiments Dr. Bowdich thinks "it is certainly a legitimate doubt to come to our minds as to how far we need fear infection from sputa which are expectorated onto the open ground exposed to the full rays of the sunlight. Not that I would relax one iota in the restriction of the disgusting habit (to say the least) of spitting publicly anywhere; it is only a question as to its danger under the condition of exposure to the sun's rays. Thus we have scientific facts to help us in trying to show the laity that the consumptive need not be treated like a leper, or as one affected with the plague, but that moderate measures will prevent his being a source of danger to those about him."

**The Bubonic Plague at Hong-Kong, in 1894.**—Dr. J. G. Adami in the *Montreal Medical Journal* for June, gives an admirable digest of the five principal essays of Japanese, French and English writers that thus far have appeared on the above subject. The closing paragraphs of Dr. Adami's paper are the following: The Hong Kong epidemic of 1894 has gained for itself a place in medical history, from the fact that during its course the bacillus of the plague was discovered first by Kitasato, and independently, after a brief interval by Yersin, while Lowson and Aoyama have given us the fullest studies yet made of the clinical features and the pathologic anatomy of the disease. We have little or no accurate information concerning the plague in China in early times. It is true that medieval writers ascribed the origin of the terrible Black Death (hemorrhagic plague) to China, but apparently without full cause. It has, however, been known to be endemic in one of the southern provinces, Yunnan, for more than twenty years, as also at Pakhoi, on the southern coast. Early in 1894 it appeared at Canton, causing the death of more than 60,000 individuals in the course of a few weeks. Hong Kong, situated as it is at the mouth of the Canton river, and having a population, in the main Chinese (about 150,000 out of a total of 163,000) became infected, most probably from Canton, and, at the latest, early in May. In June the disease was at its height, and it continued through the next two months. After August, cases were few and far between. Altogether, according to Lowson's statistics, which confessedly do not include all the Chinese cases, more than 2,600 persons were admitted to the hospitals, of whom 2,485 died, an appalling mortality of more than 93 per cent. The Chinese were in the main affected. The mortality among the Japanese (10 cases) was 60 per cent. Among Europeans (11 cases) 18.2 per cent. How many Chinese died unrecorded in their quarter of the town will never be known. Aoyama himself suffered severely from the disease and Lowson gives a full report of his case:

"The disease possessed all the typical characters; numerous dead rats and mice encumbered the infected quarters. After an incubation period of three to nine days, the infected individual became the prey of a sudden intense fever, accompanied

often by delirium, but without noticeable rigor. From the first day of the fever a bubo was noticeable, at first in general solitary, later other glands, situated more centrally, became enlarged. In some of the severest cases death occurred before the bubo had time to develop; in such there were frequent subcutaneous and submucous hemorrhages, recalling the Black Death. In 75 per cent. of the cases (Yersin) the bubo was of the nature of an 'emeroid in the secret parts' being situated in the inguinal region, more correctly in the femoral chain; the axillary glands were the next most frequent seat of primary enlargement. The swollen glands attained the size of a hen's egg. Aoyama points out that all the Japanese patients had axillary buboes, and from this fact, and from the centripetal extension of the glandular enlargement, he concludes that infection is most often through wounds of the extremities, the Chinese going barefoot, the Japanese being booted. Lowson, however, points out that all the men of the Shropshire regiment infected had femoral or inguinal buboes, and yet they were well booted—a fact which throws some doubt upon the theory of the Japanese professor. Everything, however, points to the disease being of the nature of a soil infection rather than that conveyed by water, and Aoyama's theory fits in best with the fact that in most cases the disease first manifests itself in a solitary peripheral gland. Inasmuch as necropsies in some cases demonstrated the primary affection of abdominal glands, the possibility of intestinal infection must also be acknowledged. Death occurred at the end of forty-eight hours, frequently sooner. If the disease continued for five or six days the prognosis was hopeful. In such cases the tense buboes became softened and suppurative and relief was obtained by operative discharge of the pus. At autopsies performed upon those dying from this disease, the swollen glands were found to swarm with minute bacilli. These bacilli resemble those found in the hemorrhagic septicaemias of the lower animals, the bacilli of chicken cholera for example, staining more deeply at the poles, so that when not deeply stained they appear to be diplococci. They decolorize by Gram's method and grow easily in various media. In preparations made from the tissues they frequently appear as though surrounded by a capsule; grown in broth they often form short chains, and, indeed, the appearance of broth cultures resemble those of the streptococcus pyogenes. Mice, rabbits and guinea pigs inoculated either with material from the infected corpse or with pure cultures die in from one to four days. Pigeons are unaffected. The bacilli are to be found in the blood and spleen, though not in such numbers as in the buboes. Preserved in dried films at 23 to 30 degrees C. they die in four days or so. The action of direct sunlight killed them in a few hours. In mice and other small animals the main features discovered at the necropsy are the development of a reddened edema at the point of inoculation, swelling of the nearest lymph gland or glands with profusion of bacilli, congestion of the kidneys and supra-renals and great swelling of the spleen. In man, as shown by Lowson and Aoyama, the chief anatomic changes are very similar, namely, enlargement of one or more lymphatic glands, due to multiplication of lymphoid cells, surrounding reddened gelatinous edema, some enlargement with softening of the spleen, increase in the number of white corpuscles in the blood. The liver and kidneys are congested with parenchymatous degeneration. There can therefore be no doubt that the causative agent of the bubonic plague has been discovered. In general the descriptions given of the plague contain no reference to infection of cattle, but in Yunnan the destruction of these animals has been a distinctive feature, and Yersin determined the presence of the bacillus in cattle in a most virulent form. Lowson failed to obtain more than local results upon inoculating cattle and pigs, and suggests that the cattle suffer from a disease common in Yunnan and due to a similar microbe, namely, the Rinderpest."

**Health Reports.**—The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

**SMALLPOX—UNITED STATES.**

Florida: Key West, July 1 to 5, 7 cases.  
Louisiana: New Orleans, June 20 to 27, 5 cases, 4 deaths.

**SMALLPOX—FOREIGN.**

Athens, Greece, January 1 to May 31, 19 cases, 5 deaths.  
Bombay, India, May 26 to June 2, 16 deaths.  
Calcutta, India, May 16 to 23, 4 deaths.  
Callao, Peru, May 31 to June 7, 7 deaths.  
Genoa, Italy, June 13 to 20, 2 cases.  
Guayaquil, Ecuador, June 5 to 12, 1 death.  
Madrid, Spain, June 9 to 16, 10 deaths.  
Montevideo, Uruguay, May 23 to 30, 2 cases.  
Odessa, Russia, June 6 to 13, 5 cases, 1 death.

Osaka and Hiogo, Japan, May 23 to 30, 32 cases, 16 deaths.  
Prague, Bohemia, June 6 to 13, 4 cases.  
Rio de Janeiro, Brazil, May 30 to June 6, 9 cases, 4 deaths.  
St. Petersburg, Russia, June 6 to 13, 18 cases, 6 deaths.

**CHOLERA.**

Osaka and Hiogo, Japan, May 23 to 30, 1 case.  
Bombay, India, May 26 to June 2, 12 deaths.  
Calcutta, India, May 16 to 23, 97 deaths.

**YELLOW FEVER.**

Cuba: Sagua la Grande, June 13 to 20, 60 cases, 4 deaths;  
Cardenas, June 13 and 14, 4 cases, 2 deaths.  
Brazil: Rio de Janeiro, May 30 to June 6, 12 deaths.

**BOOK NOTICES.**

*Transactions of the Southern Surgical and Gynecological Association*, Volume VIII, Eighth Session, held at Washington, D. C., Nov. 12, 13 and 14, 1895. Svo, pp. 303. Published by the Association. 1896.

Dr. John A. Wyeth, in his paper, "Dr. J. Marion Sims and his Work," says of that distinguished surgeon: "It is safe to say that Marion Sims attained the highest position ever achieved in the history of our profession. He stood alone in this; his reputation as a surgeon was so world-wide that in any capital, in any country within the domain of civilization, he could command at any time a lucrative practice. Assuredly there does not exist in the history of surgery another such distinction. In New York, London, Paris, Brussels, Berlin, Vienna, Rome, Madrid, Lisbon and St. Petersburg he found himself everywhere sought after, not only by the patients he could benefit, but by the leading members of his profession, who were anxious to pay tribute to his wonderful genius. Born amid the most humble conditions in a backwoods county of South Carolina, he died the foremost surgeon of his country and the world."

**NECROLOGY.**

THOMAS L. HOUGH, M.D., the senior member of the medical faculty of Elizabeth, N. J., died June 12, aged 68 years. He was graduated from Jefferson Medical College, class of 1856. He was one of the founders of the Union County Medical Society, and a member of a variety of charitable organizations, and has been in the forefront of most of the public-spirited movements of the enterprising city during the past forty years. His funeral was very largely attended by the prominent citizens and officials.

J. L. SELMAN, M.D. (University of Louisville Medical Department, Louisville, Ky., 1882), at Chattanooga, Tenn., June 23, aged 36 years. Dr. Selman was city physician of Chattanooga at the time of his death. The Chattanooga Medical Society held a meeting and passed appropriate resolutions.

JOSEPH T. SCOTT, M.D. (Missouri Medical College, St. Louis, Mo., 1856), at New Orleans, La., June 25, aged 63 years. During the civil war Dr. Scott served as surgeon of the First Missouri Infantry; surgeon in Guibard's Battery of St. Louis, and was chief surgeon on the staff of General Frost of St. Louis, also surgeon in Van Dorn's Cavalry regiment. At the time of surrender, in May, 1865, at Shreveport, he was surgeon in General Dick Taylor's Louisiana regiment. Dr. Scott was a member of the Howard Association, and rendered valuable help during the terrible epidemic of yellow fever in 1878. He was some years ago, a member of the board of directors of the Charity hospital.

GEORGE C. SHATTUCK CHOATE, M.D. (Harvard University Medical School, Boston, Mass., 1849), at Pleasantville, N. Y., June 26, aged 70 years. He was for ten years superintendent of the Massachusetts State asylum for the insane at Taunton, Mass. Thirty-six years ago he established his private asylum

near Pleasantville. It was in this sanitarium that Horace Greeley died.

ARTHUR G. KENNY, M.D. (Albany Medical College, Albany, N. Y., 1877), of Watervliet, N. Y., at the Troy Hospital, June 25.

T. B. WILEY, M.D. (Rush Medical College, Chicago, Ill., 1874), at Gibson City, Ill., June 30, aged 52 years.

## ASSOCIATION NEWS.

**Headquarters of the American Medical Association.**—According to a resolution adopted at the Atlanta meeting of the AMERICAN MEDICAL ASSOCIATION, the members are to determine by vote where the permanent home of the ASSOCIATION shall be located. The ballots have now been distributed to the members, who have until July 31 to cast their votes. As soon as the count is completed the result will be announced in the JOURNAL. Members may vote for any place they desire, but it is probable that the choice will be practically limited to either Washington or Chicago. Certainly the former would seem to be the appropriate home for a national organization. The other representative association of the practitioners of America, the Congress of American Physicians and Surgeons, has always held its triennial reunions in Washington, and this society would be wise to follow suit.—*Medical Record.*

## SOCIETY NEWS.

**The Fourth Annual Russian National Medical Congress** was held this year at Kiew and was attended by over a thousand physicians, who discussed various hygienic and social questions as well as the more strictly scientific subjects. The city was *en fête* in honor of the convention, and the general enthusiasm speaks well for the prospects of the International Congress to be held at Moscow next year.

**American Public Health Association.**—The twenty-fourth annual meeting of this association will be held in Buffalo, N. Y., September 15 to 18. The following topics will be taken up for consideration: "Pollution of Water," "Disposal of Garbage and Refuse," "Animal Diseases and Animal Food," "Nomenclature of Diseases and Forms of Statistics," "Protective Inoculations in Infectious Diseases," "National Health Legislation," "Cause and Prevention of Diphtheria," "Causes and Prevention of Infant Mortality," "Car Sanitation," "Steamship and Steamboat Sanitation," "Transportation and Disposal of the Dead," "Use of Alcoholic Drinks from a Sanitary Standpoint," "Centennial of Vaccination," "Relation of Forestry to Public Health," "Transportation of Diseased Tissues by Mail," "River Conservancy Boards of Health," "Prevention of the Spread of Yellow Fever." The President of the association is Dr. Eduardo Liceaga, City of Mexico, Mexico; First Vice-President, Lieut.-Col. Alfred A. Woodhull of the Medical Department of the United States Army, Denver, Colo.; Second Vice-President, Dr. Henry Sewall, Denver, Colo.; Secretary, Dr. Irving A. Watson, Concord, N. H.; Treasurer, Dr. Henry D. Holton, Brattleboro, Vt.

**Congress of Dermatology.**—The third International Congress of Dermatology will meet in London, from August 4 to 8, of this year. The general program has been published in a recent number of the JOURNAL. There will be a museum of drawings, casts, models, naked eye preparations, microscopic specimens, works and atlases pertaining to diseases of the skin. There will also be an exhibition of clinical cases and demonstrations of the same at 9 A. M. and 2 P. M. of August 5, 6 and 7, and at 9 A. M. of August 8. Anyone having anything to contribute to this department, will please address Dr. Jas. Galloway, 21 Queen Anne Street, Cavendish Square, W. There will be an exhibition of cultures and microscopic preparations of organ-

isms connected with the skin and its diseases. Any communications in regard to this department should be addressed to H. G. Plimmer, Esq., Wunderbau, Sydenham, London. The social side of the Congress will be: 1. An informal reception at the International Hall, Piccadilly Circus, on August 3, from 9 to 12 P. M. 2. A reception by the Lord Mayor and Lady Mayoress at the Mansion House, on August 5, from 9 to 11 P. M. 3. A Dinner to the Foreign Members at the Hotel Cecil, on August 7. It is advised that foreigners should arrive in London not later than Sunday, August 2, as Monday the 3d inst. is a public holiday. Information in regard to hotels will be furnished on application to George Pernet, Esq., 77 Upper Gloucester Place, London, N. W.

GEORGE THOMAS JACKSON, M.D.,  
Foreign Secretary for the U. S.

### International Periodical Congress of Gynecology and Obstetrics.—

The date of the opening of the Second International Congress of Gynecology and Obstetrics at Geneva, has been fixed for Aug. 31. The Congress will continue one week, closing Saturday, Sept. 5, 1896. The success of this scientific reunion seems assured. The eminence of the Honorary Presidents, the scientific prominence of the referees and the number of members who have joined, guarantees its success. The sessions of the Congress will take place in the Grand Aula of the University. The first general session, that of the morning of the first of September will be honored by the presence of the President of the Swiss Confederation, as well as the Chief of the Department of Public Instruction of the Canton of Geneva who will inaugurate the Congress by addresses. Morning sessions will continue from 9 A.M. until noon. Afternoon sessions from 3 to 6. The former will be devoted to the discussion of official questions, the latter to other communications. In order to make the first most interesting, the Committee of Organization will endeavor to publish and distribute among the members a synopsis or the "Conclusions" of the Referees. Manuscripts must be delivered to the Secretary at the end of the session at which they are read, and members taking part in the discussion must also present to the Secretary a synopsis of their remarks. An International Exposition of gynecologic and obstetric instruments will be opened during the Congress, and all objects entered for this Exposition should arrive in Geneva prior to August 10, addressed, University, Rue de Candolle, Geneva. Members are advised also that as the Congress coincides with the National Exposition of Switzerland, it will be prudent to engage rooms in advance. For that purpose you may address hereafter: "La Commission officielle des logements ayant son bureau a la gare de Cornavin." Members of the Congress arriving in Geneva without being inscribed can still obtain a membership card, Sunday morning, August 30, and thereafter in the Office of the Treasurer of the University. Ladies' cards will be issued admitting to the receptions and festivities.

#### PROGRAM.

Monday, 3 P.M.—Reunion of the Permanent Committee and of the founders of the International Congress. At 9 P.M.—Reception at the Palace Eynard.

Tuesday.—Opening of the Congress by President Reverdin. Address by President Lachenal. Addresses by Mons. Richard, Chief of the Department of Public Instruction and Official Delegates. 3 P.M.—Discussion of the First Official Question, viz: "Treatment of Pelvic Suppurations." Referees: Sanger, Kelly, Bouilly. Discussion by A. Martin, Richelot, Lawson Tait, Jacobs, Delettretz, Henrotin, Hartman, Rouffart, Tournay, Henrotay, Desguins, Guilloud, Caromilas.

Wednesday.—Discussion of the Second and Third Official Questions: "Surgical Treatment of the Retro-deviations." Referees: Kustner, Polk and Pozzi. Discussion by A. Martin, Bouilly, Lawson Tait, Jacobs, Edebohls, Gill Wylie, Henry Byford (Chicago), Delettretz, Steffer, Paul Pettit. "Most

Successful Method of Closing the Abdomen." Referees: Granville Bantock, La Torre. Discussion by Messrs. Martin, Lawson Tait, Richelot, Jacobs, Edebohls, Gill Wylie, Byford, Delettretz. 3 P.M.—Miscellaneous papers.

Thursday.—This day will be entirely devoted to promenade on the Lake at Vevay and excursions to Montreux-Chillon. Special program will be distributed indicating the details of this excursion.

Friday.—Discussion of the Fourth Official Question: "Relative Frequency and Most Common Forms of Pelvic Contractions in Different Races, Groups of Countries and Continents." Referees; Fancourt Barnes, Dohrn, Fochier, Kufferath, Lusk, Rein, Pawlick, Pestalozza, Treub. Discussion to be opened by Berry Hart. 3 P.M.—Miscellaneous papers.

Saturday.—Discussion of the Fifth Official Question: "Treatment of Eclampsia." Referees: Charles, Charpentier, Halbertsma, Veit, Mangiagalli, Parvin, Byers. Leaders in discussion: Tarnier, More Madden, Lindfors, Godson. 3 P.M.—Miscellaneous Papers. 5 P.M.—Closing Business Session. 8 P.M.—Final Subscription Banquet.

Sunday.—Various Excursions, International Regattas, Fireworks, etc. President, Auguste Reverdin; Secretaries, Gynecology, Dr. C. Betrix; obstetrics, Dr. Cordes.

The General Secretaries are: Dr. Betrix, for Gynecology; Dr. Cordes, for obstetrics; Treasurer of the Committee, Dr. Bourcart. Secretary General for North America (through whom all correspondence and business will be directed): Dr. Fernand Henrotin, 353 LaSalle Avenue, Chicago, Ill.

The Cleveland Medical Society held its last meeting for the summer and adjourned until September 11. Dr. J. F. Hobson read a paper on "A Report of a Case of Pott's Disease of the Spine." Dr. W. E. Wirt read a Paper on "An Original Method of Using Dry Heat of High Temperature in the Treatment of Chronic Joint Affections."

## MISCELLANY.

**Appointment.**—Mayor Swift has appointed Dr. John B. Hamilton a member of the Board of the Public Library of the city of Chicago.

**Delegate.**—Dr. George Ben. Johnston, of Richmond, Va., has been appointed one of the eight delegates on behalf of the government of the United States to attend the session of the International Periodical Congress of Gynecology and Obstetrics, to be held at Geneva, Switzerland, September, 1896.

**Antiquity of the Truss.**—Poncet has an interesting historic sketch of the evolution of hernial bandages in *Méd. Moderne*, No. 11, with a description of a recently discovered ancient Phœnician statuette of a god, at least 3,000 years old, which represents "unmistakably" several ruptures on the abdomen, with a double hernial bandage resembling those now in use.—*Centralblatt f. Chirurgie*, April 11.

**Cross of the Iron Crown.**—A cablegram has just been received from Buda-Pest, Hungary, announcing that Mr. Andor Saxlehner, of the firm of Andreas Saxlehner, of that city, proprietor of the Hunyadi Janos natural aperient water, has been decorated by Francis Joseph I., Emperor of Austria and King of Hungary, with the Cross of the Iron Crown, Order III, on the occasion of the Hungarian Millennial Celebration now being held in Buda-Pest.

**Medical College Appointments.**—The following appointments in the faculty of the Albany (N. Y.) Medical College are noticed in the catalogue for 1896-97: Herman Bendell, clinical professor of ology; Andrew McFarlane, professor of physical diagnosis and microscopy; John B. Hennessey, lecturer on materia medica; George Newman, lecturer on symptomatology; Clement Theisen, instructor in throat and nose; James M. Moore,

instructor in physical diagnosis and clinical microscopy; James Thomas McKenny, of Troy, instructor in physiology; James M. Mosher, instructor in neurology. The Bender laboratory will be in charge of George Blunner, late assistant in pathology and bacteriology at the Johns Hopkins University.

**Practicing without Diploma.**—Suit for practicing medicine without a diploma and without registration was brought against Edmund Duff of Harrisburg, Pa., by Col. Oliver B. Simmons, Chairman of the Sanitary Committee, and the defendant waived a hearing for trial at court. The action was brought before Mayor Patterson, after Colonel Simmons and the Mayor had heard a report from Sanitary Officer Block, who had investigated the matter and found that Duff was practicing without compliance with the law. The failure to report a case of diphtheria, treatment of which caused the trouble, was also brought out, but Duff asserted that the disease had not been diagnosed until Friday, when the patient died, and the Mayor dropped the case, there not being enough evidence to hold the defendant. Duff made no defense to the charge of practicing without registration and was held under \$300 bail.

**A New Biologic Laboratory.**—The corner stones of the new Hull biologic buildings of the University of Chicago were laid July 3. The laboratories will consist of four three-story structures, of Gothic design, and are the gift of Miss Helen Culver, in memory of her uncle, C. J. Hull. The gift amounted to \$1,000,000, of which \$300,000 was to be used for the buildings and the remainder to serve as an endowment fund. Since then Miss Culver has given \$25,000 more for the buildings, which makes the cost of the structures \$325,000. The address of the day was delivered by Prof. George Lincoln Goodale, LL.D., of Harvard. He spoke of the development of the bacteriologic laboratory, its aims and requirements. At the conclusion of the address President Harper spoke of the prospects of this department and said that the erection of these buildings marked the beginning of the long-looked for medical school. The assemblage then moved in procession to the site of the new buildings, where the corner stones were laid with appropriate addresses.

**Higher Preliminary Education.**—A congress of Missouri physicians met at St. Louis, June 27, and adopted resolutions looking to the higher preliminary education of medical students. The movement was started by the University Medical College of Kansas City, whose president, Dr. J. M. Allen, called a meeting of the fifteen medical schools of the State. Twelve of these schools were represented at the gathering. Dr. J. M. Allen, of Liberty, Mo., presided, and Dr. A. E. Mink, of St. Louis, was secretary. Among others present were: Dr. A. L. Burger, secretary, and Dr. J. P. Jackson, dean, of the University Medical College, Kansas City; Dr. Mark Edgerton, ex-dean of the Kansas City Homeopathic Medical College; Dr. Batey, of the University College of Kansas City; Dr. F. J. Lutz, Dr. L. C. McElwee, Dr. Bond, Dr. Steele, Dr. Loeb and Dr. Hypes.

**Varices of the Leg.**—Dr. Alexander Hugh Ferguson (*Chicago Medical Recorder*, June, 1896), describes his method of operation. He first ties the saphenous vein in two places near the femoral above the abnormal condition and a section of the vein is removed. Then a semilunar incision is made through healthy skin and extended as far down as is necessary to go until all the varices are partly surrounded, the incision is then deepened to the fascia lata. In the line of this incision all the venous supply is cut off. When the incision is completed down to the deep fascia the entire flap is raised and dissected up. The veins, normal and pathologic, are raised with the flap and the varices and branches dissected from its under surface. In raising the flap the venous communications with the deep veins are severed and ligated. This is a modification of Schedé's operation.

**Hayseed Sprouted in the Ear.**—Dr. Macnaughton Jones reports a case where the patient had been suffering from noises in the ear for some years, and had other evidences of middle ear deafness. He sought advice for the deafness, being quite unconscious of the presence of any foreign body. On examining the meatus, what appeared to be a pink sprouting mass of fungus was seen with the transmitted light. The appearance was most puzzling, and it was not until the sprouting hayseed was withdrawn that its nature was discovered. It was quite firmly attached to the wall of the meatus, being removed clean with the lever forceps. The patient then remembered having, over two years previously, at harvest time, suddenly felt as if something had entered his ear, and the tinnitus began.—*Jour. of Laryngology, Rhinology and Ology*, June, 1896.

**Oxygenized Chloroform.**—Dr. Charles S. Elder (*Col. Med. Jour.*, June, 1896) says of the new anesthetic: Few patients are gotten completely under the anesthetic by this process. They seldom have perfect relaxation of muscles and loss of corneal reflex. To this first is to be attributed the rapid recoveries unattended by nausea and vomiting. It is not true that patients keep rosy lips and cheeks during the anesthesia any more than they do with chloroform, nor do they recover any better or quicker, provided the narcoses be of equal depth and duration. Chloroform as ordinarily given is a more powerful anesthetic than when given by the new process, therefore the anesthetic is apt to be more profound unless it is administered with more care. But to argue that oxygenized chloroform is safer for this reason is to insist that it is better because it is less efficient.

**The "Unsurgeonlike Horrors" of Hunter's Time.**—The *Clinical Sketches*, in treating of the days before chloroform, reminds of the stern courage that then was demanded of surgeons. It remarks that in studying the histories of surgeons of a bygone age, we are frequently reminded of the horrors of their art before the days of chloroform. "It is not surprising to read that Abernethy 'had a most unsurgeonlike horror' of operations, and that both Cheselden and Hunter entertained similar feelings. Of Sir Astley Cooper's uncle William it is recorded that when about to amputate the leg of a man at the hospital, the patient, seeing the instruments being got ready, suddenly jumped off the table and hobbled away, whereat the surgeon expressed himself as greatly relieved: 'By Gad,' said he, 'I am glad he has gone!'"

**Women in Medicine.**—Jacobi, of New York, has a bright letter in the *Deutsche Med. Woch.* for June 18, replying to a request for his opinion in regard to women in the medical profession. He evidently thinks they have come to stay, a phase of the struggle for existence governed by economic laws, unaffected by individual or social preferences or prejudices. He expresses his regret that there are too many female medical colleges in this country, some of them which are not up to the standard of the rest, and approves of co-education as stimulating and elevating the male students. He states his impression that the incomes of female physicians average higher than those of the men, and speaks with the greatest respect of those he knows, ridiculing the idea that because a woman is not so large nor so strong as a man, she should therefore be debarred from the medical profession, any more than an undersized man, "as if any of us were Apollo, Hercules and Methusaleh combined."

**Heroism of the Daughter of Dr. Herman Knapp.**—Dr. Knapp, the well-known ophthalmologist of New York city, met with a narrow escape from death by drowning on June 20. He would, without doubt, have lost his life but for the presence of mind and heroic conduct of his daughter Ida, a young lady of 20, who was with him at his summer cottage at Monmouth Beach, New Jersey. As the day was unusually warm he decided to take his first ocean bath of the season, and his daughter watched him from the shore. Dr. Knapp is an expert swimmer, and

went out some distance in the water, but as he was on his way back she noticed that he showed signs of distress. Immediately she secured a life preserver which was lying near by on the sand, and having tied a line to it, plunged with it, dressed as she was in house attire, into the sea. Wading in the water up to her neck she just managed to throw the life-preserver to a point where her father, who by this time had sunk twice, was able to grasp it. She then struggled bravely for the shore, carrying the line with her, and both she and her father were dragged to land in an extremely exhausted condition by some fishermen who had come to the rescue from a distance.

**Not Liable for Removal of Injured Employee.**—One of the grounds on which recovery of damages was sought to be had in the case of York v. Chicago, Milwaukee and St. Paul Railway Company, which was before the supreme court of Iowa May 25, 1896, was because the company's surgeon, who was employed and paid by it to treat its injured employes, as an act of charity or humanity, wrongfully and negligently moved an injured employe from another doctor's office to a hotel, which act, it was alleged, contributed to produce his death. It was not contended that this surgeon was not a skillful one, or that the company did not exercise due care in employing him. Under these circumstances, the supreme court of Iowa holds the company not liable. It says that it understands the rule to be well settled by a large number of cases that, under such circumstances, the defendant is not liable for acts of negligence of the physician who is employed to treat gratuitously its injured employes.

**Cancer of the Pregnant Uterus.**—Dr. George H. Noble gives details of 166 cases occurring since 1866, and concludes: "A summary shows that vaginal hysterectomy should be safe in the early months of pregnancy and the puerperal state, when there is a reasonable hope for the mother. The abdominal hysterectomy should be done under the above conditions when the uterus is too large to be rapidly and safely removed through the vagina. That at or near the end of pregnancy Cesarean section (conservative) should be resorted to when the child's interest is to be considered. That Cesarean section with Freund's operation is permissible when the disease is confined to the uterus and the child viable. That in doubtful cases cutting of the cervix and rapid delivery may be judicious when the incision can be made in unulcerated or non-infiltrated tissue. That as there are four chances to one against the life of the fetus, and as an equal or greater number of mothers may be ultimately cured in the early stages of the disease, the safety of the fetus should not be allowed to hazard the life of the mother. And that, upon the other hand, the futile efforts directed to the interest of the mother when her case is hopeless should not jeopardize the safety of the fetus in the latter months of pregnancy."—*Amer. Jour. of Obstetrics and Diseases of Women and Children*, June, 1896.

**Study of the Thermodynamics of the Muscles.**—Störing publishes in the *Arch. f. Phys.*, 1895, page 499, the results of his thermoelectric measurements of the generation of warmth in the muscles during isotonic and isometric contractions, with stimulus of varying strength and frequency, prefacing his report with a description of the Fick-Gad theory in regard to the muscles. He states that the so-called "negative variations in warmth" are only produced by defective manipulation of the instrument, thus agreeing with Heidenhain in opposition to Danilewsky. The results of his investigations are that the amount of warmth generated increases proportionately to the amount of tension during isometric contractions with increasing stimulus. During isotonic contractions it is more rapid at first, but with strong stimulus it is in proportion to the "height of lift." (Nawalichin and Danilewsky.) The muscles were also measured after having been slightly fatigued by

ten to fifteen contractions, this condition being the same as when the first increased height of lift had returned to its original condition. Heidenhain had stated that the amount of warmth generated diminished more rapidly than the height of lift in fatigued muscles, but these investigations resulted differently, increased warmth being generated in the fatigued condition. The article concludes with a discussion of the possibility of applying these results in confirmation of the Fick-Gad theory, as an explanation of the processes that occur during contraction.—*Centralb. f. Phys.*, May 2.

**Therapeutic Value of Scopolamin.**—It is the best of our mydriatics. It acts promptly and efficiently, dilating the pupil *ad maximum* within fifteen minutes and paralyzing the accommodation within one hour. In almost every case the patient regains the ability to read within seventy-two hours. In its effect upon the accommodation, scopolamin stands midway between homatropin and atropin. The cycloplegic effect of homatropin lasts about twenty-four hours; often it fails to paralyze the accommodation. Atropin will paralyze the accommodation with certainty, and the effect lasts ten days, often two weeks. Repeated instillations of homatropin or atropin are necessary. In the case of scopolamin one instillation of one drop of a one-fifth per cent. solution will do the work. Less conjunctival irritation follows scopolamin than the other drugs mentioned. As a mydriatic for refraction work it is *facile princeps*. It is even more useful in iritis; one drop twice a day will often dilate the pupil when repeated applications of atropin fail. Do not use this drug lavishly, for it will produce toxic symptoms if applied carelessly. In the strength of one-fifth of 1 per cent. use only one small drop. In children and in delicate adults a weaker solution, one-tenth of 1 per cent., will be sufficient.—Dr. James Moores Balls in the *Tri-State Monthly* for June, 1896.

**Rupture of Quadriceps Extensor.**—Dr. J. B. Walker says: In comparing the averages of 255 cases of rupture of the quadriceps extensor muscle and its tendon above and below the patella, we find that under the mechanical mode 72.5 per cent. recovered completely, 12.5 per cent. in three months and 32 per cent. within six months. Whereas under the operative method 86 per cent. recovered completely; 50 per cent. within three months, and 100 per cent. within six months. In recent cases where there is not much effusion and the joint is apparently not opened, where the separated ends can be approximated and detained by suitably adjusted pads, the mechanical treatment may be carefully considered. In the hands of the intelligent general practitioner this method may be expected to bring about a complete recovery in the larger number of cases. From nine to twelve months will be required to reestablish fully the normal functions. The skilled aseptic surgeon who primarily resorts to the operative method in suitable cases (but the age and vitality of each patient must be most carefully considered) may quite reasonably hope to obtain a better result in a larger number of cases and save his patient three to six months' time. Catgut, kangaroo tendon or silk-worm gut should be used and when there is much effusion drainage should also be employed.—*Am. Jour. of Medical Sciences*, June, 1896.

**Authority to Employ Physicians for Indians.**—The provision in Section 5 of the Appropriation act of Congress approved March 3, 1875, to the effect that the number and kind of employes at each agency shall be prescribed by the Secretary of the Interior, the United State circuit court of appeals holds, in the case of *United States v. Patrick*, decided March 30, 1896, furnishes ample authority for the Secretary of the Interior to employ physicians to attend Indians. It also holds that by approving the vouchers and directing the payment of the bills for a term of years of a physician employed by an Indian agent from time to time during those years to treat the Indians in

need of medical services, the Secretary of the Interior sufficiently prescribed that one of the employes at the agency in question should be a physician, to be called by the agent from time to time, to render such medical services as the Indians required. And the court further holds that the Secretary of the Interior having authority to employ physicians, for the United States, at an Indian agency, and his subordinate, the Indian agent at such agency, having employed them, and the Secretary having approved their bills, and directed the agent to pay them out of the public funds, the United States and the Secretary were bound by his acts, both because they thus ratified them and because, by their action, they induced him to expend money for this purpose which he would not otherwise have disbursed.

**Superintendent's Power to Employ Physician and Nurse.**—The physician called by a man injured while in the employ of an electric light and power company testified that he called on the superintendent or general manager of such company and told him that he would have to have a nurse, and that the official told him to employ one, and that they would see to the physician's bill and the nurse's bill. This conversation the official denied. The trial judge instructed the jury, when an action was brought by the nurse to recover from the company for his services, that so far as the question of authority was concerned, he could not say that there was no evidence from which they might infer that the superintendent or manager referred to was not authorized to make a contract, but thought that they might draw the inference that he was authorized to make such contract as the plaintiff contended was made. This the Supreme Court of Michigan decided, June 2, 1896, *Hodges v. Detroit Electric Light and Power Company*, was correct. The court now clearly favors the view that it is within the general scope of the employment of such an official to make such a contract as that for the employment of the nurse or physician, a proposition upon which, in a railroad case, it some years ago was equally divided. Nor does it think that the question of power is affected by the fact that the injured man was cared for at his own home. But it does not think that the physician should be allowed to testify that he charged, upon his own books of account, his services to the company, lest the jury regard that as evidence that the contract was made as contended.

**Courts of Equity Refuse to Restrain Board of Health.**—Upon the question of judicial interference by injunction to restrain the abatement of what the landowner or occupant denies to be a nuisance, the cases are comparatively few, and most of them deal with obstructions to streets, highways or waterways. A patient examination of the whole course of decisions on the general subject of the police power and the summary abatement of nuisances, Chancellor Nicholson, of the court of chancery of Delaware, says has left with him no doubt that a court of equity, upon an application for an injunction to restrain a board of health or other municipal body from the summary abatement of what it has adjudged to be a nuisance detrimental to the public health, will decline to restrain the proposed action of the local body unless it is made to appear clearly that it has acted wantonly and in bad faith, or has transcended its jurisdiction. He also says that the adjudication by the board of the fact of nuisance will not protect it as will the judgment of a court, and in all cases it acts at its peril. In this case, *Liebig Manufacturing Co. v. Wales*, decided March 14, 1896, the court of chancery refused to grant a preliminary injunction which would restrain the city board of health from abating the emanation of odors or gases from a manufacturing establishment which it had declared to be a nuisance, detrimental to the public health, especially in view of the fact that the almost unlimited range of human ingenuity, in the present age of scientific discovery, seems to be equal to rendering

almost any trade innocuous in almost any locality, and in view of the further fact, that of it not being shown that the odors or gases in question were not or could not be a nuisance, whereby the public health was or might be injured.

**Skiagraphy.**—Dr. W. W. Keen, referring to plate made by Dr. A. W. Goodspeed of the University of Pennsylvania, said: "One of the most important points to be observed about the skiagraph is that the upper opening of the pelvis is so clearly seen that a measurement could be made with absolute accuracy in order to determine whether a fetus could be delivered or not in the case of a deformed pelvis. If the dimensions of the skiagraph should not be absolutely the same as those of the original pelvis, a proportionate allowance could be readily made by measuring the distance between the crests of the ilia, which could be measured with accuracy on the body or taken as a standard. Any fracture or deformity of such a pelvis could be determined very readily. Osteo-sarcoma of the ilium, fracture, or any other disease or injury altering its outlines would be perfectly demonstrable. It is doubtful whether disease of the hip-joint itself could be made out from such a skiagraph: but fracture of the neck of the femur or of the greater tuberosity could be determined very readily."—*International Medical Magazine*, June, 1896.

**Etiology and Pathology of Cancer.**—Five chief theories have been advanced to explain the etiology of cancer. 1. Conheim's theory of the origin of tumors in inclusions of embryonic tissue; 2, a specific bacterium; 3, protozoa; 4, yeasts; 5, a vegetative cell. The theory that has received the most attention for the past few years is that cancer is caused by protozoa. Ruffer has described the appearance of cancer bodies which he regards as sporozoa: spherical bodies with small nucleus and a distinct capsule. It is generally in the center of a parasite. Many of the appearances of certain kinds of cancer bodies may be explained by cell invagination. The history of the pathology of cancer differs from most other diseases in that we have had no analogy in other diseases to lead us. There are no bacteria which produce results similar to an epithelial tumor. One of the boldest conceptions of the nature of cancer is that of Adamkevicz, who states that what we regard as epithelial cells are really parasites and that what has been regarded as round cell infiltration around the growth is the space of the parasite working its way into the tissues. The part that the glands take in the pathology is not determined. Some trace the source of cutaneous cancer to the sebaceous glands, some to the rete mucosum of the epidermis and some to the sweat glands. We find blood changes in carcinoma, but no observations have so far been made to determine whether these changes precede the development of the tumor or not. The cancerous cachexia is sometimes attributed to the presence in the blood of a toxin produced by the so-called sporozoa.—*Dr. Charles J. Foote in Yale Medical Journal*, June, 1896.

**A Study of the Blood in General Paralysis.**—Dr. Joseph A. Capps summarizes his researches as follows: In general paralysis, 1, the hemoglobin and red corpuscles are always diminished; 2, the specific gravity falls slightly below the normal; 3, most cases show a slight leucocytosis, amounting on an average to about 22 per cent. above the normal. Early cases may have no leucocytosis whatever. 4, in the differential count a decrease is found in the lymphocytes along with a marked increase in the large mononuclear cells. The eosinophiles in a few cases are very numerous. In convulsions and apoplectic attacks, 1, the red corpuscles and hemoglobin are usually increased at the time of a convulsion. During an apoplectic attack of long duration they are both somewhat diminished. 2, the specific gravity is variable, sometimes increasing, sometimes diminishing at the time of an attack; 3, there is a leucocytosis after convulsions and apoplectic attacks, which is as sudden as it is usually pro-

nounced. It certainly does not appear until within a very short time preceding the convulsion, probably not before it actually takes place; 4, the degree of leucocytosis and the period of its continuance, as a rule, vary directly with the length and severity of the attack; 5, in the production of the leucocytosis the large mononuclear cells are increased relatively more than any other variety; 6, the fact that after convulsions and apoplectic attacks in general paralysis there is not only an increase in the number of white cells but a change in their character, as shown by the differential count, and at times abnormal cells appear, is an argument against the theory that leucocytosis is merely a change in the distribution of the white corpuscles.—*The Am. Jour. of Medical Sciences*, June, 1896.

**Another Death from Antitoxin.**—Dr. W. J. Nolan of Chicago writes the following to the *New York Medical Journal*:

285 LOOMIS ST., CHICAGO, June 24, 1896.

To the Editor of the *New York Medical Journal*:

SIR: In view of the discussion now going on in the *Journal*, of which I have been three years a reader and subscriber, I frankly indorse the views of Dr. Winters in regard to antitoxin in diphtheria. Of one case I must write in terms of strong condemnation. The facts are as follows: I was called to see a boy, 8 years old, pulse rapid, temperature 105 degrees, and the laryngeal appearance quasi-diphtheritic. I began the ordinary treatment, in which quinin, carbolic acid and iron formed chief parts. The result next morning was very satisfactory; all alarming symptoms were decidedly not much in evidence. Some time in the evening of this better day, our antitoxin friends raided the house and began their injections *à l'outrance*. They did not inform me, I need scarcely say; but like birds of evil omen, they swooped down on a defenseless widow and daughters, and injected mightily, nay, as the sequel proved, mortally. Need I express an opinion after this on the discovery, or at least its manipulators?

W. J. NOLAN, M.D.

**Mastoid and Intracranial Complications of Middle Ear Suppuration.**—Otoscopy affords one of the most valuable means of diagnosis. If the deeper portion of the canal is narrowed by the sinking of the superior and posterior walls, mastoid inflammation almost certainly exists. Of almost equal value is the tenderness of the mastoid on deep pressure over the region of the antrum. In palpating the mastoid the pressure should be made so as to communicate no motion to the auricle. If the case is seen early an attempt may be made to abort the attack by means of cold applications, but they should not be continued longer than forty-eight hours. The gravity of the mastoid operation has been greatly overestimated. Under proper aseptic precautions it is absolutely free from danger, and in doubtful cases is justifiable as a means of diagnosis. All softened bone should be removed from the channel leading from the antrum to the tympanic vault in order to establish free drainage through the artificial opening. The signs of intracranial inflammation are obscure in the early stages. When the process is acute a purulent collection within the brain substance is characterized by considerable temperature elevation. Intracranial complications are almost invariably fatal unless relieved by surgical interference. Operations should be performed early.—*Dr. E. B. Deuch in Am. Jour. of Obstetrics and Diseases of Women and Children*, June, 1896.

**Diuiting the Blood in Infections.**—Very large doses of artificial serum have been found to be extremely beneficial in serious conditions, retarding death and rendering most important services, while perfectly harmless. If the kidneys are still working well, an injection of several liters will attenuate the infection and perhaps extinguish it altogether. Intravenous injections produce the most rapid results; several may be needed, and to secure the most complete results it is well to supplement them with small subcutaneous injections every two hours. Lejars recently performed a laparotomy upon a young man for ruptured intestine in the midst of acute peritonitis, keeping the strength up and attenuating the infection

by injecting 26 liters of serum, resulting in complete recovery. He reports also a case of acute osteomyelitis of the femur, with continuous fever at 104 degrees and abscesses, which received 14 liters in five days; the fever declined, the infection diminished and the patient is now recovering. A man of 52, run over by a train and severely injured; fever, delirium, double amputation, etc. Fourteen and one-half liters were injected in five days and patient made a fine recovery. A young woman operated upon for an immense ovarian cyst, with every symptom of rapid, fatal termination, received an injection of 3 liters of serum at one time, and 2 more liters two hours later. Improvement followed at once and patient is now almost recovered. Charrin protests against the use of the word serum to express the simple aqueous solution used for this purpose, saying that the physiologic serum differs from it so completely that it is unscientific to designate them by the same term. He calls attention to the different results attained by administering the solution in varying quantities and ways. He has found that even a few c.c. will retard the death of animals infected by a microbe or intoxicated by the secretions of bacteria; large amounts possibly produce their effect by modifying the osmosis in some way.—*La Semaine Médicale*, May 13.

**New Investigations of Cholera "Antitoxin."**—Pfeiffer and his adherents believe that the toxins of the comma bacillus reside in the bodies of the bacteria, and do not pass unchanged into the culture fluids, while Behring's pupil, Ransom, asserts that the choleraic toxin is present in solution in the dead bouillon cultures. The results of recent experiments at the Paris "Institut Pasteur," based on the principles of Behring's antitoxin, confirm this latter view. Large animals, especially goats and horses, were immunized with cholera filtrates until in three to six months their serum became distinctly antitoxic. One c.cm. administered with a fourfold fatal dose of the toxins was sufficient to neutralize its fatal effects, although not to prevent the appearance of symptoms of intoxication. Experiments with young rabbits inoculated with 4 to 8 c.cm., and then fed with cholera vibrios a few days after, resulted in the survival of 56 per cent. and the disease noticeably attenuated in the rest. Sixteen per cent. of the rabbits not treated with serum succumbed at once to the infection. Some experiments with serum presented by Pfeiffer resulted in the survival of 45 per cent. when the serum was injected simultaneously with the toxin per os, and 24 per cent. of the control animals resisted the infection. But if injected twenty-four hours after inoculation, or with the appearance of the first symptoms of the disease, the animal could not be saved at all. The results of the series of experiments are so far from satisfactory that no attempt is made in the report to apply the conclusions to cholera in human beings.—*Deutsche Med. Woch.*, June 11.

**Protracted Simple Continued Fevers.**—Dr. J. M. DaCosta says that: "It is a mere matter of surmise what, in any of the varieties of the prolonged simple continued fever, causes the fever. That it is due to a disturbance of the heat-centers seems certain. But what gives rise to this disturbance? Is it one cause or are there several? Leaving out the hysterical cases and those of nervous origin, it appears to me likely that the fever originates from causes within the body; that either as the result of fatigue or overwork, or from impure water, or some preceding digestive disturbance, leucomaines form from vitiated secretions, of a character to disturb the heat-centers. Whether in the continued fever of the tropics heat acts also in this way, or more directly, or through blood-changes produced, is a matter on which we can, with our present knowledge, only speculate. Both here and in all these prolonged continued fevers there is a great field for chemical research, especially in the leucomaines of the uric-acid group. The treatment of the prolonged simple continued fevers is purely symptomatic. Quinin has no effect on them, nor have the ordinary antipy-

retics more than a temporary influence. Phenacetin and salol do most good, particularly in cases with headache. They are best given in small doses, a grain or two, frequently repeated, until their effect is manifest. Better still, where it can be efficiently carried out, is the cold-bath treatment, not only to lower temperature, but for its revulsive and alterative influence. Purgatives, unless contraindicated by weakness, always form part of judicious treatment."—*The American Journal of the Medical Sciences*, June, 1896.

**Dentists can not Prescribe Whisky for "Toothache."**—On a Sunday of last year a resident of Hendersonville, N. C., had an aching tooth, and went to a dental surgeon, licensed by the State Dental Association, and asked him for a prescription for whisky. The doctor examined the tooth, and told the man that he would give him a prescription for half a pint; but, on the man's insistence, he finally gave him a pint. The sequel of this was the indictment and conviction of the person who filled the prescription for selling liquor on Sunday illegally. Appeal was taken to the supreme court of North Carolina. April 21, 1896, it rendered its decision of "No error." All turned on whether a dentist is a physician, or not, within the meaning of a statute prohibiting the sale of liquor on Sunday, unless prescribed by a "physician." The court quotes the definition of Webster's Dictionary: "A physician is one authorized to prescribe remedies for and treat diseases; a doctor of medicine." A dentist or dental surgeon, it says, is one who performs manual or mechanical operations to preserve teeth, to cleanse, extract, insert, or repair them. The statutes of North Carolina recognize that dentists are not included in the term "physician," by providing separate enactments for each.

If dentists came within the term "physician," as used in the statute above mentioned, the court goes on to say that "toothache" would become more alarmingly prevalent than "snake bite," and that it would with usage become more dangerous, it says, is evident from the fact that the very first dental surgeon's prescription for toothache, coming before the court, is for "one pint of whisky." The size of the tooth was not given, nor whether it was a molar, incisor, eye tooth, or wisdom tooth; and yet, the court takes judicial cognizance that there are thirty-two teeth in a full set, each of which might ache on Sunday. The duties of a dentist are limited, is the conclusion, to the "manual or mechanical operations" on the teeth. Whenever the use of liquor is necessary, it being a remedy to act on the body, and only indirectly in any case for the teeth, within the purview of the statute, it must be prescribed by a "physician," to authorize a sale on Sunday, under such a statute.

**Hack's Truss Improved by Wolfermann.**—The *Centralbl. f. Chirurgie*, for April 11, describes a truss for inguinal hernia which absolutely prevents the escape of the intestine in all positions, according to the inventor. The principle followed in its construction was to approximate as closely as possible the effect produced when the hernial sac is pushed into place and held with the fingers. The pad of porous rubber, extremely soft and elastic, is not fastened as usual, directly on the long spring that embraces the pelvis from the crest of the ilium to the trochanter. It has two plates at the back, exactly similar, one fastened to the pad as usual, while the other, on which the long spring is mounted, is only connected with it by a hinge at the outer end. A double coiled spring near the hinge tends to hold the two duplicate plates apart. Thus the only actual connection between the pad and the long spring is the hinge between the duplicate plates at the outer end. The spring between them therefore imparts an extra elasticity to the free pad, which enables it to adjust itself automatically to any position of the wearer, even the most unusual. The two plates are not exactly flat, but present a slightly convex surface

toward the abdomen. None of the trusses in use produce an even, gentle, incessant compression of the inguinal canal its *entire length*, such as is secured with this one which Wolfermann hopes will open a new scientific era in the treatment of hernia. He ridicules the old foggy way in which it is still treated, the only reason he says, why Hack's truss has not been universally adopted. He has secured many complete cures with this truss worn day and night, as it produces absolutely normal conditions for the intestine. It is only contraindicated in cases where there are adhesions or inflammation, which require more radical treatment. In cases of congenital hernia, he applies this truss even to infants a month old, if the testes can be forced into the scrotum by pressure on the inguinal canal, but there is no use in applying a truss if the testes are still in the inguinal canal. In cases of old ventral hernia when the abdomen can not contain the viscera, he orders a suspensorium buttoned to a sling around the neck.

**Sequel of the Langerhaas Case.**—After a long delay the official report of the postmortem examination in the case of the child of Professor Langerhans, who died suddenly after an injection of diphtheria antitoxin, has been published in the *Berliner Klinische Wochenschrift*. The Berlin correspondent of the *London Lancet* (June 20) says the examination was performed by Professor Strassmann and Dr. Mittenzweig, medical officers to the Berlin law courts. The report states that previous to the fatal injection the child had taken his dinner, followed shortly afterward by some milk and cake. Death took place during a severe fit of coughing, and the necropsy showed that the trachea and bronchi were entirely filled with a gray substance, which was proved, by microscopic examination, to consist of particles of food, a good deal of the same being still present in the stomach. The uvula was swollen. The medical experts, therefore, declare that the child died from suffocation. They are of opinion that the boy vomited after the injection and that, being in a fainting state from the pain of the injection, he was not able to get rid of the vomited matter, but drew it into his larynx in the act of inspiration. They did not find any embolus of air in the pulmonary artery, as was suggested, nor was there any confirmation of the opinion that death had occurred from syncope. They therefore advised the court not to hold anyone responsible for the child's death. According to the statement of the Control Office the serum was of normal quality and the injection was, in the official opinion, justified by the present state of medical knowledge.

**A Rare Form of Pseudo-Parasitic Infestation.**—The Paris letter of the *London Lancet* for May 9, narrates a curious incident growing out of an unusual form of acarus infection. A young girl, native of Barfleur, came on a visit to her parents from Cherbourg, where she was in service. During her stay at home she consulted a medical man with a view of ridding herself of a parasite which she had brought from Cherbourg, and which, having multiplied with prodigious rapidity, had infested the house of the patient's parents and also that of a relative. Sulphur was burnt in the house, and the linen and flooring was washed with sublimate solution. The plague, continuing with undiminished intensity, the neighbors ceased visiting the infested houses and sent the denizens thereof "to Coventry." The authorities then took the matter in hand and delegated M. Edmond Perrier, member of the Institute and Professor at the Museum of Natural History of Paris, to investigate this mysterious malady. He soon discovered that the *origo mali* was the glyciphagus domesticus, an acarus closely allied to the acarus scabiei, but, unlike the latter, provoking scarcely any itching or cutaneous lesions in its hosts. This acarus is, it appears, very commonly present in houses, and it is frequently met with in the interstices of hair combs which are badly kept. It multiplies especially in houses in which organic debris accumulate. In groceries an acarus, the glyciphagus prunorum,

which is perhaps identical with the glyciphagus domesticus, often flourishes on dried fruits, such as prunes and figs. Feeding exclusively on organic matter it is only a pseudo-parasite. Besides the glyciphagus domesticus there was discovered in these same contaminated houses at Barfleur a false scorpion, the othonius, which had invaded them in the train of the first named parasite. The othonius, otherwise called the *puce des bibliothèques*, is the declared enemy of the glyciphagus domesticus, upon which it feeds exclusively. Three millimeters long, and resembling a tailless scorpion, it is recognizable by its long fore-claws shaped like a lobster's. The patient had at Cherbourg been a servant in a pork-butcher's, and it was probably at the charcuterie that she became infected. Her scalp was so full of acari that when she shook her head a cloud of them fell on her shoulders. Her father, a respectable fisherman, had his eyebrows attacked, the only symptoms being a slight irritation. A garment left by the girl at an aunt's had sufficed to infect an exceptionally clean house. M. Perrier ordered the evacuation of the houses and sulphur to be burnt during six hours in the sealed-up rooms, with the result of killing every acarus, as also the othonius. An eau de cologne and sublimate lotion relieved the persons of the sufferers of the parasite, although the treatment had to be prolonged in the case of the girl. The case is interesting in that the acarus caught at a pork-butcher's, had lain dormant for some time on the hair-comb, and transferred thence to the scalp had thriven therein for a period of eighteen months and invaded consecutively the garments. From the garments the parasite had spread to two houses and their inhabitants, and the othonius had promptly followed in pursuit.

**No Appeal from Commitment of Private Patient.**—The supreme court of Michigan holds, in case of Sparrow v. Ingham Circuit Judge, decided May 12, 1896, that section 6,779 of Howell's Annotated Statutes of Michigan, which provides that "In all cases not otherwise provided for, any person aggrieved by any order, sentence, decree or denial of the judge of probate, may appeal therefrom to the circuit court for the same county," does not apply to an order declaring a person insane and committing such person to one of the State asylums as a private patient. The supreme court says, among other things, that he would be very obtuse who did not perceive that the chief object of the statute of 1895, under which the commitment is authorized, is to furnish in the early stages of the disease the best medical treatment available, in order to effect a cure and prevent, if possible, the terrible result of permanent insanity. If appeals are allowed in these cases, they may not reach a trial and determination in the circuit court for one or two years. A writ of error will then lie to the supreme court. If error is found, a new trial must be granted, and it may be years before a final determination can be reached. Meanwhile the sick person, unless dangerous to the lives and property of others, must remain without treatment, and permanent insanity may result, where prompt treatment by skilled physicians might cure the malady. It is not reasonable to suppose or infer that the legislature intended to provide for any such condition of affairs. The argument that, holding the inquest of the probate court final will result in confining sane persons to a living grave within the walls of an asylum, the supreme court declares has no merit, and the thing itself scarcely possible, under the humane provisions of the law of that State. Its theory is that neither the court nor the physicians have any object in adjudging a sane person insane, nor have the skilled and learned physicians in the asylums any object in keeping any sane person within their walls. Furthermore, the court calls attention to the fact that one of the humane provisions of the law under consideration is that it permits the person who has been adjudged insane to appeal to the probate court to determine whether he is healed, and that from that adjudication, if favorable, there is no appeal.

**Dr. Jenner's Poesy.**—A recently discovered file of Jenner's letters shows that that eminent man occasionally dipped into versification. One of these letters written *circa* 1789, to a lady to whom he had sent a couple of ducks, reads as follows:

"I've dispatched, my dear madam, this scrap of a letter  
To say, as Miss Kent is so very much better,  
A regular doctor no longer she lacks,  
So I've sent to attend her a couple of quacks."

The lady replied:

"Yes, 'twas politic, truly, my good friend,  
Thus, 'a couple of quacks' to your patient to send,  
Since there's nothing so likely as 'quacks,' it is plain,  
To make work for a regular doctor again."

**Right of Experts to Extra Pay.**—A decision of importance to all persons who are liable to be called upon to go on the witness stand as experts has been rendered by the supreme judicial court of Massachusetts in the case of *Barrus v. Phaneuf*, May 21, 1896. The principles which it discusses and lays down apply to medical experts, with full force, although this action was brought by a civil engineer. He had been engaged by the defendant to go into court at a future day and testify for him as an expert in regard to a matter which he had examined as such. This engagement was made about six weeks before the trial. He talked over the matter, and went into court and testified, and during the progress of the trial advised the defendant's attorney in regard to the questions to be asked of himself and of the other witnesses, though he was not asked any questions which called for his opinion as an expert. To further complicate matters, he was, at some time after the agreement was made, regularly summoned by the defendant as a witness, and was paid the statutory fees, and made no objection thereto, and made no claim for extra compensation. Was he entitled to recover any extra compensation as an expert? The defendant contended that he was not, and that if there was an express promise to pay him extra, it was without consideration, and that the witness did no more than he was legally required to do under his subpoena. That a court would be without power to require the attendance of a professional or skilled witness, upon a summons duly served, and with payment of the statutory fees, although he was unacquainted with the facts, and could testify only to opinions, the court declares it would be slow to admit; but such power would hardly be exercised unless, in the opinion of the court, it was necessary for the purposes of justice; and the one summoned would perform all that the court could require of him if he should hold himself in readiness to be called upon to testify to such opinions as he might have when his turn should come. In this case, however, the court holds that the evidence showed a sufficient consideration to support a promise to pay a reasonable compensation, in addition to the statutory fees, and that the jury was warranted in finding a promise to that effect, or a mutual understanding that the expert was to be so paid. If such promise was made, or such understanding existed, it further holds that the expert's right to recover would not be taken away or lost by his omission to claim or demand extra compensation, or to notify the defendant that he should make such claim, or by his acceptance of the statutory fee without objection, or by the omission of the defendant at the trial to put any question to him as an expert witness, and the consequent omission on his part to testify as an expert. What would have been his right without such promise or understanding, the court studiously avoids stating except as above, though at the same time shows the trend of authorities would be against allowing any extra compensation.

### Hospitals.

**ERIE COUNTY HOSPITAL, BUFFALO, N. Y.**—The following appointments have been made on the staff: Consulting genito-urinary surgeon, D. W. Harrington; attending physician, B. H. Daggett; consulting surgeons, M. Hartwig, H. C. Frost;

consulting physician, A. T. Bull; attending obstetrician, L. J. Hanley; attending gynecologist, H. D. Ingraham; attending physicians, George W. Lewis, C. S. Jewett; eye and ear, Arthur S. Bennett; children's physicians, Maud J. Frye, John D. Flagg.

**HOUSE OF MERCY HOSPITAL DEDICATED.**—The formal dedication of the new House of Mercy Hospital at Springfield Mass., took place June 23, in the chapel.

## THE PUBLIC SERVICES.

**Army Changes.** Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from June 27 to July 3, 1896.

Col. Charles T. Alexander, Asst. Surgeon-General, is granted leave of absence for two months, to take effect on or about July 3, 1896, or as soon thereafter as practicable.

Capt. William B. Davis, Asst. Surgeon, will in addition to his present duties, take charge of the medical supply depot in New York city, during the absence on leave of Col. Charles T. Alexander, Asst. Surgeon-General.

**Navy Changes.** Changes in the Medical Corps of the U. S. Navy for the week ending July 4, 1896.

Surgeon L. G. Heneberger, detached from the marine rendezvous, New York, and ordered to the hospital, Widow's Island.

P. A. Surgeon E. S. Bogert, ordered to the New York navy yard, July 2.

P. A. Surgeon T. C. Craig, detached from the New York navy yard, July 2, and ordered to the marine rendezvous, New York.

P. A. Surgeon W. F. Arnold, detached from special duty in China and Japan and ordered to return home.

Asst. Surgeon H. F. Parrish, ordered to the naval laboratory, New York City.

### Change of Address.

Cummings, W. M., from Las Animas to Trinidad, Colo.

Davis, Jr., N. S., from 326 Superior St. to 291 Huron St., Chicago, Ill.

Getzlaff, B., from Wapakoneta, Ohio, to Attapulgus, Ga.

Houston, I. M., from 428 Ellis St. to 707 Sutler St., San Francisco, Cal.

Harris, John J., from 1505 Tower Grove Ave. to 5252 Shaw Ave., St. Louis, Mo.

Lewellyn, P. W., from Clarinda, Iowa, to Ragosa Springs, Colo.

Patch, Wm., from Cooksville, to Sibley, Ill.

Rees, H., from Chicago, Ill. to Scandinavia, Wis.

Southern California Practitioner, from 107 N. Spring St. to Suite 243-246 Bradbury Bld'g, San Francisco, Cal.

## ORIGINAL ARTICLES.

### MALARIA.

BY ELLSWORTH D. WHITING, A.B.

(The L. P. C. Freer Prize Essay, Rush Medical College, 1896.)

AURORA, ILL.

Malaria, or paludism, is a non-contagious, infectious disease, characterized by typical paroxysms, the principal pathologic changes being in the blood, liver and spleen. Its etiologic factor is a specific protozoon, the plasmodium malarie of Laveran, which can generally be demonstrated in the red blood corpuscle.

Malaria may be considered a primitive disease, that is, one found in newly settled countries. It attacks the settler when he turns the soil for the first time, when there is no drainage and when the shallow wells fill from the surface. As soon as the swamps are drained and the wells freed from surface water the "chills and fever" disappear.

As to the geographic distribution of malaria, it is quite extensive, being found in tropical, subtropical and temperate zones. In the northern part of Africa malaria is endemic. It was there that Laveran made his first discoveries. In Europe, southern Russia and Italy are the common seats of the disease though it is found to some extent in England, France and Germany. On our own continent malaria is endemic in the South, Mexico, Texas, Arkansas, Louisiana and Missouri, and more common in the North than was formerly supposed. In the West Indies it exists in its most malignant forms.

As to the manner in which the parasite affects entrance into the human body medical opinions differ. Until a few years ago there was a consensus of opinion that malaria was an air-borne disease, the lungs being the only infection atrium. Those who upheld this theory based their opinions upon the fact that malaria was common among people living in low, marshy regions abounding in vegetable growth. These men claimed that the organism had its habitat in the soil, from whence, under favorable conditions, it was disseminated through the atmosphere and thus readily reached the air passages and circulation of the human organism. They claimed also that while moisture was not necessary to the development and spread of the disease it greatly aided it in its growth. They maintained for this reason that night air was much more heavily charged with malarial organisms than the air during the day.

Within the last few years other investigators have gone so far as to state that malaria is not an air-borne disease in any sense of the word. After extensive investigations these gentlemen have proven to their own satisfaction that this disease is purely of water-borne origin. To maintain their position they have brought to bear very strong evidence. They cite numerous instances where gangs of laborers working

in the same malarial districts were dissimilarly affected, those drinking from the surface water suffering from the disease, while those drinking boiled water, or that obtained from deep wells, were unaffected. These men all breathed the same air both night and day. This is a strong argument in favor of the water-borne theory. It may be argued that the vitality of those drinking the pure water was sufficient to resist the action of the organism, even had it gained entrance into the body through the air passages, while the vitality of those drinking the surface water was naturally lower. This objection would hold good were only one case cited, but it must necessarily fail when hundreds of similar cases are given. Another proof of the probability of the water-borne infection is demonstrated by the fact that here, in the midst of Chicago, in the heart of winter, when there is no building and excavating, malaria is present in almost every hospital in the city. The writer has demonstrated the presence of the organism in the blood of Cook County Hospital patients this winter who have not been away from the city in many years. The air-borne theory does not explain clearly these midwinter infections while the water-borne theory does. Many streams flow into Lake Michigan from the flats of Illinois and Indiana. These streams teem with malarial organisms. They empty their polluted waters into the lake and the currents flowing northward find their way into the cribs and thence to the dwellings of the citizens of Chicago. It is a noteworthy fact that not only is malaria found in the wards of Cook County Hospital but also among families living on the finest boulevards. Taking into consideration the array of testimony on either side, the writer is inclined to lean toward the water-borne theory, yet granting that in some cases infection by air seems highly probable.

Formerly many held that the organism gained entrance into the body through the stings of insects. This theory is upheld by but few to-day.

As a rule malaria is most prevalent in the spring and fall, yet the disease is present to some extent during all seasons of the year.

Under like conditions malaria is no respecter of persons as to sex. It is, however, more common among men than women, because of their manner of life, as they are more exposed to its etiologic factor. Children under one year of age rarely have the disease.

There can be but little doubt as regards the difference in degree of personal receptivity. All persons of lowered vitality are readily susceptible to the disease, nevertheless in men full of health there is great difference in the degree of immunity. This immunity may be natural or acquired. Persons going into a malaria district seem to acquire immunity after a lapse of years, while those born in the malarial atmosphere are often never affected by the disease.

The negro is much less affected than the white man, the ratio being as three is to one.

The history of the discovery of the plasmodium malarie and the various theories set forth by the different observers as to its character furnish interesting matter for study and investigation.

At first thought it would seem as though a recapitulation of the theories and observations of students interested in the malarial organism would be superfluous, but to understand fully the following pages such a résumé will be of great advantage.

Perhaps the greatest honor is due Laveran, after whom the parasite is named; however, extensive investigations and discoveries have since been made by Golgi, Marchiafava, Celli and others.

Although Lewis, in 1879, discovered hematozoa in the blood of warm-blooded animals, Laveran, a French military surgeon, in 1880, was the first man to demonstrate living organisms in the blood of individuals suffering from malarial fevers. At this time Laveran was stationed in Algeria, where malarial fever was prevalent. This afforded him excellent opportunity for studying the disease and the parasite. Laveran made his first discovery in November of this year. While examining the blood of a malarial patient he observed, floating in the plasma among the corpuscles, motile pigmented bodies provided with actively moving filaments or flagella. The next month, in the examination of forty-four cases of supposed malaria, in twenty-six the parasite was demonstrable. As a result of his studies he describes the parasite under three forms.

1. Crescentic or ovoid forms 8 or 9  $\mu$  in length and 2  $\mu$  in diameter. These bodies are colorless and transparent except for small clumps of pigment in the center or at the ends of the organism. The pigment granules assume the form of wreaths. The bodies are practically non-motile and in some instances pale, protoplasmic filaments appear to connect the extremities. Laveran believed that the crescentic forms originated in the ovoid or spherical flagellate forms, next to be described, and had the power of returning to the spherical shape.

2. Bodies which in repose are spherical and transparent, 5 to 7  $\mu$  in diameter and contain rings of rounded pigment granules of equal size. When these bodies are found in motion they are provided with from three to five long, thread-like processes which he calls "flagella." The organism appears to use these as a means of locomotion. In length they are two or three times that of the diameter of a red corpuscle, the ends of the filaments being enlarged. When the parasite is in motion the protoplasm seems to be greatly agitated, as is evidenced by the rapid rotating and dancing of the pigment granules within. He describes the flagella as being developed outside of the organism and detached when complete in their development. He observes particles of pigment to emanate from the organism through these flagella.

3. Laveran describes a third form which he supposes to be dead organisms (cadavers). These are of spherical form, from 8 to 10  $\mu$  in diameter, granular, non-motile, not provided with flagella and contain irregularly arranged pigment granules. At times he finds in these bodies granules which are fiery red or blue in color.

Later, in 1881, Laveran added a fourth form to his classification. He describes bodies transparent and spherical containing both motile and non-motile pig-

ment granules. These bodies are as a rule small, varying in size from one-sixth to the full size of a red corpuscle. In the smallest there is but one granule of practically non-motile pigment. In the larger bodies from eight to ten motile pigment granules are present.

In summing up his discovery, Laveran says: "There exists in the blood of patients suffering from malaria parasitic elements which have hitherto been confounded with melaniferous leucocytes. The presence of these parasites in the blood is probably the cause of the manifestations of paludism."

As to the nature of the organism Laveran concludes that forms 1 and 2 consist of an accumulation of cysts, formed in the corpuscles by extra corpuscular organisms represented by the flagella. These, developing at the expense of the red corpuscles and acquiring motility, separate themselves from the products of their activity and live independent lives.

In 1882 the discoveries of Laveran were corroborated to a great extent by Richards, who also studied the parasite in Algeria. Richards describes the earlier stages more accurately than Laveran. He notes a form in which there is no pigment and advances the theory that this form precedes the stages in which little pigment is found. He discovers that as the organism increases in size and the pigment in quantity, that the corpuscle expands and loses its color and finally the cell wall breaks. He agrees with Laveran in that the organism in its perfected state consists of the flagellate form and finally concludes that the parasite is extra corpuscular although he was at first inclined to consider it as endoglobular. He advocates the theory that the number of organisms increase until the beginning of the paroxysm. He says "they produce the fever, the fever kills the parasite, and falls in its turn, the process of reproduction going on between paroxysms."

At this time in Italy investigations of a different nature were being carried on by such noted biologists as Klebs, Tomassi, Crudeli, Marchiafava, Gaule and Celli. These men, looking at the origin of malaria from the bacteriologic standpoint, were convinced that they had demonstrated a micrococcus which, when present in the human organism, produced symptoms of malaria. They found small round bodies in the blood of malarial patients which stained with methylene blue. They found also ring-shaped bodies. These they claim to be of bacterial origin. They distinguished also the pigmented bodies of Laveran and Richards, but consider these granules as degenerated debris caused by the action of the bacterial organisms upon the red corpuscles. They explain the existence of filaments described by Laveran and Richards as resulting from the temperature and show by actual experiment that normal red corpuscles heated from 40 to 48 degrees C. show these filaments. They account for the crescents by claiming that they are caused by the discoloration of a portion of the periphery of the red corpuscle, the rest retaining its color. In 1885 Marchiafava and Celli withdrew this theory of the bacterial origin and agreed with Laveran and his parasitic theory. They carefully studied all the organisms noted by Laveran and Richards, and furthermore describe organisms containing abundant pigment, within which they are able to detect a differentiation into smaller bodies. In some of these cases the pigment is collected in the center, and evidence of segmentation is present in the surrounding protoplasm,

while in others the pigment seems to be arranged in the center and segmentation complete. The fact that they observed small hyaline forms greatly influenced them in their change of position. These smaller hyaline forms they describe as consisting of two zones, an outer or thicker more refractive zone, and an inner more granular and less refracting one. These organisms they describe as ameboid and provided with filaments issuing from the outer zone. They disagree with Laveran in the position of the organism. They hold that the organism is endoglobular, while Laveran still held to the belief that they were attached to the external surface of the corpuscle. Therefore to Marchiafava and Celli must be given the great credit of being the first to demonstrate segmentation and to bring forth the theory of the endoglobular existence of the parasite. Although they are unable to prove their belief, they state as highly probable that the process of segmentation is one of reproduction. Laveran also believed that the small forms which he discovered were of embryonal nature. These men ridicule the cystic theory of Laveran and the existence of separate crescentic types.

Subsequent to the discoveries of Laveran, Richards, Marchiafava and Celli, many investigations were made, confirmatory to the observations of these men. In 1885 Councilman and Abbott made extensive research. They demonstrate the presence of the organism in the capillaries of the brain, liver and spleen in two cases of comatose, pernicious malaria. These organisms are both pigmented and non-pigmented, and within and outside the red corpuscles.

Summarizing the investigations up to this date (1885) we must describe the malarial organism as consisting of a small, hyaline, ameboid, endoglobular parasite which on development shows fine, actively moving pigment granules. These bodies, eventually filling up the red corpuscle, decolorize, and finally destroy it. Having reached the adult stage the pigment becomes collected in the center of the organism while segmentation is observed in the surrounding protoplasm. The small hyaline bodies, according to Laveran, have the power of taking the form of crescents from which pigment and flagella develop. Laveran believes that the flagella are the organisms, that they are of extra corpuscular nature and the body containing the pigment the result of cystic degeneration. On the other hand Marchiafava and Celli hold that the pigmented body is the true organism, that it is endoglobular, and the flagella simply pseudopodia.

Up to this time there had been no disagreement as to the relation of the organisms to the clinical features. It was ceded by Laveran and his followers that the various forms observed were all of the same organism. Laveran says himself: "I do not believe that there exists a constant relation between the forms under which the hematozoa exist in the blood and the clinical manifestations of paludism. One can only say that certain forms of the parasite are more often seen in certain cases, the crescents, for example, in relapses and in malarial cachexia, as I have often demonstrated."

In 1885, when Golgi published an account of his discoveries, the theories which he set forth caused a division among students of malaria. Two factions sprang up. At the head of one was Laveran, while Golgi was the leader of the second. Laveran asserts, as has been said, that there exists no relation between the clinical manifestations of the various types of the

fever and the several forms of the parasite. Golgi, however, holds that there are probably many distinct types of the parasite and that there is a distinct and readily recognizable relation between the form of parasite and clinical manifestations.

Golgi's theories are based upon the study of the parasite found in quartan ague. Although Marchiafava and Celli note in a few cases that segmentation was seen during the paroxysm, Golgi was the first to demonstrate the fact that segmentation of a group of organisms could always be seen during a malarial paroxysm. He also proves conclusively that the severity of the attack is in direct proportion to the number of segmenting organisms. In the study of the parasite of quartan ague during the first day after the paroxysm a small, hyaline, non-pigmented body in the red corpuscle is observed. This body is motile but sluggish in its movement. On the second day the body is increased slightly in size and a few granules of pigment are present in the center. The granules of pigment are large in size, of a brownish red color, and move about slowly in the organism. This organism gradually grows until six hours before the next paroxysm, when signs of segmentation become apparent. At this stage the organism has practically filled but has not distended the corpuscle. Pigment granules are still few in number and their movement sluggish. Before segmentation the pigment collects into the center; soon radiating lines divide the organism into from eight to ten segments, forming the so-called marguerite forms of Golgi. Soon the organism is seen to divide and the hyaline forms to pass out into the plasma. At the same time hyaline forms are seen to appear in the red corpuscle. Although Golgi did not see these hyaline forms enter the red corpuscles, he was firmly convinced that they were one and the same. In cases of quotidian paroxysms he demonstrates the presence of a triple infection, that is, the presence of three distinct groups of parasites segmenting on different days. Thus, one group segments every day, causing daily paroxysms. In like manner he proves the cause of the tertian paroxysm(?)

These observations have been in most instances proven by many careful and conscientious students.

Antolisei agrees with Golgi in the main, but insists that the paroxysm is caused by the segmentation and the rupturing of the red corpuscle and not by the entrance of the hyaline bodies into the corpuscles as is held by Golgi. He proves his point by showing that quinin, even when administered in full doses shortly before a paroxysm, will not stop the paroxysm or segmentation, but will prevent the hyaline bodies from entering the corpuscles.

Golgi, after having extensively studied the parasite of quartan ague, demonstrates also the presence of an entirely different type of organism as productive of the symptoms of tertian malaria. He studied this organism carefully for three years (1886 to 1889) and concludes from the result of his researches that the embryonal form of the tertian parasite is similar to that of the quartan. This form, he says, "consists of a small, round, non-pigmented, transparent, motile body in the red corpuscle, which reaches its adult stage in forty-eight hours. At the end of this time an abundance of pigment is present and segmentation with accompanying paroxysm takes place with the appearance of hyaline bodies in the red corpuscles." Golgi moreover notes other differences between the

tertian and quartan parasite which may be tabulated as follows:

*Motion.* The tertian organism in both its hyaline and adult forms is more active than the quartan.

*Pigmentation.* 1. The number of granules in the tertian type is greater than that in the quartan. 2. These granules are much smaller in the tertian. 3. Their movement is more pronounced; and 4. Their color is lighter in shade.

*Size.* As the tertian organism grows it distends the corpuscle, which loses its color, while in case of the quartan parasite the corpuscle does not swell and is but slightly decolorized. In fact, the corpuscle containing this organism seems to shrink. The adult tertian parasite is much larger than the quartan.

*Segmentation.* 1. During segmentation the tertian organism is seen to divide into from fifteen to twenty segments, while the quartan divides into from eight to twelve. 2. The segments of the tertian parasite are smaller than the quartan. 3. During the segmentation of the quartan parasite Golgi demonstrates the presence of a central refractive area, but is unable to find such an area in the tertian. This refractive area appears to have a definite wall of differentiated protoplasm and contains the pigment granules during segmentation. As regards the destiny of this latter area Golgi is uncertain. He presents two theories; one to the effect that the body remains active and enters the red corpuscle and reproduces its like, the other theory being that it is consumed by phagocytes.

Beside the methods of segmentation common to the tertian and quartan forms Golgi demonstrates another form. In this the pigment is seen to collect in the periphery of the organism, leaving a clear center in which one or two spherical, sporelike bodies appear.

In order to disprove this form of segmentation Antolisei spent much study and experimentation. He finally decided that the process was one of degeneration and that the spherules discerned by Golgi were vacuoles. When the organism had completely destroyed the corpuscle Antolisei observed a spherical area in the center of the organism near its periphery. "Soon," he states, "a transparent, distinctly outlined sphere appears in the area, and about this sphere vacuoles appear which constantly multiply in number and seem to decrease in size. Surrounding these vacuoles is motionless pigment, while the pigment removed from the central area seem to increase in motion. Sometimes the enclosing membrane bursts and a hernia of the contents of the organism results. In this cut-off or fragmented portion the same process of vacuolization continues. This process goes on until finally the organism is completely filled with minute spherules, separated by motionless pigment granules and enclosed within a membrane which is probably the cell wall. Finally this wall bursts and throws the contents of the parasite into the plasma." Antolisei concludes that vacuolation, fragmentation and flagellation are all forms of degeneration. He bases his theory upon the fact that he finds all these changes in organisms of the same size. He also claims that true segmentation rarely takes place in the circulating blood, but generally occurs in the internal organs. He bases this belief upon the fact that segmenting organisms found in the circulating blood are seldom larger than the red blood corpuscles, while the true segmenting forms found in the internal organs are much larger. He believes that the larger forms found in the circulating blood are dead organisms undergoing vacuolation or segmentation.

The comparative examination of blood taken from the spleen and peripheral circulation has been carried further by Bastianelli and Bignami. They determined that during apyrexia the number of organisms in the spleen and peripheral circulation was the same, but that during, and just before the paroxysm, many more organisms were found in the spleen than in the periphery. They explain this fact upon physiologic grounds, stating that when the corpuscles are intact there is naturally no tendency for them to collect in the spleen, but when they are the subject of pathologic change these disabled cells immediately seek the spleen for removal.

These men set forth the theory that in quartan ague the distribution of the organism is more uniform than in the tertian type. They explain this by stating that in this type there is less disturbance in the continuity of the corpuscle while it is being destroyed. They also discovered bodies provided with a small amount of pigment, surrounded by from five to ten round sporelike bodies. These they term organisms of a shorter cycle, since they found them in irregular and anticipating quotidian fevers. They agree with Antolisei as to the probable nature of vacuolization, flagellation and fragmentation, and furthermore suggest that the severity of the fever is in inverse ratio to the number of these organisms present.

Councilman, in 1887, first associated with irregular and continuous fevers another organism clearly distinct from the quartan and tertian types. He discovered a crescentic and elongated body which he found to be constant in remittent fevers. Thus he declared that he was always able to distinguish an intermittent and remittent type by the blood examination. In 1889 the discoveries of Councilman were corroborated by Marchiafava and Celli and Pietro Canalis.

The description of this type given by Canalis divides it into two classes: 1, the rapid cycle and 2, the slow or crescentic cycle. He terms this latter type the semi-lunar type.

Canalis determined that the first class generally matures in less than forty-eight hours, though he points out one case in which there is a complete cycle of only twenty-four hours. Two or three hours after the first attack Canalis notes small, spherical, ameboid organisms in the red corpuscles. About the periphery is a clear rim of ectoplasm surrounding a more shaded endoplasm which resembles a nucleus. This endoplasm at times is fragmented, resembling several nuclei. As the organism grows it becomes more active, when there appears in the periphery fine dark red or black pigment granules. As the organism reaches the adult stage the pigment gathers in the center in the form of a densely packed clump, and segmentation occurs as observed by Golgi in quartan ague. This form differs from the other forms in that it decolorizes the corpuscle even less than the quartan, contains rarely more than six granules of pigment and divides into only five or six segments.

The second or slow cycle of Canalis takes from three to five days to complete its development. It is rarely found in combination with the first, and when this does happen it is after the latter has been unsuccessfully treated. Canalis says that this form begins very much as does the first, but soon the organism assumes an elliptical form and pigment collects in the center. This gradually takes on a crescentic form, decolorizes the corpuscle and at times shows presence of double contour, thus giving evidence of a surrounding mem-

brane. These crescentic forms are seen to assume ovoid or crescentic forms, though the organism in some instances passes directly from the hyaline form into the adult spherical form without passing through the intermediate crescentic stage. Canalis states that he has noted the segmentation of crescents. In this he is upheld by Antolisei and Angelini. The pigment of these forms is non-motile, arranged concentrically in a closely packed clump, crown or wreath. He describes sporulation as taking place in the spherical stage. During sporulation the ectoplasm breaks up into from eight to ten spherules. These spherules are small and resemble the hyaline forms of the first cycle. On rupture of the organism its contents are thrown into the blood stream, the pigment granules being scattered through the plasma separately or in a clump surrounded by a membrane. Canalis notes that paroxysms occur during this process and accordingly calls it true sporulation.

Canalis differentiates between the process of sporulation and degeneration in the following points:

1. In the degenerating organism, there is no color, the ashy yellow tinge being replaced by a colorless highly refractive body.

2. The degenerate organism shows spherules, varying in size which may on close and continued observation be seen to coalesce. Thus all the spherules in an organism may unite into one. In sporulation the spores are equal in size.

3. The sporulating organism has a clearly defined double contour while the spherules of degeneration never do.

4. Degenerating forms are found in apyrexia and their appearance does not precede the presence of hyaline forms in the red corpuscles as in the case of sporulation.

Canalis demonstrates the presence of flagellate bodies in many cases of the second cycle. In every instance he finds them in the spherical, adult form of the parasite shortly before the paroxysm. From this fact he comes to the conclusion that flagellation is one of the last stages in the development of the organism.

Experiments of Marchiafava and Celli corroborate in a great measure those made by Canalis. They account for the prolonged and irregular paroxysms, not from the fact that there may be a large group of organisms which on segmenting cause this condition, but from the irregularity in the length of the cycles of different organisms. Thus, at certain times groups of organisms may segment one after the other. This, they contend, accounts for the continuous fever, the chill being covered up by the preceding pyretic stage. They conclude that the crescent is associated with pernicious forms. They cite grave cases where the crescents could not be demonstrated and also cases where the organism is present but no temperature exists. The latter phenomenon they do not attempt to explain.

These gentlemen, Marchiafava and Celli, describe the organism practically as does Canalis, noting the fact that pigment is small in quantity and appears very suddenly before the paroxysm. They state that in some instances they have seen organisms pursue the whole course of their existence without the development of any pigment. In this they are upheld by Antolisei and Angelini. They note also that the coloring matter of the corpuscle seems to collect about the periphery of the organism, being itself early

decolorized at its own periphery. This coloring matter they describe as taking on a peculiar brassy hue. They claim to have found many instances where the corpuscle was greatly crenated even when the organism was still in its hyaline form. In a few cases they were able to demonstrate segmentation in the circulating blood, but always found it in the internal organs and in severe cases in the capillaries of the brain. These investigators recognize the crescents but are not able to corroborate the observations of others as to its segmentation. They believe that the degenerative changes are present.

As a result of these investigations Marchiafava and Celli in common with Canalis claim the existence of a new type of material organism, characterized by an irregular length of cycle, hyaline, crescentic and spherical stages associated with a continued pernicious and irregular course occurring chiefly in the summer and fall and unamenable to treatment. On account of the time of appearance of this type they have termed it the "estivo-autumnal type."

Marchiafava and Bignami later made interesting observations in regard to the estivo-autumnal type. They note as does Canalis two types of parasites which they term "quotidian" and "tertian or malignant." They describe the "quotidian" as consisting primarily of a small, ring-like hyaline body seen in the red corpuscle. The organism completing its cycle in twenty-four hours and undergoing segmentation with the development of little or no pigment, closely resembles the first cycle of Canalis.

The second form of Marchiafava and Bignami, in the commencement of its cycle, appears much the same as the quotidian but takes about forty-eight hours for development, always exhibiting pigment and at times associated with crescents.

In both types few organisms are found in the circulating blood but are abundant in the internal organs. Also in both types the corpuscle is shrunken and of a brassy hue and segmentation takes place while the corpuscle is yet intact. The tertian organism is much larger than the quotidian; segmentation is observed earlier and there is greater activity in the former than in the latter.

These forms differ from the ordinary spring quotidian and tertian forms, in that they are much smaller; present ring-shape hyaline forms; contain much less pigment which is practically inactive; divide into fewer segments; shrink instead of distend the corpuscle—which turns to a brassy hue; and show the presence of crescents, which are never seen in the ordinary tertian forms.

As to the peculiar paroxysms caused by these organisms the theories of Marchiafava and Bignami are, to say the least, unique. They account for those types of estivo-autumnal fever in which the paroxysms are quotidian in character as caused by the first described organism. The fact of irregularity is explained by a tendency toward retardation and anticipation of the organism in segmenting. Thus they explain the almost continuous fever and the fever which borders upon the tertian form. In like manner they explain the irregularity of the tertian form associated with which are more severe constitutional symptoms and the presence of crescent.

The observations of Golgi in Rome in regard to the estivo-autumnal fevers go to disprove the observations of Marchiafava and Bignami. Golgi asserts that the pathologic process is not understood and that

the classification of Marchiafava and Bignami is entirely hypothetical. He finally concludes that the presence of the organism in the blood is more accidental than a direct cause of the disease. He states as highly probable that the observed organisms are the beginnings of cycles, the length of which is at present little understood. Golgi notes three stages of development: The first, an ameboid non-pigmented hyaline body seen in circulating blood. The second stage consists of small or large pigmented pre-segmenting bodies found in the internal organs. The third stage consists of segmenting bodies. He describes three forms of segmentation. The first is similar to that seen in quartan and the ordinary forms, differing in that there may be as many as fifty segments. In the second form the segments do not number more than eight or ten. In the third form the organism varies from one-third the size of a red corpuscle to even larger than the corpuscle. Segmentation in this latter instance takes place in the form of an irregular mulberry mass which surrounds the centrally located pigment. Golgi is of the opinion that these organisms are often found in phagocytes, in which they grow, segment and reproduce.

In summing up his observations regarding malarial fevers, Golgi gives to the world the following classification:

1. Fevers the cause of which lies in the existence in the blood of parasites whose habitat is principally in the circulating blood: *a*, the tertian parasite; *b*, the quartan parasite.

2. Fevers the cause of which lies in the existence in the blood of parasites whose habitat is principally in the bone-marrow and spleen. The parasite in this group he confesses his inability to classify completely and refers to the crescents as "forms the biology of which has not yet been well determined."

As a result of the investigations of other men we have many and various classifications of the organism. An ingenious classification is proposed by Grassi and Felletti, who give five separate types:

1. *Hæmamœba præcox*, a quotidian type with tendency toward anticipation.

2. *Hæmamœba immacula*, a similar organism, but more rapid and generally non-pigmented.

3. *Hæmamœba vivax*, the organism giving rise to tertian fever.

4. *Hæmamœba*, the organism of quartan fever.

5. *Laverania malariae*, giving rise to irregular fevers.

These observers are confident that their classification is the same as the quotidian type of the æstivo-autumnal classification of Marchiafava, and agree with Canalis, Golgi, Antolisei and Angelini that segmentation may occur in the crescentic forms.

Sacharoff describes a parasite found in irregular forms which corresponds to the æstivo-autumnal parasite of Marchiafava, except that it is more frequently found in the circulating blood. He gives the following classification:

1. *Hæmamœba præcox* (Gra.).

2. *Laverania* (Gra.).

3. *Hæmamœba febris tertianæ* (Gol.).

4. *Hæmamœba febris quartanæ* (Gol.).

Later Mannaberg after extensive study of the parasite, gives the following classification which he claims to have vindicated.

1. Malarial parasites with sporulation without syzygia: *a*, quartan parasite; *b*, tertian parasite.

2. Malarial parasites with sporulation and syzygia:

*a*, pigmented quotidian parasite; *b*, non-pigmented quotidian parasite; *c*, malignant tertian parasite.

The last and perhaps the most complete study of the organism of malaria has been made by men of our own country, Thayer and Hewetson of Johns Hopkins University, Baltimore. Their investigations divide the organism into three classes:

1. Tertian.

2. Quartan.

3. Estivo-autumnal.

With the exception of one investigator no one has been able as yet to cultivate the plasmodium malariae upon medium used in the culture of bacteria. This one, Coronado, claims that he has cultivated the parasite in water taken from a source whence many persons had contracted the disease. He claims, moreover, to thus have traced the entire development of the organism. He claims also to have seen the development of the flagella from the pigmented forms which becoming free broke into from ten to fifteen parts, which began anew the cycle of the organism's existence. These experiments, however, we can not accept as facts, as many other competent and distinguished men have been unable to obtain like results.

Positive results, however, have been obtained in attempts to preserve the activity of the organism outside of the body. Sacharoff succeeded in preserving the estivo-autumnal organism for seven days by means of the use of ice. The parasite at this time retained its ameboid movements and staining qualities. In the case of the tertian parasite, at the end of forty-eight hours all the adult forms had disappeared, only the hyaline bodies remaining.

Inoculation experiments have been successfully made. Gerhardt was the first to show that malarial fever could be produced by inoculation. In two cases he produced quotidian paroxysms by infusing blood from a patient suffering from this form of the disease. The stages of incubation were respectively six and sixteen days. Later Marchiafava and Celli, and Manotti and Ciarrochi made successful inoculations. In each case they found in the blood of the inoculated persons the same form of the organism as was present in the blood of the patient from whom the inoculation organisms were taken. The time of incubation was from eight to fourteen days.

Gualdi and Antolisei made inoculations from the blood of patients suffering with quartan fever, and obtained the estivo-autumnal form. From this they claim to have proved their theory that different types of the organism are not associated with different clinical manifestations. However, it was later proven that the patient from whom the blood had been taken had but shortly before the inoculation suffered from estivo-autumnal fever. The existence of the estivo-autumnal type in the inoculated person is explained by the theory that the latest estivo-autumnal organisms reaching at this time their development, overpowered the quartan parasites.

This experiment leads to interesting observations made by Di Mattei, who injected the blood of a patient suffering with quartan fever into one suffering from estivo-autumnal fever. In sixteen days there was no evidence of the existence of the estivo-autumnal parasite, none but quartan being present. He also inoculated a patient suffering with quartan fever with the estivo-autumnal organism. In ten days the quartan had disappeared, being replaced by the organism of the estivo-autumnal type.

Calandrucio, who had never suffered from malaria, successfully inoculated himself with the tertian organism. In the case of other patients he obtained positive results from inoculations of estivo-autumnal organisms.

Bein in his experiments found that he often obtained by inoculation from a quartan fever one of the tertian type, and also from the tertian the quotidian type.

From the above experiments we may draw the following conclusions:

1. The plasmodium malarie can be transmitted by inoculation.
2. The same type of organism is always obtained.
3. The average length of the period of incubation is from eleven to twelve days.
4. When more than one type of organism is present at the same time, the symptoms are produced by one variety alone, the growth of this type being associated with the disappearance of the other.

In the preceding digest of the works of the most prominent men engaged in the study of the parasite of malaria, the writer has endeavored to give some idea of the theories which have thus far been given to the scientific and medical world. At times these theories are in harmony, but perhaps oftener are opposed to one another.

It will be the object of the writer to separate from this chaos those theories which he has been able to establish through his own personal research. He will also aim, as far as possible, to set forth those theories which he has been unable to attempt to corroborate, but which have been accepted by the most competent investigators of to-day.

*(To be continued.)*

## HOW MUCH PHARMACY SHOULD BE TAUGHT IN MEDICAL COLLEGES?

Read in the Section on Materia Medica, Pharmacy and Therapeutics, at the Forty-Seventh Annual Meeting of the American Medical Association at Atlanta, Georgia, May 5-8, 1896.

BY G. WALTER BARR, M.D.

Professor of Materia Medica, Therapeutics, etc., in the College of Physicians and Surgeons, Keokuk, Iowa; Physician to Mercy Hospital; Member Illinois State Pharmaceutical Association, etc.

QUINCY, ILL.

Notwithstanding modern tendencies, the main question is not how long the college course, but what and how well it is taught. The real value a student gets out of his college life depends upon the curriculum and the thoroughness with which things are learned, not upon how much of one thing he learns. The balancing of the curriculum is the most neglected as well as the most important consideration occupying the attention of faculties. Too often that professor who is most energetic in his college work has the most of the students' time, and the laziest professor is seen least at the college. Some colleges in America turn out pathologists, some surgeons, others chemists, and a few dermatologists, the graduates in each case being weak in other equally important departments of medical knowledge.

Again, each chair should lay out its work according to a definite plan in which each part receives exactly the proper emphasis, so as to teach the most valuable things pertaining to that department in the time allotted it; the surgeon should not teach the pathology of tumors completely and say little about fractures and dislocations; nor should the chair of materia medica teach botany to twice the extent of physio-

logic action. That these truisms, so axiomatic when formulated, really need to be called to the attention of many teachers is proven by the work actually being done in colleges which are rightly considered first class institutions of medical learning. While they deserve extended consideration, they are stated here simply to logically lead up to the question which touches the interests of every medical man and is the title of this paper.

Whether the course be two or twelve years long, the chair of materia medica and therapeutics can not cover the whole field of accepted knowledge in its department of science, because the bacteriologists, the dyeworks, the African savages and the psychologists are all combined to furnish grist for the mill far beyond its capacity to utilize. The teacher must first separate the wheat from the overwhelming mass of chaff, and then again choose those grains which will afford the most valuable pabulum to his students. The need of these students is something to enable them to practice medicine scientifically, safely and esthetically. Pharmacy is an ingredient of each and all of these requisites.

Scientific medicine requires training in and the practice of great accuracy. Pharmacy conduces to this by its very character. The number of prescriptions written so as to be chemically or pharmaceutically incompatible should be no greater than the number containing mistakes in therapy or indicating errors in diagnosis. It is just as discordant to the cultured ear to hear a reference to green iodid of mercury, to have the fluid extract and the extract of *nux vomica* spoken of as two entirely different drugs as regards their dynamism, or to be informed about the tincture of pilocarpin, as it is repugnant to the educated mind to read of Bright's disease, surgery without anesthetics, or the humor pathology of boils. In both cases it is not merely the nomenclature which excites our derision, but the lack of real knowledge back of the terms used, as evidenced by the language itself. The physician who makes a diagnosis of Bright's disease and bases his therapeutics thereon is not giving the patient the advantage of the common scientific knowledge of the day; and neither is the physician who prescribes fluid extract of pilocarpus when pilocarpin is needed. It is not true that all of the galenical preparations of a given drug always have the same dynamic action; to know when differences arise in the action of different official preparations requires a knowledge of pharmacy, and not to know is to be unscientific in one's therapeutics. A widely diffused knowledge of pharmacy within our profession would at once cause the death from financial starvation of most of the proprietary medicines which now have almost as large a sale to physicians as their predecessors in the patent medicine field had to the laity thirty years ago. That this is equivalent to an immense increase in scientific therapeutics goes without saying.

The element of safety in prescribing and dispensing touches pharmacy at several points. Incompatibility with dangerous results is perhaps the least important. The difference between the intentions of the physician and the actual administration of the medicine at once suggests itself. The basic function of the Pharmacopeia and the National Formulary is to attain uniformity of definition of drugs and their combinations, so that the patient shall receive from the pharmacist exactly what the physician had in mind when

the prescription was written. Very much of the dissatisfaction with the work of the pharmacist comes from the physician writing for one thing and the pharmacist putting up what the scientific world has agreed should be so denominated, while the physician had in mind quite another thing as the definition of the noun he used. In the cases—which the writer believes to be comparatively rare—where there is actual dishonesty upon the part of the pharmacist, a comparatively slight knowledge of pharmacy would detect the fraud and conduce to the safety of the patient.

The question of esthetics in the administration of medicines has practically been decided by compulsion from the patients. We were forced to meet the homeopaths on their own ground some time ago in this respect. But there is a higher motive in palatable prescribing than to please the patient. Palatable prescriptions are taken more regularly, the exact dosage is maintained better, and the psychic effect is not to be ignored. None of these advantages can be attained without a knowledge of pharmacy unless we fly into the arms of the patent medicine purveyors to the profession.

What has been said about prescribers applies with even greater force to those physicians who dispense their own prescriptions. The pharmacist notes the error in the written prescription and telephones the doctor, who insists that there is no error and orders the prescription changed. The dispensing physician has not the advantage of this proofreader. The physician who writes prescriptions ignorantly receives the punishment himself in the contempt of the pharmacist who fills them; the dispenser, ignorant of the pharmacal art he is practicing, causes the innocent patient to suffer the effect of his pharmaceutical mistakes.

Admitting the value of pharmacal knowledge to the practicing physician, the question of how much he is to be taught must have due regard to the time that can be allotted to the subject in the college which teaches him. The teaching of pharmacology should come at the beginning of the course in materia medica. The experience of the writer, harmonized with his opinions above set forth, is that the subject should be given a full year. This means that the freshman year should be devoted in this department to pharmacology; the time may be shortened enough to admit teaching the methods and times of administering medicines in the same year. The second and third years may be then devoted to dynamic action and therapeutics; three years of a four-year course is all that the chair should be allotted in the curriculum.

Not much pharmacy, comparatively speaking, can be taught in the hours allotted to one chair for one year; but it is approximately enough for the physician; it should be apparent that the latter does not need so much as the professional pharmacist. The next consideration is, what part of pharmaceutical knowledge is most important to the physician and should be taught him. The opinion of the writer is expressed in the following syllabus:

Definition of various general terms; definition and description (with history) of the United States Pharmacopeia and National Formulary; valuable unoffical drugs, and why not admitted; the relation of proprietary preparations to scientific medicine; when they may be rationally used; nomenclature; the classification of the pharmacopeia, including definition, modes

of preparation, and peculiarities of each class of preparations, beginning with crude drugs, every detail being actually performed by the student in the laboratory assumed to be attached to the chair under a competent demonstrator; posology; prescriptions, the construction of; chemic and pharmaceutic incompatibility; esthetic prescribing (all illustrated by the student's own work in the laboratory).

This schedule does not trespass upon the domain of the chair of chemistry, and in actual application has given excellent results. Students who return as experienced practitioners express a high opinion of its value to the physician, and not one complains that the time could have been devoted better to other things. The one drawback to it has been the absence of adequate textbooks, the latter being either too elementary or else too complete in their pharmacology. It is a disadvantage to render necessary even one more textbook for the modern student. The works on materia medica and therapeutics, except Potter's textbook, slight the subject under consideration as a rule. There has lately been issued a textbook upon pharmacy which is really more than its title implies.<sup>1</sup> It is really such a comprehensive treatise upon medicinal chemistry, that many professors of chemistry will be very willing to adopt it as a text for that department, while it leaves little to be desired as a textbook correlative to the work under the chair of materia medica outlined above; its double use in this way will obviate the most serious defect in the writer's plan with which he has had to contend.

The response to the expected inquiry as to why this paper was not presented to the American Medical College Association instead of to this section may as well be made in advance. It might as well be admitted that the curricula of colleges is largely dependent upon what the general profession demands. Hygiene and sanitation will not be given much attention in colleges, in spite of State boards and legislation, until the profession is more generally awakened to the importance of this subject; bacteriology is as a rule sufficiently taught because the profession realizes its importance in the modern practice of medicine; whatever the profession thinks is the proper amount of pharmacology needed by the practitioner, that much will be taught in the generality of colleges. The question, which is the title of this paper, is therefore brought directly to the power which will make the final decision in the matter.

### THE TEACHING OF MATERIA MEDICA AND THERAPEUTICS IN RUSH MEDICAL COLLEGE.

Read in the Section on Materia Medica, Pharmacy and Therapeutics,  
at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY DANIEL R. BROWER, M.D.

PROFESSOR MENTAL DISEASES, MATERIA MEDICA AND THERAPEUTICS,  
RUSH MEDICAL COLLEGE,  
CHICAGO.

The teaching of materia medica and therapeutics in Rush Medical College is done in a lecture room, recitation rooms and the laboratory of materia medica. I have associated with me in the work eight assistants; one is the director of the laboratory, one gives the didactic lectures in materia medica and the others, as instructors, hear the recitations and assist in the laboratory work.

<sup>1</sup> A Treatise on Pharmacy by Charles Caspari, Jr., Ph.G., Philadelphia, 1895.

The materia medica is taught in the second year of the college course (a four years' course), because it is necessary, in my judgment, that the student should have a freshman's knowledge of chemistry and physiology to enable him to do good work in this branch. As an introduction to the course one hour a week in the last half of the freshman year is devoted to a lecture on medical pharmacy, by I. A. Patton, M.D., the director of the laboratory.

The subject of materia medica is divided into twenty-eight topics, and one week given to each. The subject is introduced by two didactic lectures, one hour each, given by S. L. Weber, M.D. This is followed by two hours of laboratory work and this by one hour of recitation. Five hours a week are therefore given to each topic. The whole class attends the lectures in one of the lecture rooms.

The class is divided into sections of from forty to fifty students for the laboratory and recitation work. The instructor who conducts the recitation of the section, is the assistant to the demonstrator for that section in the laboratory work.

In the laboratory work each student is furnished with a manifold copy of his day's work. He has already had two hours of didactic teaching on the subject matter. He now examines the physical properties of the drugs, makes such tests as are desirable to determine purity and show incompatibilities; either makes a pharmaceutical preparation or compounds a prescription, and at each exercise either writes a prescription in both English and metric systems or criticises a prescription written by the demonstrator.

There are three examinations in course during the term on the didactic, recitation and laboratory work, and one week is given to each. The student's final average is made up from his general recitation and laboratory work, and these three examinations. The course in materia medica, therefore, consists of 140 hours' work in the college.

**Materia Medica Laboratory.**—During the course each student has examined over three hundred crude and finished drugs regarding their physical, chemie, pharmaceutical and medicinal properties. Twelve pharmaceutical preparations have been made during the course illustrating liquors, tinctures, wines, syrups, compound syrups, infusions, liniments, pills, ointments, etc. Thirty compound prescriptions have been written, corrected and returned. Twenty prescriptions have been compounded, illustrating most all kinds of prescription work. Three hundred or more tests of incompatibility have been made; calculation of dosage for prescriptions, of percentage solutions by weight and volume; comparison of apothecary and metric systems, etc. Desk room for sixty students to work at one time and cabinet space for 120 complete sets of apparatus is provided in the laboratory.

Therapeutics is taught by didactic lectures and laboratory work. The didactic course consists of sixty hours of work. The materia medica, as far as practicable, is grouped around the great functions of the body and their diseases. The course begins with those substances acting on the digestion, nutrition (tissue waste and repair), calorification; then are considered those acting on the nervous system, organs of circulation, sexual organs, alimentary canal, those acting on the various secretions. The therapeutics of the principal disease of each of the organs and functions is made the central feature of each lecture.

The laboratory course consists of twenty-two hours instruction, the first half of which is devoted to electro-therapeutic appliances, as follows: General physics of electricity and theories of battery construction; electrolysis, cataphoresis; physiologic action in general; catalysis, electro-diagnosis, cautery, electric light, faradic batteries and currents, static and alternating machines. These exercises are illustrated by the use of batteries, electric machines, etc. The students construct the batteries, if possible. The remainder of the course is given to massage, lavage, enemata, colonic flushing, preparing articles of diet for the sick, to pneumotherapy, blistering, cupping, leeching, wet packing and hypodermic medication. Throughout the course use is made of dispensary and hospital patients for the purpose of illustrating all possible points.

The class is divided into sections of twenty; to each is assigned an instructor and the demonstrator directs the whole. A special instructor, Miss Mabel Hayes, who is the teacher of cooking in the Illinois Training School for Nurses, gives the lessons in preparations of foods for the sick.

I am very sure that since the introduction of these two laboratory courses, our students go out better prepared in materia medica and more familiar with therapeutics than ever before. These laboratory courses are still in a developmental state, and I presume each year will witness a lengthening of the time given to this work, and a possible lessening of the time given to didactic teaching.

## TUBERCLE ANTITOXIN OR ANTI-TUBERCULIN.

Read in the Section on Materia Medica, Pharmacy and Therapeutics at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY PAUL PAQUIN, M.D.

ST. LOUIS, MO.

It is probably to Richet and Hericourt<sup>1</sup> that the principle of sero-therapy is due, because they were first in formulating it fairly in their researches on the micrococcus pyosepticus. All other investigations, due chiefly to the initiative of Behring, have confirmed the almost prophetic possibilities of the claims of these two investigators, particularly on the general activity of serum as a living microbicide power.

But it is not on its general antiseptic property that the therapeutic value of serum rests, for it is inconstant. It rests on a physiologic problem, long combated, viz.: phagocytosis, so clearly elucidated by Metchnikoff. The microbicide power of serum is unquestionable. It opposes the development of certain microorganisms, but it does not exercise the preponderant influence of serum in its specific application in disease. The prevention or cure of a microbic disease rests on acquired immunity, and, immunity even natural, is not conferred by the germicide property of the blood. As evidence of this fact, we have the dog, whose blood serum is not bactericide in presence of the bacillus of anthrax, and yet this animal is comparatively immune to this affection. On the other hand, the serum of the rabbit is bactericide in presence of this germ, and yet this animal is exceedingly susceptible to anthrax. A seemingly conclusive argument that the bactericide virtue of serum is not the basis of immunity, or of the special therapeutic properties it

<sup>1</sup> I acknowledge many thoughts to D'Achalme, Hericourt and others in preparing this article.

may possess, is the evidence that heat at 55 to 60 degrees C. destroys this power, without modifying the physical, chemic or therapeutic constitution of serum.

The efforts of Hankin, Büchner, Ogata, Josuhara to isolate the bactericide substance, or substances, from serum were negative, and to-day there are thinkers who associate it with the globulicide property, which is probably an inconstant but a more or less potent factor when it does exist.

The therapeutic property of serum has been designated by the name, antitoxic, which is, in my mind, an unfortunate selection, because it implies, or at least suggests to the mind of the practitioner, that serotherapy depends on the chemic neutralization or destruction of the microbial toxins. The general practitioner is usually a busy man and has but little time and few opportunities to investigate, minutely, the intricate understructure upon which organic therapy is being raised. He almost necessarily arrives at conclusions on the significance of the words and language of the reports of scientists and bases his application of the remedies thereon. As a consequence, numerous practitioners think that the antitoxin of diphtheria kills the germs in the body very much as bichlorid of mercury would kill them in a beef broth culture, and destroys their toxins by some direct chemic action.

No one yet knows the nature of the actual element underlying the antitoxic power. Notwithstanding their splendid work, neither Tizzoni, Aronson, nor Hammersten have demonstrated that they have obtained it in purity. But very practical deductions have resulted from the remarkable achievements of Kitasato in sero-therapy of tetanus; of Behring and Roux in diphtheria, and it seems that we can not disassociate the antitoxic power, so-called, of therapeutic serum from what is termed its immunizing property.

Metchnikoff has made very convincing researches on the fundamental questions involved in the problem of immunity. Among other things he has demonstrated that rabbits, vaccinated against hog cholera, produce a serum which is both preventive and curative in new subjects. And yet this same serum was found to possess neither a bactericide nor an antitoxic property of the nature that is said to exist in diphtheria antitoxin. The influence of *this* therapeutic serum at least was not directly on the germs or their products. And even diphtheria antitoxin, which was supposed to act directly on the toxins and their creators, because of the apparent loss of vitality of the latter when mixed with the former before their injection into the system of experiment animals acts indirectly after the treatment. It certainly does not destroy the germs for they are often found in their virulence in the mouth of recovered cases, weeks after the last injection of antitoxin.

