
In describing the quartan parasite the writer will use as a clinical illustration a patient who came under his personal observation.

Jan. 15, 1896, there appeared before Prof. H. M. Lyman's medical clinic a case of malaria. Judging the case of more than ordinary interest the writer made special investigations, obtained a full history, made as many blood preparations as possible and through the courtesy of Prof. James B. Herrick obtained a thorough physical examination.

Peter A., age 34 years; born in Germany. Came to America fifteen years ago. Lived in Pittsburg five years. Since then has lived continually in Chicago with the exception of short visits to Jamaica, W. I., and Memphis. Single; locomotive fireman by occupation.

Family history—Father and mother dead. Cause unknown. Brother and sister died from a lingering disease. Personal history—regular in habits of eating and sleeping. Drinks whisky, tea and coffee moderately. Previous illness—when twelve years of age had typhoid fever. Twelve years ago had

yellow (examination of the eye was made by Dr. Hinde). 7. Tongue moist and slightly coated, mucous membrane red. 8. Ears normal. 9. Thorax—heart, relative dullness begins at third rib, apex beat one inch inside nipple line in fifth intercostal space. Pulse, regular, strong, full; 60 beats per minute. Very slight systolic murmur over mitral area and pulmonary area. No accentuation of aortic or pulmonic tones. 10. Abdomen—liver slightly enlarged. Relative dullness begins in right border sternum at fifth rib. Flatness begins in mammary line in fifth interspace. In full inspiration these limits are lowered one and one-half inches. In mammary line there is flatness to costal arch. On deep inspiration sharp edge of liver can be felt. In paracostal line flatness extends two fingers below costal arch. 11. Spleen—readily palpable. Dullness begins at seventh interspace. 12. Legs—on right shin is large pigmented scar said to have been produced by a red hot iron. Three pale parchment-like scars higher up upon same leg. On outer aspect of same leg is a linear non-pigmented scar caused by a scythe. 13. Genitals—a nodule the size of a hazelnut is found in left epididymis. 14. Reflexes—normal, no ankle clonus. 15. Sensation normal. 16. Temperature 98.8° F.

Upon microscopic examination of the blood of this patient a very interesting phenomenon was disclosed. Although in small numbers, quartan parasites were present, associated with many tertian forms. This

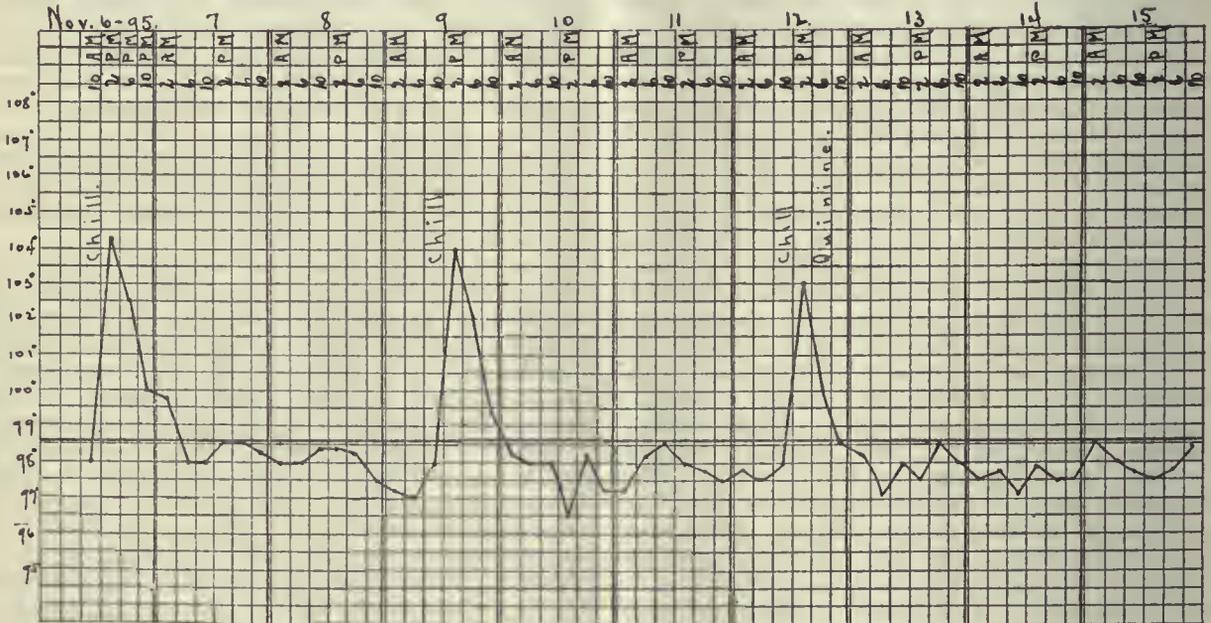

Plate XV.—INTERMITTENT QUARTAN FEVER. TEMPERATURE CHART.

severe cold and spit some blood with great quantity of slimy mucus. Seven years ago while in Memphis had malaria, which easily succumbed to quinin. Two years ago had gonorrhoea with swollen testicle. Fourteen months ago had hard chancre followed by adenopathy. No eruption or falling out of hair. Had rheumatism to slight extent.

Present illness: July 4, 1895, while working on a railroad tunnel in Jamaica, was stricken down with severe chill, which lasted one and one-half hours. This chill was followed by a burning fever, profuse perspiration and great prostration. Patient was confined to the bed for one week and had a chill every fourth day during July and August. During September and October about once a week chill would occur every other day. These chills increased in frequency until when he presented himself before the clinic he was suffering from quotidian paroxysms. During the paroxysms patient complains of frontal headaches, dizziness, ringing in the ears, spots before his eyes and pain in the back and limbs. He is weak and complains of dyspnea on exertion. Has taken some quinin, which has had no effect upon the disease.

Physical examination: Jan. 17, 1895, 4 P.M. 1. Height 6 feet. 2 Weight 165 pounds. 3. Body well nourished, very muscular, large boned and well developed. 4. Mind clear. 5. Skin—face, arms, neck and back tanned; says back is tanned from bathing. 6. Eyes, pupil moderately dilated. react to light; movements and retina normal; sclera slightly

condition illustrates and corroborates the experiments made by Di Mattei, who substituted one type of malaria for another. There is probably little doubt, as this patient was an intelligent man whose word may be relied upon, but that this fever was primarily quartan and that subsequent to the first a second infection was incurred with a group of tertian organisms. The latter parasites upon development, caused the gradual extinction of the quartan forms producing paroxysms peculiar to their type. In the case cited by Di Mattei the extinction of the original type was accomplished in a much shorter time than in this instance. (Plate xv.)

These two types of the parasite, in some cases lying side by side, furnished excellent opportunity for studying their points of difference.

As the tertian organism has been previously described, a description of the quartan will be given by comparing and contrasting the latter with the former.

In the hyalin forms these types can not be differ-

entiated, though the quartan is more refractive and more sluggish in its movements. These appear during and after the paroxysm, as in the tertian. (Plate x, Figs. 1 and 2.)

As the organism grows and pigment develops,

the organism as a whole, is much slower than that of the tertian parasite as shown by the length of time required in changing its shape. (Plate x, Figs. 6 and 7.)

As the parasite continues to grow the conditions of

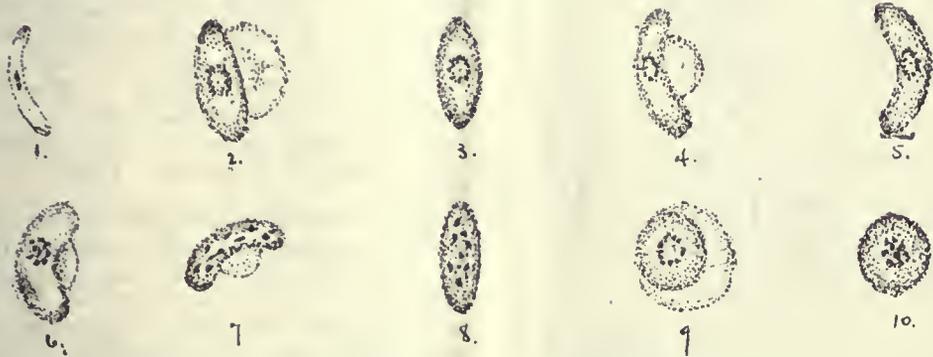

Plate XII. THE PARASITE OF AESTIVO-AUTUMNAL FEVER; LATER CYCLE.—1, 5, Free Crescents; 2, Ovoid Body in Corpuscle; 3, 8, Free Ovoid Bodies; 4, 6, 7, Crescents in Red Corpuscles; 9, Spherical Body in Red Corpuscle; 10, Free Spherical Body.

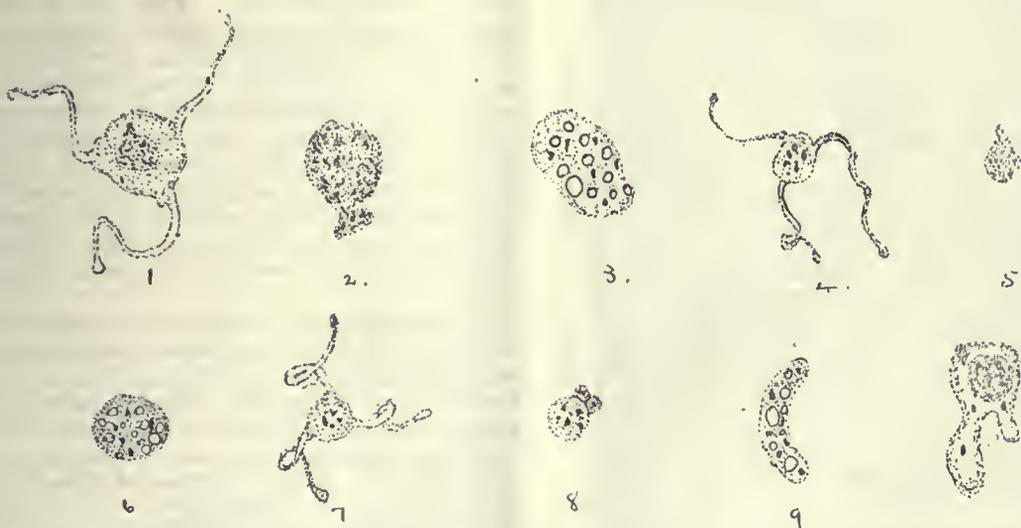

Plate XIII. DEGENERATE FOAMS (?)—1, Flagellate Body, Tertian; 2, Segmenting Body, Tertian; 3, Vacuolization, Tertian; 4, Flagellate Body, Quartan; 5, Segmenting Body, Quartan; 6, Vacuolization, Quartan; 7, Flagellate Body, Aestivo-Autumnal; 8, Segmenting Body, Aestivo-Autumnal; 9, Vacuolization in Crescent; 10, Phagocyte. Magnification—Zeiss. Obj. 1-12 oil, Oc. 5.

marked differences are seen. In the quartan the pigment granules are exceedingly large and few in number. They are of a brown, almost black, color and possessed of a slow motion. In fact, the movement of

the enclosing corpuscle differs greatly from that seen in the case of the tertian organism. Instead of becoming swollen the corpuscle either remains of a normal size or slightly shrinks and instead of becoming

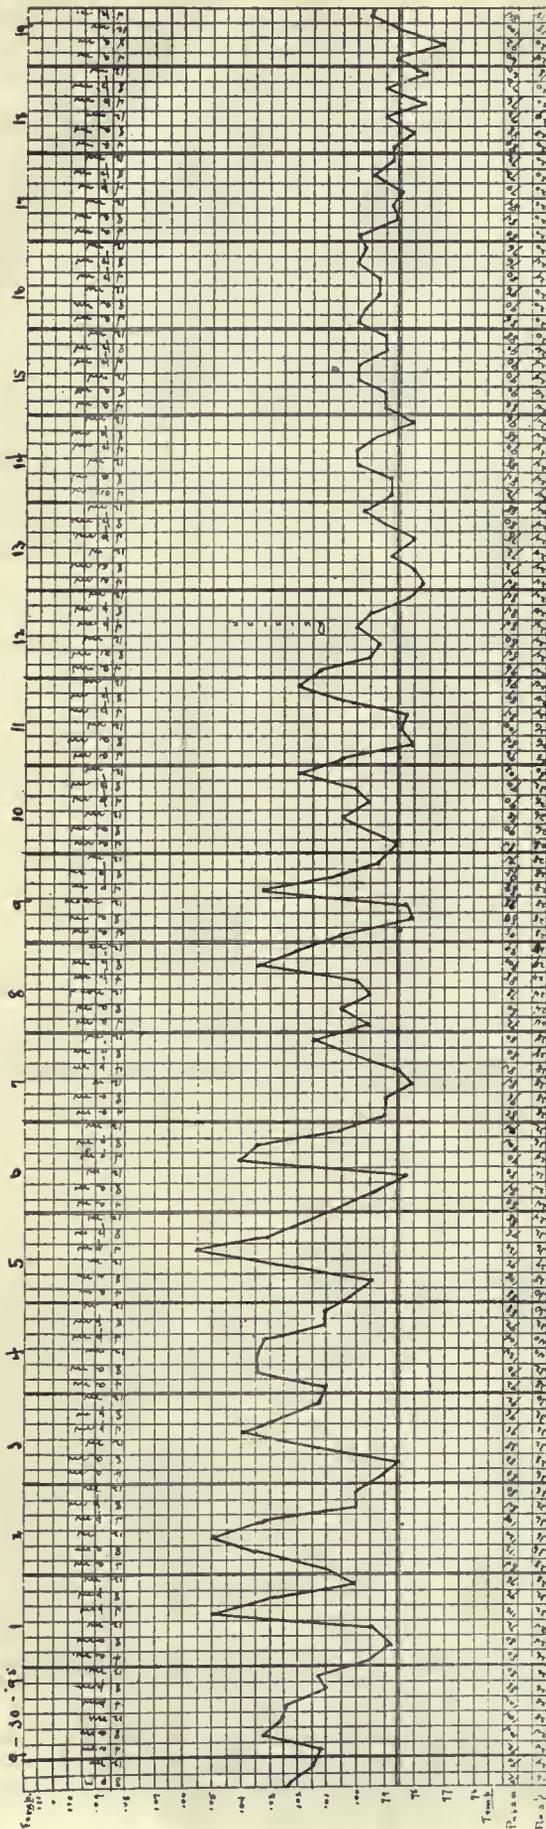

Plate XVII. REMITTENT ESTIVO-AUTUMNAL FEVER. TEMPERATURE CHART.—Chas. F., Cook County Hospital, Ward 4. See also Plate XII.

decolorized takes on, in some instances, a deeper color or a greenish yellow or brassy hue. The difference in degree of refractive power, is more noticeable as the organism increases in size.

The quartan parasite reaches its full development in about sixty-four hours or eight hours before segmentation. It is then round, slightly smaller than the corpuscle, and contains a few granules of pigment, arranged in the periphery of the organism. There is but a thin layer of the body of the corpuscle apparent, which may be overlooked on a casual examination. (Plate x, Fig. 8.)

A short time after the organism has attained the adult form, the pigment becomes motionless and signs of segmentation appear. The manner of segmentation may be similar to that described in the case of the tertian organism. In the segmentation of the quartan organism the rosette forms of Golgi are more often observed. The pigment granules form in a block-like mass in the center of the organism while radiating fibrils of differentiated protoplasm run from the center to the periphery, dividing the parasite into from eight to twelve segments. The segments acquire nuclei and constitute the spores. (Plate x, Figs. 8-12.)

In the case in question many extra-corpuscular forms were present. These were probably degenerate bodies. They were granular, at times crystallin, exceedingly irregular in shape, and contained blocks of pigment, and were often filled with vacuoles.

The flagellate forms found in quartan fever show similar characteristics as those in the tertian and estivo-autumnal types with the exception of greater sluggishness of movement. (Plate xii. Degenerate forms.)

Fragmentation was observed in this case. A pseudopodium was observed to be thrust out from the parasite, filled with slowly rotating pigment. Gradually this portion of the organism was cut away when it assumed a spherical form, the pigment continuing its motion and seeking the periphery. (Plate xii.)

In quartan ague the length of the life cycle is seventy-two hours, and the paroxysms generally appear every fourth day. This rule is not without exceptions as the paroxysms may be caused by different groups of parasites having the same abode, but segmenting at different times. When two groups segment on successive days there is produced paroxysms for two successive days with one day of apyrexia. This is termed double quartan fever. When three groups segment on successive days, a quotidian invasion results which is called "triple" quartan fever. This may be easily mistaken for the ordinary quotidian type when viewed purely from a clinical standpoint.

In his study of the organism of estivo-autumnal fever the writer has been fortunate in procuring specimens from a patient suffering from this disease in Cook County Hospital. The following history was obtained from the records of the hospital:

Charlie F., aged 15 years, born in Chicago, where he has lived all his life. School boy, admitted Sept. 30, 1895. Family history negative. Personal history—does not drink, smokes many cigarettes. Previous history—malaria, no venereal disease. Present history—has been sick three days. Had a chill, headache and diarrhea with anorexia and pain in abdomen.

Physical examination—1. Body—well developed. 2. Skin—face flushed. 3. Eyes and ears—normal. 4. Tongue—dry and coated. 5. Thorax—lungs, resonance imperfect over right lung posteriorly; no rales. Heart—rapid, second beat accentuated, no murmurs. 6. Abdomen—walls rigid, very slight tympany; pain in left iliac region and both hypochondriacal zones; is

covered with brawny, macular eruption; no rose spots. Spleen—not palpable. Liver—normal. 6. Limbs negative. 7. Reflexes—normal. 8. Glands—axillary enlarged. 9. Genitalia—negative. 10. Urine—negative.

Estivo-autumnal ague is exceedingly rare in this portion of the United States, there having been but a few cases in Cook County Hospital in many years. (Plate xvii.)

In this case under observation but few of the hyalin forms could be demonstrated. These forms (Plate xi, Figs. 1-5), however, are more refractive and smaller than those found in the tertiary and quartan forms. They possess ameboid movements, and assume at times a peculiar characteristic ring-like shape. This appearance is probably caused by the thinning out of the central portion of the organism, the corpuscle showing through. Then again, the parasites appear to have contracted into spheres. The shading disappears from the center, appearing at the periphery. In other respects they closely resemble the tertian and quartan types, except that they are not as active as the tertian, but more so than the quartan.

As the organisms increase in size (Plate xi, Figs. 6-9) minute granules of pigment appear in the peri-

sym, and have denominated them "pre-segmenting forms."

Later in the course of the disease larger, spherical, ovoid and crescentic bodies appear in the red corpuscles and free in the blood. These forms were especially abundant in this specimen. They were as large or even larger than red corpuscles, the spherical forms completely filling the corpuscle, while the ovoid and crescentic expanded one side of the corpuscle, the remnant projecting as a small segment of a circle from the concavity of the organisms (Plate xii, Figs. 1-10 A). In many cases ovoid and crescentic forms are identical. This may be proven by rolling the corpuscles upon the slide, when the ovoid bodies may be seen to assume a crescentic form. In the colored specimens the corpuscle stained faintly with eosin, the body of the parasite faintly with methylene blue, while the periphery showed a deeper color, thus giving evidence of a double contour. In many instances the periphery of the corpuscle was entirely decolorized, while that portion next the organism still retained some coloring matter. The pigment was generally collected in the form of a wreath in the center of the organism, encircling a light clear space and sur-

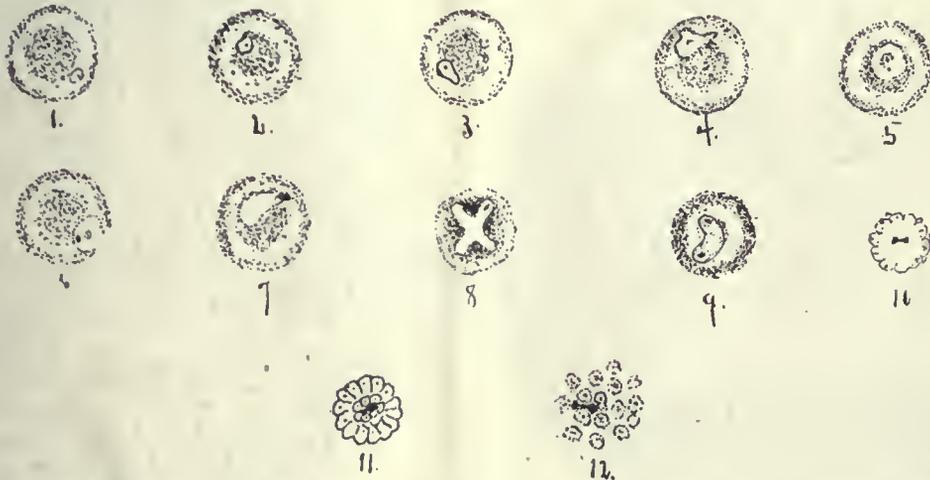

Plate XI. THE PARASITE OF ESTIVO-AUTUMNAL FEVER, FIRST CYCLE.—1, 2, 3, 4, Hyalin Bodies; 5, 6, Ring-like and Spherical Bodies; 7, 8, 9, Adult Pigmented Bodies; 10, 11, Segmenting Bodies; 12, Spores and Free Pigment. Magnification—Zeiss Obj. 1-12 oil, Oc. 5.

phery. These granules are few in number and sluggish in movement. In some instances pigment does not appear during the course of the development of the organism. This type is characterized by its small size, even in the adult stage. In this stage it rarely is more than one-half the size of the containing red corpuscle, which remains normal in size and often changes to the brassy hue observed in quartan fever. The corpuscle eventually becomes crenated and ruptures, setting free the organism. Segmentation may consist in an irregular breaking up of the organism into from ten to twenty segments, similar to that described as taking place in the tertian organism, or the pigment may collect in the center, the process occurring after the formation of the marguerite forms of Golgi. Segmentation takes place most freely in the internal organs, but it may be observed in the circulating blood. (Plate xi, Figs. 10-12.)

The writer was also able to observe in this specimen larger spherical forms with pigment granules collected in a block-like mass in the center. The bodies of these organisms stained faintly with methylene blue. Thayer and Hewetson state that they have often found these organisms from two to four hours before parox-

ysms, and have denominated them "pre-segmenting forms." Later in the course of the disease larger, spherical, ovoid and crescentic bodies appear in the red corpuscles and free in the blood. These forms were especially abundant in this specimen. They were as large or even larger than red corpuscles, the spherical forms completely filling the corpuscle, while the ovoid and crescentic expanded one side of the corpuscle, the remnant projecting as a small segment of a circle from the concavity of the organisms (Plate xii, Figs. 1-10 A). In many cases ovoid and crescentic forms are identical. This may be proven by rolling the corpuscles upon the slide, when the ovoid bodies may be seen to assume a crescentic form. In the colored specimens the corpuscle stained faintly with eosin, the body of the parasite faintly with methylene blue, while the periphery showed a deeper color, thus giving evidence of a double contour. In many instances the periphery of the corpuscle was entirely decolorized, while that portion next the organism still retained some coloring matter. The pigment was generally collected in the form of a wreath in the center of the organism, encircling a light clear space and sur-

rounded by a yellow or golden halo. The granules were very coarse and at times rod-like. These forms have decided ameboid movements. They have been seen to send out pseudopodia which are often cut off and separated from the organism. (Plate xii.)

Owing to the fact that the ordinary forms of malaria are not fatal, postmortem changes in these cases are rarely reported. In fact, the pathologic findings in the mild forms consist in the described blood changes, and an enlargement of the spleen which, in most cases, is plainly palpable. In the pernicious and continuous forms, there is higher mortality, and consequently a greater knowledge as to pathology. Constant changes are present in many internal organs. On gross examination the spleen is generally increased in weight and size. It may in pernicious cases be reduced in size and weight. This latter condition is explained by the presence of interstitial changes. The capsule is either thick and opaque, or thin and presenting evidence of hemorrhage. The organ is soft in consistency and of a dark brown or reddish black color. It is with difficulty that the Malpighian bodies can be distinguished. (Plates i and ii.)

On microscopic examination, the blood vessels of the spleen appear to be distended, with at times evidence of rupture into the pulp. Thrombi are present, composed of fibrin, red corpuscles, parasites, phagocytes and leucocytes of all types, ranging from the lymphocyte to the giant cell with its budding nuclei. The endothelial cells of the vessels are phagocytic in function, containing all foreign matter found in the macrophages. These macrophages are most abundant in the deeply pigmented pulp and contain degenerated red corpuscles, free pigment, parasites, fragments of hemosiderin, leucocytes and other phagocytes. Thus the peculiar appearance of cell within cell may be observed, and the enclosed cell may, in fact, contain a third.

Macrophages may contain as many as fifty red corpuscles. The pulp cells present a hyalin appearance. They are also phagocytic in function, containing leucocytes, parasites and pigment. In these the pigment granules often assume a very peculiar arrangement. They form dotted lines which, interweaving back and forth in the cell, completely hide the nucleus and at

On microscopic examination under low powers often no pathologic changes are apparent. However, marked dilatation of the inter- and intra-lobular veins and capillaries leading thereto is present. Pigment is generally present. It is commonly found in the periphery of the lobules. It may surround the hepatic vein and swollen capillaries, or be evenly distributed throughout the entire lobule. (Plate vii.)

On examination with higher powers the pigmentation is observed to be most abundant in the hepatic cells and vessels. These cells generally appear granular and swollen. In some areas they are atrophied. When this condition exists it may be accounted for by the presence of dilated capillaries causing pressure. The liver capillaries are engorged and are filled with leucocytes, parasites and pigment granules. The leucocytes contain organisms in all stages. Macrophages are very numerous, varying in size from the large mononuclear leucocytes to cells five times as large. They possess either one or more oval, vesicular nuclei, which stain feebly with nuclear stains. The nucleus is placed eccentrically, as a rule, and although usu-

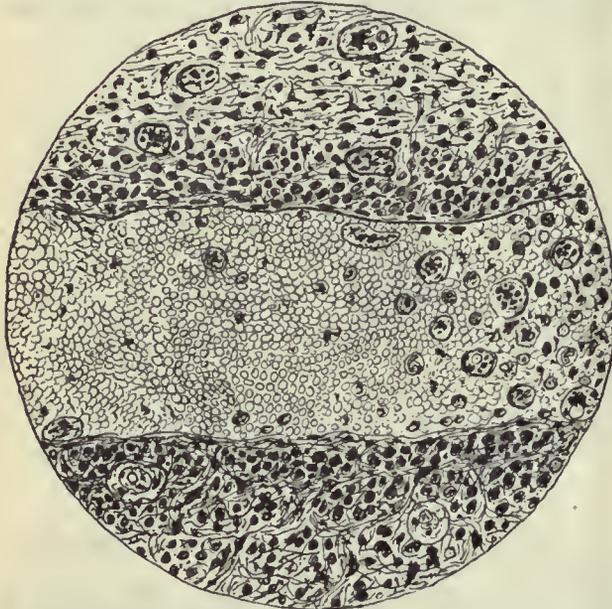

Plate I. SPLEEN.—Figure shows blood vessel containing red and white corpuscles, macrophages, pigment granules and leucocytes. Perivascular tissue shows increase of connective tissue and infiltration with round cells and pigment granules. Zeiss Obj. DD, Oc. 3. Tube length 160 mm.

times even pierce the cell wall. In these mitosis and nuclear pigmentation is often observed. The Malpighian bodies are swollen, and show evidence of lymphoid proliferation. They are, as a rule, comparatively free from pigmentation, but when this does occur the pigment is found in the large cells, surrounding the arterioles. The cells of the pulp cord are often the seat of necrosis, showing evidence of thrombosis. In these necrotic areas, degenerate, vacuolate and fragmenting cells are present.

On gross examination, the liver may be found to be either larger or smaller than normal. It is generally of a slate-gray color and normal as to consistency and weight. The surface is smooth, and the capsule thickened and opaque or thin and translucent, showing beautifully the lymphatic network. On section the color is a bronze or brown. The outlines of the lobules are, as a rule, indistinct, with deep pigmentation about the portal vessels. The small capillaries and bile ducts are often distended.

Plate II. SPLEEN—Figure shows macrophages, leucocytes, parasites, pigment granules and increase of connective tissue. Zeiss Obj. 1-12 oil, Oc. 8. Tube length 160 mm.

ally oval in form, may assume any shape. This is especially true when foreign matter is present in the cell. In some instances the nucleus is entirely absent. The macrophages may contain all of the substances found in the blood stream, and appear more active and capacious than those found in the spleen. The red corpuscles may be normal or degenerate in appearance, and contain simple pigment or the parasite intact. The degenerate forms present the peculiar "globulare rossi attonati" coloration of Golgi, but do not, as a rule, give the reaction for iron. When degeneration has not gone too far, the blue color may be produced with ferrocyanid. Leucocytes found in the macrophages present a degenerate appearance. They are glassy and swollen and show signs of fragmentation and vacuolation, and take but faintly the nuclear stains. (Plate viii.)

The endothelial cells lining the capillaries here, as in the spleen, show marked phagocytic powers. Under the microscope they appear greatly swollen; in fact, at times entirely occluding the lumen of the vessel.

The cells of Kupfer, placed between the capillaries and the hepatic cells, manifest great phagocytic powers, containing great quantities of pigment and presenting a glassy, swollen appearance.

The spaces surrounding the capillaries show marked round cell infiltration.