It is then to nature herself that we must look for the explanation of the questions involved in the action of serum in therapeutics. A necessary factor is the natural forces of the organism experimented with or treated against a microbial disease. Men or beasts sometimes recover from a usually fatal germ disease, such as diphtheria, smallpox, tuberculosis even. What produces the cure? Nature's elements to arrest the development of the germ and antagonize the effects of their poisons. What are the forces producing these elements? The phagocytes. They are the chief defenders of the body, both in a physical sense and a

restricted chemic manner, for the germs are antagonized in their development by the phagocytes, and their toxins are antagonized in their nocive power, probably by a cellular diastase.

Anti-tubercle serum is, like any other antitoxin, the product of nature to antagonize the encroachments of germ life in the system. It is produced by the organism subjected to a continuous, progressive system of saturation of the economy with the toxins of the bacilli of Koch, especially to antagonize the parasitic life of this germ. It is the defensive power which fights its advancement, step by step. Occasionally, a case of tuberculosis recovers without medical assistance. This is due to natural properties within the economy, the defensive and defense-producing forces, assisted or not by the action of outside influences, such as climate, nourishment, etc. The production of tuberculous antitoxin is due to the action of tuberculin, the germ poison in the body. Tuberculin irritates the cells; the cells retaliate by augmenting the power of the phagocytes. In other words, the action of tuberculin in a susceptible organism, consists of a reaction, more or less severe, if administered in more or less heavy doses. During this reaction, nature produces the antitoxin in the blood. Then this antitoxin or the anti-tubercle serum, or anti-tuberclelin, is filtered out and used in man by hypodermic injections, thus infusing into his blood the very antagonist which nature creates or exalts in power to arrest tuberculosis.

The theory is beautiful; the facts are demonstrated.

Bertin, Picq, Maragliano, Behring, Foa, have all experimented with naturally or artificially immune serum in the treatment of tuberculosis and the last three scientists have obtained favorable results in man and beast. It was in our country, however, that the horse was first immunized against tuberculosis and his serum used successfully on a large scale against all forms of tuberculosis. The serum produced in my laboratories is the result of several years of investigation of tuberculosis in man and beast, at the State University of Missouri, and subsequently, in private and in the special institution under my control. It consists of clear amber serum of horses having undergone the process of immunization from three to six months, the usual time to reach a non-reactionary point, by daily injections of tubercle toxins, from liquid beef cultures, at the progressive dose of 2 c.c. to 20 c.c. daily. The toxins of the germ cells, themselves, desiccated, may be used also to increase the intensity of the immunity, when the toxins cease to react before three months of injections.

The horses are always kept under observation several weeks and then examined, and tested for glanders before subjecting them to the injections of toxin for immunization. Consequently, no danger exists of transmitting animal diseases, or disease toxins of the horse to man. Furthermore, our system of filtration precludes the possibility of any germ remaining in the serum if any should be present when the blood is withdrawn from the animal.

The physiologic effects of serum, some of which are undesirable, are well known. Any serum, immunized or not, may produce erythema, urticaria, articular pains and swellings, oligocythemia, oligochromemia, local cellulitis, swelling, etc., without being in the least impure from a bacterial standpoint.

Certain elements in the serum, none of which have yet been isolated, are more or less poisonous and pro-

duce various kinds of intoxication, with varying symptoms and pathologic phenomena. Some exhibit symptoms of nervous disturbance; others of interference, more or less pronounced, of the circulatory system. Again, there sometimes occurs in protracted treatment a curious, sudden flushing of the face, apparently due to a disturbance of the vasomotor system. All of these untoward effects are usually mild and ephemeral and none of them militate against the use of serum, although sometimes, in refractory cases, one must use it very cautiously, in very small doses at first, and even substitute rectal injections for hypodermic medications.

All the efforts made so far, abroad and in our laboratory, to establish a precise and constant mode of measurement of the antitoxic or therapeutic neutralizing power of anti-tubercle serum, have failed to produce results reliable enough to constitute a sound basis of estimation. The Behring law can not as yet be applied with assurance. The effects of anti-tubercle serum in man or beast vary according to the stage and nature of the affection, the amount of special or general tuberculous intoxication, the microbic mixtures in the diseased organs, and the nature and progress of the lesions. So far, the estimation of the tubercle antitoxin is based chiefly on the neutralizing influence of a given quantity of it mixed with a given quantity of tubercle of a given strength, the mixture being afterward injected in small animals and results noted. But the fact that these small animals have different powers of resistance to tuberculin vitiates the system. So far, the best gauge we have to determine the value of anti-tubercle serum is our experience with the results obtained with a certain class of horses, immunized three to six months, with a progressively declining reaction until it is *nil*, and our results in our clinics in tuberculous patients and in our laboratory in experiment animals.

Paquin's anti-tubercle serum is absolutely free from microbes. It is put up in small vials of one-half ounce, labeled with date of production and test. Dose, 10 to 60 drops, hypodermically, every day or alternate days. As much as 120 to 240 drops have been administered, repeatedly, in successive days in special cases, with good results. Per rectum, 30 to 240 drops daily, may be safely given. The results by this method are not yet sustained by many reports, but there seems to be no doubt that rectal injections of antitoxin result in perfect absorption. Dr. Chantemesse of the Pasteur Institute, Paris states that diphtheria is as readily controlled by rectal injections of antitoxin or by hypodermic exhibitions and some other antitoxins make similar reports.

#### DISCUSSION.

PROF. EDWIN KLEBS—There is quite a new and astonishing development of interest in internal pathology in consequence of the now generally adopted theory of the bacterial nature of all infectious diseases; the idea to search for bacterial remedies has originated and fixed itself in the minds of physicians and also become popular with the laity. We will find in no other way a sure weapon against these destructive inhabitants if a certain pathological process is nothing more than a combat between the human organism and certain microbes vegetating in the body. The surgeon has profited more by these researches than the physician by the possibility of asepsis or preventing the introduction of the germs in the operations on the body. We, the physicians, find the microbes established in the body, often for a very long time. In chronic diseases such as tuberculosis there exists moreover a sort of symbiosis

between the two organisms, in which the forces of the germs and of the human body are more or less counterbalanced. An old phthisical patient may live long, seeing his wives and all his offspring die before he pays his duty to nature. That is no mere latent disease, but an actual affection, poisonous to others, but not poisonous for its own body. We say in such cases that the human organism is immunized against the germs that have taken possession of it. I remember some of our best writers, as Schiller and Stevenson, living and working wonderfully under such conditions. Women have gained under the influence of the more or less latent disease oftentimes, an unsurpassed loveliness, often celebrated by poets and highly esteemed by high minded men.

We observe many peculiar features of the disease, and standing for long years, not at all offensive. I have seen lately the case of a celebrated botanist, the disease latent for fifty years, whose long career has been an uninterrupted chain of good deeds.

All these remarks are pointing somewhat to the not yet written psychology of tuberculosis, one of the most interesting chapters of human biology. They will show that my long contested thesis of self-immunization in this disease is proved by daily observation as well as by animal experiments.

This fact opens a broad field for possibilities of healing, but also renders the task of the physician difficult, as such persons do not always realize their abnormal condition or are not willing to acknowledge it. Such patients fill all health resorts, and not always living as they should when there.

If we ask the conscientious physician what are the effects of climatic or general treatment, he will concede probably that they have more of a retarding than a healing influence.

The question will arise: Can we do more for these patients? I am quite sure that the bacterio-therapy of tuberculosis will afford us better methods.

The first principle of this therapeutics must be contained in the demonstrated possibility of killing the germs in the body; the second in the not quite solved question of immunizing the organism and of antagonizing the toxic effects of the germs. The one problem does not exclude the other, but in chronic diseases the first principle is of far greater importance than the second.

Dr. Paquin, searching to solve the second problem, as Viquerat before him, has given us some good results of the serum treatment, which I do not think are at all doubtful; but to establish the fact in a scientific manner, clinical cases alone are not sufficient. Every new treatment shows quite a number of healed or improved cases. In man it is not possible to find enough comparable cases, and the final effect can not be ascertained in an unquestionable manner. Such thesis must be proved by animal experiments, in which we can use absolutely normal animals for infection and treatment; whether we have attained our object or not the postmortem will show. I have endeavored to fulfill this task in a great number of experiments with tubercle serum, taking daily temperatures and weights through many months, but I could not effect the cure of one animal, although the infection was slight and the doses of tubercle serum large. Nevertheless, I do not say that there will be no antitoxic effect from this treatment; but unfortunately this point is not sufficiently cleared up.

On the contrary, with germ-killing substances, prepared from the tubercle-cultures I had far better healing results in animal tuberculosis. I may say that they have given me the only perceptible results.

In the guinea pig, the animal most susceptible to tuberculous infection, the greatest deposits are found in the liver and spleen. The two organs are swollen enormously and filled with yellow tuberculous matter. Even such large deposits can be healed by bacterial products. The liver shows deep fibrous scars without any tuberculous deposit, otherwise quite normal except a

little hypertrophic tissue. The spleen can be reduced to nearly normal size except always a little hypertrophy in consequence of the cirrhosis of liver, but it is quite free from tuberculous tissue and tuberculous bacilli, as also are the other organs. Such results can be obtained in three or four months treatment, whereas the control-animal, infected with the same quantity of tuberculous bacilli, without treatment died in two or three weeks.

These results are now confirmed by a long and careful clinic observation I had in Europe. In 72 cases 70 (93 per cent.) healed or were very much improved; Dr. von Ruck reports in 182 cases treated in the Winyah Sanitarium 59 (32.4 per cent.) apparently recovered cases, 56 (30.8 per cent.) greatly improved, 29 (16 per cent.) improved. *Therap. Gazette*, 1896, No. 5. That other physicians had similar results, is stated in many published observations, also indicated by the extensive use of antiphthisin in the last year, amounting to more than 50 liters of 1 per cent. organic matter.

I have devoted myself in the last year especially to a renewed study of the healing and immunizing properties of the different compounds of the tubercle cultures. I found that my first preparation, tuberculocidin (The causal treatment of tuberculosis, 1894) has an immunizing power, in a higher degree than antiphthisin,<sup>2</sup> the same as with tuberculin.

The immunizing power is conveyed to this preparation by certain substances contained in the bacilli, whereas antiphthisin is only prepared from the culture fluid. As the latter is the mildest form of tubercle-killing substance from tubercle culture, I think it best to commence the treatment with antiphthisin and later, if there is no fever, use the tuberculocidin. As the latter is more liable to produce fever than is the former, it must be given in smaller doses, from 0.1 to 1.0 c.c., and also more cautiously. The most successful cases that I have seen, were treated in this mixed manner. (I regret that Dr. von Ruck in his publication does not give separately the cases treated with antiphthisin alone, and antiphthisin and tuberculin, but I hope he will later report these cases separately and in a more detailed manner.)

## ATTENTION, AN ADJUVANT IN THERAPEUSIS.

Read in the Section on Materia Medica, Pharmacy and Therapeutics, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY GEO. V. I. BROWN, D.D.S., M.D., C.M.  
DULUTH, MINNESOTA.

A careful scrutiny of the pathway along which has traveled to us, almost from the beginning of history, the knowledge of that state known variously as hypnotism, mesmerism, bradism, animal magnetism, electro-biology, etc., on through an almost interminable list of isms, ics and ologies, brought forward from time to time by its many champions, now bright with the brilliance of popular excitement and approval, again darkened with the severity of general condemnation, hailed as a universal deliverance from all the ills of mankind's heirdom, or crushed under the ban of responsibility for crime or direful mental injury, must, I think, convince most students that the answer of the scientific bodies of to-day can be but slightly different from that given by the Roi Medical Society and the French Academy of Sciences, at Paris in 1778, which, as everyone knows, was a refusal to accept the so-called truths en masse. Yet there is something about this subject that will not down, and even though the whole may be full of fallacies and fraught with danger, still there are facts concerning

<sup>2</sup> Dr. von Ruck says in regard to this point, i. e.: The two preparations are practically identical and, so far as I have been able to observe, the therapeutic effects are the same.

certain mental influences from which the therapist has no escape. They must and do influence his every effort, and the question at issue is simply: Shall he try to ignore them and trust to a haphazard effect, or will he guide and encourage this mental and nervous action, for the furtherance of that which his medical knowledge dictates to be beneficial?

After many years of study and experiment, I find my objection to the general use of hypnotism in no wise diminished. Out of the mouths and through the pens of its warmest supporters have come to me a confirmation of my feelings of distrust, and for some time past my efforts have been directed toward the accomplishment of possible usefulness in mental treatment, without the necessity of inducing the hypnotic state; hence this article, "Attention, an adjuvant in Therapeusis." Attention because it brings us nearer to the essential principle involved.

The one thing upon which all writers agree, irrespective of their other views, is, that without the attention of the subject hypnosis would be impossible, and it matters but little whether the attention be engaged with a flash of light, the sound of a gong, fixation of gaze, or words of command, by musical sounds, animal magnetism or any other manner, so long as the flight of thought be arrested and concentrated upon the desired object.

Suggestion would be useless without the attention of the subject, although suggestion is the most useful means of producing mental impressions. Adjuvant, because as a helper in coöperation with other well-established remedies, psycho-physics can be safe and useful, as it could not be in the light of a cure. The simple facts to which I desire to direct your attention are:

1. By a proper concentration, and the guidance of the subject's attention nearly everything beneficial can be accomplished that might be possible in the hypnotic state without hypnosis, and therefore without its dangers.

2. The loss of consciousness is not always necessary for anesthesia, or action upon any particular nerve centers, and the parts under their control.

3. Much valuable assistance can be given to other therapeutic measures in a great variety of ways, not alone by stimulating the beneficial effect, but also in the arrest and avoidance of antagonistic mental influence which so often aborts the intended value of other treatment.

A brief study of certain mental and physical phenomena will bear out as at least reasonable the proposition stated, and practical evidence brought forward in the cases cited will commend themselves to your consideration in support of the deductions advanced. We know that under quite natural conditions one can become so absorbed in a good book or in a certain line of thought that familiar sounds, ordinarily distinctly audible, will pass unheard. Yet there is no reason to suppose the auditory apparatus does not carry the vibrations to the brain in the usual manner, but no consciousness of the fact exists, because one portion of the brain is inactive while the other parts have perhaps unusual activity. This we recognize as a sub-conscious state.

Wm. Romaine Newbold suggests the term, dis-ordination, as the opposite of coördination, and says the fact that a mental state can exist dissociated from the others, and without a personal consciousness, leaves no room to doubt that many may be simultaneously

dissociated, or even the entire mental system dissolved into a chaotic mass. That under these conditions there would be no memory, because memory is dependant upon association of ideas.

He describes hypnotism as a state of disordination produced by the subject being put to sleep with the sound of the operator's voice constantly in his ears, his being made aware of his presence by the sense of touch, or in some other manner, until all the elements of normal consciousness are disordinated and more or less extinguished, save the one group governed by the consciousness of the hypnotizer. That portion has had no opportunity to sleep, and naturally susceptibility to all other stimuli being lost, this one group acts with an accuracy impossible in the waking state. Epilepsy, shock, hysteria and trance state are all forms of disordination.

Disordination from shock has been remarkably illustrated in my own practice recently. A young lumberman, of good habits, was kicked in the face by a horse, his upper lip cut in the median line and the upper jaw fractured on both sides, including also the roof of the mouth. This occurred on Monday at about 7:30 P.M., and he has no recollection of anything that happened until the following Wednesday evening, when his lip was sutured without pain, though no anesthetic of any sort was used, and his first faint glimmer of a returning memory was a hazy recollection of the pins being stuck through his lip; but the remarkable part is that in this interval he had traveled fourteen miles in a sleigh and about one hundred miles (from Ely to Duluth) by rail, was able to walk about and attend to all his wants, and according to his friends' testimony, was quite rational, told about his case and answered all the questions correctly. No pain was felt until Thursday, when he became fully cognizant of all things about him; then his suffering was of course quite severe.

It is a matter of frequent notice that after unusual excitement of any nerve centers, as by study prolonged sufficiently to cause fatigue, the brain will continue to go over and over the particular line of thought, even though all the other portions of the brain are at rest, or a particular strain of music may reverberate in the same manner, in short, any impression that may have reached the brain may be repeated, perhaps in dreams, possibly in moments of sub-consciousness, but without any voluntary effort to start its cerebral elements. This condition, known as automatism, is noticeable in a variety of ways and certainly gives justification to the idea that the repetition of words intended to act upon certain centers to produce some particular effect must excite vibrations that will act automatically, and in time produce the desired effect. This, as I will endeavor to show, is precisely what does occur.

Professor Ladd of Yale University says of the mechanical theory of nerve conduction, that messages are transmitted by a series of wave motions, just as light, heat, electricity and sound, which may be accelerated or retarded by outward influences.

In certain moments of high nervous tension pain is intense, thoughts are transmitted quickly, all sensations are acute, in other words, the vibrations are more rapid, the pitch is higher, just as the tone of a tightened violin string. On the other hand, with nervous tension relaxed, all transmissions are less rapid, the human violin string is loosened. Upon these and kindred peculiarities of brain and nervous

action depend all methods of physical treatment of disease, and all of them are dependant upon attention in some form or other for existence.

John Hunter, in 1838, said: "I am confident I can fix my attention upon a part until I have a sensation in that part," and told how he prevented a magnetizer from affecting him by fixing his attention upon his big toe, moving it about constantly.

Of the influence of expectant attention, Carpenter says: "The contrast between the volitional and automatic states of attention is particularly well shown in the effects of painful impressions upon the nervous system. It is well known that such impressions as would ordinarily produce severe pain, may for a time be completely unfelt, through the exclusive direction of the attention elsewhere." Continuing, he says: "Now just as the organic impressions, which make themselves felt in pain when the sensorium is receptive of them, may exist without consciousness if the sensorium be otherwise engaged, so it may be affirmed, and on precisely the same evidence, that the organic changes which are concerned in the automatic production of thought, and of which we become conscious as ideas when the sensorium takes cognizance of them, may go on without consciousness if the sensorium be otherwise engaged."

Tuke says: "Attention may be definitely directed to the parts affected accompanied by the expectation of a certain result without the administration of drugs," and cites a large number of cures thus effected.

In further support of this theoretic superstructure, the authorities that one might cite are almost limitless. Ladd, Sully, Luys, Newbold and other investigators in mental physiology and psychology speak of these various attributes of the action of the brain and nervous system, and recite many peculiarities that have been strikingly brought to light, particularly as to cures effected by expectant attention and the imagination. As for records of hypnotism, the various faith and other cures, their funds of examples are inexhaustible, a fair proportion of which are unquestionably authentic, but for practical purposes, I shall confine my illustrations to just the things that have been accomplished within my own experience, and only such of these as will tend to show the subject in its various aspects of usefulness.

In a former paper, published in the *Chicago Dental Review*, I described some cases in which without other assistance I had reduced the temperature of patients suffering from febrile disorders, inducing restful slumber by stroking the head and extremities, as in gentle massage. One of these, a typhoid patient, whose life was despaired of by the physician in charge, with the temperature taken just before and twenty minutes after treatment had been begun, showed a decline of three degrees, the restless tossing about had ceased and sleep came to her relief, which whenever she awoke was induced again, and so continued until morning. Nature, thus assisted, soon brought about entire recovery. A case of hysteria and another of dysmenorrhea, in which the symptoms were particularly distressing, were reported as having been successfully relieved in the same manner, and the painless performance of many minor operations in analgesia, produced by suggestion, were also referred to at the time, but I particularly called attention to the fact that under certain states of hypnotic influence, while operations can undoubtedly be painlessly performed, the danger of shock is much

greater, and more to be dreaded than under natural conditions, even though the suffering might be intense.

I am more than ever convinced of this fact and find myself less willing to try to put a patient into a condition where helpless to resist; there may yet be a susceptibility to shock, extremely aggravated by the disordered mental condition.

James R. Cook, M.D., thus describes his own sensations upon being hypnotised for the first time: When told by the operator: "You can not open your eyes," says, "I was conscious that while one part of my mind wanted to open my eyes another part did not want to, so I was in a paradoxical state." In my opinion patients are frequently in a paradoxical state.

I was called by the present Secretary of this Section, Dr. W. B. Hill of Milwaukee, to take charge of one of his patients, a man of about 45 years, and at my request, Dr. Hill has written a description of the case, which is as follows:

"Mr. G., a stationary engineer, came to me during the fall of 1894, suffering from insomnia, anemia and general neurasthenia. Circulation was very poor, cold extremities, rapid and feeble heart, muscular twitchings and pricking sensations all over the body.

"Tonics and nerve sedatives were ordered, but patient could not bear any medication. Dr. G. V. I. Brown was called in the case with me and recommended massage, a suggestion which was carried out by him with marked benefit to the patient.

"An examination of the rectum revealed a large internal hemorrhoidal tumor about one and a half inches from the sphincter ani. I decided to operate by ligation and use cocain as a anesthetic. After all precautions were made, inadvertently, the cocain solution was spilled and I asked Dr. Brown to go to the patient's head. The operation was performed under hypnotic anesthesia produced by Dr. Brown, the patient experiencing absolutely no pain or discomfort either during the operation or the time the wound was sloughing off and granulating, but was given suggestions daily for several days thereafter. All symptoms of his former trouble disappeared, the patient feeling better and more vigorous than for some years.

"About two weeks (nine months later) there was a recurrence of the trouble to a slight degree; an examination showed another small tumor in the same region. I again operated, under the influence of cocain (Dr. Brown not being present), the operation was not without pain this time, although I had the same happy result as far as neurasthenia was concerned."

In addition to what Dr. Hill had kindly stated, I wish to give the following facts: The treatment given was general massage for fifteen minutes every evening at bed time, attention directed to the parts in which the circulatory process was most inefficient, with the purpose of augmenting and continuing for a longer time the effect of the increased blood supply, due to the rubbing. In the abdominal region he was massaged to cause peristaltic action and his attention directed to the part with instructions to have a passage one-half hour after breakfast. The massage concluded, he was made comfortable for the night, and a gentle stroking about the occiput and frontal region soon caused drowsiness. Over and over again were repeated, in a monotonous yet impressive manner, the words, "Sleep, sleep well, all night long. If you awaken, go right to sleep again; have a passage from

your bowels half an hour after breakfast." Upon several occasions when he was particularly restless his gaze, with eyes upturned, was fixed upon my finger for three or four minutes to assist concentration of his thoughts, and twenty deep, full breaths were taken, but at no time was the process carried so far as to produce hypnosis; the sleep, when he fell asleep, was apparently a natural one. As strength returned active movements were prescribed, and the idea of self-help inculcated to arouse his will. In exactly seven days from the first treatment the patient returned to his work, having been unable to do so for some three months. His rest was regular, digestion improved, and every morning at the appointed hour he had an evacuation from his bowels, which was remarkable in view of the fact that for many months it had been his custom to give himself an enema for this purpose and all natural effort seemed to have ceased. Anesthesia was produced during the operation upon the rectum by having the patient hold my hands, instructions having been given to keep a strong pressure as possible in order to keep his thoughts fixed upon the effort, which we were successful in doing. Not only was he conscious all the time, but in no respect did he show himself to be influenced except in the desired absence of painful sensation.

Relief was given another patient who was suffering from intestinal catarrh and had severe pain at certain hours in the day. She was instructed to lie down at about the hour the pain was expected, close her eyes and take twenty long breaths, filling the lungs quite full and exhaling slowly. The centering of the mind upon the breathing after a little training put her to sleep so readily that she was seldom able to reach the twentieth breath. The nap gave rest and quiet to her nerves, beside tiding over the painful period. Mrs. A., about 28 years old, with a history of supra-orbital pain of an intense paroxysmal character, lasting for a few moments at a time and varying from ten minutes to four hours apart, ever since she was 8 years old, night and day. Four hours was the longest period of freedom of pain remembered, except upon two occasions; once, after an overdose of some drug, five hours' rest; and after a thirty-mile sleigh ride she slept five hours. Opiates had been taken constantly, sometimes in very large doses. All varieties of treatment had been tried, both in this country and in Germany. Resection of the supra-orbital branch of the trigeminus had given no relief, pain returning the moment the effect of the anesthetic had passed. The day I was called she had fallen upon the floor in a stupor from exhaustion. As a preliminary step, all drugs of whatever nature were prohibited, and after about two or three weeks daily treatment, intervals of five, six, seven, eight, nine, ten, and even fourteen hours without pain were not infrequent. General health and spirits were, of course, improved, and fairly undisturbed rest at night was the rule. Had not treatment been unavoidably interrupted there seems every reason to have expected much greater improvement; certainly any change for the better was the most severe test. The attention was guided, but not to a hypnotic state.

As to the exact manner of practical application but little can be said, save in a general way.

In my own experience, the individual peculiarities encountered require a great diversity of methods; particularly among the hysterical is there a latent perversity which sets itself against one's prime object, and

so it frequently happens that I use the word, sleep, quite sure that such a patient will not sleep, yet, with the mind centered upon not going to sleep, other suggestions incidentally brought forward are usually quite readily effective.

Concentration of gaze five minutes, followed by twenty full, rapid inhalations and exhalations are usually sufficient for operations that can be quickly performed, such as an opening of an abscess or extracting a tooth, but the breathing must be continued without stopping until the operation is finished.

For patients suffering from digestive disturbances, insomnia, tinnitus aurium (when aggravated by nervousness) or any affection for which it may be desirable to prescribe home treatment, the method of lying with the eyes closed and breathing as before described is by all means the best. Respiratory effort is of itself a beneficial exercise, easily understood and readily adopted by reason of its simplicity.

I have treated hypnotism as a disordinated state quite different from natural sleep, in which the subject is not open to suggestion and would awaken if suggestion were attempted, for, though denied by some, this distinction is well supported by eminent authorities, and accords fully with my own observations.

The objectionable features to hypnotism, Christian science and many methods of psycho-physics are:

To say nothing of the dangers of hypnotism as regards crime and physical injury, which, notwithstanding its repeated denial by ardent advocates, is still supported by a great amount of evidence. There is beyond question the fact that repeated hypnotization causes a dangerous susceptibility. Bernheim, Binet and Feret, Luys, Faveau, DuConormeilles, Hart, Cocke and many others all admit this fact, though some claim the danger can be avoided by suggestion; nevertheless, Hart took several of Luys' patients that had been given the usual suggestion not to let others hypnotize them, and in the presence of several reliable witnesses, induced the hypnotic state without difficulty; but assuming for the nonce, every physician to be equal to the harmless management of these difficulties from the point of view of the therapist, the essential and vital difference between the treatment here recommended and the hypnotic suggestion is, the one tends to build up, foster and encourage the will force and judgment of the patient, teaches self-reliance, and increases mental power. Whereas, the other weakens and destroys, in a measure at least, the inherent will power, takes away self-reliance and the valuable notion of personality. What physician, with the patient reduced to a mere automaton, subject to every word, every gesture, every look of the hypnotizer, can tell the exact physical state; when the patient, told that he is better, repeats; "Yes, I am better to-day," or marks any improvement that may be suggested to him, notwithstanding the fact that the disease may at the very moment be on the increase, with all the symptoms masked by his mental state.

Who is prepared to become "his brother's keeper," to say, "my mind is all right; I see and know all things clearly; I will be responsible for other minds and my own also?" Surely no one who has studied deeply into psycho-logical mysteries.

The so-called healers of Christian science, while they have done wonders in developing the field of mental treatment, deal in just this manner. Perhaps I speak a little bitterly, but I have in mind a friend of

mine, who was buoyed up with the false hope and fancied improvement suggested by those charlatans, until a cancer had stolen its way so deeply into his vitals that at least a number of years of his life, that otherwise might have been spared him by correct early diagnosis and the knife, had been lost.

The one thing that retards progress is a tendency to deception, particularly in this connection. Records of psycho-physics abound with lists of cases in which the patients have been deceived in this or that manner, given bread pills and water instead of the expected remedies, etc., throughout the familiar tricks. Now, while this may be very interesting in the light of experiments, lying and deception make, to say the least, a very unstable foundation upon which to build a therapeutic structure.

I have tried to strip this subject so far as possible of odious associates, believing that if accepted at all by the medical profession and accorded the place I feel it ought to have among legitimate therapeutic measures, its advance must be in a strictly conservative manner, without mysticism, and viewed only in the light of natural mental science.

## THE PRACTICAL USES OF SUGGESTIVE THERAPEUTICS.

Read in the Section on Materia Medica, Pharmacy and Therapeutics, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY WILLIAM LEE HOWARD, M.D.

BALTIMORE, MD.

I conceive it to be your desire to have a plain statement of the uses and limitations of suggestion, and I shall confine myself to this conception. To those of you who desire a more comprehensive statement of the psychologic side of the subject I refer to my paper read last year before the Neurologic Section of this ASSOCIATION.<sup>1</sup> In this paper I shall avoid as much as possible the misnomer hypnotism, as we shall see later on that often curative effects of suggestion are produced without inducing hypnosis. To anyone familiar with modern pathology the limitations of the therapeutic uses of suggestion will be readily understood. To those familiar with the trend of modern psychology its application for harmful effects will be fully appreciated. In treating patients by suggestion it is necessary to remember one fundamental factor, *i.e.*, the subjective state of the patients. Without this latter condition you will seldom succeed in effecting your object. Without doubt the reputation and success of most physicians is due to suggestion, often unconsciously made. The great factor in the large number of cases reported by Bernheim is

<sup>1</sup> Hypnotism, its Uses, Abuses and Medico-legal Relations. Jour. Am. Med. Assn., Nov. 30, 1895.

due to the explicit confidence in him by his patients. We all know what a difference it makes in our successful treatment of patients when they have unbounded confidence in us; how soon they will respond to our suggestion; where, with a stranger, or one in whom they have little faith, treatment has apparently but slight effect. The same medicine given the patients by the physician with whom they are *en rapport* will have a far greater effect than if given by a stranger, provided that the former makes some simple but forcible suggestions regarding the effect of such medicine. When we start at the fundamental facts of suggestion it all appears very simple. To illustrate the force of suggestion I will give you a simple example. Let A., B. and C. agree to meet D. at different times and places during the day. Let them be men in whom he has confidence. On his way down to his office D. meets A.; A. exclaims: "Look here, D., what's the matter with you? You look very ill." etc. This suggestion acts with sufficient force to cause D. to drop in to a public place and consult a mirror. He soon sees that his face is pale and begins to feel weak. He throws off the idea for a while, but it will return to him at intervals. He then meets B. whose suggestions are more forcibly made; and afterward the third party. By this time, D. is in reality psychically ill, goes to his home and sends for his physician, who will find a rapid pulse and a generally disturbed condition. This is a fact that I have often demonstrated. Now, suggestion can act reversely. Hypnotism in all its stages is now an undisputed fact. Suggestion is a justifiable method in certain cases. In those obstinate and disagreeable cases of hysteria in all its forms; in insomnia, drug habit, and immoral practices which so often disrupt once happy homes, we here have a therapeutic remedy; and any physician, who, after he has made a correct diagnosis and failed to cure after using all his other resources, refuses to use suggestion either with, or without the aid of hypnosis, is not giving his patient that care and attention that he has a right to expect.

Unfortunately, through the daily press the subject has been placed in such a light as to have caused its beneficial factors to have been forgotten, and the older practitioner, with little or no knowledge of modern physiologic psychology, has looked askance at the subject. About this branch of medicine there has been too much haste, inaccuracy, fallacious reasoning, confused or contradictory ideas by a large number of our profession. I will now give you the practical side of the subject, leaving speculation and theory strictly alone. If I appear dogmatic it is only because I quote the reports of the most eminent and reputable men of science; and have not gone beyond the deductions derived from experience. I shall give you only the digest of the subject as reported the last twelve months.

The practical uses of suggestion are numerous. In certain forms of functional disturbances cures can be effected. The pains that often accompany organic diseases can be abolished. While suggestion will have no effect on organic disturbances *per se*, the relief of the accompanying pain is of vast importance, as it gives comfort and rest to the patient. The sensation of pain takes place in the cerebral cortex; it is a mental condition, it implies consciousness and hence, by an alteration in our state of consciousness as is induced by suggestion, pain can be abolished. Several cases have been reported of the cure of organic diseases of

the cord. It is only necessary to say that either the observers were mistaken in the diagnosis, or allowed their enthusiasm to warp their judgment. The internal capsule, the thalamus, the motor convolutions, the sensory tracts in the cord once destroyed are not to be restored by any form of interference. It would appear at first thought that any such self-evident fact mentioned here was superfluous; but from the large number of letters I receive from the profession I judge that this matter is not always understood.

I find, however, that I can greatly relieve a patient suffering from organic disease. The removal of anxiety, the implantation of new ideas, the removal of the habit of introspection, are oftentimes the means of breaking those vicious circles so common in the pathologic states, and removing the unpleasant psychic accompaniments. In my experience, insomnia offers the practitioner his best field for the treatment by suggestion. We can here see how it acts as a curative agent in so many functional disturbances. I generally see the patient at my office several times before attempting to produce hypnosis. After I have gained the confidence of the patient, and am satisfied as to the functional cause of the insomnia, I begin to suggest sleep. The symptoms of sleep are readily called up, they are familiar and natural, and therefore, a patient without possessing very great confidence in the operator can, without much difficulty, be made to believe that sleep has come upon him. This much gained, the patient's confidence in your powers are secured, and the field is ready for you to plant such suggestions as the conditions call for.<sup>2</sup>

Having your patient go to bed at the usual hour, you continually but forcibly suggest sleep. If you have succeeded in your tentative efforts you will be surprised to see how readily the patient will respond to your suggestions. Then I suggest how long she shall sleep, and that she will awaken refreshed and hungry. Be sure you tell her to sleep until a certain hour, for a subject under your perfect control will not always awaken unless the operator tells her to do so. One of my earlier experiences will illustrate. I was called to treat Mrs. M. who had been suffering from insomnia for several months. She responded to suggestions readily, and soon was in a state of hypnosis. About 9 o'clock the next morning there was a furious ringing of my door bell, an excited woman rushed in and said I had killed Mrs. M. Her family and friends had been trying for two hours to arouse her. Going immediately to the house I found family, physician and neighbors with their suggestions all there. Every method known to layman and doctor had been tried, but it was impossible to arouse Mrs. M. Going up to her I said firmly: "You must wake up now, Mrs. M.; wake up, wake up!" She opened her eyes and soon arose. It was her first good sleep for eight months, and the last time I ever forgot to suggest the duration of sleep to a patient.

The suggestive sleep by the Nancy method is harmless, and as far as my experience goes is a normal sleep produced by suggestion. The harm that comes from such a condition is due entirely to the purport of the suggestion made while in this receptive condition; evil suggestion can be given and will, to a certain extent, be accepted, as well as good.<sup>3 4</sup> Hence, we can see the importance of regulating the practice so that it can only be used by reputable and skillful men. Next to insomnia suggestion is most useful in

<sup>2</sup> See Dr. Schofield's Lectures, Victoria Institute, London, 1896, "Relation of Mind and Body, or the Powers of Unconscious Mind."

hysteric seizures. In those troublesome hysteric contractures of the extremities, suggestion during hypnosis seldom fails to give relief. Care must be taken, however, not to attempt to correct contractures of long standing, for as Charcot has said, when contracture has long existed, it becomes incurable. Hysteric amaurosis is readily relieved by suggestion during hypnosis. This is readily understood when we realize that hysteric amaurosis is not a systematic paralysis but a purely psychic amaurosis; a neutralization of the object perceived by the imagination. Dr. Hugh Patrick reported to this ASSOCIATION at its last meeting at Baltimore a case of hysteric blindness and pseudo-meningitis cured by suggestion.<sup>6</sup> The long and tedious list of the different phases, types and isomorphic forms of hysteria are all more or less amenable to treatment by suggestion. Cephalalgia, intellectual obtundition, pseudo-hemi- and paraplegias are conditions that are benefited by suggestion.

It is not always that the hysteria itself can be cured, but the symptoms can be removed.<sup>7</sup> The treatment of dipsomania by suggestion is now being quite extensively used. At the present time we are not in the position to make any dogmatic statement regarding its certainty as a remedial agent. I have had excellent results with cases that have tried about every other known treatment. The fact that you can abolish the nervous insomnia, eliminate the anorexia, and stop the tremors and other concomitants following an alcoholic debauch, is sufficient evidence to cause one to treat these cases by suggestion. With these functional disturbances controlled I use continued suggestion regarding the use of alcohol while the patient is in a state of hypnosis. The result has been very gratifying. Bushnell, Surg. U. S. A., says: "I have never failed to hypnotize a patient who sought treatment for alcoholism."<sup>8</sup>

Dr. Am. De Jong reports very good results by this method of treatment during the last two years.<sup>9</sup> Crothers<sup>10</sup> advises its employment whenever possible, and says: "Clinical experience furnishes many facts which seem to prove that in certain cases its value is very marked, also promising from more exact studies greater results." Dill<sup>11</sup> gives a list of eight cases of dipsomania treated successfully by suggestion. Green<sup>12</sup> gives a case of a man addicted to the abuse of alcohol, bromids and chloral cured by four hypnotizations. What I have said concerning the alcohol habit refers also to the drug habits.

Sexual perversion as a disease has been but little studied in this country; but experience has proven to me that it is quite prevalent here. Suggestion is the only method of treatment so far known that has any effect on these cases. I refer to the acquired condition, not the congenital; the latter in my hands has never been benefited. Masturbation in both sexes is generally well controlled by suggestion. It would be a work of supererogation to enter into details upon this subject when we have such classic works as those of Kraft-Ebing, Schrenck-Notzing, Moll, Ellis and many others.<sup>14</sup> Hypnotism will never supplant, in its pres-

ent status, the existing anesthetics. Local and complete anesthesia can be produced by suggestion, but it is not available in an emergency case, unless the patient happens to be one in whom we have at prior times produced complete anesthesia by this method. In minor operations when the time for operation can be extended for a few days we can attempt to get our patient into that state of receptivity that will allow of producing a suggestive anesthesia. This can be seldom accomplished at the first attempt. When this anesthesia can be produced it is far superior to our present anesthetics; being devoid of any danger. Up to the present time we have had but one reported authentic case of death from suggestion, and that death was due to the purport of the suggestion, so forcibly made as to bring about the very result that was suggested, *i.e.* death.<sup>15</sup> A case was reported last year from Paris as a death due to hypnotism. Prof. Bernheim gives the following explanation. "A man aged 37 years whom he had hypnotized to relieve the pain due to phlebitis of the leg, and whose death followed two hours afterward, was only an unfortunate coincident; as the postmortem showed death to be due to embolism of the pulmonary artery."<sup>16</sup> I have often operated in minor cases after putting the patient in a state of suggestive anesthesia. A large number of authentic cases have been reported. Wagner<sup>17</sup> gives twenty-one cases of minor surgical operations done under suggestive anesthesia, and three obstetric cases. Major operations have also been done under the same conditions. It is very useful in obstetric cases. Here to be of any value you must have frequently hypnotized your patient, and have become certain that she will respond to your suggestions at any time. The advantages of suggestion in parturition are the removal of consciousness of pain, regulation of position of limbs, body and attitude, and increase of uterine contraction of voluntary muscles. In dentistry, for the extraction of teeth, it is a most satisfactory method of painlessly operating.

What percentage of persons can be controlled by suggestion? Authorities differ. The result will depend upon the individual operator, as in any other branch of medicine and surgery. A conservative estimate would be about 25 per cent. I succeed in about 30 per cent. What class of patients is most susceptible to suggestion? Phthisical patients; children between the ages of 5 and 15 years of age; those of a neurotic temperament; last and most difficult is the hypochondriac and the melancholic. The insane, imbecile and idiots seldom, if ever, respond to suggestion in any form. A certain class of normal intellect can not be controlled by suggestion. To use a hibernianism, they will insist on keeping awake to see how you will put them to sleep. What are the requirements to be successful in using suggestion? The tact, judgment, diagnostic ability and confidence in one's self and all that makes the successful physician. Suggestive therapeutics is no "royal road" to success. It involves the same application, severe attention and experience that is necessary in all branches of medicine and surgery. Until you have had some experience you will not have

that full confidence that is necessary to impress your patient. There is no such thing as "will power," "animal magnetism," or any other so-called occult force employed. Get your patient in a state of mental receptivity by having him look at some small bright object distant about six inches from the pupils and a little above them. When the eyelids begin to close, or a fibrillary motion commences, close them gently, and in a low but emphatic tone of voice suggest sleep. Once in this state the therapeutic suggestion should be made. In a large number of cases it is not necessary to produce complete hypnosis to get satisfactory therapeutic results. If the patient is only in a state of lucid lethargy he will often accept a suggestion with good results. A new idea of the explanation of the phenomena of hypnotism has just appeared.<sup>18</sup> This is no place for psychologic discussion or polemics, but as this idea has only been put before the profession the last few days I will call your attention to it. Dr. Henry Stark of Boston says: "Hypnotism is a pathologic process depending for its origin on contagium, probably specific in character, although unrecognizable by any of the five senses."

Suggestion as a therapeutic method of treatment is only an adjuvant, often a powerful one, to go hand in hand with other rational means of hygienic and medicinal treatment, and is not to be understood as by any means being a certain cure for all ills and complaints that man is heir to. It is not a catholicon, a philosopher's stone, as many enthusiasts would have us believe.

Psycho-physiology<sup>19</sup> has placed suggestion on a sound scientific basis, and those who step from this basis and make claims that have no psychologic foundation, are those seized with the vertigo of the supernatural and condescend to serve as vouchers for the most absurd aberrations.

## THE ANTITOXIN OF TETANUS.

Read in the Section on Materia Medica, Pharmacy and Therapeutics at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY SAMUEL S. KNEASS, M.D.

ASSOCIATE IN THE WILLIAM PEPPER CLINICAL LABORATORY, UNIVERSITY OF PENNSYLVANIA.

Among the many principles on which are based our modern theories of the etiology and therapeutics of disease is that of the vaccinating or immunizing power of attenuated cultures of specific microorganisms. Although this principle is forecast by Jenner's discovery of the vaccine against variola, it is to the great Frenchman, Pasteur, that should be ascribed its first scientific development.

In 1880 this investigator showed that an attenuated culture of the microbe of chicken cholera, injected into animals, would produce a mild attack of the septicemia, and would leave them immune against a second attack. This was the first experimental fact to which numerous laboratory workers have been adding during the last fifteen years. Disease after disease has been added to the list, anthrax, hog cholera, malignant edema, hydrophobia, diphtheria, the infections due to the staphylococcus, the streptococcus and the pneumococcus, typhoid fever and tetanus.

It is not the purpose of this account to go into the

history of the subject or the various theories of immunity except so far as they bear on the subject in hand, the antitoxin of tetanus and its use in the treatment of tetanus in the human being.

The bacillus of tetanus, first discovered by Nicolaier in 1884 in tetanic animals, and afterward by Rosenbach in 1885, in the local lesion in man, was finally isolated and studied by the Japanese, Kitasato. Since then, these results have been approved by so many investigators, that we say definitely that it is proved that Nicolaier's bacillus is the specific cause of tetanus in all its clinical forms, traumatic, idiopathic, rheumatic, puerperal and of the new-born. It is the type of the specific intoxication. The bacillus growing only at the initial lesion there elaborates its toxin. An important point to remember is the extreme toxicity of the products of secretion of this bacillus. A 1-1,000 c.c. is sufficient, when injected subcutaneously, to kill an adult guinea pig. Evaporated to dryness this is represented by 0.000,025 (25-1,000,000) gm. A mouse succumbs to a dose of one-hundredth this quantity, 25-100,000,000 gm.

Brieger had found and isolated a ptomaine from tissues of a fatal case of tetanus, which he named tetanin. This was obtained also from cultures of the bacillus by Kitasato and Weyl. This substance kills animals with the characteristic symptoms of tetanus. But this is not the substance to which is due the intense intoxication of tetanus, and Brieger himself obtained a toxalbumin of much greater toxicity. This toxalbumin, the chemic relations of which we do not know, is probably only an impure form of the specific toxin; a mixture of the precipitated albumins and the toxin.

Brieger and Cohn (1893) were able to make a step in advance in the separation of a purer toxin. They used an intensely virulent veal-bouillon culture of tetanus bacillus. This they supersaturated with ammonium sulphate, and removing the supernatant precipitate, dried it on porcelain in a vacuum. Of this, 1 gm. was obtained for 1,000 c.c. of bouillon; and 1-10,000,000 gm. was sufficient to kill a 15 gm. mouse. But it was still impure. It was dissolved in water and was treated with a small amount of ammonia and basic acetate of lead to precipitate the albumins; dialyzed from twelve to forty-eight hours in running water to get rid of the peptones, salts, etc., and evaporated in vacuo at a temperature of 20 to 22 degrees C. This gave slightly yellow, transparent scales, odorless, with aromatic taste and soluble in water. It gave no reaction to Millon's fluid, nor responded to the xanthoproteic or biuret test. A slight violet color resulted with cupric sulphate and sodium hydrate; and no precipitation with the albumin precipitants, except ammonium sulphate. There was no phosphorus, and but a trace of sulphur. It is not, therefore, to be classed among the albumins. Of this substance but 1-20,000,000 gm. is sufficient to kill a mouse; or, assuming the action of the toxin to be similar in degree upon the human being, but about  $\frac{1}{4}$  mg. would be fatal to a man weighing 70 kg.

Brieger and Boer have lately been able, by another method to procure a purer and more concentrated form of toxin, and also of antitoxin. Instead of alcohol or sulphate of ammonium they used salts of zinc, the sulphate or preferably the chlorid. The filtered tetanus bouillon or the serum was diluted with five volumes of water and to this was added two volumes of a 1 per cent. solution of the salt. After

<sup>18</sup> Psychic Infection; Remarks upon the Probability of a Mental Contagium, N. Y. Med. Record, April 18, 1896.

<sup>19</sup> Crocq fils: L'hypnotisme Scientifique. Rapport à M. le Ministre de l'Intérieur, à de l'Instruction Publique. Introduction de M. le Prof. Pflüger, 1896.

standing a short time a precipitate formed. The antitoxin precipitate is dissolved in slightly alkaline water, a stream of carbonic acid passed through it. With the sulphate, the antitoxin is again precipitated; with the chlorid, it remains in the filtrate, free from the zinc salt. Any traces of the metal are further washed out by treatment with ammonium sulphid. They obtained from 10 c.c. of serum about 0.1 gm. of an antitoxic powder easily soluble in water. The toxin could not be freed from the metal. One liter of bouillon gave 3 gm. of the zinc combination, which contained about 0.3 gm. of organic matter and represented the full strength of the original filtered culture.

Wolinsky made his cultures in a non-albuminous medium composed of water, glycerin, sodium chlorid, magnesium sulphate, potassium phosphate, ammonium lactate and sodium asparaginate. The filtered culture in this medium gives a faint Millon's and xanthoproteic reaction, a slight cloudiness with phosphor wolframic acid, and no immediate precipitate with acetic acid and potassium ferrocyanid; only after six to seven minutes is there a greenish cloudiness formed. He recognized that he had but a very impure principle, but claims that it "appears to belong to the proteid bodies and that it has great similarity to the ferments."

This fact that the toxin is essentially a diastase or zymose was already put forward by Tizzoni and Catanni, a view afterward adopted by Vaillard and Vincent, E. Roux, Faber and others finally demonstrated by Courmont and Doyon. These authors called attention to the important fact that after the injection of the tetanus toxin, there is always a certain period of delay in the development of symptoms—a distinct period of incubation. They show that this is uninfluenced by and bears no relation to the amount of toxin injected. Two hundred c.c. were injected into a dog without the immediate appearance of tetanus, which only developed on the third day. An injection of 4 c.c. gave the same period of incubation. The blood and tissue juice of this dog, however, produced in an injected animal an almost immediate tetanic intoxication.

In an extensive comparison of the chemie and other relations of the several known ferments and toxins, Fermi and Celli combat this idea and try to show that the toxin of tetanus is not to be ranked among the ferments. In reading their work, however, one is not sufficiently convinced of the error, considering the similarity of many of the chemie reactions, which even they show; considering the fact that the toxin in its purity is as yet not isolated, but may still be intimately mixed with some albuminoid body, and considering the clinical facts put forward by Courmont and Doyon, one may, I think, adopt the view that the toxin of tetanus is, at least, akin to the ferments (the zymoses) and that it is by its action on the blood and tissue juices of the organism that the true active intoxicant is produced. At any rate it is justified as a working hypothesis.

Behring and Kitasato in 1890 first report the cure of tetanus and resulting immunity of animals treated with the serum artificially immunized animals. Rabbits rendered immune by their method, bore without fatal result the injection of a virulent culture of the tetanus bacillus (10 c.c.), the minimal fatal dose of which for a non-treated animal was 0.5 c.c. They showed that there was in the blood serum of arti-

cially immune animals a substance that in some way antagonized the action of the bacillus or its toxin, an antitoxin. To quote: "A mouse has been rendered tetanic, it has contracture of its extremities, and seems about to die; it is sufficient to make this injection for a cure to follow so surely and rapidly that a few days after the animal is perfectly well." Their conclusions, however, as to the therapeutic effects were not realized.

Later Behring published his method. At first, following the inoculation, injections of the trichlorid of iodine were made. But it was better to previously add this attenuating substance directly to the culture before injecting.

Five cubic centimeters of a virulent culture containing 0.25 per cent. of the trichlorid were injected into a rabbit. After a lapse of three or four days, another injection of 5 c.c. containing 0.2 per cent. of the iodine. Another pause and another injection containing less iodine, and so on for some six weeks, at the end of which time a degree of immunity was reached equal to 1 in 400 or, according to Ehrlich, to 10 immunity units. That is, of the serum injected into a 20 gm. mouse 0.05 c.c. or 1-400 of the body weight would protect it against the minimal fatal dose of the toxin. Horses were immunized in the same way by using a beginning dose of 10 c.c. of carbonized cultures with 0.25 per cent. of iodine trichlorid added and very gradually increasing the amount of toxin and decreasing the amount of the iodine salt. The degree of immunity reached was 1 to 5,000.

This, however, is only when the injection of the serum is made shortly after that of the toxin. If it is done before, the proportion is larger; instead of 1 to 5,000, it would be 1 to 25,000. Again, it refers to the minimal fatal dose. If stronger doses of the toxin are given, say one hundred times the minimum, the serum must be used in larger amounts, one thousand times as much as before or 1-1,000 of the body weight. This is of interest in the treatment of human tetanus, in which the amount of toxin elaborated, possibly often far exceeds the smallest fatal dose.

Tizzoni and Catanni, soon after the first work of Behring and Kitasato, were able to immunize a dog, a comparatively resistant animal, by injections of small amounts of tetanus toxin and slowly increasing the dose. Unfortunately they were unable to agree with Behring and Kitasato as to the therapeutic success of the antitoxic blood serum. "The development," they say, "of the tetanic symptoms is in no wise hindered when the serum is not injected before their appearance." This result, obtained upon experiment animals, is one that they would do well to apply in the cases of tetanus, in man, which were treated with their antitoxin. Kitasato himself later agreed that the greatest efficacy was observed when the injections of antitoxic serum were made before or immediately after that of the toxin.

Brieger, Kitasato and Wasserman made use of a bouillon made of thymus gland in which to produce an attenuation of the virulence. Successful in preventing tetanus in only 40 per cent. of the animals experimented on, they show that this thymus extract has a distinct toxin-destroying action.

Another method of the attenuation is by means of heat. Vaillard uses filtered cultures that have been heated to 60, 55 degrees C. and so on, gradually dimin-

ishing the temperature and increasing the amounts. Finally Vaillard and Roux make use of a solution of metallic iodine, Gram's solution, commencing with doses in the proportion of one of the iodine to three of the filtered culture and by gradually increasing the ratio were able to completely immunize rabbits. A detailed account of their method is as follows: For about seven weeks a mixture of equal parts of toxin and Gram's solution was injected into a horse in doses increasing from 0.5 c.c. to 10 c.c. Then for a while 4 c.c. increasing to 10 c.c. of toxin and Gram's solution in the proportion of 2 to 1. An injection of 1 c.c. of pure toxin was now given and repeated in increasing amounts until at the end of three weeks the animal could stand 22 c.c. After a rest of a few days 4 c.c. of toxin was given directly by the jugular vein. Five weeks after 70 c.c. could be injected intravenously without ill effects. At the end of a month's interval the serum had an antitoxic power of 1 to 50,000. Treatment was resumed and pushed until 90 c.c. of pure toxin was being injected into the jugular vein. After a pause in the treatment for two weeks, or about seven months from the beginning, the serum was shown to be protective to the extent of 1 to 1,000,000.

How does this toxin act? Many experimental facts have been brought forward to elucidate this point. Roux, and also Buchner, show that a mixture of the toxin and antitoxin retains the properties of the two ingredients; that a mixture neutral and without effect upon a mouse is still toxic for the more sensitive guinea pig. Animals treated with certain microbes, such as prodigiousus, cholera, streptococcus, etc., lose some of their resisting power and become more sensitive to a mixture, which in their normal state would have no effect. This serum then, according to them, is not, strictly speaking, an antitoxin. It does not directly or in vitro destroy the toxin. But it exercises, as Roux puts it, a stimulative action upon the cells of the organism, which augments their energy and they become able to resist the poison.

Behring has shown that an animal may become "over-sensitive," a condition occurring in the process of immunization in which the animals seeming at first immune, succumb to the tetanus toxin, although the blood serum is in a high degree antitoxic. The blood of such an "over-sensitive" horse may, in doses of 4 c.c., immunize another animal.

On the other hand, in a highly immunized sheep the antitoxin may after a time disappear from the blood, without any diminution of the immunity. It is probable that tissue immunity and the formation of antitoxin are not directly related.

On the other side, Fodoroff found that with large doses of the toxin, as sixty times the minimal fatal dose, a certain proportion of the serum necessary to prevent the development of tetanus (3 to 1 in the case of white mice), when previously mixed, had no effect when injected at different points, even when done simultaneously. Animals were injected with antitoxic serum, a dose of 0.02 mg. of which was sufficient to immunize against the minimal fatal dose of toxin in amounts varying from 50 to 200 mg., given in three to five injections. These were found to be resistant to doses of 3, 6 and even 8 mg. of toxin, the minimal lethal dose of which was 0.001 mg., but invariably succumbed to injections of 12 mg., even when given immediately after the immunizing serum. White mice which had received three daily injections

of 50 mg. of dried serum, were given, some a mixture of 50 mg. of serum and 12 mg. of dried filtered tetanus toxin, and others the same amounts of the same substance, but injected at different points. The former animals were unaffected, the latter all succumbed to tetanus. From these experiments Fodoroff assumes that the antitoxin has a toxin-destroying action.

The hypothesis upheld by Courmont and Doyon seems to lend itself more than others to the explanation of these often contradictory facts. The symptoms are produced not directly by bacterial secretion, but by a substance which is the result of the action of a bacterial enzyme. Once this true toxin is formed in the organism, it is doubtful how much it can be affected by the antitoxin, at least directly. It is upon the ferment itself, however, that the antitoxin acts, inhibiting or modifying its action, either directly or by stimulating a cellular resistance.

But these experiments have all been made with the so-called toxin of tetanus. It is the study of the effect of the serum upon animals inoculated with the bacilli themselves, that cause us further to limit its action. The work of Beck is here of interest. He used instead of filtered cultures, small splinters of wood inoculated with tetanus bacilli. A splinter 0.5 cm. long and 2 mm. thick killed a guinea pig of 400 gm. in three to four days. In a series of some twenty-six guinea pigs so inoculated, twelve recovered from more or less severe tetanic symptoms, six died from pneumonia, after an improvement of the tetanus. A series of five pigs which twenty-four hours before the splinter inoculation, were injected with 5 c.c. of a serum of an immunizing power of 1 to 4,000,000, all recovered from mild attacks. Reinoculated some three weeks after, they all died in about four days, showing that the immunity thus produced is of short duration.

Of thirty-eight pigs injected with 5 c.c. of serum at periods varying from one hour before the inoculation to twenty hours after, fourteen died of tetanus; all but one that were injected sixteen hours and over after the inoculation succumbed. The deductions we may draw from his work are that after a given period after the tetanus toxin has once developed in the organism the serum, in animals at least, is powerless.

And now the subject of human tetanus. Approaching it from the laboratory one can not but feel somewhat skeptical in regard to what is claimed for the serum by its most ardent adherents. The difference, however, of the pathologic reactions of the human and other animal organisms show us that we must look at this side of the matter from the clinic standpoint only. In general, do statistics show any reduction in the mortality in tetanus treated with antitoxin, or does such treatment seem to have any effect upon the symptoms in individual cases?

The mortality from tetanus is difficult to determine. Poucet reports 713 cases with a mortality of 90.6 per cent.; in the Civil War it was 89.3 per cent.; Richter gives 88 per cent.; Somain, 56 per cent.; Roux and Vaillard 50 per cent.; Knecht 45 per cent.; Albertoni 24 per cent.; Behring 20 per cent.; Verneuil claims 50 per cent. recoveries with large doses of chloral. In some thirty-five cases that I have collected from the current literature, the mortality is about 40 per cent. The higher percentages have been taken generally from war records, and are therefore too high; and, on the other hand, Albertoni's statistics seem too

low. It is probable the figures adopted by Roux and Vaillard are nearly correct, say from 45 to 50 per cent.; 47 per cent. is the average of the various percentages given. I have collected from the recent literature sixty-eight cases that were treated with the various antitoxins. Among these there have been thirty deaths, giving a mortality of nearly 47 per cent. But we can judge better if we examine more in detail.

Richter and Rose give the mortality in tetanus, in which the symptoms have appeared within five days after the inoculation, as 96 per cent.; the Surgical History of the War says that 85 per cent. died in the first week; of twenty cases with a mortality of 45 per cent., the death rate of those in which the period of incubation was from one to five days was 100 per cent.; from six to eight days 80 per cent.; from nine days or more 0 per cent.

We may safely say that cases developing during the first week rarely, if ever, recover, and cases, the incubation of which is over two weeks, rarely die. Of the sixty-eight cases here collected, which were treated with the antitoxic serum, but sixty-one have been recorded with sufficient detail from which to draw any conclusions. The mortality of the whole number is 41 per cent. Of the sixty-one cases thirty-six recovered, giving also a mortality of 41 per cent. A comparison of this with the probable percentage of deaths in cases treated by other means, 50 to 45 per cent., leads us to no verdict but that of not proven.

The following condensed table shows mortality of cases arranged according to the period of incubation:

Period of Incubation.	Deaths.	Recoveries.	Percentage of Mortality.
1 to 5 days . . . . .	7	1 (?)	87.5 (?)
6 to 14 days . . . . .	16	25	38
15 days and over . . . . .	2 (?)	10	16.66 (?)

The cases classed according to their incubation periods show a like similarity. Of eight in which this was from one to five days, only one recovered, and this (32) was regarded by the physician as of somewhat doubtful character. When the disease developed in from six to fourteen days after the infection there is a much lower death rate. Of forty-one cases, twenty-five recovered and sixteen died. And with an incubation period of fifteen days, two of twelve cases succumbed. These two were cases in which the period of incubation is extremely doubtful. In one the first appearance of symptoms took place fifteen days after the extraction of a number of teeth. In the other the patient, who was a stableman, had gone on attending to his duties in the stable for three weeks after his injury. In all probability the inoculation in these cases took place at a much shorter time from the development of the tetanus. If this is so, the mortality of this period would be nil.

The only conclusion it seems to me is that those cases in which the symptoms appear before the sixth day die, in spite of any antitoxic treatment, and that those in which the development of the disease is delayed beyond the second week would recover without any such treatment. Possibly the number of cases as yet reported is too small to warrant this general statement, but the results are not encouraging.

There seems to be no relation in the severity of the symptoms to the prognosis. The temperature which is generally normal or subnormal, rises more often in the fatal cases (nineteen times in twenty-seven) but this is no criterion. The shortness of the incubation period and the rapidity of the onset are two important

TABLE SHOWING THE DAYS AFTER THE APPEARANCE OF SYMPTOMS ON WHICH THE INJECTIONS OF SERUM WAS BEGUN.

Date of Disease when Injections began.	Period of Incubation.					
	1 to 5		5 to 14		15 and over	
	Died.	Rec.	Died.	Rec.	Died.	Rec.
0 . . . . .	1		2

factors. When we remember the experimental proof that the sooner after inoculation the antitoxic serum is injected, the more likelihood there is of some beneficial result, we should expect, if there be any such effect, to find it among those cases in which the treatment was earliest begun. A glance at the table will show that this is not the case. Of the sixteen fatal cases, whose period of incubation ranged from six to fourteen days, fourteen had the treatment begun during the first four days, and of the twenty-five in which the serum was injected before the fifth day, fourteen were fatal. Among the sixty-eight cases but twenty-two are reported as causing an immediate improvement in the character of the symptoms, and in many of these the injections were begun so late in the course of the disease that one hesitates to ascribe this improvement to anything but a coincidence. This agrees with many of the authorities. Berger says that "without rejecting the injections of antitoxic serum in the treatment of tetanus, we can have but the most limited confidence in its curative efficacy." Roux has said that he has never seen the serum have the least effect upon the course of the disease.

Then the early treatment after the appearance of symptoms has no appreciable effect. The symptoms are caused by the action of tetanus toxin already elaborated and producing its intoxicant effect upon the cells of the organisms. It is then too late to hope for either any antitoxic or any immunizing action. Could we but make the injection soon after the time of inoculation we might expect some result, but unfortunately this is impossible.

Another thing we notice in examining the several cases, and that is the small amounts given. Beck shows that with the Behring's serum of 1-4,000,000 immunizing power which he used in his experiment, 1-100 of the body weight must be injected. This for a man of 60 kg. would be at least 600 c.c. of serum. Much of the serum used in human tetanus is much less powerful than this.

Tizzoni and Cattani claim an immunizing power of 1 to 100,000,000 for theirs. However, Hübener has shown it to be much less, at least as furnished by Merck, and Behring and others say it is completely worthless. Roux has recently prepared a serum with an immunizing power of 1 to 1,000,000,000.

There is one department in which the serum has been of value, and that is in veterinary medicine. Dr. Nocard of Altorf gives some very favorable

reports. These come from veterinarians and others throughout France, who have used the serum immediately after operations on animals. Among 375 animals (327 horses, 47 lambs and 1 ox) the injections were successful and not a case of tetanus occurred. During the same time fifty-five cases of tetanus were observed among non-inoculated animals. Two injections of the serum are given, of 20 c.c. and 10 c.c. with a fifteen days interval between.

Picard records that, during 1891-94, fifteen horses succumbed; during 1895, in which year he used the antitoxic serum, none. Coret lost, previous to 1895, from thirty to forty horses yearly by tetanus; in 1895 none succumbed. Before the use of antitoxin he lost an average of fifteen horses each semester; in 1895, fifty-four suffered from wounds both accidental and operatory, and none died. During the same semester, among non-treated animals seven died from tetanus. Therefore eight horses were saved by the use of the antitoxic serum.

Following traumatic lesions in animals, tetanus is not such an uncommon accident as it is in man, and we may expect, as seen by the above, some definite results in its use in such cases, the more especially as it is given as soon as possible after the injury.

But in the human race we can not say that it has had that success which we first hoped for it. We should not yet condemn it, but await the results of larger doses and more powerful serum.

### ON THE TOXIC ACTION OF DISSOLVED SALTS AND THEIR ELECTROLYTIC DISSOCIATION.

Read in the Section on Materia Medica, Pharmacy and Therapeutics at the Forty-seventh Annual Meeting of the American Medical Association at Atlanta, Georgia, May 5-8, 1896.

BY LOUIS KAHLENBERG, PH.D., AND  
RODNEY H. TRUE, PH.D.

LABORATORIES OF THE SCHOOL OF PHARMACY, UNIVERSITY OF WISCONSIN.

During the last decade, work in physics and chemistry, especially in physical chemistry, has been characterized by a thorough and systematic study of solutions from both the theoretic and the experimental point of view. As a result of the activity along this line, our knowledge of the conditions of dissolved substances contained in solution has been greatly extended. Thus Van't Hoff of Amsterdam, basing his argument upon the osmotic experiments of Pfeffer of Leipzig, extended the principle of Avogadro to dilute solutions showing that equal volumes of dilute solutions having the same osmotic pressure and the same temperature contain an equal number of molecules. When Avogadro put forth his hypothesis that equal volumes of all gases under the same conditions of temperature and pressure contain an equal number of molecules, facts were found that apparently were strongly adverse to this view. Thus, when the vapor density of the chlorid of ammonium was determined, it was found to be only a little more than half as great as was required by the principle of Avogadro. This fact caused at first much opposition to Avogadro's views, but this opposition was finally cleared away when it was shown that, in the vapor of chlorid of ammonium, we have not simply the molecules of that salt, but also hydrochloric acid and ammonia molecules, the products into which the chlorid of ammonium in the vapor form is to a large degree broken up or dissociated.

The theory of Van't Hoff has had a similar difficulty to contend with. As he himself showed, his theory did not represent the facts when working with aqueous solutions of salts, acids and bases, in short, with solutions that are conductors of electricity. In his mathematical formulæ, Van't Hoff introduced a factor to overcome the departure from his theory presented by such solutions. Soon, however, Arrhenius from the interrelation between the lowering of the freezing point of the solutions and their electrical conductivity, came to the conclusion that in aqueous solutions, salts, acids and bases are to a greater or less extent broken up or dissociated into part-molecules or ions (a term originated by Faraday). These ions are charged with electricity each gram-equivalent bearing 96,540 coulombs. This latter figure is derived from experiments on electrolysis. It has well been termed the constant of Faraday's law.

Arrhenius published his theory of electrolytic dissociation in 1887 and all investigations made on salt solutions, including those of acids and bases, have confirmed this theory. In addition to the lowering of the freezing point and the electric conductivity, the elevation of the boiling point, the specific volume, as well as the optical and thermal properties, all strongly support the views of Arrhenius. This theory has given a clear insight into the processes going on in voltaic combinations and makes it possible to calculate with accuracy in advance what will be the electromotive force of a voltaic combination. In the hands of Ostwald, it has placed analytic chemistry on a firm scientific basis. In short, all the physical and chemical properties of aqueous solutions of electrolytes are well explained by the assumption that in these solutions, the dissolved substances are split up into part-molecules or ions, and that the various properties of the solutions are due to the properties of the ions. The more dilute the solution, the more is the dissolved substance dissociated and at infinite dilution, this dissociation is complete. In the case of many salts, however, namely those of the stronger bases, the dissociation goes on very rapidly with the increasing dilution so that in case an equivalent in grams is dissolved in about 1,000 liters of water the dissociation is practically complete.

Viewing these things in the light of the theory of Arrhenius we have, for example, in a solution of sodium chlorid, sodium ions and chlorin ions beside a certain amount of dissociated sodium chlorid molecules. Experiments on the electrical conductivity show that in this case, dissociation is practically complete when one gram-molecule (*i. e.*,  $23+35.5=58.5$  grams) of the salt is dissolved in 1,000 liters of water. We have at this dilution not NaCl molecules in solution but Na ions and Cl ions; we denominate them in the usual way, +Na and -Cl.

The question has often been raised: In what way do Na and Cl in the ionized state differ from ordinary sodium in the metallic state and ordinary chlorin, respectively? The difference lies in the energy possessed. Ten grams of sodium ions, for instance, contain less energy than do ten grams of metallic sodium. Supply the energy to the ions as in the case of electrolytes and we convert the ions to the metallic sodium. Sodium ions and metallic sodium are, therefore, not the same. The lack of understanding on this point caused a tardy acceptance of the dissociation theory at first, notably on the part of English chemists.

Hydrochloric acid dissociates into  $+H$  ions and  $-Cl$  ions; the  $H$  ions bearing the positive charge and the  $Cl$  ions bearing the negative charge. There exists in the solution necessarily as many positive ions as negative ions in order that electric neutrality may be preserved. A dilute solution of sodium chlorid and one of hydrochloric acid have in common  $Cl$  ions, their difference is due to the fact that the positive ion of the former is  $Na$ , and of the latter,  $H$ . To this difference is to be ascribed all the differences seen in the properties of the two substances. In general, solutions of all acids contain hydrogen ions, solutions of all chlorids contain chlorine ions, those of the sulphates contain  $SO_4$  ions, those of the nitrates contain  $NO_3$  ions. Salts of copper contain copper ions, salts of lead contain lead ions. In general, if we let  $BA$  represent the formula of a salt,  $B$  representing the basic radical and  $A$  the acid radical, then in dilute aqueous solutions, this compound is to a greater or less extent dissociated into the ions  $B$  and  $A$  and all the physical and chemic properties that such a solution possesses are due to the properties of the ions in the solution. If it is true that all the physical and chemic properties of aqueous solutions of salts, acids and bases are due to the properties of the ions, plus those of the undissociated substances they contain, does it not seem probable that the physiologic properties of such solutions are also due to these? This thought, simple as it is, has to our knowledge never before been expressed.

Many investigations have been made on the physiologic action of aqueous solutions of salts on bacteria and higher forms of plant life as well as on animals. The strength of the solutions with which these experiments were made has always been expressed in per cent. and it is probably for this reason that general considerations have entirely escaped observation. If a very dilute solution of sodium chlorid differs from a dilute solution of hydrochloric acid only in the fact that the former contains sodium ions and the latter hydrogen ions, then the poisonous action of the latter is plainly due to the hydrogen ions present. In like manner comparing a very dilute solution of sodium nitrate with a similar solution of nitric acid, the poisonous nature of the latter would be due to the hydrogen ions present. In general, if the solution is sufficiently dilute so that the acid dissolved is practically completely dissociated and the acid radical is of such a nature that in this concentration its ions have practically no poisonous action, the toxic value of the acid solution is due to the hydrogen ions present.

Now strong acids are highly dissociated in watery solutions, thus rendering them relatively rich in hydrogen ions. Weaker acids are less dissociated since their solutions contain less hydrogen ions. It must always be borne in mind that the salt remaining undissociated is present in the solution as well as the ions. That these undissociated remainders and the ions of the acid radical also exert an effect, is not to be denied but in many cases, such as that of the  $Cl$  ions in hydrochloric acid, the action is practically nil at the strength at which hydrochloric acid is effective, since a solution of common salt containing as many  $Cl$  ions as the  $HCl$  solution in question, is ineffective. The same reasoning may be applied to nitrate of sodium and nitric acid; also to sodium hydroxid and common salt. In the latter case, the solutions differ from each other in that the former

contains  $OH$  ions, whereas the latter contains  $Cl$  ions. All solutions of the bases (lyes) contain  $OH$  ions and their toxic action is due to their  $OH$  ions alone provided the metal or corresponding radical, the cation, is itself harmless at the particular concentration used. We see then that  $H$  ions and  $OH$  ions have toxic properties. That it is the ionized condition that brings this about, is shown by the fact that in the case of water where we have these constituents in practically an undissociated state there is no toxic action.

The poisonous property of a very dilute solution is, then due to the ions it contains, and if at the particular dilution in hand only one physiologically active ion is present, the effectiveness of the solution is to be attributed to that one ion. Solutions of hydrochloric, nitric and sulphuric acids are nearly completely dissociated when an equivalent in grams is dissolved in 1,000 liters of water. Hence such, or more dilute, solutions of these acids, when chemically equivalent quantities are dissolved, ought to have the same toxic effects, the  $Cl$ ,  $NO_3$  and  $SO_4$  ions in such dilution being harmless. That these radicals are harmless is shown by the effect that like concentrations of the sodium salts of these acids are harmless.

We have tested this point experimentally for the higher plants by ascertaining the strength of solution in which the roots of the ordinary field lupine (*Lupinus albus*) will just live. We have found that the limit of these acids is reached in a solution containing one equivalent in grams in 6,400 liters of water. We may say, then, that one gram of hydrogen ions distributed through 6,400 liters of water will give a solution in which roots of the lupine will just grow. It is entirely immaterial at this dilution whether we take hydrochloric, nitric or sulphuric acids, the toxic action of the solutions is the same provided the solutions contain the same amount of hydrogen ions. The molecular weight in grams, or simply gram-molecule, of acid sulphate of potassium in 6,400 liters would contain as much ionized hydrogen as a gram molecule of hydrochloric acid and should therefore have the same effect toxically. This was confirmed by experiment.

The action of about forty acids was investigated and the results point to the fact that in many of them the poisonous effect is due in great part to the hydrogen present as ions. In some of these acids, dissociation is not complete at the concentration-limit found; in other cases, the harmful influence of the anion can not be neglected.

The following table shows in the first column the names of acids investigated; in the second column is the concentration just allowing growth, expressed in fractions of a gram-equivalent of the acid per liter of water.

TABLE I.

Acids.	Concentration-limit. Equivalent.	Acids.	Concentration-limit. Equivalent.
Hydrochloric,	1-6400	Malonic,	1-3200
Nitric,	1-6400	Potas. acid oxalate,	1-3200
Hydrobromic,	1-6400	Ortho-nitro-benzoic,	1-6400
Acid potas. sulphate,	1-6400	Meta-nitro-benzoic,	1-12800
Sulphuric,	1-6400	Para-nitro-benzoic,	1-12800
Phosphoric,	1-6400	Mono-chlor-acetic,	1-6400
Chromic,	1-12800	Di-chlor-acetic,	1-6400
Hydrocyanic,	1-12800	Tri-chlor-acetic,	1-12800
Formic,	1-6400	Mono-brom-acetic,	1-12800
Acetic,	1-1600	Cinnamic,	1-12800
Propionic,	1-3200	Meta-oxy-benzoic,	1-3200
Butyric,	1-3200	Para-oxy-benzoic,	1-1600
Valeric,	1-3200	Hippuric,	1-6400
Benzoic,	1-6400	Gallic,	1-6400

Salicylic,	1-6400	Protocatechuic,	1-3200
Oxalic,	1-3200	Citric,	1-3200
Succinic,	1-1600	Aspartic,	1-6400
Tartaric,	1-6400	Glycolic,	1-6400
Fumaric,	1-6400	Malic,	1-3200
Maleic,	1-3200	Lactic,	1-3200

A glance at the results shows that the concentrations at which the plants survive vary from 1-1600 gram-equivalent to 1-12800 gram-equivalent.

For mineral acids and other strong acids in which at the dilution under consideration the anion exerts practically no influence, the concentration at which the lupines survive is determined solely by the hydrogen ions present. The concentration found is 1-6400 gram-equivalent per liter. When the lupines live in a greater concentration than this, dissociation, even in the great dilution used, is not complete. In the cases where the limit lies at 1-12800 gram-equivalents per liter, the influence of anion and in some cases, HCN, for example, the dissociated remainder of the acid, has to be taken into account.

Since this is to be regarded as a preliminary report, a discussion of the action of the individual acids is not given. This may be sought in the complete report which is to appear later.

Of especial interest is the conduct of boric acid. This is a very weak acid and is but slightly dissociated even in dilute solutions and lupine roots survive in a concentration of 1-25 gram-equivalent per liter. When mannite, which in itself is not harmful to the plant, is added to the boric acid, boro-mannitic acid is formed which is stronger than the original acid. Its solutions contain more hydrogen ions and hence should be more deadly to the plant. Experiment corroborates this since the limit-concentration of the boro-mannitic acid was 1-100 gram equivalent of the boric acid to the liter.

The following table shows a list of the salt solutions investigated. The first column enumerates the salts, the second column is the concentration expressed in gram-equivalents per liter at which the plants just survived. In the case of FeCl<sub>3</sub>, the concentration is otherwise indicated.

TABLE II.

Salt.	Concentration-Limit.
AgNO <sub>3</sub> . . . . .	1-204600 equivalent.
Ag <sub>2</sub> SO <sub>4</sub> . . . . .	1-204600 "
HgCl <sub>2</sub> . . . . .	1-12800 "
HgCn <sub>2</sub> . . . . .	1-51200 "
KCn . . . . .	1-6400 "
CuCl <sub>2</sub> . . . . .	1-25600 "
CuSO <sub>4</sub> . . . . .	1-25600 "
Cu (C <sub>2</sub> H <sub>3</sub> O <sub>2</sub> ) . . . . .	1-25600 "
NiSO <sub>4</sub> . . . . .	1-25600 "
FeSO <sub>4</sub> . . . . .	1-12800 "
FeCl <sub>3</sub> . . . . .	{ Fe. 0.0025 gram per l. Cl. 0.0047 " "
CoSO <sub>4</sub> . . . . .	1-12800 "
Co(NO <sub>3</sub> ) <sub>2</sub> . . . . .	1-12800 "
Cd(NO <sub>3</sub> ) <sub>2</sub> . . . . .	1-102400 "

From the above we see that the lupines just survive in a solution of silver sulphate containing 1-204600 gram-equivalent per liter. Since the same is true of silver nitrate, it follows that the silver in these solutions is the active constituent. Moreover, it is silver in the ionized state. To show this, silver nitrate was treated with potassium cyanid in slight excess so as to just dissolve the precipitate. It is well known that such a solution contains the ions + K and - AgCn; that is to say, there are almost no silver ions present in such a solution, the silver being combined with the Cn radical to form the complex ion AgCn. It was found that such a solution containing as much

as 1-12800 gram-equivalent of silver per liter still allowed the plants to grow. The copper salts, the sulphate, chlorid and acetate, all gave the same concentration limit, viz., 1-25600 gram-equivalent per liter. There can be no doubt that here the copper present does the work. A Fehling's solution contains copper but, as has been recently shown, is poor in copper ions. We found that a Fehling's solution containing 1-200 gram-equivalent of copper per liter still allowed growth. This Fehling's solution was not made in the usual way, but, to avoid the presence of salts in overabundance, cane sugar, copper sulphate and just enough caustic potash to dissolve the precipitate were mixed.

The limit for cobaltic nitrate and cobaltic sulphate was found to be again at agreement at 1-12800 gram-equivalent per liter. This is a measure of the poisonous effects of cobalt ions. The corresponding limit for nickel ions is 1-25600 gram-equivalent per liter.

From Table II, the corresponding figures for Fe ions is 1-12800 gram-equivalent per liter; for cadmium, 1-102400, for mercury, 1-12800; HgCn is toxically more active because the Cn ions in themselves are poisonous as is also the undissociated HgCn<sub>2</sub>.

In the case of silver and copper, it has already been shown that when these metals are present in the solutions in compound ions the toxic action is much diminished. When to mercuric chlorid, dextrin in excess is added and then enough caustic potash to precipitate the mercury present under ordinary conditions, no precipitate forms. We have here, as it were, a Fehling's solution containing mercury instead of copper. The mercury is not present in the solution as ion but is bound to the dextrin with which it forms a complex ion which is of much less poisonous action than the mercury ion. Indeed, such a solution as that just described may contain 1-3200 gram-equivalent of mercuric chlorid and still permit growth. The corresponding limit for mercuric chlorid alone is 1-12800 gram-equivalent per liter, or one-fourth as strong.

The results obtained with iron salts are of interest. Dialyzed iron chlorid containing 0.0477 grams of Fe and 0.0047 grams of chlorin per liter, just allowed plant growth. A solution of ferric chlorid first allowed growth at a much greater dilution. The limit-concentration contained 0.0025 grams iron and 0.0047 grams chlorin per liter. The dialyzed iron contains hardly any ferric ions as is shown by the fact that potassium ferrocyanid produces no precipitate in such a solution.

Again, solutions of potassium ferrocyanid contain K ions and FeCn<sub>6</sub> ions; potassium ferricyanid solutions contain K ions and FeCn<sub>5</sub> ions. Here we get the effect not of the Fe ions, nor of Cn ions but of the complex ions mentioned. These are weak toxically as shown by the fact that in potassium ferrocyanid solutions lupines live in a concentration of 1-200 gram-molecule per liter.

These results are collected in Table III.

TABLE III.  
METALS IN COMPLEX IONS.

Substance.	Limit.
AgNO <sub>3</sub> . . . . .	1-12800 gm. equivalent per l.
HgCl <sub>2</sub> . . . . .	1-3200 " "
CuSO <sub>4</sub> . . . . .	1-200 " "
K <sub>3</sub> FeCn <sub>6</sub> . . . . .	1-200 " "
K <sub>4</sub> FeCn <sub>5</sub> . . . . .	1-200 " "
FeCl <sub>3</sub>	
Fe. . . . .	0.0477 " "
Cl. . . . .	0.0047 " "

## METALS IN SIMPLE IONS.

Substance.	Limit.
AgNO <sub>3</sub> . . . . .	1-204600 grm. equivalent per l.
HgCl <sub>2</sub> . . . . .	1-12800 " " "
CuSO <sub>4</sub> . . . . .	1-25600 " " "
KCl . . . . .	1-6400 " " "
FeCl <sub>3</sub> . . . . .	0.0025 " " "
Fe . . . . .	0.0047 " " "
Cl . . . . .	" " "

Here the decided contrast, at times very striking, speaks for itself.

These results have in a large measure been confirmed by Mr. F. D. Heald, Fellow in Botany at the University of Wisconsin, who investigated the action of like substances on various other plants.

That the modern theory of solutions would throw light on the physiologic action of solutions was to be expected. We have shown that, in the case of plants, solutions of the electrolytes derive their toxic action from the ions into which they split up in great dilutions, the undissociated parts coming into account only when dissociation is not practically complete. We have here a recognition of the theory of electrolytic dissociation by the organic world. Any one inspecting Miquel's table of the efficiency of antiseptics in Sternberg's "Manual of Bacteriology" at the same time bearing in mind the theory of Arrhenius will, although concentrations are given by per cent. instead of chemieal equivalents, be able to see the corroboration of this view.

In seeking to apply this modern theory of solutions to the physiologic action of the same, we have dealt only with the higher plants thus far. Investigations along this line in bacteriology are now in progress at the University of Wisconsin, and their extension to animals is contemplated.

By working along this line, it is hoped to place the knowledge of the physiologic action of solutions of electrolytes on a better basis than the empirical one on which it has thus far rested. It seems not too much to expect that the effects of such study will be felt in agriculture, whereas its application to bacteriologic study will be highly important to our knowledge of antiseptics. The systematic study of the effects of solutions on animals from the standpoint of the new theories bids fair to yield results for the therapist. For example, if, as we have found, silver ions are very harmful to plants, then we can readily see why silver foil placed upon a wound should act as an antiseptic. The small amount of silver ions that are formed, suffice in cases to prevent putrefaction.

It is clear that the mere presence of a metal in a solution does not warrant us in drawing conclusions concerning its physiologic strength; we must also know whether the metal exists in the solution as simple ions or combined with other radicles to form a complex ion. If the addition of certain substances to a solution containing a physiologically active ion forms a complex ion of much less powerful action, it follows that these additional ingredients give us a means of reducing, so to speak, the physiologic action of the simple ion.

This paper is intended simply as a preliminary report on the work already done. The results are soon to be published in full together with the details concerning the methods employed. We shall also take this opportunity to call attention to the further applications of this view of solutions to physiologic problems.

## JOINT PHARMACOLOGIC INVESTIGATIONS BY THE AMERICAN MEDICAL ASSO- CIATION AND THE AMERICAN PHARMACEUTICAL ASSO- CIATION.

Read in the Section on Materia Medica, Pharmacy and Therapeutic at the Forty-seventh Annual Meeting of the American Medical Association held at Atlanta, Ga., May 5-8, 1896.

BY H. H. RUSBY, M.D.

NEW YORK.

When one examines the pharmacologic portions of the many ponderous volumes composing the index to the Surgeon-General's library, and those of the Index Medicus, by which the former has been succeeded, remembering that a very large part of pharmaceutical literature is not here represented, the conviction is forced upon him that our knowledge of the practical utility of medicinal plants is small beyond all reasonable comparison with the amount of time that has been bestowed upon their study. This fact is not difficult to explain, at least in part. It is largely due to the method, or rather want of method which has prevailed, by which partial investigations have been made by individuals without regard to their relation to the complementary parts, these being left undone, the part performed remaining unutilized and becoming finally buried and forgotten. This neglect has been made farther operative by the habit of investigators of failing to search the work of previous investigators in the same lines before performing their own portion, so that the same work has been duplicated over and over again, and in such a way as not only to fail of confirming, refuting, or of supplementing conclusions already reached, but in very many instances of unnecessarily and mischievously coming into conflict with them. This charge against investigators is fully and eloquently sustained by the small subscription list of the Index Medicus for many years past, throughout its entire history in fact. No class is more culpable for this neglect than medical editors, whose duty of criticising and weeding out contributions on these lines has been almost utterly neglected. This again is in a large degree due to the great number of medical journals, run almost confessedly for the most part as advertising sheets, and recognizing quantity with little regard to quality in the contributed matter.

An almost equally responsible factor is the narrow view which physicians, and especially medical teachers, have been taking of their responsibilities in the department of pharmacology. In leaving to the pharmacist the practical details connected with botany and pharmaceutical chemistry, they have gone to the extreme of ignoring these subjects almost altogether in principle as well as in fact, and have as an inevitable consequence become incapable of utilizing the rich materials which have been placed within their reach by pharmaceutical investigators. In the investigation of pharmacology pharmacy has, during the last decade, very far outstripped medicine. "Why does not the medical profession catch up," would have been a very pertinent, even if not wholly respectful title for this communication.

The joint section of materia medica and therapeutics of these two associations, which section should change its name to "The Joint Section of Pharmacology," is altogether the most competent and appropriate agency for correcting the defects to which ref-

erence has been made, and it is this which constituted the chief hope in its establishment by its leading promoters. To the great majority of observers in both professions it has never appealed from this standpoint. They appear to have seen in it merely an influence for the promotion of cordiality between physicians and pharmacists, either from sentimental considerations merely, or to accomplish the negative result of checking the friction which was apparent in certain quarters.

In this direction it has justified our expectations and we are satisfied that it has proven a success. But it must begin to do something more positive if it would not soon begin to act as a dead weight. This is to promote a new method of undertaking and carrying out pharmacologic investigations.

When the writer expected to act as chairman of the delegation from the American Pharmaceutical Association to this meeting, he planned to propose certain changes, having this object in view, in the manner of carrying on our joint work. Although absence prevents his official action in this direction, it appears desirable that his ideas should be informally presented.

The chairman of this Section and that of the delegation have followed the ordinary custom in such bodies, of contenting themselves with attending to the routine business of their offices and issuing general invitations to the members to present contributions. As a result the proceedings have been somewhat heterogeneous in character. While it is desirable that members should be left free to select any subjects they prefer, and while nothing could or should be done by a chairman to deter any one from so contributing, yet it would seem very desirable that at a meeting so peculiarly adapted as this is to the performance of joint work, some such work should be specially arranged for in advance by concerted action by the two chairmen. The chairman of the Section is elected at the preceding meeting, but the chairman of the delegation is appointed by the president of the American Pharmaceutical Association, and it has not been customary for this appointment to be made until quite late in the year. Selection of the delegates has thus to be made by correspondence, extending often over a long period, and when arrangements are perfected there is no time left for special investigation work to be done by the members of the delegation, of such a character that it would fit with related work done by the members of the Section.

The writer would therefore suggest that the president-elect of the American Pharmaceutical Association should appoint the chairman of the delegation during the session of the American Pharmaceutical Association at which he is elected, and that chairman should proceed immediately to act with the president in making up a list of delegates. The chairman should then at once confer with the chairman of this Section in regard to undertaking one or more definite pharmacologic investigations, to occupy one or more members of each of the contributing bodies. The members to do the work should be selected and after acceptance should place themselves in correspondence with one another for carrying out the work in a manner calculated to reach some definite and completed result.

An instance of failure in such an attempt in the case of the present meeting will illustrate the principle involved. It was the desire of the writer to have the subject of the viburnum barks investi-

gated. A thorough chemical study of *V. prunifolium* was first to be made and the constituents isolated in sufficient quantity to admit of physiologic experiment by some member of this Section. The active constituent or constituents being thus determined, the related species were to be examined with reference to the possession of such constituents, as well as of others, so that a just conclusion could be reached as to their claims for recognition by the Pharmacopeia and, if recognized, then as to their recognition separately or under one definition. When the attempt was made to put this plan into execution, it was found impossible to complete the work in time for the meeting, though this would have been possible had it been started at the beginning of the preceding year. There is no reason why such a plan of work by the proposed method should not run through two or more years, if its completion in one year were found impracticable. The writer believes that important practical results would follow the adoption of this plan, or some modification thereof.

### PRESCRIPTION WRITING AND PHARMACY AS PRACTICED IN OUR LARGE HOSPITALS AND DISPENSARIES.

Read in the Section on *Materia Medica, Pharmacy and Therapeutics*, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY HENRY R. SLACK, PH.M., M.D.  
SECRETARY GEORGIA BOARD OF PHARMACY.  
LA ORANGE, GA.

My attention was first directed to this subject by an editorial in the *American Medico-Surgical Bulletin* from the able pen of Dr. Wm. Hy. Porter, in which he very forcibly portrayed the evil of stock prescriptions in the hospitals. At first I rather thought, that like most reformers, he had represented the practice and the evils thereof in somewhat extravagant terms, but closer personal observation has convinced me of the correctness of his views.

Vibration is nature's law; everywhere do we notice action and reaction, condensation and rarefaction, crest and trough. Even the forces that apparently move in straight lines, when more closely studied, are found to be an aggregation of an infinite number of minute vibrations too small for the unaided eye to measure.

The noble art and science of medicine is no exception to nature's law of vibratory motion; indeed, notwithstanding her boasted conservatism she is largely the creature of fashion. Fortunately for suffering humanity, her styles do not change quite as often as the seasons, and when they do, there are usually a few facts, some reasons and more theories to explain the revolution than are produced in defense of the cut of a coat; but the reaction comes just the same.

At present we are in the midst of a season of expectancy, as a natural reaction from the polypharmacy hypertherapy of the past. Serotherapy and animal extracts seem to be the coming fad, though the quackish methods adopted by some of its promoters and manufacturers have somewhat chilled the ardor of the regular profession. It matters little whether we float on the crest of expectancy or struggle in the trough of empiricism, we find good company in both situations. Hippocrates and Celsus, Trousseau and Sydenham, Chapman and Todd, Osler and Wood represent different ideas in medicine, but are names we all honor. Wherever we are, let us "act well our

part, for there all the honor lies." Whether clinicians or therapists, when medicines are used the prescriptions should be properly written and accurately filled.

Four months spent as a student and visitor in the largest and best equipped medical colleges and hospitals in New York, Philadelphia and Baltimore, has convinced me that there is more room for improvement in prescription writing and pharmacy than in any other art there practiced.

Being interested in this department, I visited the pharmacies of these colleges and was surprised at the careless, almost slovenly, manner in which the prescriptions were written, and as might be expected, the filling was no improvement on the writing.

Analysis of 100 prescriptions found on the files of each of the five leading colleges in the East and three in the West may be of interest.

	Metric system used.	Correctly written.	Incorrectly written.	Symbols.	Stock R.
A.	0	52	48	45	45 Pa.
B.	6	64	36	36	36 J. H.
B. Dis.	4	33	67	65	65 J. H. D.
C.	0	90	10	3	13 Jef.
D.	5	96	4	2	6 P. G.
E.	1	98	2	0	2 P. C.
Western Colleges.					
F.	40	65	35		90 N. W.
G.	8	33	67		3 P. G.
R.	0			All symbols.	100 R.

The analysis of the prescriptions from the western colleges were made by my friend and pupil, Mr. W. S. Davis, now a student in Chicago.

From a consideration of these figures it will be seen that the art of prescription writing is rather below par, even in our oldest and youngest and strongest medical colleges.

Although the physicians are presumed to be familiar with the metric system, it is used in less than 3 per cent. of the prescriptions filled in the eastern hospitals. In this respect the West shows her progressive spirit, for there we find the metric system used in 24 per cent. of the prescriptions. The conservatism and training of the East shows in the correctness of the prescriptions as written, for here we have 72 per cent. correct while in the West only 49 per cent are placed in that column. How far short are our colleges and hospitals in both sections in this important particular appears when we consider that nearly one-third of all the prescriptions are incorrectly written.

The chief error lies in the careless use of symbols, not chemic, but abbreviations understood only by the pharmacist, standing for some stock prescription, such as:

R H. S. ʒi  
for  
R Hydrargyri bichloridi . . . . . 0.065  
Potassii iodidi . . . . . 30  
Aque puræ, q. s. . . . . 30 c.c.  
Mix. Sig.

or  
R M. G. A.  
for one of Dr. Pepper's favorite prescriptions:  
R Tr. nucis vomicæ . . . . . 4 c.c.  
Tr. gentianæ co. . . . . 45 c.c.  
Sodii bicarbonatis . . . . . 8  
Aque menthæ pip., q. s. . . . . 180 c.c.  
Mix. Sig.

Using signs and stock remedies gets the prescriber into the very careless and harmful habit of fitting his symptoms to his remedy, instead of the treatment to

the disease. This is one cause of the rapid growth of that most injurious form of all nostrums, so-called physician's formulæ, the ingredients of which are not known either to the physician or the pharmacist, and are used to the detriment of the former's brains and self-respect, and the latter's skill and profit.

This careless prescription writing is an injustice to the students, especially the post-graduates, many of whom graduated five or ten years ago, when only two courses were required. These men, feeling the deficiency in their early training, or wishing to brush up in some particular branch, go to the large schools and hospitals for thorough training and instruction. Imagine their surprise when after a half hour's thorough examination of blood, heart, lungs, liver, stomach and kidneys, a prescription is hastily scribbled off thus:

R M. G. A. . . . . ʒiv  
Sig., ʒii t. i. d. . . . .  
S. M.D.

Inquiring as to what these cabalistic letters represented, they receive the following reply: "Oh, that is a splendid thing for stomach troubles, and Dr. M. has made quite a reputation by its use. It contains some tr. nux vomica, gentian, soda, etc., but I have forgotten the proportions. You can find out from the pharmacist." "Doctor, wouldn't a little sanguinaria be beneficial in his case?" suggests one of the post-graduates. "Yes, I think it would, but we haven't time to write individual prescriptions for each case"

Thanking the interne or instructor for his kindness, they go to the pharmacy. This seems to be against the rules, but one of their number is an alumnus of the same college of pharmacy as the pharmacist, so they gain admittance. There they find a very intelligent Ph.G. busily engaged in mixing medicines by the gallon, and from these large bottles bearing the cabalistic signs he fills a dozen or more one, two or four ounce vials, which he corks and puts in rows ready for the labels. When asked for the U. S. Pharmacopeia he did not have one, but gave us instead a sixteenth edition of the U. S. D., a book nearly ten years behind the times. No metric weights were visible and only two metric graduates. When asked about this deficiency, he said: "Only one man in this hospital, Dr. T., uses the metric system in his prescriptions, and for these I can use fifteen grains for the gram." One of the company expressed disappointment at the neglect of the metric system by a school where so many of its teachers were graduates of European universities, and one whose name stood for progress in every department of university education; and they went to the pharmacy of the hospital proper. Here they found a younger man in charge, also metric weights (though very little used), a U. S. Pharmacopeia and some other standard works on pharmacy.

The other pharmacies visited revealed nearly the same condition of affairs, though three were not so bad for stock prescriptions, and one presided over by a doctor of pharmacy was well arranged and properly equipped.

In three out of five were found the U. S. P. and the U. S. D., and in two the Nat. Dispensatory. In all but one there was great room for improvement. It is to be hoped that our colleges now requiring four years instruction will teach their graduates to write their prescriptions correctly and the use of the metric system. At present, prescription writing and phar-

macy, as practiced in our large college hospitals and dispensaries, leave much to be desired by way of improvement.

### STANDARDIZED DRUGS.

Read in the Section on Materia Medica, Pharmacy and Therapeutics at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY HENRY B. GILPIN, PH. G.

BALTIMORE, MD.

It is interesting to study, in the evolution of the methods of drug administration, the various forms that have obtained. Beginning with the crude drug, the first step apparently was the recognition of the fact that, as a rule, the soluble principles of a drug of vegetable origin, were its therapeutically active ones. Hence it was but natural that solutions—made with hot or cold water—in the form of infusions, decoctions, etc., should have resulted. It was found, however, that the proneness of these to decomposition, and the relatively large doses necessary to secure therapeutic effects, made them objectionable. The next step was the making of tinctures, fluid extracts and similar products. The final advance has been the assaying or standardizing of the more prominent drugs and galenical preparations, such as those of cinchona, opium and nux vomica, as directed by our Pharmacopeia, and a score and more of other alkaloid-containing drugs that manufacturers themselves have adjusted to certain standards.

In these days of scientific accuracy, it would seem hardly necessary to put forth any plea in favor of standardized drugs, and yet the variability in active constituents of what are commercially regarded as good-quality drugs, makes it essential that the agitation in favor of higher standards be continued. It may be of interest to state that in over 500 assays made of six prominent drugs—which, by the way, were of the *best* commercial quality—the following percentages of alkaloids were obtained:

Aconite root 0.21 to 0.80 per cent., belladonna leaves 0.23 to 0.50 per cent., conium fruit 0.10 to 0.53 per cent., hyoscyamus leaves 0.11 to 0.20 per cent., nux vomica 1.6 to 3 per cent., gelsemium root 0.3 to 0.4 per cent. What is true of variations in strength of these drugs is equally true of many others. From the above it will be seen that the varying alkaloidal strength between extreme limits in the above mentioned drugs, is sometimes several hundred per cent; notably is this the case with aconite root. For example, to illustrate the possibilities of this variation: *two* minims of an unassayed tincture of aconite, in one case, may have the same amount of alkaloids as *eight* minims of a tincture made from another crude root. Five minims of a tincture of belladonna made from an unassayed drug may have only *one-half* the alkaloids contained in the same amount of a tincture made from another sample, or, if it be required to give *ten* minims of tincture of nux vomica, the unassayed product may contain only *one-half* the alkaloids it contains at another time. In other words, there is no safety for the physician in unassayed drugs; he must have the most uniform and reliable tools with which to work, or he will measurably fail. This is true for a number of reasons, the main one of which is, that practical medicine is not an exact science. The medical man has to deal with conditions that are far from being exact. "The human

body is a wonderfully intricate piece of mechanism with such various and varying factors to govern its cellular activities that rational medical practice can only develop most slowly." Now, if with the factor of a varying human economy the physician has to deal with varying drugs and preparations of drugs, he is doubly handicapped in his work. If on the other hand, he can be assured that the means he wishes to employ to combat disease are always definite and sure, he can ignore the factor of a possible variation in the strength of the drug as an explanation of its want of action, and assume that the use of the drug itself was not indicated, because its use failed to give certain results. But when he uses a drug of unknown strength, and fails to produce certain results he may be in doubt as to whether it was the fault of the drug, whether it was not pushed to the full limit of tolerance, or whether its application was not indicated.

So, from every point of view, the physician should be interested in obtaining the best and most uniform drugs, if he wishes to obtain, as far as possible, the best and most uniform results in medical treatment, and in this connection let me say, that the educated pharmacist is just as anxious as the physician to have products that shall be reliable and uniform.

What is true with regard to the value of accurately assayed drugs, is also true with regard to the value of accurately assayed preparations of drugs. Whether it is better for the pharmacist to buy assayed drugs, and make his own tinctures, fluid extracts and the like, or to buy the assayed preparations of a manufacturer, is a question to which we think, there can only be one right answer. It is better for the pharmacist to buy assayed drugs, and make his own preparations, for the reason that it encourages the development of legitimate pharmacy—gives the pharmacist a deeper knowledge of the drugs he is handling—and he can personally guarantee the quality of his products. He can not personally vouch for the quality of another's preparations. It may be retorted that the pharmacist can not vouch for the strength of commercially assayed drugs, but he has this advantage: he can readily verify the claims made, and make a physical inspection of the products before converting them into preparations. When he buys a fluid extract, he buys a finished product, and knows nothing of the physical condition of the drug from which it may have been made.

But whatever difference of opinion may obtain concerning this point, there can be little question as to the reprehensibility of the practice sometimes followed by pharmacists of making tinctures by simply diluting fluid extracts. Fluid extracts, assayed or unassayed, differ from tinctures in the relative amount and kind of their proximate principles, and while it may be possible to so adjust the alkaloidal strength of a diluted fluid extract to make it correspond to the proper alkaloidal strength of a tincture, it is not possible to so adjust the *other* proximate principles, because in the vast majority of cases, there exists no known methods of assay for them. Further, that tinctures contain relatively a *larger* amount of proximate principles than do fluid extracts, is shown by the fact, known to every physician, that the *dose* of a drug in the form of a tincture is *less* relatively than is the *dose* of a fluid extract, and exhibits the physiologic effects of the drug in a correspondingly less dose.

The increased use of synthetic chemicals and the

decreased use of tinctures of vegetable drugs, by the physicians of to-day, may be due, in part, to the fact that some pharmacists buy commercial fluid extracts and make tinctures from them by simple dilution with varying quantities of alcohol and water, instead of using, as the Pharmacopeia directs, drugs with which to make them; and physicians have failed to achieve the results recorded by their forefathers. Modern physicians have thrown aside the old and tried, to welcome the new synthetic compounds; but in so doing, is it not possible that the old may possess merits that make them equally as worthy as the new, if not more so?

### THE MCINTYRE ELEPHANTIASIS CASE.

BY G. LAIDLAW, M.D.

CHICAGO.

In this world of phenomena it is not strange that a physician and surgeon, practicing his profession for a number of years, should occasionally meet with pathologic conditions more or less rare, but it is strange that some should meet the most remarkable cases at every turn, so to speak. In this connection I am sure that it is the privilege of very few professional men, outside of very large hospitals, to deal with more extraordinary cases than have come to the notice and care of my much respected friend and colleague, C. J. McIntyre, C.M., M.D. As a partial proof of the foregoing assertions, I take great pleasure in presenting to the reader four different views of a patient whom the doctor has had for several years, together with a few brief remarks upon the history of this particular case and the disease with which the lady is afflicted.

The good-natured, intelligent and respectable woman, who so kindly allowed us to divest her of all metallic substance and garments and pose before the searching eye of the camera obscura, that by so doing we might obtain further light in medicine and be able to present to your view these pictures from life, is a native of America, and was born in Wisconsin. She is now 45 years of age and the mother of ten children, to five of whom she has given birth since the disease from which she now suffers began.

Eighteen years ago, while engaged in a laborious task, she sustained an injury of the abdomen, near the umbilicus, which was followed shortly after by chills and vomiting. The cutaneous and subcutaneous tissues of the affected part presented redness, tumefaction and infiltration. In a short time the acute symptoms disappeared, leaving a well-marked hypertrophy, which gradually increased until two years later, when the left leg began to be covered with scales and to enlarge somewhat. She was at this time in the fourth month of gestation with her sixth child. The abdominal trouble grew gradually worse, but the leg remained in about the same condition until seven years later, when she fell from a step-ladder and sustained a wound from a rusty nail on the right leg, just above the ankle, where, by reference to Figures 1 and 2, the mark of its point of entrance may still be seen. This accident occurred on July 5, and on August 15 she was attacked with chills and vomiting. The seat of the wound burned and throbbed and her suffering was great. The symptoms, as she described them, appear to have been those of tubular lymphangitis. At the end of two months from the date of the accident she had recovered from the lymphangitis and, as

she remarked to us when relating the history as above, "was ready for more trouble." She did not have long to wait, for in November of the same year she again fell, this time into a register hole, and wounded her left leg, which, as we have stated, was the one on which the scales appeared two years after the abdominal injury. For a third time she was attacked with chills and vomiting, on the second day after the fall. Her physician pronounced the case, when he saw it, one of erysipelas. The entire limb from toe to knee was involved, and she was very ill for four months. The tissues never returned to their normal proportions, not even to the size which they were when the accident occurred, but, on the contrary, continued to increase in size, the trouble extending all the while further and further up the limb.

Some time after this, but just how long the patient does not remember, the right leg, which had been injured by the nail, began to enlarge.

We have now passed roughly over the first ten years of the history of this case, giving the story substantially as the patient related it from memory.

Dr. McIntyre began to see the case about this time and has now been the patient's physician for about eight years, during which time he has had to deal with indolent, unhealthy and ever-increasing ulcers, the secretions from which have been composed of serum and pus, and very disagreeable to the sense of smell. The epidermis has at times become fissured and cracked; papillomatous excrescences of no mean size, made up of conglomerations of many smaller ones, have appeared, while the lymphatics have exuded lymph in large quantities. When the fissures and ulcers have reached deep-seated nerves Dr. McIntyre has had to assuage the great pain which the patient would experience; and there have appeared at many places, but particularly on the inner aspect of the left leg (seen in Fig. 2), quite large and deep-seated abscesses, calling for evacuation and the institution of proper treatment to prevent septic absorption. Meeting all indications as they have arisen from time to time, and supporting the patient in a proper manner amid conditions which at times have seemed hopeless, Dr. McIntyre has cared for the patient until now, when the case has assumed an insidious and chronic form. Large areas of vessels have become affected, and such wide-spread obliteration of them has resulted as to block up permanently their flow of lymph, thereby producing an everlasting lymphedema of the affected parts. From the history of the case it would appear that there resulted from the abdominal injury many years ago an ordinary erysipelas or reticular lymphangitis, and that from the invasion of the lymphatic channels at this time the disease dates. Later on we find one leg affected with eczema, the other with a septic wound, and finally, the eczematous one, after an injury, becomes the seat of a traumatic erysipelas. At these three seats of original attack there have occurred successive attacks of diffuse lymphangitis, each recurrence causing an aggravation of the already bad condition. Thickening and induration of the skin and connective tissue have taken place, the dilatation and multiplication of the blood vessels keeping pace with the general connective tissue hypertrophy, until we have now a case of elephantiasis Arabum which, in some respects at least, is the most wonderful on record. In support of this last remark I wish to state that it has been made after a careful examination of a great many works

on the subject under discussion, among which may be mentioned those of Hebra, Neumann, Kaposi, Ziemssen's Encyclopedia (the volume on Skin Diseases), Crocker, the London *Lancet* since 1878, A. H. Buck's Refer. Hand-book Medical Science, Keen and White's American Text-book of Surgery, Hooper's Dictionary, published in New York in 1847 by Harper & Bros., Stephen Smith's Surgery, Dr. Tittley in the *Lancet*, Vol. xx; M. Clot-Bey, A. J. Howe, etc. Felkin's case in the *Edinburgh Medical Journal*, 1889, page 779, is the only case I have found which very closely resembles the McIntyre one. In this instance the patient was an Eurasian woman.

In a general way I may close my remarks regarding this case by saying that the patient is a most hopeful, good-natured and happy woman, who, if it were not for

Extending downward from the umbilicus, corresponding to the linea alba, there is at present a fissure about four inches in length, and two and one-half inches in depth (best seen in Fig. 3), the sides of which are in a state of ulceration and discharge a disagreeable-smelling mixture of serum, pus and lymph. During the past year the labia majora and minora and clitoris have become involved, but are not as yet enlarged to any great extent, in fact, there is no chance for any considerable enlargement, for the abdomen as it hangs, or rather protrudes, downward is as stiff and unwieldy as any elephant's belly on earth. To the sense of touch, moreover, there is nothing that I know of which feels more like the hide of an elephant than this does. There is very little

FIGURE 1.

the asthma, with which she has suffered much at times for the last six years, would not complain at all, notwithstanding the fact, that in addition to her terrible state, she has no husband to care for her and is in the most destitute circumstances, with several children still requiring the care that none but a mother can bestow.

By reference to Figs. 2 and 3 a very interesting demonstration of a commencing lymphangiectasis may be seen on the lower part of the abdomen near the line of the groin. This condition is to the lymphatic vessels what dilatations and varicosities are to their congeners, the veins, and should the condition here seen, by confluence and aggregation, form distinct tumors, we will have what is called lymphangioma.

FIGURE 2.

feeling in this thick, rough, wrinkly, unctuous and void-of-hair skin. In the edema produced by other diseases and other causes there is pitting on pressure, but no part of this growth pits, even when great pressure is applied. The blood recedes to quite an extent from the point of pressure to return very slowly, indeed; but that is all.

While elephantiasis Arabum, the synonyms of which are pachydermia, Dal fil, Barbadoes leg, Elephantenfuss, mal de Cayenne, etc., may be considered a pandemic disease, we must consider it when appearing in this climate and from the causes which appear to have been responsible for it in this case, a very sporadic malady. Authors of the present day speak of elephantiasis Græcorum as lepra, and elephantiasis

Arabum as simply elephantiasis or pachydermia, it being now certain that the two are distinct. I think that when we have a case like the one under discussion and springing up in this part of the world from causes similar to those which appear to have been at the bottom of this case, the simple term lymphedema would be the best to employ, reserving the terms elephantiasis Græcorum for the lepra type, and elephantiasis Arabum for those cases found in hot climates near the tropics, particularly in Egypt, on the coast of the Mediterranean, the west coast of Africa, the Antilles (Barbadoes), Brazil, Malabar and parts of India, in all of which sections of the world it is most often met with and where, almost always, the cause of it is the entrance into the blood and lymphatics

Coast of Africa, the home of the *filaria sanguinis hominis*, every native into whose lymphatics the *filaria* gains entrance is not affected with elephantiasis. In some it produces chyluria, and in some it does not appear to affect the health at all. This fact, therefore, goes to prove that there is not in this parasitic worm, *per se*, any special poison the presence of which is necessary in order that either chyluria or elephantiasis may exist. For, unless the parasites block, by their presence, the lymph channels, there will not be chyluria; and unless they develop in sufficient numbers to produce stagnation in the lymph vessels, there will not be, from them at least, an elephantiasis. It

FIGURE 3.

FIGURE 4.

of the embryo of a nematode worm, the name of which is *filaria sanguinis hominis*, from its discovery in the human blood. For much of our knowledge in regard to this we are indebted to Wucherer, Salisbury, Lewis, Bancroft, Manson, *et al.*

With us in this country the disease probably always appears after chronic or frequently repeated acute inflammations of the blood and lymph vessels or anything which hinders the flow and favors the escape of the lymph in the lymphatics; and whether it be produced by an inflammation of the blood vessels or of the lymphatics themselves, or from external pressure, it matters not, we will have lymphedema, and following it there will be cell-proliferation and consequent increase in the surrounding tissues.

In tropical countries, but particularly on the Guinea

is, therefore, apparent that it is not necessary that we should have in this country, in order to produce genuine cases of chyluria or elephantiasis, the worm which Manson has so well studied for us, and we do not believe that the *filaria sanguinis hominis* had any part in the cause of the McIntyre case which we have just reported.

Manson says that this parasite resembles a delicate thread of catgut, animated and wriggling; and W. Essex Wynter tells us that the female has a diameter of about 1-100 of an inch and a length of 3 to 3½ inches. As yet no perfect specimen of the male has been found. The mouth is circular, without papillæ; there is a narrowing at the neck, and the tail is bluntly pointed. The parent worm is necessarily only found during operations involving the affected tissues, or in

autopsies. On the other hand, the embryos occur in immense numbers and are readily found in blood obtained by pricking the skin. They appear as active organisms, each being contained within a delicate sheath which projects slightly at one or the other end of the worm. Its length is about 1-90 of an inch and its diameter 1-3200.

Dr. Manson obtained ova consisting of oval bodies 1-500 by 1-750 of an inch. These are too wide to traverse the channels of the lymphatics and consequently become impacted and thus give rise to the conditions of elephantiasis and chyluria.

The mosquito plays a part in the spread of this disease in hot climates. Dr. Stephen Mackenzie's experiments showed that the embryos only occur in the cutaneous vessels while the patient is asleep, whether by night or day. As to what becomes of them during the period of activity of the patient nothing certain is known. During sleep, however, while the filaria embryos circulate in the blood of the sleeper the mosquito fills himself with the infected fluid and flies to some stagnant pool of water, his natural haunt, upon the surface of which he drops to die. The embryos of the filaria contained within the blood are thus set free and become ready to enter the circulation of the next thirsty mortal who drinks the water.

## THE METHODIC DESCRIPTION OF A SURGICAL DISEASE.

BY EDMOND SOUCHON, M.D.

PROFESSOR OF ANATOMY AND CLINICAL SURGERY, TULANE UNIVERSITY,  
NEW ORLEANS, LA.

(Concluded from page 83.)

FORMS, VARIETIES, COMPLICATIONS AND RECURRENCES.

The description of the forms, varieties and complications of the disease comprises that of all the points and features which are not commonly met with and the description of which would embarrass or obscure the description of the most common or frequent appearance of the disease.

Those forms, varieties and complications must be stated as due to peculiar causes; to pathologic peculiarities, to peculiar symptoms, course, termination, duration, diagnosis, prognosis, complications, relapses, sequelæ or consequences. Complications may be local or regional or general. The local and regional complications may be due to malformation, to softening, induration, neurosis, injury, congestion, inflammation, gangrene, ulcer, fistula, tumor; they may affect the skin, connective tissue, adipose tissue, tendons, muscles, fascia, periosteum, bones, medulla, arteries, veins, capillaries, lymphatic vessels, lymphatic glands, nerves, an organ special to the region. The general complications may affect the organs of circulation, respiration, etc. For each form, variety or complication state the frequency and importance.

METHODIC DESCRIPTION OF THE LOCAL SYMPTOMS  
FURNISHED BY THE SIGHT, TOUCH, HEARING.

The methodic description of the local symptoms furnished by the sight, touch and hearing are much facilitated by arranging them methodically according to each disease or group of diseases. Hence the following separate methodic descriptions:

The classification here adopted and advocated is based on the clinical manifestation which is visible and at once recognizable by the student, and which leads to the pathologic and etiologic characters which

themselves lead to the diagnosis, prognosis and treatment.

These diseases are: Malformations, injuries, neuroses, softenings, indurations, congestions, inflammations, gangrenes, ulcers, fistulæ, tumors.

They may affect the skin, connective tissue, adipose tissue, tendons, muscles, fasciæ, periosteum, bones, medulla, joints, arteries, veins, capillaries, lymphatic vessels, lymphatic glands, nerves, an organ special to the region, in all or only one of its component parts.

This plan corresponds to descriptive anatomy, a fair knowledge of which is previously necessary to study profitably general anatomy, which studies the tissues and organs of the same nature regardless of their situation and relative position. The same, in the study of surgical diseases, a descriptive and clinical knowledge is necessary before undertaking the study of the diseases from the point of view of causes or nature, irrespective of the clinical forms they may assume and the location they may affect, such as diatheses, gout, struma, tubercles, syphilis, etc. It would seem that the study of the general diseases should precede the study of their local manifestations, but experience teaches that that study is much more profitable after some clinical knowledge has been acquired.

We must here beg for indulging in repetitions which can not very well be avoided in a new subject where clearness and precision must have precedence over style and grace.

METHODIC DESCRIPTION OF FUNCTIONAL SYMPTOMS.

The methodic description of functional symptoms comprises the following features:

1. The alterations in the physical, *i. e.*, mechanical phenomena of the functions; they usually consist in alterations of movements, *i. e.*, contractions of the muscular fibers of the part or of the organ. We must state the alterations in the capacity or extent of the movements (including reflex, if any), in their duration, in their rhythm or order of succession, in their frequency or rapidity, in their intensity; the alterations in the sounds presented by auscultation, if any, stating the cause, intensity, rhythm.

2. The alterations of the chemical and vital phenomena, comprising the description of the alterations taking place in the contents of the organs; alterations of character, of losses, by gains; the alterations in the presence or action of the peculiar agent which is usually present in the organ (such as pepsin).

3. The alterations of the secretions of the organ, which should be described after a separate guide explained below.

4. The alterations in the composition of the blood in the afferent vessels; also of the efferent vessels; these must be described after a separate method, as explained below.

5. Alterations of the nerve actions and of the nerve centers which preside over the functions.

METHODIC DESCRIPTION OF THE PATHOLOGIC  
ALTERATIONS OF A NORMAL FLUID.

These present to state: 1. The alterations of the physical characters, *i. e.*, quantity, color, smell, taste, consistency and specific gravity. For each state frequency and importance. 2. The alterations of the chemical characters and of the composition, *i. e.*, of the reaction, of the qualitative analysis, of the inorganics (water, gas, salts), of the organics (albuminoids, carbonaceous, of the characteristic or peculiar substances usually present in the secretion,

such as ptyalin, pepsin), of the quantitative analysis of each component part. 3. The alterations of the anatomic elements or solid components, *i.e.*, shown by the microscope, such as salivary corpuscles, blood corpuscles, etc. We must state the quantity or number, dimensions, color, shape, structure, chemical composition (histo-chemistry), their development and organic changes. 4. The alterations in the physiologic functions of those fluids or secretions. 5. The alterations in the origin or development of the secretions. 6. The alterations of the nerve action or nerve centers.

#### METHODIC DESCRIPTION OF A NEW OR PATHOLOGIC FLUID.

This includes the following: 1. The physical characters: quantity, color, smell, taste, consistency or specific gravity, temperature. 2. The chemical characters or composition, including the reaction, the qualitative analysis, inorganics (water, gas, salts); organics (albuminoids, carbonaceous, characteristic organic substance, if any); quantitative analysis. 3. The anatomic or microscopic analysis or characteristics of the solid elements; quantity or number, dimensions, color, shape, structure, chemical composition, physiologic functions, development or origin of the solid elements. 4. The pathologic functions or uses of the pathologic fluid. 5. The development, origin, changes, etc., of that fluid. 6. Action of the nerves and nerve centers on the secretion of the fluid.

#### METHODIC DESCRIPTION OF A CONGENITAL MALFORMATION OR DEFORMITY.

This must state if it consists in the absence of the organ, partial or total, or if the organ is double; if it is an arrest of development, such as fissures, fistulae; if it is atrophy or hypertrophy, and state if it is general or bilateral; if it involves the whole region or organ or if it is partial, *i.e.*, involving a part only, or one side, unilateral; if it is homogeneous or heterogeneous, *i.e.*, of the same nature or character or not, all over; if its anatomic site is in the skin (pigment, hair, cuticle, cutis, sebaceous glands, sweat glands, vessels, nerves), or in the connective tissue, adipose tissue, tendons, muscles, fascia, periosteum, bones, medulla, arteries, veins, capillaries, lymphatic vessels, lymphatic glands, nerves, or an organ special to the region.

If the malformation is a deviation or asymmetry, we must state if it is directed upward, downward, laterally, backward or in an intermediate direction:

#### METHODIC DESCRIPTION OF AN ACQUIRED OR POST-NATAL MALFORMATION.

The same course must be followed as for a congenital malformation. We must further state if it is characterized by the destruction of the organ, partial and total, also the cause in each; softening, induration, neurosis, injury, inflammation, gangrene, ulcer, fistula, tumor, operation, cicatrix; and whether they affect the skin, connective tissue, etc.

#### METHODIC DESCRIPTION OF THE LOCAL SYMPTOMS OF A SURGICAL NEUROSES.

(Sensory neuroses; pain, neuralgia; motor neuroses, paralysis, spasms or convulsions, contractions, retractions, contractures.)

Here the subjective symptoms often occupy a considerable place.

The subjective symptoms present to state the following: 1. The frequency of the attack, daily, weekly. 2 Whether the neurosis is spontaneous, or provoked

or increased by the function of the part. 3. The seat or tract of the neurosis, *i.e.*, the spot where it begins, the line or tract which it follows as traced by the patient; the spot where it ends; state if there are spontaneous painful spots or a spot or place where the symptom is greater; also the breadth or width of the tract or course of the neurosis. 4. The intensity, degree or force; slight, moderate, great, very great. 5. The character of the pain, if any; lancinating, boring, acute, dull, sharp, burning, etc.; note the comparisons made by the patient. 6. The course or rhythm of the neurosis, *i.e.*, if the intensity is always the same; if not, describe how it is, then state the time of onset, of maximum, of decrease and of cessation; the influence of morning, noon, evening, night, midnight, dawn; state if there are remissions or intermissions during the attack, or if the neurosis is continuous until the attack is over; state the duration of the remissions or of the intermission; state if attacks are periodic. 7. State the effects of pressure by the tip of the finger or a broad surface; of light pressure or of great pressure; of short or of continued pressure. 8. State the effects of hot or cold applications; of cold weather with or without dampness; the effects of barometric changes. 9. State the mode of termination of the attack; abruptly, rapidly, gradually; if there are any critical symptoms. 10. State the duration of an attack; hours, days, etc.

The physical symptoms are the following: Eruptions or not along the course of the affected nerve or parts. Pressure on peculiar spots, at points of emergence of nerves through fascia and bones. Effects of pricking with a pin, of hot and cold applications, of electricity, with the patient's eyes closed; effects of threats to use painful methods of treatment (blisters, hot iron, etc.). Effects of fictitious medication; bread pills, hypodermics of water, of air.

The functional symptoms present to describe the alterations of the normal phenomena, of the functions of the part (as above), and the alterations by new phenomena; new position of the part, of the patient.

The regional symptoms comprise specially the irradiation of the manifestations; the sensations of heat and cold, of heaviness, of prickings of the region, of spasmodic clonic contractions, of tonic contractions or contractures.

Describe the condition of the patient immediately after an attack, the local and the general symptoms.

Describe also the condition of the patient during the intervals of an attack, the local and the general symptoms.

#### METHODIC DESCRIPTION OF THE LOCAL SYMPTOMS OF AN INDURATION, A SWELLING, A TUMOR.

The following methodic description is applicable alike to an induration, a swelling, a tumor. It comprises the description of the subjective, the physical and the regional symptoms.

1. The description of the subjective symptoms, *i.e.*, symptoms felt by the patient only, must be made according to the general description; they usually consist of pain, of peculiar sensations, of heat, of cold, heaviness, prickings, etc.

2. The physical symptoms, comprising the number of the lesions, situation (region, superficial, deep), dimensions (relative, absolute), direction, shape. The description of the superficial surface includes the extent or dimensions, shape or form (plane, convex, concave, in a vertical or transverse direction); color

(red, blue, etc.); projections (vesicles, lobules, lobes); depressions (grooves, sulci, ulcers, fistulæ); relations with the skin (loose or adherent); consistency (fluctuant, hard, soft, pulsatile without expansion, pulsatile with expansion); effects of pressure on tumor, artery and vein above and below, edema or pitting; effects of percussion. The description of the borders includes the extent or limits (circumscribed, diffused); shape or form (plane, convex, concave, regular, irregular, etc.); color, projections, depressions, relations with skin, consistency, etc. (like for the superficial surfaces). The description of the deep surface includes the mobility on the deep soft parts, also on the bones; the extent of the mobility; sessile or pediculated. The auscultation of the part should be described as above. The secretions, if any, from the ulcerations, also as above.

The functional symptoms must be described also as above explained.

The regional symptoms or symptoms presented by the neighboring organs must be described as explained above also.

METHODIC DESCRIPTION OF THE LOCAL SYMPTOMS OF A  
SOFTENING, A BURN, A FROST-BITE, A CONTUSION,  
A SPRAIN, A CONGESTION, AN INFLAMMA-  
TION, A GANGRENE.

The subjective symptoms must be described as explained in the general guide.

The physical symptoms comprise the description of the following points: The number of lesions, the situation, the dimensions or extent, the direction, the shape. The surface presents to study the color, projections, depressions; the relations with the skin (loose or adherent); the consistency, hard, fluctuant, soft, pitting under pressure of the finger, crepitant, pulsatile without expansion, pulsatile with expansion, effects of pressure on the parts, of pressure above, below and around on the skin, connective tissue, adipose tissue, tendons, muscles, fascia, arteries, veins, capillaries, lymphatic vessels, lymphatic glands, nerves, an organ special to the region; effects of percussion. The borders present for study the dimensions or extent, direction (straight or sinuous), shape (circumscribed or diffused), color, projections, depressions, relations with the skin (loose or adherent), consistency, fluctuant, soft, pitting under fingers, hard, crepitant, pulsation without expansion, pulsation with expansion, effects of pressure above, below, all around, on skin, connective tissue, adipose tissue, tendons, muscles, fascia, arteries, veins, capillaries, lymphatic vessels, lymphatic glands, nerves, an organ special to the region; effects of percussion. The deep surface of the affected parts presents to study their mobility on the deep soft parts and on the bones; the extent of the mobility. Auscultation presents to study the points explained above. The secretions of the affected parts must be studied as described above also.

The functional symptoms should be described according to the guide above explained.

The regional symptoms also.

METHODIC DESCRIPTION OF THE LOCAL SYMPTOMS OF A  
PUNCTURED WOUND, A STING, A FISTULA.

The subjective symptoms call for no special guide here.

The physical symptoms present for study the following points: The number of lesions; each should be described separately. The external or superficial orifice presents for mention its situation, size, shape,

direction, color, inversion or eversion, its smooth or ragged appearance; its projecting, depressed or sunken contour, if it is hidden or not by a fold; its consistency (hard or soft); if it is circumscribed or diffused; its mobility (loss of parallelism); if it is clogged or free, and dry or oozing (blood, serum, pus, special substances). The tract or course of the wound or fistula presents for consideration its direction toward the deep parts, upward, downward, backward or in an intermediate direction; the anatomic point toward which it seems directed; if it is straight, curved or tortuous; the cord-like sensation of the tract. The internal orifice or bottom of the wound presents for study its situation, depth or point of exit; if this orifice is visible or can be felt it should be described as the external orifice; state if it has or not penetrated, *i.e.*, injured any important structure, tendons, muscles, fascia, arteries, veins, large lymphatic vessels, lymphatic glands, nerves, an organ special to the region; state the symptoms by which each lesion is recognized. State the presence or absence of any foreign body, part of instrument, bone, etc.

Describe the secretions of the wound, if any, according to the guide as above explained.

The functional symptoms should be described according to the general guide above.

The regional symptoms also.

METHODIC DESCRIPTION OF THE LOCAL SYMPTOMS, IF  
AN INCISED, A LACERATED, A GUNSHOT, A  
BITE WOUND.

The subjective symptoms should be described as in the general guide.

The physical symptoms present for description the following points: The number of the lesions. The external solution or orifice presents for statement its situation, size, shape, direction, color; its inversion or eversion; its smooth or ragged appearance; its projecting, depressed or sunken contour; its consistency (hard or soft); if it is bruised or not; its mobility (loss of parallelism); if it is closed by a clot or oozing (blood, serum, pus, special substances). The depth or course toward the deep parts, upward, downward, forward, backward, intermediate direction; state toward what anatomic point it seems directed. The internal orifice or bottom presents to study its situation and depth; state if it has or not penetrated beyond the fascia of the region and has or not injured the important structures, tendons, muscles, fascia, arteries, veins, capillaries, lymphatic vessels, lymphatic glands, nerves, organ special to the region, and state the signs by which each lesion is recognized, also its extent; state if there is or not any foreign body (piece of the instrument, clothing, etc.) in the wound. Describe the secretions of the wound, if any, according to the guide above. When there is hemorrhage describe it according to the guide for a normal fluid.

The functional symptoms should be described according to the general plan.

The regional symptoms also.

METHODIC DESCRIPTION OF FOREIGN BODIES IN WOUNDS.  
ENUMERATION.

They may be broken points, broken blades, bullets, wadding, clothing, dirt, pieces of wood, etc. State the number, size, depth, duration of stay in the wound, changes or alterations they have undergone therein.

METHODIC DESCRIPTION OF THE LOCAL SYMPTOMS OF A  
DISLOCATION AND OF A FRACTURE.

The subjective symptoms require here no special guide.

The physical symptoms present to study the following points: The number of the lesions, situation, dimensions (extent or swelling), duration. The shape; sometimes there exists a characteristic deformity, or the parts have a peculiar position and shape, or there is a shortening of the limb or part. The surface presents for statement the color; the projections or depressions, which sometimes exist on both sides of the parts, in which case they alternate; the relation with the skin (loose, stretched, tense, adherent); the consistency of the parts (hard masses, movable upon each other or immovable, edema or pitting, fluctuation). The borders or edges of the fracture are circumscribed or diffused. The deep surface presents to state the mobility of the bones at points where they should be continuous, the extent of the mobility and the crepitation, if any, fine, coarse, easily produced or not.

The functional symptoms call here for no special description.

The regional symptoms call for the description of the shortening of the limb or part, the peculiar position of the limb or part, or of the patient himself in relation to the part; also the symptoms presented by the skin, connective and adipose tissues, tendons, muscles, fasciæ, arteries, veins, capillaries, lymphatic vessels, lymphatic glands, nerves, organ special to the region, etc.

#### METHODIC DESCRIPTION OF THE LOCAL SYMPTOMS OF AN ULCER.

The subjective symptoms call for the mention of the presence or absence of pain (indolent ulcers).

The physical symptoms present the following points to be described: The number of ulcers, situation, dimensions or extent (length, breadth, depth), direction, shape. The surface presents for description the color, the projections, depressions, consistency. The borders call for mention of the color, thickness, direction (perpendicular, slanting), regular, sinuous, dissection of the skin (undermined). The secretions, blood, serosity, pus, ichor, should be described as a fluid, as indicated above.

The functional symptoms should be described as indicated in the general guide. The regional symptoms also.

The tabulation of those methodic descriptions will greatly assist in understanding them thoroughly and remembering them more easily.

#### METHODIC DESCRIPTION OF THE SURGICAL DISEASES AND INJURIES OF A REGION.

When the region of the body, such as the neck, for instance, presents several smaller regions, we must first describe the diseases of that region as a whole and then the diseases of each smaller region.

It must be assumed that the student of regional surgery is conversant with the general surgical diseases, and to avoid useless and often confusing repetitions we must, in regional surgery, confine the descriptions to the following points:

1. Describe the peculiarities only presented by the diseases which may affect any region of the body when they affect that region, in whole or in part. By peculiarity is meant a feature or a point not common to all the regions of the body or of all the regions of that part. All the points or features common to all regions properly belong to the description of the disease in general, and should be carefully omitted under penalty of useless repetition. The peculiarities of the diseases of a region are due to, or depend upon, fre-

quency, causes, pathologic anatomy or physiology, symptoms, course, duration, termination, diagnosis, prognosis, treatment, relapses, sequelæ, forms or varieties and complications; it may be complicated by other diseases, or it may be complicating other less grave diseases. The peculiarities must be carefully described in that order, so that upon reading of the peculiarities due to the symptoms, for instance, the student may rest assured that there are no peculiarities relating to frequency, causes, etc.

2. Describe the diseases special to the region, if any, *i.e.*, not met with anywhere else or rarely so, or enumerate the diseases which are most frequent in the region, or which begin by the region to spread from there over the other regions.

3. Describe the surgical operations of the regions. If these are the same as met with in other locations, the peculiarities or modifications alone which the region calls for must be mentioned. If the operation is one special to the region it must be described with particular care and thoroughness.

4. Each region presents to study the same diseases as described above, *i.e.*, malformations, neuroses, softening, indurations, etc. Those diseases affect the skin, connective tissue, adipose tissue, tendons, muscles, periosteum, fasciæ, bones, arteries, veins, capillaries, lymphatic vessels, lymphatic glands, nerves, organ special to the region. The diseases of a region must be described after the methods or guides elaborated above.

#### THE METHODIC REPORT OF A SURGICAL CASE.

The methodic report of a surgical case comprises the description of the history of the patient, of the present state, of the diagnosis, of the course and treatment, of the termination and sequelæ, and lastly, in case of death, of the postmortem examination.

#### HISTORY OF THE PATIENT.

1. Note the sex and the age of the patient.  
2. Note the race, the nationality.  
3. Note the family history, *i.e.*, the age and the condition of health of the parents, if living; when any parent is in bad health, ascertain the name and nature of the disease and its course and duration, if possible; if dead, the age at which death occurred and the cause of death. This applies to the ancestors (father, mother, grandfather, grandmother, both on the paternal and the maternal side), to the collaterals (uncles, aunts, cousins), to the descendants (children, grandchildren); note the parent the patient resembles the most or takes after physically.

4. Note the place of birth, also the various places where the patient has lived; the duration of his stay in each place.

5. Note the effects, if any, of the various causes described above in the methodic description of a surgical disease, *i.e.*, of the geographic, telluric, zymotic, physical, chemical, hygienic, therapeutic, anatomic, physiologic, pathologic (including the disease through which the patient has gone); note the cause to which the patient attributes his disease.

6. Note the condition of health previous to the attack, also the date and mode of debut, the premonitory and prodromic symptoms (subjective, physical, functional, regional and general); note the order of succession of the symptoms, the duration of this period, the treatment undergone and the effect, the course of the disease up to the present record.

## PRESENT STATE.

The description of the present state includes actually the mention of all the symptoms presented by the patient, the subjective, physical, functional, regional, general; the guides detailed in the methodic description of a surgical disease should be here followed closely. Note the intensity of each symptom.

## DIAGNOSIS.

The diagnosis is now made in the following manner:

1. Make a résumé of the salient points or signs of the case derived from all sources, sex, age, race, nationality, place of birth, places where he has lived, effects of the various possible causes of the disease, course, actual symptoms and duration of the disease.
2. Note the diseases resembling the case.
3. Differentiate them as explained in the methodic description of a surgical disease and also further.
4. Diagnose the stage, the tendency to termination.
5. Diagnose the forms or varieties, the complications.

## COURSE AND TREATMENT.

The course and treatment call for the recording of the date, day, hour when any changes of any consequence take place in the symptoms (subjective, physical, functional, regional, general), or in the treatment (hygienic, medical, surgical, etc.), as set forth in the methodic description of a surgical disease. Note relapses (date, causes, symptoms, etc.); also recurrences.

## TERMINATION OF THE DISEASE.

The termination of the disease should be well noted; the sequelæ or consequences, if any, should be carefully mentioned.

## POSTMORTEM EXAMINATION.

The postmortem examination should be conducted after the rules laid down in the methodic description of a surgical disease; that is, the lesions of the main organ should be described first, then those of the region, then those of the distant or general organs; the macroscopic and microscopic lesions should be noted, etc.

## FINAL RECORD.

The final record must be complete; it must include all the above, also the various charts (temperature, pulse, respiration, stethoscopic, plessimetric, sphygmographic); microscopic slides, if any, should accompany the record; the pathologic specimens should be deposited in a museum with a distinct number for reference; the label should explain the main features of the case; photographs also.

## RULES TO BE OBSERVED BY THE RECORDING SURGEON.

1. Put the questions with politeness and solicitude; kindness and gentleness will accomplish more than any other policy.
2. The phenomena should guide toward the solution sought; do not shape the phenomena toward a desired solution; be led by the answers, do not lead them.
3. The number of questions must not be too numerous nor too few.
4. Use plain, simple words and expressions which the patient will understand.
5. Do not propound complex questions which bear on several points at the same time.
6. Put the questions in such a manner that the answers should be simply yes or no.
7. Do not allow the patient to indulge in too minute details which usually end in useless prattle; however, patients must be allowed a free statement; when they digress too much from the main point, bring them back to it, but

gently and with care, otherwise they may become scared or nervous or sullen; some resent it by willfully giving false answers. 8. When the surgeon doubts the veracity of the patient or when the answers lead to an extraordinary fact, the surgeon should change the terms and forms of the questions; he should cross-examine; he should return to this same point later again in the examination; sometimes it is better to return to it the next day or some other day; should the patient then give different answers on the same point, he should be reminded gently of his former answers; the version he finally adopts is usually the true one, or the fraud, if any, is more easily detected. 9. Put as few questions as possible in cases where quiet and silence is necessary, great pain, shock, etc. 10. Proceed with gentleness in the physical examination, especially of the organs of generation and of the anus, particularly in the female. 11. Do not expose the patient any more than absolutely necessary, on account of modesty and also because exposure may cause cold. 12. Questions relative to syphilis must be put with care; never in the presence of the wife or conversely, or of other parties objectionable to the patient. Avoid questions, words, movements or facial expressions which might convey an unfavorable impression to the patient. Take in consideration the social position and the character of the patients in examining them, as some are more nervous and sensitive than others.

## METHODS OF INTERROGATION.

There are two methods for interrogating a patient.

The first method consists in beginning to review all the possible features of the case, following closely the order above described. This procedure is long and tedious, because the local trouble is only discovered when the turn of the organ comes in the examination, but in obscure cases it is the safest and most preferable.

The second method consists in well determining the debut and let the patient narrate what he feels and knows, so that he will himself guide the surgeon to the affected organ, which will then be thoroughly examined, and afterward the organs at large.

## METHODS OF DIAGNOSIS.

The method by hypothesis consists in taking up at once the first disease which the symptoms suggest to the mind and to see if all the important signs fit it or not; if they do not correspond, then the next disease which suggests itself is considered, and so on until a disease is found that corresponds to all or most all the important signs.

The method by exclusion consists in precisizing the salient signs of the history; in noting the diseases to which those signs may belong, thus eliminating at once all diseases where those signs are not usually observed; in determining the diseases to which the signs do not correspond thoroughly and eliminating them one after the other according as the signs correspond less and less, so that in the end the only disease retained is the one to which the signs correspond best.

*Remarks:* 1. In cases where the data are insufficient, all the regions and organs of the body must be examined one after the other before the diagnosis can be reached, as in cases of general injury with no special localization, or where the patient is incapable of precisizing in any way or gives contradicting or vague, worthless answers, with a view either to deceive the surgeon, or because of a lack of intelligence, or

because of the absence of any predominating sensations, or when there is unconsciousness, delirium, intoxication, coma. The diagnosis is reached only by the general result of such signs as have been gathered in this way. 2. The diagnosis of a disease may be difficult or impossible at the outset or during all its course down to the termination, favorable or unfavorable, or when the surgeon is called at the time of impending death, or when the patient simulates a disease or dissimulates the disease with which he is affected. 3. In cases of disease presenting attacks or exacerbations, it is important to see the patient at the time of the paroxysm.

### A SUGGESTION AS TO TREATMENT OF GUNSHOT WOUNDS OF THE LUNGS.

BY G. H. STOVER, M.D.  
EATON, COLO.

When a case of gunshot wound of the lung is received into a hospital, the surgical treatment of the wounds of entrance and exit is now-a-days most careful. The wounds are aseptized, a sterile gauze or an air-tight dressing is applied, and as a rule they heal nicely if the patient survives the shock and hemorrhage of the injury.

The point to be made in this communication is that a case of gunshot or other penetrating wound of the lung should never be placed in a general surgical ward, even should the general condition be excellent and the patient not need a special nurse.

Numerous investigations of the bacteriology of the air in surgical wards have uniformly and conclusively shown that the air is strongly contaminated by bacteria; these investigations are so well known and their results so generally accepted that it is unnecessary to refer to the literature.

Now, in a penetrating wound of the chest involving the lung, we have our one or more external wounds which we can protect, by dressings, from contamination. But there are also the wounded air vesicles and bronchi; respiration is continually bringing the bacteria-laden air of the ward into contact with this wounded and only partially protected lung tissue; infection is pretty liable to take place; its development may be slow, it may not produce noticeable symptoms for a long time, the patient may recover from the immediate effects of the injury and leave the hospital apparently in health, only to succumb, after weeks or months, to pulmonary inflammation.

These patients should be placed in separate rooms, with as little atmospheric connection with other wards as it is possible to obtain, and careful measures taken to keep the air of the room clean. If such isolation, etc., be impossible, a respirator, which may be a very simple one, should be constantly worn. In either case the nose, mouth and pharynx should be frequently cleansed with antiseptic sprays or washes.

I do not know if many hospitals place this class of cases in general wards, but I have known it to be done, and in one case that I now recall the patient, previously a robust healthy man, died some months after leaving the hospital, of pulmonary suppuration, and I often thought this might have been avoided had he been isolated and treated as above.

### SELECTIONS.

Rush Medical College—Annual Dinner.—Remarks of Prof. John B. Hamilton:

Mr. President, Fellow Alumni, and invited Guests:—We celebrate to-night the Fifty-second Annual Commencement of Rush Medical College. We see around us many of our classmates of twenty-seven years ago, many fratres of earlier or later classes. Men are with us as our guests, distinguished above their fellows in education, in oratory and in affairs. They are here to testify their sympathy with Rush Medical College in its aims toward higher medical education, and to rejoice with us in the steps already taken.

I am not commissioned by the Faculty to make any authoritative statements, nor have I had time to examine the college records, so that any remarks I may make to-night are to be regarded entirely as an individual expression. I speak to-night as an alumnus, not as a member of the Faculty.

The history of the progress of Rush Medical College, from its foundation in 1836 to the present time, is full of interest and suggestion, and when we consider that the ultimate test of education is its value to mankind, it must be admitted that Rush Medical College stands that crucial test well. There is, and has been from time to time, a criticism of our own and other schools, as to the insufficiency of the medical teaching. These critics rarely stop to think that the character of the education of the Rush student has heretofore been based scarcely less on his environment than upon his own necessities. When a statue is made, the niche which it is to fill, frequently governs its size, and when the young graduate had to settle among tillers of the soil and villagers without special education, what need was there for a high preliminary entrance test, that would require him to waste years in the acquirement of a knowledge of the superstitions of the ancient Greeks? When there was little education of the people generally, why should the doctor so far outstrip them?

When Daniel Brainard and James Blaney taught surgery and chemistry in the old Dearborn Street school, they were furnishing the essentials, but year by year the terms have lengthened; the amount of instruction given, has increased. With the increase of days and hours of instruction in the Medical College, the necessity for higher preliminary education has become apparent. The development of some of the specialties, such as chemistry, physiology and ophthalmology, require for their proper understanding, a fair knowledge of physics and mathematics. To properly understand anatomy and embryology as now taught, some preliminary knowledge of the Greek and Latin tongue is absolutely necessary, because scientists throughout the world have to a limited extent agreed to a common nomenclature.

These new requirements, these changes, have come with equal pace with the developments of the high school, the academy, the college and the university. The young doctor when he leaves the medical school was and is still equal to his best neighbors in general education, plus a medical education. When he goes too far into medical realms he lives in another world, quite too remote to keep in touch with his neighbors. This is the key with which to explain the failure of the young professional man, who deeply desirous of more knowledge, and more culture, goes abroad, remains a few years, returns, lives in a different mental atmosphere from his neighbors, is misunderstood, unappreciated, naturally becomes misanthropic and fails.

Although it is evident that those responsible for the curriculum of Rush Medical College have kept steadily to the line of utility in medical teaching, and borne in mind the nature of the environment of the graduates from year to year, yet for the last few years it has become apparent that some of the

Let us have a Department of Public Health!

teachers at least have not agreed that everything should be sacrificed to mere utility, and, as is well known, the emotional side of the man should be developed. We have seen the donning of the cap and gown, the establishment of athletic games, the organization of college secret societies (the Nu Sigma Nu and the Phi Sigma Rho) and the affiliation with the Young Men's Christian Association. But there is a danger line in these extraneous educational aids, beyond which the student becomes a general rather than a special student. Music, painting, sculpture and poetry appeal to and develop the emotional side of man, but as Herbert Spencer said "these efflorescences of civilization, should be wholly subordinate to that knowledge and discipline in which civilization rests, and as they occupy the leisure part of life, so should they occupy the leisure part of education."

It was my good fortune, Mr. President, to be present at the opening of that noble building completed by the Faculty of this college on the corner of Dearborn and Indiana streets in 1867. At that time there was no medical college building equal to it, and the old building which it adjoined was remodded and given up to anatomic and chemic instruction. The mayor of the city, the Hon. J. B. Rice, made a speech at the opening, in which he said on behalf of the trustees and the Faculty: "We erect here a grander temple than was of old erected to Æsculapius or Hygeia, for it shall be devoted and dedicated to the sacred cause of humanity." How well this college has fulfilled its trust! The purposes of that dedication I verily believe, have been kept steadily in sight from that day to this.

The storms and financial difficulties through which this college has successfully passed, give eloquent tribute to the courage and faithfulness of the faculty and trustees. The new building of 1867 was destroyed by the great fire of 1871, in the opening week of the college term. The professors of that day, undismayed by the great calamity, bravely took upon themselves the erection of a temporary building on Eighteenth street, in the grounds of the County Hospital, and there—"under the sidewalk"—they taught without interruption, and during that time planned a new building, the present one, corner of Congress and Wood streets. When this building was finished again the professors became personally liable for the funds necessary to construct it and without a murmur they met the obligations as they fell due. A short time elapsed when it was observed that the school could not control the clinical teaching in the County Hospital, and the arrangements were not in accordance with their views; whereupon they gave away the unused portion of their grounds, without regard to future needs, mortgaged the college building for \$45,000 hospital bonds, and the magnificent Presbyterian Hospital is the result of that beginning. In the year 1891, when nearly every Eastern medical college had been aided by the hand of private philanthropy, to erect a laboratory for the study of the new field of bacteriology, no aid was visible here, but the Faculty once more devoted the entire earnings of the school for a period of three years toward the erection of the present beautiful structure on Harrison street, and taught without fee or salary.

When it is remembered that no member of the Faculty has any right to the college property, and also that the sole title to Rush Medical College and its equipment is held in trust by the trustees and their successors in office forever, the benevolent character of these repeated personal sacrifices by the members of the Faculty is apparent.

Here is an institution that without endowment, gift, or outside encouragement beyond the confidence of the people, and the love and respect of its alumni, has advanced step by step, in the face of uncommon difficulties, to a position equal to any American institution of its class, and in some respects equal to any elsewhere.

What nobler tribute can be paid to Brainard, the founder, his coadjutors and their lineal successors, than the history and record of Rush Medical College? I stand here not to eulogize this noble institution, but simply to place on record these facts.

Many of the Eastern medical colleges have had buildings given them, and chairs endowed. Philanthropists and moneyed men have vied with each other in wise liberality toward their medical colleges, but here the hand of Sir and Lady Bountiful has never been opened in the direction of its oldest medical college. The college has flourished, but at the expense of the life labor of its teaching faculty.

But we came here, Mr. President, not to eulogize or condemn, but to sing gently the praises of our Alma Mater, to have our annual reunion, to fraternize and to enjoy this hour, which, unfortunately, only comes once a year; so now with music, song and the eloquent speeches which are to follow, let us be happy. If our local philanthropist, like some of the blooded kine amid pastoral scenes, shall fail to yield milk even to the hand of the experienced milker, let us forget our wants and leave the matter to Posterity—Posterity, the sweet child! We well know who its father is and our faith in its stock leads us to believe that its burdens will be well borne. Let us tonight indulge in pleasant reminiscences and recall that Brainard in his day received the prize at the Paris Academy, that DeLaskie Miller was president of the Section of obstetrics at the International Medical Congress at Washington, that Senn's Latin thesis obtained *Magna Cum Laude* at Munich, and that Lyman, Hyde, Senn and Ingals have written books which are as lamps to the wayfarer. Last but not least, the announcement has just been made that the Rush diploma has had its just recognition at the hands of the Board of Examiners of the Royal Colleges of Physicians and Surgeons of England.

Finally, as we have so much to be thankful for, let us conclude in the language of the Bohemian Club of San Francisco, "May the Lord love us, and not call us too soon."—*Corpuscle*, July.

**The Procedure of "Blood-Washing" in Infectious Diseases.**—According to the *Medical Press and Circular*, June 10, Dr. Henri Barré has recently made an important communication to the Paris Obstetrical Society on this subject. The process, to which Dr. Barré has given the name of "disintoxication of the blood," is derived from *simultaneous* employment of two therapeutic means already made use of in medicine; the one very ancient, bleeding; the other very modern, the intravenous injection of artificial serum. The aim of this treatment is to combat the phenomena of general intoxication which manifest themselves in the course of or toward the end of many diseases, and which in themselves put in peril the life of the patient. Before this treatment is begun there ought to be brought to bear the ordinary methods at the disposition of the physician: purgatives, diuretics, stimulants, sedatives, etc., and it is not until the insufficiency of these is evident that as a last resort resource is to be had to "disintoxication of the blood." This is most often indicated in the following maladies: Uremia, eclampsia, diphtheria—when antitoxic serum does not suffice—infectious pneumonia, capillary bronchitis, malignant icterus, general acute peritonitis, cerebro-spinal meningitis, typhoid fever, measles, smallpox, scarlet fever, puerperal fever, cerebral complications of rheumatism and gout, poisoning by alkaloids, extensive burns of the skin, etc.; in short, in all cases in which there may be expected danger as much or more from general intoxication as from actual lesions of the organs themselves. In all these diseases there is to be noted a considerable diminution, if not a complete cessation, of the urinary function, and the disintoxication of the blood has for its immediate purpose: 1, to eliminate artificially a certain quantity of toxins; 2, to help to achieve complete elimination by reëstablishing the secretion of urine. The instruments

necessary consist essentially of two india rubber tubes, terminating at their extremities by a needle of a diameter a little greater than that of a Pravaz syringe. The longer of these tubes (about one and one-half inches) conducts into the veins of the arm the artificial serum from a graduated vessel placed at a position more or less elevated in accordance with the degree of force with which the flow of liquid into the venous system is required. The second tube (1 meter), of which the needle is inserted in a vein of the other arm, has its free end in a graduated vessel, and thus serves to extract blood. The flow of the two liquids by this arrangement can be so regulated that no more serum enters than blood flows out and thus the circulatory system, being always equally full, arterial tension need not be diminished, as it is a consequence of ordinary bleeding. "The quantity of serum introduced and the quantity of diluted blood withdrawn may vary between 500 grams and one liter for an adult in accordance with the degree of intoxication. As will be seen, this method of disintoxication of the blood differs materially from another method which has been styled 'washing the blood,' and which has been for some time applied by preference in cases of surgical infection. The difference consists mainly in the contemporaneity of the injection and bleeding. This prevents any severe interference with the circulatory system, and allows, if death from intoxication seems imminent, the withdrawal of the greatest quantity of blood, consequently disintoxication with the least danger to the patient. The exchange of liquids is made very quickly (in thirty to fifty minutes), so that no sharp reaction ensues; grave symptoms insensibly diminish, gradually disappear and are soon followed by refreshing sleep. On waking, the patient desires to pass water. Sometimes sweating accompanies the reestablishment of urination as in natural crises. In the three cases (two of uremia, one of infectious pneumonia) in which Dr. Barré has applied his method, cases in which everything had proved useless and in which death appeared imminent, he obtained improvement as rapid as that just described. Not only did the most serious symptoms cease, but at the end of the urinary crisis they did not reappear and the patient progressed steadily toward cure. Dr. Barré expounds the following theory to explain the phenomena of the cure: 1. There is elimination of the excess of toxins, which constitute the immediate danger; 2, the good effects continue because the bulk of blood is not diminished in volume in the system and does not need reforming at the expense of the fluids of the economy, and the arterial pressure not being diminished no obstacle to diuresis is created; 3, not only are toxins eliminated which appear to have an inhibitory action on the urinary action, but the toxins which remain become diluted and less powerful for evil; 4, as recent researches have proved, the alkaline salts have a favorable action on the bactericide power of the blood, and the method thus provides the economy with a new means of fighting successfully against the microbes. Dr. Barré believes the method will be found of enormous advantage in veterinary as well as human pathology."

**Phagocytosis in Malaria.**—According to the *Bulletin* of the Johns Hopkins Hospital, April, the above subject has been under discussion before the medical society of the hospital. This discussion was participated in by Drs. Barker, Sydney Thayer and Osler. The first named speaker took for his text the microscopic observations that were had of his fatal cases. Certain of the leucocytes are the main phagocytes, then the endothelial cells of the blood vessels, the cells of Kupffer in the liver, then the splenic cells of the pulp-cords. Their contents vary; there may be red corpuscles, sound or injured, infected or fragmented; also pigments of the blood and of the parasites; also other phagocytes.

There is manifestly a division of labor among the phagocytes, since certain of them tend to take up one set of the above

named ingesta, while others contain another sort. In one of his cases, that which is ordinarily regarded as a rare occurrence, there was a marked tendency on the part of mononuclear leucocytes to take on phagocytosis; in all the tissues parasites were found inside the large mononuclear leucocytes. It is just possible that they have taken up these parasites postmortem. Doek and others having pointed out that the malarial parasites cease their development soon after the death of the host. No blood examination was made during life. If this phagocytosis on the part of the mononuclear elements occurred during life they could not have failed being detected in the fresh blood. He also referred briefly to the physiologic question of the relation of phagocytosis in malaria to bile production is of much interest. The phagocytes can be seen passing from the spleen, which seems to be the main cemetery of red blood corpuscles, laden with broken-up capsules and with pigment; then the blood pigment is seen in the endothelial cells of the liver, next in the Kupffer cells, and finally in the liver cells themselves, as though this were a method of transportation of raw material from the spleen to the liver for purposes of bile manufacture.

With reference to the relation of phagocytosis to natural resistance and to spontaneous cure nothing can be decided. The strife is still going on between those who favor the doctrine of the phagocytosis and those who see in the blood serum the main protecting mechanism.

"As regards the form the parasites assume inside the phagocyte, it is easy to make out that a great many of the parasites rupture after inclusion, and one can see the lines of pigment running from the parasite out into the protoplasm of the phagocyte. Golgi thought that the parasites could multiply within the phagocytes, and Bignami still believes that latent infection is to be explained in many cases by the long continued life of the parasite within the phagocyte. Certainly forms of bacterial infection are described which have analogies with this view. Then, finally, as to the inclusion of some phagocytes by other phagocytes. It makes a very interesting picture to see a huge phagocyte containing within it one, two or several of the cells of the body. Sometimes phagocytes are included along with non-phagocytic cells, and sometimes a phagocyte is seen inside of a phagocyte, which in turn is within a third larger phagocyte. Sometimes the huge phagocytes look degenerated; in such a case we can conceive of a young phagocyte going into the large phagocyte after its contents or even to eat up the dying protoplasm. On the other hand, sometimes the included phagocyte looks degenerated, in which case we can think of the large, active phagocyte taking up the small one into its substance—eating up its neighbor. These curious phenomena, which I have perhaps too fancifully spoken of as the cannibalistic and thieving tendencies of phagocytes, are among the many attractive problems connected with the sociology of cells which the future has to solve."

Dr. Osler's remarks touched upon the subject of the rarity of cirrhosis of malarial origin. He said that so far as he could glean, that affection is remarkably rare in this country. "No well-marked instance of it has ever fallen under my observation. I have frequently looked for it at the Philadelphia Hospital, where we had a very large malarial material, and I think, with the exception of the one case mentioned by Dr. Welch, I do not know of any instance in the North in which the condition has been found. We have had only one case here in which clinically we suspected that the cirrhosis might be malarial.

"With reference to the irritation of the malarial pigment as a cause of fibrosis, it is interesting to call to mind the observation which Dr. Welch brought before us here a few years ago, namely, a form of anthracotic cirrhosis in which the fibrosis in the liver seemed to be due to the amount of pulmonary carbon which had reached the liver in roundabout ways."

A foot-note further refers to the contention of clinicians as

to this alleged malarial sequela, and says that the dispute has been of the warmest. Dr. Osler in his writings has insisted upon "the necessity of considering other etiologic factors, e.g., alcohol, syphilis, tuberculosis, even when malaria appears to stand in a direct relation to the disease. Of the many persons who have had malaria, very few of them have developed cirrhosis of the liver afterward. Dr. Welch states that in his autopsies in New York he met with only one case of cirrhosis of the liver that could be said to be due to malaria; that occurred in an Algerian. Bignami, the most important writer on the changes in the tissues in malaria, thinks that malaria may undoubtedly lead to subsequent cirrhotic processes, and he traces with great acumen the changes that gradually occur as a result of repeated attacks of malaria."

Dr. Thayer asserted that there is as yet no absolute proof that the "malarial parasite produces a toxin, and yet there are observations which are rather suggestive, particularly those by Brousse and by Roque and Lemoine, who have shown an increased toxicity of the urine just following the attack; and by Queirolo, who has shown that the sweat during the sweating stage is much more toxic than that obtained under other circumstances. It must be said, however, that Botazzi and Pensuti have shown that much, if not all of this increased urinary toxicity may be accounted for by the increased excretion of certain potassium salts and urobilin, as well as by the presence of peptone. Taking into consideration, however, the various symptoms of malarial fever, there is, by analogy to the other similar conditions, every reason to believe in the existence of some soluble toxic substance. The fact that in certain severe cases they were present in such small numbers in the peripheral circulation led Baccelli to think that in some instances a small number of parasites might produce the gravest symptoms owing to their excessive virulence. In their recent admirable article Bastianelli and Bignami rather dispute this and say that in no case of pernicious fever in which they have studied the tissues postmortem have they failed to find a total very large number of parasites; very few perhaps in the peripheral circulation, but numerous in the spleen, brain, liver, or gastro-intestinal tract."

## PRACTICAL NOTES.

**Non-excretion of Pathogenic Microbes with the Perspiration.**—Krikiwy describes in *Wratsch*, Nos. 8 to 10, his experience with cats inoculated with anthrax bacilli and then injected with pilocarpin. Microscopic examination of the profuse sweat induced was entirely negative in any discovery of the bacilli, although they were found in the blood and tissues.

**Cocain Intoxication.**—Several cases of poisoning from cocain are collected in the *Therap. Woch.* of June 21, most of them produced by injections in the urinary organs. In one case a syringe of 20 per cent. solution was injected into the bladder, followed by immediate death. The dose in the other less serious cases was 2 grams cocain to 30 grams water. In another case 0.5 grams injected in two doses was followed by transient edema of the eyelids.

**Boards of Health and Cemeteries.**—A law was passed in New Jersey, which was approved March 5, 1896, that provides that no new cemetery shall hereafter be established, nor shall any cemetery now existing be enlarged or any lands not now used for cemetery purposes be used for such purposes in cities of the first class, in that State, without the consent of the common council and board of health of such city, to be expressed by resolution and the approval thereof by the mayor of such city.

**Effect of Local Warmth on the Secretions of the Stomach.**—Some experiments by Prof. Tschudnowsky on normal persons with hot compresses or a Japanese heater, applied to the region of the stomach from three-quarters to three hours, showed that the general secretions and activity of the stomach were increased, with more free hydrochloric acid, and an increased power of assimilation and motor activity of the organ. These

effects persisted from several hours to several days.—*Medicina*, Nos. 3 and 4.

**Cresochin.**—Under this name a non-alkalin cresol disinfectant is prepared which is stated to be a neutral combination of tricresyl sulphonate and quinolin with tricresol. It contains 33 per cent. of quinolin and 17 per cent. of tricresyl. It is not caustic and is soluble to the extent of 1 to 25 in water. It is specially indicated as a disinfectant, since, being free from alkali, it does not set free ammonia from nitrogenous organic matter. *Druggists' Circ. and Chem. Gazette*, July, 1896.

**A New Appliance in Intestinal Surgery.**—Dr. M. L. Jamison, in the *Medical Sentinel*, June, 1896, calls the attention of his Pacific coast brethren to the fact that they can secure apposition of the divided intestine just as successfully by using a roll of half-cooked biscuit or bread dough. This can be rendered aseptic, and after using the Lembert suture, can be slipped either down the intestine or left in situ. There is not the slightest occasion for any expensive "buttons" of any kind. What is the matter with a bread stick?

**Hot Compress for Ulcers.**—*Nouveaux Remèdes* for June 24, quotes a Russian periodical in which Yakovlef announces his successful treatment of atonic ulcers with moist hot compresses, during the last three years. They will, according to Yakovlef, cure where all other kinds of treatment have been ineffectual. He ascribes their success to their favoring local hyperemia, thus improving nutrition, while being moist they do not adhere or irritate.

**Surgical Instruments and Appliances Out of Place.**—The following cases of foreign bodies left in the abdomen after laparotomy are cited in the last number of our Spanish contemporary, *El Siglo Medico*: "Sir Spencer Wells twice forgot forceps in the abdomen; Pilatte, a compress; Terrillon, a forceps; Quenu, a compress; Michaut, a roll of iodoform gauze; Severnao, two binders of 1.30 meters long. The utmost care of instruments should be taken during a laparotomy, for, as Pozzi says, a pair of forceps may slip into a basin or be carried off attached to the tumor or to a sponge without being perceived and lead to the opposite error. H. C. Coe, on two occasions, reopened the belly to search for a sponge that had fallen into a pail."

**New Hydrostatic Exploration of the Body.**—At the meeting of the Académie de Médecine, June 16, Marc Sée announced a new and effective method of abdominal palpation. When a person reclines in a bath, the front abdominal wall is lifted by the water until it can almost be said to float, while the muscles are so relaxed that the whole abdomen becomes flaccid, rendering palpation an easy matter. Sée states that he has been able to palpate in this way in the water the entire abdominal cavity, even to the spine and the sacro-vertebral angle, through the viscera.—*Bulletin*, June 16.

**Pericardotomy.**—The superiority of pericardotomy to puncture in the treatment of pericarditis with effusion is confirmed again by its success in a case recorded in the *Arch. de Méd. et de Ph. Milit.*, Nos. 1 and 2. Four punctures into the serous effusion were ineffectual, but complete recovery followed pericardotomy with local cocainization, in the fourth left intercostal space, although broncho-pneumonia of the left side intervened.—*Centralbl. f. Chirurgie*, June 13.

**Tolerance of the Pregnant Uterus.**—Ozenne has a study of the effects of traumatism on the pregnant uterus in the *Bulletin Médicale* for June 21, which confirms its surprising tolerance to injuries. Accidental or surgical traumatism in the neighborhood of the uterus often has no influence on the evolution of the pregnancy. It is more liable to affect it if in the genital zone, but in all cases it is by no means unusual to have the pregnancy continue to a natural close, and the surgeon is justified in any operation on or near the pregnant uterus, not only when it is urgent, but also when it is for the purpose of

removing any cause liable in the future to interfere with the normal evolution of the pregnancy. In two cases in which he had removed a large polypus from the neck of the uterus, the pregnancy continued uninterrupted.

**Treatment of Diabetes Mellitus with Rectal injections of Pancreatic Glands.**—Lissère has treated two cases of diabetes mellitus with fresh pancreatic glands chopped fine and left twenty-four hours in a saline solution. As the stomach refused to tolerate this, he administered it in rectal injections once or twice a day. The results were that the polyuria was very much diminished, as also the amount of sugar in the urine. Both the sugar and the diuresis returned to their original conditions whenever the injections were suspended. They also exerted a favorable effect upon the general health; the patients gained in weight and lost their excessive thirst.—*Nouveaux Remèdes*, June 24, from *Med. Obozr.*, No. 4.

**Neuritis from Compression of the Ulnar Nerve by the Bicycle.**—*La Province Méd.* of June 20 describes the experience of Dr. Destot after a long ride on the bicycle when he was obliged to grasp the handle with especial firmness for some reason. It produced pronounced neuritis of the ulnar nerve with paresis. It adds that it is very important to have the handle of the bicycle constructed on physiologic principles. The body is supported and balanced by the inner edge of the hand, and if the part of the handle grasped is perpendicular to the axis of the hand, the contracted flexor muscles of the fingers form a series of elastic cords which act like a cushion to prevent injury to the nerves from compression and the incessant jar of the machine. But if the handle is oblique to the axis of the hand the lower end presses against the root of the thumb and also compresses the pisiform, the flexor muscles no longer act in the same way and serious injury to the ulnar nerve may result.

**Helferich on the Indications for an Operation in Appendicitis.**—It is universally conceded now that the only treatment of a well-developed perityphlitic abscess is the prompt use of the knife. It is indicated by swelling in the iliac fossa, and diminished percussion, except when there is a layer of intestine above or gas in the abscess. Cutaneous inflammation is rare, while edema of the cellular tissue during the inflammation is frequent. McBurney's sign is of more importance in diagnosing chronic appendicitis than in an abscess. Roux considered a certain infiltration of the cecum as important. Lennander has not always observed Madelung's sign of the difference between the rectal and axillary temperature. Helferich advises scrupulous care in exploring, not to split the wall of the abscess. He recommends exploratory puncture only when the operation can follow immediately. It is important to examine also the rectum and vagina, as the abscess may present itself in the small pelvis and even in parts still more remote. It may even penetrate into the pleura, or any of the hollow organs of the body, when it is usually fatal. He advises prompt operation in recurring appendicitis, as it may turn into perforating peritonitis at any moment.—*Centralb. f. Chirurgie*, June 20.

**Surgical Treatment of Acute Diffuse Peritonitis.**—John Y. Brown says that prominent among the factors leading up to success in the management of intra-abdominal inflammation has been the acceptance of the doctrine that peritonitis, whether local or general, is from its inception a condition demanding the care of the surgeon. He draws the following conclusions: 1. That septic peritonitis is a surgical condition, and should at the earliest possible moment be put under surgical supervision. 2. That all cases of acute diffuse peritonitis are not necessarily fatal, and while the mortality following operation must be great, many of these cases can be cured by prompt resort to the knife. 3. That success in these cases will depend on (a)

early operation, (b) careful cleansing of the abdominal cavity by sponging and irrigation, (c) by drainage by means of glass drain, supplemented if necessary by gauze. 4. That all such cases should be operated on. No surgeon should fail to give his patient the benefit of the chance afforded by operation, no matter how desperate the condition may be; they all die without operation, and many desperate cases are cured by prompt surgical interference.—*Medical Mirror*, May, 1896.

**Formalin in Ophthalmic Practice.**—Dr. Swan M. Burnett mentions the property formalin has of diffusing itself through living as well as dead tissues, a property not possessed in the same degree by any other drug. Sublimatè coagulates albumin and limits its own field of action. Formalin should be more useful than other germicides for the class of infections in which the microbes penetrate the substance of the tissues. Excellent results have been obtained from its use in infecting ulcers of the cornea and purulent conjunctivitis. The corneal ulcer can be touched with a solution of 1 to 200 or 1 to 500, once every day, and for general use as an antiseptic collyrium of 1 to 1,000 or 1 to 2,000. Satisfactory results have been obtained with it in muco-purulent and purulent conjunctivitis. In the more severe forms silver nitrate is used in addition. In acute catarrh of the conjunctiva (pink eye) it has acted most promptly when used as a collyrium of the strength of 1 to 1,000 or 1 to 2,000 applied every four hours.—*Nat. Med. Review*, July, 1896.

**Treatment of Gastric Crises in Tabes with Cerium Oxalicum.**—The serious vomiting periodical in tabes is sometimes relieved by morphin, but its continuous use in chronic cases is not advisable, and some, like Hoffmann, have not been successful with it. Professor Bechterew, of St. Petersburg, has been using cerium oxalate for this purpose, and reports marked success with it. The vomiting seizures during the day were reduced from 200 to six in two days. The act of vomiting was rendered much easier, while the pain, thirst and nausea vanished to a great extent. The psychic conditions were also much improved, restlessness subsided and sleep returned. Urinating became slightly more difficult, but not enough to require a catheter. The most important improvement, however, was that the food could be retained, the vomiting after eating having been so much reduced. The *Therapeut. Wochensch.* of June 21 describes a couple of severe typical cases relieved by this treatment. The dose was the same as in hyperemesis gravidarum, from 0.5 to 0.10 or even 0.15 three to four times a day.

**Chaput on the Treatment of Cancers of the Rectum.**—In ten resections of the rectum for cancer, Chaput has had eight recoveries and two deaths (one due to broncho-pneumonia from ether, and the other to laceration of the ureter in an almost inoperable case). Two cases were followed by a speedy relapse, but three others have shown no signs of a relapse in the two to five years since. Another has had a relapse, but it has had no effect on the general health. In two cases there was no prolapsus; in one of them he had made a circular suture, in the other he had twisted the upper end according to Gersuny. In two cases in which he had not taken these precautions, there was prolapsus. He considers cancer of the rectum as one of the least liable to a relapse. Technique: He advises a preliminary anus made in the transverse colon a couple of days beforehand. Y-incision; resect the coccyx and respect the sacrum; make as nearly a circular suture of the two ends as possible; if impossible, twist the upper end à la Gersuny; ligatures are unnecessary; the skin is not to be sutured. Pack the wound with aseptic gauze, impregnated with a weak phenic solution. Hochenegg's method (invagination of the upper into the lower end) should be absolutely rejected. Indications: Cancers of the recto-vaginal septum, remove with a perineal incision; close the upper end of the rectum in a cul-de-sac; ensure evacuation of matters with a definite iliac or transverse

anus. Cancers of the lower part; circumscribed; circular incision with Denonvilliers incision and resection of the coccyx (Verneuil, Terrier), suture to the skin of the upper end twisted à la Gersuny. Hartmann's method (ablation by the natural route) is highly to be recommended. Diffuse; combine the perineal and the sacral incisions. Cancers of the middle region; the sacral route is preferable to the vaginal. High cancers must be attacked through the abdomen, while rectocolic cancers are best removed by the abdomino-sacral route.—*Bulletin Médical*, June 21.

**The Micrococcus of Articular Rheumatism.**—The *Gaz. degli Ospedale e delle Clin.* for June 20 contains a description of the micrococcus discovered by Maragliano and his assistants in the blood of typical cases of acute articular rheumatism. He found two microorganisms, but one, resembling a bacillus, is not pathogenic. The other produced in rabbits the symptoms of the acute form of the disease, polyarthritides, pericarditis, pleurisy with effusion, endocarditis, etc. An injection of  $\frac{1}{2}$  to 1 c.c. of bouillon culture resulted in death after sixteen days. Some healthy rabbits placed in the cages formerly occupied by the inoculated rabbits succumbed to an epidemic of arthropathy with exudation. This new micrococcus resembles the staphylococcus, but it is only half the diameter ( $0.5\mu$ ) of the aureus. It is massed in groups of six to ten, except in bouillon cultures, when it occurs in short chains or united by twos. It stains readily by the Gram method and with all the usual anilin stains. It forms an oval culture on a gelatin plate, finely granulated, with even edges, pale yellowish at the surface and growing more yellowish as it descends. In the gelatin tube culture a thin layer forms on top while the extension below rather dries up the gelatin than liquefies it. The growth is more scanty as it works downward. In old cultures it resembles a flower with notched petals, the stem spreading out above into an enlargement resembling an ovary. In agar and serum it is whitish, and the edges are even, as is also the case on potato. Cloudiness is noticeable in bouillon after the second day, which indicates that it is motile. It does not coagulate milk; it develops at the usual temperatures, but especially at 98 degrees.

**The Causes of Retroversion and Retroflexion of the Uterus.**—Dr. Hunter Rabb says that (*Cleveland Med. Gazette*, July) in the causation of backward displacements of the uterus the following factors may be concerned:

1. Congenital defects. A short vagina necessitates a forward position of the cervix; this tends to bring the fundus and anterior surface of the uterus under the direct line of abdominal pressure. The ordinary distension of the bladder now throws it backward, thus causing a displacement. A congenitally long cervix can not rest with its long axis crossing that of the vagina, but must accommodate itself to this axis; this also tends to throw the fundus backward. Where the cervix is long the body of the uterus is apt to be small and short. In such case the normal position of the uterus is in retroversion.

2. Extreme distension of the bladder throws the fundus far back in the pelvis behind the median line. When this happens often the malposition is liable to continue.

3. Impacted feces in the rectum extending up above the ampulla push the cervix down in the vagina, and thus change an anteversion into a retroversion.

4. A sudden severe strain put upon the abdominal muscles, especially when the bladder is full, brings about a retroflexion by forcing the uterus down when the pelvic floor yields.

5. Of all causes of retropositions the most frequent is a relaxation of the vaginal outlet; the relaxed outlet must be regarded as a deficiency in the pelvic floor, which leaves a smaller or larger surface over which no counter-resistance to the intra-abdominal pressure remains. Every act accompanied by intra-abdominal pressure tends to thrust out the adjacent vaginal

walls; when these have once entered the orifice they continue to be forced down, wedging the posterior wall further away from the symphysis. While the parts below give way the uterus is forced toward the outlet. The fundus rotates so far back that the pressure is finally spent on the anterior surface of the uterus and complete retroversion or retroflexion is established.

6. Finally retroversion and retroflexion may be caused by inflammatory changes in the uterine support, or by dragging of adhesions resulting from pelvic peritonitis.

**The Decadence of the Gargle.**—An editorial in the *American Therapist*, for June, discusses the question of the future of the gargle, based upon the views recently expressed by Mr. Lennox Browne, at a meeting of the British Laryngological Society. That gentleman, who is the senior surgeon of the London Throat Hospital, stated that his experience pointed distinctly to a conclusion that the time had now fully come when the gargle should be abolished in the treatment of diseases of the throat. He aimed to show that fluids were not brought into effective contact with the posterior surface of the pharynx, if used as gargles in the ordinary way. The editor of the *Medical Press and Circular* is inclined to support this view, with the following argument: He says, "It is to be feared that the time-honored gargle has outlived its usefulness, and that even its antiquity, coeval though it be with the poultice and the leech, can not blind us to the fact that it necessarily falls short of the mark when the diseased tissues are on a plane behind the posterior pillars of the fauces. Even a casual study of the conditions which obtain in the act of gargling as usually understood, will show that the fluid is kept in front of the lowered soft palate, so that it is impossible for any effects to be exercised on tissues posterior to that structure. A gargle, as ordinarily employed, is, therefore, only a mouth wash. Under these circumstances, it is really surprising that it should have been reserved for Mr. Lennox Browne to enter a protest against the continuance of a practice which is not only useless but, in presence of actual inflammation, is exceedingly painful and may be injurious.

"Mr. Browne describes, however, another method of gargling, using the term gargling in the sense of trickling a fluid through the mouth into the pharynx which is free from one, at any rate, of the objections already alluded to, viz., the method of Von Troetch, for which the directions are as follows: 'Take a tablespoonful of the gargle in the mouth, hold it in the back of the throat with the head thrown back, then, closing the nose with the finger and thumb to prevent entrance of air, open the mouth and make the movements of swallowing without letting the liquid go down the throat.' By this means the medicated fluid can, it is true, be brought into contact with the pharyngeal tissues, but the process is by no means easy to carry out in an effectual manner, and in the majority of instances it is quite out of the question. Gargles, again, are quite inadmissible in cases entailing the dorsal decubitus, such as diphtheria, in which cardiac failure has to be sedulously guarded against. Another obvious objection to gargles is, that they must perforce comprise only the most harmless ingredients, if we are to avoid subjecting the patient to the danger of poisoning in the not improbable event of any portion of the fluid escaping control and finding its way down the esophagus. Moreover, solutions thus employed must not contain any considerable quantity of an active ingredient, because they will come in contact with vastly more healthy than diseased tissue. The moral is, that gargles should give place to more scientific and precise methods of applying topical agents to diseased surfaces, especially in children, to whom gargling of any sort is virtually an impossibility. The future, therefore, is toward irrigations, sprays, lozenges, and, in the case of children, to medicated confections."

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance . . . . . \$5.00  
Single Copies . . . . . 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JULY 18, 1896.

THE EATING OF ICES.

There has been some outcry lately against the eating of ices. Hands have been thrown up in astonishment because certain ice cream has been found to contain certain adulterations, and not infrequently the deadly ptomaine. There is no question that many food products are adulterated, but that ice cream is more frequently adulterated than other articles of diet, we disbelieve. A sneer has become habitual with many when speaking of the Americans; and the American fondness for ice water and iced confections has passed into a proverb.

The truth is, however, that the Americans are simply following classic models. When our European confrères smile at our imbibition of chilled fluids, we can remind them that the old Greeks and Romans were even more addicted to the use of ice water than any of the moderns, if we may judge from the pains taken to preserve the ice. ATHENÆUS, quoting CHARES, declares that when ALEXANDER the Great besieged Petra, a city of India, he filled thirty trenches with ice, which being covered with oak boughs, preserved it a long time. The establishment of large ice houses in Rome is usually accredited to the EMPEROR NERO, although the custom of preserving ice was common among the Romans. SENECA, in writing of this, exclaims, "The Lacedæmonians banished the ointment sellers and commanded them to be gone with the utmost speed out of the country; what would have been done had they seen shops to reposit and preserve

ice"? PLUTARCH relates that ice was usually preserved by being wrapped in cloths and straw. The luxurious NERO introduced the use of snow, and wine was cooled by pouring it through a strainer<sup>1</sup> filled with snow (*colum nivarium*). Occasionally the wine was diluted by pouring snow-water into it,<sup>2</sup> but there must have been some unpleasantness attending the use of snow water, for PLINY<sup>3</sup> states that "It was the EMPEROR NERO's invention to boil water, and then inclose it in glass vessels and cool it in snow, a method which insures all the enjoyment of a cold beverage, without any of the inconveniences resulting from the use of snow. Indeed it is generally admitted that all water is more wholesome when it has been boiled; as also water when it has once been heated will become more intensely cold than before—a most ingenious discovery. The best corrective of unwholesome water is to boil it down to one-half. Cold water, taken internally, arrests hemorrhage. By keeping cold water in his mouth, a person may render himself proof against the intense heat of the bath" (*Bostock's Translation*).

But there has always been a prejudice against the use of cold liquids and cold confections. This prejudice must have been the exclusive property of the minority, for the custom has survived and we go on drinking our ice water and eating our frozen *friandes* as NERO did more than eighteen hundred years ago.

The intermediate attempts to write down the custom having failed, it must be clear that something more than a mere desire for luxurious living has continued its use. The Code of Health of Salernum said nothing against it; on the contrary, as a means of reducing cerebral hyperemia from inebriety, the advice is given:

"To drink cold water let him not refrain,  
Because it hinders all that hurts the brain."

—Holland's Translation *Flos Medicinæ*.

BRUEYRINUS insists that GONZAGES, Duke of Mantua, was killed by drinking ice water, and VALANGIN mentions the case of a nobleman, whom he describes as being in every respect a manly character. He was a great advocate for the cold bath, and in general for everything that could harden the body, and imagined that cold "*applied internally* must be as salutary as when applied externally. He often drank his liquors out of ice and ate plentifully of ice creams of various kinds. After having one day taken a greater quantity of these than usual, a fatal inflammation, which at once affected the stomach, the intestines and the kidneys, notwithstanding the assistance of three of the most eminent physicians, who did not leave him an instant, made him fall a victim to his favorite opinion."<sup>4</sup>

Most of the alleged fatalities following the ingestion

<sup>1</sup> Potter, Grecian Antiquities, Vol. 2, p. 258.

<sup>2</sup> Adams' Roman Antiquities, p. 421.

<sup>3</sup> National History, Book 31, C. 24.

<sup>4</sup> Sinclair, Code of Health, Vol. 1, p. 365.

of ice cold drinks except in large quantity rest on no better foundation than the cause in the case cited by VALANGIN, which, viewed in the light of modern pathology is simply absurd.

The profession need not ignore the object lesson that appears under their very eyes every day, namely, that unadulterated ices taken in moderation are beneficial and healthful.

We trust that one of our esteemed contemporaries which recently published a diatribe against the use of adulterated and fictitious ice cream, will not assert that this JOURNAL favors the impure product. Let us throw every safeguard against the sale of impure food and drink of every sort, and then when the sun is hot and cooling shades invite, let us eat our ices and drink our lemonades unmingled by fears of lingering poison in form of microbe or ptomaine.

#### PHYSICAL TRAINING IN THE ARMY.

It is only of late years that the value of physical training has been recognized in the Army of the United States, although the country as a whole for the past fifty years has participated more or less in the modern revival of physical culture. Some of our schools adopted the German system of gymnastics, others the French system of calisthenics and others again the athletic sports of the English. The first gives muscular development, the second grace and suppleness, the third grit, energy and determination to win. All are needful to the proper development of the soldier. At most of our military posts foot-ball and base-ball are played when the weather is favorable, but such sports do good to but few besides the players, and at many posts where the winters are long it has been reported that the only exercise of the men has been shoveling snow and distributing fuel. What is required at every post is a gymnasium with appliances and graded exercises. At West Point, as at most of our colleges, attention has been given to this subject for a number of years and four years ago a handsome gymnasium was completed and fitted up with every desirable appliance. The fourth class cadets receive instruction three times a week from October to June, each lesson forty minutes. The training is based on the German system with such additions from other systems as seem advisable to develop activity and grace as well as power. Gymnasiums have been extemporized at several of the posts by fitting up an unused barrack-room or hall with the needful appliances, and in some instances when the post provided no facilities company commanders have introduced systematic training into their barracks.

This movement has of late received a hearty impulse by the energy of Major General MILES, commanding the Army. Last year while in command of the Department of the East he issued several circulars

calling attention to measures intended to promote the physical development of the soldiers in his department. One gave instructions in methods to be adopted at posts where there were few facilities, submitting a series of exercises for the use of instructors. Another outlined a system for perfecting the training where every facility was at hand, giving due weight to the necessity for medical supervision, not only to prevent overstress but to determine the general line of exercise in particular cases where the development of the individual was unequal. A third gave instructions for training in swimming, in rescuing those in danger of drowning and in restoring those apparently dead, SYLVESTER'S method being that recommended. Since assuming command of the Army the efforts of General MILES have been devoted to extending this work to all the Military Departments. Hence for instance, on June 26 last there were issued from Headquarters, Department of Dakota, General Orders enjoining that all possible facilities and encouragement be extended to officers and enlisted men for indulgence in gymnastic and athletic exercises and all manly pastimes and field sports that tend to develop bodily activity, foster a spirit of emulation and give added interest and attractiveness to the soldier's life. These orders require that a gymnasium be established at each post and an officer designated to superintend the systematic practice of the troops in gymnastic exercises for thirty minutes a day three times a week for nine months of the year (General MILES calls for half an hour every day for nine months) and to initiate and manage all games and contests. Among indoor exercises for inclement weather are mentioned: boxing, fencing, vaulting, swinging clubs punching the bag, jumping either for distance or height with or without pole or spring board, and the use of dumb-bells, parallel and horizontal bars, swinging rings, the trapeze, the ladder, etc. For out-door practice there will be in addition to the above, the passage of ditches, fences, walls, houses and other obstacles; running, wrestling, bicycle riding, throwing the hammer, putting the shot, rowing, swimming, skating, snowshoeing and the like, according to season and facilities. General participation in such games as foot- and base-ball, quoits, tennis, golf, polo, etc., is also to be heartily encouraged.

This interest in physical training in the Army will result in many advantages. It will make life more interesting to the men now in the ranks and will tend to bring into the service a better class of young men than heretofore. It is the present advantage also of keeping the men at home in barracks and away from evil resorts. It is to be expected that the percentage of injuries will be increased but this will certainly be more than offset by a lessening of the number disabled as the result of dissipation. The special objective is however the improved condition of the

troops. These systematic exercises will make our soldiers able to answer the call to special duty at any moment by keeping them always in training; and they will no doubt give an impetus to the physical improvement of many individuals in civil life by attracting attention to the methods adopted by the military authorities, by increasing the care given to this subject at the many universities and colleges having military instructors detailed from the Army, and by stimulating the interest which the members of the National Guard have hitherto shown in their military and athletic training.

### THE NEURON.

Those of the JOURNAL readers—and we are glad to state they are steadily increasing in number—who studied anatomy and histology some lustrums ago, and supposed that these branches of medical science were at a standstill, are occasionally nettled to find nowadays that in some departments, especially neurology, rapid and even phenomenal advances are being made. In the place of our old acquaintances, the nerve fibers and nerve cells, we are confronted with neurons, axons, dendrites and other unfamiliar appellations. We learn that instead of the nervous system being composed of two kinds of tissues, the vesicular or gray and the fibrous or white, it is made up of a series of independent morphologic and physiologic units which have been named neurons by WALDEYER.

Each neuron is composed of: 1, a nerve cell; 2, protoplasmic processes or dendrites; 3, its axon or axis cylinder passing into the nerve fiber; and 4, its ending in a branched tuft. In the neurons of the anterior roots of the spinal nerves the protoplasmic processes are short and the axis cylinders long; in the posterior roots these conditions are reversed, the axis cylinders are short, the protoplasmic processes, on the contrary, are long, reaching to the periphery from which impulses are collected. These conditions are explained by LENHOSSÉK's discovery in the earth worm. In this animal there are no nervous organs like the spinal ganglia, but sensory cells or gangioblasts are dispersed through the integument with long processes reaching internally to the central nervous system and short filaments reaching externally. It would seem as if during the evolution of the higher forms, the gangioblasts have been withdrawn from the exterior and thus pulled their collecting filaments into the long process.

We learn also that the transmission of nervous impulses does not require a continuous physical structure without breaks. "Substantial continuity does not exist," says RAMON Y CAJAL,<sup>1</sup> "the currents are transmitted from one cell to another by contiguity or contact, as in the joining of two telegraph wires. This contact takes place between the terminal

branches or collaterals of the axis cylinders of one side, the cellular bodies and the protoplasmic branches of the other." Instead of afferent and efferent, or centripetal and centrifugal, to denote the direction of the nervous currents, CAJAL has introduced the terms cellulipetal and cellulifugal. For example, the end tufts of the neuron are stimulated by impressions from the exterior; this impulse is transmitted to the nucleus of the nerve cell (cellulipetal); from there it is conveyed to other terminal tufts, say in muscle fibers (cellulifugal).

According to CAJAL,<sup>2</sup> "the probable direction of the nervous movement is cellulipetal in the protoplasmic prolongations and cellulifugal in the axis cylinders." GOLGI, the distinguished Italian histologist, believed that the Deitersian or protoplasmic processes preside over the nutrition of the nerve cells, collecting nutriment for them. GERLUCH was of the opinion that the terminals were collected into a fine network, interlacing with each other and forming a support for the gray matter. It is now thought beyond question that the protoplasmic processes are for the transmission of nerve impulses and nothing else.

The simpler reflex acts can be produced by impulses from without, being transmitted along a neuron to others in the spinal cord and immediately back to a muscle fiber. It is not likely this ever actually occurs, but that the reflex acts are of a more complex character requiring the interposition of secondary neurons. The practical application of this neuron theory lies in the fact that nerve fibers are now to be looked upon as processes of the nerve cells themselves. We can therefore understand the influence of diseased conditions of the fibers on the nerve cells better than in 1857, or when WALLER announced his law: "Degeneration occurs along the whole extent of any nerve fiber which is cut off from the cell which governs its nutrition." This cell, HIS has shown us, from his embryologic researches, is in every case the cell from which the fiber originally grew, a conclusion we can, from our present knowledge of the neuron, readily understand. It was formerly supposed that the proximal part of a severed nerve, with its cell body, did not undergo degeneration but remained normal. From time to time, in patients who had suffered amputations, examination showed that these cells instead of remaining normal had undergone more or less degeneration. These clinical observations have been supplemented by experiments. NISSEL, for instance, has severed the facial nerve in rabbits and found definite alterations in its nucleus in twenty-four hours, consisting of a fine granular degeneration and rarefaction of its ganglion cells. FLATAU has confirmed these experiments by some others on the motor oculi of cats.

We can understand if the nervous system is made

<sup>1</sup> Les Nouv. Idées sur la Struct. du Syst. Nerveux.

<sup>2</sup> Loc. Cit.

up of cellular units, like the liver, kidney, etc., it must be subject to like cellular changes. Future researches will entirely recast the pathology of the nervous system and place it on a firmer basis. This will no doubt require much time and labor, but the field will abundantly repay the workers in it.

#### PARESIS AND PSEUDO-PARESIS.

Within a few years the literature of paresis or general paralysis of the insane has been enriched by numerous papers, and some different conceptions of the disorder than those that have hitherto prevailed, have been suggested. Not only its pathology and etiology, but also its symptomatology have been questioned, and the consequent confusion has induced at least one author to say that "as it at present stands, general paralysis would appear to be best defined as a progressive disease which begins anyhow but ends somehow." Whether this pessimistic conclusion is justified may be a question, but the fact illustrates the confusion that these later aspects of the question have created.

For a long time it has been the practice to recognize paresis as a marked entity, varying somewhat in its symptoms and rather uncertain in its intimate pathology, but always or generally readily recognizable. With this, however, it has been claimed exist other conditions closely resembling it but nevertheless entirely different, but with almost identical symptomatology that embarrasses the diagnosis and tends to make confusion in certain special cases. Such are the pseudo-pareses due to alcohol and lead and some conditions following fevers, malarial or otherwise, insulations and especially syphilis. This latter has been the cause of pseudo-paresis *par excellence* in the classification of certain authorities, following FOURNIER, the author of the term "syphilitic pseudo-general paralysis," who, however, has himself apparently since abandoned the idea of its being a distinct entity apart from the genuine disease. Still another form, mimicking paresis in some of its earlier phases, at least, is occasionally met with in neurasthenia, and this seems to have been generally overlooked by those who have written on the subject, notably so by DR. HYSLOP, the author already quoted, who has recently discussed these causes of confusion and who rather caustically criticises the common indefiniteness of medical notions in regard to paresis.

There is no question but that there is quite a wide range of variation in the symptoms of this disorder, and that it is impossible to make any absolutely typical syndrome to which all cases must conform. This fact has, however, long been recognized, and some have maintained that we have in this so-called disease several distinct disorders. It is also true that there are several conditions that more or less resemble it but differ in their prognosis, such as the temporary

pseudo-paresis of alcoholism, saturnism, malaria and neurasthenia. These can not indicate a permanent or serious lesion of the brain, but there is no doubt that their occurrence means a functional involvement of the same cortical regions as are implicated in true paresis. The one is due to a temporary intoxication, the other to destructive and irreparable lesion, but there is no reason why the toxic agents that usually cause only transient disorder can not, under certain conditions, induce the permanent and progressive lesions of the true disease. In this way we may perhaps account for an occasional case of paresis with no other known causal factor than alcoholic excess, over-worry or work or lead poisoning. There would be no good reason for calling such an actual progressive case pseudo-paresis, even if it were positively known that it had no other origin than one of those above enumerated. The designation should be dependent on the actual condition, not on its cause, but there is no propriety in including transitory functional disorders in a disease which is essentially and typically progressive. We can properly speak, therefore, of an alcoholic, neurasthenic or saturnine pseudo-paresis, and possibly also of a syphilitic pseudo-paresis, limiting the term in this case to a purely transient disturbance of the cortical functioning without any serious or irreparable lesion. Whether such cases often occur is exceedingly doubtful, but the exceptional instances are probably accountable for the rare cases of cures reported of progressive paresis.

Although, as already stated, FOURNIER seems to have abandoned the idea of a syphilitic pseudo-paresis, this is still maintained by many, and the more strenuously that the conviction has been growing of late years among alienists that nearly all, if not all cases of paresis are of syphilitic origin, or at least have had syphilitic antecedents. This, which is in its way, if true, a very decided advance in the pathology, meets with strong objections from some quarters. Syphilis being considered a disreputable disease, is not, to many, a very acceptable origin for a disorder that is becoming increasingly frequent in civilized society. Some of the efforts to discredit it as a cause have been so much overdone as to call out the sarcasm from FOURNIER that, according to their statistics, a man should acquire syphilis in his youth to insure against paresis in middle age. An English exchange attributes the confusion as to what is paresis or general paralysis to the growing belief in its specific origin, and speaks virtuously against the disposition to accept assumptions for facts and *post hoc ergo propter hoc* arguments in medicine. The fact in itself, however, that this theory of the causation of the disease has steadily grown in favor in spite of sentimental objections, is a strong argument for its validity, and at present it is beginning to claim both numbers and the weight of scientific authority on

its side, though it can not yet be accepted as an absolutely proven or universal truth. The cases that are not syphilitic are coming to be admitted as probably the rare exceptions; and the term "syphilitic pseudo-paresis" will probably soon be limited to those forms occurring after recent syphilis and amenable to specific medication. Even these cases can not be always definitely delimited, and the elements of time and continued observation should always be taken into consideration in the diagnosis.

A possible cause of confusion is the occurrence of senile changes in the brain. Undoubtedly there have been too many cases of paresis diagnosed in men over 50 or 60 years of age, and some cautious alienists have declined to recognize it as occurring after the latter limit. It is very possible, with an atheromatous condition of the vessels, for cortical degenerations to occur that may produce symptoms very closely resembling those of genuine paresis, and this should therefore always be reckoned with in making the diagnosis at any age.

While the occasional difficulties of diagnosis of paresis may be admitted and the possible occurrence of pseudo forms acknowledged as actual or probable, it would be no advance to question or give up its reality as a separate and well-marked disease. It may be often simulated, its characteristic of incurability may even be now and then discredited by some well-observed case, it may have long and puzzling remissions, its pathology may be in doubt in some important regards, but as a cortical disease characterized by a general, steadily progressive mental and physical deterioration, it exists as indisputably as any other affection with which mankind is cursed.

#### "THE GREAT UNREADY" VACCINATION COMMISSION.

The editor of the *Practitioner*, in his masterly Jenner number for May, recalls the fact that his great nation has been waiting seven years for the Royal Commission to speak. The courts are in a measure "tied up," waiting for a decision; while the medical profession is almost dreading a decision. The editor is moved to compare the situation with that of which HORACE wrote when he told about the peasant who took his seat on the bank of a river to wait and see the stream flow past. Or, as another writer has shaped it, "The report will not appear until just after the Greek Kalends."

One good point is made in the article to which we refer, and one that should never be lost sight of, namely: It is always the poor, the ignorant and the helpless who suffer from the fads of faddists; we and ours are relatively free from danger.

Through epidemics and rumors of epidemics the Royal Commission on Vaccination still sits in sphinx-like silence. Smallpox may come and smallpox may

go, but it goes on forever. In appointing the Commission, on May 29, 1889, the Sovereign gave its members the following injunction: "And our further Will and Pleasure is that you do, *with as little delay as possible*, report to Us under your hands and seals or under the hands and seals of any five or more of you, your opinion upon the several matters herein submitted for your consideration." The manner in which these "right, trusty and right well-be-loved" gentlemen have carried out this injunction entitles them to the gratitude to at least one section of the community, to-wit, the antivaccinists. Owing to the delay in issuing the report, vaccination has almost died out in many parts of the country. Nearly a hundred Boards of Guardians have decided not to prosecute for refusal to obey the law, and in other cases where the Guardians do their duty in the matter magistrates hesitate to punish until the Commission has issued its pronouncement. A magistrate waiting for this event seems to be like the countryman in HORACE, waiting for the river to flow past. Meanwhile the public mind is necessarily in a state of suspense from which it is from time to time roused by such incidents as the present outbreak at Gloucester. In whatever sense the Commission reports, it will now, I take it, be impossible to enforce compulsory vaccination—at any rate, until a series of epidemics once more teaches people the value of the protection they now make light of. "He jests at scars and never felt a wound." Well, we who know how to safeguard ourselves and those under our charge can look forward to the wrath to come without fear; but it is sad to think of the helpless children of deluded, ignorant, or careless parents.

In this connection, the *Medical Press and Circular* calls attention to the fact that vaccination has its friends in the House of Commons: "Despite the delay, and the supposed opinions expressed, in the forthcoming report of the Royal Commission on Vaccination, it is evident that the House of Commons is a strong center favorable to vaccination. In reply to a question last week in the House as to the recalcitrant action of a particular Board of Guardians, which had rejected a solution to enforce the Vaccination Act, the President of the Local Government Board stated that he had addressed a communication to the Board in question pointing out to them that by failing to enforce the provisions of the Act they were incurring a very grave responsibility. This announcement, it is especially worthy of note, was received with cheers, thus showing, unmistakably, that the results of the Gloucester epidemic have not been lost upon the Members of the House of Commons. The *Gloucestershire Chronicle* recently published some interesting statistics respecting the visitation of smallpox to the town to which some reference may be made, and here it may be said that the inhabitants of Gloucester owe a large measure of

gratitude to the editor of our contemporary for the unvarying, convincing and disinterested manner in which he has pointed out to his fellow townsmen the right course to take in regard to vaccination. In temperate language he has consistently advocated vaccination, simply because he has honestly satisfied himself that there was no other alternative to adopt in the presence of the terrible epidemic which was raging in the town. The statistics, moreover, which appeared in a recent number of our contemporary, regarding the epidemics, form a strong argument showing the utility of vaccination. The mortality among the total number of cases attacked was 21.7 per cent.; of the unvaccinated cases, 41.4 per cent.; of the vaccinated only in infancy, 8.5 per cent.; and of the uncertain cases, 32.2 per cent.

## CORRESPONDENCE.

### Testimonial to Dr. Davis.

PHILADELPHIA, PA., July 6, 1896.

To the Editor:—The note of Dr. Overlock in the number for July 4, relative to a medal demands some information. The medal to which he alludes is that ordered by the ASSOCIATION in 1875; see Vol. xxvi, page 35. In accordance with the instructions then given, I had a number of the medals struck off and sent to those who forwarded the money. The date on the medal does not mean that when it was issued, but the date of the origin of the ASSOCIATION. Although Dr. Davis was quite prominent in the work of organizing the ASSOCIATION, yet at that time no thought existed of having a medal issued with his likeness on it. The meeting of the profession to organize a national society was held in New York, as stated in the note in the JOURNAL, but Dr. Lewis Williams was not present. I make this mention with no captious spirit but to keep history straight.

Yours very truly,

WM. B. ATKINSON M.D.

### Another Explanation.

MONTGOMERY, ALA., JULY 6, 1896.

To the Editor:—I am sorry to have to trouble you with another explanation. But please allow me to say that I did not advocate before the Conference of State Boards of Health any such scheme of organization as that which you ascribe to me, nor anything in any way resembling it.<sup>1</sup> You are certainly writing under the influence of information that is entirely incorrect. This will be plain when the official Report of the Proceedings of the Conference of State Boards are published. The proposed bill has not taken definite shape. Only its larger provisions have been decided upon. It is some little time yet before Congress meets; and ever since the session of the Association in Atlanta I have been in a most miserable condition of health; during the last two weeks I have been in bed. Under these circumstances I have not been able to push this work as I otherwise would have done. I have been in correspondence with leading physicians in several states and have made some progress toward the proposed enlargement of the Committee.

In the meantime I take this opportunity to say through the JOURNAL OF THE ASSOCIATION that my Committee and myself will be greatly obliged for any suggestions looking to the completion of a wise and judicious bill; and this invitation is especially extended to the Editor of the JOURNAL.

Yours truly,

JEROME COCHRAN, M.D.  
Chairman of Committee.

<sup>1</sup> Our information was in writing, and from a member of the Conference.—ED.

### If She Had Only Been Batteylized.

SAN DIEGO, CAL., July 9, 1896.

To the Editor:—Apropos of recent contributions to the JOURNAL by Drs. Boal and Daniel suggesting castration as a punishment for certain derelicts (degenerates?) I enclose an excerpt from a reliable source:

"Prof. Pellmann of Bonn University, who makes a special study of heredity, has been tracing the career of the descendants of Frau Ada Jurke, a notorious drunkard, who was born in 1740 and died in 1800. Her descendants have numbered 834, of whom 709 have been traced from youth by Prof. Pellmann. Of these, 7 were convicted of murder; 76 of other crimes; 142 were professional beggars; 64 lived on charity, and 181 women of the family led disreputable lives. The family has cost the German Government for maintenance and cost in the courts, almshouses and prisons, \$1,250,000."

The details are quite as startling as those connected with the history of a colored female crook, which were published in Massachusetts some years ago. Herein is food for reflection.

Yours truly,

C. M. FENN, M.D.

### Not Antitoxin.

CHICAGO, July 13, 1896.

To the Editor:—In the JOURNAL of 11th inst. p. 113, appears the following:

"Another Death from Antitoxin.—Dr. W. J. Nolan of Chicago, writes the following to the New York Medical Journal: '285 Loomis St., Chicago, June 24, 1896.

"To the Editor of the New York Medical Journal: Sir:—In view of the discussion now going on in the Journal, of which I have been three years a reader and subscriber, I frankly indorse the views of Dr. Winters in regard to antitoxin in diphtheria. Of one case I must write in terms of strong condemnation. The facts are as follows: I was called to see a boy, 8 years old, pulse rapid, temperature 105 degrees, and the laryngeal appearance quasi-diphtheritic. I began the ordinary treatment, in which quinin, carboic acid and iron formed chief parts. The result next morning was very satisfactory; all alarming symptoms were decidedly not much in evidence. Some time in the evening of this better day, our antitoxin friends raided the house and began their injections à l'outrance. They did not inform me, I need scarcely say; but like birds of evil omen, they swooped down on a defenseless widow and daughters, and injected mightily, nay, as the sequel proved, mortally. Need I express an opinion after this on the discovery, or at least its manipulators?" W. J. Nolan, M.D."

On reading the foregoing in the New York publication of the 4th inst., inquiry was at once made as the facts, with results which led to the following correspondence:

"Chicago, July 6, 1896.

"To the Editor of the New York Medical Journal: Sir:—Not so much in defense of antitoxin—which hardly needs any—as in common justice to its 'manipulators' in this city, as a correspondent, Dr. Nolan, styles them in his letter published in last week's Journal, I ask your publication of the enclosed statement of the facts in the case he therein refers to.

Faithfully yours, F. W. Reilly, M.D."

"Chicago, July 6, 1896.

"F. W. Reilly, M.D., Assistant Commissioner of Health.  
Dear Doctor:—Referring to the letter in the New York Medical Journal of July 4, by Dr. W. J. Nolan of 285 Loomis St., I find by the notes in my visiting list I was called May 27 to that case by Dr. Bergeron who had been called and finding it was a severe case of diphtheria, referred the people to me saying he would prefer not to treat diphtheria. On my arrival I found the case extremely severe, advanced beyond the fourth day, Klebs-Löffler bacilli and also strepto- and staphylo-cocci in abundance, and every evidence of septicemia. I gave an unfavorable prognosis but injected antitoxin with a forlorn hope; and also immunized all the other five children in the family. Then I was informed by the mother that Dr. Nolan had been called on Sunday, May 23, made his second visit on Monday, and then abandoned the case. Thereupon they sent for Dr. Bergeron and by him the case was referred to me. The case was strictly a charity one and so known to be by Dr. Bergeron, and I was compelled to furnish medicine at my own expense. The child died as I predicted on my first visit. None

of the children immunized contracted the disease. The mother, who was not immunized, contracted diphtheria, was treated with antitoxin and promptly recovered.

"I did not see the case nor was antitoxin administered until July 27, the second day after Dr. Nolan had abandoned it. The mother—the defenseless widow—had given him the last dollar she had in the house. She is eminently satisfied with what I did for her child, as are all of the family, and unstinted in her condemnation of Dr. Nolan for his 'heartless neglect,' as she terms it.

Respectfully submitted,  
E. P. Murdock, M.D., Medical Inspector."

I am this morning in receipt of the *New York Medical Journal* of the 11th inst., but fail to find therein any mention of Dr. Murdock's statement of facts and am, therefore, compelled to appeal to your sense of editorial justice to say whether the caption "Another Death from Antitoxin" now seems to you to be warranted.

F. W. REILLY, M.D.

### Our Journal.

TECUMSEH, MICH., July, 4, 1896.

To the Editor:—The JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION was born and passed through its early infantile life in Chicago, arrived at robust manhood in that city, and in Chicago I vote for THE JOURNAL to remain, where it will be in touch with cosmopolitan schools and hospitals.

Respectfully,  
J. F. JENKINS, M.D.

### NECROLOGY.

CHARLES STYER, M.D., a graduate of the University of Pennsylvania, Medical Department, of 1862, died at his home

CHARLES STYER, M.D..

in Philadelphia, July 6, aged 46 years. He was surgeon to the 99th Regiment, P. V., and in June, 1867 he entered the regular army as assistant surgeon, served on the frontier in the southwest mainly, until he resigned June, 1878, to engage in private practice. In 1885, he was appointed Acting Assistant Surgeon in the United States Marine-Hospital service at Philadelphia. For several years he was also one of the Medical Staff of the German Hospital of Philadelphia. He was a prominent member and medical examiner of several social and beneficial orders, being Surgeon-in-Chief of the Royal Arcanum. He was also a member of the Grand Army of the Republic and has been Post Surgeon, Post Commander, Medical Director of the Department of Pennsylvania and Surgeon-General of the National Encampment. Dr. Styer leaves a widow and two sons. His death was found to have been caused by an aneurysm.

SIR GEORGE JOHNSON, M.D., whose death has recently been announced, was a man of mark in his day and generation, in the great metropolis where his life-work was done. Sir George

was born in November, 1818, at Goudhurst, in Kent, and was educated at the Grammer School there. At 19 he was apprenticed to a relative, a general practitioner, residing in Cranbrook, Kent, and two years later, in October, 1839, he entered the Medical School at King's College, London, where he greatly distinguished himself as a student, gaining many prizes. In the wards he was a clinical clerk under Dr. Todd, and a dresser to Sir William Ferguson, and after qualifying, he filled the post of house physician and house surgeon. In 1844 he received his degree of M.D. from the University of London, after having passed through a creditable university career. The position to which he had attained as a prominent alumnus of his medical school at once marked him out as a likely candidate for an appointment on the staff of his hospital, and in 1857 he was elected one of the assistant physicians, succeeding Royle as Professor of Materia Medica and Therapeutics. In this appointment he continued until 1863, when he became Professor of the Principles and Practice of Medicine, which appointment he resigned in 1876 when he became professor of clinical medicine. His connection with the Royal College of Physicians began when he became a member of that body in 1846. Four years later, an unprecedentedly short period, he was elected a Fellow of the College, and subsequently he held the offices of Examiner in Medicine, Junior Censor, Senior Censor, and Vice-President. The blue ribbon of science was conferred upon him in 1872, when he was elected a Fellow of the Royal Society. The following are further honors of which he was the recipient: In 1884, the Presidency of the Royal Medical and Chirurgical Society; in 1889, physician extraordinary to the Queen; in 1892, knighthood.

DR. GEORGE W. RYAN died at the Betts Street Hospital, Cincinnati, July 11, of cirrhosis of the liver after a lingering illness. Dr. Ryan was born in Louisville, Ky., thirty-six years ago and graduated with honors from the university of that city. For a number of years he was connected with the Hospital of the Ruptured and Crippled of New York, where he achieved a national reputation for his surgical work. He came to Cincinnati about twelve years ago and at once commanded a large and lucrative practice. At the time of his death he was a member of the surgical staff of the St. Mary's and Presbyterian hospitals, also a professor in the Ohio Medical college. Dr. Ryan was a whole-souled fellow well met and a gentleman who counted his friends by the hundreds. He was a single man and one of the most popular members of the University club. The remains were shipped to Louisville Saturday, where interment took place.

JAMES S. HOPE, Passed Assistant Surgeon United States Navy, who had been on duty at the Pensacola Navy Yard for two years past, died July 1, in Roosevelt Hospital, New York, after a surgical operation had been performed upon him for a tumor. The remains were carried to Surgeon Hope's old home, Norfolk, Va., for interment. He graduated from the University of Virginia, medical department, Charlottesville, Va., in 1887.

### SOCIETY NEWS.

**New York State Medical Association**—SECOND DISTRICT BRANCH.—The twelfth annual meeting convened at Albany, June 26. Ten counties were represented.

**The Tri-county Medical Society** of Ford, Iroquois and Vermilion, Ill., met at Paxton, Ill., July 7.

**State Board of Medical Examiners of New Jersey**.—The annual meeting of this Board was held at Asbury Park, N. J., July 6. Dr. William Perry Watson of Jersey City was elected president, Dr. E. L. B. Godfrey of Camden secretary, and Dr. A. Uebelacker of Morristown treasurer. The next examinations of this Board will be held at Trenton, September 15 and 16.

**West Virginia State Medical Society.**—The officers elected at the annual election of this Society were published on page 53 of the current volume, but by some inadvertence the item incorrectly made reference to the "Maryland State Medical Society."

**Scott County (Iowa) Medical Society.**—The regular quarterly meeting and annual election of officers was held at Davenport, Iowa, July 2. Officers elected for the ensuing year: President, Dr. J. H. Kulp; vice-president, Dr. E. Strohbehn; secretary, Dr. Adella R. Nichol; treasurer, Dr. Jennie McKown.

**American Dermatological Society.**—The next meeting will be held at Hot Springs, Va., September 5 to 10. Everything will be done to make the meeting a success and several papers on interesting subjects have been already promised. Dr. White will open a general discussion on the subject: "What Effect do Diet and Alcohol have upon the Causation and Course of the Eczematous Affections and Psoriasis." Charles W. Allen, M.D., Secretary, 126 E. 16th Street, New York.

**Eastern Iowa District Medical Association.**—The twenty-fifth annual meeting was held in Fairfield, Iowa, July 25. Papers were read by Drs. J. H. Etheridge, of Chicago; W. B. La Force, of Ottumwa; R. M. Lapsley, of Keokuk; D. W. Overholt, of Columbus Junction, and T. J. Maxwell, of Keokuk. The following are the officers elected for the ensuing year: President, Dr. W. H. Holliday, of Burlington; vice-president, Dr. Snook, of Fairfield; secretary and treasurer, Dr. M. C. Carpenter, Fairfield. The Association will meet next at Columbus Junction in November.

## BOOK NOTICES.

**The Student's Medical Dictionary**, including all words and phrases generally used in medicine, with their proper pronunciation and definitions based on recent medical literature. By GEORGE M. GOULD, A.M., M.D., with elaborate tables of the bacilli, micrococci, leucomaines, ptomaines, etc.; of the arteries, ganglia, muscles, and nerves; of weights and measures; analyses of the waters of the mineral springs of the United States, etc. Tenth Edition, rewritten and enlarged. Philadelphia. P. Blakiston, Son & Co. 1896. 8vo, cl. Pp. 701. Price \$3.25.

"The present volume," says the author in his preface, "is an entirely new one and is designed to take the place of the 'New Medical Dictionary' and the 'Student's Medical Dictionary,' the plates of which have been destroyed." This work is intended for students, and as an introduction to the larger and more expensive "Illustrated Medical Dictionary."

Few works have attained popularity more speedily than the dictionaries of Dr. Gould, and deservedly so. The early acceptance of the orthography advocated by the American Association for the Advancement of Science, and the undeviating way in which it has been carried out, have doubtless had much to do with their extensive sale. The only feature that is open to criticism, for the JOURNAL four years ago adopted the spelling advocated by Dr. Gould, is that of pronunciation. Anyone who may listen to any half dozen readers in our medical societies will likely hear the common medical terms differently pronounced by each. Surely the time has come when medical men may, as Dr. Foster has shown, adopt that pronunciation, which will enable them, without regard to nationality to give a common pronunciation to all words in common use by the profession. We commend this work as we had the pleasure of commending its predecessors by the same author.

**Quain's Elements of Anatomy.** Edited by EDWARD ALBERT SCHAEFER, F.R.S., and GEORGE DANCER THANE. In 3 Volumes. Appendix, Superficial and Surgical Anatomy, by PROF. G. D. THANE and PROF. R. J. GODLEE, M.S. Illustrated by 29 engravings. 8vo, pp. 76. Tenth edition. Longmans, Green & Co. London, New York and Bombay. 1896. While anatomy should not be studied "superficially," yet

superficial or topographic anatomy can not be too deeply graven into the brain of the student and practitioner; indeed, the more attention paid to superficial anatomy, the "landmarks," as Holden termed them, become more clearly visible, the diagnosis is more easily made, and error is farther removed.

The student, and as well the surgeon, will find his knowledge increased and his hand steadied by the careful perusal of this appendix to Quain's well-known elements of anatomy, prior to making a new dissection or undertaking a new operation.

(1) **Whittaker's Anatomic Model.** (2) **The Anatomy of the Human Head and Neck.** A Pictorial Representation of the Human Frame and its Organs. Graphically illustrated by means of superimposed plates, with descriptive text by DR. SCHMIDT. English translation by WILLIAM S. FURNEAUX. New York: Thomas Whittaker (1, 3 and 5 Bible House) Publisher.

These books are pictorial representations showing the anatomic relations of the parts. The plates are superimposed very ingeniously, and are intended for students in general, whether in medical classes or engaged in the study of anatomy as collateral to other studies. The coloring, while not altogether natural, is not so far off as to be violent, and the relations of the parts are as accurately shown as may be on a plane surface. We commend the works for the purposes for which they are intended, and as an aid to the teaching of anatomy in the public schools their value can scarcely be overestimated.

**Kell's Medical, Pharmaceutical and Dental Register-Directory**, with special medical, pharmaceutical and dental departments containing detailed information of colleges, hospitals, asylums, societies, with street lists, etc., for Pennsylvania, New York, New Jersey, Maryland, Delaware and District of Columbia. Fourth edition. GEORGE KELL, Editor. Philadelphia: Burk & McFetridge Co., Publishers, 308 Chestnut Street. 1896.

This directory has the merit of being up to date and is one of the most complete of its kind. Its rather lengthy title fully explains its scope. Every editor, teacher and writer, and as well the general practitioner finds such compilations extremely useful.

## PUBLIC HEALTH.

**Chicago Health Report for June** shows total number of deaths in the month as 1,895. The annual death rate on the basis of the school board's census for the year ending June 30 was 14.83 per 1,000 of population. Last month's rate was 1.17.

**Utah State Board of Medical Examiners.**—This board, which has been but temporarily organized since its appointment by Governor Wells, met June 29 and effected permanent organization. Dr. Bascom was elected president, Dr. John T. White secretary, and Dr. Dart treasurer.

**Baltimore (Md.) Health Statistics for June.**—Health Commissioner McShane's summary for June shows that during that month 647 deaths occurred in Baltimore, a decrease of 136 as compared with June, 1895. Of these 467 were whites and 180 colored. Forty-two died of infectious diseases and 76 of consumption.

**Will the Consultant get His Fee? Probably Not.**—A curious episode has arisen from a difference of diagnosis between two practitioners in a burgh in the west of Scotland. Dr. A. certified a case of enteric fever and sent the patient to a burgh hospital. Admittance, however, was refused, as Dr. B. who had charge of the hospital, diagnosed the case as one of meningitis. Dr. A., in no wise convinced of this view, sent for Dr. C., a consulting physician from Glasgow, who had no doubt the case was really one of enteric fever. Now Dr. A. maintains that Dr. C.'s fee of ten guineas is an expense to which he had been put by the burgh medical officer, and accordingly he claims that the town council ought to refund him this sum.

**The Chinese Women and Their Feet.**—The cruel and ungainly practice of compressing human feet in China has called forth some official medical remarks on the subject to the Chinese Maritime Customs. When questioned closely, not one woman in a hundred will deny that she is a constant sufferer owing to the tight bandages. Many foreigners in China imagine that after a woman reaches maturity she is free from pain, but it is contended that this is not the case. Dr. Macartney, the writer of the report, never found an elderly woman who did not complain of pain. Women with compressed feet can not stand for any length of time without great suffering; in addition to the agony endured in the early period of binding, paralysis of the legs frequently ensues on the practice, and in every case treated by him the patient recovered rapidly when the feet were unbound and left free.

**An Echo from Russia; "Let us have a Department of Public Health."**—The Russians have taken up the cry, and are urging the creation of a minister and department for this purpose, which is said to be more needed in Russia than in any other country for many reasons. The present arrangements for epidemics, etc., are utterly inadequate. Levitsky states that the total medical supplies received at one large station in the Ural, where an epidemic of cholera and typhus was raging recently, amounted in all to one ounce of sublimate, one kilogram of impure phenic acid, 20 grams of tincture of valerian and 20 grams of "Inocemzer" Drops." The present annual appropriation for hospitals in the provinces is the same for each (\$400-8500) irrespective of the size, so that one with 595 beds receives no more than one with 45.—*Bulletin Médicale*, June 21.

**Duluth (Minn.) Water Supply.**—The epidemic of typhoid fever that carried off many of the citizens of Duluth a year ago is brought to mind by a hearing which is called for Monday before Attorney General Childs. Ellsworth Benham, corporation counsel for Duluth, will appear before the attorney general and make an application for a writ of quo warranto to compel the Duluth Gas and Water company to appear in the supreme court and show cause why its charter should not be declared forfeited to the city. The ground on which the application is made is that the company failed to comply with the requirements of its charter, in that it did not supply good and wholesome water to the city. The application charges the company with wilfully placing its intake pipe close to the sewage discharge from the city of Duluth, so that it received the sewage and surface waters of Lake Superior, and that as a result of the use of the water by the residents of Duluth several epidemics of typhoid fever raged in the city and hundreds of people died.