The parasite, wherever found in the liver after death, appears somewhat shrunken. The arrangement of the pigment is beautifully shown in specimens hardened in alcohol and stained in hematoxylin and eosin.

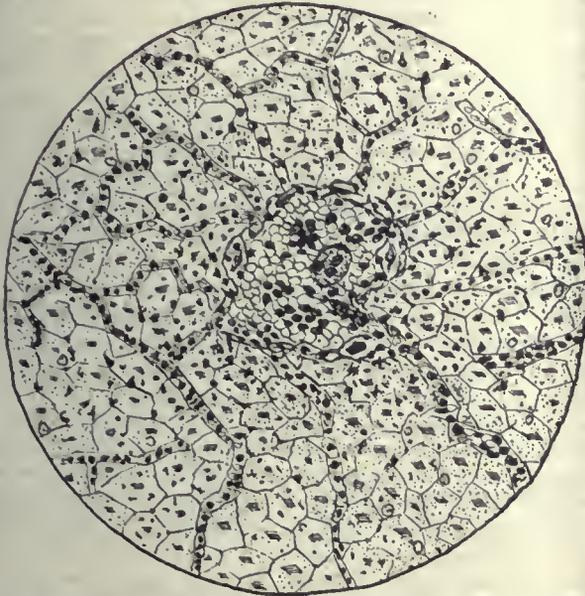

Plate VII. LIVER.—Figure shows dilatation of hepatic vein, which contains red and white corpuscles and macrophages. Parasites are seen in and between hepatic cells and in capillaries, where are also many pigment granules. Capillaries are distended and contain many leucocytes. Zeiss Obj. DD, Oc. 3. Tube length 160 mm.

Necrotic areas are common, and are associated with increase of interstitial tissue and proliferation of bile ducts. These changes may be the result of the necrosis, the presence of segmenting parasites or degenerating corpuscles, all of which produce toxic or irritating products.

(To be continued.)

## PRACTICAL NOTES.

**Sterilization of Syringes.**—Hofmeister has found that leather, like catgut, can be effectively sterilized without the slightest injury, by soaking it in a 2 to 4 per cent. solution of formalin and then boiling it. Syringes that screw together instead of being glued or cemented, are better adapted to this method. The water in which they are placed to boil must not be hot enough to crack the glass.—*Cbl. f. Chir.*, July 4.

**Experience with Salicylic Medication through the Skin.**—Combe reports nine cases of subacute articular rheumatism, temperature 38 to 38.5 degrees C., successfully treated with salicylic medication through the skin, as described in the *JOURNAL*, April 25, page 847. The pains were relieved at once; the fever subsided after the first day, and no cardiac complications appeared.—*Bulletin Médical*, July 1.

**Nephrectomy with Clamp Forceps Instead of Ligatures.**—Bobroff of Moscow recommends compressing the hilum with clamp forceps, instead of ligating it, in extra-peritoneal nephrectomy, which materially shortens the operation. They must be curved and grooved and left twenty-four hours, no longer. The *Cbl. f. Chir.* of June 27, describes the cases and the numerous

experiments on animals from which Bobroff and Fedoroff formulated these conclusions.

**Intravenous Injections of Water and Strong Salt Solutions.**—Bosc and Vedel announce that distilled water is fatal in intravenous injections, either in large doses or small, while ordinary water has no such effect unless over 120 c.c. per kilogram (dog) and 80 c.c. (rabbit) is administered. Instead of diminishing the number of mictions, like distilled water, it increases them and without hematuria. It also raises the temperature from a tenth to one degree above normal. Experiments with 7 per cent. solutions of salt introduced into the vein produced, in large doses, an intoxication like that from strychnin or chloral, with hemorrhages from all the parenchymas and intestines, especially from the meninges.—*Semaine Médicale*, June 24.

**Cause of Suppuration with Catgut.**—A new theory is advanced to explain the suppuration that sometimes follows the use of apparently sterilized catgut; that it is a chemic instead of a bacteriologic process. The chemic substance that causes it is probably due to decomposition, and therefore only fresh catgut should be prepared in the factory and demanded by purchasers, and further search for efficient antiseptics for this purpose abandoned, as well-made ordinary sublimate catgut has been proved beyond question to be absolutely sterile—*Cbl. f. Chir.* June 27.

**Skiagraphy of the Emperor.**—It is reported that the left arm of the German Emperor has been "skiagraphed" by the Roentgen rays. The experiment revealed the nature of the malformation, and the result has been submitted to eminent surgeons who believe, it is stated, that a simple operation may give partial, if not complete, use of the hand and arm.

**Physiologic Albuminuria.**—Serum albumin may appear in urine without any apparent structural change of the renal tissue. It occurs in healthy persons when there is an excess of blood plasma and after too free use of albuminous food. It is produced by conditions altering the blood pressure in the renal vessels; as after taking a cold bath or drinking copiously of cold water. The withdrawal of salt from the food will produce albuminuria, which will disappear when the salt is again given. Proteid metabolism depends on the amount of proteids ingested, for the greater portion becomes changed into circulating albumin. When large quantities of proteid matter have been ingested, what is not appropriated to the sustenance of the system becomes waste material and is thrown off through the excretory channels. It would seem then that albuminuria does not represent a pathologic condition except when it is associated with other and more reliable symptoms.—Dr. L. P. Walbridge in *Med. Mirror*, June.

**Effects of Complete Hysterectomy on the Vagina.**—Dr. S. C. Gordon says: One of the objections urged to complete hysterectomy is that it has a tendency to shorten and deform the vagina and that it also destroys the arch by removing the cervix which acts as a keystone. By the technique which he employs in hysterectomy, the broad ligaments are constantly drawn up (as soon as cut) by the over and over continuous suture. When the operation is completed by this method, the vagina is elevated above the normal position and closed by the same suture continued from the broad ligament. By this simple operation the vagina is actually lengthened by so much as it is drawn up by the suture. That this condition really obtains he has demonstrated by examinations immediately after the operation. During the past two years he has examined all cases possible that he had previously operated on and found no case of shortening or other deformity; but in two or three cases where the cervix was not removed he found a marked atrophy of the vagina. So far as he has been able to learn from others, their observations agree with his. He believes that the objection is one of theory rather than of actual demonstration.—*Jour. Med. and Science*, July.

**Lannelongue's New Treatment of Inguinal Hernia.**—Lannelongue presented four boys at the Académie de Médecine recently whom he has been treating with injections of a few drops of a one-tenth solution of chlorid of zinc for eighteen days. The scrotum and inguinal canal are swollen and hard, forming a natural truss to retain the hernia. Even when the boys cough there is no shock in the region. The probabilities are that the vas deferens will remain intact, which time alone will show. The ultimate results of this treatment are awaited with interest.

**Formal in Urinary Therapeutics.**—The *British Medical Journal* on the above subject quotes Lamarque (Assoc. Franc. pour l'Avancement des Sciences) who states that he has used formal in 1 per cent. solution for washing out the bladder and urethra, and in 5 per cent. solution for instillation in these localities. In acute gonorrhœa and in gonorrhœal cystitis the results have not been very encouraging; in the chronic gonorrhœa they have been better. It is particularly in cases of tuberculous cystitis that the treatment has been successful. The only disadvantage is the pain caused by the drug; this, however, though intense at first, quickly ceases. Daily washings with formal solutions have been effectual in stopping hematuria, relieving pain, and lessening frequency of micturition in cases where every other treatment had failed.

**Operation for Eversion of the Lower Eyelid.**—Dr. W. N. Thompson describes an operation for eversion, caused by a cicatrix resulting from removal of a tumor from the lid. "I made an incision a little longer than the eversion to be corrected and parallel to the eye just above the cicatrix, and dissected up the integument on either side of the incision, making a dissection much farther under the edges near its ends than at the center, so as to get full benefit of the sliding and elastic properties of the integument near the extremities of the incision. The ends of the incision were then brought together, and its edges held in this new position by sutures, thus changing the original transverse incision to a vertical one, and the distance between the cicatrix and margin of the lid being increased to the length of that of the incision, eversion was corrected and the lid in its proper position."—*Ind. Med. Jour.*, July.

**Urobilin and Indican in the Urine.**—Urobilin exists in normal urine in small amounts; in acute fevers it is increased four or five times. Typhoid and septic fevers, where there is rapid destruction of blood corpuscles, increase the amount. It is also increased in cerebral hemorrhages, hemorrhagic infarction, retro-uterine hematocœle and extra-uterine pregnancy. It is diminished in convalescence from acute diseases, hysteria and nervous diseases. Indican is found in excess in exclusive meat diet, Addison's disease, cholera, carcinoma of the liver, chronic phthisis, central nervous diseases, typhoid fever, dysentery and obstruction of the small intestines.—Dr. M. D. Hoge, Jr., in *Va. Med. Semi-Monthly*, July.

**Increasing Uses of Massage.**—Our Russian exchanges are advocating the application of massage to the most varied troubles, from chronic heart disease to the ambulatory treatment of diseases of the female genital organs, with which Rubinstein has relieved or cured ninety cases of metritis, oöphoritis and abnormal positions of the uterus. (*Eshenedelnik*, Nos. 44-46.) Dr. Hoadley of Chicago recommends the use of the cannon ball for self-massage in cases of habitual constipation, as suggested by Sahli in 1887. Before rising in the morning and at night, the iron ball (covered with several layers of woolen cloth, the first glued to the ball) is slowly rolled around on the abdomen, following the course of the colon. In many cases this treatment has effected a permanent cure. Any foundry will cast an iron ball for a few cents if a croquet ball or something of the kind is supplied for a pattern, although an improvement upon this is described in the *Deutsch. Med. Wochenschrift* for June 25, the addition of a wooden handle to the ball, which revolves

freely in the stirrup fitted to the handle. According to the inventor, Oetker of Oeynhausien, this renders it much easier to manipulate.

**Codein and Swabbing the Larynx as Adjuvants to O'Dwyer's Tube in Membranous Croup.**—Variot has found the tube effective in conquering the glottic spasm in certain kinds of diphtheritic laryngitis, removing the tube in three or four minutes, and assisting the nervous system to control the tendency to spasm by administering syrup of codein. Bayeux has also found swabbing or scraping the larynx with the tube an effective method of treating very membranous diphtheria. As the tube is introduced the membranes dislodged fill it, and the child chokes, when the tube should be withdrawn. The efforts to cough will then expel the loosened membrane. Some children have recovered after one operation; others have required another to complete the expulsion of the membrane or to conquer the glottic spasm. Out of the twenty-three children treated, nine recovered, three required tracheotomy, and in nine the tube had to be left permanently. There were eight deaths, a mortality of 34.78 per cent. in the twenty-three cases.—*Semaine Méd.*, July 8.

**Treatment of Cholera Infantum with Subcutaneous Injections of Serum.**—According to Reinach, the treatment of cholera infantum should aim to keep the blood from growing thick and rest the intestines, while supplying strength to the organism. He claims that all these conditions are combined in injections of serum from a horse, as he administered it to fifteen infants, in a dose of ten to twenty cubic centimeters. The effect was remarkable: The collapse passed away, the cyanosis was replaced by the natural color of the skin, the extremities grew warm again, the pulse became stronger, and the temperature rose. This improvement took place in six to seven hours and the child was cured; although in some cases a second dose was necessary. No other medication was given except rice water. The serum produces a fluidity of the blood, while it is at the same time food for the child, as Reinach states that twenty cubic centimeters of the serum contain one gram and a half of assimilable albuminoid substances, equivalent to fifty grams of cow's milk, or 150 grams of mother's milk.—*Rev. Int. de M. et de C.*, June 25 from *Munch. Med. Woch.*

**Rheumatic Iritis.**—"Rheumatic iritis," says Dr. Crittenden Joyes, "is more serous than plastic, hence we are not so apt to have adhesions as in other forms. The objective symptoms are, pink circum-corneal injection, hazy, aqueous and change in color of iris. The subjective symptoms are impairment of vision, photophobia and pain in the orbital and malar regions, forehead and top of head. The pupil is frequently dilated, but is sluggish in action. The pain is sometimes greater than in other forms of iritis. The prognosis as to vision is better than in other forms; but the duration is apt to be long. Treatment consists of hot water and atropin, together with salol, salicylates, iodid of potash or some other remedy for the rheumatic diathesis."—*American Practitioner and News*, July.

**Instrument for Removing Anastomotic Buttons Through the Mouth.**—Hagopoff has invented a flexible sound terminating in a bulb, through which is passed a double silver thread ending in a loop at the end of the bulb. It is for the purpose of drawing out through the mouth a thread fastened to the button in gastro-enterostomy. Later when the button is liberated, the sound is reintroduced through the mouth and guided by the thread can be pushed down to the button, and then withdrawn with the thread and the button, as the bulb opens a pathway for the latter. Chaput queries whether the introduction of the sound during the operation will not produce vomiting which might force alimentary matters into the peritoneum. Hagopoff has also invented an anastomotic button similar to Chaput's button, but as yet it has only been tested on cadavers.—*Semaine Médicale*, July 8.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

## SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance . . . . . \$5.00  
Single Copies . . . . . 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

## MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

## INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, AUGUST 1, 1896.

## CLIMATE AND HEALTH.

Since the earliest ages it has been a favorite theory that diseases come upon mankind through the medium of the atmosphere; and even at the present day there are to be found some, who assume with SYDENHAM an epidemic constitution of the atmosphere to account for the occurrence of certain wide spread diseases. An enormous amount of work has been done by doctors and others in observing and recording the weather, but very little has been accomplished in the way of collating these observations. It is so easy to observe and place on record, but it requires much time and labor and qualities of a different and higher order to compare and generalize. SAMUEL FERRY of the United States Army collated in 1840 the meteorologic observations made during the preceding twenty years by the medical officers at the various military posts of this country, but since then not much has been added to our knowledge of medical climatology. Accuracy has indeed been given to climatologic data, but their application to concurrent conditions of morbidity has been made only in special instances. Of late years the bacteriologist has stepped in and relieved the medical climatologist of many of its subjects of study. Many of the causative agencies of epidemic diseases have been trailed to their haunts, and although some, such as typhus, yellow and scarlet fevers, smallpox and measles, continue in their

old time obscurity the indications are that atmospheric or climatic conditions exercise only an indirect influence, powerful in some instances as in the disappearance of yellow fever on the advent of frost, but at the same time only indirect.

Although the tendency of modern research has thus been to restrict the field of climatologic study the factors of climate continue to have an importance as factors of disease. The influence of heat, cold, moisture and air movement in determining the occurrence of disease is so great that the diseases thus occasioned are known as climatic diseases. A knowledge of these is of the highest importance; and much good was anticipated when the Weather Bureau of the Agricultural Department announced that it had made arrangements for tabulating along with its meteorologic observations the morbidity and mortality statistics obtained from health officers and registrars. *Climate and Health*, the monthly journal issued by the Department was intended to be a repertory of statistic and other information appertaining to climate and its relations to hygiene, from which persons interested in the subject of the influence of the climate and weather upon health might obtain data for making comparisons to determine the relative therapeutic and hygienic merits of different climates. Thus said its prospectus; and from the very energy of the Bureau, which led it to step outside of questions of mere wind and weather, we hoped that a section of the work, which in a country like the United States of America should be done by a special Department, would be begun by the Weather Bureau and continued by it until Congress should breathe the breath of life into a Department of Public Health with ample powers to carry on its proper functions. *Climate and Health* was begun and carried out successfully. The work met with the earnest coöperation of medical men and health officers. But its last issue has been made (No. 3 of Vol. II for the four weeks ended March 28, 1896, issued June 22, 1896). A doubt as to whether its publication was authorized by the act making appropriation for the Department of Agriculture for the fiscal year ending June 30, 1897 was the cause of its discontinuance. Credit must be given to Professors HARRINGTON and MOORE, who originated and carried out the idea and to DR. W. F. R. PHILLIPS, who has so ably edited the successive issues of the publication. They recognized the needs of the situation and their own possible ability to aid in sanitary work. But this country in matters relating to the health of the people should be independent of volunteer aid of this or any kind. It should have all such work done by men specially assigned to the duty under the direction of a Department of Public Health.

Let us have a Department of Public Health!

## THE POISONS OF ALCOHOLIC DRINKS.

It is a very commonly accepted opinion that the injurious effects from the use of alcoholic beverages are due to the adulterations. Many temperance advocates make this a strong reason for not using spirits.

Recently a prominent physician condemned with great severity the use of spirits to which various poisons had been added. He enumerated several of these poisons and seemed positive that here was a source of danger overlooked before. Dealers in spirits have found this an excellent theory from which to prove the purity of their products and the risk of buying others from a rival dealer. A number of enthusiastic reformers have made exhausting chemical analyses to discover these dangerous adulterants, but without any results. One man spent two thousand dollars in procuring samples and analyzing them in New York City, but failed to find anything more than water and some cheap coloring matters. The Massachusetts Health Board examined this theory years ago and gave it up, contenting themselves with the examination of bitters and proprietary drugs and the amount of spirits which they contained.

Notwithstanding the failure to find any of the so-called adulterants, the idea has been kept alive and repeated, as if it was a fixed fact. Recently the profession has been treated with circulars, containing certificates of a chemist who writes M.D. after his name, in which he announces that from a most exhaustive search he has been unable to find any poisons in a certain brand of spirits. Then he volunteers that this was unusual and rarely occurs in the most reputable forms of spirits. A few weeks ago this subject came up before the Royal Commission on Licensing Laws in session in London. This government commission composed of eminent statesmen, physicians and business men, have been taking testimony on all phases of the drink question, with reference to license, from which they will report to parliament the changes advisable and necessary in new laws. DR. BANNISTER, the deputy principal of the government laboratory, was called on to give testimony concerning the causes of drunkenness affirmed to be due to the adulterations of spirits. He stated very positively that in the examination of thousands of samples of spirits, the only adulteration was water. That adulteration of spirits by any other substance was practically unknown. Also that age rendered spirits more harmless was a delusion. The supposed maturing of spirits by which the fusel oil was driven off was untrue. He asserted that there was no difference in the physiologic effects of spirits made ten years ago and to-day. Certain alcohols were the same irrespective of age; also it was a mere question of quantity, not of quality. The alcohols of commerce used in beverages, were nearly all the same and had

the same physiologic action. One of the commission was a distiller, and a rigid examination followed, concerning beer and various mixed beverages, which brought out the fact that alcohol was the only poisonous substance in any of these mixtures. Other very curious facts were stated relating to beverages said to be free from alcohol and contain nutrient and medicinal properties which in nearly all cases were fortified with spirits concealed in some form. Physicians who discuss the alcoholic problem and believe in danger from adulterations, will have to abandon this delusion or make some original analysis to prove their statements. Manufacturers and dealers who claim prominence and purity, must do so by showing a small per cent. of water.

Evidently there are many truths to learn in this field.

## SANITARY AND INSANITARY PLUMBING.

The *Lancet* (London, Eng.) has just published, July 4, 1896, the results of an elaborate piece of work conducted under its auspices, which will do much to disseminate among laymen as well as among the medical profession a knowledge of the system of pipes usually found in English dwellings for the inflow and distribution of water and its outflow contaminated with all the wastes of the household. Its enterprising management instituted a Commission, which investigated the faulty and dangerous conditions that are most commonly found in city houses and suburban cottages. In its report the Commission has grouped these conditions in a description of three houses, two four-story city dwellings and one suburban villa, with a ground plan of each floor, illustrations of many of the defects and a special discussion in each instance not only of the defect but of the remedial measures recommended. Although faults in plumbing were found to be exceedingly common in city houses, it is not to be supposed that all those represented in either of the two houses given in illustration were discovered in any one particular house. The insanitary conditions found in many houses are grouped under one roof merely for convenience of presentation and discussion. Three reasons are given for the existence of so many insanitary houses. First, the prevailing indifference and consequent ignorance of all classes as to the various sanitary appliances by which they are surrounded. This is being slowly corrected by the gradual education of the public through the greater interest taken in the subject by the medical profession; and this very report of the Commission will be a powerful factor to this end, as it is not intended to confine its publication to the columns of the *Lancet*. It reaches the profession in this way, but it will hereafter be published in book form to permit it to reach householders, architects, contractors and plumbers. The

second reason given for the insanitary conditions discovered is the bad work and cheap materials put into houses by unqualified or unscrupulous men encouraged by the dangerous practice of putting such work up for the competition of all who may choose to tender for it. In the anxiety of contractors to obtain work it is undertaken at prices which would yield no profit if efficiently executed; and when a work is entered upon under such conditions the natural tendency is to seek relief by scamping it in some form. It is positively stated that since the general adoption of the contract system houses are not as a rule substantially finished and the work is not of a satisfactory character. The third reason given is the cost of rectifying insanitary work. Under this heading the profit and loss of the plumber is discussed at considerable length showing how a modest profit can not ordinarily be made legitimately on small contracts. Appended to each of the illustrative examples is a detailed estimate for the alterations recommended, that those who are interested in cost may have a standard of comparison.

Prior to the publication of this report it was submitted to the Worshipful Company of Plumbers, who appointed a committee to consider it. In transmitting the criticism of this committee the company desired that it be not held responsible for the work of its specially appointed committee as the company in its corporate capacity does not take any part in what may be regarded as trade matters, but directs its attention solely to those connected with the training and registration of plumbers. This special Committee considered the reasons given by the Commission for the frequency of bad, defective and insanitary work to be generally correct. It gave approval to the recommendations for new and altered work in the illustrative cases as being consistent with the requirements of modern sanitation and fairly representing the sound plumbing practice of the present day. Finally it characterized the report as "a unique work on the subject of the efficiency and cost of plumbing work, calculated if studied attentively to assist members of the medical profession, sanitary authorities and others in arriving at a more correct judgment than commonly prevails as to the chief causes of the defective and insanitary plumber's work frequently met with and to afford them some useful information as to the cost of plumbing work which is sound in construction and sanitary in character."

The report of the *Lancet's* Commission will be studied with as much interest on this side of the Atlantic as on the other, for many of the defects and faulty arrangements described may be found in our city houses; and the recommendations submitted are in accordance with the views held by our best sanitarians. It is to be observed that while the English soil pipe is of lead and runs along the

exterior of the wall of the house the American pipe is generally of iron and is retained inside the wall (on account of our severe winters) until it makes its exit as the house drain. It is to be observed also that the English have an elaborate disconnecting chamber on the drain in place of our fresh air inlet on the house side of the trap. Our English contemporary is deserving of credit for this inquiry and report.

#### CONSANGUINEOUS MARRIAGES.

One of the questions of medical deontology that still remains in dispute is that of the opinion that should be given in regard to marriages between persons closely related by blood. It is true, physicians are not often consulted on this subject, but their expressed or published opinions carry weight, and are therefore of sufficient importance to deserve some consideration. As it is they are to be had on both sides of the question, both orally given, published in medical treatises, as well as exemplified in actual practice. It may be said to be still an open question, as far as medical authority goes, whether a man should marry his first cousin or not. As regards closer relationship, such as those of uncle and niece, or nephew and aunt, though not a legal barrier in some countries, they would, it may be assumed, be very generally or unanimously considered objectionable in the United States, or at least the greater majority of them.

At the present time the laws of many of the States forbid the marrying of first cousins, but as long as this rule is not universal it really amounts to very little. The question may therefore be put before us practically in any section of the country.

As a recent French writer on the subject, M. Paul Perrin, states, there are three views extant at the present time: 1. That consanguineous marriages are not generally harmful, but may, on the other hand, be actually beneficial to the offspring and the race. 2. That they are always dangerous to both, and should be prohibited by law. 3. That they are dangerous in any case with a family taint, but otherwise unobjectionable. As regards the first of these, M. Perrin decides that it is altogether too extreme a view, and should be rejected at once. The experience indeed of mankind is against it, the statistics of idiocy, insanity, deaf-mutism and epilepsy, to say nothing of those of the inheritance of other diseases and defects, speak strongly enough in its condemnation. Even the intermarriage of persons more distantly related seems to have its perils, and a striking example of them can be found in studying the history of the royal families of Europe, which have nearly all been for centuries intermarrying more or less closely, and which show a record of degeneracy far surpassing that of any equal number of families of the average population. With all due consideration for their numerous estimable and able members at the present

time, there is hardly a single royal family into which it would be good medical advice to counsel an honest citizen of good heredity to marry.

The second view is also too extreme in its statements at least, since there is no question but that there have been many unions between near relations without bad results, and it needs no further consideration.

The third view is after all the only one that is of practical importance, as it involves the forming of an opinion in every individual case. We can admit possibilities in either direction, but in advising for future conduct, one has to weigh probabilities rather than to consider chances more or less remote. If human stirpiculture was on the same practical basis as artificial breeding of the domestic animals, it is easy to see how certain qualities might be cultivated by inbreeding, but even were this possible experience with the lower animals has shown that it impairs the vitality and that as in the vegetable kingdom frequent changes of soil and seed are essential to produce the best results. With the artificial modes of life of civilized mankind we have a still greater probability of the production of degeneracy. The lack of knowledge of hereditary taint is no absolute proof of its non-existence in any case and there are few individuals who are aware of all the degenerative possibilities in their own family histories. When the question arises therefore, as to the advisability of intermarriage in a case where the heredity seems to be good on both sides, an absolutely noncommittal position, as advised by M. Perrin, is a prudent one, and, as in most instances advice against marriage would be at least useless, is probably the only practicable one for the family physician. Where any taint exists, whatever legitimate influence can be used against the marriage should be exerted.

On the whole it would probably be well could the restrictions in force in some of the States against intermarriage of near relations be extended over the whole country.

---

#### THE NEW NURSE.

The English journal, *The Practitioner*, has within the past few months devoted considerable of its editorial space to a consideration and criticism of certain aspects or phases of the modern trained nurse. It appears from its statements that in England there has developed a very decided inclination amongst nurses to magnify their office unduly and that the present system of training tends then to produce "not so much nurses, in the proper sense of the word, as a lower order of medical practitioners who may be useful or who may be dangerous, but who in any case are superfluous." The editor pleads for a return to common sense in the training of nurses, and asks what use it is for them to have vague notions of anatomy

or physiology in the practice of their legitimate work. The old nurse, he says, was not a thing of beauty altogether, and very imperfectly realized the ideal of a ministering angel, but the new nurse is often too good in her own estimation to confine herself to the humble but useful subordination to the physician that the situation actually demands. The latest editorial, while a continuation of the others, seem to be especially called out by the fact that the first volume of the "System of Medicine," edited by DR. CLIFFORD ALBUTT, contains a contribution on nursing, written by a nurse who thus reverses the professional situation by assuming to instruct physicians.

While in this country the condition of affairs, at least so far as anything is in evidence, does not seem to quite correspond with that in Great Britain in badness, there is yet enough to suggest a little reflection on the part of the medical profession. Human nature is fallible and a nurse's training does not eradicate or counteract all the tendencies to undue self-assertion and overstepping proper limits that a little dangerous semi-medical information would be likely to bring out in many if not in all individuals. With the multiplication of training schools (so-called) for nurses in almost every hospital, sending out diploma'd graduates every year, and the growing appreciation of their services amongst the laity, it is easy to see how the less wise among the nurses might come to have a very decided overvaluation of themselves that might lead to all the grievances of which the British editor complains. Add to this the influence of women's clubs and other female organizations, the unequal inability of doctors to impress themselves on the average female nurse and we have still further possibilities of an American experience of the present trouble of our British medical brethren. Perhaps our salvation will be found in the much greater facility of medical education for women in this country and the consequent abundance of regularly educated female physicians who would naturally resent the more quickly the assumption of what *The Practitioner* calls "doubtful demi semi doctors" of their own sex. The conceited and injudicious nurse is much more likely to be quickly snubbed by the physicians of her own sex who would naturally, under the circumstances, be more jealous of their professional dignity and would lack the masculine consideration that a male doctor might feel toward one of the opposite sex. If this notion is correct we have reason, in view of the English developments, to be thankful for the female physician.

It would be well for us, however, in the active competition of hospital training schools, to give a little thought as to the value of any very elementary instruction in such subjects as anatomy and physiology to the trained nurse, and the possible inconveniences of a little dangerous knowledge that are pointed out by

the English editor. The trained nurse is, as he says, a parasite, in the scientific sense of the word, and can have no legitimate existence apart from the medical profession to which she is subordinate. Any insubordination or assumption of special and independent functions is contrary to her purpose and dangerous to her usefulness.

## CORRESPONDENCE.

### Typhoid Fever Treatment.

POLAND, OHIO, June 15, 1896.

*To the Editor:*—I am always glad to have an opportunity to say a word for the Woodbridge typhoid fever treatment. . . . I am surprised and amazed at its success. The unusually dry summer of last year in this locality caused our wells to go dry, or nearly so, the average wells not having more than from six to eight inches of water in them, the users exhausting the supply nearly every day. This condition of affairs continued for some time and the few slight rains that we had in the early autumn washed the filth and garbage which had been decaying during the hot summer from the surface of the ground into the wells, and as a result the germs of typhoid infected the water and an epidemic of the fever prevailed in our town of about 600 inhabitants. There were in all about twenty cases. All occurred in families that I treated regularly and it fell to my lot to care for them. I had Mr. Wilson McKeown of Youngstown make an examination of the water these patients had been drinking and he pronounced it to be chemically impure. The cases were nearly all in one street and the wells were undoubtedly fed from one stream as they were of about one depth, eighteen feet. The attacks were of unusual severity from the very onset, temperature rising rapidly and soon ranging from 103 to 103½ in the morning and from 104 to 105 at 6 P.M.