**Food Laws in Pennsylvania.**—The Pennsylvania State Department of Agriculture has just issued formal decisions regarding the provisions of the food laws. Truth and precision in the labeling of foods are insisted upon, and adulteration is distinctly defined. Goods sold as "pure" must be pure, if mixtures they must be marked "compound" in a conspicuous place on the label. A very wise provision is that in any "mixture" or "compound" there must be no fraudulent or worthless article, only such as are designated "ordinary articles or ingredient of articles of food." "Salicylic acid is prohibited as a preservative." This acid has been largely used as a preservative for catsups, mince-meats, etc. Coloring is allowed in food products (except milk, which must contain no coloring matter or preservative) provided the material used is not injurious, but when used in canned vegetables the package must be distinctly and plainly marked "artificially colored." Spices do not admit of any foreign matter and therefore can not be sold as "compounds," or placed upon the market in an adulterated condition. The Pennsylvania market for ground cocoonut shells, corn meal and other standard adulterants will fall off under this construction of the law. Definite limits are prescribed for vinegar, pickles,

lard, preserves, jellies, etc. All the fifteen formal decisions are plain, honest and just. They permit harmless admixtures when definitely stated, but prohibit fraud, misrepresentation and employment of any materials whatsoever which are a menace to health.—*Pharmaceutical Era*, June 25, 1896.

**Illinois State Board of Health.**—The regular quarterly meeting of this Board was held in Chicago, July 7. Dr. F. W. Reilly of the Chicago Health Department presented rules regulating the practice of midwives and proposing to grant greater authority to municipalities in this matter, which were favorably received by the Board. A committee was appointed to draft resolutions on the death of Dr. O. O. Baines. A request was made that the diplomas of the Harvey Medical College of Chicago, be not recognized as it is alleged that this college does not fulfill the requirements of the Board. The matter was referred to the committee on the administration of the Medical Practice act. The Secretary made statement concerning the "Illinois Health University" of Chicago, to the effect that an opinion had been asked of Attorney General Moloney as to the possibility of prosecuting this fraudulent institution under the statute. This concern being chartered may under the law issue medical diplomas, but they are not recognized by any State Board of Health and a number of persons have been victimized. In case this can not be done it is hoped that the legislature will see fit to enact a law which will apply to cases of this kind.

**Do Flies Spread Tuberculosis?**—Dr. W. R. Aylett, (*Virginia Med. Semi-monthly*, June 26, 1896) gives details of investigation: "I smeared a cover-glass with sputum from a well-advanced case of tuberculosis and placed it upon a clean sheet of paper, placing around it seven or eight clean covers. The paper and covers were then placed where flies could have ready access and soon quite a number were feeding on the sputum. An inverted tumbler was lowered over them, making them prisoners without their knowledge. One of the prisoners soon deposited a 'speck' on one of the clean covers. To prevent this becoming contaminated by their feet, I removed it at once. Within an hour or two all of my covers were specked. The covers were then put through the regular cover-slip preparation, carbo-fuchsin being used for the bacilli with methylene blue as a contrast stain. On microscopic examination, the specks were found to contain from one to three thousand bacilli tuberculosis each. I have not yet tested the virulence of bacilli so obtained, but they show no signs of disintegration, seem as perfect and stain as readily as those from pure cultures."

**Death from Eating Ice.**—In the annals of the Health Office and Registry of Deaths, of Philadelphia, a half century ago or more, occurs several times, the diagnosis of "Death from drinking too much ice water." In these days of free refrigerated drinking fountains and universal use of ice in the household, there may occur, each year, a number of such cases; but they are recorded now under a pathologic and not under an etiologic heading. Last week, however, the coroner, who had investigated the death of two children in one family, gave a certificate of death from dysentery occasioned by the excessive use of ice. As they had indulged freely in so called "snow-balls," made with shaved ice flavored with fruit syrup, it was suggested that the fruit syrup might have contained some poisonous ingredient or adulterant, but the coroner's jury basing their opinion on the results of Prof. Leffman's analysis of flavoring syrups last year, which showed them to be harmless, came to the conclusion that the eating of so much shaved ice was the real cause of the fatal illness. In view of the fact that children are constantly buying and eating these balls of shaved ice, during the hot weather in our large cities, it is pertinent to inquire as to the purity of the ice, since Prudden and others have shown that polluted water is not made pure by freezing and that vari-

ous pathogenic germs are contained in ice coming from a contaminated source. Infected ice is capable of communicating infection and causing local epidemics of disease. Typhoid bacilli survived freezing in the epidemic at Plymouth, Pa., some years ago. Pus organisms and the streptococci of erysipelas are commonly found in ice coming from a source contaminated by drainage, as well as many bacilli allied to the comma bacillus or spirillum of cholera. With these observations in mind, it would be well for the guardians of the public health to take into consideration the ice supply of large cities, as well as that of milk, and especially to prohibit the sale of ice to be eaten by young children, unless it is of good quality. There are as good reasons for having sterilized ice as exist for the use of sterilized water or milk; for children's use these should be of the best quality and above suspicion.

**Washington State Medical Examining Board.**—The regular semi-annual meeting of the Washington State Medical Examining Board was held at Spokane, Wash., July 7 and 8. But six applicants for license to practice within the State appeared before the Board, one of whom failed to pass.

**Washington State Board of Health Favors a Department of Health.**—At the last regular meeting of the Washington State Board of Health the following resolution in favor of a national department of health was unanimously adopted, viz.:

*Resolved,* That this Board is in favor of the establishment of a national department of health upon the broadest and most comprehensible grounds possible. That we do not endorse the action of the National Conference of the States Boards of Health held in Chicago in June last. Believing that this does not represent the views of the majority of the boards of health of the various States, the secretary is hereby instructed to correspond with the boards of other States and also with other boards of health, with the view of ascertaining the opinions of the various boards upon the advisability of the establishment of such department by the national government.

## MISCELLANY.

**Serum Treatment for Sheep Rot.**—A member of the Pasteur Institute of Algiers has discovered a serum that will prevent "sheep-rot." All animals "vaccinated" either escape or have a mild form of the disease, from which they invariably recover.

**University of Vermont.**—The 43d annual commencement exercises of the medical department of the University of Vermont were held at Burlington, Vt., July 6. The graduating class numbered fifty-two. The valedictory was delivered by Dr. J. L. Marshall. The address of Rev. P. M. Snyder was on the Relation of the Physician to the Preacher.

**The Roentgen Rays in the Witness-Box.**—We note that the trial of an action for damages at Nancy, in France, the surgeon who had charge of the injured plaintiff was accused of having caused the damage by mistaking a dislocation for a fracture. The accusation was sustained by producing in court a Roentgen photograph, which showed clearly the bones in the dislocated position without any fracture.

**New Apparatus for Anthropometric Measurements of Criminals.**—An anthropometer and craniograph invented by a lawyer, Anfoso of Fossano in Italy, are commended by Lombroso for their extreme simplicity compared to Bertillon's complicated apparatus, besides their other advantages. The *Gaz. degli Ospedale e delle Clin.* of June 20, adds that every police station should be supplied with them.

**Roentgen Ray Visible to Insects.**—The *Centralbl. f. Physiologie* of June 13, describes some experiments with insects placed in a box, one side of which was of wood and the other of lead, and exposed to the direct Roentgen ray. The insects all assembled on the side of the box permeable to the ray, except those that had been blinded. The assumption is that it was visible to them and attracted them.

**Missouri Rule as to Burden of Proof of Insanity.**—The supreme court of Missouri holds, in the case of *State v. Wright*, decided June 2, 1896, that the burden is on a defendant who interposes a plea of insanity to sustain that defense to the reasonable satisfaction of the jury. It says that it is in the nature of a plea of confession and avoidance. It confesses the homicide, but denies the crime of it. The court also holds that a medical expert was very properly permitted to give his opinion respecting the sanity or insanity of the defendant, having for a basis the hypothetical case, together with what he had learned from an examination of the defendant.

**Treatment of Acute Pneumonia with Injections of Artificial Serum.**—Bassi of Lucca has found intravenous injections of artificial serum of benefit in acute pneumonia, when a fatal termination is imminent. He describes several cases in the *Gaz. degli Ospedale e delle Clin.* of June 6, and dwells upon the importance of gaining time with them until the crisis is past. The amount injected was from 120 to 250 grams; the instrument used was a Pravaz syringe connected with a reservoir, and the injections were made in the median basilic vein of the left arm, the day before the crisis was anticipated when possible.

**Filters for Army Use.**—Coccone has a study of the best portable filter for use in the army in the *Giornale Medico der R. Esercizio* for April, and recommends the Berkefeld-Nordtmeyer as the most practicable for the purpose, using two alternately, a day each, and boiling the one not in use in a camp kettle for an hour. He suggests a few slight modifications to add to its solidity and capacity.—*Gaz. d. Osp. e d. Clin.*, June 11.

**The Whale Cure for Rheumatism.**—It is reported that at the town of Eden, a place in Australia, which stands on the shores of Twofold Bay, there is a hotel where rheumatic patients congregate. Whenever a whale has been taken the patients are rowed over to the works in which the animal is cut up, the whalers dig a narrow grave in the body, and in this the patient lies for two hours as in a Turkish bath, the decomposing blubber of the whale closing around his body and acting as a huge poultice. This is known as the "whale cure for rheumatism."—*Annals of Hygiene*, July, 1896.

**Anomalous Case of Cinchonidia Poisoning.**—Dr. William Pepper relates the case of a patient suffering from paroxysmal tachycardia, in whom a pill of digitalis and cinchonidia sulphate—one grain of the latter—produced, within three hours, severe abdominal pains, nausea, extreme weakness and areas of angioneurotic edema. The hands and feet especially were much swollen, the color varied from moderate congestion to extreme pallor; there was intense itching, the pulse was hard during the period of intoxication, in marked contrast to the soft pulse previously noted. The conditions continued about twenty-four hours.—*University Med. Mag.*, July, 1896.

**Li's Bullet Located by the Roentgen Rays.**—While in Germany recently, the Chinese statesman, Li Hung Chang, took advantage of an opportunity to have the bullet which he carries in his cheek located by the Roentgen Rays. It will be remembered that when in Japan, arranging the treaty of peace between that nation and his own, he was assaulted by a would-be assassin, who, it was feared at that time, had been only too successful in taking the life of this truly great man. The picture secured shows the tract of the wound through the tissues of the cheek and the encysted missile slightly below the point of entrance.

**A Million Dollar Prize.**—The following curious notice has recently appeared in the New York City newspapers: "One Million Dollars Reward.—To Physicians, Surgeons, Scientists, Wise Men, and all others whom it may concern: Be it known that I, Charles Broadway Rouse, who possess considerable wealth, hereby agree to pay the sum of \$1,000,000 to any human being who restores to me my sight." The advertiser is

an eccentric Virginian who has done business in New York since the late war, and who is suffering from atrophy of the optic nerve. Some time ago he discovered that one of his former employes, a man by the name of Martin, was affected in the same way as himself. He took a great interest in his case and was very kind in securing the best medical treatment for him and otherwise providing for his welfare and comfort. Out of gratitude for this kindness he has offered to subject himself to any kind of treatment that is thought worthy of trial, and any one who believes that he has a chance of winning the million dollar reward must first test the efficacy of his treatment on Martin.

**Gunshot Wound of the Stomach.**—Dr. L. A. Woodson (*Nashville Jour. of Med. and Surg.*, June, 1896) reports a case, male, 25, operated on sixteen hours after wound was received. The patient was weak from loss of blood and abdomen distended from internal hemorrhage. The ball, 38-caliber, entered the stomach at the cardiac end and had severed the gastro-epiploica sinistra artery, which was still bleeding. The ball emerged to the right of the esophageal opening, then made another perforating wound, an inch long, in the pyloric end of the stomach. The ball was not located but the direction of its course indicated lodgement in the liver. Temperature the day after operation, 98.5 degrees. He was discharged cured on the twenty-first day. The points of interest in this case were the rapidity of healing and completeness of cure, the absolute absence of fever after the operation was performed, notwithstanding its gravity and extent, and finally that an artery the size of the one severed should have remained unsecured for sixteen hours and not have resulted in death from hemorrhage.

**The Therapeutics of Exercises.**—Dr. Randolph Faries says: Many physicians prescribe exercise, never dreaming that they are already adding coals to the fire of the disease. For example, one physician will tell a patient who is suffering from brain overwork to take riding lessons, forgetting that mental operations are required to learn to sit properly and guide the animal at first; another will advise bicycle-riding which also requires mental effort. Prescribe an involuntary exercise and the blood will be drawn from the brain to the part employed because wherever there is movement there we shall find the blood flowing in greater quantities; and in this way we deplete the overcharged blood vessels in the cerebral mass.—*Annals of Hygiene*, July.

**No Duty to Provide Specialist.**—Jones v. Vroom, decided by the court of appeals of Colorado, May 11, 1896, was brought against a firm of physicians to recover damages for the loss of an eye, alleged to have been caused by the negligent and unskillful treatment of the defendants. They had been employed to treat the plaintiff for typhoid fever. There was no evidence, and in fact no complaint, that they did not bestow upon her all the attention and skill which the nature of the disease and her condition required. Indeed, she stated herself that she was cured of the fever as a result of their treatment. The only charge in the complaint which was proven was that one of the defendants failed to send her an oculist after he had promised to do so. The court holds that, under the circumstances, a nonsuit was properly granted. It says that the defendants were employed to treat the plaintiff for fever, and their employment imposed no duty upon them to provide her with a specialist for her eye. The court took into account, furthermore, that she seemed to have had no difficulty in procuring one when she set about it, and says that presumably he could have been gotten just as readily at first.

**A Consulting Surgeoncy Declined.**—Dr. Thomas H. Manley has lately declined the appointment tendered him in behalf of the University Medical College of New York, by the Commissioners of Public Charities. Dr. Manley was among the twenty-

eight members of hospital staffs, summarily removed a year ago, by the reform government. It has since transpired, that the move was not in any sense political, but was the outcome of a medical college combination to secure all the clinical material. Hence, at the last meeting of the County Medical Association of New York charges of violation of the code of ethics of the AMERICAN MEDICAL ASSOCIATION were made against the faculties of the three regular medical colleges. It seems as that only one medical college of New York has remained loyal to the National organization—Bellevue—that must stand the brunt of attack in this investigation, as the College of Physicians and Surgeons and the University Medical College, it is said, recognize no code. The outcome of this investigation will be watched with interest, for since the beginning of the medical upheaval of last year in the New York Hospitals the JOURNAL has maintained that wrong and injustice was committed.

**Study of Hematocatharsis.**—The *Gazette Médicale de Paris*, June 20, reports some recent experiments by Delbet on the effects of diluting the blood with saline solution. He found that intoxication was prevented by it in only one case out of eight. This was a dog to whom three grams of sulphate of strychnin in a thousand solution had been injected. Immediately afterward 910 grams of saline solution were injected, and the animal was not poisoned by the strychnin, but recovered. He passed 530 grams of urine. The same dose administered later to the same dog without the saline injections, resulted in death twenty minutes later. Delbet found that where there were four millions of red corpuscles before the saline injections there were only three million afterward, but they were larger. No difference was observed in the white corpuscles. He finds that it is impossible to increase the pressure when it is normal or above, concluding from this that dilution is authorized even in cases of elevated pressure, as in eclampsia. On the other hand, a diminished pressure is brought up to normal by intravenous injections of saline solution, and it is not even necessary to inject an amount equal to what has been lost, as vigorous animals can lose a certain amount of blood without diminishing the arterial pressure, showing that they have a reserve of blood. Further experiments with dogs poisoned with atropin, and the pneumogastric consequently paralyzed, showed that the pressure of the blood could be diminished by hemorrhage and afterward increased by saline solutions, which proved that these phenomena were not dependent upon the pneumogastric.

**Latent and Disguised Tuberculosis.**—Maragliano's address with this title, delivered at the recent congress at San Remo, is published in *Gaz. degli Ospedali e delle Clin.* No. 47. It repeats the statement that traces of tuberculosis are found in one-third to one-fourth of all the necropsies. They may never have developed beyond the first original tubercle, as the organism may have proved strong enough to keep them in subjection by secreting the necessary antitoxins, and they may remain latent all through life. But debility from any cause, pregnancy, traumatism, may diminish the power of the organism to combat them, and they at once assert themselves, when an established case of tuberculosis is the result. To another category belong the cases of unsuspected tuberculosis infection of the blood which does not reveal itself in any of the usual ways, but only produces progressive anemia, emaciation, loss of appetite, suspension of the menses and other symptoms of what he calls dystrophic disguised tuberculosis. He distinguishes also another form, the trophic, with fever, intermittent or remittent, resembling typhus sometimes, with disturbances in the innervation, and even tumor of the spleen or exanthema. To this cause may be due the so-called "growing fever" of older children. It is very difficult to distinguish these forms of tuberculosis as the ordinary physical and bacteriologic tests fail. Maragliano has only attained certainty

by inoculating rabbits with the serum of suspected cases, or by inoculating the patient with tuberculin, as in testing animals.

**Antivivisection.**—Resolutions adopted at the Keystone Veterinary Medical Association, Philadelphia, June 9, 1896:

WHEREAS, Believing that the best interests of humanity are served by the judicious permission of experimental research on the lower animals, whereby the value of certain methods of surgical interference can only be determined, and the worth of certain lines of remedies, which at this particular time in the history of medical progress, seem to be based on more exact deductions than ever before, and the wisdom of fully testing these remedies on the lower animals demands no comment from any intelligent, thoughtful person;

*Resolved*, That we therefore believe that Senate Bill No. 1,552 is calculated to throw around these investigations unnecessary and unjust restrictions, and for these reasons merit our disapproval and we call upon our Representatives from this section to manifest our condemnation of this measure by their voting against the same.

JOHN R. HART, President.

W. L. RHODES, Secretary.

**Are the Bones Shaped by the Pressure of the Muscles?**—Hirsch asserts that the internal and external structure of the bones as well as their shape, is determined by their functions, and that the pressure of the muscles and tendons is not responsible for the hollows or shape. The groove at the rear of the lower extremity of the tibia is an example of an apparent rut worn by friction, but in reality it is exactly the opposite, as the groove does not extend into the inner spongy part, and is not really a depression, but is produced by a couple of ridges thrown up to protect the bone. This same process occurs wherever there is friction, which explains the formation of the sesamoid bones, etc. To confirm his statement that these grooves were not the direct result of friction even in the course of generations, Hirsch examined the oldest neolithic skeletons in the museums, finding the two ridges even more pronounced on them than is the case at present. Another argument is that it is a mistake to suppose that all the muscles fit close to the bones, the biceps for instance; and it is drawn still further away when contracted. Hirsch asserts also that the bones are not injured by severe pressure as much as by gentle continuous pressure, such as the growth of a tumor, compressing and closing the circulation in the periosteum, while they are constructed to resist the strong pressure of walking, lifting, etc.—*Centralb. f. Chirurgie*, June 20.

**"Physicians" Who Can Not Recover for Services.**—The object of the Nebraska statute providing for a State Board of Health to regulate the practice of medicine, etc., the supreme court of that State says is the protection of the sick and afflicted against the knavery of quacks. For this reason the court holds, in the case of Maxwell v. Swigart, decided June 3, 1896, that the provision that "no person shall recover in any court in this State any sum of money whatever for any medical, surgical or obstetrical services, unless he shall have complied with the provisions of this act," etc., (Comp. St. 1893, Ch. 55, Art. 1, Sec. 15), negatives the right of recovery for such services where there has been a failure to file the certificate of the State Board of Health with the county clerk of the proper county, as required by the statute. To illustrate: The plaintiff in this case alleged that on or about Sept. 4, 1891, he had made necessary proofs upon which a certificate had been issued to him by the Nebraska State Board of Health, and that when his services were performed for the defendant between Oct. 15 and Nov. 29, 1892, he was one of the persons authorized by law to be registered. On April 20, 1893, the certificate of the State Board of Health referred to was filed in the office of the county clerk. After this the plaintiff brought this action to recover for those 1892 services, and recovered judgment in the district court for \$275, the latter holding that the registration before suit brought, though after the services were rendered, was a sufficient compliance with the statute to entitle the holder of

the certificate to recover the value of his services. But the supreme court holds otherwise and reverses that judgment, on the ground that the construction the district court put upon the statute was so foreign to the general scope of the entire act that it could not be tolerated.

**A Case of "Death from Chloroform," Improperly so Called.**—Dr. Wilkinson, of Birkenhead, England, reports in London *Lancet*, June 6, a case that very well illustrates a form of the reckless allegations which get into the public press concerning the use of anesthetics. To report this death as one of "death under chloroform" was entirely unjustifiable. The true cause of death, as shown by the clinical history and by necropsy, was that of rupture of the uterus consequent upon placenta previa. The case, as abbreviated from the report in the *Lancet*, was as follows: "When called to the case I found that there had been some severe hemorrhage. Under anesthetics version was performed. The hemorrhage then ceased, and as I felt the placenta loose in the vagina I removed it with my fingers. Chloroform was given only at intervals and was ceased before the delivery of the head. Six drams were given. The patient rallied, took some ergot and assisted us with the placing of the binder, and asked if all was over. She then became restless, and after about twenty minutes we saw that death was threatening and informed the friends. The restlessness had brought on fresh hemorrhage. More ergot was given and ice was placed in the vagina, and the uterus felt for from the outside. Owing to the abdominal fat, however, it could not be felt. The pulse was 96 and hardly to be perceived, partly on account of the superimposed fat. The patient died two minutes after we had informed her friends. No transfusion apparatus was at hand. The friends, supposing that she had died under chloroform, charged us with her death and, becoming maniacal, assaulted us. They seized the ornaments and attempted to strike us. The midwife (who sent for help immediately on seeing the case) was seized and would have been hurt but for our interference. At last we were obliged to send for the police to assist us to recover our belongings and extricate the midwife from the corner of the room where she was penned up. It was reported to the police and to the whole neighborhood that we had murdered the woman with chloroform. On this account I thought it best that an inquest should be held; otherwise I should have given a certificate. At the necropsy a rupture of the cervical and uterine tissues was found four inches in length and opening into the right broad ligament. The extravasated blood separated the layers of this, and I believe that during the subsequent restlessness the peritoneal covering burst, as was found. The immediate cause of death was hemorrhage. The delivery took me about an hour and a half to accomplish, during which time bleeding continued at intervals. After the arms were brought down I felt the os and it was then intact. The rupture, which I did not suspect, must have been caused by the passage of the large head, probably by the face (which was born first) passing over that site. The papers had the case reported as 'death under chloroform,' but the resumed inquest entirely relieved me from this charge, though the report has certainly done me harm."

**The Murder of an English Physician in North Africa.**—The *London Graphic* has the following account of the apparently causeless massacre of a physician and his family in Tunisia. Dr. Leach was for a time a resident of New York city, about ten years ago:

"Dr. and Mrs. Leach, who, with their little son, were murdered at Sfax, in Tunisia, last week, were for about five years missionaries of the North Africa Mission. After residing for a few months in Algiers they removed to Tunis in the summer of 1891, and with the help of other missionaries, carried on an important medical mission among the Mohammedans and Jews of that city. A few months ago Dr. Leach requested the council of the mission to permit him to open a new station at Sfax, one of the most important cities of Tunisia, about two-

hundred miles south of his former sphere. At the present time it has a population of about forty thousand Mohammedans, a few thousand Maltese, Italians and Greeks. Dr. Leach removed from Tunis about the middle of March this year, and had since been occupied in getting his house and mission premises ready for work. He wrote on April 27 to the effect that the people were beginning to inquire when he would be ready to see patients, and he hoped to begin very shortly. It is difficult to understand the motive of the murder. Dr. Leach was a quiet and somewhat reserved man, very patient and kind in his dealings with the people. Both he and his wife spoke French, and he had a fair command of Arabic. So far as is yet known, it is thought that the crime was committed by Europeans with a view to robbery; but it seems impossible to be quite sure who the murderers were. The boy was about 5 years of age. The little girl, 18 months old, is the only member of the family who has been spared. Dr. Leach was born in 1860, at Rangoon, and was the second surviving son of Mr. William Leach, of the Medical Department of Her Majesty's Indian Army. He was educated in the military school at Fort St. George, and at Bishop Corrie's Grammar School, Madras, and studied Medicine at Edinburgh, where he qualified. He held the post of resident surgeon to the Children's Hospital, Birmingham, and afterward took one or two voyages as surgeon on the boats of the Clan Line. Then for two years he practiced at Forest Gate, East London. Subsequently he went to America to gain experience in medical mission work, under Dr. Dowkontt, of the International Medical Mission Society, to whom he was strongly recommended by the late Pastor C. H. Spurgeon. In 1889 he proceeded to Algiers with two American friends, and in 1891 joined the North Africa Mission."

#### The English Language.

We'll begin with a box, and the plural is boxes,  
But the plural of ox should be oxen, not oxes.  
Then one fowl is a goose, but two are called geese,  
Yet the plural of mouse should never be meese;  
You may find a lone mouse or a whole nest of mice,  
But the plural of house is houses, not hiee.  
If the plural of man is always called men,  
Why shouldn't the plural of pan be called pen?  
The cows in the plural may be cows or kine,  
But a bow if repeated is never called hine,  
And the plural of vow is vows, never vine.

If I speak of a foot and you show me your feet,  
And I give you a boot would a pair be called beet?  
If one is a tooth and a whole set are teeth,  
Why shouldn't the plural of booth be called beeth?  
If the singular's this and the plural is these,  
Should the plural of kiss ever be nicknamed keese?  
Then one would be that and three would be those,  
Yet hat in the plural would never be hose,  
And the plural of cat is cats, not cose.

We speak of a brother and also of brethren  
But though we say mother we never say methren,  
Then the masculine pronouns are he, his and him,  
But imagine the feminine she, shs and shim.  
So the English, I think, you all will agree,  
Is the queerest language you ever did see.

—The Commonwealth.

**The Economic Season.**—Benham: "I wish you would ask Mr. and Mrs. Jones around to dinner to-morrow." Mrs. Benham: "What is your hurry about it, all of a sudden?" Benham: "I heard Jones' doctor telling him to-day that he mustn't eat any solid food for a week."—*Texas Siftings.*

#### Cincinnati.

THE MORTALITY REPORT for the week ended Friday, June 10, 1896, shows: Deaths from all causes 112, annual rate per 1,000 16.64, deaths during the preceding week 116, deaths during corresponding week 1895 118.

**HYDROPHOBIA.**—A case of hydrophobia was discovered in the city last week and the patient died in horrible agony.

THE FOLLOWING have been added to the staff of the Betts Street Hospital: Drs. R. C. Hefebower, oculist; H. D. Hinckley, surgeon, and W. E. Kiely, general medicine.

AT THE LAST MEETING of the staff of the Cincinnati Hospital the following were elected: Chief of staff, N. P. Dandridge; secretary, John Oliver; librarian, P. S. Conner; custodian of records, P. A. Marchand.

DR. F. W. HENDLEY has been presented with an office desk, chair and set of instruments by the staff and employes of the Cincinnati Hospital.

THE OBSTETRICAL SOCIETY has adjourned until September. At the last meeting the papers read were: "Inflammation of the Endometrium," by E. W. Mitchell; "Pelvic Inflammation,"

by Charles Bonifield; "Technique of Curettage," by George E. Jones; "Pudendal Hematocele," by M. A. Tate.

DR. WILLIAM PEPPER, President of the International Executive Committee, will spend the summer at a Spanish hacienda in California.

IT IS UNDERSTOOD that arrangements are practically completed for two special trains of cars to be specially constructed for the Mexican trade. A dining-car will be provided for every three coaches. A lady's maid will be provided for each coach. Those desiring accommodations on these trains should address Dr. C. A. L. Reed of this city.

**MEALS FOR HOSPITALS.**—The several thousand patients in the various State Insane Asylums and the Epileptic Asylum will eat a uniform breakfast, dinner and supper hereafter. At a meeting of the superintendents of the various State institutions at Columbus it was decided that the six months' bill of fare will be the same for all the institutions except that the epileptics for hygienic reasons are not allowed the full quantity of meat. A sample day's bill of fare is: At breakfast, beef stew, with three to five ounces of meat to each person, three ounces of potatoes, fruit *ad libitum*, bread with one-half ounce of butter, one-half ounce of coffee, and all the milk needed; dinner, chicken potpie, six ounces of the fowl to each patient, mashed potatoes, five ounces each, stewed tomatoes, pie or pudding, bread and butter, coffee and milk; supper, sweet cake, fruit, oatmeal, bread and butter, tea and milk.

DR. JOSEPH F. CHAU of Cleveland, has applied to the State Board of Examiners for registration. He is said to be a graduate of the Hong Wo College, of O'Moon, China.

THE STATE BOARD has adopted the report of the investigating committee recommending the non-recognition of the Hygeia Medical, The American Eclectic, and the Campbell Vitapathic College.

#### Philadelphia.

DR. JOHN H. PACKARD having resigned from the surgical staff of the Pennsylvania Hospital, the board of managers elected William Barton Hopkins as his successor. Dr. Hopkins is a graduate of the University of Pennsylvania, and has served as resident physician and surgeon to the out-patient department of the Pennsylvania Hospital for a number of years. He will enter upon his new position August 1, when he will take charge of the wards for the fall term. Dr. Hopkins is a nephew of Dr. John Rhea Barton, and possesses much of the mechanical genius of his distinguished relative, who formerly occupied a prominent position in the surgical staff of the same institution.

#### Louisville.

**HOUSE OF REFORM.**—At a meeting of the trustees of the House of Reform appointed by the Governor, held recently, the following officers were elected: Mrs. Nellie G. Cheatham, wife of Dr. Wm. Cheatham, of this city, president; W. P. Walton, Stanford, secretary; D. H. Howard, Lexington, treasurer. The other members of the board are the following: Mrs. Lunsford Yandell, widow of the late Dr. Lunsford P. Yandell, of this city, Mrs. M. Charles and B. T. Conway, of Lexington. Propositions for buildings and sites for the location of the houses are being received by the board and no decision has as yet been reached.

**MEDICAL LAWS.**—The county attorney of Christian County has caused the arrest of over 100 physicians of that county charged with the violating of one of the laws which requires each physician to file a report with the county clerk before January 10 of each year containing a record of the births and deaths which have occurred in his practice for the year previous. Only one physician complied with the law, and the others claim that they were in ignorance of there being such a law on the statute books, though it has been in existence for twenty years. One doctor was fined \$20 and costs, as an agreed case, and it will be carried to the court of appeals.

**CITY HOSPITAL.**—Superintendent Barbour states that at present there are 150 inmates to the hospital, an excess of fifty over the number usually there this time of the year. The increase has been caused by the unusual prevalence of dysentery and allied troubles among the poor at this season.

**ST. MARY AND ELIZABETH HOSPITAL.**—This hospital is located very near a switch of the Louisville Southern Railroad and the inmates have been very much annoyed of late by the unnecessary whistling of the locomotives. It was made the subject of a complaint by the officials, and as there is a law against the whistling of a locomotive within one-half mile of any hospital, it will be stopped without its being necessary to carry it to court.

#### Washington.

**WEEKLY REPORT OF THE HEALTH DEPARTMENT.**—The report of the Health Officer for the week ended July 4 is as follows: Number of deaths (stillbirths not included), 153; death rate per 1,000 per annum, 28.3; death rate per 1,000 per annum for the corresponding week last year, 23.97. There was a further increase in the number of deaths in the city during the past week. As shown by the reports to the health department the mortality reached 153 as compared with 146 in the week previous, and the death rate rose accordingly from 27.04 to 28.33. The principal causes were diarrheal diseases from which 47 deaths occurred, and consumption, of which 17 persons died. Of the mortality 91 were of children under 5 years old. While there was a slight increase in the number of fatal cases of brain and heart disorders, there was an entire absence of those of the lungs in an acute form. With the exception of diphtheria, the contagious maladies remained in abeyance. Of diphtheria 3 deaths occurred, 6 new cases were reported, 8 houses were relieved of quarantines, and 11 remained placarded. Of scarlet fever no death occurred, but 1 new case was reported, quarantine was raised from 3 houses, leaving 3 still in isolation.

**THE DEFICIENCY APPROPRIATION BILL.**—The Deficiency Appropriation bill contains the following item: Pan-American Medical Congress: To meet the expense of distribution of printed report of the transactions of the first Pan-American Medical Congress, at Washington, 1893, to be appropriated out of the unexpended balance of the appropriation for the entertainment of the delegates provided by the Sundry Civil Act, March 3, 1893, \$900. All of the copies for foreign distribution have been mailed, the net cost of which amounted to \$400.

**PAN-AMERICAN MEDICAL CONGRESS.**—The Auxiliary Committee of the Second Pan-American Medical Congress to represent the District of Columbia at Mexico is composed of the following-named physicians: Drs. H. L. E. Johnson, Chairman; John R. Wellington, Secretary; S. C. Busey, G. C. Ober, G. M. Kober, S. S. Adams, C. H. A. Kleinschmidt, W. S. Bowen, J. D. Morgan, L. Eliot, C. N. Richardson, G. L. Magruder, G. W. Cook, H. H. Barker, Walter A. Mills, Surgeon Generals Sternberg and Tryon.

**APPOINTMENTS BY THE INTERNATIONAL EXECUTIVE COMMITTEE.**—Among the recommendations of the first Pan-American Medical Congress was the appointment of an International Committee on Quarantine and one on Public Health. The executive committees have appointed the Surgeon General M.-H. S., chairman of the International Committee on Quarantine and Dr. H. L. E. Johnson, chairman International Committee on Public Health, with Drs. William Pepper and C. A. L. Reed as coadjutors. Dr. H. L. E. Johnson has been given charge as chairman of the Committee on Transportation.

Dr. L. Eliot has notified the committee that he will attend the Congress and read a paper on the treatment of hemorrhage by acetate of lead.

**HOME FOR INCURABLES.**—Plans are now under way for the construction of a new wing to the Home for Incurables. The new wing will be three stories in height, the same as the

present building, and will be located near the northwest corner of the present structure. The plans have already been drawn up by Architect Walker and have been submitted for approval. The new wing will be erected out of a legacy left the institution by Mrs. Walcott, and will be devoted entirely to the accommodation of children afflicted with spinal trouble.

**HOSPITAL FOR FOUNDLINGS.**—A novel complaint has been filed at the District building against the Washington Hospital for Foundlings, at No. 1715 15th Street, N.W., to the effect that the crying of the babies is a nuisance to the neighborhood.

**BOARD OF MEDICAL SUPERVISORS FOR THE DISTRICT.**—The board of medical supervisors for the District of Columbia has been chosen and consists of Drs. C. H. A. Kleinschmidt, president of the board of regular practitioners; J. B. G. Custis, president board of homeopathic physicians; Thomas Robinson, president board eclectic physicians, with Messrs. J. J. Darlington and John Redout.

**NEW OLEOMARGARIN LAW.**—The new law governing the sale of oleomargarin is being rigidly enforced, and three prominent dealers were, upon conviction, sentenced to imprisonment and heavy fines for recent violations.

**A NEW DENTAL SOCIETY.**—The alumni of the National University Dental School have recently formed a new dental society. A large membership is expected.

## THE PUBLIC SERVICES.

**Navy Changes.** Changes in the Medical Corps of the U. S. Navy for the week ending July 11, 1896.

Medical Inspector J. C. Wise, detached from the Washington navy yard, and ordered as a member of the board of inspection and survey, July 15.

Medical Inspector R. A. Marmion, detached from the board of inspection and survey July 15, and ordered to the Washington navy yard. P. A. Surgeon S. S. White, detached from the naval academy and ordered to the "Thetis."

P. A. Surgeon G. A. Lung, detached from the "Thetis," ordered home and granted two months' leave.

Surgeon P. A. Lovering, detached from the New York naval hospital and ordered to the "Oregon."

P. A. Surgeon C. H. T. Lowndes, detached from the Washington navy yard and ordered to the naval hospital at Philadelphia.

Surgeon C. U. Gravatt, to Norfolk with draft of men and three months' leave.

Asst. Surgeon R. G. Brodrick, to the "Franklin."

#### Change of Address.

Adams, S. S., from Washington, D. C., to Mountain Lake Park, Md. Carpenter, Julia W., from Cincinnati, Ohio, to Omena, Mich.

Eads, S. E., from Science Hill to Somerset, Ky.

Goodrich, E. C., from Dyer Building to 807 Broad St., Augusta, Ga.

Ingold, Mattie B., from Baltimore, Md., to Hickory, N. C.

Kempker, J. F., from Keokuk to Valley Junction, Iowa.

Lukens, Anna, from New York, N. Y., to Wentworth Hall, Jackson, N. H.

Lanum, J. H., from Edinburg to Franklin, Ind.

Parker, W. T., from Groveland, Mass., to Toronto, Can.

Roseberry, B. S., from El Paso, Texas to Catakill, N. M.

Wiggin, F. H., from New York, N. Y., to Litchfield, Conn.

Woodbury, Frank, from Philadelphia to Glen Summit, Pa.

## ADDRESS.

### CHAIRMAN'S ADDRESS.

Delivered in the Section on Obstetrics and Diseases of Women at the forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY JOSEPH TABER JOHNSON, M.D.

WASHINGTON, D. C.

I am required by the rules of the ASSOCIATION to open our session with an address, reviewing the gynecologic and obstetric work of the year. To say something on all the topics of interest in these two great departments of medicine would consume all the time allotted to one session. I shall only attempt to briefly draw your attention, therefore, to a few of the most prominent subjects in which we are all interested.

#### PUERPERAL INFECTION.

Its causation and treatment has been the cause of much writing and discussion during the year. While something has been added to our scientific knowledge of the history and behavior of certain pathogenic germs—the general course of treatment of these cases has been simplified and shortened, instead of amplified and broadened as has been the tendency heretofore.

One of the principal points made by Lusk of New York, in his recent paper before the Obstetrical Society of Philadelphia, on "Puerperal Infection," was "that the more these cases are let alone and the more simple the treatment the more likely they are to get well." Absolute cleanliness of the physician, nurse and patient is insisted upon and greater stress than ever is being laid upon the injunction to make as few examinations as possible after learning the nature of the presentation. In ordinary cases, where there is no rise of temperature, douches are not now recommended at all. Where chill occurs, followed by a rise of temperature preceded by putrid discharges, it is still recommended to ascertain if the uterus is entirely emptied of shreds of membrane and decomposing clots. The best instrument in use is now, as it always has been, the index finger, with which portions of after-birth or membranes can be removed, using, if necessary, bimanual pressure under ether.

Curetting was condemned by Lusk as likely to open sinuses and blood vessels, and create raw surfaces, all favoring quicker and more thorough absorption, and doing in this way more harm than good. While Baldy, Hurst and others, insisted in this discussion, that the wise and cautious use of the curette was a great advantage to the patient, accompanied by at least one thorough antiseptic irrigation. The long continued, frequent irrigation of the uterus seems to be condemned from all quarters.

Hysterectomy for puerperal infection seems to be gaining ground, notwithstanding the opposition of Lusk, Price and a number of other prominent men in this country and abroad; though the cases where it is indicated are very few. In a recent paper by

Mordicai Price the operation is absolutely condemned as unnecessary in the first place, and moreover always fatal. He claims that the mortality of hysterectomy for puerperal infection is 100 per cent. Others, however, have reported successes, and it would seem as if advancement ought to be made along this line, so that cases surely doomed to death without surgical interference might possibly be saved. The great difficulty is to select the cases. So many apparently desperate cases have finally recovered that it takes great experience and wisdom to be able to say in any given case that this woman will die if her uterus is not removed, and that she will probably live if it is taken out.

The operation is useless where the infection has passed beyond the uterine walls. If colonies of germs are growing and multiplying in the general vascular or lymphatic circulation the removal of the uterus could do no possible good, but would add shock and useless suffering to the patient. The great point in the management of puerperal cases is now, as it ever will be, in the prophylaxis. Prevention here as everywhere else is better than cure.

Lying-in hospitals, which were formerly hot-beds of infection, are now under modern antiseptic management reporting a mortality of only six-tenths of one per cent. The whole system of prevention is summed up in two words, cleanliness and ventilation.

#### SYMPHYSEOTOMY.

Since its revival it has been gaining prominence as a substitute for the difficult high forceps operation, craniotomy and Cæsarian section. In perfecting the technique of the operation, the aim has been to deliver the child without laceration of the parts about the urethra, and to so secure the separated symphysis that perfect union would result. In a number of cases, however, it has come to the knowledge of the writer that copious hemorrhages have taken place from laceration of the vascular tissues about the urethra; sometimes the urethra itself being torn, and too many patients were unable to walk after recovery without serious limping, which continued in some cases indefinitely. Unless these two slips in the technique can be overcome or prevented the modern Cæsarian section may be preferred by abdominal surgeons to the revived operation of symphyseotomy.

#### PLACENTA PREVIA.

The treatment of placenta previa is always a subject of great interest. Nothing especially new seems to have been added to our armamentarium during the year, except the suggestion that hysterectomy be done for the control of the hemorrhage. The diagnosis of these cases is generally not made until the occurrence of the hemorrhage. The patient is then either not in labor at all, or she is in labor and the cervix is not completely dilated, or we may find her with a completely dilated cervix.

There is little difference of opinion in regard to the axiom that "when the placenta is previa the uterus should be emptied." There is no wisdom or safety in delay. No one can tell when the next hemorrhage will occur and whether it may not prove fatal before the arrival of the physician. It is, therefore, our duty to act wholly in the interest of the mother and relieve her from a condition equally as dangerous, as if "the famous sword of Damocles were actually suspended over her head." If the hemorrhage is progressing, with little or no dilatation, in the absence of pains, the vagina should be so thoroughly tamponed as to completely arrest the flow of blood, and contractions of the uterus encouraged. In a few hours the tamponade can be removed, the vagina antiseptically douched, and if little dilatation has occurred and hemorrhage is still going on, the vagina should be again packed. When the cervical dilatation will permit, the fetus should be turned by the combined external and internal manipulation, known as the Braxton-Hicks' method, and one leg brought down into, and plugging up the cervical canal, thus arresting the hemorrhage, by making the child serve as a tampon. Hemorrhage, the main dangerous element in the case, being eliminated, very little else remains to be done but to watch, wait and guard further progress of the labor. Rapid extraction of the child is to be condemned as unnecessary and injurious. It is not only dangerous to the child but to the vascular tissues of the cervix, which are not in a condition favorable for rapid dilatation. A number of cases have been reported of the safe delivery of the child, but in which the mother died soon afterward from hemorrhage produced by laceration of the vascular cervical tissues. The only time in the management of these cases when haste is indicated is at the beginning. Hemorrhage once arrested, the principal danger is averted. It is believed that many patients have been lost by the excited, nervous, hasty and too vigorous efforts which have been made to rapidly extract a child in cases of placenta previa.

A case of puerperal diphtheria treated by antitoxin has been reported by Nisot. He claims it to be the first on record in which the Loeffler bacillus was found to be the sole cause, and in which antitoxin constituted the only treatment. Symptoms of puerperal diphtheria are stated with much exactness and no doubt exists of the correctness of his diagnosis. Three days after using injections of antitoxin the abnormal temperature disappeared entirely.

#### SURGICAL TREATMENT OF UTERINE DISPLACEMENTS.

The surgical treatment of uterine displacements is attracting more attention this year than last. Numerous articles have appeared in the journals during the year advocating a variety of surgical procedures for their relief. Prominent among which was a paper read at a recent meeting of the New York Academy of Medicine, comparing the relative merits of the Alexander operation, ventral-fixation and vagino-fixation. Mundé, after an experience of ninety-seven Alexander operations with eighty-seven permanent cures, gave his adherence to that operation, and closed his paper with a series of valuable conclusions.

Edebohls spoke in favor of ventral fixation and closed his remarks with the following conclusions: 1, vaginal fixation of the uterus does not come within the sphere of legitimate operations in women liable to subsequent pregnancy; 2, the indications for

ventral fixation of the uterus should be limited to the utmost degree in women liable to subsequent pregnancy; 3, ventral fixation is never indicated in uncomplicated retroversion of the uterus; 4, inability of an operator to perform the shortening of the round ligaments may be an indication for ventral fixation, but not in the case of one claiming to be a specialist in gynecology; 5, ventral fixation is indicated as an adjuvant in the performance of combined operations for prolapsus uteri et vaginae; 6, ventral fixation is indicated as a closing step in all celiotomies in which the adnexa are removed and the uterus is left; 7, ventral fixation may be indicated under exceptional conditions in cases of adherent retroversion with tubes and ovaries in good condition; 8, ventral fixation may be indicated in the most aggravated cases of uncomplicated, sharp retroflexion.

Vineberg spoke in terms of enthusiastic praise of the vaginal fixation operation and reported forty-eight cases with eight relapses. Four of these cases subsequently became pregnant, one ending in abortion. Vineberg believes "that vagino-fixation is indicated in all backward displacements of the uterus, with or without adhesions, and with or without diseases of the adnexa in which surgical interference for one reason or another is demanded. It is particularly indicated when the backward displacement is complicated by moderate prolapsus of the uterus and prolapsus of the anterior vaginal wall. It finds an undisputed field in very fat subjects with thick abdominal walls, in whom the ventral fixation constitutes a serious affair, and in whom an Alexandrian operation is extremely difficult of accomplishment. The same holds good in very thin subjects with thin and yielding abdominal parietes, so far at least as ventral fixation is concerned. The operation," he claims, "can be performed in nulliparæ and even in virgins." He urges that not enough stress has been laid on the large percentage of failures, and the mortality following the Alexander operation, or upon the frequency in which it was followed by hernia.

In the discussion of these papers by Noble, Boldt, Ill, Goffe and others, Alexander's operation was favored in cases where the indications existed, ventro-suspension in exceptional cases where the Alexander operation could not be done, while vagino-fixation was condemned, unless the patient had passed the menopause and was not liable to pregnancy.

Duhrssen, who was among the first to perform vagino-fixation, as one of the legitimate outgrowths of anterior colpotomy, in a paper read before the Berlin Gynecological Society, opposes the intraperitoneal vaginal fixation, but substitutes a much more irrational procedure by recommending a transverse incision in the anterior fornix of the vagina, to which he sutures the plicæ vesicæ, while the uterus is united to the peritoneum of the plica. Duhrssen had observed after vaginal fixation twenty-eight cases of pregnancy with seventeen normal confinements. The abnormal cases present a variety of serious complications. He also reports 148 intraperitoneal vaginal fixations with only one death and one relapse.

Leipold, when this subject was discussed in the Dresden Gynecological Society, opposed vagino-fixation of the uterus, but recommended its ventral fixation. He had performed seventy-three ventral fixations and had never witnessed serious complications during pregnancy or labor. He thinks in cases where trouble has occurred during gestation, that it was due to faulty technique, whereby the uterus was

fixed too near the umbilicus, or immediately above the bladder, that the fundus plus the posterior uterine wall was fixed to the abdomen or with sutures of non-absorbable material. The proper technique consists in fixing the uterus about one inch above the symphysis, and the sutures, two in number, should be passed through the anterior and upper portion of the corpus uteri, differing from the suspensio uteri operation as recommended and performed by Dr. Kelly of Baltimore, who passes his sutures through the posterior wall of the uterus, thus suspending it as it were, in a sling. Leipold also performed eight Alexander operations, and although he experienced no difficulty in finding the round ligaments, and placing the uterus in a normal position, he found that the patients frequently complained of pain in walking, and in the inguinal canal, and he also observed that the healing of the wounds was often protracted.

#### ANTERIOR COLPOTOMY.

In the discussion of the vaginal method of reaching pelvic troubles, another operation has been evolved by Duhrssen of Berlin, a confrère of Martin, which they, with Mackenrodt, have performed several hundred times. This operation, anterior colpotomy, consists, as you all know, in a transverse or vertical incision above the cervix, when the tissues are peeled back, the bladder separated, generally by the finger, which with the ureter is pushed back, then held up out of harm's way by a retractor, to permit the examining finger to be passed into the peritoneal cavity, and the condition of the pelvic organs thoroughly explored. A good-sized uterus can be drawn through this opening, dragging with it the appendages, after the separation of any existing adhesions. Martin is enthusiastic in his praise of this operation in an article in the *Annals of Gynecology* for October, 1895, in which he reports "109 successful operations, a remarkable point about which was the loss of so small an amount of blood that no ligatures or pressure forceps were required, until the abdominal cavity had been opened." Martin recommends this operation in cases of simple myomatous tumors, movable retroflexed uteri, for the breaking up of peritoneal adhesions fixing the uterus, for cases of procidentia, for small cystic ovarian tumors, and also for the treatment of various diseases of the tubes, including pyosalpinx, hematosalpinx and tubal pregnancy. He reported four of the last mentioned operations. When the uterus is drawn down through this incision Martin insists that both ovaries and tubes follow on the posterior surface, as soon as they are freed from adhesions. He states that the adhesions are easily broken up unless they are fixed to the posterior surface of Douglas' pouch—which he still recommends should be reached through the abdomen.

Martin states that "the wound takes only from eight to ten days to heal, so that by the twelfth day the patient may be allowed to leave her bed. No local treatment is required; feverish reaction was unknown in his cases. All of the 109 cases recovered." "In the majority urine was passed spontaneously from the first." This operation of anterior colpotomy presents also advantages in cases of vaginal hysterectomy, making it possible even in cases of cancer of the cervix to draw down the fundus of the uterus into the vagina, thus enabling one to ligate or clamp the tubes, ovaries and broad ligaments in sight,

and free from danger of including the ureter or knuckles of intestine, as has been done when the blades of the clamp were thrust up through the posterior and anterior incision, to be guided in the dark, only by the ends of the fingers. The separation of the posterior vaginal wall can, in this way, be made the last act of the operation, and all septic contamination of the pelvic tissues prevented.

#### VAGINAL VERSUS ABDOMINAL OPERATIONS.

I do not wish to anticipate the discussion on vaginal versus abdominal operations, from which I expect very much of interest and profit for the Section, but even a very partial review of the progress of abdominal and pelvic surgery for the year would be incomplete without reference to this very important subject. While Péan, Richelot and Doyen of Paris were pioneers in the vaginal operation in France, Jacobs of Brussels has done more to popularize and create enthusiasm in this country by broadening the indications for vaginal hysterectomy. He has been ably seconded in the United States by Sutton of Pittsburg, Polk of New York and Henrotin of Chicago. The paper by Garceau of Boston, in the March number of the *American Journal of Obstetrics*, is one of the most descriptive and comprehensive which have appeared during the year. Equally enthusiastic claims are made, however, by advocates of the abdominal and vaginal methods of operating; each claiming advantages over the other both in facility of method and in immediate as well as remote results.

Women are more likely to prefer the vaginal operation when its claims are presented and their judgment convinced that the cure would be equally safe and permanent. The avoidance of the abdominal wound, the stitches, dressings, bandages, the scar, the supporter for six or twelve months, and the liability of ventral hernia, are all controlling arguments to the average female mind.

The increasing intelligence of the laity on these subjects, and their familiarity with abdominal and pelvic operations is no less true than surprising. Hardly a week passes by that the writer is not asked by some lady requiring an abdominal operation whether this work could not as well be done through the vagina, thus avoiding all the above-mentioned troubles. The average medical mind is likely, also, to be influenced by such statistics as are presented by Garceau in the paper above referred to, for very much the same reasons. Probably the same operators, however, who could perform 166 vaginal hysterectomies, with only four deaths would be equally successful when operating by the abdominal route. Péan in Garceau's table of statistics reports 150 vaginal hysterectomies with only 1 death; Richelot 103 vaginal hysterectomies with only 7 deaths; Landau 30 with no death; Pozzi 14 with no death; making with others in the same table, 724 operations with 34 deaths, giving a mortality of 4.6 per cent., while the mortality for vaginal hysterectomy for fibroids of the uterus is equally striking. These operations were mostly performed for small tumors, but Péan, Richelot and others have operated by morcelment on fibroids reaching to the umbilicus.

The following statistics are given by Garceau of hysterectomy for fibroids: Péan, 200 hysterectomies with only four deaths; De Ott, 100 hysterectomies with no death; Richelot, 43 hysterectomies

with 1 death; making, with others in the same table, 406 operations with only 7 deaths, and giving a mortality of 1.7 per cent.

While these operations, presenting such favorable results, are done by the most skillful men, who have gained their experience in abdominal surgery, it is probable that their success would have been quite as great, with most of these cases, had they performed celiotomy instead of vaginal hysterectomy. The great argument, it seems to me, in favor of the vaginal operation, is its completeness, the greater advantages of drainage, the avoidance of the shock occasioned by handling and exposing the intestines, infecting the peritoneum with pus, the abdominal wound, the stitches and the liability to hernia.

#### FIBROID TUMORS.

The evolution of the treatment of fibroid tumors is marching on, not only "from Atlanta to the sea," but around the world, wherever surgery is practiced, our technique and statistics are constantly improving. Martin of Chicago, my immediate predecessor in this chair, has recently, in a series of valuable papers in the ASSOCIATION JOURNAL, exhaustively treated the electrical, medical and surgical aspects of this subject. Myomectomy, morcelment, the various methods of extraperitoneal treatment of the pedicle, pan and vaginal hysterectomy, have all received much attention during the year. The statistics of hysterectomy mortality are now showing as favorable percentages as have been acquired in ovariectomy. The family practitioner has no longer any excuse for advising a patient suffering from pain, pressure and hemorrhage of a growing fibroid, that the change of life will cause its disappearance or a sure cessation of their troublesome symptoms. Those of us who have examined the subject have reported quite a large number of cases of fibroids growing after the menopause, giving rise to as disagreeable symptoms as before the change of life set in. Instead of disappearing, as was formerly supposed, they frequently take on a more rapid growth and degenerate into cysts, abscesses, calcareous deposits or malignancy. These unfavorable changes, in my experience, occur more frequently after the menopause than before. Instead of a mortality of 80 per cent. resulting from hysterectomy for fibroids, as formerly, it is now our proud satisfaction to be able to say to the family, as well as to the family doctor, that while a growing and bleeding fibroid ought to come out, the mortality accompanying the operation in good hands, is not above 10 per cent., and in early, uncomplicated cases is likely not to be more than 5 per cent.

The writer takes pride and satisfaction in stating that within a comparatively short time he has performed hysterectomy for fibroid tumors of the uterus twenty-five times by the Baer method with but one death, and that occurred five weeks after the operation from intestinal obstruction. Other reports, still more favorable, have been published in the medical journals recently, showing as good, if not better, results than an equal number of ovariectomies.

As this subject in several of its phases, is to receive attention at this session, from several distinguished delegates, I will not delay you longer by saying what will be so much better said by the authors of the papers upon our program. I desire, however, to call your attention to one or two improvements which have been made in the general management of desperate cases requiring

surgical interference. The literature of our Section has been enriched since our last meeting by a number of papers suggesting improvements in the prevention of suffering and the saving of human life. The transfusion under the skin, or directly into an open vein, of a pint or more of the normal salt solution has undoubtedly saved a number of valuable lives, not only during a prolonged operation, where there has been a considerable loss of blood, but subsequently from secondary hemorrhage. This method of transfusion has been of service also in the restoration of patients from shock where little blood has been lost. The writer feels that he would recently have lost a case, from secondary hemorrhage, following the removal of the clamps, after a vaginal hysterectomy, at the end of forty-eight hours, if it had not been for the transfusion of nearly a pint of normal salt solution under each breast.

A paper upon our program suggests greater safety and comfort from improved methods in anesthesia. While a death from the anesthetic is as rare as it is horrible, there are many discomforts and some dangers following the administration of ether or chloroform in cases of parturition and also in our abdominal, pelvic or gynecologic surgery. If the author has a method or a combination which will avoid the occurrence of nausea, vomiting and nervous excitement following operations we shall all be very grateful to him. All patients and most operators have been tormented with anxiety on account of long-continued vomiting following difficult operations; lest stitches should give way, ligatures separate and hemorrhage come on, when quiet and calm are so desirable and necessary to the safe conduct of the case. We have fortunately in the chlorid of ethyl and the muriate of cocain local anesthetics which are frequently preferred by the patients as well as operators for minor operations of short duration.

The present Chairman hopes that his successor may be able to report great developments and improvements in the diagnosis of abdominal and pelvic diseases of women, from the evolution and perfection of the *X-rays*, about which we have heard so much of late. If its promises are fulfilled we ought to find little difficulty hereafter in our diagnosis of extra-uterine pregnancy, pyosalpinx, fibroid, dermoid or ovarian tumors.

#### LECTURE.

#### ON HEALING AND IMMUNIZING SUBSTANCES OF TUBERCLE CULTURES.

Lecture delivered at the meeting of the Delaware District Medical Society, Dunkirk, Ind., June 17, 1896.

BY EDWIN KLEBS, M.D.

PROFESSOR OF PATHOLOGY IN RUSH MEDICAL COLLEGE, AND IN THE POST-GRADUATE MEDICAL SCHOOL OF CHICAGO.  
CHICAGO.

I have proven in my book on "The causal Treatment of Tuberculosis," (Leipzig, 1894) that it was possible to heal, perfectly, tuberculosis of guinea pigs and man by certain products of tubercle bacilli, advancing the theory that this effect was obtained by a secretion product of these organisms, found mostly in the fluid portion of the cultures. If this opinion is a correct one the healing process in this disease would find an analogue in a great series of well known biologic processes, such as uremia, cholemia, etc. It

must be acknowledged as a general law that every organism forms substances poisonous to itself, if they are not secreted or separated from the body by the action of glandular secretion as by the kidneys, liver, etc.

The first substance having this property of destroying tubercle bacilli, I obtained from the whole culture, and gave it the name tuberculocidin (or tubercle-killer). It was prepared by the precipitation of the poisonous products of the tubercle culture and contained substances from the fluid parts of the cultures and such as were extracted from the tubercle bacilli. It could be shown that these substances were poisonous for tubercle bacilli, and wholesome for tuberculous animals and men. But it was not yet clear whether these healing influences were derived from the tubercle bacilli or contained in the culture fluid.

The further researches had therefore to be directed toward the preparation of still purer substances for healing purposes. The second step in this direction was the separation of a substance with healing properties from the fluids alone of ripe tubercle cultures, which I prepared in the same manner as tuberculocidin, but exclusively from the fluids after having separated the tubercle bacilli. I named this substance *antiphthisin*, and could demonstrate its effect upon both animals and men. In this country the experiments with antiphthisin could be made on a larger scale, and the effect claimed for it, established beyond question. The animal experiments made by me in the Winyah Laboratory afford sufficient guarantee of its success. But it still remains questionable if we have attained the highest possible results by the use of this substance.

To attain this last aim of our scientific work we can not rely alone on the results of clinical observation, as it is wholly impossible to obtain cases enough that are quite equal as to the intensity of the infection and the degree of resistance in the bodies of the infected persons. These researches can only be completed by experiments on animals.

#### I. IMMUNIZATION IN TUBERCULOSIS.

That there exists a very high power of resistance against tuberculous processes in normal animals has been shown by myself and others, through the different intensity of infection in the various animals. I have also demonstrated that the greater number of tubercle bacilli injected in the blood are destroyed there; in rabbits not more than seventeen of a thousand bacilli, injected into the blood vessels will find the opportunity of forming tuberculous knots in the tissues. I regard the nidulation (*Nestbildung*), which we call tubercle, as the first step in tuberculosis. These nests may be developed in very small number, and the tuberculosis can remain for a very long time in a dormant or latent state, as in a single tubercle of the brain, the bones, or the lungs. The spreading of tubercle bacilli from these nests is undoubtedly a consequence of an alteration of the general health. The tubercle bacilli in such nests will not develop without some help from the body of the infected person. If these organisms which lay dormant many years in their nests, begin all at once to increase in number and then propagate by detention in the blood or lymphatic vessels, there must be a diminution in the power of resistance, produced by other diseases (measles, influenza, etc.) or by the poisonous products of the tubercle bacilli. If this is true, there can be no doubt that a great number of

the intermissions of the tubercular process, so often remarked by all physicians and patients, are effected by the natural or by the disease acquired immunity of the body. But why is this acquired immunity not developed in all cases of long standing tuberculosis? First it must be remembered that in nearly all cases of tuberculosis the first years of the disease have not the same deleterious character as the later phthisical period, so that for a long time the phthisis has been taken for a different affection. After having noted the unity of all these affections by the presence of the same organism, we conclude the difference must depend upon a change in the diseased body, whose resisting power is diminished.

From another side also this point of view is remarkably sustained. The therapeutics of tuberculosis show us clearly the helpful, sometimes healing influence of all improvements in the general health, whether they be effected by climatic, dietetic or other treatments working in this direction. But all these methods of treatment will prove inefficient if the poisonous effects of the tubercle bacilli on the strength of the organism has reached a certain point.

There are certainly two indications for therapeutics necessary in tuberculosis, the one toward the destruction of the bacilli; the other toward fortifying the infected organism. In their practical application the one without the other will not produce the highest possible effect.

The first question now on all lips will be: Can we arrive at the immunization of the normal organism, so that no tubercle bacillus will grow in such an immunized body?

My own researches to confer immunization against tuberculosis were first instituted by injecting dead tubercle bacilli into normal guinea pigs, secondly by injecting the glycerin extract of tubercle bacilli, thirdly by injecting Kochs tuberculin. The mode of preventive injections and of the following infections with living tubercle bacilli were varied in a manifold manner.

With tubercle bacilli two series of experiments were instituted, the first made Dec. 27, 1894, was commenced by myself, but executed in my absence by others. It embraced twelve guinea pigs, that received daily injections of small quantities of a suspension of dead tubercle bacilli in kresolwater in the proportion of 1 to 10. The three first animals Nos. 1 to 3 received for five days 0.2 c.c. of this mixture, together with 0.1 gm. dead tubercle bacilli; the second three, Nos. 4 to 6, 0.2 c.c. of the mixture for ten days, with 0.2 gm. dead tubercle bacilli, the third three, 0.2 c.c. of the mixture, for fifteen days with 0.3 gm. dead tubercle bacilli, the fourth three 0.2 c.c. of mixture for twenty days, with 0.4 gm. of dead tubercle bacilli.

These experiments were impaired by the cold weather of the winter and by other circumstances not necessary to state here. The worst condition was that the inoculation following with living tubercle bacilli was instituted with a material not at all efficient, as was proven by injections of the same in other, not preventively treated, animals. The tubercle bacilli were imported from Europe enclosed in a bottle without air, and were thus killed, a fact of some interest. If one encloses them in a glass tube, the ends of which are closed by cotton, and dries them by a stream of air deprived by sulphuric acid of its moisture, one can conserve their life a very long time.

From the above cause I was obliged to make a sec-

ond infection with living tubercle bacilli after my return from Europe, on March 25, three months after the commencement of the preventive inoculations. Of the above twelve animals only four could be used for the experiment, of which two had received 1 decigram, one 3 decigrams, and one 4 decigrams of dead tubercle bacilli.

Guinea pig No. 1, with one-tenth gram dead tubercle bacilli, was killed fifteen days after the second efficient infection; it showed fresh spreading miliary tuberculosis of no great extent. Guinea pig No. 2, with also one-tenth gram dead tubercle bacilli, died fifty-three days after the tubercle infection. Its temperature rose to 105 F., and there were found older tubercular changes in liver and spleen, partly cicatrized, and a slight spreading of fresh miliary tuberculosis in the peritoneum and lungs. The animal had received from the nineteenth to fortieth day after the tubercle infection six injections of Paquin's serum ( $\frac{1}{2}$  to 1 c.c. per dose) evidently without any effect. It is clear also that the preventive dose of one-tenth gram dead tubercle bacilli was not sufficient to give the animal an absolute immunity against tuberculosis three months after the preventive inoculations. The dose of living tubercle bacilli used for the infection was a large one, nearly 8 centigrams. Some milligrams of the same tubercle bacilli have killed the animals in from two to three weeks. A certain retardation of the affection of the tuberculous development can be conceded as possible in these cases. The third animal, No. 8, received 3 decigrams dead tubercle bacilli and the same quantity of living tubercle bacilli at the same time as the others. It died eleven days after the tubercular infection without any sign of fresh tubercular formation, whereas a control-animal No. 50, inoculated the same date (March 25) with the same quantity of the same tubercle bacilli died after thirteen days with all the signs of miliary tuberculosis. As this animal No. 8 received no treatment, we can affirm with greater security than before a delaying influence which was apparent three months after the preventive injection of 3 decigrams (5 grains) of dead tubercle bacilli.

The fourth animal of the series (No. 10) received twenty preventive injections, with 4 decigrams dead tubercle bacilli, and was infected in the same manner and at the same time as No. 8. After the fever commenced it received Paquin's serum, but died with miliary tuberculosis, twenty-seven days after the tubercular inoculation, which proves that this manner of preventive inoculation is not effective in all cases.

As in this whole series it was not clear whether the injection of dead tubercle bacilli had proved fatal in so many cases (an inexperienced observer thought even that the deposition of dead tubercle bacilli in lymphatic glands as proved by Mitchell Prudden and Hødenpyl, could be interpreted as spreading of active tuberculosis), I resolved to repeat the experiment in a somewhat changed manner.

Five new guinea pigs (Nos. 52-56) received, the first one, the others two injections of dead tubercle bacilli, 0.714 gm. The whole quantity was much larger than in the first series and the frequent repetition of traumatism avoided. Not one of these animals died in consequence of the preventive injections. All were inoculated with living tubercle bacilli from ten to sixteen days after the preventive injections; the first three with 5 cg. and the two last animals with 1 dg. One of these animals (No. 52) died sixteen days after the

tubercle infection ( $\frac{1}{2}$  dg., nearly 1 grain of living tubercle bacilli having been injected). The cause of death in this case was accidental, escape of illuminating gas. As all these animals showed fever (102 to 103 degrees F.) and loss of weight after the tubercle infection, the first four received a different treatment. In another publication the history of all these cases will be related in an extended manner. Here it may be sufficient to remark that No. 52, which died after sixteen days, had no signs of tubercular development. No. 54, which died after thirty-six days, was free from infection in the internal organs, some glands were caseous, containing tubercle bacilli. No. 55, which died on the thirty-third day after tubercular infection, showed all inner organs free with the exception of the spleen, which was of normal size but contained two very small gray nodules; some lymphatic glands also contained caseous matter with tubercle bacilli. A small part of the right axillary gland was implanted in a normal guinea pig, No. 82. The animal died, though treated with large quantities of horse blood tubercle serum forty-nine days after the inoculation and proved evidently tuberculous.

We see also that there were infectious tubercle bacilli in this seemingly nearly healed case (No. 55). But it may be that the previous injection of dead tubercle bacilli had a retarding influence on the development of tuberculosis.

The last animal of this series, No. 62, received 1.4 gm. dead tubercle bacilli and was ten days later infected with 1 dg. living tubercle bacilli. It died thirty days after this infection. The axillary gland of the side of injection proved caseous and contained tubercle bacilli. The inner organs were wholly free from tubercles with the exception of the spleen, which contained a small quantity of gray nodules. The conclusions from these experiments are:

1. That the injection of greater quantities of dead tubercle bacilli is not at all deleterious to the animal.

2. That a quantity of 3 grams dead tubercle bacilli to 1,000 grams weight would be very effectual to retard the development of tuberculosis, introduced ten days after the preventive injection in the animal.

It is clear that this result, so interesting from a scientific view, has no practical value. If the dosage just given is available for men, a full-grown man weighing 120 pounds would need 180 grams, more than 10 ounces of air-dried tubercle bacilli. We must therefore search whether we can isolate the immunizing substance from the tubercle bacilli. This was the object of the third series of experiments, instituted with the watery-glycerinic extract of tubercle bacilli, for brevity named tubercle extract. This fluid itself would not be suitable, because it is too much diluted. It is therefore precipitated by strong alcohol; the precipitate, soluble in any quantity of kresol-water ( $\frac{1}{2}$  per cent.) can be prepared in any desirable strength. I use it at present in 0.5 and 1 per cent. solutions. In this series nine guinea pigs of 500 grams received  $2\frac{1}{2}$ , 5 and  $7\frac{1}{2}$  c.c. tubercle bacilli extract subcutaneous injected in from one to sixteen days. Three animals received the same dose. In each division two animals remained after the infection without treatment. The whole series was progressing exactly parallel to the first series with dead tubercle bacilli. The first infection in January was ineffectual; the second was instituted on March 25 with the same material as in the first series (7.85 cgr. air-dried tubercle bacilli and 2.15 cgr. cinnabar). Three ani-

mals, Nos. 15, 17 and 21, died previous to the effective tuberculous infection. These preventive injections therefore proved much less dangerous than the parallel cases with dead tubercle bacilli. Now we observe the results in the animals without any treatment:

Guinea pig No. 14, tubercle bacilli extract  $2\frac{1}{2}$  c.c., tuberculous infection three months later; died twenty-three days after the tuberculous infection. Weight, 585 grams January 9, 635 grams March 25 (tuberculous infection), 505 grams April 15 (loss, 80 grams day before death).

*Postmortem*—Liver yellow infarcts and few gray nodules; spleen not much enlarged, smooth, miliary tubercles; lungs free from infection; glands slightly swollen, not caseated; peritoneum: some old, but *very slight fresh tuberculous development*.

No. 18, 5 c.c. tubercle bacilli extract; tuberculous infection three months later; died twenty days after the tuberculous infection. Weight, 520 gms. January 9, 690 March 10, 630 March 26, 535 April 13; gained 15 gms. Died April 14.

*Postmortem*—Liver red, flabby, contains few small gray nodules; spleen slightly swollen (1.9-1.6x1.3-1.6 inches), weight 1.85 grams, pale, a few gray nodules; lungs congested, free from tubercles; glands not swollen; peritoneum: the masses of cinnabar and tubercle bacilli in this case injected directly into the peritoneal cavity are lying under the liver; they contain great, hard fibrous masses, very few miliary tubercles only on the mesentery; mesenteric glands slightly swollen, not caseated. Slight development of fresh tubercles.

No. 20,  $7\frac{1}{2}$  c.c. tubercle bacilli extract; tuberculous infection three months later. Died nineteen days after the tuberculous infection. Weight, 520 gms. January 9, 720 March 18, 645 March 26. Died April 13.

*Postmortem*—Liver not enlarged, surface smooth, yellow tinge (fatty degeneration), few miliary tubercles on surface; spleen not enlarged (1.5-1.6x $\frac{3}{8}$  inch), weight 1.37 grams, free from nodules; lungs partly collapsed, pleuritic exudation, in the right side particularly, some suspicious nodules in the thickened pleura, substance of lungs free; peritoneum: few nodules on the right side near the injected masses of tubercle bacilli and cinnabar; glands not swollen, not tuberculous.

*In all three cases was a very slight development of miliary tubercles, no deeper tuberculous alterations of the great glandular organs (spleen, liver, lungs), as usually found in so intense infections after three weeks' standing. Tubercle bacilli extract proves therefore in a high degree immunizing.*

That this conclusion is a correct one is proved by three control-animals, guinea pigs, Nos. 26, 49 and 50, infected with the same material in equal quantities, on March 25, without undergoing preventive injection of any kind. I give the results in the same manner as before:

No. 26, tuberculous infection 0.0785 c.c. with cinnabar March 25. Died April 14, twenty days after tuberculous infection (ineffectual injection January 6). Weight, 500 grams January 18, 480 March 22, 405 April 14; loss 95 grams.

*Postmortem*—Subcutaneous tissue contains an enormous infiltration with caseous masses spreading from the abdomen to the inguinal region and back, ulcerating at the sacral region. Peritoneum: In the great net, large nodules of firm caseous tissue, containing cinnabar in the center; some exudation, beside miliary

tubercles in great number at the left side of peritoneum; tuberculous infiltration of lymphatic vessels near the great nodules; enormous tuberculous infiltration of mesenteric glands. Liver greatly enlarged, contains numerous masses of yellow tubercles, nowhere cicatrization; spleen enlarged ( $1\frac{1}{2}$ x1), firm, gray; lungs congested, somewhat collapsed (pleuritic effusion on both sides), contain numerous gray tubercles; glands, inguinal and crural, swollen, caseated.

No. 49, tuberculous infection 0.0785 c.c. with cinnabar March 25. Died April 14, twenty days after tuberculous infection. Weight, 560 grams March 26, 445 April 14; loss 115 grams.

*Postmortem*—Peritoneum: omentum majus forms a string of yellow nodules, two of them containing cinnabar, from here a spreading of tuberculous masses all over the mesentery and the right kidney; liver much enlarged, filled with yellow masses, no cicatrization; spleen somewhat enlarged ( $1\frac{3}{8}$ x $\frac{7}{8}$  inch), weight 1.88 grams, gray, firm, with many gray nodules on the surface; lungs: right lung totally gray, consolidated, in left some nodules. The injection in this case was made intermuscular on the right side of abdomen.

No. 50, tuberculous infection 0.0785 c.c. with cinnabar 0.0215 gm. March 25. Died April 4, twelve days after tuberculous infection. Weight, 580 grams March 26, 495 April 13; loss 95 grams.

*Postmortem*—Peritoneum: injection mass forms a protrusion of peritoneum, free from infection on this part, but on the great net many deposits of cinnabar, part with gray tuberculous formations, the same in the gastro-hepatic ligament, in the mesentery of spleen and in adhesions of the omentum to the liver and left kidney; liver not enlarged, contains numerous small and large nodules, the latter yellow, the former gray, sometimes containing cinnabar; lungs free, edematous; glands: substernal glands swollen and reddened.

We remark that the same tuberculous infection having made such small alterations in the animals previously injected with the tubercle bacilli extract, has without this, produced in twelve days a far disseminated peritoneal tuberculosis, the origin of which is clearly demonstrated by the cinnabar taken up with the tubercle bacilli by leucocytes and conveyed by them all over the peritoneum. In the farther progress of this affection we note in the first two control animals occur the greatest possible tubercular alterations of the liver, spleen and lungs. The same progress is made also by the tubercle bacilli, enfeebled by the preventive injections of tubercle bacilli extract, but not with the same effect. As this is the only difference in these six cases, we must say with as much certainty as is possible to obtain in animal experiments, *that the glycerin extract of tubercle bacilli produces a very high degree of immunization, proving effective three months after a very high degree of tubercular infection.* As the greatest injected quantity of tubercle bacilli extract was 7.5 c.c. to 500 gms., containing 7.5 centigrams of organic matter, the requisite quantity for men would be probably 15 eg. to one kilo., 7.5 grams for 50 kilo., or half an ounce for 100 pounds, a quantity of organic substance, dissolving readily in 50 c.c. kresol-water (0.2 per cent.). Such a small quantity would immunize a full-grown man for more than three months.

The clinical observations made by the use of tuberculoicin, that contains a large quantity of bacillus extract, agree with these results. The most success-

ful cases that I have seen in Europe and in this land, were those in which the application of tuberculoicin and tubercle extract followed the antiphthisin treatment.

The same conviction resulted from animal experiments I instituted in the last year, for the comparison of pure antiphthisin treatment and a mixed treatment with antiphthisin and tubercle bacilli extract. The tubercle-killing power of antiphthisin, proved by new experiments, must be diminished by immunizing, probably also by antitoxic influences. I will speak later about the best methods of the combined treatment. Now it may suffice to demonstrate the fact, that by such treatment the gravest tubercular changes in guinea pigs, namely the enormous tubercular development in liver and spleen, can be entirely healed. The differences in the two cases of guinea pigs, now to be related, may partly depend on a different power of resistance, but partly also on the different quantity of tubercle bacilli extract they received, the antiphthisin treatment being nearly the same.

The two animals, Nos. 109 and 110, of more than 300 grams weight, had received, before the tuberculous infection, injections of tubercle toxins, prepared by digestion of tubercle bacilli with pepsin and pancreatin, which proved non-effective, but caused high fever. Immediately afterward infected with one dg. air-dried tubercle bacilli, a very large dose, the typical tuberculous fever is developed ten days afterward, rising to 102.3 and 103 degrees average temperature.

The treatment commenced on the twenty-second day after the tuberculous infection with small doses of antiphthisin, 2 to 3 cg., sometimes 2 dg., per day, and such of tubercle bacilli extract 2 cg. No. 109 received in fifty-eight days 1.75 grams antiphthisin and 0.06 c.c. tubercle bacilli extract. No. 110 in fifty-nine days 1.51 grams antiphthisin and 0.12 c.c. tubercle bacilli extract. The daily average temperature varied from 100 to 101 degrees. During this time enormous alterations of the liver and spleen were developed; in No. 109 the spleen measured at the time of death, 142 days after tuberculous infection, two and one-fourth inches in length, one and five-eighths inches in breadth, and seven-sixteenths of an inch in thickness, whereas in No. 110 this organ at the same time measured no more than one and three-sixteenths inches in length and thirteen-sixteenths of an inch in breadth. The first contained a great number of yellow spots, the second was quite free from tuberculous matter.

The liver is very much enlarged in the two cases, but contains in No. 109 hardly any normal substance, being very hard and fibrous throughout with many yellow spots, a little more conserved liver tissue in the left lobe. In No. 110 the liver consists of quite normal hypertrophic tissue, forming flat projections between deep fibrous scars.

The lungs of No. 109 contain in all parts white nodules. In No. 110 the lungs are quite free from any tuberculous deposit.

The abdominal cavity is free from tubercles in both animals. The glands firm, fibrous; only in one inguinal gland of No. 109 was found a small purulent deposit, containing very few degenerated tubercle bacilli. A few more tubercle bacilli were found in the nodules of the lungs of the same animal. No. 110 was quite free from tubercle bacilli, so far as can be demonstrated by microscopic research.

No. 109 was very anemic, a consequence, as it seems, of the deep degeneration of liver and spleen.

But now we return to the clinical history of the cases. On the ninety-first day after the infection, ten days after discontinuing the first series of treatments, probatory injections with my tuberculotoxin 0.3 gm. were instituted. No. 109 gave a reaction to 102, No. 110 no reaction.

In consequence of this result it seemed desirable to institute a new series of antiphthisin injections. In this was used a method that had effected good results in other cases. Commencing with small doses, one gives, every day, a little more until a very large dose is reached. One recommences then with small doses, increasing to larger as long as the temperature is elevated. In No. 109 we increased from 2 to 20 cg. in eighteen days and decreased the temperature from a maximum of 102.4 degrees to 99.6 degrees average temperature, the second time from a maximum of 101.2 degrees to an average temperature of 99.7 degrees. In No. 110 there was scarcely any change of temperature, the average being between 100 and 101 degrees. It is true that this temperature was higher than normal, but we find the same elevation in nearly all healed cases; it seems that in such animals the pyrogenic toxins remain a longer time in the body than the living tubercle bacilli, and the tuberculous tissue may be deposited in some irrecognizable residues of dead tubercle bacilli.

The difference in the healing process in these two animals may depend partly upon a different normal resistance of the two organisms, but perhaps the more prolonged use of tubercle bacilli extract has had a beneficial influence on the healing process in No. 110.

## II. THE COMPOSITION OF TUBERCLE BACILLI.

The highly immunizing effect of the glycerin extract of tubercle bacilli must direct our attention more to the composition of tubercle bacilli. My researches have given me up to this time, the following results:

1. The tubercle bacilli contain a very great quantity of fatty substance, a fact first remarked by Hammerschlag and Neusky, then confirmed by Dr. von Schweinitz of Washington, D. C., who made the first quantitative determination; he found 25 per cent. fat. I commenced my researches before knowing of this last valuable work. I found not more than 22 per cent. fat, but this percentage depends very much on the degree of dryness of the bacilli. As they contain a great quantity of glycerin, a fact noted by Prof. Abell of Baltimore, in the alcoholic ethereal extract, which explains their high hygroscopic quality. The pure ethereal extract gave me a firm red colored fat melting at 42 C., 20.5 per cent. of the whole mass. But besides this fat the tubercle bacilli contain a white fatty substance that can be extracted by benzol and is not soluble in ether; this fat is harder than the first, the melting point higher, if I remember rightly above 50 degrees C. The quantity of this benzol fat was 1.14 per cent.

The second point regarding the tubercle bacilli-fat is that this substance is the single cause of the specific staining of the tubercle bacilli. The separated fat gives the fuchsin staining not destroyed by mineral acids, and tubercle bacilli deprived of this fat do not stain in the same manner. The granules stained by fuchsin in the so-called degenerative forms of tubercle bacilli are nothing but remains of this fat. They are therefore better called *atrophic tubercle bacilli*.

2. The greater part of tubercle bacilli is formed of nuclein. After extracting the fat by ether and benzol and digesting the residue by pepsin and chlorhydric acid, the nuclein can be dissolved in alkaline fluids and precipitated by alcohol. After repeated solution and precipitation we obtain a pure nuclein, containing 8 to 9 per cent. phosphorus, as much or more than was found by Miescher in the eggs of salmon.

This tubercle nuclein and the fats have no influence on the tuberculous process, that I could see in a large number of varied experiments on animals.

3. The third constituent of tubercle bacilli is the glycerin extract containing a substance precipitable by alcohol, giving biuret reaction. Whether this substance is a simple one or not, whether it acts in its totality in immunization or whether it contains only ferments with immunizing power, must be determined by further researches.

### III. THE TUBERCLE KILLING POWER OF ANTIPHTHISIN.

I will here add a short note about an experiment fundamental to my theory, now repeated with some change. In my book on page 174, I had reported an experiment (No. 23) showing that fresh tubercle bacilli are killed, if treated by a mixture of tuberculocidin and crethin (similar to tubercle toxin) prepared from the bismuth precipitation of culture fluid. Tubercle bacilli treated in this manner six days proved totally inoffensive, whereas the same, untreated bacilli killed animals by tuberculosis in fourteen days. One of the animals, that had received tubercle bacilli treated with tubercle culture lived more than a year and was found quite free from tubercles (No. 4).

I repeated this experiment with pure antiphthisin in the following manner:

Jan. 12, 1896, 25 c.c. antiphthisin with 1 per cent. organic matter was precipitated by absolute alcohol, the precipitate firmly adhering to the walls of the bottle; the alcohol was poured off, the residue was slightly warmed, washed with ether, the latter evaporated, the residue was dissolved in 2.5 c.c. freshly distilled water. Each cubic centimeter contained 0.1 gram dry antiphthisin.

In this fluid I suspended under aseptic measures a large quantity of tubercle bacilli taken from a full grown culture.

Three guinea pigs received from this emulsion injections of the same quantity, No. 146 after one, No. 118 after two, and No. 150 after three days. Two control animals of the same weight (186 to 252 gms.) were observed in the same manner, the weight being taken in the morning, also the temperature at 5 o'clock p.m. No. 148 infected with living tubercle bacilli on February 2, weighed January 13, 252 grams; February 5, 325 grams; March 19, 242 grams. It died on this date after long continued high fever (102.6 max.) forty-three days after the tubercle infection, and proved highly tuberculous; in liver and lungs many gray tubercles, the glands caseated; at the injection point innumerable tubercle bacilli; in the organs also were great quantities of them.

No. 147 remained totally free from infection and showed the following weights: January 13, 186 grams; February 5, 249 grams; gain 63 grams; April 19, 430 grams; gain 181 grams. Total increase of weight in 97 days 244 grams.

No. 146 having received February 13 tubercle bacilli, treated twenty-four hours with pure antiphthisin, showed the following weights: January 13,

186 grams; February 5, 210 grams; gain 24 grams; February 25, 195 grams; loss 15 grams. It gained in 43 days 9 grams. It died on February 25 and showed on postmortem the external lymphatic glands enlarged and slightly caseous. In the inguinal and subclavicular glands were found a few degenerated tubercle bacilli; in the other glands none. The inner organs proved quite free from tubercles and tubercle bacilli. The temperature reached on one day 100 degrees F., was generally between 99 and 100.

No. 149 having received January 15 tubercle bacilli, treated seventy-two hours with pure antiphthisin weighed: January 13, 183 grams; February 5, 209 grams; gain 26 grams; April 19, 300 grams; gain 91 grams. Total gain in 97 days 117 grams.

No. 150 having received February 14 tubercle bacilli, treated forty-eight hours with pure antiphthisin, weighed: January 13, 323 grams; February 5, 365 grams; gain 42 grams; April 19, 469 grams; gain 104 grams. Total gain in 97 days 146 grams.

The temperature of the two last animals was in April higher than normal, varying from 100 to 102 degrees. The average temperature (5 o'clock p. m.) from April 1 to 19 was in No. 149, 101.20 degrees; in No. 150, 100.78 degrees. I think that these two animals were also tuberculous, but in such a slight degree that after 100 days their growth in comparison with the normal animal was but slightly retarded; in No. 149 (gain 117 grams) by 127 grams; in No. 150 (gain 146) by 98 grams. This proves that antiphthisin, in twenty-four hours, has a marked debilitating influence on living tubercle bacilli. I have noticed that such bacilli can kill an animal in twenty-two days, but with very slight tubercle development and without fever.

The treatment of tubercle bacilli with antiphthisin for two or three days gives a far better result, as these animals lived more than one hundred days after the injection of the treated tubercle bacilli.

That the absolute killing of tubercle bacilli in antiphthisin requires a longer time (in my experiment with tubercle culture six days were required) must be explained by the large proportion of fatty matter contained in the tubercle bacilli, diminishing in a high degree the osmotic power against watery solutions. The destruction of the tubercle bacilli in the living body by tuberculocidin or antiphthisin is a much more complicated process. I think that here the chemiotaxis is of decided influence; the leucocytes, assuming these substances transport them to the diseased parts and forcing them into the interior of the tubercles, destroy their vitality, at first dissolving the fats, then digesting the protoplasm of the tubercle bacilli.

As the tubercle bacilli extract has sixteen times higher power of chemiotaxis than antiphthisin, I recommend the addition of the tubercle bacilli extract to the antiphthisin treatment or the use of tuberculocidin alone in the treatment of human tuberculosis without higher inflammatory processes and fever. As antiphthisin is the mildest form of tubercle bacilli products and has no injurious effects, it should, in such cases, commence the treatment. Two hundred c.c. antiphthisin, 75 to 100 tuberculocidin and 50 c.c. extract, taken in six to seven months seems to be a sufficient dose in most cases.

## ORIGINAL ARTICLES.

## TUBERCULOSIS OF THE MALE GENITAL ORGANS.

Read by title at the meeting of the American Surgical Association, at Detroit, Mich., May 26-28, 1896.

BY N. SENN, M.D., PH.D., LL.D.  
CHICAGO, ILL.

The male genital organs are the seat of as yet imperfectly understood conditions which predispose them to tubercular infection. The literature on tuberculosis of these organs is scanty as compared with tubercular affections of other organs, such as the lungs, pleura, peritoneum, lymphatic glands, bones, joints, meninges and skin. A careful search of what has been written on tuberculosis of the male genital organs will convince the searcher for truth and instruction that this subject has not received the attention its importance demands. The observations of many clinicians in this comparatively new field of surgical pathology present no uniform and many times diametrically opposite results. The deductions drawn in the postmortem room by professional pathologists likewise lack uniformity, and the different results obtained have often been taken as a basis to fortify the opinion of individual surgeons. This department of surgical tuberculosis is in its primitive stage and offers many inducements and opportunities for careful clinical observation, and bacteriologic and pathologic research in the future. The great obstacle to a more perfect development of the surgical aspects of tuberculosis of the male organs of generation, in the past and to a certain extent at the present time, has been, and remains, accuracy in diagnosis. Since the mystic term scrofula has been almost completely eliminated from the present nomenclature of surgical affections it has been found that many of the chronic inflammatory diseases of the male organs of generation are of tubercular nature. The important questions whether the male genital organs are the seat of primary tuberculosis, or whether the disease extends to them by a progressive infective process from the upper portion of the urinary system have not been definitely settled; each side can show its exponents whose views command respect. For my own part I am firmly convinced that in a fair percentage of cases the male genital organs are the seat of primary tuberculosis, the tubercle bacilli finding in the blood vessels of the complicated genital apparatus a favorable condition for their mural implantation, growth and reproduction. These are the comparatively rare cases of hematogenous primary tuberculosis of the male genital organs caused by the deposition, growth and reproduction of tubercle bacilli floating in the general circulation, locating in some part of the genital apparatus without a discernible tubercular lesion in any of the other organs. Such cases occur, but are few as compared with instances of secondary tuberculosis complicating tubercular affections of other organs or occurring in the course of extension of a tubercular process by continuity of surface from the urinary organs. It is my purpose on this occasion to call your attention to some of the salient points in the etiology, pathology and clinical aspects of tuberculosis of the male genital organs on the hand of the current surgical literature and shall emphasize some of the topics which have attracted my attention by my own personal observations.

*Tuberculosis of the Penis.*—The frequency with

which tubercular affections of the female organs of generation occur has recently received the well merited attention of gynecologists. The observations which have been made in this direction have reminded the surgeon of the possibility of direct inoculation during coitus. That such an occurrence is beyond the range of imagination no one can deny. Years ago Verneuil (*Hypothèse sur l'origine de certaines tuberculoses génitales dans les deux sexes. Gaz. hebdomadaire*, No. 14, 15, 1883) expressed the opinion that primary genital tuberculosis, which does not depend on scrofula is probably caused by direct infection during coition, that is, by the wandering of tubercle bacilli through the external genital organs to a point of the apparatus in which favorable conditions for their localization and reproduction exist. Poncet (*La Médecine Moderne*, Paris, July 29, 1890) reported to the French Congress for the Study of Tuberculosis an article on tuberculosis having its origin in the penis. Three varieties are mentioned: 1, balano-preputial tuberculosis; 2, tuberculosis of the mucous membrane (this variety usually showing itself first in the deep urethra), and 3, tuberculosis of the urethra which consists of fungous masses involving the peri-urethral tissues, thereby allowing the urine to infiltrate the penile structures. I have reason to believe that many of the cases of destructive lesions of the penis treated by amputation of the organ in which no recurrence followed the disease was not carcinoma as surmised, but of a tubercular character. During the last two years I have seen two cases of extensive destruction of the penis from what I believed to be a tubercular process. One of the patients under the care of Prof. Scales in Mobile was a colored man about 35 years of age, single, with no history of syphilitic infection. The ulceration commenced upon the external surface of the prepuce several years ago and was not attended in the beginning by enlargement of the inguinal glands. The ulceration and sloughing extended successively to the glands and body of the penis and finally resulted in almost complete destruction of the entire organ. Later the inguinal glands and skin covering the scrotum became involved. The inguinal glands became caseous and several well-marked tubercular abscesses developed. When I saw the patient he was confined to his bed and the discharge from the extensive ulcerated surfaces had resulted in inoculation tuberculosis which covered a considerable area of the gluteal regions on both sides. Some of the ulcers would heal from time to time when the new scar tissue would again break down and give place to an ulcerative process. No signs of syphilis could be detected upon any part of the surface of the body or in any of the internal organs. The patient had been subjected repeatedly to antisyphilitic treatment with various preparations of mercury and iodine without any improvement; in fact, such treatment appeared to aggravate the local conditions and still further impair the general health of the patient. Under anti-tubercular treatment, local and general, consisting in the use of antiseptics, balsam Peru, and later iodoform, repeated curettage, and the internal administration of guaiacol and cod liver oil, the disease was arrested, the ulcers healed rapidly, and the general health, which had been precarious for several years, was so much improved in the course of a few months that the patient was able to resume light work. I had no opportunity to make a microscopic examination of the tissues or to search for the bacillus in this case,

but I have but little doubt both from the clinical history of the case, as well as the character of the local lesions, that the affection was one of primary tuberculosis of the skin which extended rapidly to all of the tissues of the penis and later to the lymphatics, and finally to neighboring parts exposed to contamination from the profuse discharge from the ulcerated surfaces. The very fact that the lymphatic glands were converted in whole or in part into cheesy masses speaks for the diagnosis of tuberculosis and against syphilis. It is well known that in the negro tuberculosis often pursues an exceedingly rapid course. In a few weeks tubercular glands break down and suppurate, a condition often associated with quite extensive phlegmonous inflammation of the surrounding connective tissue, the consequence of a mixed infection with pyogenic organisms. It is therefore not surprising that in rare cases tuberculosis of the penis should result in extensive destruction or complete loss of the organ under the influence of a double infection in persons peculiarly susceptible to the ravages of this disease.

For a full report of this case, I am indebted to Professor Scales and Dr. Fonde:

John Mitchell, mulatto, aged 31. Entered City Hospital of Mobile, Dec. 22, 1893, with an ulcer on the balano-preputial fold and extending on the glans penis. The ulcer was cauterized with nitric acid and an iodoform dressing applied. The patient improved slightly and at the end of two months left the hospital. He returned again, after an absence of six months with the entire penis destroyed, and with a large ulcer on the nates which rapidly extended. He suffered great pain, showed serious pulmonary complications, was greatly emaciated and confined to bed for six months. During this time the actual cautery was applied, followed by dressings of a 5 per cent. solution of balsam Peru in castor oil, and also a short course of guaiacol. After the first two cauterizations there was decided improvement in the ulcer, but the third and last were followed by no benefit, the ulcer continuing to enlarge. He was, however, sufficiently improved to enable him to leave his bed for an hour at a time. The patient's condition remained about the same for four or five months, when he seemed to steadily grow worse. Dressings of iodoform were applied daily from this time until Jan. 15, 1895, when Prof. N. Senn saw the case and delivered a clinical lecture in the hospital amphitheater to the students of the Medical College of Alabama. The patient's condition was desperate at this time. The ulceration had extended by numerous ulcers closely adjoining and finally coalescing, the whole being purulent until the whole perineal region, coccygeal fissure and both nates were denuded, and in some places the destruction extended deeply. The bladder was emptied through several perforations in the perineum, and single shallow ulcers appeared on the scrotum. The entire extent of the ulceration on the nates measured ten inches vertically by nine inches transversely, being greater on the left buttock.

Dr. Senn advised a thorough course of guaiacol and tonics until the general condition of the patient would permit a thorough and radical removal of all infected tissues by curettement.

Guaiacol was commenced in doses of gtt. v, well diluted in milk, three times a day, and gradually increased until the patient was taking ten drops four times daily. He was also given a course of syrup of iodid of iron. Patient improved sufficiently in three months to leave bed and lounge around for most of the day, and slept and rested well, which he had not been able to do since his arrival at the hospital, unless under an opiate. He still suffered pain the greater part of the time. Curettement May 31; surgeon, William M. Mastin. Patient was anesthetized and the whole field of infection carefully and deeply scooped out, and edges trimmed with scissors. Some of the pockets extended deeply into the nates and some burrowing far under the skin. One at the gluteal creases penetrated nearly to the femur in the adductor muscles. A dressing of iodoform was then applied. Rapid healing followed and pain was almost entirely absent when patient recovered from the immediate effects of the curette.

Curettement July 10; surgeon, William M. Mastin. The condition very much better and healing had taken place in considerable part of the field of the ulcer. Was again thoroughly curetted with the same marked relief and improvement following.

Curettement August 7; surgeon, William M. Mastin. An occasional fresh breaking down in the cicatricial tissue beneath the surface invariably yielded to the curette and healed rapidly.

Curettement Aug. 30, 1895; surgeon, William M. Mastin. The same marked improvement. The main portion of the field showed healthy and pliable cicatrix.

Curettement Sept. 6, 1895; surgeon, William M. Mastin. Treated as before with same benefit.

Curettement October 31; surgeon, T. S. Scales. There were several small and shallow ulcers in the coccygeal fissure and in the inguinal fold on each side the scrotum, in addition to the large and deep one which remained in the gluteal crease. These were carefully scraped and iodoform thoroughly rubbed in. Followed by improvement.

Curettement Jan. 20, 1896; surgeon, James A. Abrahams. There were two remaining ulcers, one next the scrotum in the coccygeal fissure, and the other in the gluteal crease, which again received a careful and extensive removal of the involved tissue, iodoform rubbed thoroughly in, followed by healthy granulation at the bottom of the ulcer and rapid healing.

Curettement Feb. 20, 1896; surgeon, James A. Abrahams. There was steady improvement, the only large ulcer remaining was the one in the gluteal crease, which was filling up rapidly. Scraped and treated as before, improvement following.

Since the second curettement the patient has been able to do work around the hospital and acted as nurse for some time. He is six feet tall, weighs 185 pounds. Pulmonary symptoms have disappeared and he is robust, very strong and healthy. He suffers no pain. The only remaining ulcer is the one at the gluteal crease, which is now about the size of a half dollar and is shallow. This will be scraped again in a few days.

Very recently I have had an opportunity to examine quite a similar case in the service of Dr. Bouffleur; at the Cook County Hospital. In this case the lymphatic glands in the groins became involved after a considerable portion of the penis had become destroyed by ulceration and sloughing. Syphilis was suspected, but the most energetic treatment made no impression on the progress of the disease. Local and general anti-tubercular treatment with excision of the enlarged lymphatic glands, effected a speedy and permanent cure. Many sections of the diseased tissue were examined for bacilli with negative results, but the existence of isolated multinuclear giant cells furnished an additional proof of the tubercular nature of the primary disease and the secondary glandular complications. In both of these cases the base and borders of the ulcers were not indurated, the surface covered with pale, flabby, edematous granulations, the margins undermined, the overhanging skin of a bluish tint. The spongy and cavernous portions of the penis appeared to yield alike to the tubercular destruction. In neither of these cases did the disease involve the urethral mucous membrane above the level of the ulcerated surface. The strongest argument in favor of the tubercular nature of the destructive process is the fact that vigorous anti-syphilitic treatment not only failed in arresting the disease, but resulted in aggravation of the local conditions and general health of both patients, while the anti-tubercular treatment yielded the most prompt and satisfactory results.

*Tuberculosis of Urethra.*—Surgeons are familiar with the well-known clinical fact that foreign substances when introduced into the urethra are very prone to travel in the direction of the bladder unaided by any *vis a tergo*. It is reasonable to assume that microorganisms lodged in the meatus are conveyed in a similar manner along the urethral tract and unless they become arrested upon a soil propitious for their growth and development, they produce no symptoms. There can be but little doubt that direct infection of the urinary tract with the bacillus of tuberculosis occasionally takes place in this manner. Primary tuberculosis of the urethra is exceedingly rare, and when it occurs it takes place in a part of the urethral

mucous membrane prepared for the reception and growth of the bacillus by some antecedent injury or disease. Tuberculosis of the urethra must be mentioned especially as an affection which is prone to exist in cases of vesical and prostatic tuberculosis in consequence of a direct extension of the infective process from either of these organs to the mucous membrane of the urethra. It may occur in the prostatic, the bulbous, or any other part of the urethra. It is found more frequently in young females suffering from bladder tuberculosis than in men. It appears in the form of ulcers and is often attended by incontinence of urine. What English has designated as tubercular periurethritis is in reality a tubercular perineal abscess which can take its origin as well from a tubercular Cowper's gland as a tubercular urethral ulcer. I have now under my care at the Presbyterian Hospital a boy, 14 years of age, who about a year ago manifested the first symptoms of renal tuberculosis. In the course of a few months a large tubercular paranephric abscess developed on the left side which was incised but never healed. Soon after he was admitted to the hospital symptoms appeared which indicated that the tubercular process had reached the bladder. A few weeks later a urethritis set in, characterized by a profuse discharge. The meatus presented the same appearance as during the early stages of a gonorrhœal urethritis. As soon as the disease reached the urethra incontinence of urine appeared and continued until the acute symptoms subsided. Four guinea pigs were inoculated by injecting a hypodermatic syringe full either into the peritoneal cavity or the loose connective tissue in the groin. All of the animals died in the course of five or six weeks and the postmortem in each instance revealed diffuse miliary tuberculosis. In this case the tubercular inflammation extended from the kidney over the entire urinary tract in the course of a year. Long before the infection reached the bladder and urethra, the tubercular nature of the primary renal affection was established by the detection of numerous tubercle bacilli in the urinary sediment obtained from the centrifuge. Tubercular urethritis gives rise most constantly to retention and incontinence of urine. Owing to the irritation caused by the urinary secretion, which will be voided the more frequently in proportion to the irritation of the bladder present, the inflamed mucous membrane will be kept in a constant state of disease, and the more so as in these situations the tubercular infiltration is not usually eliminated, but on the contrary, steadily increases in quantity, and on this account not only excites catarrhal inflammation in the adjacent healthy mucous membrane, but also affords an increasing impediment at the deepest part of the urethra to the flow of urine, and the most appropriate local surgical treatment only suffices to check in some measure the retention of the urine. Retention eventually leads to incontinence.

Michaut (*Sur un cas d'ulcération tuberculeuse de l'urèthre consécutive à une tuberculose rénale primitive. Bulletin de la Soc. Anat. de Paris, 1887*) observed a case of tubercular ulceration of the urethra in a man the subject of pulmonary tuberculosis. The disease appeared as a hard induration five centimeters behind the meatus which simulated clinically closely a hard chancre. Later tubercular granulations appeared around the meatus and upon the surface of the glans penis. The postmortem revealed tubercu-

losis of the kidneys, and a descending tubercular process which finally reached the urethra. The part of the urethra affected was indurated and the fossa navicularis was the seat of deep ulcerations. In the differential diagnosis of urethral chancres it is well to bear in mind tubercular lesions which may so closely resemble primary syphilitic infection.

Analécot (*Ann. des Maladies des Organes génito-urinaires, November, 1893*) records a rare case of secondary tubercular ulcer surrounding and involving the meatus, about the size of a ten cent piece. The patient was a boy 14 years old and had been circumcised eight days after birth. The appearance of the ulcer and the absence of induration excluded the idea of a hard chancre. The smooth base, absence of suppuration and the regularity of its border excluded chancroid. It was not painful. The patient had for three years been suffering with bladder trouble. Micturition was frequent, painful, and at times bloody. Although no bacilli could be detected in the ulcer, inoculation with debris taken from it nevertheless produced tuberculosis in guinea pigs, and so demonstrated its tubercular nature. The ulcer had remained stationary for nearly a year.

Ahrens (*Die Tuberculose der Harnröhre. Beitr. zur Klin. Chir. Bd. VIII, p. 312*) succeeded in finding the reports of only four cases of tuberculosis of the urethra in women. It is more common in men, but its relative frequency is estimated differently by different authors. Krzywicki believes that the urethra is affected in 1 per cent. of all forms of tuberculosis and in 17 per cent. of all cases of urogenital tuberculosis. In the majority of cases it is affected secondarily both in the ascending and descending forms of urogenital tuberculosis, and with few exceptions the prostate gland is simultaneously implicated. In exceptional cases it is met with as a primary affection, and in that event is nearly always mistaken for a primary syphilitic ulcer. In the primary form the infection takes place either through the general circulation, or by inoculation, the latter mode of origin was demonstrated experimentally to a certain extent at least by Baumgarten by his experiments on rabbits. As a pathologic curiosity must be mentioned tubercular stricture of the urethra. Such a case is described by Ahrens. (*op. cit.*) The patient was a boy 16 years of age who was at the same time the subject of tubercular coxitis. The stricture could only be passed with a filiform bougie. The patient died six days after his admission into the hospital in consequence of retentio urinæ and rupture of a diverticulum at the base of the bladder. The postmortem showed a caseous exudate upon the surface in the posterior part of the urethra as far as the pars cavernosa. The bladder, testicles, seminal vesicles, ureters, and most of the internal organs were the seat of recent tubercular infection. In primary tuberculosis of the urethra, when the disease is accessible, the most energetic local treatment should be resorted to with a view of eliminating the tubercular material, while its occurrence as a secondary affection to tubercular affections of other portions of the urogenital organs calls for palliation and improvement of the general health of the patient by appropriate treatment.

*Tuberculosis of the Spermatic Cord.*—The spermatic cord or vas deferens is the connecting channel between the essential organ of generation in the male, the testicle, and the seminal vesicle. It is never the

seat of primary tuberculosis. In tuberculosis of the testicle the disease usually manifests an intrinsic tendency to advance in an upward direction, implicating the cord and, if life is prolonged for a sufficient length of time, eventually reaching the seminal vesicle. The cord becomes enlarged, indurated, and usually nodular, so that when it passes between two fingers it presents somewhat the outlines of a rosary. In some cases the cord enlarges to the size of the little finger. The swelling is either cylindrical, nodulated, or spindle-shaped. The mucous membrane is most thickened, then the muscular coat and last the adventitia. Perforation of the wall leads to tubercular abscess around it. Pain is usually absent and tenderness on pressure slight. In cases of primary tuberculosis of the seminal vesicles the infective process frequently descends along the cord to the epididymis. The surgical interest in tubercular spermatic centers in the operation for the removal of a tubercular testicle. In all cases in which the cord is affected the inguinal canal should be laid open freely as far as the internal inguinal ring and by gentle traction and the use of dull instruments as much as possible of the cord should be made accessible and removed. It has been shown that with proper care the cord can be liberated in this manner and excised to a point very near the seminal vesicle.

*Tuberculosis of the Seminal Vesicles.*—The seminal vesicles are occasionally the seat of primary tuberculosis, but in the majority of cases the disease is associated with similar affections of other parts of the genital organs, most frequently the testicle and prostate gland. Guyon believes with Lancereaux that the tubercular process begins very frequently in the vesiculæ seminales. Of twenty-six autopsies made with reference to show the frequency with which the seminal vesicles are primarily affected, he found this to be the case in two cases; in ten cases these were involved, but the prostate was simultaneously affected; in one case the prostate alone was implicated. Of thirty-six cases of disease of the seminal vesicles collected by Dreyer (*Beitr. zur Pathologie der Samenbläschen*. Inaugural Dissertation Göttingen, 1891), in eighteen the affection was of a tubercular nature. Of these cases one-half occurred in persons over 40 years of age. In three cases the vesicles were primarily affected, and in twelve the disease presented itself at a stage in which the organs were hard and nodular without any softening, while in six cases it had passed into the second stage characterized by caseation and liquefaction of the caseous material, that is, the formation of tubercular abscesses. In three cases the disease had extended beyond the capsule of the gland and had invaded the pelvic connective tissue. In one case the disease was complicated by tubercular peritonitis. Pulmonary tuberculosis was absent only in two cases. As a rule, different portions of the urogenital tract and distant organs were found implicated. The seminal vesicles can be palpated most satisfactorily by placing the patient in the knee-elbow position. In tuberculosis of one testicle the seminal vesicle on the corresponding side is frequently found affected, and in tuberculosis of both testicles the subsequent affection of the seminal vesicle is often bilateral. The existence of hard nodules in different parts of the organ which are not very tender on pressure is very suggestive of the tubercular nature of the disease. The close proximity of the seminal vesicles to the peritoneum in case these

organs are tubercular must occasionally lead to peritoneal tuberculosis.

A number of surgeons have made bold attempts to eradicate one or both seminal vesicles by operative interference. Ullmann reports from Albert's clinic a case of extirpation of the tubercular vesiculæ seminales in a patient 17 years of age, who had been castrated for tubercular orchitis. Zuckerkandl's semilunar incision between the scrotum and anus was made and the space between bladder and rectum exposed, and the posterior wall of the former made prominent by the use of a steel sound. The vesiculæ seminales and vasa deferentia were now freely exposed and could be readily dissected out as well as the upper left angle of the prostate which contained a small abscess. Only the left, apparently healthy vas deferens was left. The hemorrhage during the operation was free, and this, as well as the secondary hemorrhage which occurred on the evening of the same day, had to be arrested by a resort to the iodoform gauze tampon. Healing of the wound took place quickly with the exception of a small urinary fistula. The fistula was supposed to have been caused by division of the ejaculatory duct in the substance of the prostate. The patient left the hospital with a small urinary fistula and claimed to have experienced erections at different times. Ullmann regards primary tuberculosis of the seminal vesicles and unilateral secondary infection in the course of testicular tuberculosis as legitimate indications for a radical operation. In two cases of secondary tubercular vesiculitis Roux (extirpation of la vésicule séminale. *Congrès Français de Chir.*, 1891) followed castration for tuberculosis of the testicles by excision of one of the seminal vesicles which had become involved by the tubercular process. After the removal of the diseased testicles and suturing of the wounds he brought the patient into lithotomy position, lying on the affected side, and made an incision 2-3 cm. from the median line as far as the ischium, exposing the rectum and penetrating finally as far as the affected vesicle. By pressure with the finger in the rectum from above downward the edge of the vesicle was made to appear in the upper portion of the wound. By the use of a traction ligature the vesicle was drawn further down, separated, and with the stump of the vas deferens, was divided close to the neck of the bladder. The patient recovered from the immediate effects of the operation, but the remote results of the procedure are unknown.

Weir (*Medical Record*, Aug. 11, 1894) reports a case in which he removed both seminal vesicles through Zuckerkandl's transverse perineal incision. Schede (*Deutsch Med. Wochenschrift*, Feb. 15, 1894) successfully removed a tubercular seminal vesicle and cord. He prefers the method of Rydygier, which consists of a lateral incision extending along the border of the sacrum to that of Dittel, which is the same as that which Schede employs for extirpation of the prostate, namely Zuckerkandl's transverse curved perineal incision.

Perhaps the most complete operation for tubercular vesiculitis has been performed by Fenger. (Personal communication.)

The patient was 22 years of age with a good family history. One year before his admission into the German Hospital he contracted gonorrhœa which persisted for six weeks. During the latter part of this disease he complained of rheumatic pains beginning in the left foot and passing from there to the hip on same side, and later to the left knee and right ankle. At first the joints were not swollen, but about a week later the knee-

joint began to swell and he was confined to his bed where he remained for two weeks. At the end of this time he recovered almost completely from the joint affection. In November, 1894, he noticed that the left testicle was swollen, the swelling increased slowly until in about four weeks it was as large as the fist of an adult. When the patient came under Fenger's care the left testicle was firmer and slightly larger than the right. The epididymis was hard and nodular and slightly tender to pressure. Digital examination of the rectum showed no enlargement of the prostate, but the left seminal vesicle was felt as a hard mass, not tender to pressure. Reducible right inguinal hernia. General health not impaired. Operation April 25, 1894, in two steps, first removal of testicle and accessible part of the cord, and second, extirpation of the seminal vesicle on the same side through Roux's incision. In removing the cord after previous isolation of the testicle, the incision was carried as far as the internal inguinal ring, where the vessels were tied and the cord teased out of its canal as far as possible before dividing it. The wound was packed with iodoform gauze and sutures introduced, but not tied until after the completion of the second step of the operation. During this part of the operation the patient was turned on his left side and the knees drawn up and rectum lightly packed with iodoform gauze. Roux's incision was then made on the left side of the rectum four inches in length. A sound was introduced into the bladder to serve as a guide in making the deep dissection. The seminal vesicle was located by the finger in the rectum as an olive-shaped body. Access to the vesicle was difficult owing to the small size and great depth of the wound. Bleeding was not as profuse as was expected and was easily controlled by the use of large hemostatic forceps. The seminal vesicle was found close to the bladder and was drawn downward with Museux's forceps. During the dissection the prostate and levator ani muscle were seen and recognized. The vesicle was not encapsulated, as was anticipated, and was accidentally opened and the contents of the tubercular abscess escaped. By careful dissection with Kocher's director and scissors the vesicle, with about  $1\frac{1}{2}$  inches of the vas deferens, was removed without injuring the bladder or opening the peritoneal cavity. The prostate gland was found slightly enlarged. In the left lobe a whitish spot was seen which was incised and proved to be a small tubercular abscess. The abscess cavity with a portion of the lobe of the gland was excised. The wound was sutured and drained at each angle with tubular and gauze drains. The first wound was then closed and drained in a similar manner. Duration of operation two and one-quarter hours. The wounds healed kindly and the patient remains in perfect health, more than a year after the operation.

This case appears to show more conclusively than any other on record that a timely operation for secondary tuberculosis of the seminal vesicle, following an ascending tuberculosis of the testicle, may succeed in preventing the extension of the disease to the bladder and other portions of the urinary tract, and may even result in a complete and permanent cure. If the surgeon intends to remove both seminal vesicles, there can be but little doubt that Zuckerkandl's incision is the safest and renders the diseased organs more accessible than any other. The operation is greatly facilitated by placing the patient in the ventral position with the pelvis elevated.

*Tuberculosis of the prostate.*—Sir Henry Thompson (*The Diseases of the Prostate*, their Pathology and Treatment, London, 1861, p. 283) is of the opinion that the prostate is never the seat of primary tuberculosis. He says: "It would appear that at no period of the disease is the prostate affected alone. Some other part of the genito-urinary tract is the preliminary seat of the affection. In most cases the deposit appears to take place first in the kidney, or, at all events, to be present there in an early stage. The organs next in order of liability to the disease, among the genito-urinary group, is the testicle. Thus in 18 cases collected by myself, in which the results of postmortem inspections have been recorded, tuberculosis of the kidney is reported in 13, and of the testicle in 7. The state of the lungs has, I suspect,

not always been recorded, but in 10 of these cases they are stated to have been diseased."

Marwedel (*Aus der Heidelberger Chirurgischen Klinik des Prof. Czerny. Ueber Prostatatuberculose, Klin. Beiträge*, Bd. ix, p. 537) has written a valuable monograph on tuberculosis of the prostate in which he describes four cases that occurred in Czerny's clinic, in two of which the disease appeared as a primary tuberculosis of this organ, and both were successfully treated by laying open and curetting the fistulous tract. In the other two cases temporary benefit resulted from incising the periprostatic abscess in front of the rectum and through the incision nearly the whole sequestered gland could be removed. In these cases the destructive process had extended to the urethra, a considerable portion of which was involved. Another fatal case was not subjected to operative treatment; it was complicated by pulmonary and testicular tuberculosis. These, as well as other cases of a similar nature that have been recorded, prove that the prostate may become the seat of primary tuberculosis. Tubercular disease of the prostate is as a rule met with in young adults. Out of 26 cases collected by Socin, 13 were less than 30 years of age. It can, however, occur in men advanced in years. In one of Socin's cases the patient was 72 years old, who was suffering from the consequences of an enlarged prostate, and several months later the symptoms revealed extension of the tubercular process from the prostate to the seminal vesicles, bladder and ureters, resulting in death after a long period of intense suffering. The primary nodules are situated first in the vicinity of the tubules (*Rindfleisch*), and not, as was formerly supposed, in their interior. By confluence and caseation of the miliary gray nodules large masses and cavities are formed which may be found in one or both lateral lobes, while the middle lobe is more rarely affected. The softening of the caseous material leads to the formation of tubercular abscesses which may rupture into the urethra. In a case observed by Adams the abscess ruptured at the same time externally in the perineum. Socin observed two cases which terminated in rupture into the bladder and in one case into the peritoneal cavity. The abscess may also discharge itself into the rectum. Much less frequent than softening is calcification of the tubercular mass with arrest of the disease. It is difficult to ascertain whether or not tuberculosis of the prostate appears as a primary affection. Besides the cases cited above Béraud and Pitha have observed cases in which this appears to have been the case. Postmortem examination, however, usually reveals additional tubercular affections in adjacent or distant organs. In cases of tubercular abscess of the prostate it is difficult to ascertain the exact chronologic order in the presence of additional tubercular lesions. Socin saw two cases of what appeared to be primary tuberculosis of the prostate. The patients were respectively 28 and 30 years of age, both of whom had contracted gonorrhoea before symptoms of prostatitis appeared. Examination revealed well-marked chronic prostatitis without additional tubercular complications. One of the patients died of an acute renal affection of only ten days' duration. The postmortem showed disseminated cheesy foci in both lateral lobes of the prostate, ulcerative nephritis and miliary tuberculosis of the peritoneum, the right pleura and liver. In the other case, months after the appearance of symptoms indicative of prostatitis and vesical catarrh,

hectic fever set in with symptoms pointing to renal disease which rapidly proved fatal. The prostate was found completely destroyed and its place occupied by a tubercular abscess which communicated with the urethra. The vesical mucous membrane was the seat of numerous small ulcers, and at a point corresponding with the orifice of the left ureter, a deep ulcer; the left kidney was greatly enlarged; in the pelvis large ulcers; in the substance of the kidney many small abscesses containing cheesy material. In two other cases the tubercular prostatitis occurred in phthisical patients. Socin is of the belief that in all these cases the prostatic disease was primary. Of 26 cases of tuberculosis of the prostate collected by Socin, of which 6 came under his own observation, the postmortem showed in 24 tubercular disease in other parts of the genito-urinary organs, and only in 2 cases tuberculosis of distant organs, the lungs and bones. Most frequently the bladder and kidneys were found implicated, less frequently one or both testicles. In one case in which the epididymis was unquestionably the primary seat of the tubercular process, the lobe of the prostate on the corresponding side was similarly affected.

*Symptoms.*—There are no symptoms which are, strictly speaking, characteristic of this affection of the prostate. Undue frequency and pain in passing urine, occasionally blood in the urine, and at times the signs of cystitis, are commonly experienced. Wasting and extreme debility slowly show themselves. The symptoms present many things in common with other forms of chronic prostatitis. Only in cases in which the disease is complicated by tuberculosis of other organs are observed hectic fever, rapid loss of strength, and marked emaciation. Adams has called attention to the similarity of the symptoms with those produced by stone in the bladder. Catheterization is always very painful and should not be unnecessarily resorted to. In one case Socin observed soon after it septic cystitis. Hematuria is often present, but of no particular diagnostic value. Incontinence of urine, which often appears during the advanced stage, indicates extension of the disease to the sphincter vesicæ muscles. Marwedel found tubercle bacilli in the urine in all the four cases reported from Czerny's clinic. In one case they were also detected in the urethral discharge.

*Treatment.*—Czerny obtained good results in two cases which had terminated in abscess by laying open the fistulous tract and vigorous use of the sharp spoon. In cases in which the disease has not advanced to abscess formation he advises Zuckerkandl's perineal incision for exposing and removing the caseous foci. Sir Henry Thompson advises conservative treatment, avoiding instrumentation which, he claims, provokes irritation and aggravates the disease without conferring upon the patient any benefit whatever.

Horteloup (*De la Tuberculose génitale. Gaz. méd. de Paris*, Nov. 25, 1892) recommends in the treatment of isolated tuberculosis in any part of the genital tract, with a view of preventing further extension of the disease, the injection of a few drops of Lannelongue's solution of chlorid of zinc. In two cases of tuberculosis of the prostate he made the injections through a boutonnière incision, but the communication was made too soon after the treatment was suspended to judge of its curative effects. During the early stage of primary prostatic tuberculosis parenchymatous injections of iodoform glycerin emulsion

would appear to be indicated and might possibly prove a valuable addition to the treatment of this obstinate and unpromising affection.

(To be continued.)

#### A NOTE ON STENOSIS OF THE CERVIX AS A FACTOR IN UTERINE DISEASE.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 6-8, 1896.

BY HENRY P. NEWMAN, A.M., M.D.

CHICAGO, ILL.

Twenty years ago, the subject of this paper was one of the topics of leading interest in gynecologic circles. The literature of the day abounded with learned and exhaustive treatises upon the pathology and treatment of the affection.

The reputations of many of our pioneer gynecologists were founded largely upon their successful methods of operating for stenosis and the instruments they invented to correct the condition, as to-day they often depend upon the technique of the major surgical procedures.

J. Marion Sims, Montrose A. Pallen, Sir Spencer Wells, Savage, Greenhalgh, Barnes, Graily Hewitt, Sir J. Y. Simpson, Peasely, Emmet, Routh and Aveling, all these names and many more are associated with the rise and progress of the phenomenal career of a disease which is scarcely noticed in modern literature.

For, notwithstanding the amount of literature that was formerly written upon this subject, the hundreds of operations recorded by older gynecologists, and the nicely adapted instruments that remain as evidences of the reality of stenosis of the uterine cervix, there are some modern authorities who go so far as to deny the very existence of this affection as an anatomic fact.

Between this absolute negation and the over-zealous devotion of years past there is a happy medium wherein we may assign this undeniably important condition to its rightful place as a causative factor<sup>1</sup> in much of the gynecic disease which abounds.

Stenosis of the cervix is anything but a rare affection.

The text-book classification names the congenital and acquired forms. We are getting to know, more and more, that nature makes few mistakes, and that the abnormal conditions to be found at birth are extremely rare. Malformations of the *internal* organs of the fetus are still more rare than the various orthopedic lesions of the exterior body.

Such cases as we have been in the habit of listing as congenital are for the most part merely the persistence of the normal natal condition, and should properly be called acquired.

This brings us in accord with the modern movement toward the development of preventive medicine. It may be said without fear of contradiction that whatever may be acquired can be prevented.

This puts a great responsibility upon specialists in all fields, and enlarges the scope and province of each until the dividing line is nearly lost. Particularly is this true of gynecology in its relation to pediatrics and to obstetrics, since, with the exception of the rare malformations, and diseases due to specific infections, and unusual traumatism, nearly all gynecologic diseases have their origin in the physical errors of child-

<sup>1</sup> *Clinical Gynecology*, Keating and Coe, page 201.

hood and puberty, and the accidents or mismanagement of the puerperium.

I have said that stenosis of the cervix is not rare. It is a narrowing of the caliber of the canal, and may be situated at the external os, the os internum, or may include the whole extent of the canal.

This condition is recognized as causing sterility and dysmenorrhea, by offering a mechanical obstruction to the entrance of the fecundating element, and by preventing the free discharge of the menstrual fluid. It is of its importance in this last respect that I wish particularly to speak, and to call attention more forcibly to our obligation to the science of prophylaxis.

Whether, as some hold, menstruation has been developed in the human female as a result of civilization, a periodic protest against the progressive evolution of the higher attributes of the race at the expense of the lower, or whether it is indeed a higher manifestation of a function associated with the reproductive system in almost all varieties of animals, it is generally allowed that any abnormal disturbance of this function is detrimental to the health of woman, and a fruitful cause of gynecologic disease; particularly does stenosis give rise not only to functional derangements and actual structural disease in local organs, but various neuroses, frequently of a most serious character.

Dr. Montrose A. Pallen, in a prize essay read before this ASSOCIATION in 1867, enunciated these propositions: "1. Menstruation irregular in its character is always coincident with uterine disease. 2. All uterine abnormalities tend to a deformity of the organ, either in its neck or in its body, or both."

Ten years afterward the same writer gave to the New York County Medical Society a résumé of the subject, in which he states: "These propositions are correct in the main, without being absolutely and invariably true, particularly with regard to the first, as irregular menstruation may depend upon systemic causes, wherein the uterine disease is but functional and symptomatic.

"However, so correct is the principle that we may accept it without cavil, when we remember that the healthy functioning of any organism necessitates a healthy condition for its performances.

"No unhealthy cause can produce healthy effects; therefore from a uterus abnormal can no healthy menstrual flux proceed."

The pathology of Pallen and Schroeder is nearly thirty years old, but it is still so acceptable that I quote it here:

"The uterus undergoes involution every month during menstrual life, and if this process be retarded in consequence of congenital defect of development, or from pathologic accident, the woman's condition is in no wise ameliorated, unless pregnancy should supervene or art interfere.

"After a longer or shorter period of monthly agonies, the tissues of the cervix become indurated, frequently atrophied, the recently formed connective tissue becomes cicatricially retracted, the vessels become imperforate and the young mucoid connective tissue becomes firm and infiltrated.

"The uterus again diminishes in size, and on section exhibits an exceedingly firm, almost cartilaginous tissue, which creaks under the knife and has an anemic, cicatricial appearance. Whenever this condition exists, either in the intra-vaginal cervix or at the

internal os, we may expect to find stenosis of the canal with a very small os externum."

A cervix, therefore, presenting these peculiarities, must exert a very injurious influence on a woman's health in so far as it depends upon the regular and normal performance of the menstrual function.

In a uterus which seems to have a fairly free outlet at the cervix, the hyperemia which accompanies the monthly molimen may bring the walls of the cervix so closely into apposition that the flow is materially retarded and the secretions more or less retained.

Retention of the secretions gives rise to an elaborate sequence of gynecologic evils, chief of which are endometritis, metritis, salpingitis, oöphoritis, etc.

When we observe the sufferer from chronic endometritis with her long train of general and special ills; her dyspepsia, neuralgia in different localities, headache, backache, anemia, her many nervous symptoms and her very natural mental depression, we can not but be convinced of the grave importance of all causative factors which can be traced in the etiology of her trouble.

In the milder types we know what these conditions mean, either a prolonged course of routine and palliative treatment, or the more radical surgical procedures.

In the graver degrees where there has been extension to the tubes or ovaries, oöphorectomy, ovariectomy or hysterectomy may become necessary, to remove the local effects of disease, but not always with hope of the reestablishment of normal health in a constitution injured and disturbed by long presence of diseased conditions.

In other branches of medicine rapid strides have been made of late in the theories of the causation of disease.

Ophthalmology, for instance, has invaded the schools and with the help of public sanitation has insisted upon the better lighting of study rooms and public buildings.

The public are now looking to the medical profession with awakened interest as the conservator of the nation's health, and are offering cordial encouragement to the progressive effort for better conditions of physical life.

In our large universities there are already great and liberally endowed departments for the study of physical and sanitary problems, and the educational departments are no longer content with the old system of cramming the head with a conglomerate assortment of samples of many kinds of knowledge.

Instead, there is instituted the study of psychometry and psychology, with physics and the education of the child practically begins back in the embryonic period. Shall gynecologists be looked upon as a class who exist merely to batten on the ills of womankind, and who find their excuse for being, in the evils resulting from ignorance of the laws governing the hygiene and development of the female generative organs?

The place of rightful occupation for this specialty of ours is the highest we can hope to attain, and no higher could be desired, as custodians of woman's health and the leaders in the advance movement for improving all social and educational conditions which are mainly operative in the production of disease. To accomplish the needful reforms in this direction we must insist upon the better hygiene of puberty. In this I am convinced we would have generous public

recognition and coöperation. There is among the higher educational circles already a tendency to demand for girls the same physical advantages that are in vogue in our boys' colleges. But the higher private institutions can reach but the outer edge of this universal necessity. In our public schools and workshops the girls of 12 to 16 years of age are still plodding many times a day up and down long flights of stairs, sustaining the working hours of the day with food into which little real nutritive value enters.

They are still housed up in over-crowded, ill-ventilated apartments, when they should be breathing free draughts of vitalizing air and exercising their growing muscles in unobstructed sunshine.

I have said that at this period nature is supremely concerned with the development of the generative organs.

In the rapid transition from childhood to maturity the activities here generated demand full general nutrition and conservation of the entire physical constitution.

But at this period the growing woman is pushed to her utmost to support the intellectual and emotional faculties.

The rich current of the young circulation is turned into the channels opened by music, science and art, and being insufficient for these, the physical organs must suffer positively or relatively.

It is at this age, too, that the feminine organism begins to come under the dominance of the destructive power of custom in conventional dress and manners.

The first corset is put on and the growing body thereby constricted and deprived of the necessary freedom of respiration and circulation.

Is it any wonder that the process of pelvic development is often summarily interfered with and the infantile uterus with its small body and long conical cervix which should have changed entirely in contour and dimensions, remains as it was, with elongated, constricted canal and partially developed tissues inadequate to perform the functions so soon to be demanded of it?

In the radical changing of these conditions lies the rational basis of the treatment of cervical stenosis. This is a most striking instance of the importance of preventive treatment, and I appeal to my colleagues to use the same diligence to bring about a better environment for the developmental period of puberty as you have done in eradicating the causes of the once dreaded puerperal infections; the same zeal you have shown in establishing upon its present high plane the greatest prophylactic factor in modern surgery, cleanliness, and as our colleagues in general medicines are showing in their struggle for the prevention of all contagious and other diseases which arise from the wide-spread ignorance and neglect of nature's laws.

34 Washington Street.

#### DISCUSSION.

DR. WM. A. B. SELLMAN, Baltimore—At the last meeting of this ASSOCIATION I discussed this subject, and the relation which it bears to other pelvic diseases. I thought at that time that diseases of the cervical canal between the external and internal os were very often the cause of most serious trouble. We find many young women suffering from painful menstruation due to retained menstrual fluid. If we do not recognize painful menstruation as due to mechanical obstruction it is impossible to relieve it. At the last meeting I spoke of a means of curetting these cases, and I said that dilatation was

of little or no avail, because the tissues would contract again, so that the good accomplished by dilatation is overcome by the involution which takes place after the next menstruation. My idea in these cases is to remove a portion of the tissue. The tissue is undeveloped on account of various causes, due to bad nutrition and bad habits during girlhood. The question is how to remove the diseased membrane which brings about the various conditions. It is not normal mucous membrane; it is converted into denser fibrous tissue, and my method is to remove it, not by dilatation, but to ream it out by the reamers which I showed at the meeting last year, and my results have shown that the dysmenorrhea is overcome. Girls who have suffered month after month have been relieved after the second or third month. The canal is sensitive after the removal of this tissue, but after the second or third month perfect relief is secured, provided a reamer large enough has been used.

DR. I. S. STONE, Washington, D. C.—I think there are many cases of dysmenorrhea that are not relieved or cured by dilatation. For instance, a young girl, 19 years of age, in which dilatation was carried to such an extent that I could introduce my index finger and it would pass through the internal os. She has no apparent ovarian disease, yet suffers very much every month. I fail to see why Dr. Sellman's instrument is any better than a curette in skillful hands. With a sharp curette we can remove the same amount of tissue, whether we do it in the same manner or not.

DR. RUFUS B. HALL, Cincinnati—I think the most essential and difficult point to determine is the selection of cases in which we expect to afford relief either by dilatation of the cervix or by the operation proposed by Dr. Sellman. If we expect to cure dysmenorrhea by dilatation of the cervix or reaming it, as he terms it, by making the cervical canal larger in all cases, I think we will be disappointed in our results. It is not always possible to say that in a given case there is not local trouble above the cervix as a cause of the dysmenorrhea, and the narrow cervix of the patient may only play a minor part in the causation of her suffering, and it is not always possible to say that the cervix has nothing to do with the patient's suffering. We must go back and find out where the real trouble is. It may lie in non-development of the parts. I can see where we might, by curetting away sufficient cervical tissue to leave a large opening, bring about a still worse condition than we would have following dilatation of the cervix or the reaming-out process by the formation of cicatricial tissue. Therefore, in either operation, dilatation or the reaming-out process, or stretching the cervix, can we expect to relieve all of these cases? I do not think it is possible to differentiate every case before we operate, that is, to exclude trouble above the cervix, or a neurotic condition which has been the cause of the patient's suffering.

DR. NEWMAN (closing)—There is little more to be said. Heretofore the treatment of stenosis of the cervical canal has been considered by gynecologists as unsatisfactory. It is true that we accomplish a great deal by operative procedures and by instruments judiciously employed, but the condition returns unless auxiliary treatment is instituted. The object of the paper was to get behind the local treatment and remedy the evil before it began. This is the first responsibility of the profession.

The little instrument that I have passed around is designed for the class of cases we have with us, and presumably will have, in spite of any precautions, for all time. It has a purpose, but it is not intended by any means to supplant other treatments that are now in vogue.

## HOW TO REMOVE PUS TUBES WITHOUT RUPTURE.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-6, 1896.

BY I. S. STONE, M.D.

WASHINGTON, D. C.

The contents of pus tubes may not be infectious, but it is desirable to avoid the usual soiling of peritoneal and wound surfaces with any kind of pus. It is, therefore, in the opinion of the writer, better to make a longer incision, to tie the ovarian and ovaro-uterine arteries and free the specimen at one or both ends or sides before attempting enucleation.

The method about to be described can be used in any case; the simple ones are always easy work, but it is in the difficult cases, where there are many adhesions and a large quantity of pus present, that the writer has found the greatest satisfaction in adopting the following plan:

### METHOD.

Clamps are placed upon one of the tubes, closely hugging the uterus. The clamp may embrace about one inch of the broad ligament in its bite. The ovarian artery is either tied or clamped as near the pelvic wall as possible. A ligature may be placed on each severed end or placed before section if preferred, the incision to be made between these points. No bleeding of importance can occur after this, while the surgeon can leisurely enucleate the tube or ovary with contents safely, and with infinitely greater ease than after the ordinary fashion. In many instances the appendages can not be as readily rolled out from behind as from the front, and the separation from the broad ligament is often easier than from the bowel if strongly adherent. But the most important assistance given the operator by this method is the great amount of space afforded. There is plenty of room to work, as the tube comes right up when separated from the uterus. Quite naturally many pus sacs rupture easily, and this method will not prevent soiling the peritoneum in every instance, but that it will do so in most instances I know from frequent observation. Finally, a very serious defect in the technique of many operations is found in the large and infectious stump of the tube left after removal of the adnexa. Here an exsection of the cornua is demanded and is provided for in the beginning of the operation. The ovaro-uterine artery is ligated, the forceps removed and another deeper ligature used if much bleeding occurs. Then the exsection and suturing of the cornua is rapidly and easily done. The same technique is used on the remaining side and needs no further demonstration. The operation is easier in the Trendelenburg posture with a good light. I have used no flushing or drainage in any case of this kind for the past five months, and have had no sepsis in the wound or rise of temperature, or peritonitis or other trouble consequent upon this technique. In some cases rupture will occur in spite of the greatest care, but if a sponge is properly placed all the pus can be caught and flushing and drainage avoided.

### SUMMARY.

This method gives more space for careful enucleation. The larger blood supply is tied off at once. Smaller silk or catgut can be used as no *en masse* ligatures are used. The ligatures and sutures are

not infected. No sinus will be formed. There can be no possible danger of hemorrhage after operation. No ligatures can slip. If rupture is avoided there is no need of flushing or drainage save in very rare instances, when time can not be given to careful suturing, which must be the rare exception. It facilitates enucleation by affording another point of cleavage, namely, from the anterior surface of the pus sac. Finally, it facilitates exsection of the uterine cornua.

The sketch gives a good idea of the steps of the operation and the appearance of the uterus and broad ligament after operation. The uterus can be removed in addition to the adnexa if the surgeon so desires. The specimen here exhibited was removed on the 20th ultimo. It is very large and came from the left side. The right tube was small and a small amount of pus escaped before I knew I had a pyosalpinx to deal with. The patient recovered without trouble of any kind.

### DISCUSSION.

DR. JOHN M. DUFF, Pittsburg—I feel that with our modern experience in dealing with pus tubes, especially where the infection is of gonorrhoeal origin, that the patient would have been in less danger of infection and the subsequent history of the case would in all probability have been much better if these pus tubes had been removed through the vagina.

DR. CHARLES P. NOBLE, Philadelphia—I think all who are operating on pus tubes after the method of Tait, and who have adopted this method or one similar to it, can appreciate the great advantage which both the patient and operator have in such a method. I have been operating very much in this way for a year and a half and have been able to remove the great majority of pus tubes without rupturing. The method I have used is the same in principle. I agree with the author of the paper as to the facilities with which we can remove pus tubes in the majority of cases by this method without rupture. The author of the paper said nothing about special precautions except using a sponge in case the pus tube be ruptured. My own practice is to pack off the peritoneal cavity with folds of gauze, also to have some dry gauze packed behind the pus tube, so that should it rupture we will be in a position to get any pus that should be discharged. It is seldom necessary to rupture pus tubes unless they are down in Douglas' pouch. There are cases in which this technique is not feasible. We would necessarily rupture a certain percentage of them. Frequently I find it not only necessary to take out the pus tubes but the uterus as well. It has been said that leaving the uterus behind causes the patient no special difficulty. My own experience has been different from that of many writers on this point. By ligating the uterine arteries as well as the ovarian, we can do without drainage, when otherwise we would have to employ it.

DR. L. S. McMURTRY, Louisville—I call the attention of the Section to one point in connection with the class of cases under discussion, which I am sure all familiar with them will recognize as the most difficult that are encountered in operations—cases of suppurative salpingitis and complications that result are certainly most difficult of all cases in pelvic surgery for operation; and they present, at the same time, the very greatest variety of almost any class of cases we have to deal with in an operative way. The number of cases of suppurative salpingitis must be comparatively limited where the method that Dr. Stone has described and practiced so successfully can be applied. It is very common for these adhesions to be so firm that you can almost lift a patient off the table by them. It is also common for adhesions to the bowel, to the uterus, to the floor of the pelvis to be very strong, and these refinements of operative technique just described are difficult of application. If we endeavor to apply Dr. Stone's method generally

we will meet with many disappointments. I am sure that any technique which contemplates dealing with large accumulations of pus in the pelvis, with the degenerations and cheesy deposits to take place, and dispense with irrigation and drainage will be followed by a large number of disasters. Furthermore, the very character of the tissues themselves that are rotten from disease, in a large proportion of cases, forbids such a nice dissection as has been described.

DR. E. E. MONTGOMERY, Philadelphia—This is a class of cases that render pelvic operations much more difficult than any with which we have to deal, but in dealing with such cases I should much prefer to remove the pus tubes through the vagina rather than by the abdominal method. We have in these cases large collections of pus, where the tube from its weight gravitates into and fills up the pelvis, is shut off more or less from the general peritoneal cavity, and can be entered and reached through the vagina prior to the operation for the removal of the mass itself. Having in this way thoroughly evacuated and irrigated the cavity, we have then to deal with the tubes, shell out the sac and the uterus itself. The reason why I prefer to go through the vagina in the treatment of these cases is that we are not only able to remove the tubes and ovaries but also the uterus. After removal of both ovaries the uterus is no longer an organ of any special advantage to the individual. More than this, the trouble has originated in the uterus, and from it the disease has extended to the tubes and ovaries, and the increased connective tissue results subsequently in a decrease in size of the organ, with more or less contraction of the nerves in the uterine walls. Patients frequently, after successful removal of the ovaries and tubes, suffer for months and perhaps years. The uterus then should be removed along with the ovaries and tubes in these cases.

DR. R. S. SURTON, Pittsburg—There is no doubt but that the method which Dr. Stone has illustrated here is an improvement over the method of Tait in getting under the pus tube and shelling it out, when prolapsed and adherent, but does it follow that the pus contained in these tubes is very frequently infectious pus. Any gentleman who has endeavored to find the gonococcus in pus following gonorrheal infection will remember how often he has failed. He will often fail to find either the staphylococcus or the streptococcus. He may find, as Etheridge has done, the pneumococcus occasionally, or the bacillus coli communis. I endeavor, when I am operating in a case of pus in the pelvis, to have a bacteriologist in the operating room, give him a little of the material removed, wait a moment or two and then he tells me whether there are any pus producers found. If there are no pus producers I shut the cavity up. If there are pus producers in the cavity and you do not insert a drainage tube, you will lose your patient. The man who does the operation by the vaginal method under these circumstances will not lose his patient.

Dr. Noble tells us that he takes out the uterus in these cases, but tells me that he leaves the cervix in. That is not taking out the uterus. It is amputating the uterus at the supra-vaginal junction, and amputation of the uterus at the supra-vaginal junction and total extirpation of the uterus are two different things, mechanically and pathologically.

DR. J. W. BOVEE, Washington, D. C.—I have found in some of these cases that there is a great deal of exudate around the outer end of the pus tube or around the ovarian artery, and sometimes there is danger in ligating the outer end of this mass in the womb first. I operated in this way recently and after I had ligated the stump containing the ovarian artery and had cut it off, grasping the other end with the forceps, I found I had cut off the ureter. It was in the stump. In separating the adhesions the ureter had been lifted up. I had nothing left to do but to take off the ligature, extirpate beyond the ureter and do an end-to-end anastomosis.

DR. HOWARD A. KELLY, Baltimore—My plan in the removal of pus tubes is, in all of those cases where there is a pus sac, to aspirate and empty it as much as possible; then free the tube and surround it with gauze packing made of many thicknesses to prevent further contamination during the handling. In the rest of the enucleation I take out the tube. If the other side is diseased I take out the other, with it by supra-vaginal amputation. But I rarely do that. The importance of this matter hinges on the bacterial contents of the tube, and while in all cases we ought to be very careful, the dangers of contamination are slight. Two years ago, in January, without knowing similar work was being done on the other side of the water, I had a microscopist in my operating room to examine under the microscope any pus which appeared to contaminate the peritoneum in any way. If no microorganisms were found, no drainage. If the gonococcus was found, no drainage. If found abundant, probably staphylococci or streptococci, drainage in all cases.

DR. A. VANDER VEER, Albany—I do not intend to discuss this excellent paper, but I feel like asking Dr. Stone if he has examined the contents of this tube. (Tube on exhibition in Section.)

DR. STONE—I have not.

DR. VANDER VEER—Are you absolutely sure it contains pus?

DR. STONE—I am. I know it does.

DR. VANDER VEER—It looks to me like a hydrosalpinx. In operating for pus within the pelvis, I have no reason to deviate much from the method of operating in these cases, as I do nearly the same operation that I did years ago. We must remember that this is one of the simplest forms of pus tubes we have to deal with. The adhesions are not so strong but that you can loosen the tube. If one could have a bacteriologist present to tell him the kind of microorganisms that are found it would help matters very materially. But these cases do not have much bearing upon the serious cases of pus tubes that have gone on for two or three years and in which you have extensive adhesions to the intestines, to the rectum, and a long-standing condition of perhaps recurrent pelvic peritonitis. When you attack these cases you have something far more serious to deal with. This operation must be limited to few cases. There are not very many cases in which the doctor will be able to turn out so neatly such a beautiful specimen as he has presented here.

DR. RUFUS B. HALL, Cincinnati—This technique can be carried out only in exceptional cases. We can remove large pus tubes easier than smaller ones which are imbedded in adhesions in the cul-de-sac. We all know the great danger of secondary hemorrhage after these operations, particularly in desperate cases of suppuration. Several years ago I had to reopen the abdomen of a patient on account of hemorrhage coming on. She had been vomiting for some ten or twelve hours after operation. The case was one of large pus tubes and the pedicle was half cut off. In all of those cases where the tissues are soft, instead of transfixing the pedicle I place a ligature on the outer side of the tube and ovary, including the artery from the pelvic side, then another separate ligature beside the uterus, then I feel sure that the possibility of secondary hemorrhage, from slipping of the ligature, or cutting of the pedicle from tension on it will be obviated.

DR. STONE—When I first began to operate on these cases my technique was not as good as it is now. I do not drain as much as I formerly did. If we can dispense with drainage in these cases it is very desirable.

In reference to the remarks made by Dr. Kelly, I will say that if I can remove a vicious, malignant abscess without soiling the peritoneum, I do not care whether a bacteriologic examination is made of its contents or not. If we have an infected pus tube, I think it is difficult to enucleate all of the so-called infectious germs or germs of any kind. There is more or less shock following irrigation and handling of the intestines which is necessary in every case. I believe I am correct in saying that all pus cases are not infectious.

## THE PRESENT STATUS OF ECTOPIC PREGNANCY—A SURGICAL DISEASE.

Read in the Section on Obstetrics and Diseases of Women, etc., at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY WILLIS G. MACDONALD, M.D.

ALBANY, N. Y.

The surgery of ectopic pregnancy is mature rather than old. It is little more than thirteen years ago that Mr. Lawson Tait first deliberately performed an abdominal section to rescue a woman dying from a ruptured ectopic pregnancy. The influence of this triumph in surgery is immeasurable. The number of lives saved is innumerable. The literature of the subject in text book, transaction, monograph and journal is stupendous. Methods of operation have been so far perfected that further progress in that direction is not likely to occur. However, women are yet dying the world over without any effort being made for their relief, or even the condition being recognized during life.

In view of the great interest taken in ectopic pregnancy these deaths should, for the most part, be avoided. Investigation will show that much of the literature is controversial in character. The disputed pathology and methods of treatment in ectopic pregnancy have already employed too much type to the detriment of sound diagnosis. While fine anatomic and pathologic distinctions are abstractly valuable in abdominal surgery, yet they do not always possess life-saving qualities. The minds of those who have studied carefully at the operating table and in the laboratory the intra-abdominal conditions found are often harassed by serious doubts. The demonstration of beautifully made, frozen sections do not always convey to every mind correct impressions. It is a sad commentary to have a man argue the probability of ovarian pregnancy with you while his patient is bleeding to death in the next room. He has lost the nucleus of the thing; it is the bleeding, not the possibilities, that demands action.

After all that has been said and written, I am inclined to the belief that, stripped of their controversial portions, the lectures of Mr. Lawson Tait, published in 1888, present about all there is concerning the matter. Mr. Tait was direct in his language; his pathology was simple; his operative technique was at once rational and successful. Further progress lies along the lines of simplicity in pathology, clearness in diagnosis, and definiteness in treatment. The general practitioner must be made to do this part, but first he must be taught the clinical history and diagnosis. Discussions of primary abdominal ectopic pregnancy, the living placenta, or electricity, are of no value when measured by diagnosis. It is upon these points that it is my purpose to dwell.

How much of fully demonstrated pathology is really useful in diagnosis and subsequent treatment of ectopic pregnancy? That all ectopic pregnancies are primarily tubal is demonstrable with so few exceptions that they need not be considered in the subsequent management of the condition. They remain tubal until rupture or abortion occurs. Tubal abortion, or the expulsion of the developing ovum from the fimbriated extremity of the tube into the abdomen may occur at any time between the second and eighth week of gestation. It is neither a complete discharge into the abdomen or incomplete, being arrested in the fimbriated extremity, and gives rise to the so-called

tubo-ovarian, or tubo-abdominal pregnancies. Rupture at the site of primary attachment is, however, the more common mode of tubal delivery, occurring at any time between the second and sixteenth week. Rupture is coincident with the period of greatest possible distention of the Fallopian tube. If the ovum develops in the uterine end of the tube and uterine tissue is involved in the walls of the gestation sac, the pregnancy is said to be interstitial; if in the middle portion, infundibular; if in the fimbriated extremity, ampullar. With rupture the ovum is, either wholly or partially, discharged into the broad ligament or the peritoneal cavity, and its life usually destroyed by the accompanying hemorrhage. Where the intra-peritoneal delivery is incomplete or it occurs between the folds of the broad ligament, gestation sometimes continues until secondary rupture and renewed hemorrhage or term is reached. Hemorrhage into the membranes of the ovum may occur while it is yet within the Fallopian tube, and lead to fetal death and the development of a tubal mole. Bleeding more frequently destroys the fetus than the mother, in the first four months of gestation.

The contention that all ectopic pregnancies continuing until viability are developed between the folds of the broad ligament, is not borne out by conditions found on the operating table or in the laboratory. Repeated hemorrhage without secondary rupture of the gestation sac may destroy a broad ligament pregnancy at any period of gestation. Suppuration within the sac may lead to the discharge of the fetal bones and other detritus into adjacent cavities, or through the abdominal walls. Another termination is the formation of lithopedion and adipose. The child dies during or at the conclusion of spurious labor. The death of the placenta is not always coincident with that of the fetus. There are a number of cases illustrating this fact, one of which in my personal observation will be reported in connection with this paper.

The children who have been delivered living from ectopic gestation sacs, have many of them shown little post-natal vitality, fully half dying in the early days, and very few living beyond a year. Again, many of them show gross deformities, hemiplegia, spina bifida, cleft palate, hare-lip, contractions of the limbs and club-foot.

The uterus always undergoes sympathetic enlargement, and from its mucous membrane develops a decidua, corresponding very closely to that of early uterine pregnancy.

From a careful analysis of my own cases, and the experience of others, I believe that the foregoing pathologic statements are all that are fully demonstrated, and further, they are all that are needed for the proper understanding of the diagnosis and treatment of the condition.

### DIAGNOSIS.

The importance of diagnosis can not be overestimated in ectopic gestation, yet its difficulties are at once serious, if not at times insurmountable. The history of ectopic gestation is largely that of operations undertaken after rupture and hemorrhage, or after viability. Those operations done before rupture were often a matter of accident, or the patients were in unusually favorable circumstances. That most cases of ectopic pregnancy are first seen by the general practitioner, will not be disputed. Here is the

point: The general practitioner is bound to possess a knowledge of the natural history and diagnosis of this disease that will keep in his mind the possibility in every woman, married or single, during her child-bearing period of this condition. Suspicion, with competent consultation, is the best substitute for precise diagnosis with which I am familiar. The profession at large have suspicions of appendicitis under proper conditions, and if under other circumstances their suspicions of ectopic pregnancy can be aroused and skilled assistance called, then will a considerable advance have been made. The reason is obvious. In appendicitis, a clear, unmistakable and unequivocal statement of facts have been so briefly and repeatedly made, that all are familiar with and governed by them. All the statements are not absolutely or entirely true. There are exceptions to many of them, but they are sufficiently general in their application to form a universal basis for opinion and action. What is wanted is a similar primer of ectopic pregnancy. On reflection, it will be seen that the difficulties attending such a plan are many. There are general considerations which apply to the condition. That all women suffering from ectopic pregnancy have previously suffered from some disorders of the organs of generation is a fallacy. In three of seven cases reported at the conclusion of this paper, there was no history of prior generative disorders. One with a baby, the youngest of five children; another with a good previous history a few months married, and still another the mother of three young children. The other cases present a variety of conditions, sterility, displacement and inflammatory disease.

In order to discuss the diagnosis intelligently, subdivisions must be made. Clinically the most natural ones are: 1. Before rupture or tubal abortion. 2. After rupture has occurred. 3. The fetus *a*, living and viable, or *b*, dead.

The difficulties of diagnosis before rupture or tubal abortion are very great, and its possibility will not be admitted by all. The greater number of cases are not seen by a physician until rupture or abortion occurs. A minority come to the operating table for inflammatory disease of the appendages. There is a lack of symptoms pointing to the condition. The patient either believes herself normally pregnant, or has no suspicion of it. Nausea and vomiting may be present, with amenorrhea and mammary changes. The metrorrhagia of ectopic pregnancy does not occur, in the majority of cases, until after rupture or symptoms of impending rupture present. The one particular point upon which diagnosis depends may be stated as follows: Any woman who during her child-bearing period presents symptoms of disease of the organs of generation, of recent origin, either new or entirely different from those heretofore experienced, if associated with any of the probable early symptoms of pregnancy, demands at once a careful examination. If this point can be made sufficiently clear, many more cases will be operated on before rupture occurs.

When rupture or tubal abortion occurs other symptoms arise which at once brings the physician to the bedside. There that general rule, "Pain in the abdomen calls for careful investigation," always applies. The clinical history is of exceeding value in making clear this point. The pain associated with rupture or abortion can only be mistaken for appendicitis, biliary or renal colic, acute intestinal obstruction, or uterine abortion. With a full clinical history and a

careful physical examination, the diagnosis will be positive. Very few errors have been made and the abdomen opened to find another condition present. Few exploratory incisions are made in ectopic pregnancy.

Too great dependence can not be placed upon the expulsion from the uterus of decidual membranes. In a recently reported case where the diagnosis was chiefly based on that fact, no ectopic pregnancy was found at the operation. Membranous dysmenorrhea is associated with the expulsion of similar uterine casts. It is valuable rather than pathognomonic. Collapse is always an important symptom, and its source is to be carefully studied whether it arises from simple pain or pain associated with hemorrhage. It is not to be forgotten that many intra-abdominal conditions may give rise to collapse. Pain as a source of collapse is not always easily differentiated from bleeding or extravasation, with pain. In collapse from pain or fright, the administration of anodynes and the application of local heat is followed by reaction. The collapse from progressive bleeding is continuous, with little disposition to reaction.

After primary rupture, the fetus yet living, if the woman does not die or the fetus is not destroyed by the hemorrhage, gestation proceeds until the viability of the child becomes a contingency, or secondary rupture occurs. Very few of this minority ever reach term.

Defective clinical histories may make diagnosis very difficult. The bi-cornate uterus, uterine fibroids, may make the diagnosis difficult or impossible, and exploration of the cavity of the uterus unwarrantable. Under such conditions the patient ought to be under the most favorable auspices and in bed.

A sufficient number of cases of current intra- and extra-uterine pregnancy have occurred to keep its possibility in the mind of the surgeon. The pregnancies may date from entirely different periods. The most serious form of ectopic pregnancy is undoubtedly the interstitial. Unfortunately it gives rise to fewer direct symptoms than any other variety, yet when the rupture does occur the attack is explosive. The woman quickly bleeds to death within her abdomen. Four hours of inaction is quite sufficient.

#### TREATMENT.

What are the indications for treatment in ectopic pregnancy? The question may be conclusively answered by the phrase—a diagnosis. There are exceptions, but they are for the personal opinion of the experienced surgeon. What is the treatment? This also can be answered briefly in the interest of the patient—operative. Competent operators are so numerous and so successful in every part of this land that no excuse can be offered for non-surgical interference. When shall we operate? As soon as a diagnosis is made. Time forbids entering into the discussion of injections into the gestation sac to induce the death of the fetus, or the application of electricity in the treatment of ectopic pregnancy. These plans have been so repeatedly discussed and so universally condemned that nothing is to be gained by further consideration. If there be an advocate (there are a few yet living) of the use of electricity present, I can not hope to convince him, and admonition does no good.

It is quite superfluous to enter into the detail of operations to be undertaken at any period of ectopic-

pregnancy, but certain subjects inevitably confront us: The position that vaginal celiotomy will assume in the treatment of ectopic pregnancy, the control of hemorrhage during operations undertaken at all periods, the time of operation, the child living and viable, the management of the placenta in operations undertaken after the sixth month, the management of cases where operations are to be undertaken for the removal of the dead fetus, either disintegrating or degenerating, the management of the general condition of the patient at the time of the operation.

The patient's general conditions and surroundings will influence the time and place of operation. Where rupture and progressive hemorrhage are not coincident, operation is to be undertaken deliberately under the best hygienic conditions. Progressive hemorrhage into the free peritoneum is emergency surgery, and operation must be done without delay. An operation can be well under way an hour after the diagnosis is made. In many cities there is an ambulance service. You call it from the nearest telephone and at the same time order the sterilizers lighted, and other preliminary preparations made. The patient is wrapped in blankets and is taken from the ambulance directly to the table. During early anesthesia the abdomen is prepared for incision. The direct or intermediate transfusion of normal salt solution is a valuable measure in collapse, far more than the hypodermic administration of stimulants, and can be employed at any period by very simple apparatus. The experience of many operators has repeatedly shown the life-saving properties of saline transfusion.

The control of hemorrhage is the first indication in most operations undertaken in the early months of ectopic pregnancy. The first efforts of the surgeon are directed to that end, and with all the speed compatible with good surgery. First determine the side of the ruptured tube, and place a clamp on the broad ligament close to the uterus. When the pregnancy is interstitial, clamp both broad ligaments. These measures will control the bleeding at any period of gestation. The subsequent steps of the operation can be undertaken with greater deliberation. Usually they are simple enough, enucleation or suture of the gestation sac into the lower angle of the wound, the removal of the damaged appendage. In interstitial pregnancy, complete or supra-vaginal hysterectomy, or the resection of the horn of the uterus will be required. The choice of method will depend upon the experience of the surgeon and the condition of the patient. Hemorrhage during the later months of ectopic pregnancy from the site of living placenta, the fetus often dead and macerated, is most difficult in management.

Out of a large number of cases delivered at or about term the most serious difficulty experienced was in relation to the placenta. Two plans have been suggested: its removal with multiple ligature, and tying the cord close to the placenta, closing the abdomen in the hope that subsequent abortion will take place. Both methods have succeeded and failed. A third plan has suggested itself to me: first preliminary ligature of the ovarian and uterine artery on the side from which the placenta receives its blood supply, second the placing of Mickulicz tampon of sterile gauze over the placenta establishing pressure atrophy; third, preliminary suture of the abdominal walls, the sutures to be tied after the removal of the tampon and placenta. Such a tampon may be safely left for three days, and then

removed with the placenta, and the sutures tied. I want to add that in two cases where the fetus had died, become macerated and disintegrated, that operations undertaken through the rectum were followed by fatal hemorrhage from a yet living placenta. Both of these cases should have been attacked by abdominal section.

The child living and viable, what shall be done? A considerable number of mothers have been already sacrificed while waiting for term to arrive. A surgeon recently described as a triumph in surgery, the saving of a child suffering from pressure hemiplegia and spina bifida. Another civilization of another and less human age conducted such to the unknown early in their careers. To-day the number of children a year old and undeformed, who had their origin in an ectopic gestation sac, can be counted on the fingers of one hand. The living child is subsidiary to the living mother.

Vaginal operations undertaken for the relief of ectopic pregnancy will always be limited, yet early cases may often be remedied by this method. Where suppuration in broad ligament pregnancies has occurred, there can be no doubt of the value of this method in many cases, an abscess, incision and drainage through the vagina.

There remains yet another topic in relation to the treatment of this condition, that of the opposite ovary. No question can arise where gross pathologic changes have already occurred. It is worthy of our attention that subsequent ectopic pregnancies have occurred in appendages left at operations. The other ovary and tube should be carefully examined and removed if any evidences of disease are found to warrant the procedure. The question is placed largely on the same basis as unilateral removal of the appendages for inflammatory conditions.

In conclusion, the histories of seven cases of ectopic pregnancy are given with the results of treatment, five recovered and two died. One death to be attributed to an improper operation advised by me, the other (case 1) to carelessness or want of knowledge upon the part of the gentlemen who were in attendance during the earlier period of gestation. I believe that the clinical histories given, together with the results of the physical examination, lead to an irresistible diagnosis of the condition.

*Case 1.*—Mary R., aged 38, married, native, was seen August 16, 1894. This patient was seen only a few hours before death. Between the second and third month of a supposed normal pregnancy, she had a severe attack of abdominal pain with fainting and uterine hemorrhage. The pain was confined principally to the left side of the abdomen. An abortion was supposed to have occurred at this time. She recovered from this illness after two weeks, and was able to attend to household duties. A month subsequently a second illness, supposed threatened abortion, occurred. There was at this time a sharp attack of peritonitis. Another physician in attendance discovered an abdominal tumor thought to be ovarian in character. She again improved and was able to be about. At the sixth month she "felt life" and was satisfied that she was pregnant. All uterine hemorrhage had ceased.

The onset of labor was delayed until about the three hundredth day of gestation. She was under the care of a midwife for two days, during which time labor pains were severe, but no progress was made toward delivery. Dr. Brierly was called, and he was soon able to determine that some serious abnormal condition was present. He called Dr. Andrew MacFarlane to his assistance, and they dilated the cervix, and determined that the uterus was empty. A diagnosis of extra-uterine pregnancy was now established. Dr. J. P. Boyd saw the case, and an hour later we met in consultation. An active general peritonitis was now present. Pulse could hardly be felt in the radial artery and was very rapid. Her general condition forbade operation. She died in a few hours.

She was the mother of five children, had had one abortion in 1892, was suffering from no uterine disease at the time of this pregnancy. Autopsy: The abdomen when opened discharged several pints of foul, blood stained, flocculent serum. The normal anatomical relations of the viscera were greatly disarranged. The intestines were distended and their coats discolored. All the evidences of acute septic peritonitis were present. The gestation sac was opened and the child delivered. An effort was made to determine the source of the sac and its relations, as well as the attachments of the placenta. The intimate union of intestine, omentum and mesentery made this most difficult. The left broad ligament and uterus formed a part of the anterior wall. The posterior and superior walls were formed by adhesive, inflammatory material, intestine and omentum.

The placenta had its attachment in the pelvis, to the rectum and folds of small intestines. It could not have been removed during life without causing a fatal hemorrhage. The left ovary was not to be found, and undoubtedly formed a part of the wall of the gestation sac. The left Fallopian tube was traced with a probe some distance along the wall of the sac.

Case 2.—A. G., aged 27, married, native. April and May, 1892, she missed two menstrual periods and presented the usual early symptoms of pregnancy. At about the tenth week there was an attack of uterine hemorrhage, associated with abdominal pain. She did not improve. Breasts continued to enlarge and contained milk. Soon a diagnosis of tumor was made. The uterine hemorrhage continued and repeated attacks of abdominal pains occurred. Early in September a localized peritonitis was associated with partial intestinal obstruction, rigors and high fever. A few days later a discharge of purulent matter from the rectum was observed. Some small fetal bones were discovered in the discharge. Dr. Beach found a distinct opening into the rectum through which a portion of the fetus was removed. This was followed by considerable bleeding, although the utmost gentleness was employed. During the afternoon of the day I was called; without any interference, a second and fatal hemorrhage from the rectum occurred.

Autopsy, eighteen hours after death: The local conditions revealed a gestation sac made up of omentum, mesentery and uterus, cemented together by plastic lymph, containing a macerated fetus of about the fifth month, and a living placenta attached to the intestines and pelvic wall.

The attempts made to remove the fetus through the rectum had made a partial separation of the placenta, and it was from this source that the fatal hemorrhage came.

Case 3.—Mrs. Mary R., aged 28, married, native, was seen January 16, 1896. She was taken suddenly with "colic" early in the afternoon. At the time of my visit, the pain was so severe that repeated hypodermic injections of morphia were required. The pain was intermittent in character, or like labor pains, located chiefly in the left ovarian region. Her last menstruation occurred November 20-24, 1895, and was normal in character. About January 1 she suffered from nausea, and her breasts began to swell. She believed herself pregnant from her experiences in previous pregnancies. She suffered from a degree of uterine prolapse since her first child.

Physical examination showed an enlarged uterus, soft, with a patulous os. To the left of the uterus was a tense tumor the size of a small orange. Temperature normal, pulse one hundred and of good quality. I believed that I had an ectopic pregnancy with impending rupture. The next day uterine hemorrhage commenced and continued for two weeks. Shreds of decidual membranes were expelled. There was evidence of pelvic peritonitis for a few days. No indications for operation occurring, the patient was kept in bed. After four weeks there were no physical signs of disease in the pelvis, other than uterine prolapse.

I am of the opinion that tubal abortion occurred within the four hours between the onset of the symptoms and my second visit, and that the ovum was discharged into the peritoneum, died and was absorbed.

Case 4.—Caroline S., aged 42, married, native of Germany, entered the Albany Hospital, February 19, 1895. She suffered from metrorrhagia, which at times had amounted to severe flooding. This symptom was of six weeks duration. The beginning of the flooding was associated with severe pains in abdomen, and syncope. The pain has continued at intervals since. There was a mucous discharge from the rectum and partial obstruction of the bowels. Was unable to leave her bed without fainting. Last normal menstruation in December, 1894.

Her previous health had been good. First menstruation at 16, always regular; married at 26, mother of six children, the youngest 3 years old. All her labors were normal. Physical

examination showed a distended abdomen, resonant on percussion, and quite tender, particularly in the lower portion. Investigation showed a tumor in the right lower abdomen, coming from the pelvis, rather larger than a child's head. It was tender, slightly movable, and gave no sign of fluctuation. Vaginal touch revealed an enlarged and softened cervix with uterine hypertrophy and lateral displacement; to the right, a tumor continuous with the horn of the uterus, and bi-manually it was found to be the lower segment of the one already mentioned. The uterus moved with the tumor. The finger introduced into the rectum discovered a band-like stricture, and almost complete obstruction by the tumor. There was no distinctive changes in the breast. She had suffered from morning nausea somewhat early in January, and had had at least three severe attacks of pain. There was no evidence that decidual membranes had been expelled from the uterus.

The history presented lead to the probable diagnosis, extra-uterine pregnancy, and the operation for its relief undertaken. The abdomen was opened and the relations of tumor explored. It occupied the folds of the right broad ligament. The ligament was incised and a large blood clot and the placenta removed. Both weighed four pounds. No fetus was found. Conditions showed that the hemorrhage had been intermittent. The borders of the incision were sewed in the lower end of the abdominal wound, and its cavity drained and tamponed after bleeding vessels were controlled by ligature. The subsequent history of the case was uneventful. She left the hospital well April 13, 1895, and is now in good health.

This woman had consulted many physicians before entering the hospital, and many diagnoses had been made—cancer, uterine-fibroid, uterine polypus, and miscarriage. Since, she has given birth to a fully developed child, after normal gestation. The labor was uncomplicated.

Case 5.—Frances G., aged 24, married, native of Italy, entered the Albany Hospital, May 2, 1895. Pain and discomfort in lower abdomen, irritable bladder, uterine hemorrhage, great prostration, and subsequently fever. The duration of this illness had been more than two months. She had not menstruated in January or February, 1895, had nausea and considered herself pregnant. About the middle of March she suffered from a severe attack of colicky pain in lower abdomen, associated with flooding. It was regarded by the physician called as a miscarriage. The patient growing no better, Dr. L. F. Neumann came in charge of the case in the early part of April, and at once became suspicious of the true condition.

Her first menstruation was at fourteen, and normal. Married at sixteen, mother of three children, the youngest two and one-half years old. Had suffered in the meantime from no menstrual or uterine disorders. Her general health had been good. There is no apparent heredity. Physical examination revealed a tumor in left lower abdomen, the size of a cocoanut. It was solid, tender and quite movable. The cervix was found enlarged and softened, the os patulous, the uterus displaced to the right as an appendage of the tumor. This history indicates that the patient had two attacks of hemorrhage before the operation.

May 3, 1895, the removal of the gestation sac from the left broad ligament was undertaken. The enucleation was tedious and associated with free bleeding. The right ovary and tube were removed on account of gross pathologic changes. Drainage was employed for three days after the operation. The subsequent history was uneventful and the patient returned home in three weeks, her wound soundly healed. An examination of the gestation sac revealed the point of rupture in the tube, a small portion of permeative placenta, but no parts of the fetus.

The health of the woman is now good.

Case 6.—Florence S., aged 26, native, married, entered the Albany Hospital, May 20, 1895. Pain and distension of abdomen, fever and chills, general weakness. The beginning of the illness was on April 26, 1895, when she had a severe attack of abdominal pain and immediately began to flood, although it was not the time for normal menstruation. She was confined to her bed much of the time until May 10, 1895, when she sat up. This slight exertion brought on a second attack of pain more severe than before, associated with symptoms of collapse. Abdominal distension and tenderness came on, associated with diarrhea and fever. May 18, 1895, Mrs. S. had a well-marked rigor followed by high temperature and partial intestinal obstruction. This was repeated on May 19, and her condition became serious. I saw her on this date and aspirated a swelling in left lower abdomen, with drawing five pints of very foul, blood-like fluid, mixed with gas. The abdomen was generally distended and very tender. By vaginal touch nothing could be made out; everything was matted together. There was a very foul discharge from the vagina.

Her previous health had been fair. First menstruation at

sixteen, normal until eighteen, when it became scanty, irregular and painful, married at twenty-two, one child living, two and a half years old. Mother died of puerperal fever. Father living. There is no history of tuberculosis or tumor in the family.

She was brought to the hospital May 20, 1895; an abdominal incision was made. Adhesions were universal. A large cavity, including the pelvis and left side of the abdomen, was filled with decomposing blood clot and pus. This cavity was washed as clean as possible, and filled with iodoform gauze. There were no distinct walls to the cavity. Agglutinated intestines, omentum and mesentery enclosed it for the most part. She was taken from the table in severe shock. However, she rallied and after forty-eight hours the gauze tampon was removed from the pelvis, a large glass drain introduced, and the abdominal sutures tied for the first time. An enema was ordered shortly after and it came immediately out of the glass drainage tube. For two weeks all the bowel motions were through the drainage tube. Careful attention to the fecal fistula, repeated irrigations daily, enabled us to avoid any general infection. June 2, only a small fistula remained and the patient returned home. The bowels now acted naturally.

Late in September she returned to the hospital for relief of the fistula, but after exploration and curettement it closed with little trouble. She is well and strong.

Case 7.—Mrs. Anna DeR., aged 34, married, native, was seen July 10, 1895. She had been in bed for some time suffering from abdominal distension and pain, fever, rigors and sweating. Menstruated March 24, 1895, for the last time. In the latter part of May she was suddenly attacked with severe abdominal pain, and noticed a small tumor in the left groin. This disappeared in a few hours, but the distress continued. A week later a similar attack was experienced, after which nausea was experienced and continued. Her family physician at this time discovered a hernia which was treated by a truss. The abdominal pain continued. On June 29, an attack of vomiting, great pain and fainting occurred. She went to bed and remained there until removed to the Albany Hospital June 30, 1895. Three weeks before entering hospital flowing began and a membrane was expelled from the uterus, supposed to be a "false conception." Just prior to entering the hospital she had a chill lasting for twenty minutes. Physical examination showed the usual signs of ectopic gestation with rupture. On July 20, she was removed to the hospital for operation the following day. During the night an attack of hemorrhage occurred and her condition became serious. The operation was made early the next morning. Blood clots and fresh blood flowed from the incision, which was at once arrested by a clamp placed on the left broad ligament. The blood, fetus and placenta were at once turned out of the abdomen. The broad ligament was immediately tied and the remnant of the left appendage removed. After the peritoneum was cleared the abdomen was filled with normal salt solution, and closed with drainage—a glass tube. The subsequent history is uneventful. The woman is now in good health.

tion, has taught him to detect with almost mathematical certainty, the pathologist can step in and display his science in explaining cause and effect.

The occurrence of tubal pregnancy is regarded in widely different light by the theorist and the surgeon who has learned to deal with it practically, and who has accordingly come to understand the manifold directions in which speedy disaster may troop down upon unfortunate women subjected to this calamity. The argument that many cases get well of themselves, in the presence of the multitude of disasters possible, and in the light of the horror of some of these very recoveries, is so puerile that the surgeon of practical and positive bent can not regard them with complacency, nor consider that those who advance them have any authority from which to speak more positive than the vapors of fancy. As to the causes of aberrant gestation, we are to consider them both as anatomic and moral. They may have their origin in anatomic loss of structure or in perversion of function, such as absent ciliary motion in the epithelium, or in absolute disease of the tube, or, as I have had more than once called to my attention, in the fright of illegitimate conception. Causation can rarely be determined with certainty; there are many agencies which operate to produce the trouble. The character of the attack, the whereabouts of the patient, at what employed, are always interesting considerations. The attacks are exceedingly sudden. A vigorous woman may in a few minutes look pale and exhausted and have a very feeble pulse. Any effort to change position increases the pain and she will start with a scream; the pain may be quite general and not confined wholly to the abdomen. The rational symptoms of pregnancy are not very marked. Morning sickness is never very prominent. For weeks they may complain "on and off" of sharp pain in one groin or the other. These pains are followed by bloody discharge; the odor of the discharge is also characteristic. Later the sharp and severe pain is followed by faintness and increased flow mixed with shreds and débris. Ruptures with large effusions are easily recognized upon examination. The finger detects an ill-defined boggy tumor, the uterus enlarged and posterior or pushed well to one or the other side. If the rupture is quite recent it may be difficult to determine a tumor of any character; there is simply a feeling of general resistance. In examinations made one or two days after rupture it is easy to define the irregular boggy tumor, also to locate the uterus, determine its size, position and mobility.

There is very frequently associated with these cases a history of sterility, inaptitude to conception and mild forms of pelvic disease, abortion or doubtful abortion antedating the pregnancy some four or five years, absence of one or more periods. Very frequently there is peculiar nervous disturbance, morbid apprehensions, irritability followed by acute pain, severe and recurring, pain of a variety rarely associated with other troubles. Usually the pain is followed by anemia or symptoms of concealed hemorrhage; the common symptoms of loss of blood are prominent. It is then other symptoms develop, intra-pelvic or perineal tumor due to clot or pressure, there is characteristic vesical and rectal disturbance, peculiar central fullness of the abdominal walls. Slight distension, tympany and marked tenderness rapidly follow the first rupture, recurring hemorrhage and all symptoms become more marked. The restlessness of the patient is alarming; probably 25 per cent. die in twenty

## SYMPTOMS, DIAGNOSIS AND TIME FOR OPERATION IN RUPTURED TUBAL PREGNANCY.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY JOSEPH PRICE, M.D.

PHILADELPHIA, PA.

Careful study of the physiologic, anatomic and pathologic conditions of cases coming within our experience, while such study has not altogether removed from controversy very many subjects connected with gynecology, it has led some of us to positive convictions and to the adoption of well defined lines of practice. We are concerning ourselves less about theories, though we are not able to dispense with them altogether, but we are growing to base our rules of practice more upon the results of our observations and experiences. Pathologic systems are continually changing, one system succeeding another in quick and confusing succession. There should be no element of mere conjecture in our every day working experience. After the surgeon has discovered and relieved conditions which his experience, his observa-

hours, where there has not been prompt and skillful surgical relief. Hemorrhage is the real cause of death; they die both early and late in the history of the trouble; early, from rupture of tube, late or at term in primary sections done for saving both mother and a viable fetus. The non-contraction of the tube favors free and continuous hemorrhage. Ruptures on the outer half of the tube or about the pavilion extremity are the least fatal. As the rupture nears the uterus the hemorrhage is most fatal. These points have been demonstrated in the experience of every one who has done any considerable number of sections. So marked has been my own observation of these facts that I commonly allude to it in my cases, exhibiting it as an object lesson to those witnessing the section, and these facts have led me to classify the cases; first, ruptures in the outer half of the tube belong to the surgeon; the second or inner half go to the coroner or coroner's physician. Rarely can you improve volume, quality and frequency of the pulse in such cases where all the symptoms are as I have narrated.

It is my conviction, fortified by my own experience, counting now one hundred and twenty-eight cases with five deaths, that the operative treatment is the only one to be considered. I am fully satisfied also that these pregnancies are rarely, if ever, in the broad ligament. In the case of fetus gone to term, in my own direct and indirect experience, the child has in no instance been in the broad ligament. I regard the chief danger of the operation as that of hemorrhage. If the patient is found so weak as to render operation an almost certain failure, I resort to salt water transfusion in order to restore the arterial tension.

Rupture with fatal hemorrhage is the most frequent termination; pyemia, septicemia and peritonitis are much rarer.

Relating to such cases Goupil says: "It is but true, I fear, that we are authorized in saying that all the cases of intra-peritoneal hemorrhage arising from extra-uterine pregnancy end in death, and although death has been delayed for six months, it is wholly exceptional. This was absolutely true in my own experience until I was emboldened—I say it—until I was shamed by Mr. Hall Wright's case into opening the abdomen and saving their lives."

The consensus of opinion by those who are competent to speak from results must be for early operation. But there are, in addition, those cases to be considered in which, after primary rupture, the fetus has still lived and advanced to full term. Here the question is one of operation with the view of saving both the life of the mother and that of the child. If one is to be lost, it is my belief that it should be that of the child; that the life of the mother is of paramount consideration. The chief danger to the mother in the operation at term in tubal pregnancy is the removal or accidental detachment of the placenta. It is easy enough to remove the child and save it, if it is viable, by operating at or near term; but the danger of fatal hemorrhage from vascular walls that can not contract, as do the uterine structures, is the vital question of the operation, so far as the mother is concerned. If we do not remove the placenta the risk of septic infection still remains.

The old and non-surgical rule of leaving the placenta to slough away is too dangerous and prolonged to be practiced. The placenta should be removed in every case, or washed and hermetically sealed, thus

favoring its healthy digestion and avoiding gangrenous separation and detachment. Secondary rupture of broad ligament, discharge of placenta and fresh adhesions, or the second implantation or grafting of the placenta, have never occurred in my experience, nor have I any knowledge of such cases except that conveyed through the literature on the subject. Basing the conclusions of my judgment upon my own clinical experience, I must hold to the tubal origin and the intra-peritoneal rupture. All that follows tubal rupture is within the pelvis and peritoneal cavity, and not within the leaflets of the peritoneum forming the broad ligament.

It must be admitted that the removal of a growing and almost universally attached placenta is one of the most difficult procedures in surgery. The hemorrhage is profuse and sometimes uncontrollable; the contraction of all tissues to which it is attached simulates that of uterine tissue. Rapid separation, heat and firm pressure will commonly succeed in controlling it. As to choice of time for the operation, I am of the strong conviction that there is but one choice, and that is prompt removal when the accident is first recognized.

It is better to act promptly. The steps of procedure are clear and should be completed at any risk. It is better to contend primarily with the loss of blood than later with overwhelming sepsis. Tubal pregnancy is dangerous throughout its existence; the subject is *never safe until surgically relieved*. *Exceptionally*, is the trouble recognized before rupture. I have never recognized one before rupture, all before is conjecture rather than knowledge.

An important element of the history connected with these cases is that few of them are kept under observation with the definite purpose of removing the viable child at the period of spurious labor; alarming symptoms develop and subside, and consultation with a specialist, if they are at any time consulted, follows the death of the child, it rarely antedates it. Then all the conditions are found greatly aggravated by delay or neglect, or that which is infinitely worse than either or both, inexcusable ignorance. Consultations for suspected extra-uterine pregnancy are quite common in those peculiar cases of much-attenuated uterine walls in normal gestation, but the ectopic cases are permitted to pass through the primary rupture, recurring ruptures, almost constant pain and spurious labor, entailing impaired general health, without suspicion of the patient's peril.

An English authority has stated what, in connection with these cases, should be accepted as sound dictum: "As all know, the Fallopian tube is, in the vast majority of instances, the starting-point of extra-uterine gestation; the most common result of this is that rupture occurs usually at the second month, through some part of the tube covered with peritoneum; a result almost universally fatal if left alone, and as *invariably curable if operated on in time* by abdominal section."

#### DISCUSSION ON PAPERS OF DRS. MACDONALD AND PRICE.

DR. JOSEPH EASTMAN, Indianapolis—So far as I am able to judge from reading the literature of this subject and from experience, there is but one treatment for extrauterine pregnancy, and that is surgery. I will refer to one case which came under my observation because it was an extraordinary one, and it illustrates still further the futility of packing with ice and the use of electricity. A man supposed to be a competent electrician and well posted in the treatment of extrauterine

pregnancy by electricity tried for six months to kill the fetus and failed. He then tried packing with ice for three weeks more. When the patient was *in extremis* there was a change of physicians. On opening the abdomen, I found the sac containing a living child in such an advanced gangrenous condition that I could not for a moment think of leaving it. Following the rule which I always insist on, that we shall first find the uterus, if possible, I slipped my hand down, found the origin of the tube toward the uterus, believing that all cases of extrauterine pregnancy are primarily tubal, seized the tube at the cornu of the uterus, which felt fully as large as my wrist, and in doing so I detached a portion of the placenta from the gangrenous sac. Blood poured out freely; my assistant had gone to resuscitate the child, leaving me with a couple of nurses to do the best I could under the circumstances. Crushing down the sac (as you would crush a cherry-stone out by squeezing the cherry) with clamped forceps which I have with fingers like my own, I seized the sac below, then to my own astonishment I found the sac was adherent in a number of places to the intestines. With this clamp attached, after applying six ligatures around the points of hemorrhage, we got the gangrenous sac out, then quilting with iodized silk, we had the pedicle, to the cornu of the uterus, covered with iodoform collodion. Where we find a dead or living child with a gangrenous sac, the proper way to deal with such cases is to get at the cornu of the uterus either with clamps or ligature, shut off the blood supply, and remove the sac. I do not believe that it is good practice to leave the placenta to slough out. I do not believe there is a case where such men as Dr. Price would be induced to leave a gangrenous sac. I believe the sac can be removed in many cases with less risk to the patient than in leaving it or the placenta to slough out, or both combined.

DR. C. A. L. REED, Cincinnati—My experience has led me to attach particular importance to the symptom of shreddy metrorrhagia as an early manifestation of this condition, and I have not been able to verify the fact that this symptom occurs only after the symptoms of rupture. On the contrary, I have found that it has occurred among the earliest manifestations of pregnancy, and no doubt it has occurred when there were no symptoms of pregnancy, and I was prompted on one occasion to make a careful study of a case and a diagnosis before rupture by following the case as suggested by the symptom, and that was one case in my experience in which a diagnosis was made before rupture, was operated upon before rupture had taken place, and the diagnosis subsequently verified by careful microscopic examination of the specimen removed. Therefore we did have in this one instance a confirmation of the fact that a shreddy metrorrhagia may occur prior to the symptoms of rupture.

It has fallen to my experience to observe so few instances, that I hesitate to allude to them, for the reason that their example has led to many errors and many fatal delays; but I have seen a number of cases in which primary rupture had occurred in the broad ligaments, for the reason that there was a definite extension of the tumor downward, and no particular extension of it upward, although its upper margins were definitely outlined. The tumor became stationary and disappeared. This was manifestly a hematocele. You may say that I had no evidence that it was a case of ectopic pregnancy, but if we are justified in saying that given cases upon which we operate were cases of ectopic pregnancy by virtue of the existence and persistence of certain symptoms which lead to the diagnosis, and which diagnosis is confirmed by operation, certainly we are justified in interpreting as having similar consequences a similar aggravation of symptoms, and these symptoms did exist in the few cases that I saw. While that is true, I believe it is a dangerous expedient to rely upon absorption. The maximum of safety is upon the side of operation at the earliest practicable moment, and if we have such primary rupture with such limitation of hemorrhage, the safest expedient

is to avail ourselves of the quiescent interval and proceed to operate when we can do it without serious complication, and without being forced to deal with an exsanguinated patient.

DR. JAMES F. BALDWIN, Columbus, Ohio—There was one point made by the first essayist which is of prime importance, and that is with reference to educating the general practitioner to suspect the existence of ectopic pregnancy, and thus lead to a thorough examination and to a diagnosis. It has been my fortune within the last few months to have seen seven cases of ectopic pregnancy. Two of these were seen in my own practice, the others in consultation. In five of them the diagnosis was made before rupture and operation performed. The diagnosis was subsequently confirmed, and the five patients are well to-day. Two of these cases occurred in the same patient at an interval of six months. In each I made a presumptive diagnosis of ectopic pregnancy and operated. In two other cases no suspicion had occurred to the attending physician of ectopic pregnancy until I suggested to him that in the five cases mentioned the diagnosis had been made by the general practitioner. This case was one of ectopic pregnancy, the diagnosis confirmed, and the woman operated upon. In two cases the diagnosis was not made until repeated hemorrhages had occurred. The eighth case was one that was sent to the hospital during my absence, and the physician who sent the patient had made a diagnosis of peritonitis. The patient died within forty-eight hours after admission to the hospital from peritonitis. A post-mortem was made which revealed a normal uterus and tubes, but an ectopic gestation sac in the cul-de-sac of Douglas which had ruptured, producing a considerable amount of hemorrhage which resulted in peritonitis. This is an exceedingly rare condition, one which is denied by many pathologists.

We have educated the general practitioner to make a diagnosis in a large number of cases of appendicitis, and I think if we impress them in the matter of ectopic pregnancy until they suspect its existence when they have anything abnormal during the early weeks of pregnancy, they will make a diagnosis then or will have a suspicion sufficiently well grounded to send for an expert to make a thorough examination. When the general practitioner is educated up to this point cases of ectopic pregnancy will be diagnosed much earlier than they are now, and before rupture, and then the operation will be comparatively simple and few deaths will occur.

DR. A. VANDER VEER, Albany—Papers of this kind are lessons in object teaching. They teach the general practitioner regarding the matter of an early diagnosis in these cases.

With reference to general peritonitis, inflammation of the bowel, etc., I have lived long enough to hear papers on idiopathic peritonitis, and in abdominal surgery the comparison or difference between these terms and appendicitis have been and are presented in their true light. The general practitioner has been taught that pelvic hematocele will be absorbed, that it will disappear. Does it disappear? Look at the cases of pelvic abscess—cases where a portion of bone protrudes through the vagina and rectum. Look at the cases of secondary hemorrhage and death which occur before you are fairly in the house. Some of these cases if diagnosed early and operated upon immediately would be saved. So many papers have been presented in the past that they have mystified the general practitioner as to the classification of this condition, as to the true pathologic state present. What is the use of standing before the general practitioner and arguing with him as to the form of ectopic gestation. If you keep it up for twenty minutes your patient is beyond relief. When the clinical symptoms are presented the general practitioner must know that an operation is absolutely necessary, and we have the authority of one man who has perhaps operated more than any other in America in these cases, and he tells us emphatically what ought to be done.

Stress should be laid upon the sympathetic symptoms. The general practitioner should be educated in this matter as much

as he is in regard to cases of appendicitis, and in case he does not wish to operate himself he should call in a specialist to share the responsibility with him. I find that when we teach the general practitioner what to do he is not slow in following our advice.

DR. F. J. YAGER, Campbellsburg, Ky.—I am a general practitioner, but I am firmly convinced that in these cases of ectopic pregnancy as soon as a diagnosis is made we should operate. If the general practitioner feels that he is not sufficiently expert to undertake the operation himself he should call in a specialist. The more we study these cases the more we are convinced that delay is dangerous.

DR. RUFUS B. HALL, Cincinnati—My experience leads me to believe that a large percentage of these cases have a history of some pelvic trouble. I have known pelvic trouble to precede tubal pregnancy for at least five years in some cases. The cases are few in number in which we do not get a history of long continued pelvic trouble. We have a shorter space of time in which the patient has considered herself not entirely well since her last labor. A number of cases do not have these symptoms, but when we take the large number of cases operated on, a large per cent. of them have pelvic symptoms following some uterine or appendiceal trouble preceding their ectopic pregnancy. I have seen two women die inside of ten hours from ruptured pregnancy, before the third month of tubal gestation, as subsequently proven by autopsy. One patient lived twelve minutes after I reached the house. The time to operate is as soon as the diagnosis is made. In making a diagnosis we should not disregard the possibility of tubal pregnancy occurring in an unmarried woman, I have had two cases, one in a widow, who denied the possibility of pregnancy until after operation.

DR. J. G. CARPENTER, Stanford, Ky.—The model practitioner is a diagnostician the world over. If the general practitioner knows his business he makes a diagnosis and brings his patient to the abdominal surgeon if he does not want to operate himself. If he is the practitioner that he ought to be, he should be prepared to operate on the patient himself, because the best abdominal surgeons are made from the best general practitioners. Early diagnosis is the thing of prime importance, followed by prompt surgical interference. Operate before the patient bleeds to death from hemorrhage, before secondary lesions are set up. The patient is often unaware that she has had long standing uterine trouble. As soon as the diagnosis is made the patient should be promptly operated upon. If this was done a large number of cases that are now lost would be saved.

DR. MILO B. WARD, Topeka, Kan.—We all agree that it is absolutely essential to resort to early operative interferences in cases of ectopic pregnancy, particularly before rupture has taken place, if possible. The general practitioner must be educated to the point that in cases of ectopic pregnancy it is necessary to operate as soon as a diagnosis is made. Operative interference must not be postponed. I would like to report two cases which illustrate the danger of postponing surgical interference, but I will not do so at this time.

DR. W. G. MACDONALD, Albany—Regarding the general practitioner, I will say that in those cases which I have seen the matter of diagnosis or suspicion of ectopic pregnancy by him has been the exception, and not the rule. We must educate the general practitioner that we have in these cases certain definite symptoms.

When we are called in consultation we sometimes give diametrically opposite advice in regard to what is best to be done after the diagnosis has been made, and this puts the general practitioner in trouble. We want to act together in these matters and establish uniformity of opinion.

DR. JOSEPH PRICE, Philadelphia—The subject is not so difficult to understand, and a study of differential diagnosis is

rather easy. From a general standpoint, the general practitioner is a very much better diagnostician than the specialist. You are in the habit of calling in specialists to do your special work; sometimes after studying your cases two or three days you come to a positive diagnosis by exclusion, and now I am going to rebuke you for permitting the specialist to take the attitude which he commonly does. After studying your case you summon a specialist, he examines your patient, shrugs his shoulders, looks wise, and says he will tell you what the condition is when he opens the abdomen. The general practitioner is as good a diagnostician in a great many cases as a specialist, and when his attention is once called to a subject he recognizes and realizes its importance. I have the greatest respect for the general practitioner, and in ninety-nine times out of one hundred I have found him usually right. If we save these patients, there is no time for the specialist to be called in, because the operation must be done before the specialist arrives. I have said that at least 25 per cent. of the cases die within twenty-four hours. The symptoms are simple, physical characteristics are prominent. There is an absence of one or two menstrual periods, a delayed menstrual period, and along with this we have the characteristic agonizing pain. The attack of pain differs from any pain to which your attention has ever been called. We have the characteristic shreddy debris which is nearly always present; a rapid pulse, and the symptoms of concealed hemorrhage. In some cases the pulse may not be bad, and the symptoms are not alarming; but if the case is an acute and typical one, cut down upon the peritoneum only, and it will be found to be black. You have only gone to the peritoneum to make a diagnosis. You will find black blood beneath it in a large number of cases.

With reference to general practitioners making a diagnosis in these cases, I will say that nurses occasionally after listening to discussions in the operating room and taking a record of the case, will make a correct diagnosis. I have had nurses who have sat by the bedside of patients for some time tell me that the case looks like one of extrauterine pregnancy.

## GAUZE AS DRAINAGE IN ABDOMINAL AND PELVIC SURGERY.

Read in the Section on Obstetrics and Diseases of Women at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY MILO B. WARD, M.D.

TOPEKA, KANS.

Human life so frequently depends upon the tying of a ligature, the use of one more suture, the perfection of an operation in every minute detail, that the subject of peritoneal drainage, which is, perhaps, the most vital of all questions connected with the always grave procedure of opening the peritoneum, should never become too trite to demand careful consideration, even though much has already been written on this subject, and every phase of the question thoroughly discussed.

Viewing my failures retrospectively, I am forced to the confession that no one feature of my work has given so much cause for regret as that of insufficient drainage.

It is idle to say that drainage is needed only when the work has been carelessly done. However perfect the technique may be, it is still a fact known to every operator, that there are cases whose recovery depends entirely on the drainage employed after the surgical toilet is made. The only question for consideration then is: What kind of drainage shall be used in a given case? It is so frequently necessary in choosing the material for drainage to provide means of controlling hemorrhage, thus filling two important func-

tions at the same time, that the problem is at once solved whenever we have suitable method to meet the dual requirements. The kind of drainage so often depends upon the customs of individual operators that it is impossible to lay down any rule to govern all alike. This statement holds good in the use or non-use of drainage, for some operators use drainage in almost every case and others seldom if ever use it. Another important fact to be borne in mind in considering a question of this magnitude is, no one kind of drainage can be expected to meet the indications in every individual case. The object of this brief paper is merely to urge the importance of the thorough use of gauze, in a large variety of complications, as the material meeting the most indications and tending to save lives that would, I think, be sacrificed if other methods of drainage should be employed. My experience in the use of gauze has been so pleasing, in a large number of cases presenting the gravest complications, that I can not refrain from recommending with great emphasis this important feature in abdominal and pelvic work.

It is not my intention to deprecate in the least the usefulness of other forms of drainage; neither would I be understood as urging the use of gauze drainage to the extent of making a hobby of this practice, because there are a number of reasons why gauze should not be employed unless its use is absolutely demanded. The most potent objection to this kind of drainage is the large opening necessary through which to remove the drainage material after it has performed its proper function. Another objection to its use is the pain caused by removing the gauze, and in some cases necessitating the use of an anesthetic. These objections, however, apply only to cases where the gauze has been introduced through the abdominal parietes, because the removal of gauze from the vaginal opening does not usually cause suffering. Frequently it is necessary to employ lavage subsequent to the operation, where the field is primarily septic. In this class of cases the gauze drainage will be found the most useful, because it leaves sufficient opening to convey the fluids to the septic area.

Much has been recently said relative to the poisonous tendency of iodoform gauze when used as drainage, but I have never experienced the least untoward symptom, even when used in large quantities. Perhaps there is a difference in the kind of gauze used. My method has been to use the Johnson & Johnson moist gauze, as it is furnished in glass jars. However if there is the least question of absorbing enough of the iodoform to poison the patient, this gauze may be used in the form of a sac to come in contact with the peritoneum, and the carbolated or borated used for the filling.

It would be quite improper for me to suggest to this learned body anything regarding the minute technique of the use of gauze, and, therefore, I have only to suggest that it be used freely, and that the entire surface made raw by the separation of adhesions be covered with the gauze. In operations in the peritoneum through the vaginal route, it is very essential that a free opening should be made, thus enabling a generous amount of gauze to be used without packing it too tightly. It has been suggested by a number of operators that the gauze should be cut in long strips, so that the distal end will reach below the plane occupied by the proximal end, but I have not found this plan at all essential in order to

ensure perfect drainage. Gauze applied externally, coming in contact with that which is introduced into the abdomen, carries on the drainage quite as well, and does not require so large an amount of material.

The most natural interrogation is: What character of cases demand gauze as drainage? My answer is, almost all seriously complicated conditions of the pelvic and abdominal peritoneum, especially when the intestines are involved, and also in all cases where the peritoneum is opened through the vagina. There are no objections to the use of rubber or glass tubes in connection therewith, but I have never found it necessary to employ anything but the gauze. Where this kind of drainage is used for the purpose of controlling oozing, the result of separating adhesions, it is my custom to introduce silkworm gut sutures, and remove the gauze in twenty or twenty-four hours, and then tie the sutures, thus securing primary union of the incision. This plan may be carried out in nearly all cases of sepsis by tying a part of the sutures and introducing a smaller piece of gauze for continuous drainage.

In conclusion, I beg to state that it is my conviction and experience that many patients will undergo surgical operations and recover, when gauze is freely used for drainage, who could not survive with the use of any other material to perform this important function.

#### DISCUSSION.

DR. HOWARD A. KELLY, Baltimore—I no longer drain for tubercular peritonitis, and these cases practically all get well. The cases I drain stay in the hospital on an average of fifty-nine days, while those in which I do not drain remain on an average only thirty-nine days. The cases where I drained had fistulous tracts. When I drain I use gauze, for the reason that a glass drainage tube may do harm by introducing septic material, by its perforating the intestine, producing a fecal fistula. In the second place, it does not drain. I find pockets of fluid within half an inch of the tube walled off by intestinal adhesions. I advocate gauze drainage because it covers a large area. Any quantity can be used, and it can be employed in curved and angular spaces, and a constant capillary action is kept up. The disadvantages of the gauze drain are that the drainage is apt to stop after a while unless watched, and there is the further disadvantage in removing it because of the pain it causes to the patient. It is my plan to remove the gauze very soon if it has been used for hemorrhage; but if for sepsis, to leave it in for five or six days.

DR. CHARLES P. NOBLE, Philadelphia—The more I operate the less I drain. In the beginning I drained a larger percentage of cases than Dr. Kelly, but the longer he operates the less he drains. Of the first hundred cases upon which I operated about ninety were drained. I did not feel comfortable about my early cases unless a tube was inserted. If my patients recovered where drainage tubes had been used I felt happy. If they got well without drainage, I felt it was a fortunate accident. Further experience taught me that it was not necessary, and at present I drain but little. My experience is that gauze drainage does not drain. The serum collects in the gauze, and if you do not get it out in any other way it stays in and poisons the patient. I insert a glass drainage tube in the middle of the gauze to get the fluid out. I am quite sure after the first day that gauze does not drain by capillary action, it simply becomes impregnated with the fluid which is in the pelvis and retains it. If the case is actively septic, unless the infected gauze is removed the patient dies. In my opinion the chief function of the gauze is to pack off the infected area. I have never found it necessary to use drainage for hemorrhage, and I think that with the patient in the Trendelenburg position it can always be controlled. In a case in which it is necessary

to employ drainage for this purpose I would prefer a glass tube for twenty-four hours.

DR. RUFUS B. HALL, Cincinnati—Where I use gauze to pack off raw surfaces in the pelvis, I also insert a glass drainage tube to remove the accumulated fluid. I do not use gauze for drainage as frequently as some operators. I think gauze is indicated in pus cases where we have large denuded surfaces, because it keeps the intestines from becoming soiled, or where they will become adherent. I have employed it in many instances only to keep the intestines away from the soiled area until it was walled off. As to the best time for removal, if you remove it sooner than the fourth day the patient complains of pain. After the fifth day it hurts but very little. The lymph is not reabsorbed before the fourth day. I never think of using gauze for drainage alone, as I am so confident that it will not drain pus and blood clots. I would not use it without a glass drainage tube alongside of it, or in the meshes of the gauze where it would take up extra fluid.

DR. HENRY O. MARCY, Boston—It is unnecessary for me to rehearse the long battle some of us have had in reference to drainage. For many years I stood alone on this question and I am glad to see others coming to my views. I have laid down two rules for my own guidance. If the case is aseptic, no drainage; if septic, drainage. The reason I think gauze sometimes ceases to drain is because the operator tries to drain uphill. The proper place to drain is not through the abdominal wound, but through the vagina, and a large opening should be employed.

An objection to the application of gauze through the abdominal wound has not been referred to. The gauze will adhere to lymph if it is not disturbed. Even if it is loosened you are liable to displace organs, as lifting a considerable piece of gauze out through the abdominal opening is quite sure to dislocate the restored omentum, and if you are not very careful you have complications in consequence that are serious. Therefore, when we drain, let us drain properly, by which I mean drain by the vagina in such a way that you may profit by gravity. Let your opening be sufficiently large for drainage purposes. He who makes a small opening through the vagina and packs it tightly with gauze will certainly fail. If he makes an opening not larger than my little finger and wedges it tightly with gauze he has practically made a plug of it and has precluded the possibility of capillary drainage.

DR. GEORGE M. STERNBERG, Washington, D. C.—In regard to the general question of destruction of bacteria in wounds, the views of surgeons have been modified. Lister commenced years ago with the idea of killing the germs in the air, and then various propositions were advanced by hygienists to destroy bacteria in the water closet, and the discharges of normal individuals were to be disinfected. Now we have precise information as to what agents will destroy bacteria and in what proportion, and this precise data has been utilized by surgeons who are now very well informed upon this matter. They know that the particular micro-organisms which they have to fear are the staphylococcus aureus and the streptococcus pyogenes, and they know that the ordinary saprophytic bacteria which may drop upon the surface of a wound are not likely to do any great harm. Fortunately nature will provide for a certain number of bacteria, and even the most virulent varieties of the pus cocci are destroyed by nature. When you have a virulent streptococcus, such as you may get from the abdominal cavity of a woman who has died of puerperal fever, why then you must beware. The attenuated varieties, such as are found not infrequently upon the surface of the mucous membrane in the vagina of healthy women, must be kept out of wounds. You must take every precaution to do this, but nature will render harmless a limited number. Infection depends upon two or three things. 1, a virulent micro-organism; 2, a susceptible individual. All individuals are probably susceptible

to wound infection, but there is a difference in the susceptibility. Any woman who has lost considerable blood may be more susceptible to infection than another. Experiments have shown that alcoholics are especially susceptible and those who have been suffering from inflammation have a predisposition to infection. A streptococcus of slight virulence might produce infection, and one may have a streptococcus with increased virulence which would be extremely dangerous for a person in poor health. You are familiar with the various chemical agents used to destroy these microorganisms.

DR. WIGGIN, Connecticut—I think drainage in ordinary abdominal troubles is a mistake. It is true we have a moderate amount of infection, but in breaking up adhesions it has been my practice to shut off the general cavity before the adhesions are ruptured and to use peroxid of hydrogen in fifteen volume solution strength, and after allowing a little time to elapse, washing out the cavity with a normal saline solution and closing the wound. By following this method I have no cause of regret. I have no septic peritonitis.

DR. H. O. PANTZER, Indianapolis—I performed my first laparotomy in 1888, in which I resorted to the use of a drainage tube. I have not used it since and I have no reason to regret it. It is a clinical fact that the peritoneum is a tissue quite different from the tissues that we meet with it in wounds in other parts of the body, and it acts differently from those cavities which contain pus. The peritoneum is able to take charge of a certain amount of infection. Gauze packing is quite unnecessary, and pernicious when used to a great extent. It might be necessary in some cases to use a single layer of it, at most a double layer applied to the infected area. In most aseptic cases I use only a little bit of iodoform gauze and I have no reaction in most of my septic cases. I think iodoform gauze has a danger which has not been touched upon, namely, that of producing fistula. I know of one surgeon who has had at least one hundred cases of intestinal fistula which followed packing by gauze. I infer that the fistulae were established here because of the violence with which the gauze packing was removed. There is an incentive to remove the gauze rapidly and violently because of the pain it produces. I would suggest the use of peroxid of hydrogen to loosen the gauze from its attachments. It acts admirably.

DR. A. P. CLARKE, Cambridge, Mass.—Dr. Sternberg brought out one point that ought to be emphasized. It was recognized some years ago before antiseptic surgery came into use. Many years ago I recognized the fact that in cases where there was great loss of blood there was a tendency on part of the absorbents to rapidly absorb everything, and that in such cases where there was absorption of pus we could predict that pyemia would follow. Even in these days in cases with little loss of blood and good health drainage is unnecessary. On the contrary, in cases where there is great loss of blood, drainage should be used. An alcoholic solution should be given to restore the circulation as rapidly as possible if the germs can not be absorbed from the wounds. This is a matter of vital importance. We must distinguish between those cases which require drainage and those which do not. It is not a local trouble, but a general condition of the system. If the members will review their cases and note which ones have become poisoned, they will find it was those in which there had been great loss of blood and the patients very much reduced in health.

DR. HENRY P. NEWMAN, Chicago—This matter of drainage is of great interest, and I think some of the statistics are a little misleading in regard to its use, even those of Dr. Kelly. We do better operating than we did formerly, and our last one hundred cases are showing this. It is not to be ascribed in all instances to either the use or the non-use of the drain. Our work is cleaner; the tissues are better protected; the surfaces are less abraded; there is less handling of the intestines, less exposure, etc. Consequently we do not need to drain as much

as formerly, and necessarily we have better results. Then, too, the resisting power of the structures is correspondingly great as they are less manipulated and exposed, or brought under the influence of trauma.

With reference to the material used for drainage, I have used for the last six or eight years properly prepared wicking, which I have found far superior to gauze. It can be used in large quantities. Its threads are continuous and very easily removed. The capillary action is better and it is easier to introduce and remove. This ordinary lamp wicking is prepared very much the same as iodoform gauze, and it can be made antiseptic with any of the germicides. The advantage of this material in the abdominal cavity means simply more than drainage; it protects abraded surfaces and prevents adhesions of the intestines. I think we are learning to do away with the drain through the abdominal wall and shall soon use it exclusively through the vagina. The bugbear of vaginal infection is fast fading away.

DR. WARD—We are mostly agreed that we should not use drainage if it is not absolutely necessary. Gauze does not drain after twenty-four hours. A glass tube does not drain after twelve hours, therefore, we have gained twelve hours after that method by the gauze. Gauze will carry away all the material thrown out in the abdominal cavity. The portion on the outside will be filled with clotted blood. I believe that we should drain through the vagina where it can be done. The gauze must not be packed too tightly if we expect good drainage.

### HOW TO CURE RHEUMATISM.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY ELMER LEE, A.M., M.D., PH.B.

Vice-President American Academy of Medicine; Chairman Section on State Medicine American Medical Association. Chicago.

The names of diseases are determined, principally by the prominence of a certain group of symptoms. The disease under consideration follows the general rule. Special names are attributed to particular groups of symptoms, all of which, however, constitute merely varieties of one disease.

Rheumatism is acute when it is recent, and chronic when the disease has extended over a longer period; articular, when the manifestation is chiefly in the joints; inflammatory, when the whole body exhibits the symptoms of inflammation and pain; muscular, when relating to the striated and non-striated tissues; sciatica and lumbago belong to the same family; even gout is itself closely related in its origin, differing only in its symptomatology.

The present paper is concerned with a practical review of the author's system of managing this disease in its various forms.

Disturbance of nutrition with consequent impairment of the solids and fluids of the body, always precede rheumatism. Invasion of the soft tissues can not take place unless the functional activity of both structures is impaired. It is impossible to name the first symptom in the series of alterations of the elementary forms. But in almost all cases which have come under observation, certain functions are almost uniformly abnormal. Variation in the volume as well as the nature of the fluid elements of the body, and changes in the quality and proportion of the solids, are constant factors in the pathology of rheumatism. The influencing or producing causes of these changes in the body are, indeed, hard to exactly discover. But fortunately, they are not indispensable to successful treatment of the condition that requires remedial aid.

Whenever there are functional changes they consist for the most part, of abnormal muscular action in some portion of the body, principally with reference to the capillaries and small arteries. The same condition may be an exciting cause of other diseases, the peculiar symptoms determining the character of the affection, being dependent upon the state of the general system of the individual. Thus a given influence may produce in different individuals quite contrary symptoms. With disturbed nutrition, alteration of the fluids and solids of the body are accompanied by obstructions in the circulatory and excretory systems. Lowered vitality is the necessary result, which is the basis upon which rheumatism is determined. If functional activity remains normal, the vital resistance of the soft structures prevent retention of the impurities. There is no one portion of the economy which suffers alteration so readily as the circulating fluids. Upon the relative maintenance of the normal proportion of the fluids and solids, the health of the body depends.

It has been found by examinations of the blood that there is a loss of balance between the fluid and solid ingredients. It has also been determined by scientific investigation, that the origin of diseases lies largely in the imperfect circulation of the fluid elements of the body through the capillaries, altering in turn the functional activity of the lymphatic vessels. Congestion is a disturbance, or, an obstruction in capillary circulation, whether it be in the surface of the body or in some internal organ. The consequent result, which follows even a slight interruption in these minute passages, produces obstructions which in turn, undergo changes that are fatal to the life of the elementary cell. If the harm done is slight, and the balance of the circulation is quickly regained, the symptom of this disturbance may not be even appreciable to the central nervous system. If, however, a great number of slight disturbances in the capillary circulation occur, the resulting evidence is determined by symptoms which are noticeable. There are many causes which may produce impeded vascular circulation in the minute spaces, the chief of which is some form of exposure of the body to external influences.

The first impression upon the system is necessarily received by the nervous system, and through it the influence is carried to the muscular structures. If the vitality is sufficiently strong the evil influence is scarcely appreciable, for it is the natural tendency of the system to recover from disturbed equilibrium. Few individuals there are whose physical condition is normal; consequently, the result of even a slight cause of physiologic disturbance is often productive of disaster. The point of my argument, at this time, is to establish the value, in the maintenance of normal health, of the part which is performed by preserving the quality and the volume of the circulating fluids.

The capillaries are so exquisitely small, that even the red cells themselves are unable to enter them. The watery element of the blood alone finding its way through the millions and millions of these diminutive channels. The ultimate cell depends for its nutrition upon the albumin, the fibrin and the salts which are held in solution by the water of the blood. Ever so small a disturbance in capillary circulation interrupts the processes of nature, and, if these instances occur sufficiently frequently, morbid products are retained in the lymphatics and the intercellular spaces. The efforts of physiologic action to remove and expel these products when retarded, constitutes the first.

element in inflammatory processes. The accumulation of these minute centers of interrupted action, establish an appreciable area of disease, which spreads more and more according to the state of the tissues. When the area of inflammation is sufficiently large, and destruction of cells is advanced, the heat of the body is augmented, both by the decomposition of the morbid products, and by the physiologic disturbances produced throughout the system, constituting an inflammatory fever. With the determination of the fever, other symptoms appear which hitherto were not present in our picture of pathologic changes.

The exact pathology of rheumatism is undetermined. The analyses of the blood indicate no chemie or organic changes. The cellular structures are identical with those of usual conditions found in health. Lactic acid and uric acid and other chemie substances are not found to prevail to a greater degree than at other times. The only change that is discoverable, is the diminution of red corpuscles. The various theories concerning the cause and origin of rheumatism, in the light of the exact knowledge, determined by physie and chemie analysis of the blood, are not satisfactory. The exact knowledge on the subject consists in the single, positive statement that there is alteration in the number of red cells of the blood. In addition to this it is also able to be definitely stated that there is diminution in volume of the fluid element of the blood. These facts would seem to throw the responsibility upon the capillary circulation rather than upon change in the blood chemistry. It is upon recognition of the foregoing physical alterations of the blood that my practice in the treatment of rheumatism is founded.

Postmortem examinations reveal no changes not found in other diseases. Chemie analysis of the fluids and the solids of the rheumatic body are also negative in showing the origin of this disease. The flow of urine is greatly diminished and through this condition, it is able to determine that the volume of the blood is also diminished, corresponding precisely to the symptom of scanty urine. The average number of cases, in which the urine has been calculated as to the quantity, shows a uniform decrease as well as an increase in color and specific gravity.

After very careful examination of the extensive literature on the subject of rheumatism, my conclusions are as follows: that rheumatism is, so far as the conditions of the solids and fluids of the body are concerned, a disease not dependent upon chemie changes of the fluids; nor is it due to any particular chemical that may be found, either in the fluids or the solids of the body. The only definite knowledge that is irrefutable, is that there is a change in the physical character of the blood, consisting of an alteration of the relative proportions of fluid and solid elements.

The inflammatory processes which take place are similar to those in other diseases, under similar conditions. The differences in the forms of rheumatism are produced by variations of the intensity of the disease, and the state of health at the time of attack, of the individual. The three principal symptoms of rheumatism, namely, pain, fever and swelling are able to be explained by my hypothesis. The condition of impaired nutrition, and functional derangement of the bowels, either constipation or diarrhea, is almost constant.

Clinical experience teaches me, therefore, that the

first indication in the treatment of this disease is the supply of proper and sufficient nutrition. The next indication is attention to the processes of elimination by which the system is relieved of dead matter. Nature is the greatest remedial influence in the cure, and whatever introduces new strength and saves the vitality is the safest therapeutie. Next in order in the line of remedial measures, is to restore and preserve the normal volume of the blood. If there is a reduction in the number of red blood corpuscles, that reduction, it is found, is only relative, for there is a consequent loss of serum. This condition is exactly determined to be true, by quantitative estimation of the urine of each twenty-four hours. The high specific gravity of urine, which is referred to as a prominent symptom in febrile diseases, is evidence that there is deficiency in the liquid element of the blood. Nothing could be more natural than a waste through the kidneys in proportion to the volume of blood serum, so that this symptom is so slight in importance, relative to the ease with which it can be corrected, that it is a surprise, that so much is made of it in referring to the symptoms of disease.

Every one of these pathologic and physiologic changes which have been enumerated in the paper, are directly amenable to control by the proper use of hydriatics. There is no question as to the fact. It has been so many times proven in my clinical work during the past period of six years, that it is no longer subject to the least doubt in my mind. It is not, altogether an easy matter for those not acquainted with hydriatics, to give full credence to such positive statements, unsupported by clinical demonstrations in hospital wards. Neither is it an easy matter to learn the various processes which constitute intelligent and common-sense use of water, pertaining to the cure of this disease.

Before detailing the plan which is regularly followed in my practice, it is my wish to lay before you some therapeutic measures which were recently employed in the treatment of a case of acute rheumatism in one of the Metropolitan hospitals. The recital of this list of remedies may be instructive, as it furnished me many points for thought and criticism of the prevailing measures in vogue to-day, in the treatment of rheumatism. The list comprises the following drugs and remedies used upon one and the same patient, the result of which was the fatal termination of the patient:

Here it is: Salicylic acid, salicylate of soda, gaultheria, salol, salophen, antipyrin, iodid of potassium, wine of colonicum, iron, arsenic, strychnin, bicarbonate of soda, epsom salts, bromid of sodium, morphin, turpentine, lanolin, lard, digitalis, cod-liver oil, whisky, and menthol in alcohol. Great stress was placed upon the fact that 15 grain doses of salophen, combined with 15 grains of bicarbonate of soda, were borne by the patient at intervals of every two hours. The patient grew steadily worse from the inception of the treatment, and it would be strange indeed, had it been otherwise.

The criticism of this plan of treatment is not owing to a lack of an orthodox education, or to ignorance on my part of the recommendations of the materia medica. The practice of therapeutie has been going on for a period of, perhaps, over three thousand years, and while the list of remedies presented above does not represent the sum total of our ability in the treatment of rheumatism, neither does it reflect creditably upon the education and the intelligence of a learned

profession, and it is not strange that odious comparisons are instituted by the laity between the advancement of surgical treatment compared with that of medicine. There is some excuse in the allied sciences of electricity and other departments of physics, for imperfect processes, and room for further scientific development, but it seems to me there is hardly the same excuse for a class of highly educated, broad-thinking men who have had so many centuries during which to work, and in which to perfect the treatment of diseases of the human body.

We must remember that steam and electric energy are discoveries of comparatively recent years, and that further improvements are in order and perfectly natural; but we must also remember that the human body with its physiologic and pathologic nature has been known and practiced upon for more than thirty centuries. What hope for the future would there be if the foregoing list of remedies should be taken as the total of our ability in the treatment of this disease? If our science was no older than steam or the telephone, our mistakes would be but natural and pardonable. It is not wholly the fault of the physician that such an incongruous and contradictory collection of substances should be used in the treatment of rheumatism. The education of the people and the use of drug remedies from childhood, almost force physicians to employ them in the treatment of their cases. Beside this, the circulation of enormous quantities of spurious medical literature by commercial agents, advocating and urging the use of their patented and proprietary preparations, has a harmful and misleading influence upon the younger members of the profession, who are eagerly seeking, and ready to receive information which purports to represent the very latest ideas in therapeutics. It is not my purpose to condemn or to harshly criticise any one in particular, but rather, in a sympathetically critical attitude to point the way to the truth.

The treatment of rheumatism by hydiatic processes is based now upon an experience in practice during a period of six years. The plan which is pursued is satisfactory to the highest interest of the patient and the physician. It is something that is definite; it is reliable, and the gains that are secured in the progress of the treatment are real, and can be determined with an accuracy approaching true science. The only difficulty that is experienced in pursuing the hydiatic plan, lies in the fact that it is considered by the patient and friends as novel and, therefore, to be guarded against. Besides, the support of the profession, is withheld, owing to misunderstanding, by reason of clinical inexperience, lack of actual knowledge, and doubt, which operates to the disadvantage of both the physician and his patient. It takes a great many clinical experiences to establish the courage of one's own convictions, and until belief is based upon many carefully conducted experiments, there is always room for a question whether it is right or wrong. The disposition is, among clinicians, to prove each point in practice and to lean toward conservatism. For my part, my courage is established, and the practice of hydiatics, according to my experiences, is now approaching a definite and scientific system of therapy.

For the purposes of clinical practice the gross symptoms of rheumatism are sufficient in all cases to determine the line of treatment. It is only where experiments for scientific purposes are instituted that differentiating instruments and chemic tests are

employed. When first called to see a patient it is of course impossible in most cases to exactly determine, even to my own satisfaction, the precise nature of the affection. The first inquiries that are made of the patient refer to the general condition, followed by questions and examinations to determine the details concerning the physiologic functions. Inquiry is especially directed to the excretory system, with reference to the quantity of urine which is passed, the condition of the bowels, the appearance of the skin and the mucous membrane, and especially the state of the appetite, the kind of food taken, and the habits with reference to the nature and the quantity of fluids taken as drink. The temperature of the body, the movements of the pulse and the subjective symptoms of the patient, constitute a list of inquiries sufficiently to determine the treatment. The physiologic requirement of the system is two litres of water per day. In no single instance of a case treated has this quantity been consumed by the patient prior to his sickness.

The treatment is begun by prescribing regular, definite doses of pure, soft water at frequent intervals. Each dose of water contains some harmless remedy to satisfy the notions of the patient and his friends. The amount of water which is prescribed at each dose is scientifically determined by the whole weight of the body, the age of the patient and the degree of the fever. Starting upon the basis of an average man, two to four litres of pure water is prescribed every day, in properly apportioned doses, to avoid mistakes and excessive use of water at any one time. If the patient were of seventy-five pounds weight my estimate would be that one and one-half to two litres of water would be absorbed per day with comfort and advantage. The next process in the use of hydiatics is irrigation of the bowels if circumstances favor it. One teaspoonful of elixo, a liquid soap, is mixed with the water used for irrigations. Many cases have been treated by me, in which it was inconvenient or undesirable to practice irrigation of the bowels. It is therefore, established clinically that while irrigation is in all cases an aid to treatment, still it is not indispensable.

The third hydiatic process is the use of water upon the surface of the body. If the patient is agreeable to direction and conveniently located, the full bath is recommended. The temperature of the water should be a few degrees below the temperature of the body. When the toilet room is inaccessible or it is inconvenient to remove the patient, three bathing processes are followed in my practice: 1, sponging the body with water from a basin; 2, the wet pack; and 3, the use of my sprinkle-bath. The sprinkle-bath consists of cool water applied to the surface of the body, at intervals of two or three hours, during the day and evening, by means of a small sprinkle nozzle attached to the end of the tubing of a fountain syringe, which is suspended from a chandelier, bed-post or a nail in the wall. Swelled and painful joints are packed in a compress of cold water until relief comes. Briefly speaking, the foregoing measures have availed in the treatment of rheumatism. The precise detail work must necessarily vary in every case. The food is immaterial; whatever is the most simple, the easiest to provide and which is agreeable to the patient, is all that is required. Purposely the recital of cases has been omitted. Such recitals are tedious, and for this reason are omitted from this paper.

## DISCUSSION.

DR. LOUIS FAUGERES BISHOP, of New York—I do not think we ought to pass over the subject of rheumatism without any consideration of the fact that in all probability acute rheumatism is of miasmatic origin. I think that any one who studies the whole literature of the subject will come to that conclusion.

Further discussion was interrupted by the lateness of the hour.

## MALARIA.

BY ELLSWORTH D. WHITING, A.B.

AURORA, ILL.

(The L. P. C. Freer Prize Essay, Rush Medical College, 1896.)

(Continued from page 123.)