In the twenty cases, all except four had a temperature of 104 to 105 for days together. Delirium manifested itself early in the course of the disease in six of the cases and continued during the height of the fever. Rose-spots were apparent from the seventh to the tenth day of the disease in twelve, in eight this symptom was absent. Cephalalgia was present in all the worst cases and continued from three to five days. Hemorrhage from the bowels occurred in six cases; one had seven hemorrhages; some others from one to four.

Owing to the severity of the epidemic, I did not succeed in aborting the disease in all cases. One had an evening temperature of 105 for eighteen consecutive days, and for three days it did not vary from 105; this was the case that had the seven hemorrhages. For two weeks I did not expect this patient would recover; she was a naturally strong girl of 18 years. During the height of the disease and throughout its long continuance she was able to take a liberal amount of nourishment, which aided materially in tiding over the crisis. The long continued high temperature produced such exhaustion and emaciation that it was six months before she had recovered sufficiently to leave the house and after she was well enough to sit up it was two months before she could walk.

I followed faithfully and carefully the Woodbridge treatment from beginning to end in all of the cases; none died and all are well to-day and following their usual vocations, light of heart and buoyant in spirits, no dregs left behind as in the old method of treatment. I think that had I treated these patients by "the old method" I would certainly have lost five because the disease was of such severity from the onset. I have treated many cases of typhoid fever by this same old method in times past and upon making a careful comparison and taking into consideration the gravity of this epidemic I do not think I have

made an over-estimate of what the death rate would have been had I not used the Woodbridge treatment.

My experience during the past two years with this treatment teaches me that to be successful, all directions given by Dr. Woodbridge must be carefully followed. When the clouds are dark, do not allow yourself to be tempted to change methods, but continue the antiseptic abortive treatment to the end, and you will be rewarded by seeing your patients recover rapidly.

I have now treated forty-eight cases by this method and have been successful in every instance. Average duration of illness was eighteen days; average duration of treatment thirteen days. Most respectfully yours,

C. R. JUSTICE, M.D.

### Typhoid Fever.

WAVERLY, N. Y., July 20, 1896.

*To the Editor:*—Although much has been written upon the subject of typhoid fever of late, it seems important that the antiseptic treatment should be fully and extensively discussed. If the results obtained by many observers be verified and sustained by extensive experience, then indeed we have made wonderful strides in the management of this formidable disease.

My experience with typhoid fever during the past thirty-five years has convinced me that it is a self-limited condition or disease, and it seems self-evident that many people are immune to its toxic elements or the condition styled auto-infection, and also the so-called "mixed infection," recovery taking place after the gravest symptoms and without treatment. Many persons seem to be immune against typhoid fever, leading some observers to conclude that the disease is not infectious or contagious. Now does it not follow, if this be true, that some help in the way of rendering the system immune will diminish the ratio of mortality? Dr. Quine says no one should condemn measures claimed to produce this result, and I hold similar views. In surgical practice we realize the importance of internal asepsis in preventing auto-infection, well knowing by experience that ptomaines may be developed under conditions of shock, which destroy the patient when the traumatism in itself is not serious. Now, typhoid fever is usually accompanied with symptoms of nervous shock or depression; then does it not naturally follow that some principle of intestinal asepsis will prevent the fermentation, putrefaction or septic conditions which result?

Twenty-five years ago I adopted this view and at once discarded nearly all the usual remedies. I might say all, with the exception of calomel in small and oft-repeated doses during the first few days of the fever, and aconite in small doses to produce diaphoresis when indicated. I discontinued the use of quinin, veratrum, digitalis, iron, stimulants, etc., unless indicated by extreme exhaustion. My treatment thereafter was Merk's lactic acid, usually combined with the syr. lactophos. calcis, of the former two drams and of the latter six ounces; dose, a teaspoonful four times in the twenty-four hours; tinct. aconite in small and oft-repeated doses, when the skin was dry; no other remedies were used as a rule. I seldom saw much tympany or the dry brown tongue, seldom any sordes; why? simply because lactic acid is one of the best antiferments in the world; it prevented putrefactive changes, promoted assimilation, and the results were exemplified by recovery in 95 per cent. of all cases treated during twelve years—more than sixty cases. During the past twelve years I have treated seventy-two cases without any fatality, and in justice to Dr. Woodbridge, I should add that I have, during the past year, combined the carbonate of guaiacol, as recommended by him, with the treatment heretofore mentioned, in twenty cases, with most excellent results; in nine of the latter the disease being checked from the fourteenth to the

seventeenth day from the initial chill. In many of these cases the symptoms for a few days were severe, indicating a grave type of the disease, but almost invariably a lower plane of fever, and a marked amelioration of all the symptoms was established, the tongue and skin becoming moist, delirium diminished or abolished, tympany disappearing and patient sleeping and resting better. Occasional sponging seems to assist materially in restoring the nervous equilibrium; it has not, however, been employed with the object of reducing fever.

I have given the carbonate of guaiacol in 1-6 gr. tablets every hour through the day and three or four times during the night if the patient is often awake, for several days, and every two hours during the day thereafter while the fever continues.

I have observed the usual proportion of hemorrhage and relapses; the antiseptic treatment probably does not prevent either, but I do think it establishes the fact that relapse is not due to reinfection, but rather that the typhoid element is held in abeyance in some of the glands or adjacent lymphatics, manifesting itself after the subsidence of the first attack in a similar manner as zymotic diseases are held in abeyance during the latter period of pregnancy.

The etiology of typhoid seems to be a moot question. Perhaps a majority do not consider it contagious, but the most eminent authorities now, I believe, so consider it, and farther claim that the bacilli are carried in the dust of the atmosphere as well as in water; this I believe to be true, and am equally certain that they are given off in the exhalations from the lungs, but perhaps not to the same extent as by the feces. Now, has it ever been demonstrated that the typhoid bacilli pass safely through the stomach and enter by absorption the glands, which, by a wise provision of nature, are intended only for expulsion or secretion; is it not a more reasonable theory that they enter some of the unprotected organs and are conveyed through the lymphatics to those glands; does not the mysterious fact that they are found in remote organs tend to establish such a theory? No observer has yet accounted for their presence in such remote organs except by that route. It has always seemed a strange phantasy that the stomach, with its powerful secretion, should not be able to destroy any living organism. It certainly does in the lower animals. Is it not a more reasonable theory that the bacilli which prove virile adhere to the mucous surface of the nose, throat or bronchi, and find their way through the sewers or lymphatics to the intestinal glands and other organs?

I do not claim priority in the antiseptic treatment of typhoid fever, and while Dr. Woodbridge may not have originated such treatment, he certainly deserves a monument for his indefatigable efforts to convince the medical profession of its efficacy and importance.

R. SAYRE HENDEN, M. D.

#### A Reply to Dr. Donald Maclean's "Open Letter to the Members and Friends of the Medical Profession (Regular) in Michigan."

DETROIT, MICH., JULY 27, 1896.

To the Editor:—The Michigan Medical Legislation League is the outcome of a series of public meetings called (through the newspapers) by the Wayne County Medical Society (regular) for the purpose of enlisting the cooperation of all registered practitioners of medicine in this State, in an effort to secure from the next legislature a law to establish an adequate standard of qualification for all persons who may desire to practice medicine in Michigan in the future. These meetings were composed of all sorts of medical practitioners, many of whom were "Regulars" good and true. The sentiments expressed in Dr. Maclean's open letter are good; but his sweeping censure of the organization in question, would seem *mal apropos*, because "The League" is merely a *political body*, with no object or purpose except the one set forth, viz: that of *promot-*

*ing legislation* for the protection of the people from future unqualified practitioners of medicine. The League is *not strictly speaking a medical organization*. There is no question of medical ethics involved in the issue before us, and no creed to be assailed or defended. It is no more an "unholy alliance" than a combination of Catholics, Lutherans and Presbyterians would be, when made for the attainment of some secular object. Now, then, as any person in Michigan, in possession of any sort of medical diploma, can become a *legalized practitioner of medicine* upon the payment of seventy-five cents; therefore each and every one who has thus registered at the County Clerk's office is upon the *same legal plane!* Thus "before the law" as it now exists, the educated and the ignoramus; the Christian and the Charlatan; the gentleman and the drunkard are each on an equality; and Legislatures, as well as courts, do and always will recognize such vested rights! Our (the regular profession) efforts at convincing the people, and the politicians, of the wisdom of adopting measures which we *alone* promulgate have repeatedly failed, as the history of medical legislation, not only in this State, but in every other State of the Union attests. It is therefore practically useless to attempt the achievement of any medical legislation unless the majority of all practitioners, of all sorts, acquiesce in the movement. Obviously then, it would seem to be the *patriotic duty* of every regular practitioner in Michigan to throw aside Phariseeism and heartily aid this organization in its efforts to promote legislation for the protection of humanity and the elevation of the quality of medical practitioners in general.

The Doctor is in error when he states that there are but *two* regular practitioners on the Executive Committee of the League. On the contrary, there are *five* regulars, three "homeopaths" and one "eclectic."

E. L. SHURLY, M. D.

#### Legislation League.

DETROIT, MICH., JULY 25, 1896.

To the Editor:—I was pained to see, in to-day's JOURNAL, a communication from Dr. Donald Maclean opposing the efforts of the Medical Legislative League.

Some of his points are very good. We all admit them; but what shall we do? Dr. Maclean has been at the head of the Legislative Committee of the regular State Medical Society for twenty years, and has never accomplished anything. The number of incompetent and irregular practitioners has steadily increased. Illinois, Canada, Indiana and Ohio, in fact, all the surrounding States, have passed laws to regulate the practice of medicine, and the result is that Michigan has been the dumping ground from the surrounding territory. Shall we continue, or make some effort to limit this?

In the present state of the public mind we can not pass a law favoring regular practice. We must be liberal and take in all those now practicing medicine. By doing that, we can pass a law which will be a great improvement; it will not be perfect, but if we have a start we can easily improve and amend the law, but it is very difficult to get a new law; hence, we have joined hands with everybody calling themselves doctors to get a law passed preventing any ignorant and incompetent physicians coming into the State hereafter. That will be a great improvement. It will give the young men a chance by preventing the intense competition.

It makes no difference to Dr. Maclean or myself how many or how few quacks there are in the State, but it does make a vast difference to the new beginner; hence, I can not see why any reputable, regular physician should oppose this movement, and I am happy to say that it is the overwhelming sentiment of all regular practitioners, of all so-called "homeopaths" and of all the quacks of this State, that the further influx of charlatans and quacks should be checked.

Respectfully yours, J. H. CARSTENS, M. D.

### A New Hemoglobinometer.

CHICAGO, July 23, 1896.

*To the Editor:*—In a paper read by me before the Chicago Academy of Medicine last January (and published in *Medicine* March, 1896) on "Color Measurement and its Application in Medicine and the Arts," I ventured the assertion that the hemometers and hemoglobinometers now in use were decidedly defective, for the reasons then and there set forth. I further expressed my belief that a modification of Lovibond's "tintometer" would be found more accurate and more easy of application than any of the instruments (Fleischel's, Gower's, etc.) then in use.

I was at that time conducting some experiments with the tintometer as a measurer of blood tints and promised to relate my experiences with it when those were completed. I subsequently found that Dr. George Oliver had anticipated me in this matter and had, like myself, visited Mr. Lovibond's Color Laboratories at Salisbury, England, for the purpose of investigating certain questions in chromometry.

The result of these investigations has been incorporated in the Croonian Lectures for 1896, "A Contribution to the Study of the Blood and the Circulation," delivered last month by Dr. Oliver. The purpose of the tintometer and especially its value in hemometry are fully described in Dr. Oliver's third lecture, published in the London *Lancet* of June 20 last, and I take the liberty of drawing the attention of the profession to that particular issue.

For the further information of those who are interested in chromometry generally or in that division of it which includes the determination of the chemic constituents of the blood by variations in its color I would say that the agent for the tintometer in the United States is E. B. Meyrowitz, Optician, 104 East 23rd Street, New York. CASEY A. WOOD, M.D.

### Albumin Testing.

GREELEY, COLO., July 22, 1896.

*To the Editor:*—In our *JOURNAL* of April 11, 1896, p. 732, Dr. J. W. O'Neill describes a new apparatus for the cold nitric acid test for albumin. A more available way, giving a large surface of contact for the urine and acid, with very little mixing of the fluids, is to put the urine to the depth of about half an inch into a beaker of suitable size, *e. g.*, two inches in diameter. Take up about  $\text{m} \text{xlv}$  of the acid with a pipette. Put the point of the pipette down through the urine to the bottom of the beaker and let the acid escape slowly, especially at first. One way to be sure that the acid escapes slowly is to watch the top of the column of acid in the pipette. If this goes down slowly one may be pretty sure that the stream of escaping acid is a gentle one. Close the pipette tight again before taking it out to keep the small amount of acid remaining in the pipette from mingling with the urine.

A little calculation will show that in a two-inch beaker the surface of contact is ten times the size of that in a five-eighths inch test tube, which is the size in the O'Neill apparatus. I think Prof. E. S. Wood of Boston, was the first to point out the advantage of a large surface of contact.

One incidental point about the apparatus here described is that it is cheap and of use for more than this one test.

C. D. NELSON, M.D.

### Railroad Rates.

DUNKIRK, IND., July 20, 1896.

*To the Editor:*—Is it not about time we were agitating the matter of railroad rates to the association. I have been thinking for some time that as a society or association we have been practically ignored by the railroad companies. It is true we have had the very liberal rate of *one and one-third fare*. A party of ten going a hunting or fishing can get such a rate at any

time and on any road. Then look at the rates given other society meetings, such as the Christian Endeavor, the B. Y. P. U., etc. Also the great political conventions of the day. Within a few days of our meeting at Atlanta, the rate from Cincinnati was one fare. When we consider that the railroads get so much service from physicians and the only compensation rendered is an insignificant *pass* over a few miles of road we think it is about time to raise a howl about the rates given to our annual meeting.

And now as our next convention will be held at Philadelphia which is a great railroad center, let us investigate the matter and see if we can not get better rates. Let us hear from others on this subject.

Yours very truly,

J. B. GARBER, M. D.

## PUBLIC HEALTH.

**Poisoned with Belladonna Greens.**—A family were poisoned recently in a suburb of Paris by a dish of greens gathered in their own garden and served for dinner. Seeds of the belladonna had been sold to them by mistake for spinach seeds.

**Brooklyn Health Report.**—During the week ended June 18, there were reported 674 deaths. The death rate was 31.3 per thousand, in an estimated population of 1,125,000. Of the total deaths reported 418 or 62.0 per cent. were of children under 5 years of age, and 333 or 49.4 per cent. were of children under 1.

**Compulsory Rest for Working Women after Childbirth.**—The *Progrès Méd.* of July 4 states that the laws of Germany, Switzerland, Austria, Belgium and England compel working women to a four weeks' respite from the factory, etc., after childbirth. The Society of Public Medicine and Professional Hygiene is advocating the introduction of a similar law into France, with an allowance from the public funds during the time of compulsory rest.

**Germany Officially Investigates Colorado Climate.**—Dr. Engel Reimers, chief physician to the public hospital in Hamburg, Germany, has been sent to the United States, and Colorado particularly, to investigate the influence of the climate upon tubercular patients. The doctor believes that the experiments made with lymph and other alleged cures are as naught compared with the outdoor treatment, and that the dry climate of Colorado is ideal for that purpose.—*Col. Med. Jour.*, July.

**Water Supply of Allegheny and Pittsburg, Pa.**—The report of the bacteriologic examination of the water shows that the three Allegheny samples contained from 1,600 to 6,250 bacteria to the cubic centimeter, while the Pittsburg sample contained 656. The water of Allegheny is much worse than that of Pittsburg, but both are far beyond the limit of safety. These results fully explain the high typhoid fever rate of the two cities.

**Boric Acid in Milk.**—While the addition of boric acid to milk does not make it poisonous, it produces certain deleterious effects, which should cause its use to be prohibited. Chemically, the presence of borax not only tends to neutralize the development of acids, which takes place during the presence of fermentation, but it precipitates and renders insoluble certain salts contained in the milk which gives to it a portion of its value as an article of food. Beside this, its neutralizing action upon the juices of the stomach tends to retard digestion. Bicarbonate of sodium, so frequently used by mothers and nurses to keep milk sweet, has a similar action.—*Pac. Med. Jour.*, July.

**Decision Relative to Local Quarantine.**—Judge Albright, Pennsylvania, declares that a municipality may rightly and properly be held responsible for the maintenance of families quarantined by boards of health, because of contagious diseases. In making this declaration the court applies precisely the principle of law which is currently acted upon in all cases

where persons are deprived of their liberty through any legal process. The decision will be most helpful, as well as a wise and prudent determination of a pertinent question. It is sound public policy, and its effects must ultimately tend to secure more complete and valuable quarantine than could otherwise have been attained.

**Decision Relative to Rear Tenements in New York City.**—Justice Lawrence, in the supreme court, July 20, handed down a decision denying the application of the board of health for the appointment of appraisers to fix the value in condemnation proceedings of certain rear tenements which were ordered vacated by the board. It was asserted in the four cases on which argument was heard several weeks ago that the court could not name the appraisers, as the act under which they were to be appointed was unconstitutional, as it limited the powers of the appraisers within certain lines as to the value they could put on the condemned properties. The decision, while delaying the appointment of the commissioners, is really a victory for the board of health in that the act is practically declared to be constitutional. At the time of the hearing it was admitted by the attorney for the board that certain legal provisions had not been complied with in the petition, and an effort was made to allow the board to amend and let the question go to the court on its constitutionality alone.

**Chicago Water Must Be Boiled.**—The recent storms in the vicinity of Chicago have caused a dangerous contamination of the water supply of Lake Michigan, by driving the city sewage to every intake crib, from whence it is carried through the mains and used for domestic purposes. An analysis made July 27 of the water shows the following conditions:

Samples from	Free Ammonia.	Albumoid Ammonia.	Nitrates and Nitrites.
Fourteenth St. Station . . . . .	.001	.012	None
Chicago Ave. Station . . . . .	.001	.008	None
Hyde Park Station . . . . .	Trace	.010	None
Lake View Station . . . . .	Trace	.004	None
Laboratory tap . . . . .	Trace	.012	None

Samples from	Chlorids.	Oxygen Consumed.	Sanitary Quality.
Fourteenth St. Station . . . . .	.65	.180	Bad
Chicago Ave. Station . . . . .	.65	.190	Bad
Hyde Park Station . . . . .	.65	.230	Very bad
Lake View Station . . . . .	.65	.190	Bad
Laboratory tap . . . . .	.65	.170	Bad

Owing to the inadequacy of the pumping facilities at Bridgeport this contamination has existed for over four months, but not to the alarming extent which has been developed during the past week. Under these circumstances it is absolutely dangerous to use the water for drinking purposes without boiling. The Assistant Commissioner of Health Dr. Frank W. Reilly has given an interview setting forth the foregoing facts in the *Tribune* of July 28.

**"Spitting" in Indiana.**—The Indiana State Board of Health has issued a circular letter to all railroad officials asking them to have ejected from their trains every man who persists in spitting on the floor of the cars or stations after he has been warned not to do so. In the circular the board explains that the sputum contains the germs of la grippe, nasal catarrh, and various other diseases. It also declares that "spitting is a nasty and unnecessary habit," and explains that the Board of Health will pass a rule against spitting which will have all the force of law if the railroads will post it up and endeavor to enforce it. The circular adds: "When the rule is first published and posted up in public places this board will, of course, be loudly abused as foolish, impracticable and idiotic. Attention thus being gained, we will publish in every county reason for the action." Such a reform as the Indiana health officers have undertaken is needed in every part of the United States.

**Identity of Croup and Diphtheria Officially Recognized in Quebec.**—The following is a portion of an official circular over the signature of Dr. Elzéar Pelletier, the Secretary of the Board of Health of the Province of Quebec. It shows that formal action

has been taken by that board placing croup under the same sanitary regulations as diphtheria. "Being informed that a great number of cases of croup escape the control of sanitary authorities, and that it is mostly due to the public being generally under the impression that croup is not a contagious disease, the Board of Health of the Province of Quebec authorizes the publication of the following definitions: Croup is nothing else than diphtheria, attacking more especially the respiratory tract (larynx). The expression laryngeal diphtheria designates better than the term croup the nature of the disease and should be preferably employed. Distinction should always be made between croup or laryngeal diphtheria, which is contagious, and false croup or laryngismus stridulus, which is not contagious. There are no membranes in laryngismus stridulus or false croup. The cough of croupal form which characterizes this disease is due only to a nervous element."

**Mortality by Casualty from an Insurance Standpoint.**—The *Medical Examiner* reviews the recent publication by the Mutual Life Insurance Company of New York on the above subject. The author, Dr. E. J. Marsh, is the statistical medical director of that company. It says: "The record is very interesting, but, after all, there is no broad principle to be deduced. So many died from railroad accidents, so many murdered, so many suicided," etc. We can hardly agree with the broad statement of the author that "no examination can give any protection from chance of accidental death." In all application blanks questions are asked regarding occupation, environment and physical defects, which, if rigidly and correctly answered, will give protection from chances of accidental death in some cases. That is one reason why they are inserted. The answers to the questions alone will cause the company to decline, provided the answer is such as to show an element of danger. Often an applicant is presented who is perfectly acceptable in all respects, save the possible element of danger from occupation and environments. No company, for instance, would accept a powder or dynamite maker, be he ever so healthy, knowing that any moment he may be blown to atoms, and yet no one but the medical examiner may have conveyed the information to the company. The examination revealed this fact, and, therefore, is a refutation of the unqualified statement of the Doctor in his essay. We fail to discover anything regarding the apparent fact, if it is a fact, that accidents run in families, so to speak. All underwriters have noticed that certain families seem to be destined to die from accidents; it may be one particular kind of accident, or it may be simply from violence. Why is it? Is it because there is a careless trait in the family, or is it due to physical defects in hearing or seeing? Or is it the old doctrine of fatality? Whatever it is, certainly accidents do occur again and again in a family. When this is the case it is best to investigate the applicant presenting the family peculiarly on general principles. The pamphlet is the result of the experience of the company represented and may not be the experience of another. Each company presents its own experience in this respect, and is governed by its own figures.

**On Baths for Public School Children.**—The *Boston Medical and Surgical Journal*, July 16, advocates the above named innovation, and argues in favor of the School Committee of Boston following German example, by the experimental introduction of shower baths into a school about to be built in the most squalid and congested section of the North End. The writer believes that, even where municipal baths are most numerous and well devised in Europe, the policy of providing special bathing facilities in schoolhouses for the children who resort to them for instruction has developed rapidly in the last decade and is now highly approved. The initial impulse to the wide-spread and admirable system of municipal baths now so common in Great Britain and on the continent is ascribed by the *Boston Herald* to the success which attended

the establishment of Liverpool's first public bath and wash house in 1842. That the Boston School Committee should be forced to consider the question of school baths before even the site of the first of Boston's municipal bath-houses has been determined bespeaks an enhanced and diversified interest in school hygiene in the community. Fortunately the advocates of school shower baths can point to the result of ten years' experiment by school boards in Germany and Switzerland. It would appear from the evidence cited from European experience that school shower baths have proven popular, cheap and efficacious wherever they have been given a fair trial. They are admitted to be very much cheaper, both in respect to original cost and cost of maintenance, than any other form of bath. Being self-cleansing, school shower baths have commended themselves to sanitarians and hygienists as superior to tub baths. If, as is claimed by Dr. Hartwell, bathing and dressing-room appliances adequate for bathing 2,000 children weekly during school hours can be placed in the Paul Revere School at a cost of less than \$3,000, we are inclined to think that the School Board will do well to test the matter practically. It is admitted by the education authorities that schoolhouse air in Boston is bad. It is probably as bad in the North End as anywhere in the city. We have little doubt that the comfort, health and efficacy of teachers and pupils in the new school would be greatly enhanced, as a result of the purer air which would be had if the bodies of the pupils who come from "unplumbed" houses were occasionally subjected to a warm shower of water during the winter months.

**Health Report.**—The following health reports have been received in the office of the Supervising Surgeon-General, Marine-Hospital Service:

SMALLPOX—UNITED STATES.

New Orleans, La., July 11 to 18, 3 cases.  
Pensacola, July 11 to 18, 1 case.

SMALLPOX—FOREIGN.

Callao, June 14 to 28, 61 deaths.  
Genoa, Italy, June 5 to 12, 1 case.  
Gibraltar, June 28 to July 8, 1 case.  
Guayaquil, July 3 to 10, 2 deaths.  
Hamburg, July 4 to 11, 1 case.  
Licata, June 27 to July 4, 3 deaths.  
Madrid, June 30 to July 7, 22 deaths.  
Matanzas, July 3 to 10, 1 case, 1 death.  
Montevideo, June 12 to 19, 1 case.  
Odessa, Russia, June 27 to July 4, 11 cases, 4 deaths.  
Osaka and Hiogo, June 20 to 27, 49 cases, 20 deaths.  
Prague, June 27 to July 4, 2 cases.

CHOLERA.

Yokohama, June 12 to 19, 1 case, 1 death.

YELLOW FEVER.

Matanzas, July 3 to 10, 100 cases, 46 deaths.  
Sagua la Grande, July 4 to 11, 59 cases, 7 deaths.  
St. Petersburg, June 27 to July 4, 14 cases, 7 deaths.  
Warsaw, June 13 to July 4, 7 deaths.  
San Juan, Porto Rico, May 1 to 31, 14 cases, 4 deaths; June 1 to 30, 17 cases, 2 deaths.

## NECROLOGY.

VINCENT LOMBARD HURLBUT, M.D., died July 24, at his home, 2342 Prairie Avenue, Chicago, Ill., of Bright's disease. Though most of his busy life had been spent in Chicago, Dr. Hurlbut was a native of New York State, where he was born in the town of West Mendon on June 28, 1829. His father was Dr. Horatio N. Hurlbut, a descendant of the Puritans. As a child he moved with his parents, first to the town of Sparin, Crawford County, Pa., and later to Jefferson, Ashtabula County, Ohio. Graduating from the Jefferson Academy, he studied medicine, first under his father at home, and later in a medical college at Cleveland. In 1851 he came to Chicago and entered Rush Medical College, from which he graduated the next year. During the same year he began the practice of his profession and followed it with unflinching application.

He soon gained prominence in his profession, and for a generation had been one of the leading physicians of the city. In 1873 he was appointed surgeon of the Woman's Hospital for the State of Illinois, and long held that position. He was a member of the AMERICAN MEDICAL ASSOCIATION, of the State Medical Society, was Vice-President of the Cook County Medical Society. Dr. Hurlbut was a thirty-third degree Mason and one of the oldest and most widely known members of that order in the West. He entered the Blue Lodge in 1860 and took the various degrees until he reached the highest, receiving the thirty-third in Boston in 1864. From 1863-5 he was commander of Apollo Commandery and in 1867 he was made Grand Commander of Illinois. In 1871 he was elected Generalissimo of the order, and in 1877 was chosen Grand Commander of the order at the triennial conclave at Cleveland, Ohio. Notwithstanding his success and honors he was very unostentatious in his manner and his acts of charity were innumerable, ever ready to alleviate suffering and unhappiness. Our genial colleague will also be greatly missed by former habitues of the old Grand Pacific Hotel, to which hostelry he was house physician for over twenty years.

PAUL P. PRENDERGAST, M.D., of Brooklyn died July 10, in the twenty-fourth year of his age, in consequence of an attack of pulmonary tuberculosis that made its onset about one year ago. He was a native of Brooklyn and a graduate in 1894 of the College of Physicians and Surgeons, New York. He was a nephew of Dr. J. J. Prendergast and the late Peter Paul Mahoney, M.C. He had been ailing for about eighteen months from pulmonary symptoms, which are supposed to date back to the time when he was in the hospital. He was very fond of his profession and for six months after the symptoms of his disease were discovered he continued to study in the class of surgeons to which he was attached at St. Mary's Hospital. He was for a time at Seney Hospital. He was also for a time an assistant at the Sloane Maternity in New York. Before his illness Dr. Prendergast was in good health. He was six feet tall and weighed nearly two hundred pounds. But his health failed to such a degree that it was considered expedient that he should leave the city. He went to Saranac Lake in the Adirondacks, where he spent about a year. He returned home early in the present year and later took a trip to California. While in the mountains of the Pacific coast he contracted what is known as the mountain fever. His health gradually grew worse. He realized his condition and came home to die, a victim to hospital tuberculosis, hastened and fostered by an over-zealous attention to clinical study.

THERON Z. GIBBS, M.D., of Fort Ann, N. Y., was killed early in July, by being struck by a train while he was crossing the track near his home. He was born at Shoreham, Vt., in 1826. He was graduated from the Castleton Medical School in 1853. He practiced in New York State until the breaking out of the war, when he entered the volunteer service as an assistant surgeon of the Fifteenth New York Engineers, becoming full surgeon in 1863; his regiment was then with the Army of the Potomac. He was ex-President of the Washington County Medical Society and had been the health officer of Fort Ann from 1888 to 1890, in which town he had practiced fully thirty years. He was a member of the State Medical and other societies. He had been twice married and is survived by his widow and three children.

WILLIAM A. PIPER, M.D., of Philadelphia died July 6, aged 77 years. He was a graduate from Jefferson Medical College, in 1844.

JAMES THOMAS PETTUS, JR., M.D., of New York City died on July 13, at Reading, Pa. He was a graduate from the College of Physicians and Surgeons, New York, of the class of 1844.

S. H. BOTTOMLEY, M.D., of Chicago July 26, from a complication of kidney troubles. Dr. Bottomley was born in Birmingham, England, fifty-one years ago, and came to Chicago in 1866. He was a graduate of Lind University, and during the Civil War served as a surgeon.

## SOCIETY NEWS.

**The Central Texas Medical Association.**—This association was in session at Waco July 14 and 15. Among the papers read and discussed were "Medical Legislation," by Dr. J. D. Law, and "Hypnotism in Disease," by Dr. R. W. Park.

**Chautauqua County (N.Y.) Medical Society.**—The annual session was held at Chautauqua July 14 with a large attendance. The following officers were elected for the ensuing year: President, E. S. Rich; vice-president, Morris N. Bemus; secretary, C. A. Ellis.

**Medical Society of the County of Clinton, N. Y.**—This society held its semi-annual meeting at Plattsburg, July 14. Dr. Henry C. Fisher, U. S. Army, was elected an honorary member of the society. An interesting paper, entitled "Purpura," was read by Dr. Taylor, who also presented a clinical case in illustration.

**The Lexington and Fayette County (Ky.) Medical Society** meeting was held at Lexington, Ky., July 13, and the following officers were elected for the ensuing year: President, R. L. Willis; first vice-president, J. C. Carrick; second vice-president, J. Y. Oldham; secretary, R. C. Falconer; treasurer, Ed. Green; librarian, N. L. Bosworth.

**Oneida County (N. Y.) Medical Society.**—A meeting of the Oneida County Medical Society was held at Utica, N. Y., July 14. Dr. Dye presided. Dr. F. H. Peck read a paper on "Ununited Fractures." Dr. Glass reported two cases in which the Murphy button had been successfully used. Dr. A. I. Simmons gave a sketch of the life of the late Dr. Claude Wilson of Waterville. Dr. Smith Baker also paid tribute to the deceased.

**Wyoming County (N. Y.) Medical Society.**—The annual meeting was held at Warsaw, N. Y., July 14. The following officers were elected for the ensuing year: F. R. Barross of Attica, president; A. E. Ellinwood, vice-president; A. B. Straight of Perry, secretary. Papers were read by Prof. Floyd S. Crego of Buffalo, "Value of Animal Extracts in the treatment of Nervous and Mental Diseases;" James E. Walker of Hornellsville, "Renal Auto-intoxication;" Cordelia E. Greene, "Leprosy on the Hawaiian Islands." The next meeting will be held in Castile the first Tuesday in October.

**The XIVth Congress of Internal Medicine in Germany.**—A feature of this congress which has been much commended, was the presentation of each address in two parts, one by a physician and the other by a surgeon, who regarded the subject from such different points of view. It was held at Wiesbaden in April. Nothing of an epoch-making character was presented, although Ewald used that term to express his appreciation of Baumann's discovery of the presence of an organic compound of iodine in the thyroid gland, "which gave us our first real insight into its essential elements, and cast in a new mold the application of the thyroid preparations to therapeutics, without contradicting our previous knowledge." "In Baumann's thyroiodin we have secured the long-sought exactness in the amount and strength of doses, and as it contains all the essential elements of the gland, it can be substituted for the fresh, the desiccated and the extracts of the gland." Ewald administers it in very small doses at first, gradually increasing, but always keeping within a daily maximum of ten tablets, corresponding to 3 mgr. iodine. The fact was established once more that the fever of infective diseases is now considered a salutatory reaction of the organism in its struggle with the microbes. The revulsion of feeling in regard to the effect of alcohol in fevers was also noticeable, and the rapid fall of temperature in septic and puerperal fevers after the administration of large quantities of alcohol dwelt upon. Rosenfeld announced that urotropin and urea are efficient in the treatment of uric diathesis, and 5 to 20 grams of urea a day produce no incon-

venience. The diet must include caseate of sodium, peptone or aleurone, and meat, fat and sugar be excluded. Uric acid diminished 24 to 70 per cent. under this treatment. Noorden stated that lime combined with a phosphate is eliminated rapidly by means of increased intestinal secretions, and is therefore much to be preferred to sodium and potassium in preventing renal concretions of uric acid and keeping the blood in a neutral state. By avoiding intestinal irritation, the use of four grams a day of monophosphate of lime can be kept up quite a long while.

## MISCELLANY.

**Trained Masseurs for the French Army.**—The war department of France has established three schools where massage is taught as a science to a corps appointed for the purpose. One is at Paris, another at Lyons and the other in Algeria. The course requires six weeks.

**Training School for Nurses Wanted in Rio Janeiro.**—*O Brazil-Medico* is urging the establishment of a training school for nurses of both sexes at Rio Janeiro, where the articles in the press on the abuses in the National Insane Asylum are now quite in vogue. Buenos Ayres already has a model establishment of the kind.

**Rape in Virginia.**—Section 3,680 of the code of Virginia defining rape, was amended in March, 1896, substituting fourteen for twelve, as the age of the female affected thereby; extending its application to any female who is an inmate of a deaf, dumb or blind institution who is a pupil therein, and reducing the minimum penalty of confinement in the penitentiary from ten to five years.

**Two New French Hospitals.**—The one at Clichy was erected through the generosity of Jules Gouin, at an expense of \$240,000. It occupies a large square, one side of which is devoted to a model apartment house for working men. The other hospital is at Auteuil, and is chiefly designed for the training of army nurses. There are twenty-five beds, a large garden and an open space in the rear that could be filled with tents in time of war so as to extend the capacity of the hospital indefinitely. It is the work of the Association des Dames Francaises.

**The "Laryngoscope."**—We have received No. 1, Vol 1, of the *Laryngoscope*, a journal devoted entirely to the consideration of diseases of the nose, throat and ear. The journal intends to fill the niche between the strictly special and the general journals, with that class of physicians who confine themselves entirely to the treatment of the diseases mentioned or who pay especial attention to these troubles while maintaining a general practice. We extend the hand of fellowship to the new journal.

**Virulence of Klebs-Loeffler Bacillus Slightly Attenuated by the Action of Roentgen Rays.**—The *Prov. Med.* of June 27 (Lyons) reports some experiments with cultures and diphtheria toxins exposed for seven hours to the Roentgen ray. Cultures made and animals inoculated afterward with them showed in each case a slight diminution in the virulence. The bacilli did not develop so rapidly in cultures, and the animals survived four to nine hours longer than those inoculated with toxins that had not been exposed to the ray. It adds that Lortet considers the action of the ray beneficial in augmenting the resisting powers of the animal exposed to it, rather than in impairing the virulence of the microbe.

**Our Mexican Exchanges.**—The monthly bulletin of the Health Department of Mexico is not the usual dry record of statistics, but a handsome, blue-covered, 32-page pamphlet containing several popularly written and instructive articles on hygiene and the prophylaxis of various diseases, printed with large,

clear type. The statistics are also compiled in a manner that will render great services to science in time. The publications of the Academia Nacional de Medicina are also conducted with great enterprise, and according to modern methods. A special scientific study of the plants of Mexico is now under way, which is already an important contribution to science. Another journal is conducting a special and comprehensive study of the manifestations of tuberculosis in Mexico.

**Thrombus of the Labium.**—Dr. S. A. Goodwin reports a case occurring after a natural and easy confinement. He says: The mass increased until it had acquired the size of a newborn child's head, exceedingly painful, and extending to the perineum. The labium was everted so that it appeared to be covered externally by the mucous membrane. We applied cloths wrung out of hot water and solution of acetate of lead, and succeeded in keeping it from rupturing. The tumor became dark in color, almost black, and very hard. In three days the tumor was ruptured and contents removed, which was a dark coagulation of blood. The wound healed rapidly, and in five weeks all that remained to indicate any abnormality was the cicatrix.—*Ind. Med. Jour.*, July.

**Injured Person's Duty.**—In the personal injury case entitled West Chicago Street Railway Co. v. Stephens, the appellate court of Illinois, held, July 1, 1896, certain instructions erroneous which required the plaintiff to show what part of his injuries were attributable to the original cause as separated from those due to the lack of care by him in getting cured of them, as not stating the rule of law in regard to the duty of one who receives an injury is under to take reasonable care that his injuries shall not, by undue neglect, become aggravated, also because such instructions failed to include the element that the plaintiff had knowledge, or reasonable cause for knowing, that he needed better care and attention in getting cured than he gave or caused to be given to himself, and that such increased care and attention were within his means and power.

**Experimental Tuberculosis Attenuated by the Roentgen Ray.**—Lortet and Genoud report a series of successful experiments with guinea pigs inoculated with tuberculosis in the inguinal region. Three selected at random out of the eight inoculated, were tied to a board on their backs, and the inoculated region exposed to the Roentgen ray for one hour each day, from April 25 to June 18. Ganglionic abscesses developed in the control animals, which discharged spontaneously a whitish suppuration; the inguinal ganglia grew soft and could not be distinguished from the surrounding tissue. The animals also showed great emaciation. On the other hand, the three animals exposed to the Roentgen ray gained in weight; they had no abscesses, and their inguinal ganglia remained hard and distinct, with no tendency to suppuration. These results prove that the Roentgen ray materially modified the acute development of the tuberculous infection, and justify its application to human beings, especially children, with superficial tuberculosis, limited to the pleura, or with tuberculous ganglia in the mesentery.—*Bulletin Médical*, July 1.

**New Application of the Roentgen Ray. Fluorescent Screen.**—An important advance in the application of the Roentgen ray to medicine is described in the *Semaine Méd.* for July 1. Instead of taking photographs, it is now possible to look directly into the body and see the skeleton with our own eyes. This is accomplished by means of a screen made by gluing a piece of cardboard  $\frac{1}{2}$  mm. thick, on a pane of glass. A square piece is then cut out of the center, 10x25 cm. and the space thus left on the glass is filled with the finely pulverized chemicals, which we know become fluorescent under the Roentgen ray; double cyanid of potassium and platinum, or double cyanid of barium and platinum. This is covered with another piece of cardboard the same size as the first, enclosing the chemicals. If this

screen is held at the cathode end of a Crookes' tube concealed in a pasteboard box or covered with a cloth, the part of the frame that holds the chemicals is instantly illuminated, and a hand interposed between the illuminated frame and the invisible Crooke's tube, becomes transparent, so that nothing but the bones can be seen. Promising results have already been secured by Buka, Roentgen, Salvioli, Lewy, Grunmarch, du Bois-Reymond, etc., who have distinguished the skeleton and organs throughout the body, and diagnosed several cases of arterio-sclerosis, etc., with amazing accuracy. Becher of Berlin adds the suggestion that lime water injected into the stomach or intestines or the introduction of air prevents the passage of the Roentgen ray.—*Deutsche Med. Woch.*, July 2.

**Bicycle Riding among Those Having Unsound Legs.**—Mr. E. B. Turner, the author of a series of special reports in the *British Medical Journal* on "Cycling in Health and Disease," has not found that this form of exercise is injurious in cases of impaired venous circulation. He says ordinary varix of the lower limbs, however produced is very frequently much benefited by regular cycling, but if the enlarged veins be of considerable size, a stocking should be worn. Out of a very large number of such cases the writer has never seen the slightest increase which could be put down to riding, not even in men who raced long distances on the road and path, while in many cases of infiltration of the skin and varicose eczema, a perfect cure has resulted. A suspender should always be used if the rider has a varicocele, as a protection from injury by the saddle, when the roads are rough and lumpy. Piles diminish and cease from bleeding in a wonderful fashion by the time a few hundred miles have been judiciously covered, and though external masses must remain, they do not as a rule increase.

**Complications and Sequelae of Diphtheria.**—The complications are those of extension to or ulceration of the respiratory tract and involvement of other regions from toxin poisoning. Locally there is hemorrhage, due to ulceration, from the nose, throat and bronchi; occasionally petechial hemorrhages under the skin and other skin rashes, especially erythema, appear. By extension of the process or by inhalation of particles of membrane, acute bronchitis, more especially capillary bronchitis, or broncho-pneumonia with atelectasis or gangrene, may develop. Kidney symptoms are common, albuminuria is present in severe attacks; occasionally suppression of urine is present, and rarely, dropsy develops later. Heart failure or fatal syncope may occur at any time during the attack or after convalescence has commenced. Of the sequelae, paralysis are the most important. They appear usually during the second or third week of convalescence, in from 10 to 15 per cent. of cases. One of the most common is that of the velum palati. Sometimes the eye is involved and strabismus, ptosis or loss of accommodation may result. Facial paralysis sometimes occurs. One of the limbs may be involved. Occasionally multiple neuritis develops.—Dr. Howard Van Rensselaer in *Albany Med. Annals*, July.

**Subcutaneous Injections of Artificial Serum in Anemia and Septicemia.**—The meeting of the Académie de Médecine, June 30, was chiefly devoted to a discussion of this subject. Péan closed the discussion by remarking that all were evidently unanimous in regarding subcutaneous injections as marvelously effective in hemorrhages and acute anemia, and as a possibly useful adjuvant in septicemia. But as to intravenous injections the few remarkable successes announced here and there are isolated cases, and he believes it is better to return to the subcutaneous method. Pozzi mentioned a case of "veritable resurrection" from death in post-operative septicemia. He strongly advocates subcutaneous injections as effective, harmless and easily administered. Pinard stated that in the Baudelocque clinic they lost every woman in acute anemia from hemorrhages, from 1882 to 1893. Since 1893 he has been treat-

ing these cases with subcutaneous injections of artificial serum and has not lost one of the seventeen presented. He has never had occasion to inject more than 1400 grams in the twenty-four hours. Tarnier has also seen four women revive when they were practically dead from excessive hemorrhages. He has never used the artificial serum in septicemia. Champonnière deprecates the use of enormous injections, and has never found the serum beneficial in septicemia. Porak has used the subcutaneous injections to advantage in eclampsia.—*Bulletin Médical*, July 1.

**Patent Medicine Scandal at Bellevue Hospital.**—The *Boston Medical and Surgical Journal* for July 2 reports that motives other than scientific have brought to pass a scandal of magnitude, concerning which the medical staff of the hospital concerned has shown a quiescence, if not acquiescence, that apparently merits its condemnation by the profession and the public. It may have been the "fault of Mayor Strong," as has been said, but the staff is not obliged to continue on duty if an outrage is committed against its most sacred principles. The *Journal* says: "Considerable comment has been caused of late by the setting apart of the Commissioners of Public Charities, in spite of the protest of the medical board of the hospital, of one of the alcoholic wards of Bellevue Hospital for the use of a certain physician of New York, but not connected with the institution, who is to treat patients by means of a secret remedy which he claims to have discovered. This physician is Dr. Isaac Oppenheimer, and the curious part of the matter is that up to the present time he has been a regular physician in good standing, being a graduate of the College of Physicians and Surgeons (in the year 1876), a Fellow of the Academy of Medicine and a member of the Medical Society of the County of New York. In the only case that has thus far been made public of which Dr. Oppenheimer had charge the patient, who had been transferred to the Bellevue from the Harlem Hospital, died a few hours after his admission to the ward. In this case, however, the Doctor asserts that the man was suffering from an advanced stage of Bright's disease, and that he made no attempt to treat him with his new "cure."

**A Medico-legal Case Affecting a Young German Practitioner.**—The *Medical Press and Circular* makes comment on a recent medico-legal case in Germany. The central figure of this case was a young medical practitioner of Spandau, who became qualified in 1893; he was accused of causing bodily injury through negligence. About a year ago a young woman, recently married, presented symptoms of threatened abortion. She consulted two medical men who agreed as to her condition. She then placed herself under the care of the accused, who declared that a harmless operation was necessary. This she consented to, and the operation was performed, with the result that the patient died of hemorrhage two and a half hours afterward. What the operation was is not clear, but it appears to have been a curettement of the uterus, in the course of which perforation of the walls of the uterus took place. As a result of the postmortem examination the young practitioner was accused of culpable negligence. The two principal medical witnesses were the Kreisphysikus, Dr. Reinicke and Prof. Landau. Whilst Dr. Reinicke laid the whole of the blame on the accused, Prof. Landau laid it on "the present state of scientific knowledge and the defective clinical training of students. Operations such as the one in question were not taught practically to young practitioners, and they had to gain their experience from their patients. Moreover, science followed the fashions, and there was a widely-spread school that had given up the plan of observation and waiting, and taught a method of treatment that the witness must characterize as brutal, and must, therefore, lead to brutal consequences. The accused appeared to belong to this modern school; the woman

was, therefore, not the victim of his negligence, but the victim of the modern tendency of medicine. The court then requested a written opinion on the matter from Dr. Landau, and at the same time a control opinion, or Obergudachten, from the Royal Medizinal Collegium. It is well to bear in mind that Prof. Landau is not an ordinary professor of gynecology in charge in either of the teaching clinics, but a professor extraordinary with a privilege of private teaching."

**American Tenacity.**—M. Patenôtre, the French Ambassador, went crabbing the other day at Cape May. He soon caught a crab, and not being familiar with the creature he grasped it with his left hand. Then the crab promptly caught him. The ambassador was evidently both pained and surprised. He instinctively grasped it with his right hand, and the crab in turn seized his right hand. Thereupon the captain of the yacht went to the rescue of M. Patenôtre, who remarked: "Ze tenacity of ze creature is so very much Americaine!"

**Oregon Opium Law Constitutional.**—In 1887 the legislature of Oregon passed "An act to regulate the sale and gift of opium, morphin, eng-she or cooked opium, hydrate of chloral or cocain." It provides that no person shall have in his or her possession or offer for sale any of the drugs enumerated, who has not previously obtained a license therefor, unless, as it clearly implies, it be obtained on the prescription of some duly qualified physician or pharmacist for medicinal purposes. The license is to be issued only to regularly qualified physicians who keep a stock of drugs and medicines for their own use in prescription, and regularly qualified druggists. This law the supreme court of Oregon holds constitutional, in the case of *Luck v. Sears*, decided April 27, 1896. Speaking only of opium, it says that it is an active poison, and has no legitimate use except for medicinal purposes, though it is frequently used to produce a kind of intoxication by smoking or eating, a loathsome, disgusting and degrading practice, which results not only in pauperism and crime, but also in the serious impairment of the mental and physical condition of those who indulge in it. The sale and disposition of such a drug, it therefore thinks, may unquestionably be regulated and controlled by law, and whether its nature and character is such that, for the protection of the public, its possession by unauthorized persons should be prohibited, is a question of fact and public policy, which belongs to the legislative department to determine. The discretion of the legislature in the employment of means which are reasonably calculated to protect the health, morals, or safety of the public is very great, and so long, as it does not infringe upon the inherent rights of life, liberty and property, either directly or through some limitations upon the means of living or some material right essential to the enjoyment of life, its determination is conclusive upon the courts. And, while the State can not assume to be the guardian of morals, it has the undoubted power to enact measures calculated for the suppression of such form of vice as threaten its welfare by generating disease, pauperism and crime. No right secured by the fundamental law is interfered with or impaired by this legislation relating to opium, because the possession and use of the drug are not restrained thereby, so as to destroy its value as a remedial agent, its only recognized legitimate use. The principle maintained by some courts that the legislature can not make it a crime to have in one's possession intoxicating liquors, although it may regulate, or even prohibit, the sale and disposition thereof, the court declares has no application here.

**Drill Regulations for the Hospital Corps, U. S. Army.**—The new drill regulations will probably be issued before this paragraph is in print. The board of officers to whom the revision was entrusted consisted of Majors Hoff and Havard and Captain Cabell. The booklet is of the same size and style as the last edition. There is practically no change in the methods of falling

in the detachment, or of marching and maneuvering it without litters; but it is to be noted that officers will not hereafter wear swords at drill, and hospital stewards and acting stewards will wear the belt but no equipment of any kind unless specially ordered. In paragraph 48, which describes the recently adopted hand litter, is the first notable change from the old regulations; and paragraph 49 which formerly read: "One pair of regulation slings is permanently attached to each litter" now reads: "One regulation sling is issued to each private as part of his equipment." On this change is based the material changes in the new drill regulations. With the slings fixed on the handles of the litters the bearers at every command to lower litter had to become unhitched from them and at every lift litter they had to get into harness again and have it adjusted, while in many of the movements the bight of the sling when not on the shoulders of the bearer had to be looked after specially to prevent its getting in the way. With the present individual slings the bearers have merely to slip the loops of the sling on or off the handles when they want to lift or lower the litter, and as the bight is always on their shoulders it is never in the way. This simplifies the drill greatly, and it is in fact a return to the method of the Leavenworth board, published in 1890, the fixed sling now discarded having been introduced in 1893. The illustrations, with the exception of the diagrams for the marchings, are all new. The slings on the men, the new style of army cap and the absence of the large sword bayonet-like knife give the members of the hospital corps an unfamiliar appearance.

**Diaphragmatic Hernia.**—S. M. Fortier, M.D., reports a case in *N. O. Med. and Surg. Jour.*, July: Patient, a colored male, aged 41 years, states that until two weeks prior to his admission in hospital, he has never been sick. At above mentioned time he was stricken with severe abdominal pain, which necessitated his abandoning work. His condition grew steadily worse, pain more acute, constipation, distension of the abdomen supervening, and exacerbations of vomiting were noted. Examination at the hospital: Conscious and answering questions rationally, but intensely collapsed; abdomen much distended, especially in left hypogastric region. Percussion revealed a tympanic sound, extending to the lower border of the fourth rib on the left side. Auscultation showed an absence of the vesicular murmur. Auscultation of the opposite lung revealed a supplementary puerile respiration. Heart sounds normal, although rapid and tumultuous; apex beat displaced slightly toward the right. Patient complained of a dull pain in the umbilical region, followed at times by lancinating pains. Dyspnea marked, not persistent and progressive, but coming on in paroxysms. Hiccough, a permanent and distressing symptom, was accompanied, at times, by vomiting. Deglutition, although easy, was followed by immediate vomiting. Any movement on the patient's part would aggravate the symptoms. An enema of soap and water was administered, high up, through the rectal tube, but with no results. The diagnosis of intestinal obstruction was made and the patient transferred to the operating room. His condition was so alarming that it was deemed inexpedient to interfere surgically. Pulse 150; respiration 45; temperature subnormal. The patient was surrounded with cans of hot water and stimulants given. He rallied under this treatment, but died the next day. Autopsy: Great distension of the transverse and ascending colon and cecum was observed. Descending colon collapsed. The obstruction was found to be due to the passage of the colon through the diaphragm, to the left of the median line and behind the central tendon. It was impossible to remove, by traction, the intestines from the thorax, as a previous inflammation, following gangrene of a portion of the strangulated gut, had firmly agglutinated the adjacent structures. The left lung was collapsed, the pleura forming a part of the hernial sac; adhesions

were firm, especially in the fifth interspace, and pointing of the sloughing gut was observed to have taken place in this region. This report shows the difficulty of the diagnosis of diaphragmatic hernia.

**Kroencle's Surgical Experience with Carcinoma of the Stomach.**—In sixty-seven cases (patients from 27 to 66 years of age), twenty-six were inoperable; in twenty-two cases he performed exploratory laparotomy; in four gastroenterostomy, and in fifteen resectio pylori. In one of the latter 13 cm. of the small and 22 cm. of the large curvature were resected. The patient is now, a year and a half after the operation, pursuing his usual occupations in good health. Of the rest, four died and ten recovered. Five still survive without a relapse; two died from intercurrent diseases, and four had relapses after an average of 597 days (one after 794 days). The immediate deaths were due to collapse in two cases, in one to inflammation of the lungs, and in another to gangrene of the lungs and peritonitis following necrosis in the region of the suture. He recommends morphium ether for the necrosis, and the strictest asepsis. The preliminaries, emptying the stomach and bowels, are to be as limited as possible. He remains loyal to the Billroth-Wölfler method as superior to all others, and asserts that Kocher's success in his operations is due to his fine technique rather than to his method. He gives a little milk and tea the day after the operation and abandons rectal feeding the fourth day. In only one of the four cases of gastroenterostomy was the result satisfactory; the vomiting and distress passed away for three months, when death ensued. He urges a more accurate knowledge of the indications of this operation. Six of the cases of carcinoma that seemed operable but were not operated upon, survived an average of 209 days, the inoperable 77 days, and after exploratory laparotomy 139 days. The article in the *Beiträge zur klin. Chir.*, Vol. XV, No. 2, is completed with photographs of the preparations made of the cases.—*Centralbl. f. Chirurgie.*

**Injections of Carbolic Acid in Scrotycysts.**—Dr. Victor H. Coffman advocates its use in preference to the knife or irritating injections of iodine, on account of simplicity of application, efficiency and freedom from danger. His method of treatment for hydrocele is as follows: By the use of the hypodermic syringe, one dram of 95 per cent. solution of pure carbolic acid, inserted into the superior part of the tumor, guarding the superficial veins of scrotum, is injected forcibly into the sac without previous evacuation of the fluid. Should the tumor be excessively large, two drams will be necessary for the first treatment; withdraw the syringe slowly after two minutes, preventing escape of fluid, apply a little vaselin to the surface, or mop the parts with alcohol if any of the acid has escaped, put on a dressing of gauze to protect from oozing, and the patient is permitted to go about his occupation, no risk incurred or pain endured. Within twenty-four hours a slight reaction follows, which lasts from two to five days, and the size of the tumor diminishes gradually. Should it not recede, then repeat the injection, and within one month all traces of enlargement disappear. For bursa of the patellar tendon, a dram of acid is injected, and a second injection of one-half dram, five days thereafter, is necessary in about one-third of the cases.—*Western Med. Review*, July.

**The Mauser Rifle in the Cuban Revolution.**—The *London Lancet* quotes an article in the *Revista de Ciencias Medicas* of Havana, written by Surgeon Enrique Pedraza of the Spanish Army, on the effects of the Mauser projectile as seen by him in the present war. He points out the great difference which exists between this and the older forms of projectile, as the Remington and Freire Brul. These latter being much larger and having a smaller initial velocity cause large openings and carry septic materials into the wounds they make which are therefore very difficult to render aseptic on the field and consequently when

they come under proper treatment in a hospital are in a condition which is very difficult to manage, especially when, as is frequently the case, the hemorrhage has necessitated the use of perchlorid of iron which increases the size of the wound, or when a bone has been hit, and, as usually happens, even at a distance of 100 or 150 yards, is shattered. The Mauser projectile as issued in the Spanish army is 3 centimeters in length and 7 millimeters in diameter, and consists of a hard nucleus of lead and antimony coated with steel, outside of which is a coating of nickel and copper alloy, the whole weighing 13.7 grams and having an initial velocity of 632 meters per second, which enables it to pierce a Krupp steel plate 10.5 millimeters in thickness at a distance of 50 meters. Such a projectile ought, it might be thought, to produce a clean and minute wound with little hemorrhage, easy to close on the field and therefore likely to heal rapidly in the hospital, more especially as the bones would be bored rather than shattered and as there would be little chance of foreign matter being introduced into the wound by the projectile itself. These expectations are, however, by no means always realized, and the first few cases of primary wounds from a Mauser projectile which Dr. Pedraza saw at Manzanillo very greatly surprised and disappointed him. With longer experience, however, he learned that the benign results he had expected to see do occur, but only when the enemy is 150 yards or more distant. When the patient is shot at from ten to seventy yards the destruction of the tissues is very great, and it is this that has given rise to the suspicion that explosive bullets were being used, especially as the orifices of entrance and outlet are sometimes so small that they can scarcely be seen. The explanation suggested is that the shock which the enormous velocity of the projectile produces on entering the soft parts causes them to behave as a fluid or semi-fluid does when enclosed in a box and "shot through," the hydraulic pressure bursting the sides, or if an opening be left, driving a column of the fluid through it. As to how far any destruction of the projectile itself may be a contributing factor he has no direct evidence, but from specimens he has seen of the Wagner and Mänlicher projectiles after experiments made by Dr. Cardenal, which he showed at a lecture before the Cataluna Academy of Medicine, he thinks it probable that the projectiles do become more or less disintegrated when they hit at short distances. In striking contrast to such wounds are those produced at 150 yards or more by the Mauser rifle. Here the entrance and outlet are very small and there is but little evidence of internal destruction, even bones being tunneled through without fracture, and as aseptic treatment is possible from the first a rapid recovery may usually be anticipated. Thus, in one case where the projectile entered the abdomen in the eighth intercostal space on the right side, passing through the stomach and coming out three fingers' breadth on the left of the sternum, though the ninth rib was fractured and the patient suffered from vomiting, hematemesis and fever, he very soon improved and recovered completely. In another case the projectile entered the left frontal eminence passing out by the right parotid region. The patient suffered from concussion of the brain, with some difficulty of vision of right eye, but recovered in twenty-six days. If, therefore, it could be arranged that fighting should never occur at less than 200 yards distance the Mauser would, Dr. Pedraza thinks, be a most humane weapon.

#### Hospitals.

**THE GERMAN HOSPITAL, SAN FRANCISCO, CAL.**—At the regular July meeting of the board of directors the following staff of physicians was elected for the German Hospital: Visiting physicians, J. F. Morse, H. Kreutzmann, G. Dresel, R. Baum; consulting physicians, Beverly MacMonagle, W. A. Martin, D. W. Montgomery, L. Newmark, M. Regensburger, Paoli de Vecchi, A. Wilhelm. Max Saloman retains the position held by him for the past two years as city physician of the society.