Before entering upon a systematic study of the organism, a description of the manner in which specimens are obtained may be of advantage.

The technique of obtaining specimens for a fresh examination, though simple in theory, presents many slight, but annoying, difficulties in actual practice. The main points ever to be kept in mind are cleanliness, quickness and skill of hand and eye. The instruments necessary are a small lancet, two pairs of blood forceps, slides and cover slips. The site of puncture should be thoroughly cleansed, first with soap and water to remove dirt, secondly with alcohol to remove oily materials, and then allowed to dry.

Blood for examination may be taken from any part of the body. In adults the finger tip or lobe of the ear is most satisfactory. The writer has had most success in taking specimens from the lobe of the ear. Here there is practically no pain; a very minute puncture only is required to obtain the necessary amount of blood; it is out of the sight of the patient; immobility is easily obtained and infection is not liable to follow. The puncture of the finger tip is painful; being in the sight of the patient much annoyance is caused in children and hysteric subjects and there is more danger of infection. In infants the most desirable site is the inner surface of the heel.

Great cleanliness should also be observed in the preparation of the slide and cover slip. Both should be thoroughly cleansed immediately before using. In preparing the cover glass it should first be allowed to stand in 25 per cent. sulphuric acid for one half hour. It should then be washed in alcohol and finally dried with a perfectly clean and dry silk or linen handkerchief. In the preparation of the slide such precautions are not necessary as cleanliness can be secured by brisk rubbing.

If it is convenient it is of great advantage to have the slide as near body temperature at possible. This may be obtained by the judicious use of the alcohol lamp or by friction at the hands of an assistant.

The site of operation and the necessary articles being in readiness, a slight puncture, directed upward, is made in lowest point of the lobe of the ear. The lobe is then turned upward and the blood allowed to flow without pressure. The first few drops are wiped away when a cover glass held in blood forceps is touched to the summit of the following drop as it emerges from the opening. The slip is then quickly transferred to the slide. In order to guide and steady the hand that the cover may not touch the skin, the following procedure may be followed. Let the left hand, which is holding the lobe of the ear, rest against the neck of the patient, then by placing the fingers of the right hand, in which the cover slip is held, lightly upon the left hand, steadiness and accuracy of tactile

sense may be acquired to a remarkable degree. It is also of advantage to hold the forceps as near the cover slip as possible.

If the cover slip and slide have been perfectly cleaned; if the operation has not taken too long and the cover glass has not touched the skin nor the drop been too large, the blood on touching the slide will immediately spread out between the slide and cover glass. No pressure should be applied. On microscopic examination the corpuscles will be seen to lie separate and distinct side by side and unaltered in the surrounding plasma.

Often in spite of the most careful preparations the drop of blood will not spread, a condition which the uninitiated will be at a loss to explain. This may be explained in four ways at least:

1. After immersing in sulphuric acid, the acid may not have been entirely washed away. Especially does this occur when a number of slips are washed at the same time. Long cleansing in water is necessary to thoroughly remove the acid. When the acid can not be tasted it will do no harm in the spreading, fixing and staining processes.

2. A raveling may be found lodged in between the slide and cover slip, which prevents the hugging of the slide by the cover glass.

3. The surface of the slide may be uneven.

4. The slip may be warped.

Blood prepared in this manner will keep from one and one-half to two hours without crenating and may be kept longer by anointing the edges of the cover slip with vaselin or glycerin. In the examination of blood for the organism of malaria a one-twelfth oil immersion objective with ocular number five is recommended. These high magnifications are not absolutely necessary. Laveran made his first observations with dry lenses of low powers.

The preceding methods are the simplest and most practical for clinical work. Some observers use methods much more complex. Hayem's slide is used to some extent. This consists of a hollowed out slide. The drop is placed in the depression and protected by a cover slip. Plehn describes a most elaborate method by which he keeps microscope, slide and specimen at body temperature. He mounts his specimens in parafin and thus keeps them intact for three hours.

In the preparation of dried specimens for future staining the technique is the same except that instead of placing the drop collected on the slip upon the slide, it is placed upon a second slip, held likewise with blood forceps. The slips are left in contact from one to two seconds when they are drawn apart being continually held by forceps and the lines of force kept parallel. They are then set aside to dry with the clean side down. The drying process takes but a few moments.

When it is necessary to take dried specimens without aid, the operator is compelled to fall back upon devices which may best suit the circumstances. The writer has been very successful in the pursuance of the following plan. One cover slip is placed upon a clean piece of paper at the very edge of a table while the second cover when the drop of blood is collected is placed upon the first. As the blood cements the slips together both are raised by lifting the one in the grasp of the forceps when they may easily be separated.

Before specimens can be stained they must be

fixed. Fixation consists in bringing about some molecular change in the corpuscles in which condition certain elements take certain stains. The nature of this process is not known. Some say that the change is that of coagulation of the albumin, but this can hardly be true as carbolic acid does not fix blood. Fixation is probably simply a process of dehydration.

There are many methods by which blood is fixed. This may be accomplished by passing through a flame, heating at 120 C., immersing slips in picric acid, mercuric chlorid, absolute alcohol, osmic and glacial acetic acid or alcohol and ether, equal parts. The writer has been most successful in the use of the latter method. He generally leaves the specimens in the fixing agent for twelve hours but good results have been obtained after one-half hour's fixing. Unsuccessful attempts at fixing with alcohol and ether often arise from the fact that the alcohol is not absolute or contains enough acid to destain the specimen. Commercial alcohol is rarely pure. The reagents used in the fixing of blood should be distilled for the purpose and kept in an air-tight container.

Results obtained from heating on the graduated bar are variable, due to the fact that it is exceedingly difficult to keep the bar at an even temperature. In this method of fixing, an ordinary one-burner oil stove is used. Across the top of the stove is placed a copper bar two feet in length, four inches in width and one-eighth of an inch in thickness. After the bar has attained a stationary degree of temperature, the boiling point is determined. This is accomplished by dropping water upon the bar and noting the point at which it boils. At this point a line is drawn across the bar and a row of slips, smear side down, are placed one inch within this line. The specimens are permitted to remain at this temperature from one to three hours. Although simple of description this method is open to many criticisms. The apparatus must be continually watched, as a rise of temperature ruins the specimens. It is best to protect the bar as much as possible from drafts and to determine the temperature every few moments with water.

Many investigators have used an oven in which the temperature may be accurately regulated. By means of this device good results have been obtained.

The parasite of malaria takes the stain of all basic anilin dyes. It is unaffected by the acid dyes except when they are of great strength and left in contact with the organism a long time. These facts have given rise to a host of methods of staining, a description of all of which would be futile; therefore a few of the more important ones will be described.

An exceedingly interesting and ingenious method is given by Celli and Guarnieri, who succeeded in staining the parasite while alive. For this purpose they employed aseptic ascitic transudation in which methylene blue was dissolved. They placed this solution over the site of the puncture, allowing the blood to flow with the fluid, which was quickly transferred to the slide. It was then kept in a warm moist chamber for three hours, when the organisms were seen to be well stained. This method, however, does not procure permanent specimens.

Chenzinsky successfully stained specimens which had been previously fixed and dried by placing them for five minutes in a mixture composed of a 50 per cent. aqueous solution of methylene blue, and an equal amount of 5 per cent. of eosin, in 60 per cent. alcohol.

A cumbersome yet ingenious plan has been devised by Feletti. After allowing a 25 per cent. alcoholic solution of methylene blue to dry upon a slide he places upon it a cover slip upon which a drop of blood has been collected. He then surrounds the cover slip with parafin. The serum of the blood dissolves the methylene blue, which stains the organisms.

Mannaberg, after fixing the specimens in alcohol and ether, equal parts, for half an hour, stains them in a concentrated aqueous solution of methylene blue for an equal length of time. After having been washed and dried in water, the specimens are left for thirty minutes in a 2 per cent. solution of eosin in 60 per cent. alcohol. They are then washed, dried and mounted in balsam.

The method described by Romanowsky is effective yet impracticable for routine work. Immediately before using, he makes a fresh solution composed of one part of a filtered, saturated, aqueous solution of methylene blue, to two parts of a 1 per cent. watery solution of eosin. The specimens, fixed by heat, are floated smear side down upon this mixture, contained in a watch glass. The specimen is covered by an inverted glass and the whole enclosed in a moistened beaker. The specimens are allowed to remain in this solution from one-half hour to three hours. By this method Romanowsky claims that he stains the red corpuscles red, the parasites blue and the nuclear chromatin violet.

Mannaberg has devised a method by which he brings out in great clearness the finer structure of the parasite. At first the dried specimens are floated for a few moments upon distilled water, and after being dried are bathed in dilute acetic acid until there is a complete disappearance of the hemoglobin. The specimens are then permitted to float for two hours upon the following fixing solution:

Concentrated aqueous picric acid . . .	20 c.cm.
Distilled water . . . . .	30 c.cm.
Glacial acetic acid . . . . .	1 c.cm.

The specimens are next placed in absolute alcohol for twenty-four hours. After this they are stained from twelve to twenty-four hours in a solution consisting of one part of hematoxylin (hematoxylin grams 10 to 100 c.c. acid alcohol) to two parts of a .5 per cent. ammonia alum solution. The specimens are destained in acid alcohol (hydrochloric acid 25 per cent., alcohol 75 per cent.) and ammonia alcohol (three drops of ammonia to 10 c.cm. 75 per cent. alcohol). They are then washed in 8 per cent. alcohol and mounted in balsam. By this method the parasite and leucocytes are stained blue, the red corpuscles being colorless.

The preceding methods and numerous others have been used since the discovery of the organism by Laveran and the staining methods set forth by him. Moreover, the method advised by him, although the simplest and oldest, is most practical and efficient for ordinary use. Laveran fixes blood in alcohol and ether equal parts. He first places the specimen, for thirty seconds, in concentrated aqueous eosin, and after washing and drying, stains for thirty seconds in concentrated aqueous methylene blue.

In his experimentation with staining the malarial organism the writer, although he has used the methods of Laveran to considerable advantage, has been most successful in the use of methylene blue alone. He finds that as the organism is endoglobular, its outline is blurred to some extent by the eosin. Speci-

mens stained in aqueous solutions are more easily decolorized by washing in water than those stained in alcoholic solutions.

No definite limit can be given to the length of time and strength of dye required to properly stain a specimen, even when the strength of the staining reagent is known. These points can be accurately estimated for normal blood, but as it is a rare occurrence for two pathologic specimens to be physiologically the same, their staining is necessarily a subject of great variance. To procure a properly stained specimen it is necessary to obtain its stain-absorbing qualities by making a test specimen. This is accomplished by applying a stain of known strength for a certain noted time. Using this as a guide, a good specimen may be obtained by varying the strength of the stain and length of the time of its application. A good standard for comparison may be found in the leucocytes. When the small lymphocytes take a deep blue stain and the large polynuclear neutrophils a faint blue, the methylene blue is of proper strength. When the leucocytes are thus colored the malarial organism will be distinctly stained and therefore recognizable. The eosin should but faintly color the red corpuscles.

When the staining is completed previous errors, if they exist, are brought to light. If acid is present, specimens refuse to stain. If the specimen is thick individual corpuscles are not distinguishable. If the blood has been allowed to dry before separation of the slips the corpuscles are not arranged evenly, but in concentric circles and rows. If the blood was forced from puncture there will be a large amount of plasma present which will obscure the field. If fixing material has not been pure, the specimen will not stain. If the heating apparatus has become overheated the corpuscles will be ruptured, charred and disintegrated.

In the examination of blood for the "plasmodium malarie" most satisfactory results are obtained by examining fresh specimens. The great advantage of this method lies in the fact that the ameboid movements of the organism may be observed.

The organism must be differentiated from, 1, blood plaques; 2, vacuoles; 3, discs of red corpuscles; 4, crenated corpuscles; 5, oil globules (?).

1. The blood plaques are colorless, extra-corpuscular and might be readily mistaken for hyalin forms of the organism, were the ameboid movement not considered. The plaques are more translucent, their outlines more clearly marked and irregular than hyalin bodies. There is a tendency toward the grouping of the plaques in grape-like clusters. On staining they take the methylene blue, as does the organism, and must be differentiated by position and contour.

2. The vacuoles are lighter in color, translucent, outlines distinctly marked, are non-motile and always spherical in form.

3. Discs of red blood corpuscles are spherical and when present are usually found in large numbers and situated in the center of the corpuscle, except in cases of poikilocytosis. These discs are of indistinct outline, non-motile, and when present in small numbers they can only be differentiated from resting hyalin bodies by staining methods.

4. Crenated corpuscles appear as coarsely spiculated balls. These spicula are caused by the irregular contraction of the cell wall of the red corpuscle(?). Although colorless these spicula appear black when

viewed through reflected light, and on this account are often mistaken for pigmented organisms.

5. It is scarcely necessary to differentiate hyalin bodies from minute, spherical, translucent, rapidly moving bodies which are frequently seen in the blood of malarial patients. These particles are found in normal blood and their nature is unknown, but they probably consist of oil globules from sebaceous glands, commingled with the blood during its exit from the puncture.

It is of vast importance in the differentiation of the hyalin bodies from the foregoing bodies to note the kinds of motion visible under the microscope. In the field can be seen distinct currents, probably produced by heat radiation. These currents give to the corpuscles a vibratory, oscillating and rotary motion, which is in turn transmitted to the contents of the corpuscle. These movements are possessed by all of the previously described bodies, plaques, vacuoles, discs, crenated corpuscles, and oil globules, and must not be confounded with the ameboid movements of the malarial organism, which is entirely independent of currents; is slow and characterized by a change in form of the parasite.

Through the opportunities afforded by the medical clinics of Rush Medical College and the medical wards of Presbyterian and Cook County Hospitals the writer has been able to observe and study the blood changes in many malarial patients. The classification proposed by Thayer and Hewetson will be adopted in the following description:

In describing the tertian parasite the writer will make use of a series of specimens taken from a patient in Cook County Hospital, exhibiting tertian paroxysms. Specimens were taken every four hours, night and day, for forty-eight hours. In this manner a complete cycle of the life of the organism was obtained. By a microscopic examination of these specimens stained with methylene blue the entire development of the organism was traced with remarkable accuracy. Fresh specimens were examined as far as possible. The patient's history is taken from history sheets of the hospital, and the temperature recorded by the writer at the time the specimens were taken. The blood count was made after the series was completed.

James W., admitted Feb. 2, 1896; age 31; born in Scotland; single; carpenter by trade. Family history: father had stroke of paralysis some years ago, but is still living; otherwise negative. Personal history: has been in Chicago eighteen months; drinks occasionally, smokes, habits regular, no venereal history; has been working of late in Brighton Park. Previous illness: measles and whooping cough. Present illness: had first chill last April, which was followed by chills every other day. These disappeared upon the administration of quinin, but reappeared late in September, occurring every other day. The attacks were again stopped by quinin. The last attack began February 1 and patient has had a chill every other day since. Chills occur between 6 and 8 o'clock in the morning. During the chill the patient complains of great pain in the back, head, left side and shoulder; the chills are followed by high, burning fever, profuse perspiration and great prostration. Appetite poor and bowels regular.

Physical examination.—Body well nourished; mind, clear; eyes and pupils normal; tongue, clean; pulse, full and strong; thorax, well developed; heart negative; lungs, negative. Abdomen: liver normal; spleen (palpable) is situated in mammary line from sixth rib to one inch below costal arch. Limbs, negative; no adenopathy. Hemoglobin, 67½ per cent.; red corpuscles, 4,500,000; white corpuscles, 5,000.

In this description of a serial examination the writer shall attempt to follow out the development of the organism, commencing with the group of hyaline bodies

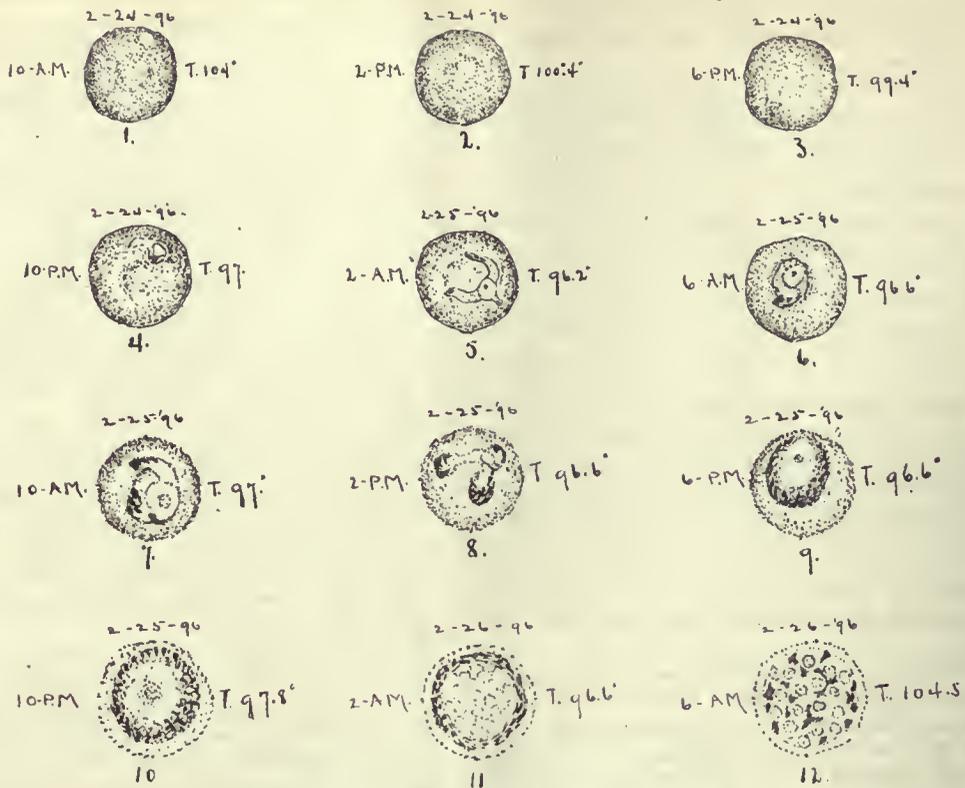

PLATE IX.—THE PARASITE OF TERTIAN FEVER.

EXPLANATORY.—1, 2, 3, Hyaline Forms; 4, 5, Beginning Pigmentation and Appearance of Nucleus; 6, Appearance of Nucleolus; 7, 8, 9, Further Development of Organelms; 10, Full-grown Organism; 11, 12, Segmenting Forms. Magnification—Zeiss, Obj. 1-12 oil immer., Oc. 5. From James W., C. C. H., W. 4. See also Plate XIV.

present in the first specimen. However, he wishes it distinctly understood that he does not for an instant intimate that the separate stages of the parasite described include all the organisms present in the blood at the stated times. As a matter of fact, in every slide examined adult, intermediate and hyaline bodies were demonstrable, although these latter forms in some instances were present in small numbers. In

the great majority of cases of malaria examined by the writer he has been able to demonstrate every form of the organism at any time during the course of the disease. This fact has therefore led him to conclude that pure forms rarely or never exist. The symptoms are caused by larger groups of organisms.

The first specimen (Plate ix, Fig. 1) was taken Feb-

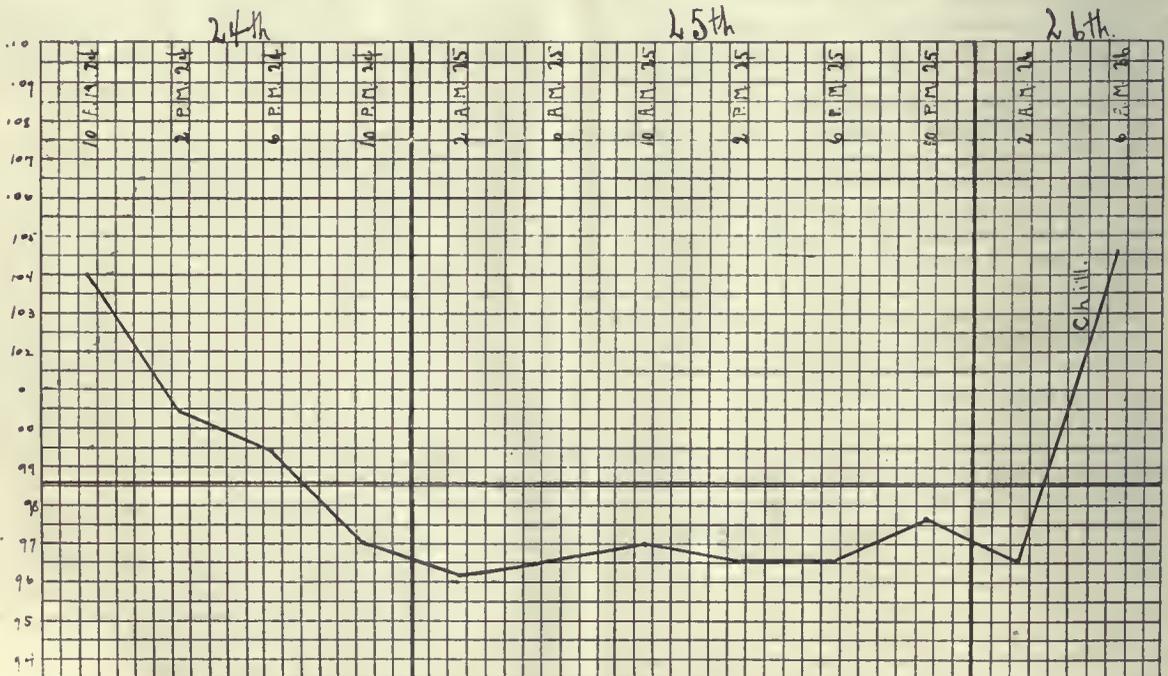

PLATE XIV.—INTERMITTENT TERTIAN FEVER, TEMPERATURE CHART. James W., Cook County Hospital, Ward 4, February 24, 25 and 26, 1896. See also Plate IX.

ruary 24 at 10 o'clock in the forenoon, one hour after the chill, the temperature being 104 degrees F.

On examination of fresh specimens, many organisms were present in various stages of development, the hyaline forms, however, being in the greatest numbers. These consisted of small, round, endoglobular motile bodies. The amoeboid movement at this stage was marked, a complete change of shape taking place in a few moments. These forms have been described as colorless, but this is probably not strictly true, as they seem to possess a very faint shade of color similar to that of the red corpuscle. The borders were indistinct, the blending thus produced often making it difficult to distinguish the point where organism ended and corpuscle began. Although there were organisms within and outside the corpuscles, none were seen in the act of entering, a circumstance which has never been observed. At this stage no nucleus could be demonstrated in the fresh specimen.

Specimens were also stained with methylene blue. The periphery of the organisms took a greenish-blue stain, fading toward the center into a lighter shade of the same color, indicating the embryonic nucleus. In this specimen, beside the adult and hyaline bodies many degenerate forms of the organism, together with degenerate red corpuscles and free pigment granules, were present.

The second specimen (Plate ix, Fig. 2), taken the same day at 2 P.M., the temperature having fallen to 100.4 F., showed a large number of hyaline forms somewhat larger than those observed in the first specimen. These possessed the same activity, no pigmentation was demonstrable. A marked decrease in the number of adult organisms was noticed, also the absence of free pigment.

The third specimen (Plate ix, Fig. 3), taken the same day at 6 P.M., the temperature being 99.4 F., showed the same characteristics as the foregoing, except that the hyaline bodies were larger and a more clearly defined nucleus was present. This nucleus nearly filled the organism. In most instances it was round, regular and distinctly outlined. On staining with methylene blue, while the surrounding protoplasm took a deep greenish-blue color, the refractive nucleus showed a faint blue. No nucleolus was demonstrable.

Specimen four (Plate ix, Fig. 4) taken the same evening at 10 o'clock, temperature 97 F., showed that the organisms had increased in size, and for the first time an increase in size of the red corpuscles was noted. Slight pigmentation was also observed in the periphery and pseudopodia. This pigmentation consisted of small brownish granules or rods, closely resembling bacilli. These were in rapid motion. This motion was not brownian in character, as the granules appeared to pass from one portion of the organism to another. The nucleus was well marked. By careful focusing, a small area at the side of the nucleus, encroaching upon the cell body, was observed in stained specimens. This area, which is composed of chromatic filaments, stains with methylene blue and corresponds to the nucleolus of Mannaberg, Feletti and Grassi, and was demonstrated in only a few instances. At this stage the peculiar forms which the parasite assumes were very apparent. At times the organism would lengthen out into a long, curved, crescent shape. Again it would assume a spherical contour, or the form of a cross.

The fifth specimen (Plate ix, Fig. 5) showed a pro-

gressive growth in both size of organism and number of granules. There was also present a pronounced increase in the size of the corpuscle with a noticeable decrease in its coloring matter. However the most marked new feature was the decided prominence of the nucleolus which though scarcely perceptible in the former specimens could be easily seen in this one. The chromatin fibers in one instance filled up fully one-eighth of the nucleus while a few could be traced to the nuclear membrane.

Specimens six, seven and eight (Plate ix, Figs. 6, 7, 8) showed a decrease in the number of organisms present. However, in those present there was noted an increase in pigmentation, size of organism and corpuscle.

On examination of specimen nine (Plate ix, Fig. 9) several startling facts were brought to light. As if by magic the field teemed with organisms in numerous instances, as many as ten organisms being present in the same field at the same time. The explanation of this phenomenon, that is, the great difference in the number of organisms present in so short a time, probably is that the parasites were collected in the internal organs when specimens six, seven and eight were obtained. These organisms showed especially a great growth of nucleus and nucleolus. In many cases the ectoplasm, or portion surrounding the nucleus, staining deeply and containing the pigment, formed but a narrow band around the nucleus. The nucleus often seemed to be double, consisting of two equal or unequal portions. On close observation and careful focusing it was possible to distinguish narrow bands of ectoplasm stretching over the nucleus or endoplasm, but not *through* it. Some organisms of normal size and appearance were present which appeared to possess no nucleus, but here again very often careful focusing showed that we were probably looking upon that portion of the ectoplasm which covers the endoplasm. In some instances organisms of this description showed no nucleus whatever. There were moreover, many large extra corpuscular, irregular, granular, pigmented bodies having no nuclei which were probably degenerated organisms. These bodies were often filled with vacuoles.

In specimens ten, eleven and twelve (Plate ix, Figs. 10, 11, 12) were found many adult forms which in size equaled that of red corpuscles. These were endoglobular or free in the plasma. When intra-corpuscular the corpuscle was greatly enlarged and decolorized, the cell wall showing as a thin film. The pigment granules were motionless.

In specimens eleven and twelve (Plate ix, Figs. 11-12) segmentation was observed in two forms. In the first a very large nucleus was observed, in which, and partially filling it, could be made out faintly staining, sporelike bodies, numbering from fifteen to thirty. The second form showed the organism diffusely and faintly stained throughout, in which pigment granules and sporelike bodies were scattered. This second form was probably a later stage of the first described, and resulted from the rupture of the nuclear membrane, setting free the sporelike bodies or daughter-nucleoli into the ectoplasm. These bodies seemed to contain distinct nuclei, and though non-motile while in the organism, appeared to acquire motion on reaching the plasma of the blood. In no instances was fragmentation observed, nor Golgi's rosette forms.

Thus we have followed the tertian organism through

the cycle of its existence, and have once more arrived at the hyaline forms.

As regards the function and mode of reproduction of the elementary parts of the organism there is to-day a difference of opinion. Grassi and Feletti are of the opinion that the process of reproduction originates in the nucleolus. This, on dividing, is at first surrounded by the nuclear juice, a semifluid substance, which, together with the fibrils running from the nucleolus to the nuclear membrane forms the nucleus. In a short time these daughter nucleoli receive membranes and constitute the spores. The pigment is developed and retained in the surrounding ectoplasm. These pigment granules he supposes are formed from the hemoglobin of the corpuscle, but do not react to tests for iron.

Romanowsky goes so far as to say that by the use of eosin and methylene blue he has been able to distinguish karyokinesis during segmentation.

Mannaberg, in speaking of the development of pigment, agrees that it is first seen at the periphery of the organism in the outer plasma or ectoplasm. His theory of reproduction is unique. He holds that the nucleolus shortly before segmentation entirely disappears, withdrawing from the nuclear portion of the organism into the ectoplasm. It soon reappears in the nucleus and segmentation progresses as described by Grassi and Feletti. Investigators agree that reproduction is in all probability accomplished in the same manner in the parasites of tertian and quartan fever, but in the estivo-autumnal type no nucleus has as yet been demonstrated.

There is to-day, as there was at first, a difference of opinion in regard to the nature of the flagellate bodies. The two theories still exist, Laveran and his associates contending that these forms are reproductive in their functions, while Golgi and his followers insist that they are degenerate. The theory that they are produced by thermic influences has been generally abandoned.

(To be continued.)

## A NEW OPERATION FOR THE RADICAL CURE OF INGUINAL HERNIA.

BY GEORGE TULLY VAUGHAN, M.D.

P. A. SURGEON, U.S. M.-H.S.; IN COMMAND UNITED STATES MARINE-HOSPITAL SERVICE AT PHILADELPHIA, PA.

Of the various operations for the radical cure of inguinal hernia, I believe it is generally agreed that those of Bassini and Halsted respectively are the best; as to the choice between these two methods there is some difference of opinion.

Unquestionably the method of Bassini comes nearer to restoring the tissues to their original condition and relations before they were stretched and distorted by the protruding viscus than any other operation now before the profession, and the number of relapses following this operation when carefully done is probably less than from any other.

Halsted's method has the appearance of strengthening a naturally weak place in the abdominal wall by increasing its thickness beneath the cord by the addition of the aponeurosis of the external oblique and some fibers of the internal oblique and transversalis muscles, but he brings the cord straight through the entire thickness of the abdominal wall (except the skin and fascia) at a point slightly higher and more external than the normal position, dividing par-

tially the external, internal, and transversalis muscles in order to do so.

In the operation proposed the normal inguinal canal is obliterated, the cord is placed deep, next the peritoneum and passes through the abdominal wall both obliquely and where it is strongest, more than half the circumference of the anterior opening being formed by bone and tendon.

Another advantage is that the two ends of the inguinal canal are placed nearer on the same level, so that a viscus engaging in the posterior end would not have the same tendency, not being aided by gravity, to descend through the canal, as it does when the anterior opening is lower than the posterior.

Two objections would naturally be suggested to this operation; 1, that division of the muscles forming the conjoined tendon weakens the abdominal wall, and 2, that the new position of the cord may produce constriction and harm the testicle. To the first objection it may be said that with aseptic care and accurate approximation the muscle unites through the medium of muscular tissue not connective tissue. (See Senn, Principles of Surgery 1896, p. 46, and others) and is probably as strong as ever.

So far as I have heard, Halsted has had no trouble from dividing the muscular fibers above the internal ring and relapses from Halsted's operation, judging from my own experience, are owing to the cord being brought straight through the abdominal wall instead of obliquely, and, that this opening is surrounded by yielding muscle unsupported by bone or tendon. In reply to the latter objection I can only say that there has been no interference with the integrity of the testicle in any of my cases. The objection to bringing the cord out over the symphysis pubis in a more exposed position is of no importance.

The operation is performed as follows:

1. Make an incision over the inguinal canal from the internal abdominal ring to the center of the symphysis pubis through the skin and fascia; then split the fibers of the aponeurosis of the external oblique, exposing the cord and hernial sac.

2. Separate the sac from the cord, ligate or sew across well within the internal ring and cut off the redundant part.

3. Divide the conjoined tendon through its muscular part four or five centimeters above its insertion including the internal pillar of the ring, down to the peritoneum, avoiding the deep epigastric artery.

Separate by blunt dissection the conjoined tendon from the rectus and pyramidalis muscles down to the pubic bone and place the cord in this position between the conjoined tendon and rectus. The cord still passes through an oblique canal at its anterior portion, as the conjoined tendon overlaps the rectus and pyramidalis for two and a half centimeters or more, being inserted in front of these muscles. Unite the divided ends of the conjoined tendon and of the internal pillar with mattress sutures, and accurately approximate them with continuous or interrupted sutures.

4. Close the old inguinal canal with interrupted sutures, uniting Poupart's ligament to the conjoined tendon, and in the outer part including the transversalis fascia over the cord. I usually pass two or three of these sutures through the conjoined tendon to include the edge of the rectus.

5. Unite the superficial structures with a continuous suture and the skin with a subcuticular suture.

Kangaroo tendon is the best suture material to be

used throughout the operation. The cord is thus placed next the peritoneum and brought obliquely through the abdominal wall at the strongest point. This operation is more difficult and requires rather more time in its performance than that of Bassini. I have performed it only five times but so far as known the results are all that could be desired. One patient was seen five months after the operation. He had been at work and was then in good condition. The others have not been heard from though they were requested to write to me in case of relapse.

## SELECTIONS.

**Pica or Dirt-eating Among Children.**—In Volume I of the *Edinburgh Hospital Reports* for 1895, Dr. John Thomson publishes a study of this morbid habit in the various parts and periods of our planet. It is his belief that the dirt has a well defined hygienic value, and is eaten by children for medical purposes. The physical ailment which brings on the appetite for dirt is in most cases anemia, which simply means a running down of the system. In these cases, the habit might be formed from an instinctive craving for earthy salts, such as iron and lime, just as a cat or dog, when needing a little physic, will eat a blade or so of grass. The eating of substances of various kinds which are not wholly indigestible, but are also devoid of any natural attractiveness of taste, is a morbid habit which has often been observed both in human beings and among certain of the lower animals. Many names have been applied to this craving, such as pica or kitta (the Latin and Greek words for a jay or magpie), geophagie, allotriophagia, malacia, mal d'estomac; and it has been observed to occur under a considerable variety of conditions. From his experience and that of others in the reported cases collated by him, Dr. Thomson formulates the following eight principal points of the natural history of this affection: 1. Surroundings and upbringings. Some of the patients had been much neglected in every way; but quite as many of them were evidently, so far, at least, as their bodily condition was concerned, most carefully tended. The moral training may, perhaps, have been deficient, however. 2. Bodily condition. In many of the cases diarrhea existed, in some otorrhoea, and other minor complaints. In most there was no sign of organic disease, no special anemia, and no indication of the presence of worms. No connection could be traced between the commencement of the habit and the state of the teeth, or of the diet in any case. 3. Mental condition. All the children seemed quite normal mentally, and there was no other bad habit constantly, or even frequently, found associated with this one. 4. Beginning of the habit. When the pica began it was often difficult to fix the time exactly, because it had attracted so little attention at first; but the age given varied from four to eighteen months. Probably this depended chiefly on the chances the child had of getting at the forbidden articles, his freedom from restraint, and his powers of locomotion. 5. Cessation of craving. It is interesting to notice that in those cases where the habit was formed in early infancy, and where the patient was some time under observation, the craving ceased entirely (in all but one instance) at about the age of three years. This seems probably connected with the growth of the child's intelligence and the widening of its interests. 6. Substances eaten. In some cases only one or two abnormal things are eaten; in many, almost anything within reach is swallowed. From the cases reported here and elsewhere it seems that the variety of the unnatural substances craved for is much more limited in cachectic cases than in those beginning in young babies. 7. Physiognomy. Children who have suffered from pica for some time usually have a peculiar look about the face. Their complexion has not the rosy tint of healthy child-

hood, it lacks clearness, and is dull and unhealthy looking. 8. Results of the practice. In those of the cases in which the children were allowed to indulge their craving to any great extent, there was always some diarrhea, and occasionally obstruction from impaction of hard bodies in the rectum. In none of his cases was the patient ever seriously ill as the result of the habit, but instances have been recorded which have ended fatally. Under the head of treatment, the author holds that medication plays but a small part, while a modification of the morbid environment is the main issue, and in this relation the following summary will point out the chief indications: 1. Keep the child away from the substances for which he has a morbid craving. All habits are strengthened by practice, and their hold slackens under disuse. 2. Improve the condition of the digestion. It seems more than likely that local uneasiness often plays some part in the etiology. 3. Improve the general health. It is to the weakly that such cravings come, and the strong readily throw them off. 4. If possible, change the child's surroundings and take his mind up with new things, and let him be kept busy and happy. 5. The small amount of dirt eaten by children will do little harm of itself, but the great danger is that they will ingest something poisonous or some parasite which, once entering the stomach will reverse the operation by preying upon the patient.

**Diagnosis and Indications for Treatment of Intra-Abdominal Injuries Without External Evidence of Violence.**—Dr. John B. Deaver says: In severe intra-abdominal injuries there are a few symptoms common to all, and in the majority of cases warrant immediate operation. Most prominent of these is pain accompanied by shock. The pain is not like that of ordinary intra-abdominal affections, but is accompanied by consciousness of impending death. When vomiting is associated with agonizing pain and tympanites is also present, indications point to intestinal or vesical rupture. Collapse with evidences of rapid exsanguination point to hemorrhage from rupture of one of the larger vessels, liver or spleen. There is often a characteristic rigidity of the abdominal walls, due to intra-abdominal irritation. It is sometimes so pronounced as to call to mind the checker-board appearance of the normal abdominal wall as represented in sketches by artists of former times. This condition of the walls is invariably associated with some form of serious lesion. In injuries of the abdomen in the female, pregnancy normal or extra-uterine, ovarian tumors, pyosalpinx, etc., must be borne in mind. Rupture of any of the solid viscera is usually followed by fatal hemorrhage.

The symptoms of rupture of the liver are usually great lividity of the skin, marked embarrassment of respiration, distention of the abdomen which is not altogether tympanitic, itchininess of the skin, and, if the patient survives the immediate effects of the injury, jaundice. Rupture of the gall-bladder or biliary ducts may occur as the result of blows upon the abdomen, especially if the gall-bladder be filled with gall-stones. The commonest seat of rupture of the biliary organs is the cystic duct. Peritonitis follows rupture of the gall-bladder or ducts. If the tear be small and the leakage slow, the escaping bile may become encysted and the peritonitis remain localized. If rapid, there will be general peritonitis and death. If there be no rapid extravasation, there will be collapse, vomiting and dyspnea and abdominal pain. If the bile escapes into the general peritoneal cavity, there will be prompt general acute peritonitis, with intense jaundice and clay-colored stools. When the gall-bladder has been ruptured death almost invariably follows.

The treatment of laceration of the liver, gall-bladder, hepatic, cystic, or common duct resolves itself into prompt surgical interference.

If a tear of the liver be superficial, by early operative interference we are enabled to remove the blood and bile which

have escaped into the peritoneal cavity, to surround the rent with strips of gauze with a twofold object: 1, to prevent a second invasion of the peritoneal cavity by blood or bile; and 2, to invite adhesions between the liver and parietal peritoneum. The hemorrhage can be controlled by searing the torn surfaces with the actual or thermal cautery or packing with gauze strips. When the tear in the liver is of such a character as to permit of suture, the latter, which should include the capsule, should be used. If there is doubt as to the thorough control of the hemorrhage by the sutures, the wound should be treated by the open method, gauze strips being placed between the liver and the parietal peritoneum to the outer side of the line of suture. When the gall-bladder, the hepatic, cystic, or common duct has been torn alone or in connection with injury to the liver, it may be necessary to establish a biliary fistula; however, the attempt, if possible, to suture the bladder or duct should be made.

Injury to the splenic artery or vein is invariably followed by sudden death. The symptoms of ruptured spleen are those of exsanguination, precordial pain, gasping and shortness of breath (air-hunger), weak, rapid pulse, vomiting and thirst. When the spleen has been the seat of the injury under consideration its removal should follow.

Rupture of the kidney varies in intensity and location. Laceration of the pelvis or ureter is not immediately fatal as hemorrhage is not profuse. The inflammation following obliterates the duct, consequently there will be developed in a few days a hydronephrosis, with a corresponding tumor of the loin. The kidney will sometimes become a multilocular abscess after long periods of time when the impervious ureter atrophies. Collapse invariably follows severe injury of the kidney and is accompanied by pain in the lumbar or hypochondriac region, vomiting and an anxious countenance.

If there is a history of severe injury to the abdomen or loin, followed by faintness, anxious countenance, coldness, vomiting and severe abdominal pain; if the urine contain blood in quantities, either clotted or mixed, immediately or within a day or so after the accident; if in several days pus appear as well as blood; if there is a rigidity of the lumbar or abdominal muscles and ureteral pain with retraction of the testicle; and if these symptoms are followed by enlargement of the lumbar and hypochondriac regions, with percussion dullness, we may be fairly sure that extensive renal laceration has occurred. Rupture of the ureter is extremely rare; in a few cases reported, the tear was so close to the hilus of the kidney that practically they may be considered as rupture of the kidney itself. The symptoms are the same and the treatment identical.

There are many symptoms common to both gastric and intestinal rupture and can be described together. The immediate symptoms are faintness, collapse, agonizing pain, either localized or general, weak, rapid pulse, thirst, vomiting, tympanites, and rigidity of the abdominal walls accompanied by extreme tenderness. The facial expression is indicative of the serious nature of the intra-abdominal lesion. We should never wait for secondary symptoms if the patient's condition warrants operative interference. Where operation has not been resorted to the above symptoms may redevelop at a later period in an insidious and unexpected manner, and the patient suddenly expire from either shock or general septic peritonitis due to intestinal perforation from pressure necrosis. Incomplete tears of the stomach do no produce sufficient symptoms to render their recognition possible. When the wound is in the immediate neighborhood of the pylorus, and particularly if it is longitudinal, it will be necessary to introduce the sutures in the line of the long axis of the stomach in order to avoid constriction of the orifice. The early recognition of rupture of the bladder is of paramount importance to a successful termination of a case. The introduction of a catheter will definitely settle the question of its rupture. If no urine escapes, but

instead a few drops or a considerable quantity of blood, the inference should be that the organ has been torn. Before the catheter is withdrawn a measured quantity of boric acid or normal saline solution should be injected, when if the full amount thrown in is not recovered there can be no question of the nature of the injury. If the tear be intraperitoneal more liquid than that thrown in may be recovered or perhaps less. Where the tear is so small as to prevent the free escape of the injected fluid or where the opening in the bladder is valve-like, occasioned by a loop of intestine becoming herniated through it, this means of diagnosis may fail. In either event the prevesical space should be immediately opened, when it can be decided whether an extra- or intraperitoneal rupture exists. When the rent in the bladder is extraperitoneal, it is necessary to drain the prevesical space by a drainage-tube carried through the abdominal incision; if the urine has found its way along the sides of the pelvis, drainage should be introduced laterally through an incision above and to the outer side of the middle of Poupart's ligament. The bladder is also to be opened by a lateral incision through the perineum. The diagnosis of injury to the vascular system is unsatisfactory at best, as the injury to the vessel may be complicated by an injury to the abdominal viscera, entirely overshadowing the blood vessel lesion. The prognosis is grave under all circumstances, even when there has been only a contusion; there is the possibility of future aneurysm from weakened vessel wall, the result of the trauma.—*University Med. Mag.*, July.

**Malarial Parasitic Infection Diffused by Air-Currents as Well as by Water.**—Dr. P. Manson has given in the *London Lancet*, a clear and concise statement of his views regarding the spread of malarial fevers, inclusive of his original theory that the mosquito is the intermediate host of plasmodium or malaria, with many observed facts and his conjectures dovetailing in with those facts, in order to complete the parasitic cycle. "It can not be doubted," he says, "that there are many cogent reasons for believing that the plasmodium malariae on leaving man, and as a normal step in its life history, becomes parasitic in the mosquito, and that in this insect it enters some cell—as any gregarine or coccidium would do—and probably develops into its reproductive sporulating form just as it does in the blood corpuscles of man. What then? How can its spores get out of the mosquito so as to increase and multiply and preserve its species from extinction when, in the course of nature, the mosquito dies? How, too, does it spread over the land and how does it get back to man again? Before attempting to answer these questions, I must first describe very briefly a passage in the life of the mosquito. The female mosquito, after she has filled herself with blood—the male insect is not a blood-sucker—seeks out some dark and sheltered spot near stagnant water. At the end of about six days she quits her shelter and, alighting on the surface of the water deposits her eggs thereon. She then dies and as a rule falls into the water beside her eggs. The eggs float about for a time and then in due course each gives birth to a tiny swimming larva; these larvæ, in virtue of a voracious appetite, grow apace, casting their skins several times to admit of growth. Later they pass into the nymphal stage during which, after a time, they float on the surface of the water. Finally, the shell of the nymph cracks along its dorsal surface and a young mosquito emerges. Standing, as on a raft, on the empty pelt the young mosquito floats on the surface of the water while its wings are drying and acquiring rigidity. When this is complete it flies away. The young mosquito larvæ to satisfy their prodigious appetites devour everything eatable they come across, and one of the first things they eat, if they get the chance, is the dead body of their parent, now soft and sodden from decomposition and long immersion. They even devour their own cast-off skins. In examining mosquito larvæ one often comes across

specimens whose alimentary canals are stuffed with scales, fragments of limbs, and other remains of the parental insect. As we have seen that the mosquito larva devours its own and its neighbor's exuviae, we can readily understand how, once gregarines have been introduced into a pool of water, the larval mosquitoes in that particular pool become infected by the parasite. But as the mature mosquito, when she quits her nymphal husk, also contains numerous gregarines we can also understand how she, too, carries the infection with her, scattering it about the country in her feces or conveying it to any other pool where she may lay her eggs and afterward die. Her body is then devoured by her progeny, or by any other mosquito larva that already chance to be in the pool. Along with her body the larva swallow any gregarine germs it may contain, if they have not already been picked up by the larva when feeding on the mud at the bottom of the pool. Does not this little story of the gregarine indicate the way, or a way, in which that other mosquito sporozoon, the plasmodium malariae, multiplies? Does it not indicate how this parasite, in which man is so much interested, passes from mosquito to larva, from larva to mosquito in never-ending series? Does it not indicate how the plasmodium disease of mosquitoes spreads from pool to pool and is scattered broadcast about the country, and does it not indicate how it may get back to man again? We can readily understand how the mosquito-bred plasmodium may be swallowed by a man in water, as so many disease germs are, and we can readily understand how it may be inhaled in dust. Mosquito-haunted pools dry up. The plasmodium in the larva and those that have been scattered about in the water finding themselves stranded by the drought and so placed in a condition unfavorable to development, pass into a resting stage, just as they do, when by quinin or other means, man is rendered temporarily unsuited for their active life. The dried specimen of the pool, blown about by the winds and currents of air, is inhaled by man, and so the plasmodium finds its way back again to the host from whom its ancestors had, perhaps, started generations back. I would conjecture that on entering man and on entering the larval mosquito it develops into a flagellated spore similar to the flagellated spore into which it develops in the mosquito's stomach. In this way it would be enabled to penetrate the mucous surfaces and get into the human blood-cell. Many mosquitoes die without getting to water; all male mosquitoes die without seeking water. They may die far from water, blown away, as we know mosquitoes are, by winds. The bodies of such mosquitoes fall in time on the soil and decompose. The parasites they contain pass into the resting stage, and in this form they also may be carried into the air by currents, or be blown about as dust, or be shaken out by man when he disturbs the soil. In this way the plasmodium may find a route back to man again. In this way, too, we may explain the occurrence of those cases of malaria which apparently, though not really, are unconnected with swamp or stagnant water. Such is my view of the life history of the malaria parasite, and the rôle of the mosquito with regard to it, and the process by which man becomes infected."

**Pyelophlebitis; Operation; Death.**—The *May Scalpel* reports that Dr. Godlee has operated in two cases of hepatic abscess due to the above-named cause. A warehouseman, aged 41, had an acute illness in June, 1895, which left him with pain in the region of the liver, for which he was seen in September. He had a hectic temperature and one rigor. There was obvious swelling of the liver. The diagnosis lay between suppurating hydatid and abscess. The abdomen was opened on October 18 and a large abscess found at the front of the liver. A drainage tube was inserted. There was a slight improvement for a day or two, which was not maintained. Postmortem, there was old inflammation about the cecum, clotting of the right branch

of the portal vein, and the corresponding part of the liver was riddled with abscesses. The left portal vein was patent, and the left lobe of the liver was free from suppuration. The patient had also purulent meningitis. Remarks were made on the pathology and treatment of this condition. A somewhat similar (fatal) case, a previously healthy Scotch manufacturer, aged 58. Disease began insidiously a month before he came under notice; there was very rapid enlargement of the liver accompanied by rigors. An abscess was found upon the under side of the liver, containing about one pint and a half of stinking pus. The patient was very feeble before the operation and died of shock. Mr. Arbuthnot Lane recalled the case of a patient who had suffered from attacks of what at first appeared to be biliary colic, but the distension of the gall bladder was associated with tenderness over that region and her temperature rose to 103 degrees F. He made out the presence of stones in the gall bladder, and cut down and removed them. It was adherent to a large intestine. He left a tube in, though he made no attempt to see whether there was anything in the transverse fissure, owing to the numerous adhesions. Moreover, there was no jaundice. He saw her a morning or two after the operation just after an attack of the old pain had come on. Her temperature was then normal, but it rapidly ran up to 107 F., and she died seven hours later. Postmortem they found an abscess behind the portal vein, and the liver was filled with large hemorrhagic patches. Although no opening into the vein could be made out it seemed absolutely certain that the abscess had burst directly into it or one of its branches.

## PRACTICAL NOTES.

**Massage in Treatment of Post-operative Intestinal Obstruction.**—A Ernest Gallant, M.D., says that by early massage we can give immediate relief, independent of the use of laxatives or enemata, and that in these cases the bowels move more readily and with less stimulation than when massage is delayed. Laxatives tend to increase gas formation and intensify peristalsis, thus adding to the pain and discomfort. Enemata can not reach above the ileo-cecal valve, and cause colitis, rectal tenismus and proctitis, followed by exhaustive diarrhea. Intestinal cramps from gas or too active cathartics may be relieved by repeating the rubbing at frequent intervals. Infection of the line of wound union or damage to structures involved in the operation by massage thirty hours after operation is not likely to occur.—*Mathews Med. Quarterly*, July.

**Identification of Morphin in Toxicologic Cases.**—J. B. Nagelvoort reports results of experiments to determine the stability of morphin under certain conditions. A practical test seemed to be needed to determine how small a quantity of morphin could be isolated and identified; the sensitiveness of morphin to different reagents being well known,  $\frac{1}{8}$  grain was taken. This was dissolved in a plate of soup, selected to imitate volume and contents of a human stomach in natural condition. The next step was to mix 0.050 gram morphin with a suitable portion of refuse meat, fat and some bulk of vegetable matter. Ten mixtures of this kind were left to putrefy for fifty days, in a warm room, covered with a glass jar. Three mixtures of the same quantity of morphin with human flesh, furnished by the medical school, were also left to putrefy. At the end of the fifty days' exposure morphin was searched for in all the mixtures by the methods of Dragendorff, Stas-Otto and Graham (the dialysation process), due precautions being taken against confusion in the chemic reactions. Characteristic morphin reaction was obtained in each case. No better conclusion can be drawn than that a popular belief in the destructive power for alkaloids, of the decomposition of cadavers, has no foundation in the facts.—*Am. Jour. of Pharmacy*, July.

**Infantile Scurvy.**—Lack of fresh food is the most important cause of infantile scurvy, the use of the proprietary foods and condensed milk produces more than all other causes combined. Even fresh milk in small proportions is not sufficient to insure protection. It has been shown more recently that proprietary foods, condensed milk, and cow's milk too freely diluted are not the only offenders, but that sterilization or prolonged boiling of new milk of good quality is sometimes an important factor in the development of infantile scurvy. The diagnosis of this disease is a matter of some moment, the more so since the failure to institute treatment early is often followed by fatal results. The diseases for which it is most apt to be mistaken are rickets, rheumatism, stomatitis, congenital syphilis, infantile paralysis, osteitis and sarcoma. As a rule, however, symptoms of scurvy are so pronounced that there is but little difficulty in making a diagnosis when the condition is borne in mind. On the treatment of the disease there is but one opinion, and that is that the best results are secured by the prompt substitution of "living food," such as fresh milk, fresh beef-juice, and orange-juice for proprietary food, condensed milk and sterilized milk.—*University Med. Mag.*, July.

**The Lewaschew Method of Substituting the Effusion in Pleurisy with Equal Amount of Salt Solution.**—This method was first announced at the Berlin International Congress, but further success with it impels L. to recommend it in still stronger terms, as he has now a record of fifty-two cases, all followed by marked relief and prompt recovery. Thoracocentesis is first performed and as the effusion is gradually aspirated, it is replaced by physiologic salt solution, which prevents the collapse of the organs into the empty pleura, while the solution is gradually absorbed and exerts a general tonic and local antiseptic effect. The *Therap. Woch.* for June 28 devotes ten pages to a complete résumé of the results and technique of this treatment.

**Diabetes in Early Infancy.**—W. B. Bell, in the *Edinburgh Med. Journal*, reports the following case: A. B., aged 3 months 5 days; parents noticed that the child was very restless, suffered from a very intense thirst, and required a large quantity of fluid in addition to the breast. They also noticed some increase in the amount of urine, and that there was a good deal of cutaneous irritation around the genitalia and thighs. Occasionally the child was very drowsy, and his breath had a peculiar odor. The child was born as a face presentation and the labor was protracted and difficult, but not instrumental. Parents both alive and healthy; one sister healthy; one aunt on the father's side, died from diabetes mellitus. The patient is a well-nourished male child. Urine in excess, but amount not estimated or specific gravity ascertained. Clear and with a sweet taste, containing a large amount of sugar by Fehling's, Moore's and Johnson's tests. Marked weeping eczema of the privates and thighs, especially in the folds. Patient fretful and restless. Breath normal, excessive thirst, bowels regular.

**Head-Swaying in Children.**—Dr. William Osler, in the *Montreal Medical Journal*, June, has the following case to report of a neurotic affection that is well-nigh unique. He says: "Among the curious coördinate movements in children, head-nodding and head-banging are among the most interesting. The following case presents an interesting condition, which I do not remember to have seen described, in which the head is swayed from side to side in a rhythmic manner: E. C., female, aged 5, third child; always healthy; when born was not a blue baby and instruments were not used. Developed naturally and had no trouble with teething. Both mental and bodily growth were normal and she is now a well-nourished, healthy-looking child, very bright and intelligent. She is a Hebrew, and many members of the family are excitable and nervous. The parents are bright, intelligent people. From the time the child sat up it was noticed that she moved the head from side to side, or dropped it on the shoulder and this habit has persisted. The

father states that it was noticed from the very earliest infancy. She never has had any other movements; never any rotation of the head, or head-nodding, or any twitching of the muscles of the face or of the arms. She is not a mouth-breather and she sleeps quietly. At times, however, she is very restless and gets on her hands and knees in her sleep and bores her head into the pillows and climbs up until she knocks her head against the foot of the bed, as her father says, 'rooting about like a pig.' She never has had spasms, and has been a very healthy child in every respect."

**Dolphin Oil in Acne.**—Dr. Boeck, in *Annales de Dermatologie*, says that dolphin oil inhibits the growth of bacteria in the skin, and consequently he finds the following useful: Camphorae 0.30, acidi salicylici 0.50, sulphuris precipitati 10, zinci oxidi 2, saponis 1, olei delphini 12. Misce. Make the application each night; wash the face in the morning with soap and warm water.

**Local Treatment of Diphtheria with Sodium Hyposulphite.**—Dr. Henry A. Wickers writes to *Lancet*, for June 3, that in his opinion, the above named treatment has been too much neglected by his medical confrères. He has for some time been using a solution of sodium hyposulphite as a local application in diphtheria and has been well satisfied with the results, three or four applications having generally been sufficient to clear away the false membrane. The solution is prepared for use by mixing equal parts of pure glycerin and a saturated solution of hyposulphite of sodium in water, and is applied with a brush to the exudation and inflamed fauces once or twice daily or as often as may be deemed necessary. The glycerin by its adhesiveness keeps the solution longer in contact, and also, by its well-known local action, helps to relieve that engorgement of the mucous membrane which seems especially favorable to the growth of exudation. It is probable that the hyposulphite has a continuing action as a germicide in the following manner: Chemic decomposition is first set up by contact with the acid secretions of the mouth and throat, sulphur and sulphurous acid in a nascent state being set free; the latter being gradually converted by oxidation into sulphuric acid, would in the same manner decompose further portions of unchanged hyposulphite, and so on until the hyposulphite was exhausted. This local treatment will not interfere with the general treatment, which must be adapted to the necessities of each individual case.

**Lactation Atrophy of the Uterus.**—Dr. Hiram N. Vineburg says: "Whether or not puerperal hyper-involution apart from lactation frequently occurs must be left to future investigation. To its non-occurrence may be attributed many of the gynecologic cases seen in private practice. By examinations up to the twelfth puerperal week the condition can be recognized, if existing, and the ill consequences of deficient involution averted. Care should be taken that the hyper-involution does not become permanent." He summarizes his observations as follows:

1. Modern researches tend to prove that post-puerperal involution consists chiefly in a retraction and contraction of the individual muscle-fibers whereby the whole uterus is reduced in size.
2. When involution goes on to its full completion the uterus is reduced to a size smaller than that of the non-parous organ.
3. This condition of complete involution is known as post-puerperal hyper-involution. It is principally seen in nursing-women, and from this circumstance has received the cognomen of *lactation-atrophy*.
4. The so-called lactation-atrophy is a normal and desirable condition. It is temporary in its duration; but very rarely, under unfavorable circumstances, may become permanent.
5. When the parturient is unable to perform the function of lactation it is the duty of the physician to endeavor to bring about hyper-involution by other means at his disposal. An observance of this course will prevent many a woman from developing a host of gynecologic affections which frequently result from imperfect involution.—*Am. Jour. Med. Sciences*, July, 1896.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance . . . . . \$5.00  
Single Copies . . . . . 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JULY 25, 1896.

THE JOURNAL ITSELF.

Owing to the increase in the number of pages of the JOURNAL and the larger issue, we are obliged to go to press earlier than heretofore. We therefore request correspondents to send their communications so as to reach us not later than Tuesday instead of Wednesday as heretofore. We herewith append the detailed statement of the circulation for the last six months:

Jan.—1st week . . . 6,500	April—3d week . . . 6,800
“ 2d “ . . . 6,700	“ 4th “ . . . 6,900
“ 3d “ . . . 6,800	May—1st week . . . 7,000
“ 4th “ . . . 6,800	“ 2d “ . . . 8,000
Feb.—1st week . . . 7,000	“ 3d “ . . . 8,000
“ 2d “ . . . 7,000	“ 4th “ . . . 7,200
“ 3d “ . . . 7,000	“ 5th “ . . . 7,100
“ 4th “ . . . 7,200	June—1st week . . . 7,000
“ 5th “ . . . 7,200	“ 2d “ . . . 7,100
Mar.—1st week . . . 8,100	“ 3d “ . . . 7,100
“ 2d “ . . . 8,000	“ 4th “ . . . 7,200
“ 3d “ . . . 7,900	
“ 4th “ . . . 8,100	Total . . . . . 188,300
April—1st week . . . 7,800	Weekly average for
“ 2d “ . . . 6,800	six months, 7,242 4-13

Our members should be reminded that the Treasurer, HENRY P. NEWMAN, M.D., Venetian Building, Chicago, is ready to receive the annual dues; and to those not present at the Atlanta meeting, who have not already responded to the Treasurer's call, we wish to remind them that their great weekly costs vastly more money than it did a few years ago, and that prompt payment of dues and subscriptions are more than ever necessary. Let every member help us

obtain a new member, and we can celebrate the semi-centennial at Philadelphia with one of the strongest medical organizations in the world.

THE ANNUAL REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA.

We have read this document with more than ordinary interest and pleasure, for it shows how keenly alive the British Government of India have become to its sanitary interests.

The report deals not only with the sanitary situation in India, but gives the returns of sickness and mortality among the European and native troops and prisoners in India for the year 1894. With the last we can have only a passing interest, but with the progress of sanitation in India, the whole world is interested. We have been included among those who have frequently animadverted on the indifference and neglect of the ruling power in that empire. We have urged that any nation was responsible for maintaining endemic cholera and yellow fever centers within its jurisdiction. We have set forth this sin of omission as an infringement of the *jus gentium*, that should be recognized in international law. The specific examples, the bad object lessons, were Spain in its failure to arrest yellow fever in Cuba, and Great Britain in its failure to stamp out cholera in India. The world has suffered untold misery from these preventable diseases, and the nations responsible for their maintenance have been apathetic. Spain is now suffering the loss of the flower of her army. Regiment after regiment sent to Cuba becomes decimated and leaves most of its gallant membership in eternal sleep. The *febre amarilla*, rather than the bullets of the patriots, plays havoc with Castilian and Aragonian alike. The expenditure of a few millions in carrying out sanitary measures would make Cuba one of the most healthful spots on the globe. Spain has deliberately shut her eyes to this fact, and allowed the island to become a land of death to all comers. If that were all! This insanitary apathy has cost this and other countries thousands of lives, and incalculable loss to commerce both by sea and land. If Spain shall lose Cuba at this time, every civilized country will rejoice, because, with other and different government, "yellow Jack" will cease to prey upon the world's commerce from Cuban ports.

English rule in India should be welcomed by the world, so far as advances in civilization are concerned, but up to a very recent period, it is questionable whether, in view of her neglect to carry out sanitation, the world would not be much better off with Russia in full control. Russia knows how to stamp out cholera and plague within her dominions, and she not only has the power to enforce sanitary regulations where necessary, but never yet has failed to exercise it.

Such being the general views held by hygienists in

this country, it is a great pleasure to take up the report of the Commissioner and see that great work is now being done throughout the Empire.

The water supply is being looked into, and it seems at last likely that renewed energy will be shown in the next succeeding reports. The enormous mortality from cholera throughout India and Burma is stated by the Commissioner (Surgeon-Major General CLEGHORNE), page 168, to be 529,049 as against 218,113 in 1893 and 762,695 in 1892.

What may be done in the matter of prevention of cholera by proper management is well shown by the result of the precautionary measures taken in the Northwestern provinces. We quote from the report:

"Turning now to the *Magh Kumbh* of 1894. In view of the large assemblage expected, special arrangements were made as soon as the site for the fair could be definitely fixed. This, owing to the direction of the main stream of the Ganges after the heavy rains in the hills in October, 1893, could not be done until late in December. It was decided to lay out the main site of the fair on the Cantonment land on the right bank of the river, between it and the Beni embankment, which runs north from the fort to the village of Daraganj. It was arranged that the religious brotherhoods or *akharas* should be encamped on an island in the bed of the river near the left bank, their encampment being connected with the main site, on the other side of the Ganges, by a bridge of boats. The general site, on alluvial land, immediately north of the fort, comprised a broad street of shops, and to the north of this again, an extensive camp, with broad thoroughfares and lanes which left the main roads at right angles. On the island a broad road running eastward from the bridge of boats divided the camp in two. At the general site the municipal water was laid on, the numerous standposts, each surrounded by a platform of flagstones, being situated at a convenient distance from each other. All wells were closed and fenced in, so that no one could use water from them. It was not practicable to supply the municipal water to the camp on the island, but arrangements were made for a supply from the main stream of the Ganges, access to the back waters being prevented by a cordon of police. Conservancy was thoroughly carried out. At the general site, dry earth latrines were used, solids and liquids being collected in separate vessels and conveyed to a distant trenching ground by means of a light tramway. On the island there were trench latrines, round which were placed police cordons. Ample urinal accommodation was provided. Rubbish and sweepings were removed in carts, except when the accumulations were very large, when they were burned at convenient places. Provision was made for the prompt removal of the sick to hospital for treatment. For police, sanitary and medical purposes, the general site was divided into five areas and the encampment on the island into two, and arrangements were made for continual patrolling by day and night. The Deputy Sanitary Commissioner was placed in executive charge."

The result was that out of the vast multitude comprising more than one million five hundred thousand persons assembled on February 5, only 185 died from January 9 to February 20. Of these deaths 47 were

due to fever, 59 to dysentery and diarrhea and only 3 deaths to cholera.

There is no longer any doubt that with the steady improvement of the water supply and the prevention of pollution of the supply, cholera may be eradicated from India as thoroughly as from England itself.

The report on inoculation by HAFKINE, which was submitted to the government August 25, 1895, is printed in full, with a rather noncommittal comment (see p. 269). Altogether the report shows wonderful sanitary progress.

#### HEMATOZOA IN THE LOWER ANIMALS.

The recent discovery by SURGEON-CAPTAIN BRUCE of the Indian army that the tsetse fly of Africa acts as the carrier of living virus is of interest from a double standpoint: First, to the student of human and comparative pathology, in clearing up the origin of a mysterious disease; and, second, as furnishing another instance of an insect carrier of contagion. For the last fifty years, from the time of LIVINGSTONE, successive travelers have regaled us with accounts of the ravages of this fly. We learn that it is a terrible scourge to live stock and that it is one of the greatest obstacles to colonization in the central part of the "dark continent." The tsetse fly (*Glossina morsitans*) is slightly larger than the common house fly; it has a slender proboscis, nearly twice as long as its head, and is able to puncture with great force. Its bite is fatal to the ox, horse, ass, sheep, dog, and elephant; the goat, buffalo, antelope, zebra and man himself are not seriously affected by it. In fatal cases, after an incubation of short duration, the animals have fever, followed by marked anemia, marasmus and dropsy for several weeks or even months.

The geographic distribution of the insect is extensive, though rather erratic. It is found in localities here and there over Central Africa from the Transvaal to the Zambesi, on the right bank of the latter, and from Zanzibar as far inland as Ugogo. In these situations it is to be found in low-lying localities, the borders of marshes and water holes, and in beds of reeds. The fly makes a loud buzzing noise which is said to cause more terror among domestic animals than the lion's roar. Horses which have passed unscathed through the fly country and become immune are called "salted," in South African parlance, and command extraordinary prices.

Up to the time of BRUCE'S discovery the nature of its virus was unknown. LIVINGSTONE, who was one of the first to give an accurate description of the insect, attributed it to the glandular secretions; other observers to germs of some description. MÉGNIN was of the opinion that the fly carried anthrax virus from one animal to another. BRUCE has discovered that the fly itself has nothing to do with the disease save as the carrier of a living virus from infected to healthy

animals. This virus is a flagellated infusorian, apparently identical with the *Trypanosoma Evansi*, which was the cause of a similar disease among the live stock in India. Some ten years ago RAILLIET had nearly solved the problem, for he wrote: "In reality the tsetse can merely be regarded as a carrier of virus and its bite is only dangerous when its proboscis has been previously infected. With regard to the virus that it habitually inoculates, it is difficult in the present state of our knowledge to say what it actually is," etc.

Horses, mules and camels in India are attacked by a pernicious anemia to which the name "surra" disease has been given. The disease, which is invariably fatal, is characterized by fever, rapid emaciation, extreme debility and death, in marasmus and coma, occurs in from ten to sixty days. The mortality from the disease in India and Burmah<sup>1</sup> is enormous. Blood drawn during life has an increase in the number of white cells with a diminishing number of the red; the latter are mostly crenated. In the midst of the corpuscles is seen an organism with a long, flexible tail. EVANS, who first discovered it, supposed it was a *spirillum*; CROOKSHANK, after a minute examination, recognized it as a flagellate infusorian, and BALBIANI gave it the name of *Trypanosoma Evansi*. A similar flagellate organism is found in the blood of rats and hamsters in England and on the continent of Europe. According to LINGARD the Indian *trypanosoma* is innocuous to Indian rats, in the blood of which it is found. The disease is inoculable. Dogs and monkeys have been successfully inoculated; rabbits are very susceptible, though the disease is not so fatal in them. Dogs appear to be spontaneously affected and die. (FLEMING.)

The question arises, is there any relation between these three forms? This might be partly settled if experiments with the European *trypanosoma* showed it to be pathologic for horses. However, while the Indian form is only feebly pathologic to the ox, the African form is deadly. A writer in the *British Medical Journal*<sup>2</sup> suggests that "the European, Indian and African trypanosomes, although closely resembling each other morphologically and biologically, yet differ in their pathologic properties, the trypanosome of Europe being innocuous in the case of all animals, the trypanosome of India, if deadly to certain domesticated animals, being almost innocuous to the ox of that country, while the African trypanosome is deadly to nearly all four-footed domestic animals, the ox included. Seemingly, the pathologic qualities of the three varieties are graded, as it were, by climate or by breed or by other circumstances. A similar peculiarity has long been known to exist in connection with the bacillus of anthrax, which, though fatal to the sheep of Europe, does not affect the Algerian sheep."

It seems that the hematozoa in the lower animals play fully as important roles as we know their congeners do in man.

#### WATER SUPPLIES.

We seldom notice a new book editorially, but we have at present before us one which fills a long felt want: WM. P. MASON'S "Water Supply, Chemical and Sanitary," as announced by the gold lettering on its handsome red cover, but "principally from a sanitary standpoint," according to the title page. Our health officers and sanitary men have been waiting for several years for a book of this kind. If W. RIPLEY NICHOLS had lived they would have had it several years ago, for he gave them its nucleus in his article on "Drinking Water and Public Water Supplies" in 1879, in the first volume of Buck's "Hygiene," and this nucleus, but for his untimely death, would have expanded *pari passu* with the extension of his experience. DR. SMART of the Army published excellent directions for sanitary water analysis in the Reports of the National Board of Health, and in the same volumes the account of MALLET'S investigation into the value of the processes of water analysis presents a fund of information concerning the analytical results given by waters of known quality. DR. SMART'S article on water in Wood's Reference Handbook of the Medical Sciences was also of value. DR. FLOYD DAVIS of Des Moines, Iowa, and DR. LEFFMANN of Philadelphia, gave us excellent little books on the sanitary analysis of water and Professor MASON himself contributed a booklet, known to but few because it was printed mainly for the laboratory use of his students, and yet from the precision of its directions it was worthy of a more extended publication. Nor must we forget the valuable work of the State Board of Health of Massachusetts on filtration, published in recent annual reports, nor the many special reports on the water supply of particular municipalities by health officers and special committees. In England we have had new editions of WANKLYN'S book condemning waters on the ammonia and albuminoid ammonia distilled from them; of FRANKLAND'S condemning them on the absolute quantities of the organic elements; the relation between the carbon and nitrogen and the skeleton of sewage as represented by the nitrates in solution in the water; articles by TIDY on the oxygen required to oxidize organic matter and by EKIN on the dangerous character of waters containing more than so many milligrams of nitrates per million of the water, and so on. But all these publications, with the exception of NICHOLS' article, dealt merely with the laboratory work of analysis and the more difficult work of translating the results of the analysis into an opinion on wholesomeness or unwholesomeness that could be understood by the laity. These authors took the water supply into the laboratory and told us all

<sup>1</sup> Nour. Dict. Prat. de Méd. Chir. et Hyg. Vétérin, xii, Paris, 1885.  
<sup>2</sup> May 16, 1896.

about it from the laboratory point of view, so that we came to know this quite well; but what we did not know, yet wanted to know, what we could not find out from chemic and medical books, was how the water supply came to be a water supply. In Washington we knew all about the dam and the conduit, the reservoir and distributing mains, and in Chicago about the tunnels, but about the methods of water supply and its purification in other cities we were ignorant, because the publications mentioned gave us nothing from the engineering and financial points of view. Fortunately Professor MASON went to Europe and enlarged his experience, not only of laboratory methods, but of methods of purification on the wholesale scale for municipal supplies. As a result of his European trip and his earnest desire to promote purity of water supplies for home consumption, his small but valuable laboratory brochure has blossomed into what may without flattery be called the best work on water supplies in the English language. The author is modest; he speaks of his work as a compilation, which he hopes will prove of interest to several classes of men quite widely separated in tastes and occupations; to the physician, who wishes to keep in touch with this particular phase of sanitary science, but whose time does not permit of his undertaking such investigations personally; to the hydraulic engineer, whose professional duties prevent his sifting out from the mass of recent bacteriologic and chemic results such facts as bear upon his specialty; to the water analyst or the chemic student, who may seek to employ analytic methods widely used and largely based upon the report of the Committee of the American Association for Advancement of Science, and finally to the general reader, who as a water consumer feels a natural interest in the continually recurring water problem of the day.

Critics have on several occasions stated that medical men in discussing a professional subject are never satisfied unless they go back to HIPPOCRATES and drag it along through the ages to show their perfect familiarity with it. Professor MASON starts from HIPPOCRATES, but in his defense it is to be noted that he does place M.D. after his name and that although he does begin away back he does not fail to bring his subject up to date. He shows the connection between water supply and such diseases as malarial fever, typhoid fever and cholera, citing the instances on which the argument is based instead of dealing with vague assertions of the belief of certain medical men. He describes the filter bed system so common in Europe, so practically unknown here, not only from chemic, bacteriologic and sanitary points of view, but from the practical and financial. Rain, ice and snow water; river, stored and ground waters; dug, driven and deep wells, receive full consideration, and our knowledge of them is brought up to date. But it is

needless to go over the whole subject. The volume will be of value to all those mentioned by the author in his preface as bringing to their notice matters that could be found heretofore only by hunting over the entire field of sanitary literature.

---

#### SECRET CURES OF INEBRIETY IN BELLEVUE HOSPITAL, NEW YORK.

The commissioners of charities in New York have considered it their duty to place two wards of Bellevue Hospital at the disposal of a physician who has a secret cure for inebriety. This physician is not a member of the hospital staff or board, and apparently proposes to prove to a skeptical public that his remedy is of such value that the authorities must adopt it at once. But literally he has secured a golden opportunity to pose before the public as a great deliverer and benefactor. The newspaper accounts from day to day of the treatment, and the interviews and statements of cured men, far exceed the wildest dreams of any gold-cure specifics in the past. The superintendent and the various reporters, together with some of the political managers, assume that it is wonderful. Even the mayor is impressed and convinced, and altogether it is the most startling exhibition of therapeutic wisdom and knowledge, outside the profession, seen for many years. Several weeks have past, and the cured cases are still posing in letters to the public as examples of this marvelous cure, which, strangely, is veiled in mystery. In the meantime the physician visits the wards three times a day, administers the drug and the reporters call regularly to write up the results in the dailies. The public write letters to the hospital authorities and physicians for information to the extent of hundreds daily. The next step will be the endorsement by some leading clergymen, and the sale of privileges to use it in other hospitals. This is said to be an experiment which the authorities feel justified in conducting, but where are the medical board and hospital staff? Are they considered incompetent for this work? Perhaps they are aware of the nature of the remedy and are willing the trial should be invested with mystery and quackish glamour; or perhaps they are powerless in opposition to the hospital authorities, and dare not protest for fear of losing their places. At all events their silence is strange and unaccountable, and the suspicion which gathers about such an effort should be dispelled by some authoritative statement of their position. If the lay authorities of a hospital arrange for and conduct therapeutic experiments outside of its medical board we shall expect a new era. The various specifics and empiric cures will seize this new method of advertising and utilize it to its greatest extent. The moribund gold-cure speculators awake and listen to the glowing accounts of this Bellevue experiment, and turn away with anguish that such an oppor-

tunity did not occur in their day. On the other hand the new armies of quack curers watch with breathless interest this pioneer effort to turn the wards of great charity hospitals into places for advertising their drugs. Two New York medical weeklies have protested against this movement, while a third journal, which is usually very outspoken, has preserved a dignified silence.

We shall follow with great interest this experiment and shall hope its results will come to us by other mediums than the daily press and the hysteric assertions of its so-called cured victims.

## CORRESPONDENCE.

### An Open Letter to the Members and Friends of the Medical Profession (Regular) in Michigan.

DETROIT, Mich., July 20, 1896.

An organization calling itself "The Michigan Medical Legislative League" has, in a printed circular, appealed to you and to me for aid and comfort in its efforts to accomplish a certain self-imposed task, namely: "To secure through organized effort just and equitable laws regulating the practice of medicine in Michigan and to promote the interests of the medical fraternity." Truly a noble object and worthy the utmost effort of every lover of science and friend of humanity. The Executive Board of the League consists of three irregulars and two members of the regular profession.

For almost a quarter of a century in this State, I and my professional associates have labored and waited and hoped for the accomplishment of this, which is plainly declared to be the main "object" of the "Legislative League." It is needless to say that its attainment is as dear to our hearts to-day as it ever was. We stand ready now as in times past to do anything and everything within the bounds of honor and decency to secure legal medical protection for the sick and suffering. It is therefore with extreme sorrow that we feel compelled to say that the course of procedure and policy publicly avowed by the "Legislative League" is, in our opinion, deserving only the pity and contempt of every true friend of regular medicine and every individual who sincerely wishes to do what he can for the relief and protection of the sick and hurt. The plainly avowed ultimate "object" of the so-called league is the securing of an act of the legislature as follows:

A BILL to establish a Board of Registration and to regulate the practice of medicine, etc. Of this proposed bill Section 1 reads: "The people of the State of Michigan enact that the Governor shall appoint nine physicians, residents of the State, *not more than four of whom shall be regular*, two homeopathic, two eclectic, one physiomedical (whatever that may be) who shall constitute a Board of Registration in Medicine."

Section 3 reads: "All persons engaged in the practice of medicine and surgery in any of its branches and all who wish to begin the same in the State shall apply to this Board to be registered and for a certificate of such registration."

If this bill had originated with non-professional politicians, or with quacks and irregulars, the pitiful degree of recognition accorded the adherents of true science and the followers of every great and noble name in medicine and surgery from Hippocrates to Pasteur and Lister might have been dismissed with a smile of ridicule and contempt; but coming, as it appears to come, from men who still profess loyalty to honest scientific medicine, words fail us to adequately express our amazement and sense of humiliation. The regular profession of Michigan numerically exceed all other so-called schools or sects in the proportion of two to one. In the matter of talent, education, character and influence the difference is surely immensely

greater. Can it then be possible that the representatives of the great profession of honest scientific medicine in this State are ready and willing to join forces with every quack and pathy and sect for the purpose of securing a law which in the most practical and unmistakable manner declares the inferiority of regular and the superiority of irregular medicine? Many years ago the profession of this State submitted to a severe rebuke at the hands of the AMERICAN MEDICAL ASSOCIATION for having even thought of a somewhat similar proposition. Can it be possible that at this late date the regular profession in Michigan feels itself so feeble and unable to maintain itself that it stands ready to defy the public professional sentiment of this and all other lands and in the hope of obtaining a little milk and water degree of protection (*for themselves rather than their patients*) enter into a combination and unholy alliance with its most insidious and meanest foes, and place the balance of power in the hands of the enemy?

The occasion is, in our opinion, critical. The honor and the good name of the profession in Michigan is at stake. It is not yet too late to rescue that good name and keep it safe from disgrace and misfortune. For myself and others who love and honor our profession, we earnestly implore the members to come forward at this time and openly approve the only attitude consistent with the honor and best interests of the profession. Let us earnestly and persistently oppose any and all legislation which tends to increase the power of the quack, the charlatan and the sectarian, and which at the same time degrades and humiliates the only real school of medicine, namely, that school which rises above all pathies and all sects and seeks only the welfare of the sick and suffering and in doing so eagerly accepts anything and everything which holds out reasonable hope of being practically useful. Let us as a profession demonstrate by our lives and our works our claims to legislative recognition and convince the people that *our* interests are *their* interests.

Legislation so earned and secured would be a glorious triumph for science and for humanity. Legislation obtained by compromise and abdication and unholy alliance with everything and every creature in the shape of a medical parasite only confers upon the latter undeserved honor, while it stamps the word *shame* upon the brow of each one of us in Michigan who claims to be, to the best of his ability, the representative and the exponent of the noblest of all professions.

Perfection can not be claimed for any man or set of men, and we have no choice but to confess to many failures and imperfections on the part of the regular profession in this State and everywhere else. Nevertheless the fact remains that our aims are avowedly higher and in practice our record incomparably grander than that of all the other so-called schools and sects combined.

Why, therefore, in the name of all that is true and good, should we condescend to join hands with any sect, school or pathy, thereby uplifting that which we condemn and despise and at the same time dishonoring that for which we have always been willing to do our utmost to protect and save?

DONALD MACLEAN, M.D.

### Leprosy.

NEW YORK, June 23, 1896.

To the Editor:—I inclose a letter just received from Dr. Wm. Havelburg, the Director of the Bacteriologic Laboratory, Hospital dos Lazaros, Rio Janeiro, Brazil, which will be of interest to American dermatologists.

Yours truly, ALBERT S. ASHMEAD.

"Rio de Janeiro, May 26, 1896.

"Dear Dr. Ashmead:—I take for granted that you are conversant with the German language, in which I can express myself so much more easily. Accept my best thanks for your many different messages, either of a literary or other charac-

ter, and I beg you will excuse me for not having rendered my thanks to you before, as I have been prevented by very sad private occurrences.

"Your different publications have interested me very much. In regard to the modern way of doctors concerning serum-therapy, I am thoroughly skeptical. Perhaps diphtheria has, for some time been your field; in regard to leprosy, we hardly could talk of such, as long as the culture of the lepra-bacillus has not been made. Those experiments made in Colombia (with Carrasquilla serum) appear to be very naive. I neither believe in nor trust them.

"You mention a proposition made by Dr. Goldschmidt, regarding a leper congress. That gentleman is known to me by name and by many publications. Although I have not had the same experiences of therapeutics as those which Dr. Goldschmidt has published, I feel with regard to a congress that a real motive is wanting. The increasing danger of leprosy is well known. The Culture States, in their administrations take due regard of hygiene and protect themselves, and those States which do not do so, can or will not, and they do not understand the affair. Particular progress in our knowledge of leprosy and its treatment has, in the last years, not been made. Therefore, what are we going to do with a special congress? He who in this matter wants to talk about it, finds ample opportunity in the general congresses (Interior Medical Dermatologic Hygiene, or the International Congresses).

"I am just about undertaking a journey to Europe for study's sake, and intend to visit the leper hospital in Bergen. I would be highly interested to learn how much knowledge they have there in regard to lepra.

"While in this way answering some of the points of your letter, which has greatly interested me, I greet you and sign myself always your devoted friend,  
WM. HAVELBURG."

**A Cure for Whooping Cough.**

GAINESVILLE, FLA., July 16, 1896.

*To the Editor:*—In Keating's Cyclopaedia of the Diseases of Children, the assertion is made that one-fourth of the infant mortality of London is caused from whooping cough, and from a study of the vital statistics as published in Public Health Reports issued by Supervising Surgeon-General Marine Hospital-Service I believe that the same ratio will hold good in many other cities. Having for a number of years used, with such happy results in this affection, a combination of old and approved remedies, I feel it to be my duty to publish the formula, feeling assured that almost any case can be cured in a week if the remedy be properly used. Where the doctor can not supervise the administration of the medicine and thinks it not advisable to push the drugs to their physiologic effects the length of time necessary for a cure may be longer than a week, but the distressing paroxysms and dangers to life will have been quickly overcome.

This is the formula as I usually write it:

- R. Tinct. belladonnæ . . . . . ℥iv to ℥vi
- Phenacetin . . . . . ℥iiss
- Spirits frumenti . . . . . ℥i
- Pl. ext. castanæ (chestnut leaves) . . . q. s. ad ℥vi

M. Sig. : Shake well.

Dose : From 10 drops for a one-year-old to teaspoonful for ten-year-old child, every two to six hours.

I am inclined to think that the substitution of atropiæ sulphate for the tinct. belladonnæ would be a more elegant prescription, but I have had such good results from the formula as written above that I have had no occasion to change it.

This remedy should be given every two hours or oftener until the flushed face or dilated pupils show that the physiologic effects of the belladonna has been obtained, then the dose can be lessened or the interval between doses lengthened, but the effects must not be allowed to die out until the parox-

ysms of cough have ceased which will usually be after a very few hours.

When one member of a family has developed the disease others who have been exposed can be prevented from developing any unpleasant symptoms by administering a few doses of the remedy.

R. A. LANCASTER, M.D.,

Ex-President Florida Medical Association.

**Typhoid Secondary Infection.**

WOODHULL, ILL., July 20, 1896.

*To the Editor:*—It was with considerable pleasure and satisfaction that I read the decision of the court of appeals of Colorado, Jones vs. Vroom, reported in our JOURNAL, July 18, page 169. The reason it is interesting to me is that I have a case pending, to come in the October term of court, where I have been sued for the loss of an eye from typhoid fever. My case was one of four cases that got their contagion in the same locality. Three different physicians treated the four cases. They were all extremely bad cases and they all died except this one case which lived, but has lost the sight of one eye from sloughing of the cornea. The case you reported appears to be very similar to mine, except the fact that they promised to provide a specialist and did not, while I simply did the best. I could, never claiming to be a specialist. If you know of a record of any similar cases to the one you reported, or mine, and could advise me where to find the record, it might do me some good in my coming trial. My case is on the streets, fat and apparently well, but blind in one eye.

Respectfully,

W. S. McCLANAHAN, M.D.

**The Business Committee.**

CHICAGO, July 15, 1896.

*To the Editor:*—I wish to call the attention of the members of the ASSOCIATION to a recommendation made at the last meeting by the Business Committee. The recommendation was not presented to the ASSOCIATION until the last session and was then, through a misapprehension I am sure, laid on the table. The belief that those who voted to lay the resolution on the table, would have voted to adopt it had they understood its provisions; and the belief that it is much easier to consider a proposition of this kind between meetings, than it is in the hurry of a session is my excuse for presenting it now. The recommendation was as follows: (See JOURNAL May 16, 1896. Page 988).

"Resolved, That there be made an Executive Council of five, consisting of the three officers of the Executive Committee, and two members chosen by election. Of this Council of five, one must belong to the Section on Practice of Medicine and one to the Section on Surgery and Anatomy. To this Executive Council shall be delegated all the duties of the Executive Committee, during the intervals between its meetings."

The resolution is perhaps a little ambiguous, but the intention is very simple. It only gives permission to the Executive Committee to delegate their regular duties to a smaller committee of their own number, during the intervals between the meetings. It is impracticable for the whole committee to meet, but a sub-committee of five could meet and would be of great service in preparing for the annual meetings, and in attending to such matters as would naturally come before them. No new powers or duties are delegated to this committee. They only act upon such questions between the annual meetings as come under the jurisdiction of the Business or Executive Committee during those meetings. Those being questions that do not particularly belong to any other officer or committee, it would be a decided gain to have some one with proper authority to consider and act upon them at any and all times. The ambiguity in the resolution as presented from the Executive Committee is in the first sentence. Had that been something like this, the resolution would probably not have met with opposition:

"Resolved, That there be made an Executive Council of five, consisting of the three officers of the Executive Committee, and two other members of that committee to be elected by the Executive Committee from their own number." This certainly does not involve a change of the constitution. It scarcely involves the necessity of reference to the general session, as it is a simple delegation of powers by a large committee to a smaller committee of their own number.

Very truly yours,

HORACE M. STARKEY, M.D.

### Drops His Membership.

ROCKFORD, IOWA, July 20, 1896.

To the Editor:—I have been a member since the New Orleans meeting in 1885, but now drop it to get membership in the Medical Society of the Mississippi Valley, whose meetings are usually more easily reached.

Yours truly,

LUTHER BROWN, M.D.

### Location of the Journal.

CHICAGO, ILL., July 13, 1896.

To the Editor:—In the JOURNAL of the 11th inst. a Chicago correspondent wishes to change his vote on the permanent location of the JOURNAL to Washington, D. C., and in stating his reasons, says: "Financially, as I notice from the advertising columns, the principal support of the JOURNAL comes from east of the Alleghenies, I do not see that the ASSOCIATION would be any worse off." Such a statement led me to examine the facts on which it should rest. Doubtless the advertisements in the JOURNAL vary more or less from week to week. In actually examining the advertisements in the JOURNAL containing the letter of your correspondent I found considerably more advertising space occupied from west of the Alleghenies than from the east. Then turning to the more important source of financial support, that from members and subscribers, I found the last complete list of paying members and subscribers was published in December, 1891. A fair count showed the total number of members and subscribers in the United States at that time to be 5,028. Of these only 1,967 were from east of the Alleghenies, allowing Alabama, Georgia and Florida to be included in that division; while 3,061 were from west of the mountain range. Indeed, the seven States usually called northwestern, viz., Ohio, Indiana, Illinois, Iowa, Minnesota, Michigan and Wisconsin furnish more members and subscribers than all the States east of the Alleghenies from Maine to Florida. And Illinois alone furnishes one-third more patronage to the JOURNAL than all the six States east of New York.

In regard to your correspondent's allusion to the proximity of the JOURNAL in Washington to the Library of the Surgeon-General's Office, the Army Medical Museum and the Smithsonian Institute, it is sufficient to say that the medical libraries and institutions in Chicago, with the ample list of exchanges and new publications coming to the JOURNAL'S OWN office, afford a wider field for reference and study than its editorial corps can find time to cultivate. And his allusion to proximity to congress, and the influencing of congressional legislation, fairly raises the question whether it is more desirable to have the JOURNAL converted in a few years into an *organ of medical politics and specialism*, or to keep it as it is, the strictly professional organ of the great body of practitioners of medicine in the United States.

Yours truly, N. S. DAVIS, M.D.

SAN JOSE, CAL., July 8, 1896.

To the Editor:—Permit me a word on the question of permanent location of the JOURNAL OF THE ASSOCIATION. This question has been submitted to the members of the ASSOCIATION, and each one should have been allowed to come to his own conclusion and cast his ballot in accordance therewith without any attempts at electioneering or log-rolling from any

quarter. The editor has wisely abstained from any suggestions whatever. This is as it should be. But the silence has been broken by Dr. Newton of New Jersey. If electioneering is in order there may be a thousand members who would like to have a say. Shall we say it? If so extend the time of voting a month or two and keep everything else out of the JOURNAL and we will have a picnic. I move that there be no further electioneering allowed in this matter.

Yours truly,

A. C. SIMONTON, M.D.

## BOOK NOTICES.

**A System of Medicine**, by many writers. Edited by THOMAS CLIFFORD ALBUTT, M.A., M.D., LL.D., F.R.C.P., F.R.S., F.L.S., F.S.A. Volume I. New York: Macmillan & Co., 66' Fifth Ave. London: Macmillan & Co., Ltd. 8o, cl. Price \$5.00.

This is the beginning of an elaborate "system," which is destined to become a very important addition to our literature. The work is a pioneer in many directions, as will be seen by glancing at the synopsis of this volume.

The first division contains articles on: 1, Medical Statistics; 2, Anthropology and Medicine; 3, On Temperament; 4, On the Laws of Inheritance in Disease; 5, Medical Geography of Great Britain; 6, Inflammation; 7, The Doctrine of Fever; 8, General Pathology of Nutrition; 9, General Pathology of New Growths; 10, Principles of Drug Therapeutics; 11, Climate in Treatment of Disease; 12, Artificial Aerotherapeutics; 13, Balneology and Hydrotherapeutics; 14, Medical Applications of Electricity; 15, Massage: Technique, Physiology and Therapeutic Indications; 16, General Principles of Diets in Disease, or the Feeding of the Sick; 17, Diet and Therapeutics of Children; 18, Nursing; 19, Hygiene of Youth; 20, Life Assurance.

After these comes the second division, devoted to "Fever," of which part I consists of 11 pages on sunstroke, and part II is on the infections. This is disposed of in sixteen separate articles as follows: 1, General Pathology of Infection; 2, Septicemia and Pyemia; 3, Erysipelas; 4, Infective Endocarditis; 5, Puerperal Septic Disease; 6, Furuncle, Carbuncle; 7, Epidemic Pneumonia; 8, Epidemic Cerebro-spinal Meningitis; 9, Influenza; 10, Diphtheria; 11, Diphtheria; 12, Tetanus; 13, Enteric Fever; 14, Cholera Asiatica; 15, Plague; 16, Relapsing or Famine Fever. The volume concludes with a very full index. The illustrations are excellent. No library will be complete without this work. In the treatment of diphtheria, Herringham views favorably the serum treatment, but it is only mentioned as a special treatment. His usual treatment in practice is set forth on p. 744, and is seen to consist of the usual topical and general remedies. Sulphuric acid receives a favorable mention, although we are instructed (p. 745) no drug is a specific, "and the indications for their use must be left to the judgment of the practitioner who is directing their use." The best way of giving chlorate of potash, he says, is by the old-fashioned chlorin mixture. A foot note states that chlorin vapor was recommended by J. Johnstone as early as 1779.

In enteric fever, Dreschfeld mentions the antiseptic treatment, calomel receiving the first notice. Of this drug he says, p. 852: "Of its antiseptic virtue there can be no doubt, and experimental investigations have shown that it readily kills bacteria, that it prevents butyric acid fermentation—a fermentation brought about by microorganisms, that it checks the formation of products of decomposition usually found in the digestive tract (indol, skatol), and that it does not interfere with the action of the unorganized ferments of the saliva, gastric and pancreatic juices (Wasseljeff)." Concerning use of perchlorid (bichlorid) of mercury he says (p. 852): "One-half to 1 drachm (2 to 4 c.c.) of the solution of perchlorid of

mercury, with 1 or 2 grains (.06 or .12) of quinin given every four hours for several days, has been highly recommended by Sir W. Broadbent, especially when the motions are offensive and accompanied by much gas, the abdomen much distended and the fever high. Calomel and perchlorid of mercury are only to be given for a few days; but within the last few years more thorough antiseptic treatment has been advised, and numerous drugs have been recommended, not so much with the object of checking the action of the typhoid bacilli which have already passed the intestines and reached the internal organs, as with that of acting on any toxins as yet unabsorbed, and particularly of checking fermentation and the action of numerous microorganisms found in the alimentary canal, the growth and development of which are favored by the presence of the typhoid bacillus, and the product of which may be absorbed through the ulcerated surface of the intestines." In conclusion he says: "My own experience from a number of cases in which the various antiseptics have been tried, makes me think well of this treatment, though it is certainly inferior to the cold water treatment."

Lack of space alone prevents a more extended notice of the highly scientific articles which make up this first volume, and give it character as an able exponent of *fin de siècle* British medicine.

**Transactions of the Medical Society of the State of New York** for the year 1896. Published by the Society, 1896; 8o, cl.; pp. 544.

We notice with pleasure the following remarks of the President, Dr. Roswell Park, in his inaugural address, *Transactions*, p. 15: "It is now more than fourteen years since an event in the history of this society, which has had a most marked influence not only upon its affairs, but upon professional matters throughout the land. I allude to the differences of opinion which brought about a separation of this organization from the AMERICAN MEDICAL ASSOCIATION. Whatever the causes which operated at that time to cause this deplorable state of affairs, it is certain that they have since been made less operative. I am sure that a majority of members of the national body long to see this society restored to its early affiliation, and I am sure that a majority of our own members would gladly welcome the day when harmony might be restored, and when the national ASSOCIATION would again receive our delegates with their old-time cordiality. That day, it seems to me, draws ever nearer, and were it not for the ill-advised and much-deprecated animosity of a few opponents of peace and good will, would be plainly in sight. I would urge upon our members the importance of hastening by all judicious means the restoration of former relations and the election once more of delegates to that ASSOCIATION just as soon as we are assured that they will be received in the same spirit in which they are sent. Only the prejudices of a comparatively small number of men stand in the way of this most desirable accomplishment. I urge no lowering of our dignity; only that the actions of fifteen years ago by men who did not then understand our position, and who are perhaps not yet moved by the liberal spirit of the age, be forgotten, and that brothers of the noblest of all professions again clasp hands across the breach which was not of their own making." The committee to whom was referred the President's address reported on the foregoing recommendation as follows: "That this society approves of the sentiments expressed in the President's address concerning the relations of the Medical Society of the State of New York and the AMERICAN MEDICAL ASSOCIATION, and is ready to cooperate in any plan compatible with the dignity of both organizations whereby existing differences could be adjusted in the interests of professional harmony and in accordance with the liberal spirit of the age." In addition to the numerous scientific articles, the volume contains a biographic sketch of Dwight Morgan Lee by D. A. Gleason, memorial of Judson C. Nelson by Frank H. Green, and a memorial of Erastus D. Chipman.

<sup>1</sup> *Transactions*, p. 37.

**Le Gonocoque.** Par le DR. MARCEL SÉE, Ancien Interne des Hôpitaux de Paris. Cl. 8o. Pp. 359. Paris: Felix Alcan. 1896.

This monograph gives an exhaustive study of the gonococcus, and the results of several years of study of that interesting object. The literature of the subject has been diffused in the pages of medical journals and in different languages. The author has gathered in this volume all the important facts concerning the microbe of Neisser. The work is divided into two parts, viz.: Experimental and Clinical. There are four chapters in the first part, viz.: I. Microscopic Examination. II. Cultures in (a) Albuminoid Media, (b) Acid Media. III. Biology of the Gonococcus. IV. Inoculations. The second part is divided into eight chapters, viz.: I. Microbes of the Urethra. II. Importance of the Gonococcus in Urethral Pathology. The Urethritis Non-Blennorrhagic. III. The Process of Blennorrhagic Urethritis. IV. Complications by Direct Propagation of Urethral Blennorrhagia. V. Blennorrhagia of the Genito-Urinary Organs of Woman. VI. Blennorrhagia Inoculated Within the Genital Organs. VII. Gonorrhœal Metastases, Generalized Blennorrhagia. VIII. Conclusions Relative to the Biology of the Gonococcus in the Organism and Its Diagnosis. General conclusions. There is also an appendix in which is given the details of many experiments and observations and a fairly complete bibliography since 1893.

**In Sickness and in Health, a Manual of Domestic Medicine and Surgery, Hygiene, Dietetics and Nursing. Dealing in a Practical Way with the Problems Relating to the Maintenance of Health, the Prevention and Treatment of Disease, and the Most Effective Aid in Emergencies.** Edited by J. WEST ROOSEVELT, M.D., late physician in charge of Seton Hospital for consumptives; visiting physician to Bellevue Hospital, and attending physician to Roosevelt Hospital, New York. Complete in one volume of over a thousand pages, illustrated with four colored plates and numerous engravings. Full analytic index. Sold only by subscription. D. Appleton & Co., Publishers, 72 Fifth Avenue, New York. Price, cloth, \$6.00.

What a vast gulf between the old domestic medicine of a quarter of a century ago and this highly scientific one under the reviewer's notice! It is questionable whether notwithstanding the great advances made in popular education, this work will not prove too scientific; and with perhaps the exceptionally practical chapter on hygiene by Dr. Armstrong, be passed over by the average lay reader as too technical. The large class of college-bred men and women will find it exactly adapted to their needs. The others will find it valuable for reference, but probably will not read it *seriatim*.

The precepts are sound, the theories correct and the advice given is uniformly excellent, and in accord with the latest teachings of medical science. No attempt is made to supplant the family physician, as it is obvious that the treatment of disease and the operations mentioned can only be instituted by a trained physician.

**Philadelphia Hospital Reports.** Volume III. 1896. Edited by GEORGE E. DE SCHWEINITZ, A.M., M.D., member of the Ophthalmic Staff, Philadelphia. Printed by M. H. Power. 1896. Pp. 221. Cl.

These reports are carefully written and reflect credit upon the authors and editor. There are some twenty-five original articles, exclusive of tables, by such well known physicians as Tyson, Packard, Anders, Deaver, Bevan, Horwitz, E. P. Davis, C. K. Mills, Sinkler, Dercum, Lloyd, Stellwagon and others.

**Transactions of the American Association of Obstetricians and Gynecologists.** Vol. VIII. For the year 1895. Philadelphia. Wm. J. Dornan. 1896. Pp. 404. Cl.

The abstract of the proceedings of the interesting annual meeting, which forms the subject matter of this volume, was duly published in the *JOURNAL*, Oct. 5, 1895. We have now only to add the notice of the appearance of this volume, and to congratulate the society and its veteran secretary, Dr. Wm. Warren Potter, on the appearance of this carefully edited and hand-

some volume of Transactions. The volume includes portraits and obituary sketches of Franklin Townsend Jr., of Albany, J. Edwin Michael of Baltimore, Thomas Keith of Edinburgh, and L. Ch. Boisliniere of St. Louis.

## PUBLIC HEALTH.

**Health Report of Salt Lake, Utah.**—The Board of Health report for June: Number of deaths 52, against 27 for same month last year; death rate per thousand 8.91, against 4.62 last year.

**Definite Diagnoses Required.**—The Board of Health of Spokane, Wash., at the meeting of July 6, passed a resolution that in future the health officer shall not accept "heart failure" and other indefinite terms as the sole cause of death in returns. This rule will be strictly adhered to by the health officer in the future.

**Smallpox in Cuba.**—Reports to July 14 from Cuba, show that smallpox is proving more deadly than yellow fever. The fever is epidemic at the seaport towns, where the Spanish troops are garrisoned, but the smallpox is virulent throughout the interior. A recent letter from Dr. Caminero, United States sanitary inspector at Santiago de Cuba, says there are 2,000 cases in that city, which has 16,000 population.

**Colorado State Board of Medical Examiners.**—The Colorado State Board of Medical Examiners, July 7, granted licenses to practice to seventy-eight physicians who presented their diplomas from reputable medical colleges, date of graduation being in each case indicated. The annual election of officers of the board was then held, which resulted in the choice T. J. Forhan, M. D., of Rouse, as president, and T. A. Hughes, M. D., of Denver, for secretary and treasurer.

**Crusade on Rear Tenements in Jersey City, N. J.**—The Board of Health of Jersey City, have begun a crusade against poorly ventilated and improperly drained tenement houses, particularly rear tenements. During the last three weeks diphtheria has raged in the city and twenty-three deaths have resulted. On July 13 seven new cases were reported, and July 14 eight more. The outbreak is believed to be due to poor ventilation and bad drainage.

**Vaccinate the Children.**—An old and valued correspondent of the JOURNAL, who is one of the most efficient health officers in the United States, writes to us as follows: Now is a good time to begin a systematic effort to arouse the profession to the truth (so much obscured by the battle against humanized vaccine by the commercial methods used to further the various "brands" of animal vaccine) that *given, a typical vaccine, it must be properly used to be efficient and to avoid "accident"* which is as a rule caused by a broken vesicle admitting the infection of septic or other foreign disease cause. I wish you would fire a shot in that direction, for it is a fact that physicians avoid vaccinating now where, when we were students, they considered it a simple duty, in infancy.

**New Health Laws Desired in Indiana.**—Dr. J. N. Hurty, Secretary of the State Board of Health, has sent out a letter to the doctors of the State, outlining a proposition of the Board to bring about at the next session of the Legislature the enactment of a new health law, the present one being considered inadequate. It is proposed to have a State Board of seven members appointed by the Governor, with no salaries attached except for the commissioner chosen by the Board, who shall be experienced in sanitary matters, chemistry and bacteriology. A sanitary laboratory shall be established where all necessary sanitary analysis and bacteriologic examinations and all health work may be done for the people without charge. A modern health board without a sanitary laboratory in charge of skilled and learned specialists would be almost helpless. County

health boards shall consist of two physicians and a lawyer or business man, appointed by the commissioners. One of the physicians to be made secretary and county health officer. Secretary to be paid \$10 a year for each 1,000 of population, except in counties of over 100,000. The other two members to receive no salary. Expenses to be paid by the county. Duties and powers to be carefully defined.

**Health of Buffalo, N. Y.**—Buffalo's death rate for the first six months of this year is reported at 11.67 per thousand. The *Buffalo Enquirer* enumerates the causes of the reduction of mortality, some of which are of interest: Frequent examination of all lodging and tenement houses; the maintenance of a bacteriologic laboratory at which free tests of all suspected cases of diphtheria and consumption may be made; the sanitary inspection of schools; a weekly examination, chemic and bacteriologic, of the public water supply; the prompt reporting of contagious diseases by telephone at the expense of the city; the placarding of houses in which there are cases of diphtheria or scarlet fever; the medical and sanitary inspection of all premises exposed to infection; a health office open day and night for the reception of reports and complaints; the publication of reports concerning work done by the several bureaus; the examination of the premises of all milk dealers by sanitary officers and plumbing experts; the registration of all dairy herds from which milk is supplied to consumers, showing by the certificates of a veterinary surgeon whether the cows are free from tuberculosis; a register containing reports concerning all cases of disease on each milkman's delivery route. Particular attention is given to the milk business.

**Regulation of Midwives in Chicago.**—In this JOURNAL of May 2, 1896, there was published the action of the Illinois State Board of Health concerning the practice of midwifery, based upon a communication from Dr. Frank W. Reilly, Assistant Commissioner of Health of Chicago. This action authorizes municipal health authorities to prescribe rules and regulations governing midwives in their respective jurisdictions, which rules, when approved and adopted by the Board, have the force and effect of law, as do all rules and regulations of the Board. Dr. Reilly has acted promptly on this authorization and has submitted to the Board a code which, if judiciously enforced, can not fail to save many lives and curtail the fast-growing encroachment of the midwife upon the legitimate field of the practitioner.

That there is need of some such regulation is shown by a recent brief search of the records of the coroner's office which discloses no less than thirty-four cases of unfortunate women and girls who have come to an untimely and cruel end through the unregulated practice of midwives in Chicago. Mention was made of one of these in the JOURNAL article above referred to; another came to light on the 24th ult., when a woman was arrested for the third time in seven months for procuring abortion resulting in death. Under instructions the woman was discharged on the ground, as alleged, that there was "no use in holding her to the grand jury, since she had been twice acquitted on trial, although she once admitted in the criminal court that she had used the catheter (found on the postmortem) pushed through the uterus and lying in a bed of pus in the omentum." Close on the heels of this came the arrest of two most notorious abortionist midwives—the postmortem of their victim showing lacerations of the fundus and a perforation through which a loop of intestine had been dragged down, torn apart and the fecal contents filling the cavity. The details of some of the cases are simply sickening—the least offense, but the most frequent, being failure to remove the placenta and consequent death from septic peritonitis. In only thirteen of these thirty-four cases was there any clue to the operator; but this is of minor importance, since in no case was any punish-

ment inflicted and the women are allowed to continue their nefarious pursuits unhampered by any restriction or regulation. It is obvious that the midwives' victims who find their way to the morgue and become the subjects of a coroner's inquest represent but a small number of the total, whose deaths are attributed to other causes.

The rules and regulations follow, in effect, the lines of the Austrian code which, in a modified form, have been approved and urged for adoption in Great Britain. They are as follow:

RULES AND REGULATIONS FOR MIDWIVES IN THE  
CITY OF CHICAGO.

Under the authority and with the approval of the State Board of Health of the State of Illinois, the Department of Health of the City of Chicago hereby prescribes the following rules and regulations for the practice of midwives within its jurisdiction.

Wilful violation of any of these rules will be visited by prosecution under Section 12 of the State Medical Practice Act, or by suspension of the right of practice, according to the gravity of the offense.

Rule 1.—No person shall practice midwifery in the City of Chicago unless authorized so to do by the State Board of Health of the State of Illinois. If authorized to practice only midwifery the certificate of said Board conferring such authority shall be kept in view in the office or reception room of the midwife, for the information of those seeking her services and for the inspection of the proper city officials. For the purposes of these Rules and Regulations all such duly authorized persons, and none other, shall be known as midwives.

Rule 2.—Within thirty days after the approval of these Rules and Regulations by the State Board of Health, every midwife then engaged in the practice of midwifery in the city of Chicago shall register her name and address with the Medical Inspector of Midwifery, Room 2, City Hall, and shall exhibit to said medical inspector her certificate from the State Board of Health. And thereafter no midwife shall engage in practice in Chicago until she has so registered.

Rule 3.—Midwives shall attend cases of natural labor only. In any case which is not "natural" as hereinafter defined, the midwife shall at once tell the family that the assistance of a physician is necessary. The family shall be asked to choose the physician; but, if too poor to pay, the midwife shall immediately send for the nearest Department physician. A list of Department physicians who will assist in such cases without pay must be kept by every midwife. The list may be obtained at Room 2, City Hall.

"Natural labor" is hereby defined to be one which occurs at or near full term (nine calendar months); one in which the head and no other part presents; and one in which there is none of the conditions specified in the following:

Rule 4.—A midwife must seek the assistance of a physician in any of the following conditions:

A. *During Pregnancy.*—1. When she has discovered or suspects a narrow pelvis. 2. When there is hemorrhage. 3. When the patient is threatened with an attack of any illness of a serious nature. 4. When a pregnant woman dies suddenly.