**CITY HOSPITAL, MARQUETTE, MICH.**—The new city hospital threw open its doors to the sick of the city July 13. The following named physicians compose the staff: Geo. J. Northrup, A. Desjardins, O. G. Youngquist, F. McD. Harkin, A. A. Foster, J. H. Dawson, E. B. Patterson, C. G. Dick, H. J. Hornbogen.

#### Louisville.

**ANTHRAZ.**—An epidemic of anthrax has been found raging in the herd of milk cows owned by a dairyman in the western portion of the city, a number of deaths having occurred among them. The health authorities have taken the matter in hand and have isolated the herd, burned the carcasses and are boiling and burying the milk from the rest of the herd. Thus far the trouble has been limited to this one herd and no serious spread is anticipated, owing to the prompt action of the city and State officials.

## THE PUBLIC SERVICES.

**Army Changes.** Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from July 18 to July 24, 1896.

Capt. Paul Clendenin, Asst. Surgeon (Ft. Warren, Mass.), is hereby granted leave of absence for one month.  
Capt. Edgar A. Mearns, Asst. Surgeon (Ft. Myer, Va.), is granted leave of absence for three months, to take effect on or about Aug. 3, 1896.  
Capt. Geo. E. Bushnell, Asst. Surgeon, extension of leave of absence granted is further extended one month.

**Navy Changes.** Changes in the Medical Corps of the U. S. Navy for the week ending July 25, 1896.

Asst. Surgeon L. Morris, detached from Indian Head proving ground, ordered home and granted one month's leave.  
Asst. Surgeon F. C. Cook, detached from treatment at the New York hospital and ordered to proceed home.  
Medical Director G. H. Cook, detached from special duty at Philadelphia and ordered to take charge of hospital there.  
Medical Director D. Kundleberger, detached from duty in charge of hospital at Philadelphia, ordered home and await orders.  
Medical Inspector W. G. Farwell, ordered to special duty at Philadelphia attending officers.

#### Change of Address.

Armstrong, C. L., from La Due to Webster Grove, Mo.  
Berling, A. E., from 360 Blue Island Av. to 512 Ashland Boul., Chicago, Ill.  
Burns, R. J., from Rockford to 101 Galena St., Freeport, Ill.  
Bishop, L. F., from Morriatown, N. J., to 30 W. 86th St., New York, N. Y.  
Habermaas, A., from 3154 Shenandoah Av. to 3317 S. 18th St., St. Louis, Mo.  
Luebbera, A., from Dallas, Texas, to 2432 Larimer St., Denver, Colo.  
Makeun, G. H., from Philadelphia to Crescon, Pa. (until September 15).  
Prentiss, D. W., from Aix la Chapelle, Germany, to Zurich, Switzerland.  
Rockey, A. E., from The Marquam to 671 Giffon St., Portland, Ore.  
Rohé, Geo. H., from Catonsville to Sykeville, Md.

VOL. XXVII.

CHICAGO, ILL., AUGUST 8, 1896.

No. 6.

## ADDRESS.

### CHAIRMAN'S ADDRESS.

Delivered in the Section on State Medicine, at the Forty-Seventh Annual Meeting of the American Medical Association at Atlanta, Ga., May 5-8, 1896.

BY CHARLES H. SHEPARD, M.D.  
BROOKLYN, N. Y.\*

*Fellow Members:*—It was both with diffidence and reluctance that I accepted the honor and obligations of the chairmanship of this Section, a place which has been held by some of the most distinguished and gifted members of the AMERICAN MEDICAL ASSOCIATION, and for the time being I rely upon your patience and generosity.

The amount of useful information that has been diffused from this Section since it was first organized, has been possible only by the indomitable energy and self-sacrificing work of those who have labored in its field. They have plowed and sowed, and while we gather the fruit of their labors, it is also incumbent upon us to do our share in the promotion of the work.

Unfortunately, outside of the medical profession, but comparatively few minds are possessed of a practical knowledge of sanitary matters. Hence the necessity of continually reiterating and disseminating what many of us consider the most commonplace truths, until their full acceptance shall render our land a sanitary Eden.

The healing of disease is a most noble work and worthy of all praise, but he who teaches how to prevent disease is engaged in a higher and holier cause. It is not a question of how far it is well to go in destroying one's own business, for the lover of his race realizes that his own higher interests are bound up with the welfare of the people. We are now in the kindergarten state of knowledge regarding many of the most important sciences that bear upon the prevention of disease. Far reaching as recent developments appear to be, the glory of those yet to come will undoubtedly cast them into the shade in the distant future. It is a matter for which to be thankful that one is able to devote a life to the advancement of ideas that may prove of incalculable benefit to mankind.

The ideal physician would be the State physician, whose position and income assured, would enable him to devote his entire time and best powers in seeking the highest interests of the community in the prevention of disease.

For ages men have sought for a panacea. New remedies become candidates for public favor with surprising rapidity, and are popular for a time, only to be displaced by a new candidate. Strive as we may, we are convinced that never will a remedy be found to obviate the penalty sure to be exacted by violated law. Preventive medicine will teach people how to live, and then ignorance and panaceas will die

a natural death. This is worthy of the earnest attention of the ablest minds, and will produce most important results. The loss of time on mere effects, instead of the original causes of disease, is like giving attention to the branches, instead of striking at the root of the deadly upas tree.

The first work on preventive medicine was furnished us by Moses, the great lawgiver, nor has it yet been surpassed by any modern discoveries. Granting all that is claimed for antitoxins of various kinds, and for vaccination as a preventive of smallpox, these are but so many milestones in the progress of preventive medicine, which shall yet lead to the cause of the original disturbance. Diphtheria, scarlet fever, etc., are filth diseases, and smallpox belongs preëminently to this class. Preventive medicine, with the aid of personal hygiene, will yet enable us to avoid all filth diseases of whatever kind.

As Rome carried civilization with her conquests, so shall preventive medicine, and this Section, as its representative in the AMERICAN MEDICAL ASSOCIATION, continue to diffuse a saving knowledge of human life in its all-conquering march.

It is well to look back occasionally, in order to measure our progress. Among the subjects which have been advocated by this Section were soil drainage and improved systems of sewerage, the better housing of the poor in our cities, the registration of vital statistics, civic cleanliness, quarantine reform and, more recently, improved pavements and public baths.

History tells us that sanitary measures, methodically carried out, are invariably followed by improved public health and a decreased death rate. But for the important sanitary measures carried out by the rulers of Rome, the eternal city would never have become the mistress of the world. Had it not been thoroughly drained, a large part of it would have been uninhabitable. The sanitary works of Rome, introduced when she was at the acme of her glory, have been a model for ages past, and will so continue for ages to come. Her enormous aqueducts, particularly those built by Agrippa, were virtual rivers brought into the city to flush the streets and sewers, and to supply all public and private requirements.

Before the streets of London were paved the inhabitants were as great sufferers from periodic fevers as are those of the most unhealthy rural districts in our own country. It has been computed by an eminent authority, Sir Lyon Playfair, that in one county alone in England, the pecuniary burden borne by the community in the support of removable disease and death, amounted to the annual sum of twenty-five millions of dollars.

After the paving of Dijon, the ancient capital of Burgundy, in the middle of the fourteenth century, dysentery, spotted fever and other diseases, became of less frequent occurrence in that city.

The evils of a certain form of modern architecture in our cities is a growing one that should be thoughtfully considered. The crowding together of tall buildings, necessarily depriving the lower floors of proper sunlight and ventilation, is one of the modern aggressions that is not of unmixed benefit, even in a business sense, involving the health of the occupants of all such buildings. The deficiency of sunlight and insufficient ventilation common to these structures, seriously affects the eyesight of multitudes, and the depressing effect of confinement and labor in the vitiated atmosphere, under such circumstances, render the occupants fit subjects of temptation in the shape of tobacco and other narcotics to satisfy the craving for the absence of the healthful stimuli of fresh air and light and thus render them liable to disease in every shape. The height of buildings should be in proportion to the width of the street. As a prominent and conscientious architect, Ernest Flagg, has well said in the May number of the *Cosmopolitan*: "It is best in this matter to place a curb upon private greed for the public good."

The disposal of the sewage of cities is a subject that is demanding more and more attention, for what now goes to waste, to the pollution of rivers and obstruction of harbors is a menace to health, besides being a pecuniary loss to the community. Sewage should instead be so disposed of as to be devoid of danger, and a profit to the city.

From its noiselessness, cleanliness and consequent comfort, the improvement of street pavements by the use of asphalt is intimately related to the health of the community, and this was strongly urged by Dr. Bell, in the *Sanitarian*, over thirteen years ago. It is now rapidly growing in favor, and making way for the horseless carriage which is to banish to the country districts the horse and his insanitary surroundings.

It is proper here to refer to the *Sanitarian*, the first journal in this country devoted to sanitary subjects, as the source from which I have been able to glean many facts on the progress and present status of preventive medicine in the United States, and also to the editor who projected that periodical in the same year that this Section was organized, and of which he was the first chairman twenty-three ago. This publication presents essays by the most distinguished sanitary authorities on a great variety of subjects, and the gist of sanitary medicine in all its phases.

Dr. Bell's activity as a sanitary reformer prevented the yellow fever from reaching the city of Brooklyn from Bay Ridge and Fort Hamilton in 1856. He fought against the quarantine system as it then obtained, and succeeded in reforming it on the basis of the regulations which he devised and reported to the National Sanitary Convention in Boston, in 1860. He devised measures in detail relating to departure, as the primary means of preventing the conveyance of infectious diseases from one place to another, and their introduction into new places. Moreover he instituted and successfully practiced, under the auspices of the National Board of Health, measures which prevented the yellow fever from being conveyed to other places from New Orleans, in 1879, without restricting commerce, and with the result of raising all the quarantines against that city within six weeks.

In a contribution to the Report of the New York Board of Charities for the year 1876, on the "Rela-

tion of Insanitary Conditions to Pauperism, Vice and Crime in New York," Dr. Bell suggested a mandatory law requiring assessment, seizure and destruction, at public expense, of a stated few of the worst tenement houses in the city and the conversion of their sites into grass plots, annually, as an efficient means of reform; means that would not only weed out the worst from year to year, but continually promote the improvement of the remainder, whose proprietors would not allow them to be destroyed, and the legislature has recently conferred the power of so doing, in a modified form, on the health authorities.

Municipal sanitation in New York and Brooklyn on a scientific basis, began thirty years ago, under the auspices of the Metropolitan Board of Health. The average death rate in New York, per 1,000 of the population, for the ten years preceding that date was 33.39; for the first ten years following it was 29.70; for the ten years ending December 31, 1894, it was 25.48. The death rate for 1895, according to the last report from the State Board of Health, was 18.25 per 1,000. Surely it would be difficult to find more significant results of practical sanitation equivalent to saving of about eight lives per 1,000 of the population, annually, and amounting in the aggregate, measured by the present population and death rate, to 14,464 lives annually.

One of the most imperative necessities for preserving the public health is an ample supply of pure water, and it is to be hoped that some better medium than lead pipe will soon be found for conveying drinking water through our houses. The more pure the water the more it acts on the lead to absorb the poison, and therefore it becomes the more dangerous. Possibly aluminum may come in to supply this pressing need.

The character of the public water supply is the first and chief concern of every intelligent sanitarian, for in that lurks the means of transmission of all the most virulent and fatal of the infectious diseases. As population increases the sources of contamination multiply and it becomes more and more difficult to secure an abundant supply of pure water. Rain water falling upon the earth's surface becomes more or less contaminated from the soil, with mineral matters, which it holds in solution, and should be used with caution. The home of the most deadly of the microscopic enemies of man is water. Many of the epidemics that have desolated different countries have been caused by the use of impure water. Cholera, typhoid fever and dysentery are fostered and disseminated almost exclusively through the medium of drinking water.

While the use of water ranks high as a remedy for many diseases, its greatest value is in the prevention of disease. Never was the true theory of disease understood until it was put forth by the advocates of the hygienic system of treatment, otherwise called water cure, which was very popular about the middle of this century. While not now conspicuously prominent as a separate system it has had a powerful influence in modifying the practice of all the other schools. Disease was known only by its phenomena and medicines by their effects. The true definition of disease is remedial effort, an action to cast out impurities. It wastes vital power, as a man would expend his strength to eject a thief from his premises. When people understand that disease is a vital struggle in self defense they will cease to fear it. They will fear only

its causes and instead of trying to suppress the symptoms will endeavor to remove the causes. Disease and the *vis medicatrix nature* are one and the same thing. When in the progress of knowledge it comes to be understood that in all relations between living and dead matter, the dead is passive and the living active, then the application of this truth to foods, remedies and poisons will settle many vexed questions and place mankind on the high road to perfect health.

It would be a profitable investment for any city which is suffering by reason of a polluted water supply to expend all the money that may be required for the substitution of a wholesome supply, either by going to new sources or by purifying the supply on hand. This can be demonstrated easily by figures that men of ordinary intelligence would be obliged to accept. The loss to several cities throughout our land from typhoid fever during the past year which has been traced to the water supply has emphasized this fact. A few of the cities have taken up the work of purifying their water by filtration, and in every case the decrease in the death rate has been most satisfactory and warranted all the outlay. This is a work that should be carried out by the cities in their corporate capacity rather than left to private enterprise. Where all are to be benefited all should be interested.

It is but trite to say that the Section on State Medicine has a most comprehensive work on hand, including as it does, preventive medicine, public hygiene, public baths, street paving, together with cleanliness of the streets, disposal of the garbage, factory inspection, cattle inspection, milk inspection, employment of child labor, cremation, etc. I will trespass on your time only to refer to a few facts in preventive medicine.

The camera and the bicycle, by calling people out into the open air, and giving them pleasant occupation and mental stimulus, is doing more to prevent disease than all the doctors in the land. We may be very thankful for the sudden popularity of the bicycle, in that it has given a wonderful impetus to the question of good roads.

The blessings of sunlight and fresh air should be more appreciated. The sun is the godfather of us all. The source of all light, heat, electricity, and energy, what wonder that it was once worshipped as the Creator. The future will recognize it not only as the best disinfectant, an all powerful preventive of disease, but also as a wonderful healer of disease. The more people can be taught to live in pure air out of doors, and bask in the rays of the sun, the less of disease there will be to prevent.

The Women's Health Protective Association of Brooklyn, N. Y., is doing a most useful work by preventing litter in the streets, by burning of garbage, and more and above all by endeavoring to abate the nuisance of expectoration in the public streets and conveyances. When that is accomplished there will be less of disease floating in the air ready to be inhaled at every breath.

The study of the microscope is gaining new impetus every year and giving us more and better information in regard to the minutiae of life. The knowledge of microbic life is so intensely attractive as to absorb the whole time of many students of eminent degree, and the wonderful results developed have many times astounded the world, and will in many ways help to prevent disease, by teaching us what to do in emer-

gencies, and yet what is now known may be considered as but the forerunner of what is to come. New facts have been so rapidly developed as to dazzle the imagination with their possibilities.

Already have the X rays, lately discovered by Roentgen, produced a profound impression upon the public mind. The correct view of this new radiant energy will undoubtedly soon be formed, when new experimental data appear. In the meantime we can rest assured that a new entrance to the region of the ether phenomena has been opened, and the importance of this fact can hardly be overestimated. It may be that the rays will be proved identical in kind with vibrations of light, heat, or electricity, already well known. It may be on the other hand, a new form of energy. It is easily possible that the new photography, when fully developed, may reveal to us secrets of cellular growth, glandular activity, and the like, that have hitherto proved inscrutable. The power of looking through a man, as reported by Mr. Edison, may yet lead to still greater discoveries in the prevention of disease.

No more desirable work has been done by any board of health than in looking after the adulteration of food, as in Ohio for instance. Of all the liars in existence, none are worse than those who advertise to furnish food or medicine and really deal out that which is bound to cause disease and leave ruin in its path. If there was a soul above filthy lucre in the patent medicine vender there would be none of this. To protect the ignorant public is the god-like mission of State medicine. But when we get pure food, much of it needs cooking, and cooking schools are immensely useful as a preventive of disease, not alone to prevent the waste of valuable portions, but also to be able to derive therefrom sound tissue for the building up of the entire man into his most vigorous condition.

The bad work that people make in dosing themselves with patent medicines, without a physician's prescription, is not unfrequently punctuated with a sudden death from overdosing with antipyrin, sulphonal, or some other coal-tar preparation. Children should not play with edge tools. The teachings of preventive medicine will do away with such work.

Another thing in which it is most desirable that the public should be enlightened, is the imperative need of rest, instead of what is called stimulation; that what are called tonics or stimulants are used only at a ruinous expense to the vitality, and if people would take time for recreation and recuperation, they would obviate the necessity for their use and prevent more disease than ever was cured.

If ever our people are to be redeemed from the thralldom and unmitigated and unlimited curse of tobacco using, it must come from the teachings of preventive medicine.

There is an immense amount of ignorance abroad in the community on the subject of health and the proper way of living to secure the best physical condition, and there is a corresponding need for instruction in such matters. That is why the charlatan has such free play in this country. One of the most important of all studies for old and young is that of personal hygiene. This it is that protects from personal contagion. This do and thou shalt live! That do and thy body shall become a fertile breeding ground for all manner of disease! The earlier in life this is recognized the more surely will success crown man's daily pursuits.

In fact, the very best preventive of all disease is a condition of well nourished physical purity, combined with a mental and bodily alertness that leads to the enjoyment of all good work. Such a one can walk through pestilence unharmed, will live out all his days, and, barring accidents, be gathered in when his full time shall have come, like a shock of corn fully ripened.

The delights of mental pursuits, in calling its devotee out of himself to the attainment of certain truths or facts and the vantage ground gained by every such conquest, giving broader field and more expansive view with intensified joys, place mental pursuits among the more desirable means for preventing disease and prolonging life.

The multiplication of intellectual entertainments and resources, that give the people something to think about and occupy their minds to the exclusion of things of a lower grade, is to be welcomed by all who place a higher faith in prevention than in cure. We very well know that if we can fill the minds of the young with the good, there will be no room for the bad.

Laugh as we may at the vagaries of the teacher of what is called mental science, there is a germ of truth at the foundation of it all. The mind reacts upon the body as well as the body upon the mind. We can magnify or minify our troubles; therefore if weak and delicate invalids can be made to believe that they are to get well, they are thereby in a better condition to become well. So also with one who girds himself up to face disease and disaster. He is by so much less liable to the disease or disaster, and should it overtake him he is better fitted to cope with the emergency.

The little that has been accomplished is but the forerunner of what is to come. The time is not far distant when the people will demand that all these desiderata shall be taken up in a manner commensurate with their importance, and then public baths will be made as free to the people as the postoffice and the public school. Good roads will be uniformly extended throughout our country, and kept in proper condition. Dwelling houses, and business houses as well, will receive their full modicum of sunlight and ventilation, pure water will abound, and excreta, along with garbage, will be disposed of with advantage to the community. Our public schools will be well lighted and ventilated, the children will be taught the evils of the indiscriminate use of narcotics of all kinds, and the pupils will not be overworked by a too cumbersome curriculum.

It will be a happier day for all when the people in their representative capacity shall take charge of all vagrancy, see that all who can labor shall have the opportunity, and those who are disabled properly cared for. This also is preventive medicine, and is but coöperation, wherein the people shall demand reforms to be carried out by the government, which is, or should be, but the expression of the will of the people. Thus will state medicine fulfill its highest duties. By some this might be called socialism, but the whole world is traveling that road. Our AMERICAN MEDICAL ASSOCIATION is but a step in coöperation by liberal minded men, lifting us for the time being out of the slough of competition, and our Section on State Medicine is preëminently socialistic in that it seeks the benefit of the mass through the power derived from the people in their collective capacity.

If ever legislation regarding public questions shall be elevated above the plane of practical politics or personal gain, we may obtain some results that will help to promote the best interests of the community, instead of, as at present, being made the foot-ball of conflicting parties.

Let us bear in mind that we are responsible for this condition of things, that it is every physician's duty to take an active and intelligent part in all political matters, and not leave them to the ignorant and vicious. When this is thoroughly carried out, and direct legislation comes in, a new era will be inaugurated.

A bill has been introduced in the Senate, creating a new cabinet officer who shall be known as Secretary of Manufactures and Commerce, and certainly this is of great importance to all of our industries, but of still greater importance would be a Secretary of Public Health, for if the health of the community is not assured, the industries are of small account.

While State medicine has saved the world from an immense amount of charlatanism and superstition regarding avoidable disease, there are larger fields and higher ground waiting for occupancy by the interested students who are to bless the community by their new discoveries. The range is too vast for any one department, but all will combine in this, that their work shall bless and lengthen the days of man, for all the achievements of the true physician are the common heritage of mankind, and thus is he to become one of the most potent of all the civilizing agencies of the future. This forward march is to go on, and blessed are we who are permitted to take part in the work, insignificant though that part may be.

During the past year the harvest of death has been very great in the ranks of medical men, particularly among the younger members, leaving gaps that will be hard to fill. The demands of modern society are too exacting, and the results of the pace that kills are sometimes realized too late. From out of our own ranks have gone Dr. Joseph Jones of New Orleans, Dr. James E. Reeve of Chattanooga, Tenn., and Dr. C. G. Comegys of Cincinnati, Ohio. They rest from their labors, and we shall see them no more, but the bright example of their noble work will remain to bless all the land.

Gentlemen, I am proud that you have thought me worthy to assist in your deliberations, and shall enter upon the duties of our session with an earnest desire to forward the good work.

Hopefully then, do I commit to your hands the pleasant task of spreading over this vast country the ennobling light of your wisdom and experience.

---

**Excessive Doses of Bicarbonate of Sodium in Hyperacidity of the Stomach.**—Tournier relates a couple of cases of intense gastric pain caused by hyperacidity, relieved by large doses of bicarbonate of sodium, with no accompanying inconveniences. The amount prescribed was 20 to 30 grams a day, which the patients increased to 60 and 65 grams, before obtaining permanent relief. The male patient continued these large doses for two to three years, securing a permanent cure, with no return of the gastralgia in the four years since. The other case was a young woman, who took at last 60 to 65 grams for a month, with the result of much improved gastric conditions and a gain of three kilograms in weight. She took the soda in a powder every half hour, followed each time with a little milk, of which she carried a small bottle with her when she left home. The elimination of chlorid of sodium in the urine amounted to 36 grams per liter, testifying to the actual transformation of the sodium in the organism.—*Province Médicale*, June 27.

## ORIGINAL ARTICLES.

INTESTINAL OBSTRUCTION AFTER  
LAPAROTOMY.

Read in the Section on Obstetrics and Diseases of Women at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY HENRY O. MARCY, M.D., LL.D.

BOSTON, MASS.

The internal hernia, so-called by the early authors, possesses an entirely new and increased interest, since intestinal obstruction occurs more frequently than formerly, as a sequel to the surgical invasion of the abdominal cavity. I believe also that this is a far more common cause of death than usually supposed, since the success attending the surgery of the abdomen has emboldened many surgeons to undertake a great variety of operations, considered unwarranted a decade ago.

Before entering into any general discussion of the subject, it has seemed instructive to give a brief report of all the cases of intestinal obstruction following laparotomy, which have come under my observation.

*Case 1.*—Mrs. C., aged 31, married, has three children. April 14, 1890, I removed a dermoid cyst of the left ovary weighing eight pounds. Right ovary size of an egg, capsule thick and friable. Peritoneum covering pedicle parted easily under constriction of the suture. Marked nausea after etherization. The stump was touched with liquid carbolic acid and covered with iodoform. The uncovered peritoneum was scarcely larger than a split pea. Convalescence comfortable, with primary union of the abdominal wound, which was closed without drainage. Bowels moved the third day; kept open by saline laxatives. On the seventeenth day symptoms of intestinal obstruction supervened, with nausea and vomiting, slowly becoming more pronounced. On the twenty-second day it was evident that grave danger was imminent, every effort to evacuate the bowels having proved futile. Assisted by the late Dr. Trenholme of Montreal, I reopened the abdomen and found two loops of the lower portion of the small intestine firmly adherent to the stump of the right ovary. The adhesions were separated with difficulty. The intestines were not very much exposed, and yet the shock was very pronounced and for some hours danger of death seemed imminent. Convalescence was slow but satisfactory. The patient remains well up to the present, entirely free from abdominal pain.

*Case 2.*—Mrs. L., aged 35, married, has borne children. General health fair. On July 13, 1892, I performed vaginal hysterectomy for cancer. Operation less difficult than usual. The broad ligaments were constricted by clamps which were removed the second day. The third day nausea and vomiting supervened, rapid elevation of temperature and death occurred on the fifth day from intestinal obstruction, not clearly recognized until autopsy, since it was believed that septic peritonitis was in process of development. On examination it was found that a loop of the lower portion of the small intestine was adherent to the stump of the right broad ligament, but the lymph adhesion was easily separated. The intestine above was filled with a large quantity of dark-colored fetid fluid, and it is believed that the symptoms of septic poisoning came from the absorption of the products of decomposition of this fluid. There was no peritonitis and the pelvic wound was uninfected. The adhesions could have been easily freed by an abdominal section.

*Case 3.*—Mrs. C., aged 42. General health fairly good, although she had suffered long from pelvic troubles. Two years previous I had removed the right ovary, which was cystic, resulting in an adherent tumor cocoon size. Recovery was rapid and uneventful. For six months prior to the second operation a cystic tumor of the left ovary had developed until it reached a point above the navel. Operation Nov. 28, 1892, Dr. James R. Chadwick present. The omentum was found somewhat adherent on the line of the old cicatrix. The tumor was removed with difficulty, owing to its being bound down by adhesions. Recovery from the operation was not satisfactory, shock pronounced and nausea persistent from the first. All the symptoms became slowly more aggravated, until at the end of the third day it was apparent that intestinal obstruction was threatening the life of the patient. Upon re-opening the abdomen a loop of small intestine was found

constricted by an old omental band of adhesions upon the left side, just above the brim of the pelvis. It is very probable that the intestine became entangled at the time of operation. It was easily freed and the operation was completed in a short time, but the shock following was very pronounced, the patient never rallying from it, and death supervened in a few hours.

*Case 4.*—Mrs. G., aged 52. General health good. She had suffered severely from a rather rapidly growing multiple uterine myoma, which was impacted in the pelvic cavity and extended to the umbilicus. Operation Oct. 24, 1895, assisted by Drs. H. D. Didama, Syracuse, and D. T. Nelson, Chicago. The operation was not difficult, the most noteworthy feature being that a small firm lobe of the tumor was so fixed to the right lower vaginal cul-de-sac that upon removal the adjacent peritoneum, although not bleeding, was dotted with minute red points. At the time of operation it was remarked that such a condition of the pelvic peritoneum would favor intestinal adhesions. The tumor was dissected to the cervical neck, resected and the arteries separately ligated and the peritoneum intra-folded by a running continuous buried tendon suture which left no abraded peritoneum other than the portion already described. It was deemed unwise to drain the depressed portion through the vaginal canal and for better protection it was covered freely with sterilized aristol. There was considerable shock following the operation, but the patient rallied well and for forty-eight hours gave every promise of easy recovery. Nausea and vomiting then ensued with elevation of temperature and abdominal distension. Intestinal obstruction was recognized, but the danger was not thought sufficiently imminent to warrant surgical interference, until suddenly the condition became too grave to render the procedure, even as a forlorn hope, advisable. Death occurred about seventy-five hours after the operation. Nausea and vomiting persisted to the end. Six hours before death the temperature began to rise from about 101 degrees until at death it had reached 107 degrees. Autopsy showed adhesion of the lower part of the small intestine to the punctated portion of the peritoneum. It was readily separated. The intestine about the point of adhesion was greatly distended by a large quantity of dark-colored fluid, evidently having undergone decomposition prior to death. The line of union of the intra-folded peritoneum was perfect. There had been no pelvic serous exudation and no septic infection.

*Case 5.*—Miss S., aged 44. Operation performed Nov. 30, 1895, for removal of a large adherent uterine myoma, assisted by Dr. Nelson of Chicago, Dr. Cilley of Boston, and Dr. Berrymore of St. Johns, N. B. The operation was long and tedious, followed by pronounced shock. Rallied well and on the second day the conditions seemed favorable for recovery. Nausea and vomiting commenced about thirty-six hours after the operation. Not very pronounced until twelve hours later, when it was evident that intestinal obstruction had supervened. I reopened the abdomen and found a loop of the lower part of the small intestine involved in adhesion of the omentum, situated in the right iliac region. The small intestines were greatly distended by gas and fluid, and were manipulated with some difficulty. At the time of the operation temperature was 101; immediately following the operation there was a large fluid defecation. Within an hour it was noted that she was in profound shock, from which she never rallied, death occurring some hours later. The most noteworthy feature was the elevation of temperature, which rose steadily about a degree an hour, reaching 107 degrees before death. I twice used an intravenous injection of saline solution, each time introducing nearly a pint. The flagging heart immediately responded, giving a comparatively slow, full, compressible pulse. The effect, however, soon subsided, notwithstanding the use of digitalis, strychnin and nitro-glycerin, used freely hypodermically.

*Case 6.*—Mrs. K., aged 34, never pregnant, married eight years, advanced cancer of the cervix from which she had suffered severely in her general health. Vaginal hysterectomy Dec. 7, 1895, assisted by Dr. C. E. Miles of Boston. Operation difficult, owing to a long narrow vagina and the extent of the disease. I sutured the broad ligaments and introduced gauze drainage. Convalescence seemed well established the tenth day, when symptoms of intestinal obstruction supervened. Upon opening the abdomen a loop of the lower portion of the small intestine was found incarcerated by an old band of adhesions which crossed the pelvis in the region of the right ovary. This was easily divided and the intestine freed. The abdominal wound was closed without drainage. Fecal evacuations soon followed with speedy relief. The shock following the operation was pronounced, but the convalescence was uneventful. The patient is well at the time of writing.

*Case 7.*—Mrs. D., aged 42. Very nervous organization, but in fair general vigor, although a severe sufferer for some years

from a retroverted, adherent, enlarged uterus, cystic ovaries and diseased tubes. The bowel had been freely evacuated, only fluid food in small quantities often repeated given for some days before the operation, with as large quantities of water as could be easily taken. Operation March 18, 1896. It was difficult, owing to the imbedding of the diseased adnexa in the pelvic cavity. After the removal of the diseased structures, the enlarged, retroverted uterus was brought forward and sutured upon each side to the abdominal wall. The pelvic peritoneum was reformed by lines of buried tendon sutures, leaving only a small portion of the fundus of the uterus uncovered, which was partially denuded of its peritoneum, owing to old adhesions. The small intestines were covered by the omentum with great care, the fundus of the uterus dusted with sterilized aristol and a vaginal drain of iodoform gauze carried through the posterior cul-de-sac into the vagina. Patient rallied well from ether. The night following the operation was comfortable. Nausea and vomiting ensued on the morning of the 19th, with a singular weakening of the heart's action, followed by rapid elevation of temperature, reaching before death 107 degrees. The skin was mottled with dusky patches some hours prior to death. These conditions were believed to be due to intestinal obstruction. The gauze drain was withdrawn and an effort made to examine the pelvis through the opening, but without avail. The general condition forbade reopening the abdomen. Regardless of every effort the patient died about forty hours after the operation. The autopsy showed a loop of the lower part of the small intestine attached to the fundus of the uterus, which was separated with the greatest ease. The intestine above was filled with several pints of a very fetid, dark-colored fluid believed to have undergone decomposition prior to death.

The cases reported were all operated on under the most favorable of hospital appointments and with the very best of attendant care.

I purpose to confine myself to the salient points offered in a review of the cases just reported.

*Anatomic Relationship.*—It will be noted that the portion of the intestine involved in the obstruction in each case was the lower part of the ileum, and that the obstruction was caused either by an adhesion of the intestine to an abraded peritoneal surface, or by a constriction.

Owing to the erroneous teaching of a leading English authority, it has been too generally accepted that, in the normal condition, the small intestines do not descend sufficiently to enter the pelvic basin. Since it was found that more commonly the portion of the intestines strangulated in inguinal hernia was a loop of the small intestine, this author ingeniously advanced the theory that the hernia itself was due to the elongation of the mesentery, causing the dislocation of the intestinal loops, rather than to a previous weakness of the abdominal wall. The measurements made by this distinguished anatomist seemed to show that the distance from the root of the mesentery to the intestinal loops was so short that only by dragging upon them could they be pulled down sufficiently to enter the pelvic basin. I do not doubt the correctness of his observations, but it must be remembered that the postmortem rigidity and fixation of the parts furnish conditions quite different from those found during life. My studies of hernia early led me to a consideration of this subject, and my observations, based upon the examinations made in about a thousand laparotomies furnish abundant proof that the small intestines, the ileum especially, in its normal range of motion includes a juxtaposition of the pelvic structures and organs.

Here the intestines are less protected by the omentum which intervenes between them and the abdominal wall, where the omentum is interposed, and it is a question by no means settled satisfactorily, if normally the omentum lies between the basic folds of the small intestine and the pelvic structures. It prob-

ably does not and so gives easy explanation why portions of abraded pelvic peritoneum are especially liable to offer points of attachments to the superincumbent intestinal folds.

A study of the large intestines shows ample reason why obstruction does not usually occur in this portion of the intestinal tract. That part within the pelvis, and which may be more or less involved by surgical manipulation, is within easy range of digital and instrumental examination, and the solution of any complications is easily determined. Ascending above the pelvis, the remaining portion of the large intestine, because of its position, construction and relationship, only very rarely can become involved in intestinal obstruction, and as a consequence may usually be excluded in the differential diagnosis.

The mooring of the cecum is generally sufficiently fixed to preserve its relationship unimpaired, but pathologic conditions arising from the appendix are much more common causes of intestinal obstruction than was earlier supposed. Adhesive bands frequently extend to the surrounding parts, which may become causes of intestinal obstruction by producing constriction of an incarcerated loop. In one instance of intestinal obstruction, I found an abnormally long appendix encircling the small intestine near its junction, and fixed by inflammatory adhesions. This had caused a slowly developing intestinal obstruction, which had been complete for some days ending in fecal vomiting before operation. Elsewhere the intestinal canal was normal.

In three of the cases here reported, two fatal, it will be observed that intestinal obstruction occurred from incarceration of the lower portion of the small intestine, caused by adhesive bands of old formation. In the two fatal cases a laparotomy had been performed some years previous and, although both were nonsuppurative cases, adhesions had formed, probably caused by undue pressure of opposing peritoneal surfaces, owing to pathologic conditions. When, as in these cases, the omentum becomes the offending structure, I know of no anatomic guides that will lead us to the part involved. Hence, the surgeon must examine carefully a wide area, without special direction except the guidance taught by the individual history.

*Diagnosis.*—The foregoing histories teach a wide difference in the severity of symptoms from that of intestinal obstruction as usually observed in volvulus, or strangulation resulting from hernia. Here, even in volvulus, in umbilical and femoral hernia, where the symptoms are the most acute, a considerable longer period ensues before the patient is *in extremis*. In the last case reported, death occurred before it seemed possible for a fatal issue to follow from an arrest of the intestinal fluids, where also the greatest care had been exercised in emptying the intestinal tract, and preventing fermentation by use of salol, etc.

In none of the fatal cases reported, was the integrity of the intestine endangered, and it is not to this we look for the cause of death, as has usually been considered the greater danger in cases of constriction of the bowel in hernia.

To what then are we to attribute the cause of death? May it not be, in the first instance, the operation which has so lowered the vital processes, which hold their sway over the living structures, as to admit changes to ensue which otherwise would not occur?

These vitiating processes are rapidly augmented by the fermentative changes which occur in the superincumbent intestinal contents. These fluids are not extraneous, that is to say, only in very small part consisting of the ingesta, but are made up largely of the albuminoid secretions, vitiated products of the glands, together with the fluids poured out by the obstructed blood circulation. The chemic products resulting from this decomposition are crystallin and in solution easily reënter the blood current, producing a septic infection of the most virulent character.

Changes in the hepatic structures occur early and the devitalization of the tissues, at first pronounced, go on *pari passu* in geometric ratio until the individual is destroyed by acute blood poisoning, rendered far more rapid from its initiation having commenced under such unfavorable circumstances. Peristalsis of the intestine lessens at an early period because of a reflex paralysis of the local inhibitory nerve centers and, as a consequence the opposing peritoneal surfaces remain more nearly at rest, and at the point of injury the effused lymph rapidly becomes organized. Nausea, vomiting, diminution and arrest of peristalsis, abdominal distention, accompanied by general constitutional depression, with increasing thirst dependent upon lack of absorption are among the earlier symptoms. Possibly local pain, which however, in my cases has been absent, may point to the site of adhesion. A marked elevation of temperature is relatively not an early symptom. The nervous centers are disturbed by an indefinite anxious foreboding, the pulse becomes accelerated, respiration often shallow and rapid. The latter is probably due to an interference with the action of the diaphragm. These symptoms may be complicated by a general peritonitis, and have without doubt often been mistaken for it. However, a careful analysis of symptoms will generally enable the observer to make an accurate, differential diagnosis.

*Prevention.*—Although in not more than one per cent. of laparotomies, does intestinal obstruction occur, and in my own experience the percentage is about one-half less than this, when it does take place the complication is so severe, and the fatality so great that the fear of intestinal obstruction may well be considered the nightmare of the abdominal surgeon. Therefore it is of the utmost importance that every precaution possible should be taken to prevent its occurrence. Believing that its causation depends in a large degree on the abrasion of the peritoneal surfaces about the site of the operative field, one of the first queries that arise is, how may this be lessened or avoided? It was for this very purpose, that years ago I introduced to the profession various methods of plastic surgery of the intra-abdominal and pelvic structures. These I constantly practice and enthusiastically advocate in order to restore all injuries of the peritoneum.

In the removal of tumors I cover with the greatest care, the healthy peritoneum over their pedunculated attachments. Where, for any reason, it is necessary to remove the uterus, for a long period I have divided the tissues in such a way that the cervical stump can be carefully closed over by the double intra-folding of its peritoneal investment. This I do by the use of the parallel running suture, the stitches taken in such a way that when drawn upon, the suture itself is completely buried, and the peritoneum lies in easy, accurate approximation without tension. If a ureter is laid

bare, the peritoneum is covered over in the same manner.

In the removal of the appendix, the stump is always covered and peritoneal abrasions are intra-folded where the integrity of the same has seemed doubtful. In some instances I have even closed the entire peritoneum across the brim of the pelvis, at its basic attachment, to the floor of the bladder, thus completely obliterating it. By these measures, in this class of difficult cases I have found it possible to attain another very desirable end, that of closing the abdominal wound without drainage.

Here also, for many years, I have taken the precaution to approximate the abdominal peritoneum with the same care, in order to prevent adhesions of the omentum to the line of the wound, and with most excellent results. Since 1892 there has occurred in my experience the three cases above reported where death has taken place from peritoneal adhesions. In the first, a case of vaginal hysterectomy, it was thought wise to use clamps which left uncovered the divided peritoneum of the broad ligament. However, in a majority of vaginal hysterectomies by careful manipulation it is possible to suture across the everted peritoneum. When this can not be effected, the raw surfaces can usually be protected by gauze. It may however, happen as in Case 5, that pathologic changes have ensued at some previous period, leaving resulting inflammatory bands. I know of no way to provide against such complications, unless it may be in doubtful cases to open the abdomen from above also, in order to deal intelligently with existing conditions.

In Cases 4 and 7, at the time of operation, doubts were entertained as to the method to be selected. In Case 4, where the pelvic peritoneum seemed scarcely abraded, the results show that it would have been wiser to have adopted one of two alternatives. A vaginal opening might have been made and the parts protected by iodoform gauze, or the depressed portion of the peritoneum have been sutured across at its upper part. It is probable this would have been the better of the measures to have adopted, since it would have added very little to the traumatism and taken less time than the opening of the vagina and the introduction of the vaginal drain. It was, however, covered with a thick layer of aristol, which I can not doubt would prove ample protection in the majority of instances.

In Case 7, the uterus should have been removed. The organ had long been bound down by adhesions which were separated with difficulty. The protection, however, seemed ample, by the free introduction of iodoform gauze which was so packed about as to cover the denuded peritoneum. The point of adhesion was very near the fundus of the uterus where the gauze had become displaced. I can not question the wisdom of removing the uterus in many cases where, until a very recent period, such a procedure would have been considered unsurgical. It adds comparatively little to the difficulties or severity of the operation and permits the covering in of the pelvic peritoneum in an even fold, from side to side, entirely across the pelvis.

*The omentum.*—Where for any reason the omentum has been involved in the pathologic changes, it becomes very important to examine it carefully, and if rents have occurred to close them. This is best effected with a continuous tendon suture. It should then be replaced with the greatest care, and if any

points of abrasion appear they should be well dusted with aristol.

Cases 3 and 6 are instructive; Case 3 where it seems very probable that a more careful observation should have been made and the attachment of the omentum to the anterior abdominal wall, resulting from a former operation, should have been separated. In Case 6, it seems as if every precaution had been taken to prevent such an occurrence. The omentum which had been carried up to the region of the liver by the large myoma was somewhat changed in its structure. The parietal peritoneum had long remained in direct contact with the myoma and by friction was also changed in structure. The omentum was spread out evenly over the intestines and brought well down to the brim of the pelvis. There was no bleeding from the separated points of attachment, and the pelvic organs were carefully cared for by the plastic repair of the peritoneum. This had been lacerated in various directions, and the left ureter was exposed for several inches. No points of attachment to the pelvis were found, the effused lymph leaving them smooth and unadherent. The abdominal peritoneum was also intact. The constriction was well down on the right side at the brim of the pelvis and was easily freed.

It is not supposed that any better measures for the prevention of intestinal obstruction could have been instituted and the resulting adhesion of the omentum to the side forming the band was probably the more easily induced, owing to the changed conditions resulting from the long pressure of the tumor.

*Treatment.*—The object of this paper and the analysis of this series of cases is a practical deduction as to what may be done when this most grave of all complications in abdominal surgery occurs. This is the more important, since authors are singularly at variance and apparently without definite reasons as to the selection of the means to be employed. Unfortunately, medicines, in the hands of all, fail to be of much value, except so far as hypodermic medication may control pain and perhaps materially aid the great motor nerve system.

It is evident that the entire alimentary tract above the point of constriction becomes early paralyzed and incapacitated to do more than permit the absorption of crystallin substances in solution.

It may be doubtful if our efforts to stimulate peristalsis, even if successful, do not hasten the fatal issue, unless they are equal to the forcible separation of the intestine at its point of occlusion. If this supervene a happy issue will be attained and prompt relief afforded. This is often seen in the unfolding of a displaced intestine with the disappearance of all untoward symptoms.

One of the most extraordinary of the conditions which supervene in intestinal obstruction is the rapid accumulation of fluid above the occluded part, and, although the thirst is usually excessive, the absorption even of water from the stomach does not take place, and it is probably a positive detriment to add to the rapidly accumulating fluid by even the administration of water. Vomiting certainly does harm unless by the forcible strain the adherent parts may be separated. This rarely happens, and in case a loop of intestine is incarcerated must add to the mechanical impedimenta.

If then we are deprived of the administration of medicines by the stomach, and if thus given, they are to the detriment of the patient, what remains at our

command as a means of relief? Since fecal evacuation is the desired end to be accomplished, experience in other conditions would teach that injections and medicamenta, applied to the lower bowel, might be of service. The foregoing discussion of the anatomic construction of the large bowel teaches us why we would not expect the constriction to occur in this part of the alimentary canal, unless, indeed, in rare instances the pelvic portion of the canal is involved as the result of our surgical interference. If this has happened, rectal examination will determine the fact and probably enable us to deal easily with the occlusion. Other than this, the benefit to be derived from large injections, even if they penetrated to the transverse colon, is exceedingly doubtful. The still further distension of the abdominal cavity is certainly to be deprecated, the pain and discomfort of the patient tend to weakness, and the reflexive stimulation of the peristalsis of the small intestine thus aroused induces nausea and vomiting, which is an injury unless it may, in itself, be sufficient to free the obstruction.

If, as happens in a majority of cases, the portion of the alimentary tract involved is the lower part of the small intestine, then we may determine why our efforts, applied to the large intestine are so utterly futile and the result only a loss of time and exhaustion of the patient.

It is the more important to consider these probabilities, since one of the primary rules laid down for the treatment of intestinal obstruction is the use of large enemata, variously medicated. That sufficiently careful consideration has not been given to this phase of the subject, that the obstruction does not lie in the large intestine except by the rarest of accidents, I cite the recent experience of a prominent English authority who, after using enemata freely without relief, made an artificial anus above the sigmoid flexure only to permit an easy escape of the injected fluid. It is needless to remark the patient died unrelieved of the obstruction.

If summoned to the relief of the sufferer in such desperate cases, what shall be advised? Certainly not to do harm if we can do no good. Assuming that, prior to the operation, we know that the alimentary canal had been properly emptied so that, at the time of operation, the bowel was in the best possible condition to bear its necessary manipulation, then it is clearly our duty to keep the stomach empty. It seems to be equally important to desist from the common practice of fretting and exhausting the patient by large, repeated rectal enemata. It is true that a certain amount of water may be absorbed which the system very much needs, but that can be accomplished by much less violent measures. Hypodermic medication of morphia is of value, but this is better given in small doses, often repeated. More recently this valuable remedy has been decried under the belief that it caused an interference of peristalsis, even to the producing of intestinal paralysis. It is indeed strange if opium which has been relied upon for generations as the remedy of greatest value in nearly all the intestinal diseases can now be considered by any as the cause of obstruction and its administration criminal. Its use should be minimized to the moderate relief of pain.

Strychnia, digitalis, nitroglycerin are remedies, to be used hypodermically, of much value in holding in conservation the rapidly ebbing vital force. Nature's own powers are not to be held in too light esteem,

since in the most desperate of conditions she triumphs occasionally. Of this we were never so fully aware as at the present, since the laparotomist is often called upon to examine the battle ground of previous victories, as he studies the results, where intestines have been banded to each other and the neighboring parts, and yet, within limitations, able to perform their functions for an indefinite period.

Although, as in the operation for appendicitis, it may be in the minority of cases that the aid of the surgeon is justly called to attempt to restore the damages incident upon his previous work, a considerable class of these cases doubtless exist, and when to re-operate is a question that may never be settled. When the weight of evidence points clearly not alone to obstruction as the impending danger, but that nature is powerless to remedy it, there can be but one rule, as in strangulated hernia, operate at the earliest possible moment for the relief of the incarcerated organ. A reopening of the abdomen within two or three days after the primal operation must ever be considered a formidable surgical measure, not alone in that the patient is necessarily in a serious condition from the previous operation, but that these conditions have become greatly intensified owing to the constriction in the alimentary canal. It is important to first wash out the stomach by means of the stomach tube. Often a large quantity of fluid will pour out with much advantage in the subsequent result. This I have done at times for years. Our previous knowledge of the intra-abdominal conditions is of the greatest value. We must keep in mind the portion of the intestine probably involved, and the location where we are likely to find it. This usually is the small intestine, generally the ileum, and the location the site of the surgical operation. Since this is more commonly the pelvic basin it is the first location to be explored. The second is in the neighborhood of the appendix. These having failed to furnish results, we are to examine carefully the omentum and its relation to the small intestine. A careful observation of these factors in the order proposed is of the utmost value. Nothing is more to be deprecated than the aimless searching in the abdominal cavity, and the evisceration of the patient by the rolling out of the distended intestine, as is often practiced in the blind search for the constriction.

The inflated intestines are ever protruding, but as far as possible are to be avoided, since the inflation itself teaches that this can not be the part involved. On the contrary, a portion of the intestine that is empty and flat is likely to lead almost at once to the constricted part. Here as elsewhere intimate anatomic knowledge of the abdominal cavity and its contents is of the utmost practical importance.

Etherization should be minimized. My experience with oxygen gas leads me to think favorably of it as an adjunct to chloroform. The operation should be undertaken under as favorable circumstances as possible, conducted with coolness, deliberation and dispatch, since the resources of the surgeon are rarely more severely taxed than in this dilemma.

Owing to the severe shock incident to an operation as above described, it has been recommended and practiced to make a small opening in the abdomen and through this withdraw the first inflated fold of small intestine that presents, suture it to the peritoneum and open. This gives temporary relief, permitting the escape of the pent-up toxic elements and

affords time for the patient to rally from the extreme depression incident to the obstruction. As soon after as the general condition will permit, a third operation is undertaken for the relief of the constriction, at which time operative measures for the cure of the artificial anus are also instituted. In a dilemma of severe complications there may be conditions that would cause such a temporary operation to be favorably considered, and it is well for the surgeon to keep in mind the possibility of its advantage.

In review, I am constrained to add emphasis to the practical importance of the preparation of all patients for laparotomy. The condition of the nervous system is important. The lowering of the nervous tension is a very great gain. The substitution of hope for fear, and confidence in the outcome is of much more value than I earlier believed; and why should not this be true, since the best definition of life itself is the equilibrium of the vital processes in their sway over the organic matter which they hold in control?

The intestinal canal should be carefully emptied and peristalsis kept active at the time of operation. It is better to employ only fluid food for some days prior, and antiseptics, such as small doses of calomel and salol, I believe to be of value. Time is an important factor in the operation, but this is no excuse for undue haste or inaccuracy of work.

Intraperitoneal surgery must ever be of the highest order, and accuracy and completeness of detail must go hand in hand in every process to prevent infection. When these great surgical laws have been complied with recovery is in direct ratio with the minimizing of the devitalization of the patient. These are the almost ideal results which modern surgery has attained and upon their practical application depends the marvelous success of the surgeon of to-day.

#### DISCUSSION.

DR. A. H. CORDIER, Kansas City, Mo.—In the majority of instances we will find the obstruction near the junction of the small with the large bowel. It is impossible to locate this dangerous condition when we are operating through the vagina. The argument which Dr. Marcy has presented is in favor of doing these operations through the abdominal wall. The work then is complete. It is not the specimen alone for which the surgeon should seek in doing abdominal operation. He should seek to liberate adhesion and relieve the patient of all likelihood of intestinal obstruction following the work. At the time of operation we will find the bowel flaccid—comparatively speaking, empty, with adhesions. These adhesions may not have given trouble prior to operation, but with the amount of handling which of necessity must be done in operating, either through the vagina or abdomen, if the adhesions are not separated, we have following the operation great distension of the intestines, and following that a semi-paresis. We have the difficulty of a paralyzed bowel to contend with and inability to force the contents of the bowel beyond the seat of obstruction. We must separate the adhesions and liberate the bowel. I am satisfied that many cases, reported as dying from some form of sepsis or peritonitis, would, if a careful postmortem was made, be found to have died from intestinal obstruction, the sepsis and peritonitis being secondary, because the gaseous distension can not relieve itself.

DR. E. E. MONTGOMERY, Philadelphia—Too much stress can not be placed upon the early treatment of cases of intestinal obstruction. The distension which takes place in the upper part of the stomach may be relieved temporarily by introducing a stomach tube, washing out the stomach, allowing a large quantity of gas to escape, removing the contents of the stom-

ach. This takes away the pressure against the diaphragm, relieves respiration and facilitates the heart's action. This should be tried once or twice, and if the patient continues to suffer from intestinal obstruction the proper plan would be to reopen the abdomen. I must take exception to the remarks of the last speaker, that in these cases it indicates the necessity of opening through the abdomen in cases of pelvic disease. Cases operated upon through the vagina are not more subject to intestinal obstruction than are those operated through the abdomen. I have not seen a single case of removal of the uterus through the vagina for inflammatory conditions in which the subsequent convalescence of the patient was disturbed by symptoms of obstruction.

DR. RUFUS B. HALL, Cincinnati—It is a difficult matter in any given case of intestinal obstruction to make a positive diagnosis until the patient is practically dead, and that is why a reopening of the abdomen in such cases gives such a high mortality. The differentiation of intestinal obstruction is difficult. Many times I have been on the point of giving the patient an anesthetic to reopen the abdomen, and in half an hour afterward my patient was convalescing and recovered without trouble. If we only knew that the patient had obstruction we could probably save them all.

DR. HENRY P. NEWMAN, Chicago—The fact that we have these cases of intestinal obstruction following laparotomy should stimulate us to better, more thorough and complete work. True, the obstruction usually occurs in desperate cases, but if the patients are handled with care and with the utmost thoroughness, they will frequently escape this accident, particularly if we exercise caution in covering abraded surfaces with peritoneum and the vaginal tract with omentum. As to the protection of abraded surfaces after laparotomy that can not be covered with peritoneum, they may be kept apart by the proper application of gauze or wicking.

It was my misfortune to lose a case of vaginal hysterectomy recently from intestinal obstruction, which probably could have been avoided if someone had been at hand to watch the case. Unfortunately, I was called out of the city at the time. Presumably a portion of the intestine had become adherent and was drawn into the fold of the vagina, causing obstruction and death.

In regard to the proper application of gauze after vaginal hysterectomy, the gauze should not penetrate the abdominal cavity. It should be applied in a manner to guard against hernia and a means of drainage, but should not come in contact with the intestine. Furthermore, it is important to begin the use of mild catharsis to stimulate peristalsis early, and here let me enter a protest against the use of opiates. Morphine is sparingly used at the present time in laparotomies, and I think it ought to be. On the other hand, use laxatives early, beginning twenty-four hours after your operation, particularly where there is an accumulation of gas and perhaps great distress.

DR. J. W. BOVEE, Washington, D. C.—I had the misfortune to lose a case from intestinal obstruction following abdominal section, the woman dying on the fifteenth day after operation. She progressed nicely for five days, and then the bowels did not move for one or two days. They moved again on the seventh day. On the ninth day she was taken with considerable pain in the region of the cecum. I commenced with catharsis, but could not move the bowels, although I used enemata and also croton oil. On the fifteenth day I opened the abdomen and found two or three coils of the small intestine down in the right side of the pelvis attached to the posterior surface of the broad ligament from which I had removed a tubo-ovarian abscess. I separated the adhesion with scissors, closed the abdomen as quickly as possible, and did it with scarcely any anesthesia, realizing that it was a desperate case. I make it a point now to close raw surfaces

in the abdomen if the condition of the patient permits and move the bowels as soon as possible. Within twenty-four hours after the operation I commence salines.

DR. GEORGE WM. REYNOLDS, Chicago—One of the fruitful causes of intestinal obstruction is the manner in which the abdominal incision is closed. It is my practice not to include the parietal peritoneum in the deep sutures. Frequently, in tying them, where we penetrate the peritoneum, loops of intestine are caught and obstruction follows. My practice has been to sew the parietal peritoneum separately, including in my deep sutures the muscles, the fascia and the external skin.

DR. JOSEPH TABER JOHNSON, Washington, D. C.—It is altogether possible that by passing the same suture down through both sides of the abdominal incision and up through the other side by the time the operator is ready to close the abdominal wound, tying off one suture after another, a knuckle of intestine or piece of omentum may get in between the stitches and produce adhesions which result in intestinal obstruction. I have known one or two cases due to this cause. There is no doubt but that a great many cases can be prevented by perfect operating, leaving as few raw surfaces as possible, taking great care in separating adhesions that exist about the tumor itself, and by the covering of all raw surfaces in the manner suggested by the paper. The diet question after operation is one of importance. I had the misfortune to lose a patient some time ago when a difficult hysterectomy had been performed. The patient was about ready to go home. She was exceedingly anxious that evening to have some veal cutlets. She partook of them and had an attack of indigestion shortly after which brought on vomiting. She vomited until she died. A postmortem was made and a twist of the small intestine was found. The intestine below the twist not larger than a pencil, while above it was as large as my wrist. If we had been able to diagnose the case when the first symptoms of intestinal obstruction came on, we doubtless could have separated the adhesions caused by the intestinal obstruction and saved our patient.

DR. MARCY—Had I written upon this subject a year ago I probably should have taken a different view of it, but during the last year the cases which I have reported occurred. If you will look carefully over reports of cases you will find that intestinal obstruction following laparotomy is more frequent than we formerly supposed. These cases point out the necessity for more careful, thorough work in order to avoid this accident. It is a question in my mind whether the pelvic structures are protected by the omentum, and that is the reason we are so likely to have intestinal adhesions occur in the pelvic region. The normal range of motion of the small intestines, including the pelvic basin, gives emphasis to that remark.

In reference to the vaginal route, I do not exactly agree with Dr. Montgomery. Blind surgery may be stigmatized as bad surgery. Vaginal surgery is necessarily in large measure blind surgery, in that the eye does not direct the hand. In one case that I lately saved there was an old band of adhesion which had nothing whatever to do with the carcinomatous uterus which I had previously removed. Under this old adhesion was a loop of intestine which had become incarcerated. It was freed and the patient recovered.

In another case, twenty-two days after operation a double loop of the small intestine was found united to the stump from which I had removed an ovarian cystoma. In this case we reopened the abdomen and saved the life of the patient.

## HYSTERECTOMY AS AN ACCOMPANIMENT TO BILATERAL REMOVAL OF THE APPENDAGES.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY REUBEN PETERSON, M.D.

GRAND RAPIDS, MICH.