B. *During Labor.*—1. In all cases of unnatural position of the child and if possible before the liquor amni escapes. 2. In presentations of hands or feet, or when the cord presents with the head. 3. In every case where, from the smallness of the pelvis or largeness of the child's head or from any cause whatever, the descent of the head is interfered with. 4. In disturbance of the labor pains, leading to delay of birth; or in cases of excessive pains followed by exhaustion; or where a child, whose head has already deeply descended, is not delivered for two hours after the opening of the mouth of the womb and the escape of the liquor amni. 5. In bleeding, at whatever time in labor it may occur. 6. In presenting placenta. 7. If the afterbirth be not expelled an hour after the birth of the child, even if no bleeding has occurred. 8. In all cases of rupture or tear of the perineum as soon as such occurs. 9. In all cases where abortion or premature labor is threatened or has occurred. 10. In twins or multiple births when there is delay of more than half an hour between the deliveries or when there is any complication, and in all monstrosities. 11. In all cases of apparent sickness or threatened danger, as well as on the sudden death of the woman. 12. In the apparently dead newborn child. 13. In all cases of stillbirth, no matter what the stage of development of the child.

C. *During Childbed.*—1. In the lying-in woman when there is a rise of pulse or temperature (101 degrees F. or over) rigor, tender abdomen, stoppage of the lochia or bad smell of the same. 2. In all cases of illness attacking the newly born child,

and especially if the eyes show redness or other signs of inflammation.

When a physician is sent for to a protracted labor the midwife shall, when possible, send a written description in a few words of the cause of the delay, such as "narrow pelvis with head presentation," "cross presentation," "hemorrhage during the afterbirth period," and so forth, so that he may know what it will be necessary for him to take. If a patient or her relations wish a physician called in, even if the midwife does not see any abnormal symptoms, she is not to object or try to persuade them not to do so. The choice of the physician—except in the case of a Department physician—rests with the patient or her relations, and the midwife is not to express any opinion unless requested to do so. The midwife must inform the physician truthfully and accurately of all she has observed about the case previous to his arrival and stay as long as he wishes, to assist him and conscientiously carry out his orders.

Rule 5.—Under no circumstances shall any midwife have in her possession a set of obstetric forceps, or any other instrument for the performance of an obstetric operation nor any drug or instrument or other article which may be used to procure an abortion or to cause or hasten the expulsion of a fetus, whether at term or otherwise. Nor shall any midwife give or advise the use of any drug or medicine, except the simple domestic remedies commonly used in the household. Any violation of this rule shall be considered evidence that the midwife performs operations and practices medicine in violation of Section 10 of the Medical Practice Act, and is subject to the penalties prescribed in Section 12 of said Act.

Rule 6.—Every midwife, in addition to her usual equipment, must be provided with a case book, in which she shall keep a full and correct record of all cases of labor attended by her. This book shall be subject to inspection by the Department Medical Inspector, and shall be open to the physician (if one is called in), who may write therein, and sign, his own remarks upon the case in hand.

Rule 7.—Every midwife shall make and keep a registry of each birth at which she professionally assists or advises; and shall report the facts thereof to the Department of Health on the blanks furnished by the Department within five (5) days after each such birth.

Rule 8.—Midwives must keep themselves and all their appliances scrupulously clean and must avoid contact with sick persons and decomposing substances of every kind, so that their fingers, appliances or clothes may not contain any infective material which might be conveyed to the lying-in woman during examinations and thereby produce puerperal or child-bed fever. They are strenuously enjoined before touching a lying-in woman to wash their hands and instruments thoroughly with a disinfectant. It is particularly dangerous for a midwife who is attending a lying-in woman, or any sick person, where there are foul-smelling emanations, to go direct to another case without first thoroughly cleansing her hands and appliances and changing her clothing. Unless the cleansing process be thoroughly carried out even after a healthy confinement there will be remains of blood and other fluids on the fingers, and especially under the nails, which will there decompose and be dangerous to the next case attended. The midwife must, therefore, keep her nails cut short and preserve the skin of her hands from chaps, injuries and indurations.

Rule 9.—After assuming charge of a lying-in case the midwife must not leave the patient during delivery and must stay with the woman at least one hour after the expulsion of the afterbirth in a natural labor. In cases of other labors or in threatened danger she must always await the arrival of the physician and remain with the case so long as he thinks necessary and faithfully carry out his instructions. The midwife shall see to the proper ventilation of the lying-in room, and to the keeping of the bed and body linen in a thorough state of cleanliness. She shall be responsible for the cleanliness, comfort and proper dieting of the mother and child during the lying-in period, which in a normal case means the time occupied by the labor and a period of ten days thereafter.

Rule 10.—No midwife shall visit—much less nurse or attend—a case of chicken pox, diphtheria, erysipelas, measles, membranous croup, scarlet fever, smallpox, whooping cough or other contagious or infective disease. If she should unfortunately be exposed to such contagion or infection, she shall report the fact to the Department and shall not attend or visit a lying-in case until she has thoroughly disinfected her person and clothing and has been pronounced safe by the medical inspector. In the case of a lying-in woman contracting puerperal fever or any septic condition whatever the midwife must abstain from attending any other woman at the same

time. A midwife must not under any circumstances assist in the laying out of dead bodies.

Rule 11.—In apparently dead-born children at or near term, in whom no sign of putrefaction has developed, the midwife, in the absence of the physician, who must be summoned at once, should practice the methods of resuscitation taught her until the child breathes regularly or for at least half an hour.

Rule 12.—Midwives must conscientiously guard the secrets of their patients and must only divulge them if the law requires them to do so.

**Health Report.**—The following health reports have been received in the office of the Supervising Surgeon-General, Marine-Hospital Service:

SMALLPOX—UNITED STATES.

New Orleans, La., June 1 to 30, 11 deaths.  
Shelby County, Tenn., June 1 to 30, 3 cases.  
Mobile County, Ala., June 5 to July 5, 2 cases.

SMALLPOX—FOREIGN.

Bombay, India, June 9 to 16, 8 deaths.  
Calcutta, India, May 30 to June 6, 1 death.  
Corunna, Spain, June 13 to July 4, 1 death.  
Genoa, Italy, June 27 to July 4, 1 case.  
Madrid, Spain, June 23 to 30, 11 deaths.  
Matanzas, Cuba, July 1 to 8, 3 cases.  
Montevideo, June 6 to 13, 4 cases.  
Moscow, Russia, June 13 to 20, 1 death.  
Nogales, Mexico, July 4 to 11, 6 cases.  
Odessa, Russia, June 20 to 27, 9 cases, 2 deaths.  
Osaka and Higo, Japan, June 13 to 20, 86 cases, 27 deaths.  
Prague, Bohemia, June 20 to 27, 2 cases.  
St. Petersburg, Russia, June 20 to 27, 7 cases, 6 deaths.  
Tuxpan, June 20 to 27, 2 deaths.  
Warsaw, June 13 to 27, 5 deaths.

CHOLERA.

Bombay, India, June 9 to 16, 5 deaths.  
Calcutta, India, May 30 to June 6, 49 deaths.

YELLOW FEVER.

Matanzas, Cuba, July 1 to 8, 63 cases, 39 deaths.

## SOCIETY NEWS.

**Wayne County, New York, Medical Society.**—The annual meeting of this society was held at Lyons, N. Y., July 14, and was largely attended. The opening address was made by President T. H. Hallett, of Clyde. The following officers were elected for the ensuing year: President, J. W. Atwood, of Marion; Vice-President, Alice Brownell, of Newark; Secretary, A. A. Young, of Newark; Treasurer, Darwin Colvin, of Clyde.

**Iowa and Illinois Central District Medical Association.**—The annual meeting of this association was held at Davenport, Iowa, July 9. The guest of the meeting was Dr. Frank Billings, of the Chicago Medical College, who read an interesting paper on pyelitis and exhibited plates illustrative of the subject. The following officers were elected for the ensuing year: President, Charles M. Robertson, of Davenport; Vice-President, J. R. Hollowbush, of Rock Island; Secretary, E. S. Bowman, of Davenport; Treasurer, A. W. Cantwell, of Davenport.

**The Winnapsiogee Academy of Medicine** held their first annual meeting at Laconia, N. H., July 6. The following officers were elected for the ensuing year: President, A. W. Abbott, Laconia; Vice-President, P. S. Foster, Laconia; Treasurer, Joseph Theriault, Laconia; Secretary, George H. Saltmarsh, Lakeport. The post-prandial exercises were presided over by President A. W. Abbott, and included addresses by Governor Busiel, Dr. Conn and others. Dr. Conn gave an able and interesting address on "The Progress of Antiseptic Surgery," in which he contrasted surgical methods of to-day with those of forty years ago. In closing he said:

"The triumphs of surgery are very startling to the laity, and in fact, the profession must keep step to the music else they are in danger of being considered a back number. The time has gone by when any one can imitate Mr. Bergh, who was a great friend of the animal creation and took every occasion to stand up for their rights. He was throughout his life the

acknowledged leader of the anti-vivisectionists in America. In a lecture on this subject, after describing the experiments of Dr. Robert McDonald, who successfully practiced the transfusion of animal blood into the veins of a dying person, Mr. Bergh comments as follows: 'In other words, this potentate has discovered the means of thwarting the decrees of Providence and snatching away from its Maker a soul which He had called away from earth.'

"To us as a profession it seems as if the above was the utterance of an insane person, but we are told that Mr. Bergh was a thoroughly honest, upright man, and believed that he was doing a good work. We will grant that his intentions were of the best, that he was heartily in sympathy with the brute creation, that his object in life being the saving of animals from any unnecessary suffering he had a great work to perform. At the same time any man who would express himself as he is recorded to have done, and at the same time not express any sympathy for poor suffering humanity, must have been without some of the common instincts of human love, or else he had delusions, of which devotion to the brute animal was one, and complete disregard of the rules governing the good Samaritan was another."

## NECROLOGY.

**ADOLPH OLDENDORFF, M.D.**, at Carlsbad, June 16, in his 65th year. Founder and editor of the new periodical, *Zeitschrift f. Sociale Medicin*, and a prolific writer for medical journals, encyclopedias, etc.

**LUIGI VILLA, M.D.**, Professor at the Institute Sieroterapico at Milan. The promising career of this talented devotee of science was closed abruptly last month, by an accidental scratch on the finger received while inoculating an animal with some virulent culture (glanders). Death ensued in about a fortnight.

**LELOIR**, Professor of Dermatology and Syphilology, at Lille, France. Although only in his 41st year the list of the various articles and works he has published, as given in the *Progress Medical* of June 27, nearly fills two closely printed pages.

**W. SCHLESINGER, M.D.**, at Vienna, in his 58th year; editor of the *Wien. Med. Blaetter* until recently and founder of the "Ambulatorium" for poor sick women.

**JOSEPH BARKLEY, M.D.**, died at his home in Leesburg, Ky. after an illness of less than a week, aged 69 years, on the 11th inst.

**SAMUEL SEXTON, M.D.**, died in New York city on July 11. He was born in Ohio in 1833; a graduate of the University of Louisville in 1856, and five years afterward was appointed an assistant surgeon of the Eighth Ohio Volunteers, and served in Virginia. He came to New York after the war and established himself as a successful aurist. He lectured in the New York Eye and Ear Infirmary and was a member of many societies besides having been decorated in 1889 by the Venezuelan Government for services in the cause of public education. He was the author of numerous reports and pamphlets on aural and dental subjects. He was Past-President of the American Society of Otologists, a fellow and office bearer in the Academy of Medicine, and an interested member in a number of scientific and patriotic organizations.

**M. S. THOMAS, M.D.**, at Leavenworth, Kas., July 9, aged 66 years. He graduated from the University of Maryland School of Medicine, Baltimore, Md., in 1853. The diseased came to Leavenworth in 1856, and at the commencement of the late Civil War he was a surgeon at Fort Leavenworth. At the breaking out of actual hostilities, however, he resigned this position and entered the Confederate service as a surgeon, serving in the Army of North Virginia throughout the war. At the close of the struggle he returned to Leavenworth and resumed the practice of his profession. He was physician-in-charge, St. John's Hospital and St. Vincent's Orphan Asylum, Leavenworth, member of the Kansas State and Eastern Kansas Medical Societies and President of the Leavenworth County Medical Society.

R. L. DUNN, M.D. (Tulane University, Medical Department, New Orleans, 1859), at Yazoo City, Miss., July 10, aged 60 years.—A. J. Rutherford, M.D. (University of Buffalo, Medical Department, Buffalo, 1889), at Milwaukee, Wis., July 11, aged 36 years.—Samuel H. Griswold, M.D. (Castleton Medical College, Castleton, Vt., 1844), at Rutland, Vt., July 13, aged 78 years.

## MISCELLANY.

Oliver N. Huff, M.D., has resigned his position as Medical Superintendent of the Palmyra Springs (Wis.) Association, and will resume his practice in Chicago.

**Free Medical Tuition.**—Governor Atkinson announced nineteen appointees to the Augusta (Ga.) Medical College, July 9. A number of years ago the State gave \$10,000 to this college with the understanding that the governor should be allowed thereafter to send two pupils from each congressional district in the State each year free of tuition. This privilege was not taken advantage of for a number of years as the law was overlooked.

**New York Post-Graduate Medical School.**—The fifteenth annual announcement of the New York Post-Graduate Medical School and Hospital has just been issued. Five hundred and forty-two physicians from all over this continent have attended the courses at the institution during the past year. More than one thousand operations were performed in the hospital, which is one of the largest in the city, containing special wards for babies and children, while nearly twenty thousand patients were treated in the outdoor department.

**Extension of the Bertillon System in New York State.**—The work of establishing the Bertillon system of identifying criminals has just been begun at Sing Sing prison. On July 3 Mr. George Porteous, formerly the chief of the identification bureau at Chicago, arrived at Sing Sing with a supply of the instruments used for measuring bones, cranial angles, etc., and after instructing the officials there in the manner of measuring criminals and classifying the descriptions he will proceed to Brooklyn, where it has been decided to introduce the method into the Kings County penitentiary.

**Intoxicants and Sunstroke in Australia.**—The *Medical News* states that during the month of January there occurred over three hundred deaths from sunstroke in Australia. When called upon to offer suggestions relative to its prevention the Board of Health promptly informed the Colonial Government that of all predisposing causes none was so potent as undue indulgence in intoxicating liquors, and in its treatment nothing seemed to have a more disastrous effect than the administration of alcoholic stimulants. After this precaution, suggestions were offered regarding the selection of proper clothing, etc.

**Connection between Articular Rheumatism and Pneumonia.**—Oliva describes in the *Gaz. degli Ospedale e delle Clin.*, No. 60, a couple of cases of typical pneumonia appearing as a tardy complication in acute articular rheumatism. In one case Fränkel's diplococci were found in the sputa. He concludes that articular rheumatism, in certain cases, is evidently produced by Fränkel's diplococci. Maragliano also notes (No. 74) broncho-pneumonia as a complication in the course of various kinds of infective diseases, in most of which Fränkel's diplococci were observed in the sputa.

**Plural Ectopic Gestation.**—P. Minehard, M.D., reports a case with the following points of interest: At the time of rupture the tube contained two fetuses, each with its individual placenta. One fetus was small (two and a half inches long) and flattened. The other fetus was normal in appearance and about thirteen inches long. At the time of rupture the patient had not menstruated for nearly nine months. The patient

never had any symptom that indicated disease of the uterus or of the appendages. The tube on the opposite side was healthy in appearance. The patient is now in the fourth month of uterine pregnancy and does not present any sign of tubal or ovarian disease.—*Am. Jour. of Obst. and Dis. of Women and Children*, July.

**Human Actinomycosis.**—The *Nordisk Med. Arkiv*, 1895, No. 27, reports the number of cases treated in the hospitals of Sweden to date as 84, but Ljunggren adds 27 in his own practice in the province of Schonen, where it is also quite prevalent among the cattle. He ascribes it to the common habit of chewing grains of corn. The location was the cheek, mouth or neck, except in one case of peritoneal actinomycosis, and another that affected the general health. All recovered after the indicated treatment: Extensive incision, curetting and rinsing the infected focus, and drainage.

**The New Religion—Pasteurism.**—The *Journal de Méd. de Paris* ridicules the way in which the French and some others have installed the antitoxin treatment as a fetish, putting up statues to Roux in Paris, and offering all kinds of sacrifices on his altar. It remarks in its usual sarcastic style that the Parisians consider the Institut Pasteur a sort of Olympus, with Roux and Marmorek for the gods, who promise their followers health and happiness in this world instead of waiting for the next. It concludes that in five years antitoxic serums will have had their day and been relegated to oblivion, quoting Auerbach: "Behring's serum is more dangerous than useful" (*Cbl. f. Inn. Med.* No. 18); Gottstein: "It does not confer immunity, and has no prophylactic action" (*Therap. Monatsch.* No. 5), and Soerenson, "It is useless in cases of croup" (*Ib.* No. 3).

**Action of Porcelain Filters on Viper's Venom.**—Porcelain filters do not allow the ferments and toxins of microbes to pass through them, nor the toxic elements in the venom of vipers. But it is known that this filtered product is not entirely without physiologic action, as it raises slightly the temperature of animals inoculated with it. Phisalix reports that he inoculated guinea pigs with strong doses of the filtered product, which would have been immediately fatal if they had not been filtered. Twenty-four hours later he injected a fatal dose of the unfiltered venom. The control animals promptly succumbed, while the others resisted perfectly. They had therefore been effectively vaccinated. These experiments showed that the toxic and vaccinating elements are distinct substances. Their separation by the filter is an additional support of the theory of vaccination by specific substances.—*Semaine Médicale*, June 24.

**A Cactus Alkaloid, Pellotin.**—From a species of cactus, known to the Mexicans as "pellote," Dr. Hefter, of Leipzig, has separated the active principle which he has named pellotin. Professor Jolly of Berlin has made a number of experiments with it upon patients in Charité Hospital, Berlin, following those previously made by Dr. Hefter upon animals and himself. He found that three-quarters of a grain would almost always cause several hours of sleep, and that no subjective symptoms followed its use beyond a little giddiness in about 20 per cent. of the patients. He observed, however, a marked influence upon the pulse rate, which was ten to twenty beats slower during sleep, but returned to normal on waking. It is estimated that half a grain is equivalent to fifteen grains of trional or thirty grains of chloral hydrate. The alkaloid is quite insoluble, hence the hydrochlorate is always employed.—*Medical News*, July 4.

**Budapest Exposition.**—We are pleased to advise our readers that at the Milleniel Exposition now going on at Budapest, the owners of the Franz Josef Natural Aperient Water have established a special department for the convenience of all medical practitioners visiting the Exposition. Copies of the leading medical journals of the world are kept on file there and

arrangements are provided for the reception and care of all mail matter, and those contemplating visiting the Exposition are cordially invited to make this department their headquarters for receiving their letters, conducting their correspondence, meeting their friends and consulting the various medical journals while on the Exposition grounds. Letters may be addressed care of the Franz Josef Aperient Water Exhibit, Milleniel Exposition, Budapest, Austro-Hungary. Any inquiries of those intending to visit the Exposition may be addressed to the American representative of the Spring, Elijah J. Molloy, 101 Beekman St., New York City.

**Indications for Radical Cure in Inguinal Hernia of Children.**—First try and reduce the hernia with a light and suitable bandage, which may alone produce a cure. If the hernia is accompanied by ectopic testis, the bandage must be made specially for it. The latter alone only indicates an operation when it is found impossible to protect the testes from the pressure of the bandage. If difficulties arise in the application of the bandage, then surgical intervention is inevitable. With incarcerated hernia the radical cure should always follow herniotomy. The radical cure must always be performed without regard to the age of the child, in cases of very large scrotal hernia. Under 6 years it consists in ligating the hernial sac and then tamponing the hernial cavity, according to Karewski's method. Above this age, Kocher's method is to be preferred.—Schoenfeldt in *Memorabilien*, April.

**Hennig's Successful Treatment of Diphtheria with Lime Water and Ice.**—Commenting on the statistics gathered by the government, of serum treatment in diphtheria, showing a mortality of 12.9 per cent. Hennig states that he has only lost 3.06 per cent. during the last eighteen years, 59 out of 1,927 cases. His method is the prompt and continuous use of pure lime water every fifteen minutes night and day, freely gargled and some swallowed, made fresh each time, with an ice bandage applied to the throat outside. He uses for the latter a beef's esophagus, as lighter, cheaper and better for other reasons than a rubber bag. It is filled with ice and extends from ear to ear, securely fastened at the ends to prevent the escape of water. He insists also on absolute cleanliness, nourishing food, with egg lemonade and vanilla ice cream, and alternate doses of liq. ferr. sesquichlorat. and sol. kal. iod. He treats nasal and laryngeal complications with lime water also, sprayed from a Richardson atomizer for several minutes at a time, into the patient's wide open mouth while he breathes tranquilly.—*Therapeutische Wochenschrift*.

**The Toxin of Tuberculosis.**—Numerous experimenters have endeavored to separate the disease producing principle or toxin in tuberculosis, and their observations may be summed up as follows: Prudden and Hodenpyl have ascertained that the poisonous substance (or substances) is not present in the nutrient media in which the bacilli are grown, but fixed in the bodies of the bacilli themselves in a very resistant form. The poison is not altered when within the body, for a considerable length of time, so that a person will recover from tuberculosis only after the dead bacilli are gotten rid of, or the poison rendered harmless. Maffucci claims that the toxic substance evolved by the tubercle bacilli acts only after a long period of time has elapsed. Riechet and Hericourt have separated a toxic substance from these bacilli which is poisonous to tubercular rabbits, but has no effect upon healthy ones. Thomas Weyl has succeeded in separating an extremely poisonous substance from cultures of the tubercle bacillus, and to which he has given the name toxo-mucin.—Dr. Chas. F. Craig in *N. E. Med. Monthly*, July.

**Rupture of the Uterus; an Unusual Case.**—Dr. Sherwood Dunn reports a case which he saw at Professor Richelot's clinic, Paris: On opening the abdominal cavity M. Richelot found a soft tumor intimately adherent to the peritoneum which he

first thought to be a neoplasm of the ovary, and then, by reason of its soft, mushy consistency, a possible pyo-salpinx, or caseous or dermoid cyst. On carefully separating the adhesions and following it downward, it was thought to be attached to the uterus. On circumscribing the pedicle he discovered that it was not attached to, but really protruded from a rupture, opening into the uterine cavity about the size of a silver dollar. He enlarged the opening and carefully detached and removed the mass; and not until then was it found to be a placenta weighing from one to one and one-half pounds. The patient passed a comfortable night with but little chloroformic vomiting, but the following day the temperature became elevated and she died on the evening of the second day after the operation. It is probable that the placenta, when expelled through the ruptured uterus, came in immediate contact with the peritoneum, and an adhesive membrane was thrown out which protected the neighboring organs from contamination. When this protection was removed, both from the peritoneal surface and the uterine cavity, the septic material caused blood-poisoning to which the patient succumbed.—*Pac. Med. Jour.*, July.

**Vesical Tumor.**—The *Clinical Journal*, May 13, quotes from *Annales des Maladies des Organes Génito-urinaires* the following case: Dr. Ferria has observed the case of a patient, aged 24, who complained of painful micturition and hematuria. This latter symptom had been two years in existence, hemorrhage occurring at considerable intervals at first; latterly more often, with increased pain and frequent urgent desire to empty the bladder. The hemorrhage occurred more abundantly at the close of the act of micturition till shortly before advice was sought, when severe pain occurred at the beginning of the act and bleeding on almost every occasion, and only at the beginning also, the remaining urine being limpid. On examination it was determined that there was a considerable degree of retention, and that while the prostate and seminal vesicles seemed normal, the sound, when introduced, on approaching the neck of the bladder came in contact with a surface apparently irregular and friable. On relieving the retention the catheter enabled Dr. Ferria to recognize a tumor in the bladder. Suprapubic cystotomy was performed, and a papilloma found on the anterior bladder wall to the left side, about three finger breadths from the urethral orifice. The pedicle was slender, 2 and 1½ centimeters in length, and the tumor was of half a walnut, with a prolongation on one side which reached the neck of the bladder and penetrated the prostatic urethra.

#### Discontinuance of "Climate and Health."

U. S. DEPARTMENT OF AGRICULTURE, WEATHER BUREAU.  
WASHINGTON, D. C., June 22, 1896.

The discontinuance of the publication, *Climate and Health*, is announced to take effect with the end of the present fiscal year, June 30, 1896. Vol. II, No. 3 (four weeks ended March 28, 1896), will be the last issue of *Climate and Health*. It has been deemed necessary to take this action in view of a doubt having arisen as to whether the publication of *Climate and Health* was authorized by the act making appropriation for the Department of Agriculture for the fiscal year ending June 30, 1897. With the discontinuance of *Climate and Health* will also terminate the weekly collections of the statistics of mortality and morbidity that have heretofore been published therein, and the physicians and health officials who have cooperated with the Weather Bureau in collecting these statistics are requested to return, by mail, under the Departmental frank, all blank forms and franked envelopes on hand upon the receipt of this announcement. The Chief of the Bureau wishes to express to all coöperators his sincere appreciation of their voluntary services rendered in connection with the publication of *Climate and Health*. It is the intention of the Chief of the Bureau to have prosecuted during the coming fiscal year a number of special climatologic studies, and it is expected that the statistics collected during the present fiscal year will be of much value in this connection. The results of these special researches will, if their importance justifies the so doing, be published in the form of special bulletins, at such times and in such shape as the circumstances may warrant and make necessary. WILLIS L. MOORE, Chief of Bureau.

**Puncture in Hydrocephalus.**—Schilling reports in the April *Memorabilien* his experience in four cases of hydrocephalus treated with puncture, two of which recovered. Ages, seven weeks to a year and a half. The oldest child was taken with convulsions a month after an attack of influenza, with vomiting, strabismus and absence of spastic phenomena. Head increased in size to 57 cm. The left ventricle was punctured and aspirated, and 300 c.cm. was removed, followed by violent convulsions and collapse. A week later another puncture removed 270 c.cm. and the head measured only 45 cm. Phosphorus treatment and recovery. Three years have passed since, and the head now measures 52 cm. The youngest child was relieved of 2 c.cm. of a bloody serous fluid from the right ventricle, although puncture of the left ventricle had been barren. Marked improvement followed, but strabismus and vertical nystagmus later ensued. There was a suspicion of meningitis in this case, due to septic infection from the rite of circumcision. The cases not benefited were congenital hydrocephalus and tubular meningitis. Schilling recommends puncture of the side ventricle as an easily performed operation. A broad elastic bandage should be applied to the head afterward, and phosphorus administered.

**Fallopian Tube Tabloids Among the Latest Therapeutic Innovations from London.**—The *Medical Press and Circular*, June 10, considers with all due seriousness the alleged innovations of extracts of extra-glandular origin. It says: "Although it is discordant with medical opinion that any of the tenets of homoeopathy should have a place in educated medical practice, we admit that the most modern phase of therapeutics trends in this direction. The fashion just now is to prescribe for the disease of any organ an extract from the active principle of that organ itself. Thus it happens that the firms which cater for advanced therapeutic ideas of this sort are offering to the profession suitable preparations of such active principles. Messrs. Burroughs, Wellcome & Co., for instance, announce that they are ready to supply: Salivary-gland tabloids for use in amyloseous dyspepsia; pineal-gland tabloids for softening of the brain, etc.; nuclein tabloids for nervous prostration, etc.; kidney-substance tabloids for diseases depending upon disturbance of the renal functions; cervical lymphatic-gland tabloids for glandular swellings, etc.; Fallopian-tube tabloids for neurotic affections; liver-substances tabloids for uremia, etc.; spinal-cord tabloids for brain diseases. They have retained the services of a former pupil of Pasteur, who devotes his whole attention to this branch of the business, and who maintains that the active principles can be thus isolated and preserved in perfection. No doubt, if disease does not 'mock the meat it feeds on,' these preparations will prove effectual."

**The New York County Medical Association.**—At the June meeting of that society the special committee on hospitals made a report condemning the action of the appointing powers in the city institutions, in part as follows: "The committee desires to report that though it has used its best endeavors to secure a just balance of evidence in the hospital patronage affair, yet the testimony given before our body has been given entirely by the profession and not by the colleges. The faculties have ignored our communications and have kept strangely silent. Yet the very fact of their casting honorary positions broadcast among those physicians who were unjustly removed from places long and ably filled is circumstantial evidence that injustice was done at the instigation of the colleges, and that peace offerings are now necessary. The campaign of the colleges is one of deception, and in order to make such a campaign successful it was necessary to ensure no medical man being appointed a Commissioner of Public Charities, as the whole scheme would have been transparent to a physician. Several members of the faculties waited upon the Mayor and urged that 'no doctor should be a commissioner, as that would break up the harmony between

the colleges and the board.' Having thus rendered deception less easy of discovery, they proceeded to hoodwink the Mayor and the board, making many statements which you have seen exposed as perfectly ridiculous by the medical journals. The latest plan is to give a sop to complainants for quieting purposes, and then to address the commissioners with the idea that the profession was satisfied. These sops are appointments as consulting physicians. As is well known such an appointment is only a superannuation and practically is of no value to anyone; but the idea seems to be to convey to the commissioners the impression that injustice has been righted, while concealing the fact that the appointees are not returned to their old places, but are expected to be satisfied with positions that exist only on paper."

**Investigation of the HCl Secretion and Motility of the Normal Stomach.**—Schüler has been investigating the action of the healthy stomach. He finds that the quantity of free and combined HCl varies very much at times in the same person and in different persons. The maximum of free acid is between 0.05 and 0.2 per cent.; of acid in combination, between 0.012 and 0.11 per cent.; and of total acidity, between 30 (0.11 per cent.) and 70 (0.26 per cent.). When the free acid amounts to more than 0.22 per cent. and the total acidity is over 70, there is hyperacidity. (This limit is too high for some persons.) The figures refer to Ewald's test meal; the time required for digesting it was found to be from 45 to 75 minutes. Pentzold's statement was confirmed that acid was secreted later with solid foods than with broths, etc., but was then more concentrated. Meat and milk were found to be about equal in inducing the secretion of the acid, while porridge and potato soups were followed by a smaller total amount of acidity. The effect of various medicines and foods was also studied. Salt, five grams, produced no effect on the digestion, while sixteen grams diminished the HCl secretion and interfered with the peptic action of the gastric juice. Twenty-four grams first stopped and then stimulated the secretion of HCl. Bicarbonate of soda first stopped the secretion of acid, but this was followed later by an increase in the secretion, which rose then to normal and above. Repeated doses of it (7-1-2-2-1 grams) resulted in permanently diminishing the amount of acid secreted, while increasing the amount of mucus. Bismuth subnitrate was found to be a genuine antacid, and it diminished the amount of acid secreted without any subsequent increase. HCl medication produced no apparent effect on the degree of acidity. The motility of the stomach was studied by means of fistulas on dogs, 17-27 cm. below the pylorus. It was found that the temperature of the food had a great influence on the emptying of the stomach. Three hundred grams of spring water at 18 degrees C. had all gone from the stomach in ten minutes, while water at 28 and 40 degrees retarded the motility of the stomach to a marked degree. Ice water first retarded it for fifteen minutes, and then stimulated it, the first retarding effect extending to the muscles of the pylorus. Solid ingesta remained longer in the stomach than fluid foods. Milk can leave the stomach almost as rapidly as water (dogs). Carbonic acid in statu nascendi diminishes the motility, to which Schüler ascribes the favorable effect of bicarb. sod. a few hours after meals, in some gastric affections. From the *Zeitschr. f. klin. Med.* xxviii and xxix., in the *Centralblatt f. Phys.* April 4.

**The Action of the Pupil and its Relation to Disease.**—Irritation myosis is found in all inflammatory affections of the brain and meninges. In these affections, when the myosis gives way to mydriasis, it has the same significance as in opium and chloroform poisoning, *i. e.*, it indicates paralysis and a probable fatal termination. We find this form of myosis in apoplexy, which may thus be distinguished from embolism. It occurs early in the development of tumors near the oculo-motor center or

nerve. It is seen in the beginning of an hysteric or epileptic attack, in neuroses of the parts supplied by the fifth nerve and in morphin habitues. Paralytic myosis is found in those conditions affecting the integrity of the spinal cord above the dorsal vertebrae. The sclerosis, destruction of the cord by traumatism, tumors, caries of the cervical spine, late stages of this portion of the cord, etc., cause this form of myosis. In acute mania the appearance of this form of myosis following mydriosis is prognostic of dementia. Irritation mydriosis is found in hyperemia of the cervical cord, irritation of the cervical cord by morbid growths, or from spinal anemia and in the primary stages of tabes. An increase of intra-cranial pressure and sensory excitement by intestinal worms will cause it; physical influences produce it in mania, melancholia and parietic dementia. What is known as Rampoldi's signs of phthisis is a fluctuating irritation of mydriasis. Paralytic mydriasis is found in progressive paralysis, and diseases of the base affecting the third nerve; Knapp saw it late in thrombosis of the cavernous sinus; orbital and intraocular tumors and glaucoma cause it by destroying the ciliary nerves. Diseases at the periphery of the afferent apparatus have this form of mydriasis as a symptom if the process has destroyed their functional activity. This form of mydriasis sometimes comes as a post-diphtheritic paralysis.—*E. C. Ellett, M.D., in Memphis Medical Monthly, June, 1896.*

**Problems in Army Medical Administration.**—Lieut.-Col. A. A. Woodhull, Chief Surgeon, Department of Colorado, has lately been testing the ability of the medical officers of his department to deal with active service conditions. He has issued a series of problems in which the surroundings of a command with all the observable conditions affecting the troops are particularized, and the medical officer is required to state what would be his course of action and to give his reasons for adopting it instead of some suggested alternative. He has ample time to mature his views in solving the problems, as although the last series, No. 4, was issued June 30, 1896, the time limit for solution is December 31, next. In active service prompt action is often imperative, as in the selection of a camp when two sites are available, each of which has its advantages more or less offset by insanitary conditions. The time given to the consideration of the arguments for and against each site in the hypothetical case will assuredly be productive of good results should the officer who has solved such a problem be confronted hereafter with the necessity of choosing. Colonel Woodhull's last series consists of the three following problems: 1. A regiment of regular cavalry, with two lieutenants of the medical department attached, is cooperating with a brigade of infantry against a large body of outlaws carrying on a guerilla warfare. The troops are armed with the modern small-bore firearms, and the outlaws with large-bore muzzle and breech-loading rifles, shot-guns, muskets for buck and ball, and a few modern weapons. The climate of the region corresponds to that of Arkansas in the summer; the country is broken and wooded, interspersed with prairies of moderate size; there are numerous small streams with rocky beds the hills and alluvial banks in the lowlands; there is freedom from swampland, but the banks of the lower streams are marshy; the country is sparsely settled and not well cultivated but there is grazing for the animals; the villages are very small and the population, generally speaking, is disaffected. There are no available railroads and few good country roads. As a rule the cavalry will be broken up into troops or smaller bodies engaged in running down the guerillas who have descended from the hills, in cutting off their escape into the hills and occasionally in penetrating the hills in pursuit or search of them. There will be few collisions of masses, but a number of harassing encounters with resulting casualties. At the end of three months the outlaws will have been disarmed

or will have surrendered. A base hospital for the infantry, to which cavalry may be admitted, will be established on a stern-wheel boat on a navigable stream fifty miles by land from the average line of the mounted operations. State in a general way what supplies would be required for three months' field service, especially the kind of tentage and the transportation for the disabled. What detachments of the Hospital Corps would be necessary? How will the sick list proper probably be made up, and what proportion and character of casualties may be anticipated? How will the medical service generally be rendered, bearing in mind that the cavalry will usually operate in detached bodies of a troop or less? As the senior of the two officers, indicate what you would anticipate and how you would provide in advance for the sanitary, the medical and the surgical care of the troops without drawing upon the infantry in the field. 2. A division of newly-raised infantry volunteers recruited in the central Western States, goes into three brigade camps, a mile apart, on the left bank of the Ohio, above Fort Thomas, June 1. The camp was originally intended only for temporary purposes, but circumstances prolonged its occupation until September 30. The usual diseases affecting such troops prevailed in due course, but by July 10 the sick list represented 10 per cent. of the strength and there had been ninety deaths in camp. Visiting the camp as a medical inspector, July 15, and continuing as such for these and other troops until this camp was broken up, what would you expect to find the medical condition had been and to be at the time, what diseases would you fear might arise or continue to prevail, and what result would you hope to attain should your advice be followed, with reasons. Give in this connection a carefully prepared schedule of the advice proper to be tendered for the preservation of the health of these troops. 3. A general engagement has occurred between forces of nearly equal fighting capacity and equipped with modern arms. During the night the enemy, who has been on the defensive, retired, leaving his dead, a large proportion of his severely wounded still on the field, and his hospital two miles in rear of the line of battle with 300 badly wounded. With these there were left five officers and twenty-five enlisted men of his medical corps, with tents, medical supplies and subsistence for one week, but no transportation. The army that held the field went into action with 30,000 men of all arms (divided into two corps) present, of whom 25,000 were actually engaged. The battle occurred in October in latitude 38° 30' north, ten miles south of a river navigable for fair-sized steamers. The field base was on that river against which the defeated army had been advancing. The country is fairly level and moderately wooded with three good country roads five miles apart, but with no railroad between the base and the battlefield. The medical director was informed twenty-four hours in advance of the probable site and time of the battle. What arrangements should be made for the field and base hospitals? What number of wounded should be expected and how would they be divided, in anticipation, among those requiring no transportation, those who could be carried in army wagons and those for whom ambulances would be necessary? Explain the arrangements made for the medical department, assuming that the full complement of medical officers and men is with the troops and that the base hospital is independently equipped. The army moves forward at daylight after the battle and anticipates contact with the enemy's rear guard, leaving one regiment of infantry to guard the hospitals and for urgent outside fatigue. The Medical Director remains throughout the day and rejoins the army in the night. Explain in such detail as convenient how he will have been engaged through the day and write out the principal orders he will give for the disposition of his own wounded and those of the enemy. It may be assumed that it will rain hard within twenty-four hours after the battle.

**Cleanings.**—(*Semaine Méd.*, June 24.) Efficacy of faradization of the uterus in accelerating delivery and arresting postpartum hemorrhage. Three cases.—(*Revue Int. de M. et de C.*, June 25.) All that is sold for entire wheat flour is not always what it pretends to be. Capsules keep the thyroid gland fresh longest. A new operation for hemorrhoids removes the tumors if the skin does not adhere to them, ligates and divides them and sutures the skin again. An inguinal hernia is described, 55 c. long, 40 in diameter and 95 in circumference. 3,000 boils and carbuncles successfully sprayed with hot phenic solution à la Verneuil. Athetosis found to be almost invariably preceded by diphtheria.—(*Therap. Woch.*, June 28.) Recovery from abdominal extirpation of a large myoma and duplex uterus.—(*Progrès Méd.*, June 27.) Able illustrated article on the lesions found in multiple neuritis.—(*Gaz. Méd. de Paris*, June 27.) Coli bacilli found in the blood of gastric fever cases. Intense hemophilia in female infant.—(*Union Méd. de Canada*, July.) Milk diet with cream of tartar lemonade, absolute prophylaxis of puerperal eclampsia.—(*Deutsch. Med. Woch.*, June 25.) Beneficial effect of the constant current in a few cases of traumatic peripheral paralysis.—(*Nouveaux Remèdes*, June 8.) Painting the nipples with cocain will suppress the lacteal secretions.—(*Wiener Klin. Rundschau*, June 28.) Efficacy of compresses wet with alcohol in incipient phlegmons. Case of gallstone causing supuration and finding its way into the pleura and bronchus, until the stone and pus were coughed up. Demonstration that sulphureted hydrogen is formed in the mouth during mastication, which digests alone certain vegetables.—(*Cbl. f. Chir.*, June 27.) Fraenkel's method of narcosis: Before administering the chloroform, he injects 1 c.cm. of a solution of morph. muriat. 0.15; atropin sulph. 0.015; chloral hydrat. 0.25. He has never had a fatal case nor severs asphyxia in twenty-two years. Artificial creation of bone tissue by implanting calcined bone.—(*Medittina*, No. 8.) Cholera found to produce grave lesions in the brain.—(*Tidsskrift for den Norske Laeg.*, June 15.) Beneficial action of antispasmin in whooping cough confirmed. Dose under 1 year 0.01 to 0.015 three or four times a day, 0.02 under 3 years, and 0.04 over 3. Or by this formula: Antispasmin, 2; aquæ dest., 900; elixir pectoral, 98.

### Louisville.

**DEATH REPORT.**—There was a total of seventy deaths for the past week and eight stillbirths. Consumption was the cause of nine. One case of diphtheria and four of scarlet fever were placarded.

**DR. H. HORACE GRANT** will deliver the annual address on Surgery at the next meeting of the Mississippi Valley Medical Association.

**BOARD OF SAFETY.**—Impeachment proceedings have been instituted against the Board of Public Safety by the Common Council and the trial will be by the Board of Aldermen. Among the charges submitted by two members of the council to the Board of Aldermen are the following: General and intentional disregard of the enforcement of the laws of the State against gamblers and gambling, pool-rooms, and houses of ill-fame; the ordering a discontinuance of a list of these houses which is required to be kept by the police department under orders from the above board; the creating of great confusion in the financial accounts of the city hospital and alms house by causing the discontinuance of all the financial books of the institutions, making it impossible to tell the cost per month or year of either institution, and making it possible for unjust and false claims to be brought in against them, and the bringing in of claims which should be charged to another year; the wilful violation of an ordinance passed by the council providing for the number of officers in charge of the Eruptive Hospital by their wrongfully increasing the number of paid employees and fixing illegal salaries, without the consent or approval of the mayor or council and to the injury and prejudice of the city treasury and the city service, for all of which they claim the Board is guilty of usurpation in office for which they and each of them ought to be removed from office.

## THE PUBLIC SERVICES.

**Army Changes.** Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from July 11 to July 17, 1896.

Major Clarence Ewen, Surgeon, leave of absence on account of disability is extended one month on account of disability.

Col. Dallaa Bache, Asst. Surgeon-General (Hdqs. Dept. of the Platte), is granted leave of absence for two months, to take effect on or about July 15, 1896.

Major James C. Worthington, Surgeon, extension of leave of absence granted on account of sickness is further extended one month on account of sickness.

**Navy Changes.** Changes in the Medical Corps of the U. S. Navy for the week ending July 18, 1896.

Surgeon R. C. Persons, orders to duty at naval hospital revoked and ordered to continue on present duty.

P. A. Surgeon H. N. T. Harris, ordered to the Pensacola navy yard.

Surgeon S. H. Dickson, ordered to the "Texas."

Asst. Surgeon J. M. Moore, detached from naval hospital, Norfolk, and ordered to the "Texas."

Asst. Surgeon A. Farenholt, detached from the "Monterey" and ordered to the Mare Island hospital, Cal.

**Marine-Hospital Changes.** Official list of changes of station, and duties of Medical Officers of the U. S. Marine-Hospital Service, for the period from June 21 to July 15, 1896.

Surgeon George Purviance, to assume temporary command of Service at Philadelphia, Pa., for thirty days, July 3, 1896.

P. A. Surgeon C. T. Peckham, placed on waiting orders, July 3, 1896.

P. A. Surgeon J. H. White, to proceed from New York, N. Y., to Key West, Fla., for special duty, July 10, 1896.

P. A. Surgeon G. T. Vaughn, granted leave of absence for thirty days, July 7, 1896.

P. A. Surgeon W. G. Stimpson, to assume temporary command of Service at Port Townsend, Washington, July 3, 1896.

Asst. Surgeon E. K. Sprague, to proceed from Boston, Mass., to New York, N. Y., for temporary duty, July 10, 1896.

Asst. Surgeon H. W. Wickes, granted leave of absence for twenty-seven days, July 8, 1896.

Asst. Surgeon J. B. Greene, to proceed from Baltimore, Md., to Pt. Pleasant, N. J., for physical examination of crews of life saving service, July 13, 1896.

Asst. Surgeon W. M. Jordan, to proceed from Birmingham, Ala., to New York, N. Y., for temporary duty, July 13, 1896.

### PROMOTIONS.

Asst. Surgeon J. A. Nydegger, commissioned by the President as Passed Assistant Surgeon, July 7, 1896.

Asst. Surgeon W. J. S. Steward, commissioned by the President as Passed Assistant Surgeon, July 8, 1896.

### APPOINTMENT.

William M. Jordan, of Alabama, commissioned by the President as Assistant Surgeon, July 7, 1896.

### Change of Address.

Baughman, J. N., from Flat Lick, Ky., to 617 Chestnut St., Evansville, Ind.

Caldwell, J. R., from West Liberty, W. Va., to St. Clairsville, Ohio.

Collins, R. G., from 5059 State St. to 5139 Wabash Ave., Chicago.

Guyon, E. F., from Pseudotou, Ore., to Montpelier, Idaho.

Kellogg, G. M., from Las Vegas, N. M., to 2310 Indiana Ave., Chicago.

Kellogg, W. H., from Oakland to Palo Alto, Cal.

Lewis, W. M., from 154 N. Spring St. to 248 Wilcox Building, Los Angeles, Cal.

McDaniel, E. D., from Mobile, Ala., to Milton, Fla.

Osborne, G., from 75 Rush St. to 161 Michigan St., Chicago.

Roy, G. G., from 1½ Edgewood Ave. to 20 E. Ellis St., Atlanta, Ga.

Sefler, Carl, from Philadelphia, Pa., to Saranac Lake, N. Y.

### LETTERS RECEIVED.

Abrahams, R., New York, N. Y.; Appleton, D. & Co., Chicago.

## ORIGINAL ARTICLES.

### PUERPERAL FEVER; ITS PROPHYLAXIS AND TREATMENT.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY E. E. MONTGOMERY, M.D.  
PHILADELPHIA, PA.

The mysterious condition known as puerperal fever has been a prolific theme for discussion. Its insidious character, its multiple lesions and its grave mortality sometimes depopulating lying-in hospitals or causing the death of every parturient woman in a district, have naturally directed interest to its study.

When we review the conflicting theories as to its genesis we find they may be resolved into two views; the one, the more simple and concrete, but less satisfactory, which seeks to associate the disease with the discovered anatomic lesion. With the development of the anatomy the distinction of the lesions has become more delicate and is limited to the tissues, as peritonitis, adenitis and the various abscesses of the pelvis. This is the localization theory. The other theory is that known as the essential doctrine, that the disease is due to some special miasm or infectious poison from which has been evolved the microbic etiology.

The repetition of cases of similar character in the same institution, or the same district naturally led to the recognition that it was an infectious disease and to the supposition that it was due to a special miasm. The specific identity of this poison was ably championed by Fordyce Barker, who claimed that puerperal fever was a distinct disease.

The researches of Pasteur rendered it probable that it was due to the presence of microorganisms which were conveyed to the victim by contact, through the atmosphere, or had developed as ferments in her body. Siredey as early as 1875 determined the absolute similarity between surgical and puerperal infections, and further asserted that puerperal peritonitis was secondary to a uterine lymphangitis. The continuous association of certain forms of bacteria in the uterine discharges of puerperal fever, the ability to develop similar septic conditions in the male by the injection of these organisms or their products, demonstrate the certainty of their baneful influence. Bumm, as a result of his researches into the microorganisms of puerperal sepsis accepts two forms of infection; 1, putrid infection, produced by retained portions of placenta, decidua or blood clots infected by the saprophytes, various bacilli and cocci, developing a condition known as sapremia; 2, the septic form, the result of the presence of the pyogenes, the streptococcus and staphylococcus. Vidal claims to have seen a fatal case of puerperal suppuration which was apparently due to the bacterium coli.

The investigations of Doleris have demonstrated

the identity of the streptococcus of erysipelas with that which results in puerperal fever, or sepsis. Careful investigation no longer leaves a doubt that the puerperal inflammation is induced by a streptococcus identical in its characteristics with the streptococcus of erysipelas and the pyogenes. It can not be denied that inflammation of a less intensity may develop from infection by the staphylococcus. Some cases of peritonitis and puerperal lymphangitis are undoubtedly produced by the bacilli of putrefaction. Rarely the bacillus coli communis may engender a suppurative peritonitis. The process of infection is greatly facilitated by obstetric traumatism, the existence of previous attacks of gonorrhoea, and the presence of bacilli in the vagina.

The streptococcus conveyed to the patient by the finger of the physician, or nurse, or by instrumental manipulation during or following labor, makes its habitat in the debris of the mucous membrane, in the lymphatic fluid and blood clots at the situation of the placenta, in the material which forms the lochia, or vaginal discharge following parturition. The canals of mucous glands, tears of the cervix, vagina and vulva afford opportunity for further development; without producing marked effect upon the uterine or tubal surfaces the infection may pass through these organs and produce violent and dangerous infective processes in the ovaries or peritoneal cavity. The writer has seen one case in which there was developed an abscess of the ovary without any uterine or tubal complication. In this case, the uterus and tube afforded access of infection to an ovary which was probably rendered more vulnerable by the existence within it of the corpus luteum of pregnancy. The infection proceeds by continuous extension through the Fallopian tubes to the peritoneal cavity, but in addition it extends through the lymphatics and blood vessels. The multiplication of germs results in the formation of ptomain or toxin products. The increase of the toxin results in irritation, swelling, congestion and the exudation of liquid plasma into the cellular tissue. The presence and multiplication of the germs results in the destruction of the vitality of the infected tissue, the necrosis in mass of large layers of tissue, producing a superficial acute gangrene, or pseudo-diphtheria. The condition is always pus-producing and septic.

Clinically we find the disease varies in different patients. This is due to the varying immunity to the microorganisms. The varying power of resistance in different individuals produces different types. These have been resolved into three: first, inflammation, and local suppuration; second, inflammation and migratory suppuration, and third, hypertoxic infection without suppuration. The point of infection varies in labor and abortion. In the latter, the placental site, and erosions of the cervix will generally be the avenue through which the infection has found

alcohol. The bedding and personal clothing of the patient should be clean, the vulva should be washed with soap and hot water, the bowel emptied by an enema and an antiseptic douche given. Digital vaginal exploration should be infrequent and only after careful disinfection of the hands. Instruments should be sterilized by boiling. Long continued manipulation, instrumental delivery or manual delivery of the placenta, should be followed by antiseptic intrauterine irrigation.

The parts should be carefully cleansed subsequent to delivery, the placenta carefully observed to make sure no portion remains, and the uterus should be left firm and well contracted. Laceration of the vagina and vulva, unless the tissues are bruised or the vitality destroyed by long continued instrumental delivery, should be at once sutured; excoriations may be cauterized by carbolic acid. The vulva should be covered with an antiseptic pad which should be changed as frequently as it becomes soiled. With each changing, the vulva should be cleansed with an antiseptic solution. Aside from the immediate postpartum irrigation mentioned, intrauterine or vaginal douching should not be practiced.

But physicians will reply that they have attended large numbers of confinement cases without such precautions and no bad results have followed. This may be true. With ordinary precautions the chances are favorable, and much depends upon the condition of the patient. Not every patient, fortunately, to whom contagion is conveyed, yields to its influence. The normal secretions of the vagina are unfavorable for germ culture. The tract is irrigated by discharge of the liquor amnii and swept clear by the passage of the fetus. Many eminent obstetricians, among whom may be named Lusk, are content to depend upon these conditions in ordinary cases; still, the preliminary douching does not seem useless.

Treatment of *infection* may be considered as, first, maintenance of the powers of resistance; second, production of immunity; and third, the resort to surgical procedures for relief of local manifestations. This classification of treatment has reference to septic conditions. Sæmia or putrid intoxication is relieved by removal of the decomposing placenta, portion of membrane or blood-clot, and subsequent irrigation and drainage. The diagnosis is determined by the character of the lochia and the digital exploration of the uterine cavity. Decreased or absent lochia, elevation of temperature, rapid pulse, depressed, anxious countenance, should betoken the suspicion of beginning sepsis. It may or may not be accompanied by local tenderness. Exploration of the uterine cavity reveals a smooth surface, which should confirm the diagnosis. The rapidity with which the vital forces are depressed contraindicates the use of depleting agents, unless it be the moderate use of purgatives to aid in elimination. Early resort should be made to the use of tonics, stimulants and easily assimilated and nourishing food. The most efficient stimulant will be found in strychnin, which should be given for effect, and may be administered hypodermically in doses of gr. 1-15 every two or three hours, where there is much depression. Opium, morphin and anti-pyretics should be given with great circumspection. For the control of temperature, cold sponging or the cold pack should be practiced. Pain, whenever possible, should be relieved by the ice bag. The natural tendency of disease germs is to develop toxins which

are toxic to themselves, and render the individual immune to further ravages. The better the nutrition, the more the strength is sustained, the earlier immunity will be secured. In many cases, however, the progress of infection is so rapid, the intoxication so profound, that the patient can not survive until immunity has become established. As we can not foretell in any individual the virulence of the infection, nor the possible powers of resistance, the use of an antitoxin should be considered as indicated wherever infection is recognized. This is best given by hypodermic injection. These injections of streptococcus antitoxin should be given in doses of 25 c.c. once daily for four days. They may be made into the cellular tissue of the abdominal wall, or into the buttocks or thighs. Of course, every precaution must be practiced to render their use aseptic.

Bacteriologic study should be made of the secretions, but as the large majority of septic troubles arise from the presence of the streptococcus, valuable time may be saved by immediate use of the antitoxin.

The following history is of interest: A young woman gave birth to a child February 18, at 6:30 P.M. Twenty-four hours later her temperature was 103.8 degrees, pulse 130, the next evening 104.2 degrees. Her husband at the time was suffering from numerous boils, and her physician, the day following her confinement, developed an onychia of the right index finger. The writer saw her upon the sixth day, when her temperature was nearly 102 degrees; the uterus was large, situated to the left side, quite tender, and vaginal examination disclosed some induration in the left broad ligament. The vagina was inflamed and filled with thick muco-purulent material with no especial odor. The vagina was carefully irrigated and scrubbed, the uterine cavity cleansed and packed with iodoform gauze, an opening made into Douglas' pouch, some flakes of lymph removed by irrigation and a gauze drain inserted. Her symptoms improved for two days, and then became aggravated. An erysipelatous blush was noticed extending from the vagina to the buttocks, and the vulva much swollen. This extended in a wave-like course until the entire body became involved. March 11, over three weeks from her confinement, the temperature had been but twice below 100 degrees and now was nearly 104 degrees, with a renewal of the erysipelas at the vulva. The antitoxin was now begun and given daily for five days after the first dose, and the temperature subsided and convalescence was subsequently uninterrupted.

*Surgical Measures.*—Curettement is advised early. If the condition is due to putrid intoxication this procedure, followed by irrigation and drainage, will give prompt relief. In streptococcus infection the germs are imbedded in the mucous membrane, sinuses and wall of the uterus, so that a curettement would not accomplish their complete removal, and affords more surface for ptomain absorption. Hysterectomy has been advocated, but it is a question whether in this form of infection the tissues have not been invaded to such a degree that the removal of the uterus would be ineffectual. The first aim should be the establishment of immunity, then local manifestations should be treated as they make their appearance with the assurance that farther spread will be avoided.

Let us have a Department of Public Health!

## PUERPERAL INFECTION; ITS PATHOLOGY, PREVENTION AND TREATMENT.

Read in the Section on Obstetrics and Diseases of Women at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY R. R. KIME, M.D.

ATLANTA, GA.

The term "puerperal fever" should be abandoned, as it is too broad and includes conditions which are not peculiar to the puerperal state, hence misleading.

Puerperal septicemia as used by many is also objectionable; it should be limited in its application and used only to indicate cases of true septicemia. Text-books and lexicons define "puerperal fever" as an acute infectious disease due to septic inoculation. Some authorities apologize for the definition, and well they may under the present light and knowledge of these conditions.

In writing upon this subject, some five years since, for the Tri-State Medical Association I endeavored to demonstrate the existence of two general classes of puerperal infection. Such a view then met with strong opposition and some of our best authorities wrote me such a distinction could not be maintained. To-day I am more fully convinced than ever that we have a septic and a putrid infection occurring during the puerperal state and that they can be distinguished bacteriologically, pathologically and clinically. We may have cases of mixed infection, as in other diseases, but that does not justify the wholesale grouping of all these cases under the cloak of septicemia as is done by many authorities, even at the present time. As our knowledge of puerperal infection becomes more accurate, our bacteriologic demonstrations more definite and our clinical histories more minute, we will find the distinction between *putrid* and *septic* infection broadens in the same proportion.

Putrid infection, or sapremia, is due to the absorption of ptomaines developed by putrefactive bacteria or saprophytes; the bacilli remain localized in the dead tissue; the alkaloid, being absorbed, produces constitutional symptoms in proportion to the amount imbibed, is not contagious nor inoculable from case to case, except where foreign substances are retained in the uterus. Putrid infection can not graft itself in healthy tissue, foreign or dead tissue must exist as a nidus for its development.

Septic infection or septicemia is due to invasion of septic germs producing constitutional and local disturbances by their presence and invasion of new tissue with absorption of leucomains, their alkaloidal development. They enter living tissues; migrate from point to point, entering the circulation; are highly contagious and inoculable from case to case. Streptococci are said to travel one centimeter per hour, penetrate the tissues and spread by the lymphatics and blood vessels. A variety of germs are capable of producing septic infection; among the most frequent are the streptococci and staphylococci. The infection may be local, affecting the endometrium (Bumm), extending, may involve the lymphatics (lymphangitis) or the venous channels (thrombo-phlebitis) with various complications and general systemic infection. It is here we may have the much-talked of pelvic cellulitis, with or without abscess formation, salpingitis with or without pyosalpinx, pelvic peritonitis and even general peritonitis, while the thrombo-phlebitic variety may result in multiple abscesses in the uterine wall.

Prevention of puerperal infection is accomplished by strict asepsis in obstetric practice, as well as thorough emptying the uterus and securing proper contractions with repair of lacerations. All recognize the necessity of strict cleanliness of physician, nurse, patient, bedding and everything that comes in contact with the patient. We do not desire to sing the old song of "antiseptics in obstetric practice," but for the sake of suffering women desire to urge the necessity of *strict asepsis* and often of disinfection. Even after the physician's hands have been scrubbed with soap, warm water and brush the application of ammonia, solutions in proper strength of creolin, lysol, carbolic acid or mercuric chlorid can do no harm and will often add to the safety of the patient. The patient should have a warm bath, vulval region washed with soap and warm water and a disinfectant will add to her safety. She should be dressed in clean clothing suited to the occasion, placed in a clean bed properly arranged, bowels moved and bladder emptied, then she is ready for labor.

As to use of the antepartum douche there is a difference of opinion, which has been well presented by Charles Jewett, M.D. (April issue *American Gynecological and Obs. Journal*). He states that the statistics at the Dresden Clinic (Leopold) show that of 5,784 cases douched, 82 per cent. were free from fever; of 4,088 cases not douched, 94.8 per cent. were free from fever, which goes far to establish the claim that the antepartum douche is useless and it should not be used, especially in private practice, except for cause. In hospital practice among the lower classes there is greater necessity for its use. If diseased conditions be present, indicated by a "yellowish, greenish or fetid discharge, especially of excoriating character," then prophylactic vaginal disinfection is required. Unless such conditions be present nature's protective, lubricating, disinfecting vaginal secretion is too important a factor in labor to be interfered with.

Postpartum douches, as a rule, are to be condemned as useless and frequently injurious, by exposing the patient unnecessarily and increasing the risk of infection.

After labor cleanse the patient externally with an antiseptic solution and apply antiseptic vulval pad. The antiseptic pad properly applied and attended to, adds to the comfort and safety of the patient, lessening the risk of infection, especially if any cough be present. The vulval region should be cleansed two or three times a day with 1 per cent. solution creolin, lysol, 3 per cent. carbolic acid, 1 in 2,000 mercuric chlorid or saturated solution of boric acid. As few vaginal examinations as possible should be made. The patient, unless some special contraindication exists, should be lifted up over a vessel in bed for the bowels to move or kidneys to act, thus favoring vaginal drainage. The thorough emptying of uterus and securing proper contractions of the same are preventive measures of great importance, as the presence of placental tissue, membranes, blood clots, etc., is an inviting field for germ development and essential for putrid infection. The repair of lacerations, especially of perineum, should not be overlooked, as such repair closes raw surfaces and closes avenues for infection.

The treatment of puerperal infection is a subject of grave importance and especially so at the present time, when hysterectomy and abdominal section for these conditions seem to be a fad. I am confident that a far greater number of cases of infection occur

than the general profession are willing to admit and that many cases of mild infection are overlooked or attributed to other causes; severer forms are treated as other diseases and when the patient dies the death certificate reads typhoid fever, malaria, inflammation of bowels, etc. The recorded deaths do not represent the actual number, much less the vast number of cases of infection that either recover or go through life maimed.

If the obstetrician could follow up his work closely he would frequently find results of infection which he had overlooked or attributed to other causes, but his services usually cease with the puerperal period and later the patient seeks the specialist for advice and he frequently finds results due to infection after labor or abortion.

Drainage is the most essential factor in the treatment of puerperal infection. It is a process of elimination from the uterine cavity, alimentary canal and abscess cavities by tubular or capillary drainage and cathartics. For uterine drainage the tubular form is the best, and salines for alimentary drainage. During pregnancy we have a hyperplasia of tissue with consequent increased vascularity of the generative organs, which must be reduced after the uterus is emptied by a process of retrograde tissue metamorphosis requiring great activity of the lymphatics. This process, with an open placental site, accompanied by the traumatism of labor render the parts very vulnerable to the entrance of germs and absorption of toxic principles. We have as a natural result of labor or as an acquired pathologic result a discharge from the uterine cavity, following delivery, in which nature throws off waste material by a process of elimination or drainage. This discharge contains cellular elements of the blood, leucocytes and other débris which can not be drained off by gauze. We tampon with gauze to check hemorrhage and wall off septic material in abdominal work. Shall we tampon the uterus with gauze, checking nature's process of elimination, choking up nature's channels with débris and dead leucocytes laden with septic germs, by placing an impenetrable barrier in the way of their exit, or shall we imitate nature and give free egress to all noxious material? Does the successful surgeon tampon a large abscess cavity with a small opening with gauze alone, especially where there is a septic process and necrotic tissue? As a rule, abscess cavities have a protective wall around them which lessens dangers of absorption, thus favoring the use of gauze, but not so in septic infection. Large opening and free drainage is the rule in surgery. In puerperal infection one can not secure a large opening or free drainage with gauze tampon. Again the dangers of gauze packings are very greatly increased by curetting off the endometrium, especially in septic infection. The curette should rarely, if ever, be used in septic infection; it is too dangerous and deleterious in its results.

Frequently we hear physicians say, "I curetted, disinfected and tamponed yet the patient died"; and it might be added as a result of the treatment. If a curette is used at all it should be a large dull one and used simply to hook up tissue which, as a rule, can be more readily removed by forceps, and not used with a view of removing endometrium or even adherent tissues, as is done by some. In putrid infection the curette can be used vigorously, the uterus tamponed and yet the patient recover regardless of the treatment; but nature is not so well able to overcome

such treatment in septic infection, and it is frequently a method of manufacturing cases for hysterectomy.

These remarks are applied to cases of infection after labor and not cases of abortion prior to the fourth month. Infection after incomplete abortion, in the majority of instances, are typical cases of putrid infection and easily relieved by the curette, disinfection and tampon, because we have different conditions to deal with.

To make a clinical distinction and give separate treatment for putrid and septic infection would make this paper too lengthy, so we will briefly consider them collectively.

As soon as puerperal infection is diagnosed, irrigate the uterine cavity with a disinfectant fluid, then remove any foreign substances that are present by a method least likely to injure the endometrium and best suited to the individual case and dexterity of the operator, then irrigate freely again. If much hemorrhage, irrigate with very hot water containing comp. tr. iodine or alum; never tampon except for serious hemorrhage, but introduce as large-sized drainage tube as cervix will admit. Soft rubber tubing is as efficient as any and may be used in the form of a † or loop with perforations in the uterus, and the T or free ends of loop left in the vagina, which ends should also be perforated to allow free egress.

If capillary drainage is also desired a strip of gauze can also be carried up into the uterus by the side of the drainage tube with free end left in the vagina or, if desired, may be carried out to antiseptic vulval pad, but I prefer at this time to dispense with the pad, using a pledget of absorbent cotton, so as not to obstruct drainage. The end of the strip of gauze in the uterine cavity may be saturated with pure camphorated phenol before introduction, so as to prolong disinfection of the uterine contents and is far better than any suppository for such purpose. Boric acid, pure, may be also carried into the uterus on the gauze, and a tablespoonful left in the vagina is efficient. Drainage tube should be removed once or twice in twenty-four hours, uterus irrigated with disinfectant solution, *not too strong*; carbolic acid, boric acid and creolin are best. If uterus is relaxed or there is hemorrhage, a solution of compound tincture iodine should be used. It may be added to carbolic solution. Weak solutions should be used, as strong ones will interfere with nature's process of repair. If the tube is removed but once a day a vaginal douche should be used midway between times. The drainage should be continued until patient has fully recovered. At commencement salines should be given to produce free catharsis, thus eliminating poison, relieving pelvic hyperemia and abdominal distension and pressure.

The combined use of drainage tube and salines will control temperature far better than antipyretics and relieve pain better than opiates, beside they are curative by relieving the cause and more permanent in results. The coal tar derivatives, as antipyretics and opiates for pain, only combat symptoms, depress the patient, interfere with elimination of effete material, assimilation of food and obscure symptoms; in short, injure more patients than they benefit. They should never be used except in extreme cases of high temperature or severe pain as a palliative measure until other treatment can be instituted. Sulphonal is the best soporific. Viburnum and the bromids act well in some cases. Quinin in ten grain doses at four hours' intervals at first, later in smaller doses, is efficient in

checking germ development, counteracting toxic principles, sustaining vitality of the patient and controlling the tendency to chills. Strychnia given every four hours, combined with pepsin, disinfectants and bitter tonics best suited to the individual case, are essential as well as good nourishing diet given systematically. In debilitated cases stimulants are needed and frequently artificial foods will be required to keep up the vitality of the patient. Of these I have found beef peptonoids, panopeptones and malted milk most reliable. After acute symptoms have subsided some of the most assimilable forms of iron are beneficial. Frequent alcoholic baths with or without quinin are useful in tranquilizing the patient, stimulating cutaneous surfaces and checking profuse perspiration.

If the above outlines of treatment with the efficient, systematic, persistent use of the drainage tube are carried out, surgical measures will rarely be required in puerperal infection. I found from inquiry of eighteen leading gynecologists and obstetricians, five were opposed and thirteen in favor of hysterectomy for puerperal infection. Of fifteen cases reported by them up to that time, eight died, making a death rate of  $53\frac{1}{3}$  per cent. The advocates of hysterectomy advise it for disease limited to the uterine body, such as septic metritis, multiple abscesses in uterine wall, uterine thrombo-phlebitis and gangrene of uterus. The diagnosis of such limitation of septic processes is very difficult and mistakes are frequent, with disastrous results. In a majority of cases of septic infection the septic process has extended beyond the uterus, involving other tissues with systemic infection which can not be reached by hysterectomy, but when it is local such an operation is indicated. Most gynecologists that favor hysterectomy advise to curette and tampon the uterus, and if the patient does not improve or grows worse, then remove the uterus. With them it is not a question of diagnosis, but a failure of a certain line of treatment to give relief, which indicates hysterectomy, and that line of treatment frequently creates the demand for the operation in cases of *septic infection*. Pus accumulations in the pelvis can frequently be relieved by vaginal drainage, as advised by Dr. Henrotin of Chicago, thus saving lives that would be sacrificed by more heroic measures. Pyosalpinx, ovarian abscess, etc., the secondary localized results of infection, should be dealt with on the same principle as when produced by other causes.

In conclusion, I again emphasize the fact that use of the drainage tube, with treatment as outlined above, will save more patients than all surgical measures combined; and more important, the uterus, tubes and ovaries will be preserved for future usefulness and the surgeon's conscience left more at ease.

## GONORRHEA IN THE PUERPERIUM.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-Seventh Annual Meeting of the American Medical Association at Atlanta, Georgia, May 5-8, 1896.

BY ALBERT H. BURR, M.D.

ATTENDING PHYSICIAN PROVIDENT HOSPITAL,  
CHICAGO.

In these latter days of widespread knowledge of aseptic measures for shielding the parturient woman from harm, the occurrence of puerperal sepsis is looked upon, even by the laity, as evidence that some one has blundered, and the attendant is fortunate if he escapes the charge of criminal negligence or inexcusable ignorance. If the infection of the lying-in

woman happened only during labor, or her subsequent stay in childbed, the charge might be sustained with justice, but we are convinced that it happens more frequently than is apprehended that an infection has antedated childbed by weeks or months, if indeed it has not preceded conception itself and invaded territory absolutely beyond the reach of any possible antiseptic treatment.

With a unilateral pyosalpinx, or a tubal infection, existing before pregnancy, or a subsequent gonorrheal infection of vulvo-vaginal glands or urethra, who can be certain, even though forewarned, that he can be effectually forearmed against such dangerous and hidden foes?

I confess to a feeling of insecurity in every approaching case of confinement where I know beforehand, or have reason to suspect, the existence of gonorrheal infection, either active or latent. In an obstetric experience of five hundred cases I have had three fatalities, each of which is directly traceable to gonorrhea. In many of the remaining cases of puerperal sepsis, more or less severe, I have found by clinical history or by microscopic verification, the presence of a gonorrheal infection. An epitome of the

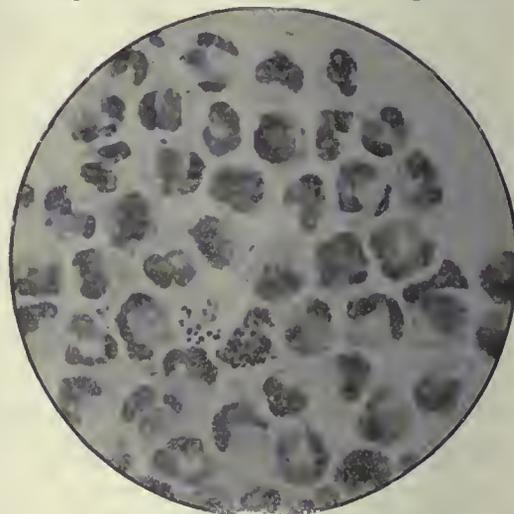

Plate 1; Case V.—Gonococci from ophthalmia neonatorum, fifth day after birth.

fatal cases, with a few added cases of non-fatal sepsis, culled for their instructive features, may serve to emphasize dangers too often ignored by the unwary. Moreover, it may comfort the troubled soul of some good brother who, believing he has neglected no reasonable precaution for the safety of his patient, has met with disaster where it was least expected. It may enable him in the future to trace the offending cause and place the responsibility where it rightfully belongs.

*Case 1.*—Elizabeth B., single, aged 20; French Canadian; primipara of vigorous physique, progressed in labor without incident until the separation and expulsion of the placenta brought with it a gush of most offensive fluid, the stench of which drove other attendants from the chamber. No odor was present at the rupture of the amnion. Nothing abnormal was apparent in the secundines. The child was robust. Here was a case of encysted septic material behind the placental attachment which no possible foresight or treatment could have reached in preparation for an aseptic confinement. Thorough infection of the whole placental site and of the parturient canal with a most deadly poison was instantaneous and inevitable. Peritonitis developed in thirty-six hours and ran its distressing and fatal course in less than a week, despite antiseptic uterine irrigations and other recognized treatment. In the absence of an autopsy the only logical conclusion is that the location of the decidua over the cornua had converted an

infected tube into a closed sack which discharged its saprophytic contents into the uterus when the detachment of the placenta had freed its uterine orifice. The vocation of the woman makes gonorrhœa the most probable cause of a pyosalpinx.

*Case 2.*—Emma M., aged 20 years; German; married ten months; remarkably strong in physique; consulted me soon after marriage for metrorrhagia. Examination revealed an acute vaginitis, characteristic of gonorrhœa. Subsequent examination of the husband showed an acute urethritis. These symptoms in the wife yielded promptly to treatment and pregnancy soon put an end to metrorrhagia. Both husband and wife, however, had recurrent attacks of sub-acute gonorrhœa during the wife's pregnancy. Confinement was normal, on March 12, 1888. Antiseptic vaginal irrigation was practiced for several days. No untoward symptoms resulted until March 20, the eighth day, when a severe chill occurred followed by high fever, but without pelvic symptoms which never became a factor throughout her fatal illness. General systemic intoxication, however, persisted to a high degree. Knowing the previous history, uterine irrigation was practiced twice daily. On March 24 temperature suddenly arose to 108 degrees, which was quickly reduced by cold packs and antipyrin. Dr. H. W. Byford saw the case in consultation the following day and curetted for diagnostic purposes, with negative results. March 30 temperature reached 108.5 degrees with delirium and typhoid state, severe arthritis of shoulder and hip joint, followed with temperature of 103 to 104 degrees, till fatal termination April 5, on the seventeenth day of fever

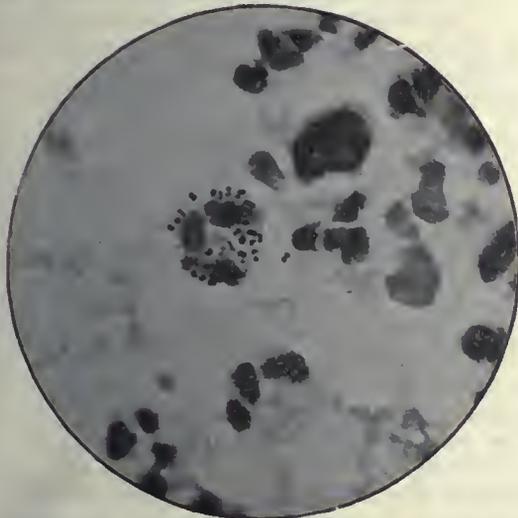

Plate 2; Case V.—Gonococci from cervical discharges, ten weeks after childbirth. Subinvolution.

and twenty-fourth day from confinement. The good health of the patient at childbirth, the sudden onset of high fever, the absence of bowel symptoms, exclude typhoid fever. My distinguished consultant concurred with me that gonorrhœal infection was the most probable direct or indirect cause in this most singularly virulent case.

*Case 3.*—Luella B., American, single, aged 18, consulted me because she had not menstruated for several months. Under a suspicion of pregnancy an examination was obtained, revealing a four months' pregnancy and an acute vaginitis, believed to be gonorrhœal. The case was lost sight of until summoned to her confinement. Labor was normal in all respects. On the fourth day there was a chill followed by high fever from an acute metritis. This was controlled after two or three days and patient was dismissed on the eighth day. In one week there was a recurrence of symptoms which again responded to treatment as before. Patient was about the house again when she had a second recurrence, under the care of another physician, and died, as I learned, one month after childbirth.

The following three cases of puerperal sepsis are interesting on account of microscopic verifications.

*Case 4.*—Ida H., four months married, was delivered at full term by a midwife. On the fifth day after the confinement I found her with a temperature of 105 degrees and an acute arthritis of hip joints with immobility of lower extremities. The child was suffering from acute ophthalmia. The pus, from which a slide was prepared, showed the gonococcus in abundance. The father acknowledged having had gonorrhœa

a few months before marriage. Mother and child made a good though tedious recovery under appropriate treatment.

*Case 5.*—Mrs. Ida T., age 21; ten months married. Labor normal. On the fifth day child developed ophthalmia of gonorrhœal infection. (See plate I.) The condition was at once explained to the father, who stated that he had an attack of gonorrhœa four months before marriage, but considered himself cured at the time he wedded his wife. He remembered having had some gleet (?) afterward. On the seventh day the mother had a chill with fever and acute arthritis of shoulder joint of right side. As pelvic symptoms were absent, no irrigations were given. Mother and child were discharged convalescent on the twelfth day. Ten weeks later the mother came to my office suffering from sub-involution. Microscopic examination of cervical discharges showed gonococci. (See plate II.) Case yielded promptly to treatment.

*Case 6.*—Mrs. Amelia S., age 26, primipara, was well advanced in second stage of labor when seen for the first time. Labor terminated without incident. Child developed gonorrhœal ophthalmia on the fifth day. (See plate III.) On the tenth day the mother was dismissed, after a good recovery, much to the relief of an anxious medical attendant. Two days later an urgent call in the early hours of morning cut short my slumber and dispelled my sense of security. Patient had a violent chill in the night, followed by high fever, with acute metritis and pelvic pain reflected to the diaphragm, causing dyspnea and a sense of suffocation. Before making intra-uterine irrigation a slide from the cervical discharge was obtained and the inevitable coccus came to light. (See plate

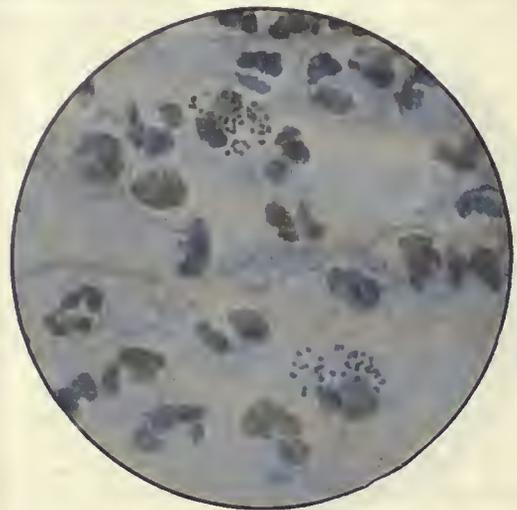

Plate 3; Case VI.—Gonorrhœal ophthalmia in babe five days old.

IV.) The husband being an actor an investigation behind the scenes was undertaken, disclosing a history of infection a few weeks before the confinement of his wife, whom he unfortunately infected also before he was aware of his own condition. This complication was almost a fatal experience, but finally yielded and the mother was again convalescent in one month. The ophthalmia in the child was also quite obstinate for some time, though daily applications of silver solution, grains xxx to the ounce, was faithfully and thoroughly applied with brush to the whole conjunctival sack.

This list of well determined gonorrhœal sepsis in childbed could be extended, but enough has been detailed to serve our purpose.

To summarize: All the above cases were primiparæ much above the average in physique and general good health. Their delivery was without complication or instrumental interference. All necessary examinations or manipulations were guarded against sepsis. In no case was there more than the usual slight laceration. In all, the presence of gonorrhœa is closely proven except in case 1, where the tubal abscess is believed to have been the result of a gonorrhœal infection previous to conception. Three of the cases developed rheumatoid arthritis during the pyrexia. This is a well known complication due to systemic infections of the gonorrhœal germs or their ptomaines.

No doubt exists in my mind from the evidence in the cases above enumerated and others which I could add to the number, that the microscope and other means of investigation as to the gonorrheal infection would clear up the etiology of many septic complications and fatalities in childbed. These unnecessary woes too frequently attendant on motherhood, and the sad lessons taught on the tables of our gynecologists, take away the bliss of ignorance from our profession and add to our knowledge the responsibility and imperative duty of vigilant measures for prophylaxis. Every case of gonorrhea in the male should be treated as a matter of serious import, for even though it may seem trivial to him, it may blight the lives of those to whom he may and probably will transmit the disease. Who of us having daughters do not look with apprehension as to their future health and safety in the relation of wives and mothers? If "whatsoever a man soweth, that shall he also reap," were harvested by himself only, the baneful results were evil enough, but when he sows pathogenic seed to germinate in the organisms of innocent, unsuspecting, unprotected mothers and babes the calamity is ten fold, for the perils of death, of invalidism, of sightless eyes, are

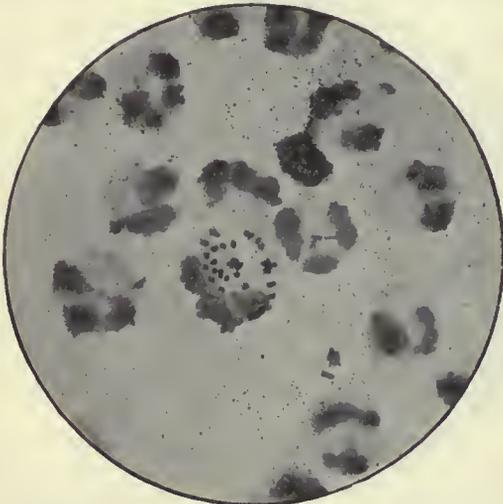

Plate 4; Case VI.—Gonococci from cervical secretions, twelve days after confinement. Acute metritis and pelvic cellulitis.

far beyond the dangers he willingly hazards to gratify his sinful lusts.

To what extent these things prevail can not be fully known, but every physician who is not stupidly ignorant or wilfully blind to the fact, knows that they are of very frequent occurrence. When we consider that the majority of males (Ricord estimates 80 per cent. for France; Noeggerath believed the same ratio held good for New York City) have been affected at some period of life with a gonorrheal experience more or less persistent, how can it be otherwise, under the present sociologic conditions, that a large number of prospective mothers in or out of wedlock, innocent victims or *particeps criminis*, become the unfortunate hostesses of pathogenic germs that place them in dire perils at childbirth, perils which are all the more deplorable because unnecessary and preventable.

Noeggerath believed that "90 per cent. of males affected with gonorrhea remain uncured, and of every hundred women who had married men formerly affected by gonorrhea hardly ten remain well." These may seem like extreme views, but even liberally discounted the figures would still show a lamentable state of affairs.

Prince reported that 60 per cent. of the blind in the asylum in Jacksonville, Ill., were the victims of ophthalmia neonatorum.

Noeggerath gave us the warning that gonorrhea was the most fruitful cause of woman's pelvic woes long before Neisser discovered the specific diplococcus, so beautifully demonstrated in the photo-micrographs exhibited with this paper.

Man is so constituted as to remain indifferent to many evils by reason of their frequent and long-accustomed occurrence. He is also averse to any measures that curtail the indulgence of his animal instincts, regardless of consequences to others, but the day will come in that higher evolution of preventive medicine when an enlightened public will demand protection by quarantine, by restrictive legislation and by penal enactments against individuals infected with this loathsome and dangerous disease.

It will be a righteous advance when the State shall afford some protection to the innocent by placing legal barriers to the marriage of all individuals who, by competent medical inspection, can not present certificates of freedom from all contagious and hereditary diseases. Nor should the line be drawn on the male sex only. The advanced medical woman could confer no greater boon upon her sex and humanity than the accomplishment of reforms along these lines.

2036 Indiana Avenue.

#### DISCUSSION ON PAPERS OF DRS. MONTGOMERY, KIME AND BURR.

DR. E. E. MONTGOMERY, Philadelphia—In regard to the treatment suggested by Dr. Kime, I must agree with him as to the inadvisability of using the curette in cases of puerperal sepsis. I do not believe it has any special advantage, because the streptococci are buried in the tissues to such a degree that they are not removed by an instrument, and an increased irritation is produced by the curette which furnishes a more favorable soil for the development of the trouble. I believe that the future treatment of puerperal diseases will be in the use of serumtherapy. It is believed that an individual can be rendered immune to further ravages of germ products, and that the first thing to be done in the treatment of such cases, after a diagnosis of sepsis or sapremia has been made, should be the administration of antitoxin in such doses as will render the patient immune to further ravages. The local manifestations should be treated without fear of further development.

DR. RANDELL, Baltimore—I had quite an extensive experience in the management of severe cases of puerperal sepsis. A large number occur in the practice of every general practitioner that are simply mild infections due to putrefactive organisms; a number of cases occurring after abortion are of this variety, and the only thing necessary is to thoroughly clean out the uterus, making some antiseptic application to the endometrium. Under the various methods that are used the cases recover after one local treatment. But we have a large number of cases in which there is either a mixed infection or in which the streptococcus plays usually a very important part in the uterus of women after confinement, and these cases have to be attacked most energetically or they will die. If any practitioner will keep actively at work in treating them, he will cure a large proportion. A great many cases of puerperal sepsis which have come under my observation and care have been severe ones. My treatment has been similar to that which has been advanced in the paper, with some slight modifications. Some of these patients can be saved by washing out the uterus with an antiseptic solution every six hours, if the infection has not advanced too far. In some of the cases you may have a superficial gangrene at the placental site, due to streptococcus infection, and you should use the curette in

order to remove the gangrenous material, then apply inside the uterus a 15 per cent. solution of carbolic acid and 10 per cent. of iodine.

DR. JOSEPH EASTMAN, Indianapolis—I believe that many cases of puerperal infection are largely due to the filthy poisonous syringes that are used by midwives. I recall an instance where I jokingly asked if they had a good syringe that I could use. Yes, was the reply. It was one that had been used by the neighbors for three or four years. Taking syringes and dipping them in bichlorid of mercury solutions is useless. The nozzles of such syringes should be sterilized by boiling before they are used. But far better than that is the idea to raise the patient sufficiently in bed to empty the uterus by vital force. Drainage by packing with gauze and curetting are carried to extremes. Savage, in his work on the "Anatomy of the Female Pelvic Organs," long ago taught an important physiologic principle. It is this: If there is a foreign substance in the cavity of the uterus, the cervix contracts tightly to hold it in. If there is a foreign body in the cervix, the fundus forcibly contracts to expel it. With the fundus continually contracting, the hyperplastic tissue is reduced and the absorption of septic material is interfered with.

I protest against scraping the cavity of the uterus with a sharp curette. I would not think of using anything sharper than a dull wire curette in the puerperal uterus.

The gentleman who read the last paper made an important point; one we can not mention without some feeling of concern. It almost makes one shudder to think of the number of young men who are not permanently cured of gonorrhoea. There may be a granular patch in the urethra, or a stricture above it, and the poison is conveyed to the virgin wife after marriage.

DR. J. T. PRIESTLEY, Iowa—I desire to say a few words from the standpoint of a general practitioner. I practiced the obstetric art before the introduction of the antiseptic practice of midwifery, and I have practiced it since with very much better results than before. I thank Dr. Montgomery for the suggestion of serum therapy. I think it a good one, and if carried out will be of benefit in many cases.

I prepare myself for attendance upon an obstetric case the same as I do for an abdominal operation. I think the same cleanliness of hands and other things brought into contact with the patient should be carried out. I do not use any intrauterine antepartum douche. I insist that when the douche is given the point of the nozzle of the syringe should be boiled. I do not hesitate to go from a case of scarlet fever or any contagious case, and attend a case of midwifery, if I have time to prepare myself.

My practice covers a territory in which women are largely attended by midwives during confinement, and I see many cases in which there is elevation of temperature after delivery. I do not wait to find out whether it is sapremia or septic infection, but take a Mundé curette, which is very large, almost the size of the curve of my finger, and use it to curette the uterine cavity. It has no sharp cutting edge, and with it the uterus can be easily scraped. At the same time I flush it with sterilized hot water. I formerly put in gauze packing. I did not realize at first that there was a difference between tamponing and draining by the use of gauze. Where tampons are used we simply do much harm. If a piece of wicking is used we can establish drainage and do good, in many of my cases I drain with ordinary iodoform wicking, after cleansing the uterine cavity with a dull curette. I think I have benefited a great many of my patients by this procedure.

DR. HENRY P. NEWMAN, Chicago—In regard to the uterus in the puerperal condition it is usually large and flabby and will fall with the turning of the patient to either side, or if the patient is lying on the back it is very apt to be more or less retroverted. Here is where I object to the use of the tube, excellent as it is alone, it does not drain. In other words, you

do not drain with a tube up-hill. If you supplement your drainage with iodoform wicking, you will find that it is more efficient and you will accomplish much more than by means of a tube. It is my practice to use wicking rather firmly in the upper part of the uterus. I do this not for drainage alone, but to stimulate uterine contractions in the lower half as it approaches the internal os. It is placed simply for drainage and not for the purpose of a tampon in any sense. It is applied loosely and a single strand projects from the surface. Under these circumstances drainage is efficient either with or without the rubber tube.

With reference to the use of the curette I am not partial to a sharp one, although a dull one or the finger may be used to remove débris in puerperal cases. However, in a patient after abortion I resort to curettage and use it in conjunction with mopping out the uterus the same as in a non-puerperal uterus, and I rely more upon swabbing than irrigation. If the micro-organisms are beyond the reach of the curette, they are assuredly beyond the reach of the ordinary antiseptic wash. But with stronger solutions than those mentioned, namely, phenol or iodized phenol, which is practically 50 per cent. each of iodine and carbolic acid, I swab out the entire uterine cavity, and follow this with washing by sterilized water. These cases are not disturbed if the temperature does not rise, or symptoms of a grave order do not again manifest themselves. Irrigation, if it is done at all, I believe, is necessary in gonorrhoeal infection.

DR. R. R. KIME, Atlanta—I would call attention to and emphasize the fact that drainage can not in all cases be attained by gauze, and in some instances it is necessary that the gauze be supplemented with a drainage tube. If you have a large flabby, retroverted uterus, you may introduce a strip of gauze and you will not drain the hemorrhage. If you put in a strip of gauze by the side of the tube, you may carry off the liquid and solid materials. We should remove the septic condition.

DR. A. H. BURR, Chicago—The object of my paper was to call attention to a matter which seems to have been neglected, and which is an important factor in puerperal complications. Perhaps all of the infection that occurs to innocent women is the result of ignorance on the part of the husband, or he who later becomes the husband. There are thousands of young men who never would become the subjects of gonorrhoeal infection if they were properly enlightened, and if perchance they contracted this disease, certainly would not infect the innocent. I do not think it right that we should dismiss this subject in a trivial manner, by any means. I do not suppose we can wipe out this matter of gonorrhoeal infection by legislation any more than we can wipe out original sin by legislative enactment. But we can educate the young men as to the dangers of gonorrhoeal infection. I believe I am within bounds when I make the assertion, that if it were not for gonorrhoea and its sequelæ, the gynecologists would lose half their patronage.

### DEGENERATIVE CHANGES THAT OCCUR IN UTERINE FIBRO-MYOMATOUS GROWTHS.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-seventh Annual Meeting of the American Medical Association held at Atlanta, Ga., May 5-8, 1896.

BY AUGUSTUS P. CLARKE, A.M., M.D.

CAMBRIDGE, MASS.

The presence of uterine fibroid growths has for the past few years given rise to much discussion among gynecologists; the consideration of the surgical treatment they have demanded has received much attention, and measures of procedure, in some instances apparently opposite, have sometimes been adopted.

The success attending the removal of fibroid growths either by partial or total hysterectomy has brought the subject of such neoplasms more prominently before the profession and has stimulated to such an extent inquiry into the necessity of adopting the more radical, surgical expedients that only the most careful clinical experience and pathologic investigation will be found capable of furnishing the data for determining the proper solution of the question.

It was formerly believed that when a fibro-myomatous growth underwent a retrograde process from electrolysis, or from other measures of treatment, or from spontaneous action, the conditions thus induced were always favorable; later experiences have shown the fallacy of such inferences, for certain pediculated subserous fibroids in taking on such phases become harder and more unyielding from the presence of the excess of the fibrous over the muscular element and from the consequent calcareous deposits occurring in the interstices. The pressure of such a mass on one or both ureters may cause contracting kidney and lead to a fatal result. Such growths, when not entirely pediculated or wholly subserous, may cause partial occlusion of the ureters, that may result in renal complication. Cases with the history of such sequela have occurred in my own practice; notes of autopsies made in my earlier practice clearly show that measures of relief could have been effected by merely resorting to abdominal incision and ligation of the pedicle or enucleation of a partially subserous mass.

The single as well as the multiple interstitial variety of fibroid growths may, besides giving rise to exhausting hemorrhage, be productive of baneful results of pressure upon important vessels and structures. Suppuration is another sequel that may appear; contraction and the consequent cutting off of the arterial supply may lead to suppurative changes and liquefaction of the mass, as occurred in a case in which I resorted to total hysterectomy for relief. The patient had for a long time suffered from repeated chills, febrile reaction, sweating and other constitutional symptoms as the result of the morbid changes that had gradually taken place in the growth.

In another case the patient, a married woman aged 47 years, had suffered for a considerable period. At the time I was called, the constitutional symptoms were unusually marked; the fibro-myomata were interstitial and had evidently undergone such serious alteration as to preclude the possibility of adopting operative measures for relief. A resort to surgical procedure for the removal of the growth in an earlier stage would undoubtedly have been attended with success.

In another case there was a history of gradual development of the growth which had been productive of uterine hemorrhage. The growth proved to be a large submucous fibroid in a state of advanced gangrene and had given rise to a marked septicemic condition of the organism. After some difficulty I succeeded in effecting the removal of the sloughing mass and in overcoming the constitutional disturbances that had supervened. These cases differ materially from those of the submucous variety, in which a mere dilatation of the lower segment of the uterus may be effected and in which the removal of the growth by morcellation with the curette and scissors suffices for a cure.

Fibroids, though liable to increase from excitation of the menstrual periods and during pregnancy, espe-

cially those of the submucous variety and those akin to the myxomatous class, may, nevertheless, undergo marked diminution after parturition, and may apparently disappear, from contraction of the uterine tissue during its normal involution stages. I doubt, however, whether such growths when once firmly established in the uterine tissue ever wholly disappear, unless their extrusion takes place through the medium of the various channels by hyper-physiologic constriction set up in the muscular element enclosing the neoplasm; they may for indefinite periods remain unaffected, but they are liable to become the foci of malignant or semi-malignant degeneration. Clinical observation and suspicions aroused from circumstantial evidences that fibroids may assume after the lapse of time a malignant degenerative change, have opened new fields for investigation. The teachings of the older pathologists were for the most part to the effect that fibroids were benign growths.

The advance made in pelvic and abdominal surgery have led to most careful scrutiny of the pathologic and histologic elements presented by the various stages of these growths; they have strengthened the view that had for some time been entertained that these neoplasms are subject to malignant change. The results obtained in the majority of instances can not be satisfactorily explained by regarding such growths as being benign in character but having nevertheless their development complicated more or less with that of malignant formations. The record of cases coming in my own practice shows unmistakably that the malignant degenerative changes to which these growths are prone are not of rare occurrence. The history of uterine morbid processes is often helpful in reaching just conclusions respecting the genesis of the disease. The favorite haunt of uterine cancer is in the cervix uteri; it often shows its development in the fissures of the lacerated portion. This may occur from long continued and repeated irritation to which the parts have been exposed. From this center the morbid process may radiate and extend to the upper segments of that organ. The characteristic symptoms of the disease with the cachexia of malignant invasion are early accompaniments. In malignant degeneration of fibro-myomata the morbid processes leading to the development present other aspects. The early appearances of fibroids may not be attended with any definite constitutional peculiarities. There will be no facies of a distinctive type; except for the results that may be attendant on metrorrhagia or menorrhagia, the occurrence of the irregular outline of the growth and the consequent pressure or other annoyances experienced the patient may have the appearance of being in almost perfect health. In the unmarried or in those who have not suffered from cervical laceration the lower section of the uterus may be entirely free from the morbid invasion. The same freedom in this part of the uterus may continue after a uterine fibroid has assumed malignant phases until the development has extended downward. Martin of Berlin has reported cases of uterine fibroids that had undergone cancerous as well as sarcomatous degeneration. Boetticher reported cases of this character as early as 1884 and Schroeder also collected cases which have been reported. In some instances there had been a proliferation of the adenomatous mucosa to the deeper parts of the growth which gave rise to adenoid cancerous change. Emmet, prior to the dates above mentioned, reported instances under observa-

tion in which the tissue of a single fibroid wholly underwent the metamorphosis into sarcoma. He mentions also cases in which cancerous development had taken place; he refers to Klebs, who had made mention of fibro-myomata of the uterus, in which the myxomatous and sarcomatous development had occurred. Klebs, according to Emmet, had held to the view that genuine cancer can only "proceed out of fibromyomata in those cases in which the formation of the tumor extends to the surface of the mucous membrane." Emmet refers to the possibility of an aneurysmal development upon a uterine fibroid by the dilatation of some of the principal vessels. Some two years since there came into my own practice the case of a woman in whom a sarcomatous growth, as a secondary development, had occurred in the omentum. At times I could make out marked pulsations and a purring thrill; an abdominal section made a little later did not, however, reveal an aneurysmal sac. The conclusion reached was that the pulsation must have been imparted by the deeper vessels.

Fatty degeneration is another change which fibroids may undergo. This alteration may occur under the influences of pregnancy, which may take place, notwithstanding the existence of a large myomatous growth. A seemingly practical disappearance of the growth may partly result while the patient is in the pregnant state; in such an event the alteration may be hastened along with the occurrence of the involution of the adventitious uterine tissue. Such transformation is more likely to take place in cases in which the growths have been of myomatous formation. In my own practice I have met with a few such cases. I have always entertained, however, the conviction that they were remnants of the retrograded neoplasms which might become the source of further morbid change. In some cases the liquefied contents of the growth may be absorbed while the more solid constituents may remain and become walled off by the development of indurated tissue.

In other cases in which the growth continues, there will be beside myomatous tissue much fibrous element; the fluid portion may in part be absorbed leaving cavities of varying size within the growth. Neoplasms in this condition, though often termed fibro-cystic, do not belong to the classification of cystic developments since the cavities thus formed are destitute of a lining of epithelium.

Another form which has a practical significance to the abdominal surgeon is that resulting from the occurrence of enormously enlarged vessels or capillaries; these vascular elements may develop at the expense of the connective and muscular tissues of the tumor. The occurrence of these teleangiectatic myomata may be a fruitful source of hemorrhage and thus threaten or destroy the life of the patient. Early surgical interference offers the best opportunities for relief. The growth with excessive development of lymphatic vessels and dilated lymph spaces, termed myoma lymphangiectodes, is not, so far as I am aware, of common occurrence. The extensive edema accompanying such cases necessitates at times prompt surgical treatment.

Inflammation in the tissue of a fibroid may extend to the arterial coats (producing arteritis) and lead to the obliteration of the lumen of those vessels (endarteritis obliterans) and consequent deprivation of nutrition of the growths; this may cause them to slough and to become gangrenous. Sloughing or gangrene

may occur in large interstitial fibroids by their being subject either spontaneously or otherwise to excessive intraparietal contraction. Rupture of its connection by the direct expulsion of the mass may lead to the same condition. Colloid degeneration may take place in the deeper portion and may give rise to conditions similar to those in which the tumor becomes liquefied.

Sudden hemorrhage, or an apoplexy (as the rapid extravasation of the sanguineous fluid is sometimes termed) may produce cavernous spaces that become occupied by coagula or serum; this sometimes leads to a disorganized condition. The contents may in part be absorbed; the residue remains quiescent for an indefinite period or becomes the focus of suppuration or of other advanced secondary changes. The amount of blood with which fibromyomata are supplied varies to a considerable extent. In most tumors of this character the vascular element is not plentiful. The capillaries in some of the forms are prominent while in others special artificial injections that are made show that but few vessels permeate the mass. The irritation and hyperemia with which the adjacent mucosa may be subjected are undoubtedly the cause of the hemorrhagic tendency; this condition may induce ulceration and sloughing. When fibroids are present in cases of pregnancy they may offer an impediment to the normal development of the uterine tissue and so lead to profuse hemorrhage and abortion. Beside the occurrence of the degenerative changes as above mentioned there have occurred the formation of melanotic deposits that have shown a close relation with the development of malignant disease.

Calcification of fibromyomatous growths as already stated is an occasional sequel; so also is the production of tissue resembling cartilage, which as a secondary result has occurred in the mass. One of the most frequent transformations, which without doubt fibromyomata may undergo, is their contraction and atrophy after the cessation of their normal development. Myxomatous changes and submucous alteration tend to the destruction of the growths. The intraparietal contractions to which they are subject serve to hasten the production of polypi and the commencement of extrusion from their normal sites. All these several kinds of secondary transformations occurring in fibromyomata are productive of further expulsive processes that often require only timely surgical interference as measures supplementary to the effecting of their complete removal.

#### DISCUSSION.

DR. W. G. MACDONALD, Albany—The most important point connected with this paper is in relation to the matter of development of malignancy as associated with tumors of the uterus, ordinarily said to be fibromatous in character, that condition with which our literature is full, a condition developing from the mucous membrane of the body of the uterus, a malignant endometritis, or adenoma, which is to a certain extent confusing. There is no tumor of the uterus, fibrous or fibrocystic, which is malignant. If a tumor presents clinically all of these conditions, macroscopically and under the microscope, which we ordinarily term a fibroid tumor, if after its removal there develops from the pedicle a subsequent tumor, the tumor was not a fibroid. It was a sarcoma. It may not have been primarily so, but it was subsequently, or at the time of removal. We can make this matter of malignancy always very simple as associated with the uterus and with all other bodies of the organism when we say that malignancy in tumors only

manifests itself in the two conditions of sarcoma and carcinoma. When a fibroid tumor at the menopause is quiescent for a few months, then within a period of three or four months shows a disposition to increase, we may reasonably conclude that it is a malignant tumor, and the probability is that there is grafted upon it an irritation in the uterus, a condition of sarcoma. These tumors, under the peculiar malignancy which occurs, take upon themselves the condition of sarcoma, and in six months they increase more than they have in sixteen years. When you have a supposed fibroid tumor of the uterus which has shown little growth under your observation for a period of three or four years, and then begins to increase in size, you can not too soon remove it. It is an important consideration in relation to these changes that they occur in fibroid tumors.

DR. CHARLES P. NOBLE, Philadelphia—It has been my experience to have operated on a large number of cases of fibroid tumors, and many of the women did not know they had them until after the menopause. They probably existed, but were small and gave rise to no symptoms until after the menopause, so that my own experience amply supports one point in Dr. Clarke's paper, that fibroid tumors which have given no symptoms before the menopause very frequently take on rapid growth after it, give pressure symptoms or cause hemorrhage after the menopause.

I distinctly recall three cases of tumors which became sarcomatous after having been operated on. Two of the patients died from recurrence. Another case has a recurrence at this time, so that of the three cases of sarcoma two are dead, and in the other death will follow sooner or later. These cases at the time of operation were designated by a pathologist as myxomatous, but subsequent development showed that the tumors were sarcomatous. The second case was one of spindle-cell sarcoma, and in the last case the tumor was necrotic and sarcomatous. We find carcinomatous changes after fibroids, but I have not seen a carcinomatous change in the tumor itself. I believe that is extremely rare. I have seen a number of cases of carcinoma of the cervix as a complication of fibroid of the uterus. We are all familiar with the necrotic changes in fibroids. We have to operate on sloughing fibroids. This change is most common in the submucous variety and the sloughing is due to efforts on the part of the uterus to throw off the tumor, so that traction takes place on the capsule and shuts off the blood supply. I have operated on necrotic fibroids that were not submucous. No doubt, this change occurs before as well as after the menopause. We can not dwell too strongly upon these facts in the history of fibroids, and can not condemn too emphatically the old teaching, that after the menopause uterine fibroids will disappear.

DR. CLARKE—I do not know that there is much more for me to say on this subject. I recognize the fact that the changes which I have dwelt upon in my paper are the more important parts of what I intended to bring out. I have met with cases and followed them up for many years. Some of the cases of fibroid tumors were treated by electricity and other methods, and it was said that the tumors would undergo contraction and diminish in size, but subsequently would become larger and larger, causing death of the patient. I collected a number of these cases in my earlier experience. I have been very much interested in this question for years and am satisfied that fibroid tumors do take on a malignant change, and it is not owing to the original disease mentioned. A woman with a cancerous uterus is not likely to survive for ten or fifteen years. We know for the most part, that when it occurs in the uterus, two or three years are about the limit of cancer, and that it goes on from bad to worse, unless operation is resorted to. Sarcoma rarely lasts for five or six years, and these cases can not be regarded as sarcomatous or cancerous all this length of time. When a woman, seemingly in good health and of good florid complexion, with no cachexia, no cancerous or malignant appearance, has a tumor which suddenly takes on malignant changes, we can not remove it too soon if we would prolong the patient's life.

## SOME SUGGESTIONS IN THE PROPHYLAXIS AND MANAGEMENT OF PUERPERAL ECLAMPSIA.

Read in the Section on Obstetrics and Diseases of Women at the Forty-seventh Annual Meeting of the American Medical Association at Atlanta, Ga., May 5-8, 1896.

BY H. D. THOMASON, M.D.

ALBION, MICH.

My experience in the prophylaxis, treatment and management of puerperal eclampsia has been confined in recent years entirely to private practice, yet it has been within my province to observe a sufficient number of cases to form some deductions and conclusions. However, I shall lay no actual claim to originality in inception. My suggestions are gathered from applications largely original with others.

The pathology and etiology of puerperal eclampsia is still an unsettled question—theories are numerous as well as contradictory; the text-books, and chairs in medical schools are brimming over with them, but nothing as yet has been positively proven, settled, or definitely accepted by the profession as a whole. As practitioners at the present time we necessarily occupy the position of clinicians awaiting instruction. Until pathologists are able to present to us true indisputable pathologic facts we must fall back upon our own clinic experiences. But to properly apply and employ even these we must have some definite ideas of our own relative to the etiology and pathology of puerperal eclampsia. The probabilities are that not every case of puerperal eclampsia is the result of the same pathologic cause. We find ardent advocates who maintain that nephritis and its resulting uremia, either apparent or disguised, is alone the offending cause, still closely agreeing with Lever, who, in 1842 supposed albuminuria to be the *casus belli*. Others maintain with Lusk that albuminuria may be a physiologic, even a diagnostic feature of pregnancy and that puerperal eclampsia is the result of renal insufficiency and albuminuria and uremia have nothing whatever to do with the matter. Again, others take the position instigated by Cohen of Hamburg, that there exists a cerebral eclampsia, organic cerebral lesions; while opponents to this belief declare these lesions to be the result of congestion and other causes, and at best are but secondary. A plausible theory has recently been advanced by Poe (Transactions Louisville Academy of Medicine) that puerperal eclampsia is the result of obstruction to the portal circulation due to hepatic cirrhosis causing peptonemia and producing either uremia or anemia. That there is an undue portal pressure during the period of gestation he claims to be proven because of hemorrhoidal enlargements during this stage and that all circumstances that increase tension, increase liability to eclampsia; as instanced by its frequent occurrence in primipara, and the older the primipara the greater the liability. With others he also recognizes that peripheral nerve irritation alone may be the sole cause of convulsions. King and others advocate as the cause of eclampsia pressure of the gravid uterus upon the inferior vena cava, the iliac veins, and upon the kidneys, thus producing passive congestion. While Halbertsma in 1883 introduced a theory which perhaps at the present time is received with as much favor as any other, that puerperal eclampsia results from pressure of the gravid uterus upon the ureters, thus to a great extent occluding the caliber, seriously interfering with their function and producing urinary

stasis. But to review or discuss the various theories of the causation of puerperal eclampsia is not within the scope or purpose of this paper. As already intimated puerperal eclampsia is not to be attributed to one identical cause in every case, so it is possible that each of the advanced explanations and theories may have more or less ground for truth when applied to certain individualized cases. For the purpose of this discussion let us broadly assume that puerperal eclampsia arises, 1, from the retention and absorption of toxins, no matter from what pathologic source, but due to the pregnant state; 2, from the result of peripheral nerve irritation; 3, from hysterical causes.