During the past five years decided changes have taken place in the methods of dealing with pelvic inflammatory diseases. Prior to 1890, it was the established custom in America to deal with irreparably diseased appendages by removal solely through an abdominal incision. Deliberate hysterectomy as

an adjunct to ablation of the tubes and ovaries was not practiced. Péan in 1886 removed by the vagina the diseased uterus of a patient whom he had failed to cure by a previous removal of the appendages. From this and similar cases he sought to establish the principle that for certain forms of pelvic inflammatory disease hysterectomy as well as removal of the appendages should be performed. His work along these lines, which was reported before the Paris Academy of Medicine in 1890, seems to have attracted but little attention in this country. Operators of large experience who had carefully followed up the history of these cases, subsequent to the operation of bilateral ablation of the adnexa, were forced to admit that many of their patients were not restored to health. Many still suffered from hemorrhagic and purulent uterine discharges and the reflex symptoms, which had prominently figured among the indications for the operation, persisted to a greater or less degree. In order to do away with these unfavorable sequelæ, portions of the uterus were surgically treated. It was urged that in every case where the appendages were to be removed for chronic inflammatory disease, the uterus first should be thoroughly curetted and drained. Also that the tubes should be dissected out of the uterine cornua in order that no diseased tissue be left behind. Although these procedures were carefully carried out there still remained cases which presented the old train of symptoms. Hence when Polk's paper<sup>1</sup> on "Hysterectomy (supra pubic) for Salpingitis and Ovaritis" appeared in the latter part of 1893 in which hysterectomy was advocated for every case where both appendages had been removed for serious disease, the idea, coinciding as it did with the clinical observations of many operators,<sup>2</sup> was eagerly seized upon by prominent gynecologists throughout the country and immediately put into practice. Since that time hysterectomies have been done by the score in this class of cases. Is it not well to pause after three years' work in this line and ask ourselves *not* how many uteri have been removed during this period, but how much has been learned from careful microscopic and bacteriologic examinations of these removed organs? In other words, do the pathologic lesions found in the ablated uteri confirm the correctness of the reasoning of those who, mainly upon clinical grounds, advocate hysterectomy in certain inflammatory pelvic diseases. Henrotin<sup>3</sup> at the last meeting of the American Gynecological Society states that "the position of advanced, observant gynecologists who are not hampered by tradition or custom or afraid of their own stubborn dogmatic expressions in the past can be stated as follows: 'In every operation for septic diseases of the female generative organs which demands the removal of the tubes and ovaries, hysterectomy should also be performed unless there are contraindications forbidding it.'" I consider this a fair statement of the present position of surgery upon the subject. The whole question will turn upon the interpretation placed upon the phrase "contraindications forbidding it." The more carefully the removed uteri are studied in connection with the history of the case and the condition of the pelvis found at the time of the operation, the nearer we will be to determining what will constitute a contraindication. If it can be shown that certain pathologic uterine lesions either of the mucosa or of the deeper structures are susceptible of cure without removal of the organ, then considerable advance has been made

toward establishing another contraindication. On the other hand microscopic examination of the removed organ may show such decided morbid changes in its structure as to render any curative treatment short of ablation ineffectual. This line of research may not be the easiest or most enticing. One would far rather have a universal rule for guidance, such as is laid down above, but conservative surgery does not advance along these lines. For example, it is much easier to adopt a universal rule to operate for appendicitis in every case as soon as the diagnosis is made. Yet those who advocate and observe this rule are in the vast minority and ever will be, so long as it can be proven that a certain percentage of cases recover by adhering to other modes of procedure. The technique of hysterectomy has been so perfected that in the hands of the skilled operator the mortality is increased but little over that resulting from removal of the tubes and ovaries alone. This fact, however, does not justify one in removing the uterus in every case. While clinical experience has shown me that a certain percentage of my cases were not cured after their pus tubes were removed, on the other hand it has demonstrated that certain cases recovered after this treatment. It seems to me it is plainly the surgeon's duty under these circumstances to endeavor to solve the problem why one set of cases recovered and the other did not. The reason must lie, other things being equal, in the condition of the uterus at the time of the operation. How can these different conditions be studied and definite rules of procedure be established except it be upon both pathologic and clinical grounds. Yet a perusal of the literature emanating from our gynecologists upon hysterectomy for inflammatory affections will show that their conclusions have been arrived at mainly from a clinical consideration of the subject. That this is a dangerous mode of studying any surgical question and one liable to lead to grave errors is demonstrated by the abuse of ovariectomy when it was performed for symptoms and not for demonstrable pathologic lesions. I fail to see the line of reasoning adopted by Polk. He, the advocate, par excellence, of conservative surgery, who would leave in an ovary or part of one with everything else removed, advocates the removal of the uterus in every case of bilateral ablation of the appendages because *some* cases fail of cure without this additional procedure. What right has he or anyone to justify his position by claiming that the "emasculated uterus" is a useless organ and hence should be sacrificed? It should be sacrificed if it is so diseased that no known procedure can effect its cure and that should be the only justifiable ground for its removal. One who claims so much for thorough dilatation and curettage of the uterus, in the way of depletion and drainage, should surely obtain better results than are shown by his advocacy of the proposition to perform hysterectomy in each of these cases.

I am making a plea against the adoption of any universal rule in regard to these cases as if it were finally settled. I claim that the surgeon has no right to remove the uterus after removal of the appendages unless he is convinced that the organ is diseased beyond the hope of cure by less radical methods. Krug<sup>4</sup> in the discussion of Polk's paper, said he had "never found a healthy uterus when there had been such inflammatory disease in the tubes and ovaries as would warrant bilateral salpingo-oophorectomy." It

is not a question of the uterus always being diseased in these cases. As most inflammatory disease of the adnexa arises from some form of intrauterine affection, it would be remarkable if the uteri were perfectly healthy. The question is how much are they diseased and how can this disease be cured? I would not underrate the work of those who were the first to advocate hysterectomy for inflammatory disease. I consider it a great step in advance and for certain conditions it is the only procedure which should be adopted. But I believe that the prediction of Baldy made two years ago in a paper<sup>5</sup> on this subject, that uteri would be removed which might safely be left, has proven true to a far greater extent than one could have predicted. Even if the uterus be a functionless organ after bilateral salpingo-oöphorectomy, I do not think the most radical operator would urge its removal for this cause alone, if he could determine in which cases it could "safely" be left within.

The investigations of Wertheim<sup>6</sup> have thrown considerable light upon gonorrhœa of the uterus. They would tend to show that the deeper uterine structures are affected to a greater degree than was formerly supposed. There is in many cases infiltration of the muscle with hyperplasia of the vessel walls. That the gonococci<sup>7</sup> can penetrate into the muscularis is considered highly probable by Wertheim though he has never bacteriologically demonstrated their existence.<sup>7</sup> That a metritis with sensitiveness and general enlargement occurs in gonorrhœal disease of the uterus is a well known clinic fact, but that it is due to the gonococcus has never been proven because the muscular tissues being an unfavorable soil for the germs they either perish or pass on through the uterine wall to the peritoneum. Madlener<sup>8</sup> asserts that he actually demonstrated the gonococci in the muscular tissue in one case where the uterus was removed seven weeks after confinement.

Gonorrhœal disease of the uterine deeper structures offers then an explanation of the unsatisfactory results obtained by treatment through the curette and drainage. Removal of the endometrium leaves the deeper structures still diseased and in a short time the old symptoms will again appear. For this reason Werth<sup>9</sup> claims inasmuch as it is impossible clinically to distinguish these forms of endometritis where the deeper tissue is involved, that a thorough cauterization after curettage should always be made. He recommends liquor ferri and shows that after its use a regeneration of the epithelium is delayed.

The conclusions were arrived at from a careful microscopic examination of uteri removed after curettage performed some days previously, and are therefore more valuable than mere theoretic conjectures in the matter. In another article<sup>10</sup> he shows that the endometrium is never entirely removed, patches untouched by the curette remaining. The cornua were most likely to be spared.

Just what percentage of cases of inflammatory disease of the adnexa are due to gonorrhœa it is hard to say. Probably 25 per cent. would be a conservative estimate. It is generally conceded that Noeggerath's<sup>11</sup> picture of latent gonorrhœa and its frequency was exaggerated. Yet no one can question the important role played by the gonococcus in the production of pyosalpinx. Apparently gonorrhœa of the uterus is especially difficult of cure, and this should have weight in deciding whether hysterectomy should follow removal of pus tubes.

Schauta<sup>12</sup> takes a very decided stand in this matter. From the results of his observations he finds that only 59 per cent. of cures result when both appendages are moved and only 23 per cent. where one side is removed. When this lesion is due to gonorrhœa, he, like Tait, claims that when one side is removed the other should be also together with the uterus. This recommendation is not based, it seems to me, upon sound scientific principles and is not advocated by the majority of gynecologists. If this dictum be followed then we practically concede that we are powerless in the presence of gonorrhœal disease to effect a cure short of hysterectomy. While the investigations referred to have shown us why frequent failures result from our efforts to cure gonorrhœa of the uterus, still, I do not believe that every case of gonorrhœal endometritis is incurable. A certain proportion of the 25 per cent. will no doubt fall under this category and in time we shall be in a position to recognize these cases and act accordingly. Much will depend upon the wishes of the patient in cases where one side is unaffected<sup>13</sup>. She may demand the most radical operation if there exists a possibility of the other side becoming affected. On the contrary she may be desirous of bearing children and be willing to risk the possibility of a secondary operation from the failure of intrauterine treatment. Schauta makes every effort to establish the diagnosis of gonorrhœa prior to operation and during the progress of the latter has the contents of the pyosalpinx examined for the gonococci. If gonorrhœa is found to exist both adnexa and uterus are removed on the ground that the gonococci work irreparable change in the uterus while the inflammation of the appendages due to streptococcus and staphylococcus infection is usually one sided, the uterine lesion heals and consequently the uterus can safely be left. As more than 50 per cent. of the cases of inflammatory disease of the adnexa are believed to arise from infection after abortions or the puerperal state, it will readily be seen that if Schauta's claims be true there are many cases where the uterine lesions will either be cured or amenable to treatment after the removal of the adnexa.

More such investigations should be made and by the collections of bacteriologic and clinical data, rules can be formulated which will be of universal value to the surgeon in deciding what should be done in a given case. Whatever may be said to the contrary, hysterectomy is a much more radical procedure than bilateral removal of the adnexa and should never be performed except when demanded for the cure of the patient.

Some advocate hysterectomy on the ground that 12 per cent. of chronically diseased adnexa requiring removal are found to be tubercular upon microscopic examination and that the uterus may be also affected.<sup>14</sup> This position is strengthened by the observation of Cullen,<sup>15</sup> who thinks tubercular disease of the uterus is usually secondary to that in the tubes. But tubercular uterine disease is usually demonstrable by the examination of scrapings and hence it is possible to have a fairly clear idea of the condition of the uterus prior to the operation. Where the uterus is found to be tubercular it should always be removed, because of the difficulty of curing it by intrauterine treatment. Where the microscopic appearances of the adnexa show tubercular deposits, it would seem advisable to remove the uterus because of the serious nature of

the disease, the possibility of the uterus being affected and the difficulty of curing tubercular uterine disease by the curette. If the microscope shows tubercular disease in the appendages unsuspected before, the uterus can be removed by a secondary operation.

At the last meeting of this ASSOCIATION a former chairman of this section, Dr. Eastman, remarked in speaking of hysterectomy for fibroids, that he was not sure of what the after-effects of complete removal of the uterus would prove to be, that he found vaginal prolapse, cystocele and rectocele following some cases, and that he would be obliged to suspend judgment until he had operated on more cases by this method. This was said by a man who has probably performed as many if not more complete hysterectomies than any operator in the country. It would seem that the lesson to be learned from the remarks of such a man, was to be cautious in urging that the uterus be removed. It is generally conceded that when we are obliged to remove an organ, it is a practical acknowledgment of defeat. Starting from this defeat however our efforts involving removal may end in victory as regards the health of the individual.

We must continually keep before our minds the two great classes of cases calling for bilateral removal of the adnexa, and it is only necessary to recall our past cases to find examples of each.

The first is where there is advanced disease, usually chronic, involving both adnexa. The tubes and ovaries, whether filled with or free from pus, are bound down in the posterior cul-de-sac and to the omentum and bowels by dense adhesions. Much labor must be expended in enucleating these masses and much injury may be done the uterus in separating it from the pus sacs. Repeated infections with resulting metritis and endometritis have also greatly impaired its integrity. Here the indications are clearly for removal of uterus. Its peritoneal covering may be so injured that, if left, it will be firmly bound down by dense post-operative adhesions and give rise to great suffering. These are the cases where hysterectomy will give brilliant results as compared with the older methods. But these are not the usual but the severe cases and fortunately the exceptions.

The second class is the one we are considering in this paper. Here the recurrent attacks of pelvic peritonitis have been fewer, hence the adhesions less. The tubes and ovaries may be the seat of purulent collections, or their contents may have become changed to a cheesy material with thickening of the walls. The fimbriated extremities of the tubes are closed and no conservative operative procedure can be entertained. The uterus is enlarged but fairly movable. The masses on either side having been removed without much difficulty, the operator is confronted with the question of whether hysterectomy shall follow. His decision will depend largely upon the condition of the uterus and the possibility of its being cured by treatment directed to its interior, aided by the atrophy resulting from the removal of the appendages. Careful, recorded observations, both pathologic and clinic, will result in rules which will guide the surgeon in his choice of procedure.

#### DISCUSSION.

DR. JOSEPH EASTMAN, Indianapolis—I am intensely pleased with Dr. Peterson's paper. The gentlemen who run to extremes, who ride hobbies to the extent that some of those engaged in this work have done, have been severely reprimanded by the President of the AMERICAN MEDICAL ASSOCIATION, as well as the incoming President, during this meeting, and it is encouraging indeed to see a young man come in here and present such a conservative paper, in an aggressive way, that neither the criticism of Dr. Cole nor of Dr. Senn touches him or a word he has uttered. He did not know when he wrote this paper what they were going to say, yet he has disarmed their criticism and has effectually parried their stroke. From that lesson we take warning, and the people, as well as the attending physician, will attach importance to these words and admonish us that the surgical pendulum has swung to the extreme, and that uteri and ovaries have been sacrificed that might have been saved by either medical or conservative surgical treatment. I am pleased with the paper from beginning to end. We see the sparkling diamonds of surgical thought crystallized and matured. We see from beginning to end science, surgery and sense.

DR. EDWIN WALKER, Evansville—The question of diagnosis has been hinted at, but I think our diagnosis should extend outside of the pelvis. Many of these recurrent cases have diseases which have nothing whatever to do with the sexual organs, and until we clearly recognize this and properly treat the cases we will never cure them. We all know there are a class of neurasthenics, who are often anxious to be operated on, and after having been treated surgically are no better than before. Many of the cases reported as incurable are not really pelvic diseases. The number of uteri which give trouble, after the removal of the appendages, it seems to me, must be small. From my own experience, I can recall but two cases, and in both of these there was a persistent purulent discharge. Neither of them has been operated on since. I think in both I recommended extirpation. But because in these rare instances we have such cases that are not cured, it is by no means a just conclusion that all should be treated by total extirpation. The point I wish particularly to make is that before a diagnosis is made our examinations should extend throughout the whole system, and not the pelvis alone.

DR. HENRY P. NEWMAN, Chicago—I regret that these conservative remarks were not injected earlier in our proceedings. Some sweeping statements have been made from time to time regarding radical operations performed for the relief of inflammatory diseases of women, and it is certainly to be deprecated. We are oftentimes in a position to be criticised, as we have been at this meeting by two prominent men. For that reason I am pleased to have heard Dr. Peterson's able and conservative paper. At the same time it is a very aggressive contribution. I like the tone of it and wish to thank the author for it.

DR. J. W. BOVEE, Washington, D. C.—I do not have a dread of the gonorrhoeal uterus, that the essayist has. It does not seem possible that this condition is beyond our aid. When a uterus is to be removed for the cure of a diseased condition, if the gonococcus travels through the walls, how can we feel any safer in removing the uterus for gonorrhoea than in removing it for cancer? It may be, that I have had a unique experience, because it is a revelation to me that there is so much

evil resulting from this class of work, or in following this class of procedures. I have not had bad results following abdominal section.

DR. RUFUS B. HALL, Cincinnati—I endorse the sentiment and views expressed by Dr. Peterson most heartily.

DR. PETERSON—I am very much obliged to the members for their complimentary remarks, but I wish the paper had been more freely discussed and not complimented so much. We are continually meeting with this question which we have to solve at the operating table, and while it is easier perhaps to adopt a universal rule, still it does not seem to me as though along these lines our department of science will progress.

Dr. Bovee spoke about the fear of the gonorrhoeal uterus. Possibly he misinterpreted some of my quotations from Schauta. I simply said that the investigations of this man and others have shown that where the gonococci penetrate into the muscular tissue, they leave such a damaged condition that it is difficult to cure the cases by curettage. By these investigations we are enabled to compare the ravages produced by the gonococci, the streptococci and the staphylococci. The inflammation is entirely different from cancer.

### VAGINAL VERSUS ABDOMINAL SECTION FOR SMALL TUMORS AND PUS IN THE PELVIS.

#### DISCUSSION.

DR. R. S. SUTTON, Pittsburg—It is especially appropriate that this discussion should take place in the former home of Robert Battey, whom we all revered, and who has passed to his final reward for the noble services which he extended to suffering women. His first conceptions led him to remove the ovaries by the vaginal route, and it is especially gratifying to American surgeons that this route is still held by all as a proper one, and by many as the better one in suitable cases. The question of this route or the upper or abdominal route for the removal of pus tubes is the one first before us. The advantages of the vaginal route are multiple. The removal of the uterus with the suppurating appendages opens the way to perfect drainage. It also disposes of an organ which is pathologic and useless, and which if left may afterward become the seat of other pathologic changes. The rate of mortality for the removal of pus tubes by this route is exceedingly low, probably in good hands not above 3 per cent. The objections to an abdominal wound are removed and the convalescence of the patients is remarkably short and free from febrile features. The point on which many are at variance is the disposition of the uterus. I hold that the whole question hinges upon the pathologic condition of the uterus itself. If the uterus is a focus of infection, loaded with pathologic germs, such as the gonococci or bacillus tuberculosis, streptococci or staphylococci, it should be removed with the appendages, and no portion of it should be left. I hold further that a uterus deprived of the ovaries and tubes is a useless organ. That it may become, if left, a future incubator for cancer cells, gonorrhoeal or tubercular germs, and is quite as dangerous, or more so, than the appendix vermiformis, which surgeons do not hesitate to remove for prophylactic reasons. We have been told that we might as well remove the penis after male castration as the uterus after removal of the ovaries. The cases are not analogous. The anatomic construction of the uterus and penis are not alike, they are not equally liable to the same diseases, and their position with reference to the bladder is totally different. The uterus lies hidden in the pelvis, behind the bladder. The penis is attached to the bladder in front, and every few hours it is thoroughly washed out by the urine discharged from the bladder. It is impossible that it should harbor and incubate pathologic germs to the extent that the retained uterus may do. It is probable that Jacobs and others are right in fixing

the causes of diseased appendages about as follows: 75 per cent. for gonorrhoeal infection, 10 per cent. for tubercular, and 15 per cent. of extraneous or other causes, including cancer. In addition to the occurrence of pus in the tubes, we may have abscesses form in the pelvic cellular tissue, the infection entering abrasions and being conveyed by the lymphatics. By the vaginal route, then, collections may be reached without disturbing the uterus. I urge that an infected uterus should be taken out with the appendages, and that a uterus deprived of them is of no use and is dangerous; that its removal adds greater safety to the operation.

As to the question of the removal of fibroids by the vaginal route: Large fibroids should be removed by the abdominal route by the method laid down by Crobak, and popularized in this country by Baer. Submucous fibroids may generally be safely enucleated per vaginam. Pediculated fibroids, as a rule, large or small, are better attacked by the abdominal route. But what of the small fibroids affecting the wall of the uterus? I do not believe that we have a right to deliberately destroy a uterus by either route in all such cases. Such tumors may often be shelled out and the woman afterward bear children.

But the President reminds me that my time is up. I will only say that the uterus bearing a small fibroid in its walls may be exposed by anterior colpotomy, and that often the tumor may be incised and shelled out, and the uterus safely returned to the pelvic cavity.

DR. W. E. B. DAVIS, Birmingham, Ala.—The man who has executed much successful work through the vagina will be loathe to change, and *vice versa*. Both operations have a large field, and it is well that we have two routes by which to reach the diseases of these important organs.

Dr. Sutton rightly emphasized the fact that the choice of operation depends largely upon the decision as to the disposition of the uterus in bilateral diseases of the appendages. Undoubtedly the question hinges on this point, and he very properly devoted much of the time allowed him in its discussion. I agree with him that if the uterus is to be removed, when the bilateral operation is necessary, that the vaginal route should be selected in a large proportion of such cases. However, it should be the aim and pride of every surgeon to preserve everything consistent with thorough surgical work, and not to sacrifice important organs because it can be done with only small mortality. He and others tell us that the uterus has no function after the removal of the appendages, but they have not demonstrated this, and on the contrary we know that the sexual life of the woman is very much better preserved by leaving the uterus, and that the mental effect is also much better. A slow convalescence, or even a second operation is preferable to its removal unless very much diseased. It is a reflection on the correctness of the reports of complete recoveries of such a large percentage of cases by many most excellent surgeons, when the uterus was not removed, to accept the argument now being used in favor of hysterectomy in all these cases. I can not agree with Dr. Sutton that pus in the tubes is due to gonorrhoea in 75 per cent. of cases. I think that puerperal infection is the cause of more than 50 per cent. Tubercular infection is rarely the cause and is not so important as his discussion would indicate. However, the importance which he attaches to gonorrhoea is against his argument for the removal of the uterus, as the infection from this source is not deep, and can be removed with the curette. Because some patients are not completely cured by the removal of the appendages is no argument for hysterectomy in every case where the bilateral operation is required, for nearly all these can be relieved by a thorough curettage. Some large uteri will require in addition to this the ligation of the uterine arteries with a high amputation of the cervix; only a small number of cases will need hysterectomy.

Vaginal incision for the drainage of pus in the pelvis, not confined to the tubes, is a most valuable method of treatment, and has been practiced for a long time with gratifying results. A large percentage of these cases have required no further surgery. More recently large pus tubes and ovarian abscesses have been incised and drained through the vagina with permanent recoveries in a large proportion of cases. These are the very cases where the vaginal operation and hysterectomy have been recommended so highly by the French surgeons. Yet a large percentage can be relieved by vaginal incision and drainage. If not completely relieved, the patient's condition will be made better by getting rid of the pus, and later on an abdominal operation can be done and the patient cured by the removal of the appendages, and perhaps of one side only. The uterus can nearly always be saved by this method of procedure. It is not best to do a radical abdominal operation at first, as recommended by the leader of the discussion. As to the mortality of the two methods it is very low in both and one possesses nothing over the other from that standpoint. The object of the surgeon now should be, not so much toward still further reducing the death rate from the operation, but to relieve these cases and preserve as far as possible organs which have so much to do with the woman's health and happiness. For that reason the abdominal operation is preferable, as the aid of positive sight is given, thus affording an opportunity for conservatism. It affords a wider field of operation and hemorrhage is more easily controlled. After the operation is commenced it can be changed to suit the conditions found, which could not be known before the abdomen is opened. Extensive adhesions can be much more readily dealt with. There is less danger of intestinal, vesical and ureteral fistula. There is less labor to the surgeon. More time is required for the patient to be out of bed, but the additional time thus spent is beneficial to these cases whose nervous systems have been greatly impressed by long suffering. It may be urged against the abdominal operation that a small number of cases of ventral hernia would follow. The scar is also an objection. In view of the great advantages furnished by the Trendelenburg position for positive diagnosis and thorough work we must all agree that the abdominal route has a field in pelvic surgery that can not be supplied by the vaginal operation. Very little was said by Dr. Sutton in regard to fibroids. I think if a fibroid is large enough to require removal that it can be better dealt with by the suprapubic operation.

DR. J. W. BOVEE, Washington, said he had been operating by both methods and had found that both are needed in this class of cases. A great many fibroid tumors may be operated on from below, as through the opening made in anterior colpotomy by the incision along the anterior vaginal wall meeting one that parallels the front wall of the cervix a growth having a diameter of four inches may be removed. So that for small fibroids in the anterior wall of the uterus the vaginal route is a very good one. There are also some pus cases in which it is absolutely necessary to take away the pus and yet not prolong the anesthetic and the operation. These demand a vaginal incision. They should not be classed with operations in which organs are removed. For ordinary pus cases, fibroid tumors of some size and nearly all intrapelvic diseases that require entering the peritoneal cavity he prefers the abdominal route because it is much the simpler and the cosmetic objections have no place in the work of good, clean surgeons. He does not believe it necessary to remove the uterus in but few of the cases in which the appendages are removed. His experience in this may have been unique for he had cured nearly all the cases he had operated on. He usually curetted first and then, putting the patient in proper position did the abdominal operation. If the patient is too weak for all this he curettes after recovery from the section. In many women the sexual sensation is greatest in the cervix and many of them do not feel that they are so

much different from other women if they can touch the cervix with the finger. We can not completely ignore the ideas they have on these subjects. At the present time he employs drainage very little but may be led to use it more in the future than he has in the past. He believes that tuberculosis of the Fallopian tube is rarely primary and that usually it extends from the peritoneum to the tube and later infects the uterus. So that tubal peritonitis does not necessarily require removal of the uterus as Dr. Sutton would have us think. The very small per cent. of cases in which infection of the cellular tissue to the side of the uterus occurs need not be considered in this connection. To continue the ovarian function he has been in the habit of leaving at least a portion of an ovary whenever it was possible to do so, in all abdominal cases. It at least prevents the sudden onset of the menopause just when the woman is endeavoring to recuperate the powers that were so severely taxed during the progress of the disease for which the operation was necessary.

DR. L. S. McMURTRY, of Louisville—This discussion is limited to a choice between the abdominal and vaginal route in operating for inflammatory diseases of the uterus and its adnexa and for uterine fibro-myomata. We should never lose sight of the principles which should guide all operations here, requiring the greatest preservation of organs and functions consistent with thorough work and permanent cure. It is indeed a crude conception of surgery which would do away with a diseased organ or structure by amputation or complete excision. It is a higher standard of surgical art which, while removing diseased and disintegrated structures, preserves all organs capable of restoration to normal structural integrity. This is not sentiment, but a great principle of surgery which should be generally applied. To remove the uterus for suppurative disease of the uterine appendages, upon the basis that after the ovaries and tubes have become disintegrated the uterus is no longer useful, is a violation of this principle. I have seen uteri exhibited to societies which had been removed under these conditions, and which presented no evidences of positive inflammatory lesions, while the suppurating tubes and ovaries, with adhesions and multiple pus sacs, were left to the chances of gauze drainage. I submit that this is not good surgery, and although the patient may be symptomatically cured, the surgical work is neither thorough nor accurate. This operation in such a case is little more than drainage from below, which as a valuable life-saving temporary operation has been long recognized and applied in pelvic surgery.

The advantages of the supra-pubic incision are numerous and demonstrable. The facilities for a clean operation are greater than by the vagina. The danger of wounding bowel or bladder is much less. The abdominal route furnishes a field for open work where every step may be seen, and every danger and complication may be measured and dealt with intelligently. Ligation of vessels can be done deliberately and securely; adhesions separated, and previously unrecognized complications (such as appendicitis) properly treated. More complete and refined surgery can be done by the abdominal route than is possible by the vaginal approach. A more judicious operative scheme can be carried out and more careful application of conservative principles is possible. Moreover, when the operation is completed by abdominal section, the operator has a clear apprehension of the condition within to guide him throughout the subsequent management of the case. Experience of many operations and many operators, dealing with every phase and variety of disease, has demonstrated the efficacy of the abdominal route. Skilled and experienced operators have perfected operative methods which have stood the test of practical application. The objection urged against abdominal section that a scar is left as a reminder of an operation is trivial. In my own experience I have never known a patient to allude to this. The danger of hernia is not great.

In my observation and experience the shock is not severe in either operation ordinarily, and is about equal in the same grade of cases. The danger of injury to the hollow viscera is much greater by the vaginal route.

All these considerations apply with even greater force to operations for subperitoneal and interstitial uterine fibromyomata of any size whatever requiring radical operation.

DR. JOSEPH EASTMAN, Indianapolis, thought the question of accurate diagnosis in these cases had been overlooked. It was very important; we must deal with facts and not fancies. He was surprised that Dr. Kelly advocated the partial removal of the uterus in these cases, whether done from above or below. If it is diseased, the whole of it should be removed and nothing left to carry infection. The decision as to the method to be employed must depend on the history of each individual case. He agreed with Dr. Kelly that a diseased appendix is frequently associated with diseased tubes, probably in 10 per cent., and possibly 25 per cent. He was also fully in accord with Dr. McMurtry that everything possible should be left. The vaginal route has advantages to recommend it in individual cases where the uterus is diseased as well as the tubes. He wished to protest against the discharge of patients as soon as the eighth day. He thought there is an analogy between the opening of the pelvis by either route, and much the same precautions should be used. There is no excuse for such extensive packing with gauze in the vaginal method as had been recommended. In many cases the wound could be closed as perfectly as in abdominal section, and that was the plan he had adopted with great success.

DR. I. S. STONE was surprised that attention had not been called to the selection of cases. Where the patient is very ill, suffering from sepsis, and can not endure the shock of an abdominal operation, a simple incision through the vagina as advocated by Dr. Noble was the only thing to do. He thought there was less shock in the vaginal operation. He thought the time would never come when the abdominal operation for fibroids would be discontinued.

DR. RUFUS B. HALL, Cincinnati, Ohio—I am of the opinion that the vaginal route will not be the one of election in fibroid tumors of the uterus, larger than an orange, after the enthusiasm of the operation has had time to abate. I know from practical experience that when the uterus is much enlarged from a fibroid it is difficult if not impossible to get working room and deliver the uterus without morcellement. The difficulties of this procedure contrasted with the ease and success attending the removal of tumors by the abdominal route has induced me to use the latter in all cases where hysterectomy was indicated and the tumor and uterus combined were too large to remove by the vaginal route without morcellement. I believe the vaginal route gives us a new means of operating in septic cases which are in no condition to be subjected to section. It places them in a position to be relieved of their septic condition by opening the abscess into the vagina. We can occasionally save the patient's life by so doing, and if necessary make a second operation later to remove the diseased organs. For many reasons I do not believe it is good practice to attack every case of suppuration in the ovaries and tubes through the vagina in preference to abdominal section. We must not lose sight of the fact that in many of these old pus cases, the bowel and omental adhesions need surgical attention for the relief of the patient. This can not be given as satisfactorily through the vaginal route as it can by the abdominal. How many times have you liberated a coil of ileum or an omental adhesion in approaching these pus cases by the abdominal route which needed the attention of the surgeon fully as much as the pus collection which caused them. It is a well recognized fact now that except in acute cases, very rarely is the pus infectious. Therefore, there is very little risk in chronic cases of infection from that

cause and the argument used by the advocates of the vaginal route, that it will avoid infection is not of much moment. In all acute cases where the pus can be readily reached by the vaginal route, I prefer that, and in those desperate cases where we must temporize, as in those narrated by Dr. Noble yesterday, I would incise and drain and make a second operation later if necessary for relief.