Unsatisfactory and uncertain as the pathology of this affection is, by far the larger number of cases are the result of the first cause, and to this group, principally, we will confine our attention, for to this class prophylaxis is the more important. It should be the rule of practitioners to educate their clientele to the importance of placing themselves under medical observation in the early stages of pregnancy, for it is the duty of the physician systematically and frequently to maintain a close observance of these patients during the period of gestation. Eclampsia seldom comes unheralded—the cases are indeed rare that do not show some prodromic indications if looked for by a careful observer. Frequent urinary analysis, chemic and microscopic, should be resorted to. The presence or absence of albuminuria or casts and other abnormal conditions should not only be determined, but the quantitative analysis as to urea and other urinary elements be made to establish the presence or absence of renal insufficiency, and the daily quantity of urinary excretion carefully observed. When we find urinary abnormalities during the stage of gestation it is sufficient to place us on our guard, but when this is coupled as it often is with edema, functional cardiac disturbance, impairment in vision, headache, or other well recognized prodromic symptoms there can be no mistaking the probabilities and dangers, and the advisability of prophylaxis is unquestioned. My habit is to have these patients placed upon an exclusive milk diet, urge them to drink large quantities of sterilized water, stimulate the excretory function of the skin by steam and hot vapor baths, and see that the bowels are kept abnormally active; a most successful method to accomplish the latter result is a daily enema of a saturated sulphate of magnesia solution. By this management, briefly outlined, I have seen the prodromic indications greatly modified, and in some instances entirely disappear and the patient tided through to full term and a normal delivery. If we have reason to believe that the prodromic condition of the patient is the result of pressure of the gravid uterus upon the ureters, thus occluding their caliber and producing renal stasis, upon theoretical grounds it would seem that a daily catheterization of the ureters according to the Howard Kelly method, as practiced by him for other renal affections, would be applicable here as a prophylactic measure. I confess I have never yet employed this means, but it is my purpose to do so when a suitable opportunity presents. But when despite all ordinary prophylaxis, the prodromic condition of the patient does not improve, when we have every reason to believe that if allowed to go to full term the patient must face the horrors and dangers of eclampsia, then the advisability of inducing premature labor as a prophylactic

agent is to be seriously considered. Doubtless like other members of this section it has been my lot upon various occasions, having watched the prodromic symptoms as the period of gestation advanced, grow more and more apparent, to feel with misgivings that just so soon as the pains of labor advanced, at full term, just so sure would it be necessary to meet the responsibilities and emergencies of eclampsia. Though taken by surprise at the unexpected appearance of convulsions when prodromic symptoms were not expected or recognized, seldom have I been mistaken in my anticipations when the symptoms have been previously present. It is in such cases as these, when we are convinced that if allowed to go to full term the patient will be subjected to the ordeal of convulsions, I hold to the opinion that when we are satisfied of the viability of the child, we are not only justified but it is our duty to bring about premature labor: 1, for the ground of safety and comfort of the mother; 2, for the welfare and safety of the child.

A case coming under my own observation will illustrate: Primipara, aged 26; history of fatal nephritis in both father and mother; at fifth month of pregnancy exhibited prodromic symptoms, which steadily increased to full term, albuminuria, casts, scanty urine, excessive edema, headache, weak, rapid heart, disturbed vision. At the beginning of second stage of labor was attacked with violent convulsions; rapid delivery by forceps was accomplished, convulsions continued after the delivery of a dead child, and chloroform, chloral and veratrum viride barely saved her life. Convalescence was slow and tedious, complicated with phlegmatia dolens extending over six months, and traces of albuminuria could be detected for three months longer. Two years later patient became pregnant again; the same prodromic indications of equal severity presented at the same stage as in first pregnancy, and despite ordinary prophylaxis, increased steadily; patient was tided along until the middle of the seventh month when in view of previous history induction of labor was decided upon. This was accomplished under strict asepsis; while under anesthesia one slight convulsion occurred at time of dilatation of os, but patient was delivered of a live child and recovery was uninterrupted and complete.

When the viability of the child is unquestioned and the procedure is accomplished under strict aseptic conditions I am of the opinion that this is an important prophylactic method too often neglected. Why should a woman be subjected to six or eight weeks' unnecessary sepsis, accumulation and absorption of toxins? Is it not reasonable to infer that the safer course is induction of labor, prevent accumulative toxemia, and remove the exciting cause. The same arguments can be advanced in regard to the child. It is very well established that there is a relation existing in puerperal nephritis bearing upon the nutrition of the fetus. While the arterioles in the maternal kidneys are undergoing occlusion by products of disease, a similar occlusion and change is taking place in the placental vessels, thus jeopardizing and interfering with the blood supply to the fetus. This is one factor that accounts for infant mortality in eclampsia, and it is a reasonable conclusion that the same toxemia that threatens the mother also threatens the child. Dr. Barnes (British Med. Asso. 1888) claims maternal albuminuria to be the cause of intra-uterine

death—whatever the cause, a viable child's chances are better extra utero than when exposed to intra utero toxic influence, accumulative degenerative changes in its source of nutrition, the jeopardy of violent maternal convulsions and delay in delivery at full term. My experience has necessarily been limited to a few cases where this prophylactic method has been adopted, but I have had no cause to regret its employment, and in properly selected cases believe it to be a valid and useful prophylactic measure. The fact that cocain applied to the os, as treatment for eclampsia, suggests its use as a prophylactic when convulsions are anticipated, the rationale based upon the fact that pressure upon and dilatation of the os act, in at least some cases of eclampsia, as an exciting cause. We are led to believe from clinical experience that this is an important factor in certain cases. We doubtless can all recall instances where we have excited the convulsions simply by a digital examination, passing a finger through and perhaps dilating the os. Theoretically, at least, cocain may have its place as a prophylactic. My experience in its use has been limited to normal labor. When in some cases I have used it with apparent good effect just prior to the full dilatation of the cervix to alleviate the so-called agonizing stage of labor, I have had no reason to presume that it acted as a prophylactic, as in none of them was eclampsia anticipated. Under the head of reflex causes for eclampsia the bladder may play an important part. An instance is cited in the American System of Obstetrics (Vol. II. page 79), taken from La Motte's observations, where violent and threateningly fatal convulsions were instantly controlled by relieving pressure of the fetal head upon the bladder and drawing off a large accumulation of retained urine. An instance came under my observation, a case of placenta previa in a multipara, age 28 years; labor was terminated by podalic version and resulted in loss of child, but the mother in fair condition, save some necessary exsanguination. Case was left in charge of inexperienced hands. According to reports there had been difficulty in urination following delivery, and on the sixth day convulsions appeared. When I saw the patient she was in deep coma with rapid and thready pulse. The unusual size of her abdomen attracted my attention, and urine had been passed continuously, drop by drop. The catheter relieved the bladder of an immense amount of urine, but the patient was so exhausted from combined influences of placenta previa, distended bladder and convulsions she did not rally, and died in a few hours. Whether death was due to peripheral nerve irritation from distended bladder or uremia, was not determined, but the case suggested to my mind a practical prophylactic measure, to be assured in all cases of pregnancy and during the puerperal state that the bladder is emptied at proper intervals. So much prophylaxis authorities and experience teach, that eclampsia is most frequent during labor and less frequent after, but the relation is not definitely determined for the reason that labor often comes on as a direct result of the convulsions and many attacks that rightfully belong to the period of gestation are recorded as occurring during labor. The management of puerperal eclampsia depends upon the period in which the convulsions occur. If prior to fetal viability we must remember our duty to the child as well as to the mother, and so far as we can, in justice to the latter, adopt expectant methods, endeavoring

by all means at our command to tide the crisis on to months of viability, but under no circumstances must the mother's life be jeopardized by fatal delay, or allowing continuance of frequent convulsions. The statistics of Lantos and Lohlein demonstrate that convulsions cease after the emptying of the uterus in 69 to 80 per cent. of cases, and Dührssen, the powerful advocate for the active method of immediate delivery, establishes the fact that even the severest operations, Cæsarean section included, properly performed under asepsis and complete anesthesia, does not render the prognosis less favorable. Therefore, in cases where convulsions persist, and we are convinced that toxemia or some condition due to pregnancy is endangering maternal life, no time should be lost in emptying the uterus, and the child sacrificed for the welfare of the mother. When months of fetal viability have been reached, at the first suggestion of eclampsia it seems to me there should be no diversity of opinion as to the advisability of at once securing evacuation of the uterine cavity.

A recent contribution of Zweifel (*Centralblatt für Gynäkologie*, Nos. 46-47-48, 1895) demonstrates the superiority of this active treatment, advocated by Dührssen, as contrasted with the expectant method. Of 129 cases of eclampsia treated in the Leipzig clinic, 49 were treated by the latter (expectant) method, with a resulting mortality of 16, or 32.6 per cent., and 80 cases by the active method, with a mortality of 12, or 15 per cent. Objections have been urged against the active management on the grounds, 1, that even when the uterus is emptied there is no guarantee that convulsions will cease, and 2, that the manipulation and difficulty in securing evacuation aggravates the condition and further endangers and complicates the case. The fact that approximately 80 per cent. actually do cease when the uterus is emptied is a sufficient reply to the first objection, and the second objection is more apparent and anticipatory than real. I have not as yet encountered any serious difficulty in promptly evacuating the uterus of its contents. I have never had to resort to even slight incisions of the cervix; I would not hesitate to do so if necessary. I have never failed to secure dilatation of the cervix by the Barnes dilator attached to the Allen surgical pump or some of its modifications. On several occasions, under anesthesia, full cervical dilatation and delivery by forceps were both accomplished in less than an hour, when there was no evidence of uterine contractions, or any sign whatever of beginning of labor. I begin with this instrument familiar to you all, then follow by this modification of a Barnes dilator, and so on until in a short time the cervix will admit the hand for version or forceps for cephalic delivery. In primipara I found more time consumed in delivery by the forceps than in dilating the cervix. A case taken from my record will serve as a type of several others. Mrs. V., aged 16, primipara, unusually small and girlish form, suddenly attacked with eclampsia middle of seventh month of pregnancy; had one convulsion after another before seen. Catheterization of the bladder resulted in withdrawal of scanty and high-colored urine, loaded with albumin. No uterine contraction, and os closed. Chloroform was administered, the surgical pump and Barnes dilators employed; dilatation was accomplished without incisions, the forceps applied, and within forty minutes from beginning of operation a live child was delivered. Coma continued several hours,

but no more convulsions; the catheter had to be employed for several days, but patient made rapid and complete recovery. In antepartum convulsions, where child is viable, time is precious; I no longer waste it temporizing with venesection, veratrum viride, pilocarpin, chloral or any other means, but proceed with all possible haste to the evacuation of the uterus and in a great majority of cases nature assumes her eliminatory functions and little if any further therapeutics are required. In those cases where eclampsia continues after delivery, or when the onset is post partum, the indications for management vary, depending upon the condition or type of the patient. If the plethoric, with full bounding pulse, and other symptoms, all pointing to congestion, we have no remedy that can compare in its potency to venesection. We have no time to wait for the action even hypodermically of veratrum or pilocarpin, for at this time they are but poor substitutes for venesection, though they may be utilized as adjuncts. In this type venesection, thorough and sufficient, is the remedy par excellence, and other eliminatory means, such as hydragogue, catharsis, diaphoresis, etc., are not to be neglected. On the other hand, when the type is anemic, pulse weak, rapid and thready, we should hesitate to employ venesection. Here veratrum in 20 or 25 minim doses hypodermically administered is applicable; pilocarpin, while highly recommended, has failed to inspire the confidence we have in veratrum. The intravenous injection of one-half to one quart of normal saline solution, strongly advocated by Dr. Emory Lamphear of St. Louis, has in my hands yielded satisfactory results, though experience with it has been limited.

Since the advent of asepsis in obstetrics and gynecology, we are emboldened to adopt more active and effective measures in the treatment of eclampsia than formerly. The results have been good, and we have grounds to hope that the march of progress in the future will still lessen eclamptic mortality, and render this complication less to be feared by the obstetrician.

#### DISCUSSION.

DR. AUGUSTUS P. CLARKE, Cambridge, Mass.—With regard to albumin in the urine in these cases, I think it can be reasonably said that it is not as important a factor as some physicians would have us believe. In some cases in which no albumin is found the kidneys may be in a state of advanced disease. Such a case came under my observation some time ago. The patient had been examined for disease of the kidney. The urine was examined by several experts and pronounced free from albumin, and the kidneys were considered to be in good condition. In a little while the woman died, and postmortem examination showed advanced cystic degeneration in one kidney. The other was healthy. The lesson this case teaches is that we must not rely too much upon albumin in the urine, or upon the microscope, but must judge by the symptoms, and if we find edema or symptoms pointing to kidney trouble we can infer where the site of the difficulty lies, and if the prophylaxis is properly carried out there will be perhaps no need of further treatment.

DR. JOHN M. DUFF, Pittsburg—If I understand the essayist properly, he suggests that as a prophylactic against puerperal eclampsia, where we have the premonitory symptoms, he would produce premature labor as soon as the child was viable. In a very large number of cases of albuminuria during pregnancy, and where the premonitory symptoms of eclampsia exist, the woman goes on to term and is easily delivered without eclampsia. Only last week I had a case of this kind. Two physicians brought the patient to me last fall and begged me bring on

abortion. They again brought her back when she was seven months advanced in pregnancy, and I said to them, wait until she has a convulsion, and I will bring on labor. I attended her last Tuesday night, and I have never had a nicer case of labor in my life. I think it is bad teaching to have our young men go out and practice medicine with the idea that whenever a woman has the premonitory symptoms of puerperal eclampsia premature labor should be produced. You will find a great many cases in which it is not necessary. I could give quite a number of cases illustrating and emphasizing this point.

DR. J. W. BOVEE, Washington, D.C.—There are a great many cases of puerperal eclampsia in which there is never found a trace of albuminuria, while there are others in which traces of albumin are found in the urine, but the albumin does not come from the kidneys. It is true there are a great many cases in which the albumin comes from the kidneys. If we find traces of albumin in the urine we should be at least suspicious; if we find renal casts we should be still more suspicious, but we should not be very much alarmed until we find a diminution of the solids in the urine. If you have a small amount of urine, or a normal amount in twenty-four hours, with a diminished amount of solids, and this will be indicated approximately first by the specific gravity then we have reason for alarm. Methods should be put in vogue for an increase of excretions. The method of giving sterilized water and milk is very good, hydragogue cathartics are used for this purpose with hot baths, and anything which will produce an increased exudation of solids by compensation, because we may not get the kidneys to do their full duty. I would say in cases where Bright's disease exists before pregnancy and it becomes worse during labor we will have edema of different parts, probably, and some effects, such as headache, retained solid matter, urea and urates and others, then the idea of bringing on labor is more important in that class of cases. During pregnancy, while the patient is doing fairly well we should not bring on premature labor until puerperal convulsions have appeared; and even in these cases by using the hot pack, jaborandi and bleeding, with transfusion of normal salt solution at the same time, coupled with hot baths and hydragogue cathartics, we can stop the puerperal convulsions and the case will often go on to the full term of delivery. This is practiced in the hospital with which I am connected very successfully and we do not think of bringing on labor unless the convulsions are severe.

DR. J. R. RATHMELL, Chattanooga—To take such a broad position as to bring on labor in all of these cases is not, in my opinion sound teaching. In many of them there is a chance of saving the fetus and the mother. *Appropos* of this discussion I recall a case which came under my care wherein it was not necessary to bring on premature labor. I believe we would be justified in dealing with these cases in the manner—that has been outlined if pregnancy is near its close. It is comparatively safe to interfere within two weeks of the time of full term, but if it is longer than that, five weeks, as it was in this case, it seemed in the judgment of the consultants wise to let the patient alone when she was under the influence of the remedies that have been mentioned and was free from convulsions within twenty-four hours, during which time she had five, and in four weeks from that time she gave birth to a living healthy child under the most favorable circumstances.

DR. W. G. BOGART, Chattanooga—I want to protest against the idea of producing abortion or premature labor in all of the cases where convulsions present themselves. Just before I left home I saw a case in consultation. The lady had been suffering for some weeks. On examining the urine I found it heavily loaded with albumin. I expected convulsions in this case. The patient was then within a week of her confinement. She had a very difficult confinement. When she gave birth to her first child, she passed through two and a half or three hours of hard labor without any convulsions. The second child was a shoulder-

and hand presentation and became impacted. The patient was in labor from 8 to 11 P.M., and finally the labor was so difficult that we had to deliver the child. She passed through labor without a single convulsion or even a symptom of one. I left the patient in a rather critical condition three or four days after confinement. I present the case simply to show that the urine was heavily loaded with albumin and yet no convulsions occurred. This case is not the only one that I recall.

DR. FISH, Milwaukee, said it was his custom, as soon as his services were engaged, to make an examination of the urine of the pregnant woman in order to determine the presence or absence of albumin. Cases were cited to show that the presence of albumin was not always a safe criterion alone for bringing on premature labor. In the treatment he never uses pilocarpin, as recommended, for the reason that it is liable to produce edema of the lungs, and on this account he considers it a dangerous remedy. In one case of puerperal eclampsia, the woman had a pulse of 140, but under the continued use of veratrum viride and morphia it dropped to 70. He believes that if the pulse is reduced to that point and kept there convulsions will not return.

DR. GILLESPIE, Tennessee—I use a little chloroform until I get the woman well under the influence of veratrum. I have used Norwood's tincture, commencing with 15 minims hypodermatically, which is repeated in three to five minim doses, and sometimes it requires four or six doses, but very often the second dose is sufficient to stop the convulsions. After the patient is under the influence of the veratrum I stop the administration of chloroform.

As to prophylaxis, I think most cases can be prevented by keeping the bowels well open, attending to the diet, prescribing the proper amount of exercise, and giving the patient something to act on the kidneys. If there is one remedy that I use more than any other it is the hyposulphite of soda in dram doses every three or four hours until it acts on the bowels. When it does not act freely I give a dose of salts. It not only acts on the bowels, but kidneys, and prevents auto-intoxication.

DR. B. M. HYPES, St. Louis, Mo.—In my opinion, the weak point of our practice as general physicians is that we are constantly allowing our patients to go into the hands of surgeons and consultants by not properly caring for them during pregnancy, and I hope that all physicians will take their patients in their own hands the moment they are pregnant, watch them, and not permit a month or even two weeks to go by, after they are six months advanced in pregnancy, without making a thorough examination of the urine in order to ascertain whether the kidneys are acting normally or not. The urine of the pregnant woman should be frequently examined and the quantity passed in twenty-four hours measured. The solid constituents of the urine should be measured also, in order to determine whether the urates are properly eliminated, and when you use proper remedies and apply them in time you prevent puerperal eclampsia.

Physicians do not always make a proper distinction between the character of different forms of puerperal eclampsia. We have hysterio-puerperal eclampsia, and epileptiform eclampsia. Furthermore, we have eclampsia during pregnancy from cerebral disease, but it is my belief that 99 cases out of 100 of eclampsia during pregnancy and the puerperal state arise from insufficient action of the kidneys in eliminating the poisons or the toxins in the blood of pregnant women. The different kinds of convulsions must be separated in order to be properly treated. No one would think of giving veratrum viride in a case of hysterical convulsion; neither would the author of the paper attempt to induce premature labor without properly separating and classifying his cases. Much will depend upon the severity of the symptoms or convulsions. Premature labor is produced with the idea of saving the mother first, or both the mother and child if possible.

DR. THOMASON—I desire to thank the members for the free discussion of my paper. I think I have been partially misunderstood. I do not wish the members of the Section to entertain the idea for a moment that because albuminuria is present in the case of a pregnant woman it is a sufficient cause for the induction of premature labor. I do not regard albumin as a pathognomonic symptom of approaching eclampsia. But we all feel safer if the urine does not show albumin in these cases. Its presence is suspicious. I should want other evidence than the presence of albumin in order to bring on premature labor. In the paper I have presented to you I have merely given my own experience, and I must say that I have better results if I bring on premature labor, particularly when the prodromic indications are sufficiently severe to warrant it.

## FIBROID TUMORS OF THE UTERUS, WHEN AND HOW TO OPERATE.

Read in the Section on Obstetrics and Diseases of Women at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY ALBERT H. TUTTLE, M.D., S.B.

CAMBRIDGE, MASS.

It is but a short time ago an opinion was more or less universally maintained that fibroid tumors of the uterus were benign growths. The fact that hysterectomy had such a high mortality at that period made the "cure worse than the disease," and probably did much to place these tumors in this relatively false position.

With improvements in technique and correspondingly excellent results in the removal of the uterus, it is no longer necessary or wise to wait until life is in immediate danger before recourse to the radical treatment of fibroids by surgical measures, but before the health of the patient is reduced by hemorrhage, inflammation, chronic suppuration and pain, to a delicate condition, and the dangers of the operation are further increased, as well as the difficulties by the complications of inflammation—pus and adhesions—to say nothing of the degenerative changes, the increase in the size of the tumor, and the effects of pressure on the ureters, there must be a time when certain indications exist for the truly conservative removal of these growths.

That this period for active surgical interference varies greatly in the opinion of various operators from the radical view of Jacobs, who considers that the presence of a fibroid tumor is itself sufficient reason for the removal of the uterus, to the conservative extremes of the electro-therapeutists, needs only to be mentioned, and it is this fact that has prompted me to express the conclusions derived from my personal experience in the treatment of these growths.

Small sub-serous tumors, when they give rise to pain and tenderness, interfere with motion and locomotion, produce reflex and nervous disturbances, or directly by pressure make more or less troublesome the functions of menstruation, defecation and micturition, should be removed. They are best extracted through the abdominal route, by enucleation. The peritoneal flaps are sewed together with fine animal sutures and the uterus dropped into place.

Whenever an interstitial fibroid has reached any considerable development, or a number of small ones have increased the size of the uterus above that of the fist, the uterus and fibroids should be removed en masse, to prevent changes which sooner or later will surely result from the constant pressure exerted upon

the uterus. Baer's supra-vaginal amputation of the uterus is the simplest operation.

Whenever the fibroid condition is complicated by inflammatory changes, either in the growth itself, the pelvic cellular tissue, uterus, tubes or ovaries, a total extirpation should be performed. I know of no better method for the complete removal of the uterus than the vagino-abdominal method, which I have devised and already described. Unless the symptoms are urgent I would recommend a long period of rest and local treatment as a preliminary to surgical treatment (six weeks to two months), as by this means much of the infiltration and subsequent danger of auto-infection will be avoided.

Whenever the common complications of a fibroid tumor, pain, hemorrhage and serous discharges are uncontrollable, the uterus should be removed. Unless there are extra-uterine complications, Baer's supra-vaginal amputation should be preferred.

When a fibroid uterus is complicated with pregnancy, and one or more nodules rapidly increase in size, early interference is demanded. Often the fibroids can be removed without disturbing the contents of the uterus; but an early removal may necessitate killing of the fetus, in which case operators will become divided in their course of procedure; some, to give the mother the best chance for life, will remove uterus and fibroids early, or the contents of the uterus, others will wait until near term and do a Cæsarean or Porro's operation, while a few will do nothing until labor sets in, when they will attempt to raise the tumor out of the pelvis so as to admit the passage of the child. Each case demands special consideration; a multi-nodular fibroid uterus is less likely to be disabled to the extent of complete incapacity for performing the function of expulsion of a fetus, and at most make the condition of delivery simply one of inertia uteri; a single fibroid is apt to increase to dimensions sufficiently great for the mechanical obstruction of delivery, and at term will nearly always be found in the pelvis or the lower segment of the uterus, a point it has reached from the force of gravity, no matter where the place of origin.

One or more growths of hen's egg size may not seriously interfere with full term delivery, but a growth of this dimension in the early months of pregnancy is more than likely to attain dangerous proportions before the time has arrived for the natural expulsion of the child. If the growths alone are removed a subsequent ventral hernia will usually more or less rapidly follow the final delivery at the site of the abdominal incision, and must be considered among the indications for the removal of the fetus.

The danger of sepsis from auto-infection is increased in the abortion of a fibroid uterus.

When a fibroid uterus is complicated with pregnancy, the problem to be solved is not one of comfort or health, but the serious condition of life or death, therefore surgical interference should not take place until a study of the condition of the patient and the relations of the tumor and uterus show clearly to the operator that there are greater chances of life with operation than without.

When failure in health occurs in a woman having a fibroid uterus, and no cause for the same can be found, unless it be the condition of the uterus, for which the tonic and medicinal methods of treatment are unsuccessful, hysterectomy, a supra-vaginal amputation, should be performed as *dernier ressort*.

## CONSTIPATION; SOME OF ITS EFFECTS AND ITS NON-MEDICINAL TREATMENT.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY E. S. PETTYJOHN, M.D.

ALMA, MICH.

The large number of people suffering from constipation and its effects, and the clinical difficulty met in obtaining relief therefrom, leads to the conclusion that the full significance of this affliction and its deleterious influence are not comprehended either by the people or the profession.

In its reciprocal influence this condition sustains both a causative and a resultant relation. Constipation as a functional disorder may be defined as an abnormal condition of the great colon and the entire intestinal tract, manifested by the unusual retention of excrementitious material, both as to *quantity* and *time* of evacuation. It may be owing either to diminished action of the muscular coat, to the diminished secretion from the mucous membrane, or both, to defective innervation, to habits and occupation, climate or diet, in addition to which there seems to be an infinite variety of causes.

A study of the history of 300 cases shows that about 60 per cent. of patients are suffering from this ailment, and that the number is proportionately larger among women than among men.

Congenital constipation may occur dependent upon the anatomy of the colon, the water being absorbed by a reduplication of the colon itself, especially the descending part, as that part is longer in infants in proportion as compared with the ascending and transverse, and hence liable, by being crowded down into the pelvis, to flexures and reduplications that favor impaction.

In adults the transverse colon is most liable to variation in length and position, and being smaller in diameter than the ascending, aside from congenital malformation, may be bent downward almost to the pubes by long continued distension, forming a sharp bend at the sustentaculum hepatis and at the splenic flexure, as has been found in two cases under the writer's observation.

In considering this condition, we regard individual habit and idiosyncrasy and compare with the rule, as persons do become constipated without notable or sensible inconvenience to themselves, without manifesting any of the local symptoms, and while having regular and apparently sufficient evacuations.

We come to the consideration of constipation more on account of its relation to other ailments and the entire system, than because of the mere inconvenience induced. The intestines and colon and the rectum are considered as digestive, eliminating and secreting organs, and also as organs of absorption.

With their great extent of retiform tissue enclosing a multitude of blood vessels and nerve ramifications, with their mucus follicles and valves of retardation, with their glands, lacteals, arteries and veins, the powers of retention and absorption belonging to this tripod are beyond compare. The wonder is that all the contents which enter are not taken into the circulation.

While the colon and rectum have not the digestive office we have long supposed, their absorptive power is greater than has been thought, and the quantity

absorbed is in proportion to the time of contact and concentration of the substance. While these organs seem in a certain sense endowed with the power of selection they do absorb digested aliment, medicines and deleterious material with about the same avidity.

The intestinal nervous system is noticeably complex. Filaments are received from the pneumogastric, the sympathetic and from the lumbar cord. After having been distributed to the plexus of Meissner under the submucous coat and the plexus of Auerbach between the muscular planes, branches thence supply the glands, muscles and blood vessels. Some preside over the absorbents and secretions, others over the peristaltic muscular movements, others over the intestinal circulation. Not only do these medullary and ganglionic systems direct the functions of the intestines, but through them the nerve centers of the brain have a direct influence over the entire apparatus. Since all functional action in the system is reciprocal, it follows that the functional activity of the chylipoietic system must effect the nutrition of the brain and entire nervous system.

We acknowledge that human life is a constant professional activity of elimination and repair, metabolism occurring everywhere. Observation is demonstrating the part taken by bacteria and microbes in this process in the mouth, stomach and intestines. In the chemic, fermentative and putrefactive changes thus occurring, ptomaines are being constantly produced which, when absorbed as toxic and excrementitious substances, produce retrograde changes in the quality of the blood, diminution of the red blood corpuscles, and by supplying an infected or imperfect nutriment to the brain, become a prominent factor in the production of cerebral anemia and nervous debility only limited in its effect by the shortening of the microbial longevity from the effects of its own secretions. If this deficiency of nutrition or the supply of toxic material be continued, the increased nervous irritability is followed by a decrease, and withdrawal of nourishment is followed by brain exhaustion.

From the normal intestine Babes isolated five species of bacteria, whilst an enormous number of microorganisms were found in the large intestine and feces. Bouchard says: "The conditions favorable for the maintenance of putrefaction are so numerous that we ask whether digestion can ever go on normally?" While the hydrochloric acid of the stomach neutralizes the infectious agents, they are passed into the intestines in a state of latent activity, when fermentation again begins. While the bile arrests fermentation, it is also capable of putrefaction, which is no doubt one of the causes of the offensive breath in constipation. We thus find the small intestine, and especially the large intestine, in a condition to pass products of putrefaction and toxic substances into the blood current. Since our most inoffensive and most valuable foods (meats) produce toxic substances; since the bile contains poison and the putrefactions of undigested residue produce poison, and the fecal matter is toxic, with all of these shut up in the intestines and colon, how can the guilty (those who do not believe in defecation), or even the innocent, escape destruction? If the kidneys are acting well, some of the toxics escape through the urine, and if the skin is eliminating, it furnishes relief, but these are rather remote sources of exit for so large a quantity of excrement when the way to the outside world is so close at hand.

Hypochondria, nervous depression, nervous headaches, functional neurasthenia, migraine, vertigo, disorders of nerve sensibility, noises in the ears, dyspepsia and depression incidental thereto, with a long train of psychic, nervous and nutritional troubles, are directly or indirectly the result of constipation. Even when many functional difficulties seem to be the primary disease, they only form an arc of a vicious circle begun with the nucleus of constipation.

The mechanical pressure against mesenteric blood vessels by over-distended bowels, especially if long continued, causes increased flow of blood to the brain and a temporary hyperemia with its concomitant symptoms, like an Esmarch bandage about a limb, or a sudden cooling of the surface of the body which in winter is the cause of more frequent cerebral hemorrhages than at other seasons, or like the sudden suppression of the menses or of an hemorrhoidal discharge, or even the straining at stool, all of which are to be avoided in apoplexy and cerebral congestion, on account of the increased pressure of blood in the brain which they produce.

The nervous system, as the master tissue of the body, needs the highest nutrition, and hence is most easily disturbed. It is fed in its truest sense by the overflow of nutriment after its refinement and elaboration in other tissues. Whether the nerves are nourished by the plasma reaching the axis cylinder at the nodes of Ranvier or not, we believe with Waller that the nutritional activity of nerve fiber is in the direction of its normal physiologic activity. Any inhibition of this function will lower the nerve excitability. A long period of repose not only lowers the excitability but, if continued beyond a certain limit, atrophy and degeneration occur in the nerve substance itself.

Continued unusual pressure produces excessive activity of the nerve supplying the part, excitability is finally abolished and exhaustion of the nerve occurs locally (as in over-distension of the bladder), or it may even produce a neuritis. A constantly overloaded condition of the bowels may produce either of these local results on the nerve filaments themselves. The effect of this travels backward to the controlling ganglia in the lumbar cord and defecation, to some degree a reflex act, when its directing center is not sensitive to the controlling impulse of the brain, does not occur promptly, and the constipation thus reacts upon the whole system.

In patients who complain of symptoms referable to the spinal region, and where there is entire absence of anatomic affections of the cord, and often when these manifestations are united with cerebral symptoms and there is general disturbance of the entire nervous system with a neurotic heredity, it is very frequently a functional trouble. Such a case recently came under my care (from the country), a Miss M., aged 32. She had previously been afflicted with convulsions, supposed to be epileptic, at and since puberty, but had had none for two years previous to my seeing her. She complained of attacks of severe occipital pain when she would become nauseated and dizzy. At the same time she would have a convulsive-like attack with irregular tremors and a peculiar nodding and swaying movement of the head, which she said she was unable to control. She also had pain in the cervical and lumbar region, deep-seated. These attacks occurred irregularly from one to twelve weeks apart. She was an invalid each time from five to fifteen days.

She had been treated for several years and informed by her physicians that she had epilepsy and disease of the spine. Thorough examination revealed absolutely no signs of spinal disease nor anatomic disturbance of the cord. After three months of treatment she fully recovered, beside having gained eighteen pounds in weight. The late Dr. Jewell believed and taught that the effect of constipation might produce a condition of the brain akin to, or that could be classified as, transient mania.

The first elements in curative treatment, I consider good food and good digestion. The diet should consist of coarser foods such as would leave a residue and aid in increasing the bulk of fecal accumulations. Broths, fish with the skin, fresh meats not too tender, whole-wheat and graham bread, mush, hominy, corn bread and all green and watery vegetables, baked potatoes with skins, and cereals containing hulls and fine seeds, prunes, figs, apples with the peeling and all fruits generally. Rest in the recumbent posture for a half hour or more both before and after eating is of value.

Massage on anatomic principles I place first in the mechanical treatment. The manipulations should not be used until two hours after a meal. The thighs should be flexed and the abdominal walls relaxed. The treatment should be given dry, stimulating first the skin, then the walls of the stomach, the different sections of the colon and the intestines. Pétrissage given so as to impart an oscillating and vibratory movement, combined with the varieties of tapotement, are the best forms of treatment. Cases of obesity and atony of the muscular coats and chronic intestinal and gastro-intestinal catarrh are relieved in two to four months. The intestinal secretions or increased obstruction of the bile duct is relieved, the peristaltic action is stimulated, and the contents of the sigmoid flexure and entire colon are pressed toward the rectum. If there are biliary calculi no pressure should be made on the adjacent parts, although usually pressure should be made over the fundus of the gall bladder, to assist the bile toward the intestine. The stimulation of the skin, which is here supplied by the last seven dorsal nerves the same origin as the splanchnics, as well as the plexus of Auerbach, and the mechanical effect of moving pressure do bring favorable results.

In the use of the cannon ball three or four pounds in weight the patient or operator should be thorough and systematic. The ball should be rolled over the entire abdomen, being used for five or ten minutes morning and evening, the treatment ending by the patient balancing the ball for a few minutes on the navel.

In gymnastics all movements that use and strengthen the abdominal muscles, such as lying on the back and raising the limbs perpendicularly, the flexion at the hips, twenty or thirty times each morning and evening.

Rowing, horseback riding and cycling are helpful if used regularly. While it is best to have a definite hour, that is not essential, but when a time is fixed, if the preceding half hour is devoted to the voluntary contraction of the anal sphincter muscles, the reflex effect is to aid in stimulating the peristaltic action. Time should be given, and one should go for relief on the first prompting.

The faradic current of sufficient strength to produce contraction of the different portions of the intestines and colon is helpful. The galvanic current; the

cathode in the rectum, large anode over abdomen, repeated daily at the same hour is effectual.

Hydro-therapeutics have proven successful remedies in the author's practice. Drinking large quantities of cold water on arising and an hour before meals, and two or three hours after food, taking during the day 70 to 80 ounces, beside that with the meals, is of exceedingly great value. This remedy, with regulation of habit, has cured many cases.

Fomentations to the bowels, stomach and liver daily and a cold pack to the bowels at bedtime, have been successful. Alternation of hot and cold to the spine and the cool bath have shown results.

The difficulty I find in the use of any, or a combination of these measures, is to induce the patient to be systematic and persistent in following directions. But I am thoroughly convinced that by these means producing constitutional and local effects, more satisfactory results are obtained than with medicines, and when the patient recovers, he stays well.

That constipation has a psychic and a moral effect the laity recognizes, and we will all agree with the author who says: "Those persons whose bowels are freed by an easy, regular movement every morning, so soon as they have breakfasted, are meek, affable, gracious, kind, and 'no' from their mouth comes with more grace than 'yes' from the mouth of one who is constipated."

## THE SURGICAL TREATMENT OF RETRO-DEVIATIONS OF THE UTERUS.

Read before the New York State Medical Society, at Albany, Jan. 28, 1896.

BY AUGUSTIN H. GOELET, M.D.

PROFESSOR OF GYNECOLOGY IN THE NEW YORK SCHOOL OF CLINICAL MEDICINE.

It will be admitted that a cure of retrodeviations of the uterus is seldom, if ever, accomplished by the ordinary methods of treatment and that they demand more careful consideration than is usually accorded them. The routine plan of inserting a pessary and dismissing the case from further attention is an error, unfortunately, too often committed. The pessary can only be regarded as a splint which is serviceable as an aid to other measures in bringing about the desired result, but nothing more and will accomplish very little unaided. It may be true that all such displacements of the uterus do not require surgical intervention for their cure, but when structural changes have taken place in the walls of the organ nothing else will yield a prompt and satisfactory result. A pessary might be worn throughout the lifetime of these patients and even if it maintained the uterus in a correct position a cure would never result and she would never be able to go without it, unless something else is done to overcome the conditions which produce the displacement or are consequent upon it.

These displacements do not necessarily require always a grave surgical operation for their rectification, since frequently a trachelorrhaphy or curettage, or both combined, in conjunction with appropriate after treatment will be sufficient in many cases. It is only where there is fixation from adhesions that it may become necessary to open the abdomen, break them up, bring the uterus forward and suspend it from the anterior abdominal wall.

On account of the difference in the pathologic condition in the uterine wall, retroversion and retroflexion should be dealt with differently. In retroversion one

of two conditions may prevail. The uterus is either soft, being in a state of subinvolution, or it is hard, the condition being one of sclerosis. The latter is believed to be an advanced stage of the former, both being regarded as different stages of metritis. In retroflexion, if it has existed for any length of time the condition of the anterior and posterior walls is quite different. The anterior wall is put upon the stretch and the posterior wall is contracted and shrunken, its structure being dense and hard because of interference with the circulation and nutrition making the displacement permanent.

Associated with this condition of metritis there is always an endometritis, in both retroversion and retroflexion. Therefore in both forms of displacement dilatation with careful curettage is demanded as a preliminary step in their treatment, but in retroversion the uterus should subsequently be carefully packed with gauze to secure depletion and drainage, and to stimulate contraction, and in retroflexions a glass drainage stem should be employed because it will act as a splint and maintain the uterus in a straightened position. With the aid of absorbent iodoform gauze packed in the vagina this is readily accomplished.

#### TECHNIQUE OF CURETTAGE AND TREATMENT OF RETROVERSION.

The patient is anesthetized after previous preparation which should include shaving the vulva and irrigation of the vagina with a hot solution of bichlorid.

Fig. 1.—Author's Speculum.

1 to 4000, or a 1 per cent. solution of lysol, hot. She is then placed in either the dorsal or lateral (Sims's) posture, as is most convenient for the operator. The speculum represented by the accompanying cut (Fig. 1)<sup>1</sup> will answer equally well for either position. The cervix is seized on the right side with the angular

Fig. 2.—Author's Angular Tenaculum Forceps.

tenaculum forceps (Fig. 2),<sup>2</sup> which is held in the left hand, and the dilator (Fig. 3)<sup>3</sup> is introduced up to its shoulder. The necessary degree of dilation should be done slowly and gradually so as to prevent injury to the parts, especial care being taken to prevent the instrument slipping and producing laceration.

<sup>1</sup> The author's speculum possesses many advantages over the Sims's speculum or the bi-valve or tri-valve instruments, on account of the convenience of manipulations afforded and because it is self-retaining in both positions.

<sup>2</sup> The special advantage of the author's angular tenaculum forceps is that the strain is against the curved sides of the points and not directly against the points as in the case with the straight instrument, hence it does not cut out or slip and produce laceration of the tissues seized by it.

<sup>3</sup> The author's dilator is designed to effect slow gradual dilatation without injury. The curve is less acute than that of dilators in general use and the ratchet catch attached to the handle holds the dilatation as it is accomplished, but at the same time it can be quickly relaxed at any time by pressure of the little finger upon the spring when the instrument seems to be slipping.

The dilatation accomplished, the double current irrigator (Fig. 4) is inserted to the fundus and the cavity is washed out with a hot 1 per cent. solution of lysol. The next step is the curettage, and it must be done with special care. Every part of the cavity is gone over and all diseased membrane is thoroughly removed. Selecting a medium-sized rigid dull curette the posterior surface is first curetted, commencing at the left (patient's right); then the anterior and lateral surfaces are treated in like manner. Substituting a smaller curette the membrane is removed from each cornu and the fundus. Then with a sharp curette the

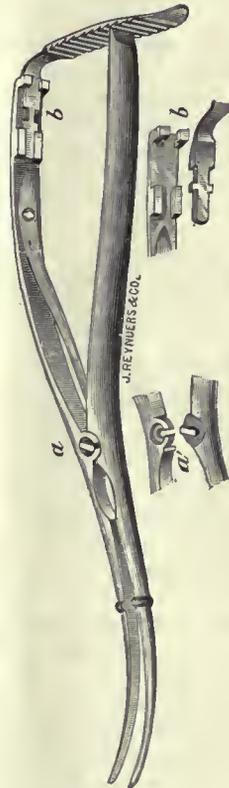

Fig. 3.—Author's Uterine Dilator.

Fig. 4.—Author's Double Current Irrigator.

hypertrophied tissue about the internal os is removed. This being accomplished, the cavity is again thoroughly irrigated with a hot solution of lysol and it is then ready for the insertion of the gauze. This is best accomplished by means of the applicator forceps (Fig. 5). Iodoform gauze (20 per cent.) which has been rendered absolutely sterile is used. A strip an inch wide and a yard long is carefully introduced into

Fig. 5.—Author's Uterine Applicator Forceps.

the uterus leaving an inch or two of the end protruding into the vagina. The vagina is then tamponed with the same gauze (cut into strips two inches wide) in such a manner as to maintain the uterus in a correct position. Since the gauze will cease to act as a drain when it becomes saturated it should be removed and renewed every twenty-four hours. At the same time the uterine cavity should always be thoroughly irrigated with the hot solution to remove all debris and secretions. This after treatment should be continued for a week, during which time the patient is confined to

bed. At the end of this time a vaginal pessary is adjusted so as to maintain the uterus in a correct position, and the case is kept under observation for several weeks, the uterine cavity being washed out once or twice every week as necessity demands. This is to be continued until a healthy condition of the endometrium has been restored, as will be evidenced by the absence of débris or mucus in the washings.

If these details are observed carefully there will be no rise of temperature in these cases and the result of the curettage will be permanent. There is no necessity for the complicated process of preparing the gauze which has been advocated by some writers. It is only necessary to insure its absolute sterility by submitting it to the necessary degree of heat for a sufficient length of time.

After this operation and the subsequent after treatment, the uterus will quite rapidly resume its normal size and condition if it has been maintained in a correct position by the pessary which should be worn for several months.

#### TECHNIQUE OF THE TREATMENT OF RETROFLEXION.

The dilatation and curettage is done in these cases in the same manner as described for retroversion, but instead of inserting gauze into the uterus a glass drainage stem (Fig. 6) is inserted to serve as a splint and maintain the organ in a straight position until a normal condition of its walls can be restored. This stem is two inches long, is perforated through the center for drainage and its size is No. 12, English scale.

Fig. 6.—Author's Glass Drainage Stem.

After curetting the cavity and irrigating with hot lysol solution, the stem which has previously been rendered sterile is introduced and held in position by a tampon of iodoform gauze packed carefully around the cervix. Additional tampons of the same gauze are inserted in front of the cervix forcing it backward into the posterior cul-de-sac of the vagina, thus throwing the uterus forward into a position of anteversion.

The stem should be removed every day, the cavity of the uterus washed out with lysol solution and after cleansing it the stem is reinserted. At the end of a week, during which time the patient is confined to bed, a pessary is carefully adjusted to take the place of the vaginal tampon and maintain the uterus in a correct position. The stem is retained for a day or two longer with only a loose wad of gauze against it to prevent it slipping out. If it is found that the pessary will sustain the organ in a proper position the stem may be removed and the patient is permitted to get up. The pessary must be worn for several months until it is found that the uterus will retain a normal position without its support.

Almost every case of retro-displacement of the uterus not fixed by adhesion or exudation, is satisfactorily amenable to this method of treatment. When slight or very recent adhesions complicate the case they may sometimes be broken up by careful manipulations through the vagina under anesthesia without opening the abdomen. Then the above operative procedure is to be adopted as in those cases when adhesions have not existed. When the organ is bound down by exudation this should when possible be

removed first. When a lacerated cervix complicates the displacement it should be repaired at the same time, but in these cases the gauze packing will have to be dispensed with because it might interfere with proper union.

In dealing with retroflexion if it is necessary at the same time to do a trachelorrhaphy, the drainage stem can be used without danger of interfering with union of the freshly united surfaces if the operator is careful in making the denudation to leave ample room for the new cervical canal, and not draw the sutures too tightly. When the adhesions are firm and numerous they should be broken up by the finger inserted into the abdominal cavity through a small incision and the uterus should be brought forward and suspended from the anterior abdominal wall after the manner described by Howard Kelly.

#### TECHNIQUE OF SUSPENSIO UTERI.

After proper preparation of the patient she is anesthetized, the bladder is emptied and an incision about two and a half to three and a half inches long is made through the abdominal wall just above the pubis opening into the peritoneal cavity. Two fingers of the left hand are inserted and the uterus is loosened from its attachments and the fundus is brought forward and up into view. The edge of the peritoneum on each flap of the abdominal wound is next seized with pressure forceps and drawn out. A curved needle carrying a medium-sized silk ligature is inserted through the peritoneum and subperitoneal fascia on the left near the lower angle of the wound and is next inserted upon the posterior face of the fundus and then through the peritoneum and subperitoneal fascia on the right flap of the abdominal wall, at a point opposite its insertion on the left. When this ligature is tightened it brings the posterior face of the fundus snugly up against the anterior abdominal wall. A second suture is inserted near the other on the abdominal wall and just below the other on the posterior face of the uterus. When this suture is tightened it throws the uterus forward still more into a position of anteversion. These sutures are tied carefully so as to maintain an equal strain on each, bringing the uterus up snugly against the abdominal wall, and the abdominal wound is closed in the usual manner.

One advantage claimed for this operation over that of ventrofixation is that the uterus is not permanently fixed in an abnormal position, but it eventually recedes somewhat and remains suspended by two firm fibrous cords in an easy position of moderate anteversion and is fairly movable.

The patient is confined to bed for two or three weeks and is directed to wear an abdominal support at first upon rising. No pessary or additional support will be needed after this operation, but injuries to the pelvic floor should be repaired at the same time in all cases. When done in properly selected cases this operation should be uniformly successful and the mortality is *nil*.

Alexander's operation, which is only applicable when the uterus is movable, is unnecessary, its chief disadvantage being the prolonged convalescence it entails. The operation described above for movable displacements is preferable because it can be done quickly and necessitates only a week's confinement in bed. It is a rational procedure because it aims at a cure of the coexisting metritis and endometritis which is the maintaining cause of the displacement.

It has been suggested to apply Alexander's operation to fixed retrodisplacements after first incising the posterior cul-de-sac and breaking up the adhesions. This may be easy when the adhesions are not very extensive, but the difficulty of securing thorough asepsis by this route is certainly an objection as well as the time which this and the added Alexander's operation involves. All things considered, suspensio uteri is to be preferred when the organ is adherent.

Of the other operations recently suggested for overcoming these displacements, that of incising the posterior cul-de-sac of the vagina and bracing the uterus up by means of gauze crowded into the peritoneal cavity behind it, does not appear to be either wise or justifiable. A retroversion may be thus overcome but I fail to see how it can maintain a retroflexion even temporarily in a correct position. The chief objection to this procedure, apart from its faulty principle, is that it substitutes an exudation for the utero-sacral ligaments which are destroyed, and the cervix remains fixed to the rectum, an abnormal condition for many reasons objectionable.

Vaginal fixation does not appeal to me as either rational or justifiable since it substitutes a fixed ante-flexion for a movable displacement. The recent unfavorable reports of protracted and complicated labor when it follows this operation certainly constitutes a very serious objection to it. Its originator, Mackinrodt, has abandoned it.

Upon the whole the operations described above for movable displacements and suspensio uteri, when the uterus is adherent or when disease of the adnexæ complicates, are I believe the most satisfactory and the results, so far as my observation goes, bear me out in this conclusion.

351 West 57th Street.

## PREVENTION OF TUBERCULOSIS.

Read at the Pennsylvania State Medical Society, Harrisburg, Pa.,  
May 19, 1896.

BY E. B. BORLAND, M.D.

Clinical Lecturer, Diseases of the Chest, Medical Department of the  
Western University of Pennsylvania; Assistant Physician  
to the West Pennsylvania Hospital, Member Amer-  
ican Medical Association, etc.  
PITTSBURG, PA.

Under the light of recent investigations, the old theory of inherited tuberculosis is at best questionable. Congenital tuberculosis is comparatively infrequent. The so-called hereditary predisposition is now known to be general debility, which may arise from many causes. Any weakling has this predisposition, no difference what degree of health his parents enjoyed. All weak persons, especially the young, are liable to contract tuberculosis, if the three essential factors of infection are present, viz., debility, abrasions and bacilli.

*The three essential factors of infection.*—In the convalescence of typhoid fever, for example, we have two out of the three essential factors of infection. The same factors are present in the convalescence of measles and whooping cough, viz., debility and abrasions of the mucous membranes. The third essential factor of infection is easily supplied by the millions of tubercle bacilli which can be found in almost every public building, hospital ward, railway and, especially, the modern chariots of Juggernaut and centers of infection—the electric and cable cars, the floors of which are regular cuspidors.

That the bacillus discovered by Koch in 1881 is the

specific cause of tuberculosis is not questioned by the medical profession at the present day. The principal routes of infection are the respiratory tract, mainly in adults, and the alimentary tract in children.

*Two principal sources of infection.*—That raw milk, and the air containing dried sputum, are the two important sources of tubercular infection is self-evident to any painstaking observer. The former may be held responsible for nearly one-fourth, and the latter more than one-half of all cases of infection. The large number of cases of abdominal tuberculosis in small children fed on raw cow's milk, is evidence of the importance of this source of infection. Marfan demonstrates the great danger of infection from sputum, in the following observation: Twenty-two previously healthy factory employes worked for many years together in one room. In the year 1878, two men suffering from ulcerative pulmonary lesions were added to their number, and these two latter expectorated freely on the floor. Between the years 1884-89, thirteen of the original twenty-two died of tuberculosis. Was this an accident or the plain result of the violation of a sanitary law?

*Transmission of infection.*—It is quite probable that infection is often carried from its original source to susceptible individuals by the common drinking cup, the common communion cup, cigar makers, careless barbers, money, handkerchiefs, kissing, the long skirts often worn by women, instruments, especially dental instruments, which often do not get even a rinsing with water until they have been used in several persons' mouths.

*Vitality of the tubercle bacillus.*—It will withstand freezing and dessication for weeks and months, and has been found alive after being buried two years. Koch produced tuberculosis by cultures nearly two years old. It should be borne in mind that the germs in fresh sputum or secretions are more virulent, that is to say, more likely to infect and harder to destroy, than after exposure to air and sunshine for several weeks. Nuttall found not only millions but billions of tubercle bacilli in the sputum of one patient in twenty-four hours.

*Measures to prevent infection.*—It has been estimated that about fifteen per cent. of milch cows are tubercular. The question arises, how is this source of infection to be controlled? The answer is, by destroying all infected animals as soon as a diagnosis can be made, and always sterilizing or boiling milk before using.

The physician is the guardian of health in the home, and it is his positive duty to teach his patrons preventative medicine. If he is grounded in the faith to a degree warranted by the facts, he can soon be the means of molding public opinion so that it would be decidedly unpleasant for any respectable person to be seen expectorating on any floor or sidewalk. Church-going people get along without expectorating on the floors of their places of worship, and this is evidence that all respectable people can do the same. Legislation, making expectoration on floors and sidewalks a misdemeanor, would control the vicious class.

A step in the right direction has recently been taken by the New York Board of Health. It directs the removal of carpets and matting from the floors of cars and boats, and the placing of cuspidors containing suitable disinfectants where needed.

The rule should be absolute, forbidding any or all persons from expectorating on any floor or sidewalk.

Patients with ulcerative pulmonary lesions should not be allowed to expectorate in any place, either out or in doors, except in vessels containing suitable disinfectants.

Heat, solution of corrosive sublimate, 1 in 500 (acidulated with tartaric acid to prevent the coagulation of albumin), or carbolic acid, 1 in 10, will promptly destroy the tubercle bacillus.

Large, well-glazed cuspidors with perpendicular sides should be used (surrounded, if necessary, by screens) and cleaned daily, would protect public buildings and homes. Public conveyances to be protected by suitable vessels filled with sawdust, dampened with a 1 in 250 bichlorid solution. Patients with ulcerative pulmonary lesions should carry a small, wide-necked, glass-stoppered bottle containing a small quantity of the bichlorid solution for a pocket cuspidor, to be used only when out of reach of floor cuspidors. Handkerchiefs costing not over one-eighth of a cent apiece could be carried, in an emergency, and burned after using.

Patients should be instructed to rinse out their mouths frequently with warm water containing a little essence of wintergreen. This precaution to be attended to before eating, for the protection of the patient, and after expectorating, for the protection of others as well. Kissing should always be prohibited. It has been estimated that a patient in the ulcerative stage of pulmonary tuberculosis lives about two years. During this period he is a constant source of danger to his family and a menace to society. At a cost of not exceeding \$50 and a little trouble, his sputum could be destroyed and his family largely protected from infection. Latent tuberculosis needs no precautions.

For the poor, hospitals especially designed for consumptives, and for their exclusive use, should be provided by the State as a matter of humanity, economy, and protection to the public health. The watchword should be, isolation for the patient who can not or will not be governed by the necessary sanitary regulations.

The disinfection of rooms and houses in which patients with ulcerative lesions live, or have lived, within two years, is a matter of vital concern. For this reason alone, tuberculosis should be classed by law with the infectious diseases, and be placed under the supervision of bureaus of health.

The Assembly of this Commonwealth now provides for the supervision by health officials of ten contagious and infectious diseases, viz., smallpox, diphtheria, scarlatina, typhoid fever, typhus fever, yellow fever, cerebro-spinal fever, Asiatic cholera, relapsing fever and leprosy.

The last two diseases in this list are so rare as to be almost a medical curiosity, yet were added to the list only last year; and an infectious and contagious disease which is the direct and primary cause of more deaths (14 per cent.) than all of the above ten, with measles and pertussis included, was omitted.

Ventilation is a much neglected measure of prevention. It has been estimated that each adult individual requires 3,000 cubic feet of fresh air per hour. In a room containing 1,000 cubic feet the air should be changed three times an hour to prevent the carbonic acid gas from rising above six parts in ten thousand.

Probably not one room in ten will meet this requirement. While only a fraction of a cubic foot of car-

bonic acid gas is thrown off by respiration, an ordinary small illuminating gas burner will throw off six cubic feet an hour. A natural gas stove, without chimney outlet, is one of the most pernicious air poisoners ever invented. It renders the air in an ordinary sized room unfit to breathe in a few minutes. The most efficient means of ventilation we have in the average home to-day is the old-fashioned fireplace. Provisions for the entrance of fresh and escape of foul air should be made near the floors and ceilings of every living room, in such a way as to avoid draughts. Permits for the erection of all buildings should specify that ample means be provided for ventilation, and official inspectors should see that the specifications are carried out. Electricity is to be the light and possibly the source of artificial heat in the near future.

The knowledge that we now possess of the pathology, the three essential factors of infection, the common sources of infection, the common routes of infection, the means at our command to prevent infection, ought and can stamp out, if acted on intelligently and promptly, more than one-half of the cases of tuberculosis in the next twenty-five years, and 90 per cent. of all cases in the coming century.

Sentiment in intelligent, sensible, respectable people can be aroused and cultivated. With the ignorant and vicious nothing succeeds like an absolute fiat.

#### H. H. HOLMES.

BY EUGENE S. TALBOT, M.D., D.D.S.

FELLOW OF THE CHICAGO ACADEMY OF MEDICINE.

That Herman Webster Mudgett, better known as H. H. Holmes, was a criminal *par excellence* is beyond doubt, but how far and in what respects he was a degenerate, in the accepted sense of the term, is worthy of serious consideration.

Few criminals have received more public attention, but despite this, many essential details of his history are wanting. Very little has been stated as to his heredity. He claims to have come from a respectable New England stock and to have been religiously and carefully brought up. As a boy he does not appear to have been a scapegrace, and no criminal charge is there on record against him. He married at 18 or 20 and commenced the study of medicine at Burlington, Vt. From there he went to the University of Michigan, where he claims to have graduated in medicine in 1884.

According to his own account, after graduating he taught school and practiced medicine in New Jersey for about a year, but it would appear that before this he had already, with a confederate, conspired to defraud life insurance companies, an industry he never entirely abandoned and which finally brought him to the gallows.

Just when he assumed the name of H. H. Holmes is not certain, but probably not long after this. He himself says it was done when he went before the Illinois Pharmacy Board in 1886. From that time he has been known by that name and under it started in business as a druggist in the outskirts of Chicago, where he went into rather extensive and complicated transactions, chiefly of a crooked character. He managed, however, to keep in fair standing with his neighbors, and at one time was actively interested in church and religious matters.

During this time he had abandoned his New Hamp-

shire wife and child, and without divorce, married in 1887 a Miss Belknap. Some years later in the same way he married a Miss Yoke in Denver under the name of Henry Mansfield Howard. He is supposed also to have contracted another bigamous marriage with Minnie Williams (one of his supposed victims). Beside these he had irregular relations with other women. In 1894, shortly before his final arrest for the murder of Pitzel, he revisited his old home and lived as husband for a few days with his first wife, to whom he told a romantic fiction anent his absence.

Between 1886 and 1894 there is no full account of his doings. They included an extensive series of swindles and forgeries. His transactions covered many parts of the country. He ranged from Canada to Texas and Colorado, often in trouble but generally managing in some way to escape the most serious consequences of his crimes. These were in their way often remarkable for their boldness and impudence. He negotiated for the sale to a gas company of a gas-

H. H. HOLMES.

making machine which was actually running on gas stolen from the company's own mains. He admits "deals of a somewhat similar nature."

While his confessions, generally, have been unreliable, it is probable that the above is safely inside the truth. He was emphatically a man of affairs, but his business transactions were so shady in their nature that the obscurity that enveloped them has been dispersed as yet only to give a glimpse such as the above.

It was during this period that he built his celebrated castle, with its secret chambers and passages, dark rooms, trapdoors, etc. Here he employed the female type-writers and other employes whose mysterious disappearance has done so much to make his popular reputation as a murderer. As far as this crime is concerned it must be admitted that the evidence against him is altogether circumstantial, his confessions and statements being notoriously and boastfully mendacious, in the main. Out of the twenty-seven murders he admitted in his latest confession shortly before his exe-

cutation, the majority of the victims are still living. Even his dying admission that he had been responsible for the sacrifice of two lives from criminal operations can not be accepted as perfectly reliable, considering his character for untruthfulness. He seems to have had little or no regard for human life, and as a dealer in "stiffs" and a defrauder of life insurance companies his operations were often enough suggestive of murders, even if these were not often committed.

The history of the Pitzel case, where it appears he made away with his confederate and then later with three of his children, and seemed to be planning the deaths of the widow and remaining family, distributing the deaths about the country in such a way as to avoid suspicion, must be fresh in the mind of the reader.

Holmes in his personal appearance, like Wainwright (whom he much resembled in his criminal career), presented nothing specially repulsive in his appearance. He was quiet, mild in manner and voice, fairly well educated, neat in dress and could pass anywhere for a respectable business or professional man. During his long criminal career he appears to have had no particular ambition, except to succeed in his crooked operations and to ingratiate himself with women, for whom he seems to have had a more than normal inclination.

Mentally, there was no lack of acuteness. The fact that he managed to escape justice so long is an evidence of this. When he was finally arrested his behavior was peculiar and shifty. He told contradictory stories, and when his case came to trial he dismissed his lawyers and insisted on managing his own defense. Though he showed some aptness in examining witnesses, he was finally obliged to recall his counsel and give the case into his hands. The jury found him guilty almost without leaving the box. Perhaps the one witness whose testimony was most convicting was his latest bigamous wife.

Holmes made numerous statements and confessions to detectives and others and published a book while awaiting trial which purports to give an account of his life.

The most remarkable of these confessions, however, was that published in the *Philadelphia Inquirer* of April 12, three or four weeks prior to his execution. In this he reports the details of twenty-seven murders and claims that he was a case of acquired moral idiocy; that he presented numerous facial stigmata of degeneracy that had grown upon him, during his criminal career. Eighteen of the twenty-seven victims in this confession are living. Its author acknowledged its falsity within a day or two of its appearance.

It was not merely criminal vanity that prompted it, for he received for it a very substantial compensation of several thousand dollars. Throughout his imprisonment, his acquisitiveness was shown in this and other publications for which he received money, and in propositions of blackmail for persons he contemplated involving in these confessions.

While in Philadelphia, Jan. 30, 1896, I had the opportunity of making a careful physical examination of H. H. Holmes, with the following results:

The subject was a 35 year old American, 5 feet 7½ inches in height, weighing 150 pounds. The occiput was asymmetrical and prominent, the bregma sunken and the left side of the forehead was more prominent than the right which was sloping. The hair was brown, and on body and face excessive. The face was

arrested in development. The zygoma was arrested and hollowed on the right side.

The pictures of Holmes published in the daily papers and in his book, do not, to my mind, portray the features of the man as I saw him in his cell. Figure 1, comes the nearest as he appeared when I saw him. His face was cleanly shaven, except moustache, very thin and much emaciated, presenting the appearance of being in a decline, due perhaps to confinement and a tendency to consumption. He had a cough, and the chances are if he had been allowed to remain in confinement he would have succumbed to tuberculosis.

Figures 2 and 3 show the antero-posterior and lateral shape of head. The right ear was lower than the left. The nose was long and very thin; stenosis of nasal bone very marked. The septum deflected to left, nose to the right. The thyroid gland was arrested. Strabismus in left eye, inherited. The left higher than the right. Slight protruding of the upper jaw; arrest of lower. The mouth on the left side drops lower than on the right. The width, outside of first molars was 2. Width outside first bicuspid 1.62. Height of vault, 63.

Figures 4 and 5 upper and lower jaw. The alveolar process was normal with the exception of the process about the second molar on right side which was hypertrophied. The teeth were normal in size and shape, the third molar undeveloped.

Marked pigeon breast, left side more prominent

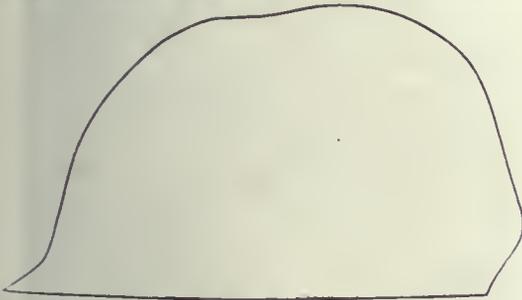

FIGURE 2.

than right. Chest arrested with tendency to tuberculosis.

Arms: Right normal. Left one and one-half inches longer. He was right handed. His legs were long and thin. The tibia flattened. The feet medium in size but markedly deformed. Depression on left side of skull at bregma, said to be due to fall of brick at age of 30. Sexual organs unusually small.

The jaws were unusually long as compared with the width, with a semi-saddle arch on the left side of the upper jaw. The molars of the lower jaw and left upper had been extracted in early life. The hypertrophy of the alveolar process, the want of development of the third molars and the general abnormal development certainly display a very unstable nervous system in his early life.

In twenty years' experience, I have never observed a more degenerate being from a physical standpoint. Holmes in his confession published, stated that ten years ago he was examined by four men of marked ability and by them pronounced mentally and physically normal and healthy. "To-day, I have every attribute of a degenerate a moral idiot." Is it possible that the crimes, instead of being the result of these abnormal conditions, are, in themselves, the occasion of degeneracy? . . . within the past few months these defects have increased with startling rapidity; as is made known to me by each succeeding examination," etc.

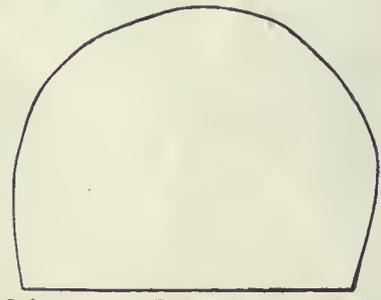

Holmes was examined ten years ago, not to ascertain stigmata but for life insurance, and the Bertillon system was not used at all since only criminals are thus examined, for identification. When these examinations are made, only one arm, finger and part of the body are measured, and not both sides for comparison.

While I was making my examination, I called his attention to a number of deformities which he was not aware he possessed.

Being a medically educated man, he certainly should have been better acquainted with these malformations, but he had evidently given this subject little attention since he was quite ignorant of the cause of two most marked deformities: The too deep depressions in the left frontal and occipital region of the head. These he claimed were due to a brick falling upon him at the age of 30. The marked deformity of the chest walls he claimed to be due to pneumonia.

Both deformities were stigmata of degeneracy. Holmes, since his confinement, had no doubt lost flesh, which made these deformities appear more prominent. That they had developed as a result of his criminal tendencies is perfectly absurd. They must have developed with the osseous system, which would be complete by the 26th year; nor will acromegaly account for them.

Holmes has been called an extraordinary criminal,

Left. FIGURE 3. Right.

but he certainly was no more of a criminal than Wainwright,<sup>1</sup> who was well known in his time as an essayist and better as a forger and murderer. From the standpoint of literary and artistic culture Wainwright stood higher than Holmes. Like Holmes, he attempted to defraud insurance companies and there is no doubt he poisoned a girl for this purpose. Holmes' habitual criminality was modified by his education and antecedents. He had sufficient ability and self-control to successfully pass for a respectable citizen and to keep his criminal transactions so distributed as to territory and covered that only the self-interested perseverance of a life insurance company prompted by a hint from an ex-prison acquaintance could reveal them. His mental defects, so far as they existed, seem to have been confined to his moral sensibilities. He apparently had none of that sense of moral dictation which is a part of the constitution of every normal individual. He acted entirely as an egotist, perfectly capable of appreciating the possible immediate consequences of his acts and more than ordinarily expert in managing in one way or another in avoiding them, but utterly lacking in even the utilitarianism commonly expressed in the old adage that honesty is the best policy. While the murders have mainly created his popular reputation, they were but incidents in his consistent criminal career. He had

<sup>1</sup> See Havelock Ellis' "The Criminal," p. 13.

no regard for others' rights or lives. Doing away with a mistress or a confederate when she or he become inconvenient was an easy matter to him. His education, his dissecting-room training and subsequent specialty helped to remove original superstitious fears that might restrain the average criminal. He seems to have been utterly lacking in any lasting or sincere affection or attachment. A man who could deliberately desert successively two wives with their children would be capable of abandoning others whose relations were less intimate.

Havelock Ellis remarks<sup>2</sup> that whatever refinement or tenderness of feeling criminals attain to reveals itself in what we should call sentiment or sentimentality. One of the characteristics of Wainwright's essays is their sentimentality. Himself, when in prison, he described as the possessor of "a soul whose nutriment is love, its offspring art, music, divine song and still holier philosophy." This sentimentality cropped up in Holmes in the letters to his first wife whose pathetic nature so impressed his counsel. It was also shown in his successes with women.

Holmes was certainly a degenerate physically, as the numerous stigmata he bore proved, but he was not more of one than many moral men and good citizens. There was, with the defects, undoubtedly a certain defectiveness and want of balance of the nervous system, but it can not be said that this necessitated the career he chose. If he were a "born criminal" it was not evident till after he had passed his minority and his moral imbecility did not apparently reveal itself to any very striking extent during his boyhood. He followed the course of many young men, who, on leaving the associations and restraints of home fall into evil courses, only he went farther and under pressure, it may be of want and misfortune, adopted to the fullest extent the anti-social and aberrant career of a criminal. There was, possibly, always a certain defect in his moral constitution which was checked in its effects by the restraints and training of his earlier years and might have been overcome entirely had his will been directed into proper paths. His case seems to be largely, if not altogether one of acquired moral obtuseness, not of complete congenital moral insanity.

FIGURE 4.—Lower.

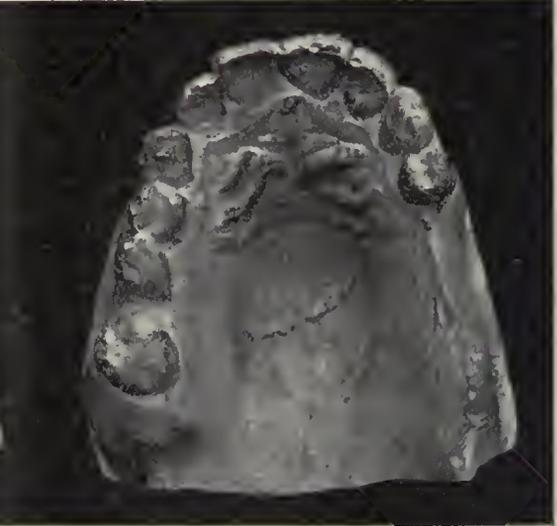

FIGURE 5.—Upper.

His crimes were apparently all deliberate and cold-blooded. In his arrangement of his building, "The Castle," he made provisions for various kinds of crooked work. Only in this way can be reasonably explained this seemingly crazy piece of architecture. There is no evidence in his record that Holmes was insane in any way except it be morally.

In his apparent disregard for human life he was less peculiar than would at first sight seem. When a man has an object in view, which to him is a supreme motive, nothing will stand in his way. Holmes had no regard for the law if he could avoid its punishments, no conscientious scruples to govern his conduct. The taking of life was no more to him than to the Sultan of Turkey, a hanging judge or a military commander, who will sacrifice a forlorn hope to gain an advantage. It is not so improbable, therefore, that he may have been a more or less wholesale murderer, if he found people in his way. He may have disposed of his victims and regarded it only as an inconvenient necessity. There is nothing in his character to make this intrinsically improbable.

How far he was handicapped morally by his constitution, is a question that can not be decided absolutely, but probably not more than the average criminal, who is generally of a more or less degenerate type.

It has been assumed that his vanity and egotism were excessive and evidence of his abnormal mental constitution. First, however, it ought to be proven that these existed to any such extent as is inferred. This can not well be done from his history. He was not obtrusive in his manner and his very choice of life made it impolitic, to say the least, to such publicity, and in his way he was very politic. He had ample confidence in himself, as was shown by his attempting his own defense. This may be taken as evidence of egotism, but he can hardly be said to have been obtrusively egotistic. His numerous statements in regard to himself were apparently not so much prompted by vanity as by a desire to make a profit from them. This was especially true of his last noted confession, which was one of the best remunerated productions of fiction based on fact that has been brought out in the country.

<sup>2</sup> The Criminal, p. 152.

There was certainly one striking psychologic peculiarity about the man; lying seemed to come naturally to him. He did it sometimes apparently without object. In this, however, he was not altogether unique, but there are marked examples, never in their acts passing over the line of legality.

Summing up the character of Holmes, we would say that he was, first of all, a swindler, a *chevalier d'industrie* and a *roue*. Money and women seemed to be his objects in life, especially the former, and he was perfectly unscrupulous in his methods of gratifying his ruling passions. His professional and general education, which he seems never after the first failure to have attempted to utilize properly, only served to make him the more dangerous and probably aided to make him a murderer as well as a seducer, bigamist, forger and thief. He may have had some congenital deficiency in his moral make-up, but the absolute lack of moral dictation of his later life, was due to or greatly aggravated by his self-chosen environments.

### TUBERCULOSIS OF THE MALE GENITAL ORGANS.

Read by title at the meeting of the American Surgical Association, at Detroit, Mich., May 26-28, 1896.

BY NICHOLAS SENN, M.D., PH.D., LL.D.

PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION, ETC., ETC.  
CHICAGO.

(Concluded from page 187.)

*Tuberculosis of the testicle and epididymis.*—Except in cases of acute diffuse miliary tuberculosis the essential organ of generation in man is seldom the seat of primary tuberculosis. On the other hand, primary localization of the tubercle bacillus not infrequently takes place in the epididymis, when the infection often extends from here to the testicle. There must be vascular conditions or other local predisposing causes which are concerned in determining hematogenous infection of a tubercular nature in the epididymis which are absent or present to a lesser degree in the testicle. The epididymis is more often the seat of acute infective processes which prepare the soil for the bacillus of tuberculosis than the testicles which, to a certain extent, may explain the greater frequency with which primary tuberculosis occurs in the former than the latter. It must also be remembered that in descending tuberculosis from the upper portion of the urinary tract, the epididymis is exposed first to infection, and the patients often succumb to the primary disease and its complications before a sufficient time has elapsed for the testicle to become involved. There still prevails the greatest diversity of opinion among pathologists and surgeons in regard to the epididymis being most frequently affected in cases of urogenital tuberculosis.

Councilman (System of Surgery, Dennis, Vol. i, p. 246) believes that in such cases the most common seat of the primary disease is the epididymis. He says: "It may be confined to this or the testicle may be affected by continuity. The epididymis is converted into a more or less firm, caseous mass. From this the disease extends along the vas deferens, which becomes enlarged, and on section the interior is found to be lined with a whitish caseous tissue. In both the vas deferens and epididymis, the seat of the disease is primarily in the epithelium, and later takes the form of a tubercular inflammation. Seminal vesicles on the same side become affected in most cases, or they may be passed by and the disease appear in

the prostate or bladder. Up to this point it is easy to see how the infection has taken place. The extension has been in the direction of the secretion, and the bacilli could be carried along with the secretion. From the bladder the extension is in a direction opposite to the flow of the secretion; with or without any involvement of the ureter, infection of the pelvis of the kidney and of the adjoining kidney tissue takes place. It is probable that the bacilli find suitable conditions for growth in the ureter and grow along the walls, just as on the surface of a solid medium, until the pelvis of the kidney is reached. There is no other way for infection to take place from the bladder to the kidney than along the ureter. There is no lymphatic or vascular connection. The proof that this is the usual route of infection in genito-urinary tuberculosis is shown by the certainty with which the disease can be traced step by step, and the extreme rarity of the disease in females as compared with males. In some cases the disease appears to be primary in the kidney and the infection may take place in an opposite direction."

My clinical experience corresponds with the views of Councilman that in more than 50 per cent. of urogenital tuberculosis the disease has its primary starting point in the epididymis.

We shall see in considering the etiology of this disease that there are many authorities who take the opposite ground and affirm that urogenital tuberculosis most frequently has its origin in the upper portion of the urinary tract.

*Etiology.*—Aievoli (Eriberto sur la tuberculosi di testiculo ed epididimo. Morgagni, p. 657, p. 728, 1891) made experiments on guinea pigs by injecting into the testicle and epididymis tubercular material and pure cultures of the tubercle bacillus. Only in one case did he find tubercle bacilli in the lumen of the seminal ducts, but in all instances there was produced an inter-canalicular proliferation, so that the walls of the canals were perforated and large masses with caseous centers were found in which pseudo giant cells could be demonstrated. In some places an attempt at cure by sclerosis could be found at the same time, also tubercle production in the vicinity of blood vessels and the interstitial tissue. He believes that such an inter-canalicular tuberculosis is possible without direct inoculation, as the bacilli may reach the interstitial tissue through the lymph stream. The results of these experimental reseaches are closely allied with the observations of pathologists concerning the gross pathologic anatomy of testicular tuberculosis. The disease in the epididymis is caused frequently by a descending infection from the prostate and seminal vesicles, but it may originate in the epididymis primarily, as tubercle bacilli have been found on several occasions in the seminal ducts in healthy testicles in phthisical subjects. The process begins in most cases in the epididymis in the form of conglomerate tubercles which are conspicuous for the number and size of the giant cells. The tubercle elements are derived mostly from the interstitial connective tissue, but part of the product may be furnished by the epithelial cells and other tissues of the seminal ducts. Infection may extend along the urogenital canal from the kidney to the testicle; as a rule, however, tuberculosis of the testicle begins in the epididymis. Sometimes the testicle and epididymis are affected simultaneously in cases of general miliary tuberculosis. "The fact that the spermatic

artery divides when it reaches the epididymis may account for the localization of the disease in the latter organ; the slowing of the blood current always favors bacterial growth. Infection may also occur through the vas deferens. The conditions for localization of the microbes after their entrance into the urethra on their way to the vas deferens, are not so favorable as in the latter organ." (White.)

The predisposing causes are: Inherited soil, antecedent or coexisting disease of the testicle and trauma. The disease begins more frequently in the globus major than the opposite end of the organ. Later the testicle and its envelopes are invaded by direct extension of the infective process from the epididymis to those organs. Age appears to have a positive determining influence in the production of tuberculosis of the epididymis and testicle. Salleron ascertained the age in 47 cases of tuberculosis of the testicle with the following result: 20 to 30 years, 36; 30 to 40 years, 6; 40 to 50 years, 4; 50 to 60 years, 1; total 47.

It appears that tuberculosis of the testicle is most prevalent during the most active period of sexual function, that is, in patients from 20 to 30 years of age. Kocher remarks that the disease frequently occurs in young men soon after marriage. This corresponds with my own personal observations.

Julien (De la tuberculose testiculaire. Arch. Gén. 1890) reports 17 cases of tuberculosis of the testicle in children in the service of Lannelongue. Of these six were less than two years of age; the remaining patients were from two to thirteen years old. Heredity could be traced in four of ten cases. The disease often appears in the acute form or at least with symptoms of a subacute orchitis. In twelve of these cases the spermatic cord was affected. In four cases the affection was complicated by hydrocele of the tunica vaginalis, and in one case the prostate and vesiculæ seminales were implicated. In children there is little, if any, tendency to the extension of the disease to other organs. The affected organ is generally destroyed either by ulceration or absorption, a complete *restitutio ad integrum* being rare. In spontaneous cases the organ atrophies and is usually covered by a pale, adherent scar. Hutinel and Deschamps (Étude sur la tuberculose des testicules des enfants. Arch. Gén., p. 257, 1891) maintain that tuberculosis of the testicle in children is by no means infrequent. In children the disease occurs most frequently in the form of an acute infiltration. It is seldom a primary affection, but forms a part of a general diffuse tubercular process. The peritoneum especially is frequently involved. The chronic form is often overlooked because it occurs as a chronic, painless induration. Otherwise the disease resembles the same affection in the adults, resulting in caseation and abscess formation. It is only in such cases that the authors favor an operation. The results of castration in children are not encouraging. These authors are more inclined to conservative treatment by local applications and internal medication.

Rintelen (Ueber Hodentuberculose mit Berücksichtigung des Doppelseitigen Auftretens derselben. Inaugural Dissertation, Würzburg, 1881) collected twenty-five cases of double tuberculosis of testicle beside six cases which he saw in Rosenberger's clinic. In fifteen of these sufficiently accurate data could be obtained in reference to the course of the disease. The right testicle was affected first ten times; in the remaining cases the disease commenced in the left

testicle. In only one of these cases was the patient less than ten years of age. Three of the patients were from 20 to 30 years old, six from 30 to 40, and fourteen more than 40. Of the last number most of the patients were between 50 and 60 years of age.

Reclus (Du tuberculose du testicule et de l'orchite tuberculeuse. Thèse. Paris, 1876) is of the opinion that tuberculosis of the testicle can exist as a local affection without any tendency to dissemination, local or general. Clinical observation has shown that in about one-half of all cases of testicular tuberculosis pulmonary phthisis is absent, while autopsies show that the lungs are not implicated in about one-third of all the cases. In about 50 per cent. of all the cases the disease is met with in persons before the age of puberty, while it is found in about 2.5 per cent. of all patients suffering from pulmonary tuberculosis in persons over 15 years of age.

As exciting causes most authors enumerate traumatism and chronic gonorrhæal inflammation in the posterior portion of the urethra and the epididymis. Cryptorchism is mentioned by Nepveau and Kocher as one of the most potent of the exciting causes. Gonorrhæal epididymitis is mentioned frequently as a precursor and often imparts to the tubercular process a very malignant type. Such a case is reported by Birch-Hirschfeld. (Archiv f. Heilkunde, 1871, H. 6.) A soldier, 24 years of age, who was in perfect health, contracted gonorrhæa, which led to acute epididymitis. In the course of eight days he died of military tuberculosis. Miliary tuberculosis is found in the peritoneum, especially well marked at the internal inguinal ring on the side of the affected testicle; miliary tuberculosis of the pleuræ, lungs, meninges, liver, spleen and kidneys. The epididymis was found transformed into a cheesy mass. In the testicle itself numerous intercanalicular miliary tubercles were found and a few cheesy nodules the size of a pin. According to Salleron (Arch. Gén. de Méd., July and Aug., 1869), of fifty-one cases of tuberculosis of the testicle, four times the testicle was affected, thirty-seven times one epididymis, ten times both epididymes. With the exception of tuberculosis of the remaining genito-urinary organs, he saw tuberculosis of other organs only in one case. Only in two cases did the disease prove fatal. Of forty-seven cases, thirty-six were from 20 to 30 years of age. It will be seen from the statistics that have been quoted that while no age is entirely immune to tuberculosis of the epididymis and testicle, the disease occurs most frequently in men from 20 to 30 years of age, at a time when the sexual organs are in a state of highest physiologic activity. As exciting causes figure most prominently gonorrhæal epididymitis and traumatism.

Sir Astley Cooper in his classical work (Observations on the Structure and Diseases of the Testis, London, 1841, p. 162) gives the following pathologic description of what he called serofulous inflammation of the testis: "Upon examining the epididymis and testis, when affected with this disease, I have found a yellow spot in the former, surrounded with a zone of inflammation. When the spot ulcerates in the center, the matter which it contains is not pure pus, but it is composed of fibrin and serum, with a slight yellow tinge. I have seen such spots in the globus minor, but more frequently seated in the globus major of the epididymis. In the testis there are generally several similar spots, accompanied by the same inflammatory zone; and yellow streaks are also found amidst the

tubuli. Scrofulous abscesses in the testis are sometimes accompanied by a granular swelling, like that which exists in the simple chronic diseases."

That the tubercular nature of the majority of cases of chronic inflammation of the testis has been admitted only for a comparatively short time is evident from a paper written in 1870 by B. Beck (*Zur Käsigen Infiltration und multiplen Abscessbildung des Hodens. Deutsche Klinik*, No. 1 u. 2, 1870). He insisted that it would become necessary to separate from what had formerly been included under the head of scrofulous affections of the testicle some cases which were of a tubercular nature. The tubercular form of orchitis he claimed seldom, if ever, existed as an isolated affection; the complicating tubercular affections in other organs he regarded as an important diagnostic aid in differentiating between the tubercular and scrofulous forms of inflammation of the testicle. Miliary nodules of the testicle he saw only once in the case of a child who died of miliary tuberculosis.

*Pathology.*—The naked eye morbid appearances of tubercular epididymitis and orchitis are fairly well understood by the mass of the profession. We find there as elsewhere the same retrograde metamorphoses of the tubercular product, coagulation-necrosis, caseation, and in the majority of cases liquefaction of the caseous material, only exceptionally arrest of the disease and calcification of the degenerated products of the tubercular inflammation. Some doubt still remains in reference to the primary starting point of the inflammatory process and the histologic structure of the tubercle tissue and the manner of local dissemination of the disease. Reclus (*Du Tubercle du Testicule et de l'Orchite Tuberculeuse. Thèse, Paris, 1876*) makes a sharp distinction between tuberculosis of the testicle and the epididymis. According to this author tuberculosis of the latter nearly always occurs in the caseous form. Occasionally it presents itself in a reticulated form, composed of the sections of the dilated convoluted tubules of the epididymis, the caseous contents of which has fallen out. Very often the vas deferens is affected, but according to Reclus never farther than 5 to 6 ctm. from the epididymis, an observation which does not correspond with the author's experience, who has repeatedly found the entire cord involved from the epididymis to the seminal vesicles.

Reclus recognizes the independent localization of the tubercular process in different parts of the genital tract and places little weight on the descending or ascending theory of the infective process, as he has repeatedly found tubercular nodules of the same age and size in the epididymis and prostate. In 79 cases he examined *in vivo*, he found the disease unilateral in 21, while the seminal vesicles were invariably affected on both sides. That this observation is not entirely reliable becomes very evident from Fenger's case related above. It is generally conceded that the epididymis is much more frequently affected than the testicle because reliance was mainly placed upon the results of clinical examinations. In thirty-four autopsies Reclus found the epididymis affected singly in only seven instances, twenty-seven times simultaneously with the testicle. Tuberculosis of the testicle without a similar affection of the epididymis is an exception, as he found only three such cases in literature. In the testicle the tubercular process is met with either in the form of caseous foci, miliary

infiltration, or both forms are combined. The arrangement of the tubercles is usually symmetrical, corresponding to the division of the seminal tubules. The nodules are generally found in the periphery of the organ, while the caseous foci are centrally located. Fibrous tubercles which pursue a chronic course are also found in the testicle. Microscopic examinations have satisfied Reclus that the miliary form can not be separated so easily from the caseous variety as taught by Virchow. With Malassez, he locates the primary nodules in the walls of the seminal tubules, and not as was done by Tizzoni, Gaule and Steiner, in the inter-canalicular connective tissue. He was able to remove the nodules when he resected portions of the seminal ducts showing their connection with the ducts. He believes that the process begins in the endothelial envelope which surrounds the tubules, which according to Ranvier, constitutes a continuous sheath of all tubules, and maintains that the interior of the lumen is affected secondarily. During the progress of the disease "granulations composées" are found which can only be isolated with portions of several tubuli seminiferi. While this histologic process is regarded by the author as characteristic of testicular tuberculosis, in the epididymis the process begins in the subepithelial elements of the tubules. The microscopic appearances of tubercle tissue in the parenchyma of the testicle is the same whether the disease occurs as a primary affection, or in consequence of extension from the epididymis. In the primary form the foci are few and large, varying in size from a hazelnut to that of a walnut. During the early stages of the disease the nodules are much firmer than the surrounding normal parenchyma of the organ. The mass is surrounded by a vascular zone. Central caseation, softening, abscess formation and perforation often follow in quite rapid succession. If the disease of the testicle is secondary to tuberculosis of the epididymis the nodules are more numerous and the disease presents more the appearance of an infiltration. The tubercles are found between the seminal tubules which are separated from each other by the tubercular product. The interstitial connective tissue as well as the adventitia are infiltrated with small round cells. The vascularity of the affected part is at first increased, but as the nodules increase in size the vessels disappear in the center and with them the tubules. According to Rindfleisch, only the adventitia disappears, while the propria becomes edematous, but remains and can be identified in the cheesy product for a long time.

Curling (*On Diseases of the Testis, Philadelphia, 1878, p. 335*) in the later addition of his work has expressed the opinion that the disease is originally developed within the tubules of the testicle, and the result of microscopic examinations have induced him to adopt this view. He continues and says, "Anatomic considerations indeed support the opinion that abnormal nutrition in the cellular contents of the tubes induces the formation of miliary tubercles in their walls without at all negating the development of tubercle in the intertubular tissue as seen by Virchow, or in the adventitia of the blood vessels as observed by Nepveu. Indeed, the discrepant views upon the matter may be explained by assuming that different observers have regarded what has been found in particular cases as the result of some general law. With reference to this the suggestion of Klebs is valuable. Admitting that in acute miliary tuberculosis where

the dissemination of the virus is effected by the vascular system, the blood vessels and their surroundings are the seat of the tubercles, he has seen preparations by Langhans where the tubercles were in the interior of the tubule, and Klebs adds that "It would be very desirable to ascertain whether this was uniformly the case in the so frequent extension of tuberculosis from the older nodules in the epididymis to the body of the testis."

Salleron (*Mémoire sur l'affection tuberculeuse des organes génitaux de l'homme*. *Archiv Gén. de Méd.*, July and August, 1869) as early as 1869 observed in his military practice fifty-one cases of tuberculosis of the testicle. The testicle itself was affected only four times, the epididymis on one side thirty-seven times, on both sides nineteen times. Only in one case was he able to ascertain *intra vitam* the existence of pulmonary tuberculosis, a fact which is in opposition to the experience of Curling and Louis, but which he supported by nine accurately reported cases and two autopsies. With the exception of the vas deferens and the seminal vesicles, he found the remaining portion of the urogenital tract free from tuberculosis.

Years ago Friendländer found miliary tubercles in the testicle in cases in which no other organ was found affected. (*Sammlung Klinischer Vorträge*, 1873). Nepveau (*Contribution à l'étude les tumeurs du testicule*, Paris, 1872) found miliary tubercles upon the walls of blood vessels in diseased testicles complicating secondary renal and primary pulmonary tuberculosis.

Rindfleisch calls attention to the unusual size of tubercles in tuberculosis of the testicles which, according to his observation, vary from the size of a pin's head to that of a walnut. In the testicle the first infiltration usually shows itself as fibroid tubercle, as a light yellow or grayish white hard and tough nodule in the parenchyma of the organ. In miliary granulations the tubercle appears under the microscope as described by Langhans, in the center a giant cell, around this epitheloid cells, and in the periphery a small round celled infiltration, the cellular elements imbedded in a reticulum of connective tissue. Kocher (*Krankheiten des Hodens, Nebenhodens und Samenstranges*. Pitha u. Billroth, Bd. III, p. 3, B. p. 273) is also of the opinion that the primary starting point of the disease in the epididymis is in the intertubular connective tissue. The contents of the tubules are increased by proliferation of the preëxisting tissues of their walls. The infection begins most frequently in the globus major and extends from here to the remaining parts until the entire organ is transformed into a hard nodular mass. Cheesy degeneration of the contents of the tubules results in destruction of their walls and coalescence with the intertubular products, when a tubercular abscess forms which frequently ruptures spontaneously.

Gaule (*Anatomische Untersuchungen über Hoden tuberculose*. *Virchow's Archiv*, Bd. lxxix, pp. 64 and 213, 1887) regards tuberculosis of the testicle as a catarrhal inflammation of the epithelial lining of the seminal tubules which leads to stagnation of the secretions and caseous degeneration of the inflammatory product which, owing to the thinness of their walls, are prone to undergo ulceration. According to this author the process begins in the epididymis and later extends to the testicle, where it assumes another character, as the intertubular connective tissue soon takes part in the process of tissue proliferation. In

the epididymis the process is apt to remain circumscribed and favorable to the development of a fibrous nodule limited to the interior of a single tubule. While the contents of the nodule may undergo caseation, the existing irritation extends to the adjacent intertubular tissue and gives rise here to fibrous products frequently in the vicinity of the septa. Later adjacent tubules are included in the process and undergo similar changes, constituting the condition described by Reclus as "granulations composées." The local and general dissemination of tuberculosis of the testicle and epididymis are well shown by the observations of Guyon. (*Clinique des maladies des voies urinaires à Necker*. *La Castration pour Sarcocele*; *Ann. des mal. des org. gén. urin.* p. 445, 1891.) He found in twenty-eight postmortems on persons the subject of tubercular disease of the testicle that the lungs were affected in only eleven. In 222 clinical observations on patients suffering from urogenital tuberculosis which he examined during a period of twenty-five years, forty were cases of isolated genital tuberculosis, seventy-four of the urinary organs, and only 108 of combined urogenital tuberculosis. Of forty-two additional postmortems, one was a case of isolated genital tuberculosis, fourteen cases of combined tuberculosis of the urinary organs, and twenty-seven of combined urogenital tuberculosis. Seldom is the testicle or epididymis the only part affected. He believes with Lanceraux that the tubercular process begins very frequently in the vesiculæ seminales. In thirteen cases all of the genital organs were affected. In 127 clinical cases in persons before the age of puberty, suffering from urogenital tuberculosis, the prostate was affected fifty-six times, prostate and seminal vesicles eleven times, the epididymis alone two times, all of the genital organs fifty-eight times. Among these there were two cases in which it could not be positively ascertained that the prostate was involved and the same uncertainty existed in reference to the seminal vesicles in six cases. According to these statistics the course of the disease in men is therefore more in the direction from within outward than from without inward, a fact which Guyon advances as a warning against the too frequent performance of castration. Not infrequently the tubercular affection extends from the epididymis or testicle to the tunica vaginalis.

Simmonds (*Ueber Tuberculose der Scheidenhaut des Hodens*. *Deutsche Zeitschrift f. Chir.* Bd. xviii, p. 157) made a careful examination of eight tubercular testicles obtained from six patients operated upon in the clinic at Kiel, and postmortem specimens obtained from the hospitals at Hamburg, in all twelve testicles. In eight of these specimens tubercles were found in the tunica vaginalis, in one case the testicle was atrophied, while in three specimens the tubercular process was not far advanced. These cases appear to prove the incorrectness of the statement made by Klebs that the tunica vaginalis is never affected, at the same time they call the attention of the surgeon to the necessity of examining the tunica vaginalis carefully and subject it to operative treatment, if the disease has extended to it in cases of tuberculosis of the testicle treated by castration.

*Symptoms and Diagnosis.*—Tuberculosis of the testicle and epididymis is a very insidious disease. It is often overlooked by the patient for a long time and frequently erroneously diagnosed by the physician. In the absence of tuberculosis of other por-

tions of the genital organs and the urinary tract, the disease usually begins in the globus major of the epididymis, much less frequently in the body or opposite pole of the organ, as a hard, almost painless, swelling. During the progress of the disease additional nodules form and very frequently the patient's attention is attracted by a more rapidly increasing swelling, a complicating hydrocele. The absence of any well marked symptoms during the incipiency of the disease is the reason why such cases come so rarely under the care of a surgeon at this time. From the globus major the disease spreads to the body and globus minor and then extends along the vas deferens.

After an elaborate description of the signs and symptoms of scrofula, Sir Astley Cooper (Op. cit. p. 160) gives a very vivid clinical picture of what was then considered as scrofula of the testicle in the following language: "One of the testicles, even in very young children, sometimes becomes enlarged and very hard, but without pain or any other inconvenience, and the disease is accidentally discovered by the parents or servant. In this state of indolent increase it remains for many weeks, months or years, and then, under improvement of the general health, the enlargement subsides and the gland resumes its former state. More frequently it enlarges at the age of puberty, and from that period to twenty years, and not infrequently this disease appears in both testes, marked by the same hardness, and such absence of suffering, that the person does not for a length of time seek any medical aid respecting it. The part is free from pain as well as tenderness. The scrotum is unaffected; its veins are not enlarged; and, but from its bulk, the patient suffers no inconvenience, but even in children, although more frequently at puberty, the inflammation sometimes proceeds to suppuration; this generally occurs within the globus major of the epididymis, but I have known abscesses form in the cauda or small extremity of that organ. The body of the testicle but rarely suppurates, until after the epididymis has ulcerated, when the testis becomes affected and the scrotum puts on a livid hue. Ulceration next ensues, indicating the presence of an abscess, which discharges ill-formed pus and some semen; if after the age, the opening under these circumstances is extremely difficult to heal, continuing for months and even for years before it closes. In some persons one abscess after another forms and discharges, and when one testis has suppurated, if the other has been hard, it is liable to put on the same action, discharges itself and continues equally obstinate, resisting all the means of treatment for a greater length of time. Ultimately the testes diminish, secrete but a small quantity of semen, and they continue to waste until but little of them remains and their function almost entirely ceases." Astley Cooper and his contemporaries had no correct idea of the intrinsic tendencies of tubercular inflammation of the testicle to extend to the remaining organs of the genital tract and the urinary apparatus. The essential clinical features of this disease have been elaborated since their time.

Reclus (Op. cit.) is of the opinion that chronic orchitis and epididymitis are often confounded with tuberculosis. The abundance of interstitial connective tissue produced in the course of these affections leads constantly to progressive atrophy. These conditions are often characterized by a nodular condition of the swelling which resembles so closely tuberculo-

sis. They occur either in the course of an acute, or begin as a chronic process. Usually, however, the swelling is much more marked than in tuberculosis. If the testicle alone is affected it finally is reduced in size to that of a bean behind the normal epididymis. Kocher regards as the most characteristic symptoms of tuberculosis of the testicle and epididymis rapid development of swelling and early softening of the inflammatory product and the absence of acute subjective symptoms. According to this writer the maximum swelling is often reached in eight days, or at least in a few weeks which soon softens and perforates, resulting in the formation of a fistula which may continue for years, the swelling remaining stationary. Kocher's observations in regard to the acuity of the local development do not correspond with the result of my own experience. Such a course is an exceptional one.

Barling (Double Acute Tubercular Disease of the Testis, London *Lancet*, April 9, 1892) describes a case of double galloping tuberculosis of the testicle, an affection to which Duplay called the attention of the profession as early as 1876. The patient was 30 years of age, who five hours after a severe external injury noticed quite a large swelling of one of the testicles. One of the interesting features in this case was the fact that the epididymis was free, the disease being limited to the testicle. In a short time the opposite organ became similarly affected. Examination of the testicles after castration showed in each of them cheesy cavities, a large one in the right and a number of small ones in the left. The immediate vicinity of the cavities was occupied by a dense and greatly increased connective tissue. In one place in a cavity tubercular bacilli were found, but the most patient search did not result in finding giant cells. The whole process was characterized by an infiltration with granulation and epithelioid cells combined with catarrh of the seminal tubules, followed by caseation. I can readily understand that in the event tuberculosis develops in a testicle or epididymis the seat of an injury or antecedent inflammatory disease, that it might in rare cases pursue such an acute course, but in the majority of cases it is noted for its insidiousness and chronicity. The patient's attention is usually first attracted by slight pain or discomfort and tenderness in some part of the gland, generally the epididymis, which on examination is found to be somewhat enlarged, prominent, nodular and indurated. The state of the testicle is often marked by circumscribed effusions of fluid in the tunica vaginalis, the surfaces of this membrane being partially adherent. The disease often remains stationary for months, a year or more. During the course of the disease one of the prominences begins to increase, so as to be observed externally, and to feel more painful and tender; the skin over it becomes adherent, changes to a livid color and ulcerates, when the softened cheesy material is evacuated. The abscess formation is generally followed by a fistula which communicates with the primary tubercular focus. Similar changes may take place in other parts of the testicle, resulting in two or more sinuses leading into the interior of the gland. If all of the tubercular material is eliminated in this manner, the sinuses after a long time may heal, leaving the testicle usually in an atrophied condition. The disease may remain limited to one testicle, or after months or years make its appearance in the opposite organ. As a rule, the vas deferens is early

affected, the infection often extending its entire length in a short time. In primary tuberculosis of both testicles both vasa deferentia may remain intact. The tunica vaginalis is usually implicated in the form of an adhesive periorchitis. As this affection is not attended by any well-marked clinical symptoms, its existence can be surmised by the appearance of hydrocele. The hydrocele, usually of a serous type, may attain a considerable size, but more frequently it is circumscribed. In rare cases the vaginalitis is of a suppurative type, and then makes its appearance under the clinical picture of an acute abscess. Tubercular affections of other organs precede or occur simultaneously with the tubercular orchitis. Next to the vas deferens the disease extends most frequently to the seminal vesicles, next the lateral lobes of the prostate are most frequently implicated. From here the disease is prone to involve the urinary organs, first the bladder, next the ureter, and finally the kidney.

In the differential diagnosis must be considered acute and chronic inflammations of another type and syphilitic affections. In tuberculosis the swelling in the epididymis is usually larger than in other forms of inflammation. Tenderness and pain are conspicuous symptoms in gonorrhoeal epididymitis, absent or slight in tuberculosis. If any doubt exists in the diagnosis between gumma and tuberculosis the patient should be given the benefit of the doubt, and should be subjected for a sufficient length of time to an active antisyphilitic treatment. The tubercular inflammation is clinically characterized by periodic exacerbations. Examination of the remaining genito-urinary organs for tuberculosis, as well as the more distant organs in which this disease is liable to appear, is absolutely necessary and will often clear up a doubtful diagnosis. In tuberculosis the indurated vas deferens is not tender to pressure and is usually nodular, while funiculitis caused by other forms of infection is attended by pain and tenderness.

*Treatment.*—The rational treatment of tuberculosis of the testicle and epididymis must necessarily depend on the location, stage and extent of the disease, and the existence or absence of complications. In miliary tuberculosis involving the organs on both sides, the treatment must be supporting and expectant, as in such cases a speedy fatal termination is inevitable from the primary pulmonary affection or diffuse miliary tuberculosis. In tuberculosis involving other parts of the urogenital organs the treatment must be directed accordingly. Tuberculosis implicating the organs on both sides simultaneously, or in succession, is almost positive proof of the existence of an older tubercular process in some other organ, or the extension of the tubercular process along the genital tract beyond the reach of successful surgical treatment. The cases best adapted for successful local treatment are those in which the disease appears as a chronic affection and is limited to the organs on one side, with limited or no extension along the vas deferens. Tuberculosis of the epididymis leads to impotence if both organs are affected. If the disease is limited to one side, function may remain unimpaired. Castration must therefore be regarded as the normal procedure in cases of uncomplicated, unilateral tubercular epididymitis. This statement becomes more apparent and forcible when we consider that reinfection can always occur if the diseased organ is permitted to remain. As positive contraindications to castration must be considered the following:

1. Extension of the tubercular process to parts not within reach of a radical operation.
2. Tuberculosis of both testicles, as the second organ is usually involved by extension of the infection from one to the other through the vasa deferentia.
3. Tuberculosis of important adjacent or distant organs.

Castration may become necessary as a palliative operation for the relief of symptoms in cases where the disease has resulted in the formation of tubercular abscesses and suppurating sinuses. A great diversity of opinion still prevails among surgeons regarding the value of castration in the treatment of tuberculosis of the testicle and epididymis. The results following this operation appear to have been quite at variance in the hands of different operators.

Terillon (*Essai Critique sur la traitement de la tuberculisation du testicule. Bull. Gén. Thérap.*, p. 140, 1882) favors castration, and advises that the operation should be performed before abscesses have formed, as by removing the source of suppuration the general condition of the patient is improved. He regards pulmonary tuberculosis as an absolute contraindication to castration. Simultaneous tuberculosis of the prostate and seminal vesicles may or may not be regarded in the same light, according to circumstances. Richet is nearly of the same opinion in reference to the indications for castration, only he opposes the operation more decidedly when extension of the disease to other parts of the genital tract has occurred.

Stenger (*Inaugural Dissertation, Berlin, 1889*) gives the result of thirteen cases of castration for tuberculosis of the testicle which occurred in the Royal Clinic at Berlin from 1883 to 1889. Seven of the patients remained free from local recurrence or evidences of infection of any other organ at the time the report was made. In three of the cases tuberculosis of other organs existed at the time the operation was performed, and in the last three cases the final result could not be ascertained. In seven other cases the tubercular product was removed by vigorous use of the sharp spoon, in five with a satisfactory result, and in two pulmonary infiltration existed at the time the operation was performed, which progressed uninfluenced by the operation. From a study of these cases he came to the conclusion that the timely removal of the diseased organ, or a thorough local operation, is instrumental in preventing general infection.

Finkh (*Ueber die Endresultate der Castration bei Hodentuberculose. Beiträge zur Chirurgie, Bd. ii, p. 407*) has ascertained the ultimate results in twenty-nine cases of tuberculosis of the testicle treated in Bruns' clinic at Tübingen by castration. Of these cases the right testicle was affected twelve times, the left eight times, and nine times both testicles were diseased. At the time the report was made in 1886, fourteen were living and free from relapse or tubercular disease of any other organ. Among these were nine in which one testicle was removed and five double castrations. Of those that died, eight succumbed to non-tubercular affections. Of these five were single and three double castrations, the former with a period of immunity varying between three-fourths to twenty-two years, the latter with from five to thirty years. To these must be added a case of double castration in which death occurred twelve days after operation from exhaustion. Six died of tuberculosis, all single castrations, and of these only in one case did the dis-

ease extend to other parts of the genital tract. In one case life was prolonged for four years, and against the six who died of tuberculosis stood thirteen who remained well after five years and more. The infected pelvic portion of the cord furnishes, according to this author, no contraindication to an operation, as in seven cases in which this condition was found the result of the operation proved satisfactory. These results are certainly more favorable than those which are obtained by the average surgeon. In my own cases I have frequently observed relapse in unilateral castration, and in two cases of double castration the disease, after a year or two, attacked the seminal vessels, prostate and bladder, and finally death resulted from tubercular pyelonephritis.

It seems to me that the cases are exceptional in which double castration is justifiable. Castration appears to have yielded satisfactory results in cases in which the disease was unilateral and the testicle was removed before the disease had extended to other parts of the genital organs. The reports of a number of cases in which the disease was unilateral and complicated by tubercular vesiculitis, treated by castration and excision of the seminal vesicles and even a portion of the prostate, resulted favorably. In the removal of a tubercular testicle it should be taken for granted that the vas deferens is infected, and as much of this structure as possible should be excised.

Conservative operations of different kinds have been made for a long time in the treatment of the so-called scrofulous testicle. Malgaigne excised caseous nodules with the bistoury; Delpech, Boyer, Velpeau, Bonnet and Bouisson gave preference to chemical caustics, such as chlorid of zinc, caustic potassa and Vienna paste. Later Verneuil recommended the actual cautery which was replaced later by the Paquelin cautery. The use of the thermo-cautery is strongly recommended by Fergue and Reclus (*Traité de Thérapeutique Chirurgicale* T. ii, p. 912) in cases in which the cheesy deposits are few or single. The same authors are in favor of iodoform-ether injections 10:90 when the affection is more diffuse. A few drops of this solution are injected into each nodule and the little punctures sealed with iodoform collodium. In cases not amenable to conservative treatment they recommend without hesitation castration. I have used for some time parenchymatous injections of iodoform glycerin emulsion during the early stages of tubercular epididymitis with the most satisfactory results. With a small trocar the epididymis is penetrated from end to end and the injection made slowly as the canula is withdrawn. Under moderate pressure from one drachm to a drachm and a half of the emulsion can be injected, thus permeating the affected tissues with the anti-bacillary agent. The injection should be repeated every week or two. If the disease is complicated by hydrocele the fluid should be evacuated and a small quantity of emulsion injected. The pain following this treatment only lasts for a short time. For a few days the swelling increases and tenderness is more marked. The increased tissue proliferation which is excited by the action of the iodoform is a potent element in arresting the extension of the disease and in preventing further degenerative changes in the tubercular tissue.

Terillon (*De l'intervention chirurgicale dans la tuberculose testiculaire. Progrès Méd.*, No. 3, 1886) has given evident and iodoform gauze tamponnade a fair trial in the treatment of tuberculosis of the epi-

didymis advanced to the stage of abscess and fistula formation, but on the whole he gives castration the preference as he believes evidently, cauterization and drainage as a rule yield only temporary beneficial results.

Keyes (*Annual of the Universal Medical Sciences*, 1892, Vol. III, page 3.) removed by means of the curette the whole tubercular epididymis, a section of the spermatic cord being then found to be extensively ulcerated; an inch and a quarter of that was removed. The function of the testicle had been already destroyed by cheesy foci along its course, and the patient knew he was practically castrated before the operation was undertaken, but he was much more pleased with the result than if the testicle had been removed. The wound healed rapidly by first intention, the relief of the patient being complete.

Villeneuve (*Marseille Médicale*, July 30, 1889) prefers thorough cauterization with the Paquelin cautery to castration in the treatment of tuberculosis of the testicle. He cites cases and defends his position by what appears to be plausible reasoning. Kocher uses the sharp spoon, followed by the application of a solution of chlorid of zinc 1:4, or repeated applications of the strong tincture of iodine when the disease has advanced to the formation of abscesses and fistulae.

Lannelongue speaks highly of a solution of a chlorid of zinc as a parenchymatous injection before suppuration has occurred. The injection is made around and not into the tubercular infiltration.

Ozenne (*Gazette des Hôpitaux*, Feb. 23, Aug. 9, 1893) reports success in one case of tubercular epididymitis and favorable progress in a few others, from injections of 10 per cent. solution of chlorid of zinc, after the method of Lannelongue. In the successful case he injected at four sittings in seven different places of the diseased area, 2 drops at each puncture. Moderate, temporary reaction followed. Some months later, one little tubercular nodule remaining, a single injection was given. After the last treatment all active signs of the disease disappeared. From what has been said on the treatment tuberculosis of the testicle it is evident that this subject remains an open chapter. In recent cases of primary tuberculosis parenchymatous injections of iodoform glycerin emulsion or chlorid of zinc deserve a trial. If this treatment does not prove satisfactory after a fair trial, castration should be performed before the disease extends to additional organs. In limited abscess formation the use of the sharp spoon and iodoform gauze tampon may prove efficient, but if the disease resists these measures castration is absolutely indicated. If the disease is bilateral palliative treatment should take the place of a radical operation in the majority of cases. Castration is positively contraindicated when the tubercular affection of the testicle is complicated by tuberculosis of any important internal organ. Simultaneous tuberculosis of the prostate and seminal vesicles does not necessarily contraindicate castration.

**Cascarin as a Substitute for Cascara Sagrada.**—Cascarin is the active principle of the bark of the rhamus purshiana, and is analogous to, if not identical with, the frangulin contained in the bark of the frangula. Schoenlaub recommends it as a substitute for cascara sagrada in habitual constipation, one to four pills at night, each 0.1 gram. It produces a sure and certain effect, while it never gripes.—*Nouveaux Remèdes*, June 8, from *Swiss Woch. f. Chem. and Pharm.*, No. 12.