DR. A. H. CORDIER, Kansas City, Mo.—The aim of the surgeon in the application of his methods is to obtain the maximum benefit with the minimum sacrifice of structures and the least amount of risk to life, and the saving of time and pain to the patient. These various results are best obtained by one surgeon by the following of a technique to him easy and successful, while another is equally successful in obtaining the same results by a procedure differing wholly or in part. With many surgeons the choice of operative procedure determines his success, while others possess that rare gift of making a success of any or all methods, and are to be congratulated and admired by those of less dexterity. Some never make a success of any method, and are constantly scanning the pages of foreign literature for something new to try. In this way much harm to surgery is wrought, and many lives lost. I would not be misunderstood on this point, as I do not in the least desire to place a depreciative stamp on any good and safe surgery, be it a foreign or home procedure, but I do desire to enter a protest in the matter of hastily accepting the revival of a class of surgical procedures discarded some time ago in this country, lately revived in part of Europe. I refer to the draining and partial removal of the diseased appendages, and the total removal of the uterus in cases of double tubal disease. It is perfect surgery, or as nearly perfect surgery as is possible, that all surgeons desire, but before accepting precepts involving human life or comfort all evidence should be brought to bear on the topic, duly analyzed and weighed for its proper worth. It is from this standpoint that the writer desires to discuss the subject of vaginal hysterectomy as described and practiced by many of the French and a few of our American gynecologists. Some men in other professions achieve renown by the mastership of their art; for instance, Paderewski, whose dexterous and delicate touch on the ivory keys of his piano has startled and charmed the people of two hemispheres. However, there is but one Paderewski. The limit and character of the pathology should form an indication as to the nature and extent of the surgical procedure. A flaccid and pus-infiltrated uterus, with, possibly, numerous foci, surrounded with pus-laden tubes and ovaries, should be removed, the choice of operative procedure being the one which, in the opinion of the surgeon, offers the most favorable conditions of immediate recovery from the operation, a permanent relief of the constitutional (septic) manifestations and the local symptoms resulting from the presence of these structures and the repair of the damage to surrounding organs wrought by their presence. In an old recurring puriform disease of the uterine adnexa, where the adhesions are well organized and where the intestinal, bladder and omental attachments are firm, the vaginal method would be fraught with more danger than the abdominal. These cases have established in part a peritonitic immunity by a prolonged and gradual process of auto-sero-therapy, consequently the abdominal method is not so liable to inaugurate an acute dangerous peritonitis or septicemia as is often the case in the acute or primary attacks if operated on. Some of the advocates of the vaginal method, only a short time ago, maintained that it was an admission of incomplete operation to use drainage, yet they advance the claim for good drainage by the vagina as an argument in favor of the vaginal route.

It has long been an established and demonstrable fact that in the majority of instances the uterus is capable of taking care of itself, and that it does not give rise to any trouble by its pres-

ence after the diseased appendages have been removed. I do not understand why an organ with a good and free natural drainage should not recover, and yet (as is claimed) an ovarian abscess or parts of diseased tubes with walls as thick and shaggy as a cocoon recover with only an opening into the vagina.

The vaginal operation is not an easy one, neither is it as quickly performed as the suprapubic. In comparing the relative ease with which the manipulation can be carried on through an abdominal incision and an opening in the vaginal vault, it must be remembered that the bony resistance met with by the impinging of the hand against the pubes is unyielding, differing very much from the pliant muscle of the abdomen under anesthesia.

A small percentage of post-operative hernia is found following in a large series of abdominal incisions, but these are discovered by the patient and not by the surgeon, and are not of such frequent occurrence as to be used as an argument against the suprapubic incision. Time and close investigation of the vaginal cases will reveal an equal or larger amount of vaginal bowel protrusions.

1. The operation of vaginal salpingo-hysterectomy in many instances is incomplete; 2, it takes longer to perform it; 3, there is more danger from hemorrhage; 4, the uterus is removed in many instances where it should be saved.

DR. E. E. MONTGOMERY, Philadelphia—The object of all surgical procedures should be conservative; that no organ whose function could be maintained should be sacrificed. In dealing with pelvic disease we can not claim that any special procedure should be followed in every case to the exclusion of any other; that both the abdominal and the vaginal routes have their advantages in special cases. The vaginal procedure, however, is a conservative one, inasmuch as it enables us frequently to treat conditions without the sacrifice of the organ. It enables us to evacuate pus collections in the broad ligament on either side, or even in the tube, and after irrigation to pack the cavity, so that it subsequently becomes obliterated and the patient is relieved of the diseased condition without loss of function. In those cases in which both tubes are involved to such a degree as to render them functionally useless and their retention prejudicial to the health or life of the individual, none will question the wisdom of their removal. In such cases the infection has begun in the uterine endometrium and extended from it to the tubes and ovaries. The removal of the tubes does not, consequently, remove the entire diseased tissue. In some cases it will be found that pus extends down to and into the uterine end of the tube, so infected tissue remains after the removal of the tube. In all cases, the inflammation which has existed in the uterus has given rise to plastic exudation and enlargement of the organ, which subsequently produces distress and discomfort after the involution has been completed. The contraction of the walls, compressing the nerve filaments in the uterine structure, produces various hystero-neuroses of a distressing character, so that in every case in which it is desirable to remove both ovaries and tubes it is preferable the uterus should accompany it. Those who do this operation through the abdomen leave the vaginal portion of the cervix, forgetting that this has its own lymphatics, is subject to reinfection and in continued irritation may develop malignant disease. Where the tubes and ovaries alone are removed, we not unfrequently find patients suffering from hemorrhage of a regular or irregular character, purulent discharges, so that the patient may have to undergo a curettement in order to overcome the symptoms.

In the removal of the pelvic organs the vaginal route affords the preferable procedure, for the reason that through it we can thoroughly remove the uterus, ovaries and tubes with less interference with the abdominal viscera, than by the abdominal section. As the opening is made in the most dependent

portion the drainage is more effective; no ligatures are used to be subsequently infected and keep up a sinus; convalescence of the patient is less uncomfortable and more rapid; the abdominal wound, cicatrix and sequelæ are avoided. The dangers of injuring the intestines and ureters are about equal in the two procedures. The abdominal method, however, affords the advantage that a better opportunity is given to repair damage.

## DRAINAGE VERSUS RADICAL OPERATION IN THE TREATMENT OF LARGE PELVIC ABSCESES.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY CHARLES P. NOBLE, M.D.

SURGEON-IN-CHIEF, KENSINGTON HOSPITAL FOR WOMEN,  
PHILADELPHIA, PA.

It is my purpose in this paper to call attention to the value of drainage in the treatment of large pelvic abscesses, and to contrast the results which can be secured by this method of treatment with those which have been obtained by the more radical operation of abdominal section, together with the removal of the pus sacs—whether of ovarian, tubal or other origin.

It will be well, to avoid misapprehension, to point out that only a specific class of cases is under discussion. It is not my purpose to discuss the treatment of suppuration in the pelvis in women in general. The ordinary case of pyosalpinx or abscess of the ovary, chronic in character, is not considered. We are concerned to-day only with those cases of extensive suppuration in which, in general, in addition to pyosalpinx or abscess of the ovary, there exists an intraperitoneal abscess, and in which the pelvic viscera are matted together by extensive exudate; and very frequently, at the time the patient comes under the observation of the surgeon, active inflammatory or septic processes are going on, which have confined the patient to bed for weeks, so that she is greatly reduced in strength, and unprepared to resist the shock of a serious surgical operation.

Until May 1, 1894, I had never employed drainage without abdominal section in the treatment of this class of cases, but had always operated upon them by abdominal section and the removal of the diseased parts. This radical method of treatment has yielded in my hands, as it has in those of others, many brilliant cures, and others which were eminently satisfactory, although long continued; but, on the other hand, the mortality following this operation has been relatively high. Instead of a mortality of 5 per cent., it has been nearer 25. Every operator of experience, with whose results I am familiar, has had in dealing with this class of cases, similar results; hence, I believe, it is unnecessary to further elaborate the present status of the treatment of this class of cases by radical operation. Had we no other method of treatment the results obtained by this would be eminently satisfactory, as a spontaneous cure is a very rare event. Fortunately simple drainage, intelligently applied, has wrought a revolution in the results which can be obtained in that treatment.

Since May 1, 1894, I have operated by simple drainage, without a death, upon eight patients, each a typical and very marked example of the class of cases under consideration. Seven of these were very critically ill at the time of operation. They had been confined to bed with septic fever from three to eigh-

teen weeks, and I feel certain that if operated upon by abdominal section, at least six of the eight would have died of shock or septic peritonitis. A short history of each case is appended:

*Case 1.*—Mrs. X., a multipara, was seen in consultation with Dr. Dunn, May 1, 1894. Her last child was born March 27, 1894, and in the meantime she had suffered from a mild but persistent septic infection, which had resulted in the formation of a true pelvic abscess. The pus had burrowed along the inguinal canal, and was making its way to the surface of the groin. The patient was extremely feeble from the long continued sepsis, and in bad condition for a major operation. This case was treated by direct incision into the groin, with evacuation of the abscess. A thoroughly satisfactory but tedious convalescence resulted. Some months later Dr. Dunn informed me that this patient was entirely well.

*Case 2.*—Mrs. M., aged 23, a nullipara, was seen May 18, 1895, in consultation with Dr. Robinson. About a week before this her uterus had been dilated and curetted because of the existence of an endometritis and catarrhal salpingitis, with resulting sterility. Some days after the operation symptoms of peritonitis manifested themselves. The peritonitis was of moderate intensity, and it seemed not unlikely that the inflammation would undergo resolution. About June 24, it became evident that suppuration had taken place, and that pus was collecting in Douglas' pouch. At this time the patient's condition was very serious, so that a radical operation by abdominal section offered very little prospect of a favorable termination. On June 26, an incision was made into Douglas' pouch, and the abscess evacuated and washed out. A very satisfactory and rapid recovery followed, and since that time there have been no unpleasant pelvic symptoms. An examination, however, shows that the left tube is adherent.

*Case 3.*—Mrs. B., aged 30, 2 para, was delivered Oct. 24, 1895. The labor was tedious and instrumental. The first labor had been easy and the delivery spontaneous. During the second pregnancy there had been persistent and annoying pain in the right inguinal region. About thirty-six hours after labor, the patient had a chill, with a temperature of 103 or 104 degrees, and in spite of the treatment instituted, the temperature fluctuated between 99 and 100 degrees in the morning, and between 103 and 104 degrees in the afternoon, until November 12, when I saw her in consultation with Dr. Cross. At that time a well marked mass could be made out high up in the false pelvis and in the region of the cecum. The diagnosis lay between an appendicitis with an abscess and an abscess of puerperal origin. The absence of any history of foul smelling discharge from the uterus, and the fact that on examination the uterus and broad ligaments were not found abnormal, and especially that no exudate could be felt even high up in the pelvis, inclined me to accept a diagnosis of appendicitis, which had been arrived at by Dr. Cross. Operation was advised, and on the 13th a direct incision was made into the mass, evacuating a large amount of pus. Unfortunately the ileum was adherent under the point of incision, and was opened for a distance of half an inch, requiring suture. This patient was so weakened, as the result of the septic poisoning which had continued for eighteen days, that it was desirable to avoid a radical operation, as the prospect of recovery from a radical procedure was very unfavorable. A steady improvement followed the operation, but the sinus did not close, and it was evident that either a diseased appendix or uterine appendage must be removed in order to effect a cure. On March 2, Mrs. B. was operated upon by abdominal section, in the Kensington Hospital for Women, and the right uterine appendage was removed. The persistence of the sinus was due to the presence of a small pyosalpinx. She is now rapidly recovering her health and strength.

*Case 4.*—Mrs. L., aged 22, 2 para, was prematurely delivered November 20, by a midwife, of an eight-months child, which lived only a short time. November 28, she had a chill, and subsequently developed an inflammation in the right inguinal region. She was seen December 7 by Dr. Stoner, who found her much prostrated, complaining of general abdominal pain, most marked in the right iliac region. A small mass was detected upon pressure in the appendix region. Her temperature was 100 degrees, and pulse 112. Under treatment the general condition improved, but the mass in the iliac region increased in size. On December 11, I saw her in consultation with Dr. Stoner, and a very large mass in the appendix region could be made out. On this day the symptoms had become aggravated and an immediate operation was urged. Consent to this was refused, but on the following day she was taken to the Kensington Hospital for Women. In the meantime her condition had become worse, her pulse was above 130, and

temperature 103 degrees. The peritonitis was evidently extending, and she was becoming decidedly septic. She was operated upon in the night. A direct incision was made over the mass, but adhesions had not formed between it and the abdominal wall. The general peritoneal cavity was packed off with gauze, the abscess cavity was opened and the pus evacuated. The abscess extended well up behind the cecum. No attempt was made to find the appendix. The abscess was drained with gauze and rubber tube. The patient's condition was no worse than before operation. During the night edema of the lungs developed, and the following day when the first urinary examination was made, it was found that acute nephritis was present, and the casts found indicated that the patient had been recovering from the nephritis of pregnancy before operation. The patient was so ill for ten days, that it was impossible to say whether she would rally, but she finally made a good recovery, and is now quite well.

*Case 5.*—Mrs. S., age 31, 5 para, was first seen Dec. 20, 1895. She had been in bed since September 21, and had a distinct history of ectopic pregnancy with rupture. She was quite feeble from the long continuance of the pelvic peritonitis, and had lost about fifty pounds in weight. Operation was advised, but for a time not accepted. January 1 she was admitted to the Kensington Hospital for Women, and on examination it was discovered that a sinus was present behind the cervix, through which the femur bone of a fetus was removed. As her condition improved for some days after admission, she was not operated upon until January 14, when the sinus was dilated and the vaginal wall incised, and a pelvic abscess in front and to the left of the rectum was washed out. Most of the fetus and clots had been discharged before the operation. She made an uninterrupted recovery, and at this time is doing full work and feeling well.

*Case 6.*—Mrs. K., aged 25, 1 para, was seen Jan. 28, 1896. She gave a history of inflammatory attacks extending over several years, and stated that she had been advised to have her ovaries removed. She had been bleeding irregularly since Nov. 8, 1895, and there was reason to believe that she had an early miscarriage at that time. Inflammatory symptoms had manifested themselves some three weeks before my visit, and had been growing steadily worse. She had had rigors, followed by a temperature of 105 degrees, and was decidedly septic. The pelvis was filled up with a large mass, more especially on the right side. Her condition grew steadily worse, and the peritonitis extended from the pelvis to the abdomen. On the 31st the pelvic abscess was incised from the vagina and a large amount of pus evacuated. Her convalescence was very satisfactory. She was out of bed in three weeks and has since steadily improved. The appendages are adherent and the history of the case indicates that it will be necessary to remove them to effect a cure.

*Case 7.*—Mrs. R., aged 40, 8 para, 2 miscarriages, last one Jan. 4, 1896, at the sixth week of development. The ovum was discharged after one day. She apparently had very little trouble, and was out of bed on the tenth day. About two weeks later she was seen by Dr. Walker. She had severe pain in the hypogastrium, and later in the left groin. At no time did she have much fever, but a persistently rapid pulse. I saw her with Dr. Walker on February 22. Her pulse was 120 and temperature 101 degrees, and a large mass was outlined between the uterus and bladder, extending into the left broad ligament, and in addition there was evidence of pus formation under the skin in the left groin, the exudate extending well up toward the ribs. The following day I made an incision in front of the cervix, pushed off the bladder from the uterus, and introduced my finger into an abscess cavity, which extended from slightly to the right of the cervix well over into the left broad ligament. About four ounces of pus was discharged. A second incision was made into the groin and a large abscess evacuated. The pus in this location had evidently burrowed along the round ligament, and was external to the abdominal muscles. The following day the temperature was 102 degrees, but the patient's condition was much better. She gradually improved, and the temperature and pulse became normal after three weeks. At this date she is entirely well and an examination shows that the left ovary and tube have escaped infection. Her pelvic organs are normal, with the exception of some old lacerations.

*Case 8.*—Mrs. B., aged 28, was delivered Dec. 18, 1895, at full term, of her first child. Marked hydramnion existed and about two gallons of liquor amnii was discharged. The patient was delivered instrumentally by Dr. Robinson, under full antiseptic precautions. A poorly developed child was delivered alive, who died of convulsions after two days. Forty-five minutes after delivery Mrs. B. was attacked with convulsions, which were very severe and persisted in spite of active treat-

ment, especially with the *veratrum viride*. The patient improved so far as the convulsions were concerned, but was much dazed mentally, and soon developed decided mania. On the fifth day there was a slight chill, and a decided one on the twelfth day. The lochia was normal throughout. The patient continued to be very ill physically and did not improve mentally. The temperature in the evening ranged from 101 to 104 degrees F. For a long time there was no tenderness or indications of inflammatory processes about the pelvis, but after the sixteenth day the abdomen became tympanitic. On the sixty-third day a mass was recognized behind, above, and to the left of the uterus, but there was no complaint of tenderness. I saw Mrs. B., with Dr. Robinson, on February 21 and advised operation, and on the 26th was able to reach the pus sac by vaginal incision, introducing the fingers well up behind the uterus, and puncturing the sac with scissors. A large amount of very offensive pus was discharged. The sac and pelvis were irrigated and a large gauze drain introduced into the pelvis. Improvement was manifested at once; within a week the mental condition was greatly improved, the insanity disappeared within two weeks; the temperature became normal after five days and remained so. The present condition of the patient is very satisfactory. The nature of the pus sac was not discovered.

A review of what has been accomplished in these cases, by this simple operation, will be of interest:

Case No. 3 has had a secondary operation to remove the pus sac. Her condition was most critical at the time of the drainage operation and the result of saving her life is eminently satisfactory. The other patients are feeling well and at least two of them are permanently cured.

Two of the cases, Nos. 1 and 7, were puerperal in origin, and the abscesses were of the broad ligament. Drainage from the vagina or loin will permanently cure all such cases. Heretofore I have made an exploratory abdominal section to definitely determine the condition of the uterine appendages. Hereafter I shall simply drain the abscesses when this is possible and save the patient the ventral incision.

The prospect for a permanent cure in two other cases is excellent. Case No. 4 may have a recurrence of appendicitis but where the abscess has been large frequently the appendix sloughs away, or is so infiltrated with pus that when resolution takes place it becomes obliterated. Case No. 5 has adherent appendages as the result of an extensive hemocele and exudate, due to the ruptured tubal pregnancy. But this sac has been drained and become obliterated. This patient feels perfectly well.

The remaining three patients feel and consider themselves well, but it is not unlikely that the diseased appendages which they have will give further trouble and require removal.

My own experience in the use of drainage, in the treatment of such cases, has been too limited to make profitable an expression of opinion as to the percentage of permanent cures which can be obtained. My advocacy of the operation is based upon the fact that it is a life-saving procedure, and that in a certain percentage of cases a permanent cure will be effected. By this method of treatment either a cure can be obtained with little or no risk to the patient, or a critical and highly dangerous operation can be avoided. At the very least, establishing drainage permits the patient to recover from sepsis, and to have her strength built up by judicious feeding and medication. If a radical operation be demanded, it can then be done when the patient is in a favorable instead of an unfavorable, or even a desperate condition.

#### DISCUSSION.

DR. JOSEPH PRICE, Philadelphia.—While Dr. Noble has directed special attention to pelvic abscesses and desires the

exclusion of pus tubes and ovarian abscesses, at the same time he has introduced and discussed a number of other subjects. The management of abscess in cellular tissue, or in the pelvis, in the palmar or plantar fascia, is precisely the same. These is but one specific or radical treatment, that of incision and drainage. They are not enucleable and never have been. So it seems difficult to reconcile these points with many gynecologists. There seems to be an impression that a certain class of men have but one method of managing so-called pelvic abscesses, and have but one pathology; not so at all, nor has it ever been so. I am sorry that all abscesses are not of tubal and of ovarian nature in all parts of the body. We can not enucleate mammary abscesses in the axilla as we do pus tubes and ovarian abscesses. The removal of abscess is ideal treatment. Abscesses in cellular tissue in any part of the body should be treated by incision and drainage, and about all cases so treated recover. If you have an abscess in the cellular tissue of the pelvis, with matted viscera limiting it, there is but one treatment, and that is to free the matted viscera, and in that much you have done something that will relieve the condition, at the same time the result is death, for even after incision of these abscesses obstruction follows, or the symptoms remain permanent, and death follows from obstruction or advancing peritonitis, particularly in the puerperal cases. It is common in puerperal cases to find a puddle of pus, and in twenty-four hours the parts are covered with lymph, and a simple incision does not always save; but section, freeing the adherent bowel, with a thorough toilet with drainage from above and below, does save. You may find cases with black congested tubes, which should not be interfered with. There is nothing more to be done other than a thorough toilet, followed by drainage. If in those cases you arrest sepsis you save them. If you fail to do that, they all die. It is sepsis pure and simple. Just in that direction copious drainage, or free gauze drainage from above and below, or the so-called open wound treatment has been popularized, and I fear the profession fail to recognize what extensive drainage from above and below by the open treatment does. It simply arrests the progress of sepsis. It is copious drainage, and you find some recently reported cases of that character. I might allude to a case recently reported by Dr. Hare, of Philadelphia. The boy was taken ill on Friday evening. Dr. Hare saw him at half past seven Saturday evening with well-marked trouble about the head of the cecum. He was vomiting, had a pulse of 120 to 160, condition alarming. He was taken hurriedly to the hospital, his abdomen opened, a gangrenous appendix removed, and a toilet made of his whole peritoneal cavity. The patient had all the symptoms of a severe general septic peritonitis. His condition seemed hopeless. After a thorough toilet the symptoms improved, and within thirty-six hours after operation the drainage tube was removed and the abdomen closed. Symptoms again became alarming. Arrest of sepsis had primarily taken place, but it was not continued by drainage. After the removal of the drains again symptoms of sepsis developed and the incision was reopened, drainage reestablished sepsis arrested, and the boy recovered. None of us surely will question the fact that this was not a case of septic peritonitis. Drs. Keen and Hare are both abundantly capable of determining that fact. I allude to this case in order to emphasize those points that have been brought out, because so many practitioners say that cases of general purulent septic peritonitis are not saved. I can refer them to suppurative forms of general peritonitis where we have saved nearly all of them. We have but little fear of pus in the pelvic cavity. I have many times seen the peritoneal cavity deluged with pus.

DR. W. E. B. DAVIS, Birmingham, Ala.—I am sure we all appreciate the paper which has been presented by Dr. Noble, because it emphasizes a surgical procedure that has been adopted and resorted to for a long time. It is life-saving when

further surgery would endanger the life of the patient, for as Dr. Price said on a previous occasion, "It takes but a feather's weight to depress the beam," in such cases. Usually these cases have been confined to bed for weeks and to do anything more than evacuate the pus and relieve the septic condition is dangerous. And while this is an incomplete procedure and should be so explained to the patient, and that a more thorough operation will be required later, still a certain percentage of the patients will be cured. There may be some adhesions left behind, some trouble still in the tube, but they are practically cured. A radical operation in a large number of cases will have to be done later. This should be borne in mind and impressed upon the patient.

As to the adhesions to which Dr. Price refers, in cases of puerperal infection the adhesions to the omentum and intestine, after the pus is evacuated, give way. I have opened the abdomen and found very few adhesions. In one case I opened a large abscess of the right tube which had its origin in puerperal infection. The woman had a pulse of 140 to 150, she came near dying from the evacuation of this pus, but recovered; had no more unpleasant symptoms, and was delivered of a child some three years later.

DR. W. G. MACDONALD, Albany—The cases which have been so clearly reported by Dr. Noble, belong to a class which may be said to be neglected cases of accumulations of pus either in the pelvis or about the head of the cecum. I quite agree with him as to the benefit derived from the operation which he has done, yet at the same time I do not believe it will cure his patients in the majority of cases. Probably in the case of appendicitis, where he has opened and drained these abscesses it will be the last of the appendix, but not always so. I have found it necessary under similar conditions to resort to secondary operations after some months to remove the stump of the appendix. It would astonish many men if they had a large area of induration in the right iliac fossa to find after six months there were very few adhesions.

A number of years ago Dr. Clinton Cushing recommended a procedure which Dr. Noble has described. He presented a dilating trocar and referred to a method of drainage by douching. I have employed for some time that method in suitable cases. I have put drainage tubes between the dilating trocar and kept them in four or five weeks, and have seen cavities evacuated. I then took out the drainage tube, and at the end of three months there was a relapse, and I had to repeat the operation. Finally I have been compelled to remove the uterine appendage on that side by making a clean abdominal section. But I do gain this advantage, in that my patient is in a better general condition. This is not always true. Only a few days since I had occasion to operate on a case of pelvic abscess due to puerperal sepsis. I made an incision through the abdominal wall just parallel with Poupart's ligament. The abscess presented there, so that I did not include very much of the peritoneum. The abscess had several pockets which I evacuated and drained. The difficulties of abdominal section in the removal of the uterine appendages are not great. I have made a considerable number of abdominal sections in those cases, and I have not experienced serious difficulty in removing the damaged appendages.

DR. E. E. MONTGOMERY, Philadelphia—It is true, as has been said, that this procedure does not always result in cure of the cases, that we can not promise as much for it as the more radical procedure, and we must necessarily subject the patient to a more radical operation in order to effect an absolute cure. But this method affords us a means of treating cases which would otherwise be exceedingly dangerous to treat by radical procedure, cases that are so depressed, in which the condition of debility is so marked that we can not hope for a favorable result if we proceed to a radical operation at the time. It also affords an opportunity for curing some cases and

preventing a sacrificial operation, where if the abdominal method were resorted to it would be necessary to remove the organs in their entirety. Whether the abscess be in the cellular tissue, broad ligament, or tube, and there is a large accumulation, and the tube is distended at the expense of the broad ligament, so that we can determine pus on one side of the pelvis, and the symptoms indicate that it is inflammatory, we are enabled to evacuate the pus, wash out the cavity, or practically curette or scrape it before thoroughly removing the diseased tissue, then packing it with gauze to bring about contraction of the abscess cavity and subsequent obliteration. A mistake is often made in the treatment of these cases in making too small an opening. For instance, in using a trocar and passing through it a drainage tube. It is preferable to make a free incision across the posterior surface of the vagina, opening into the broad ligament and operating through it, pushing the ureters aside, making a free opening into the sac, subsequently packing it with gauze in order to bring about its obliteration. I have been practicing this method for a number of years and have seen cases recover from the operation where there were large collections of pus, where the operation through the abdominal cavity would have been dangerous, and very little trouble has resulted to the patient during convalescence.

## PHARMACEUTIC NOTES.

Read in the Section on Materia Medica and Pharmacy, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY EDGAR L. PATCH.

BOSTON, MASS.

*Liquid Extract of Malt.*—"What value have the liquid extracts of malt of the market that is not possessed by the common beers, ale, lager and porter?" This question has been frequently asked us. We give the results of the examination of several prominent market makes in comparison.

	Extract. Per cent.	Alcohol. Per cent.	Converting power.
No. 1,	10 . . . . .	3.59	none
No. 2,	10.1 . . . . .	5.33	none
No. 3,	14.7 . . . . .	2.34	none
No. 4,	10 . . . . .	6.45	none
No. 5,	10 . . . . .	4.86	none
No. 6,	7 . . . . .	3.47	none
No. 7,	8 . . . . .	3.8	none
Lager,	5 to 9 . . . . .	3.5 to 5	none
Ale,	6 to 10 . . . . .	10. to 14	none
Porter,	5 to 7 . . . . .	6. to 8	none

As these liquid extracts do not possess a particle of diastasic power it is not reasonable to suppose that they are of more value than any beer possessing the same proportion of extract and alcohol.

The thick, non-alcoholic extracts average to contain about 72 per cent. of solid extract and to convert from eight to eleven times their weight of starch. A fluid extract made from select malt by repercolation, using a menstruum of 18 per cent. alcohol by weight will contain about 13 per cent. alcohol, about 30 per cent. of solid extract and convert fifteen times its weight of starch.

Diluted with two parts of water it would be superior to any of the liquid extracts in all qualities but one. It would not be as agreeable in taste as the products prepared by direct fermentation.

*Solution of Nuclein.*—What shall the pharmacist dispense when this article is called for? No. 1 is an alcoholic solution and is said to be made from thyroid and thymus glands; dose, hypodermically, two to five minims diluted with water, price \$5 per ounce. "Indicated to counteract a disorganized state of the blood." Two c.c.—0.001 residue, a little more

than 5-100 of 1 per cent. Gave no ppt. or change when diluted with water, the alcohol gently evaporated and the residue tested with Mayer's reagent.

No. 2.—Non-alcoholic solution made from yeast, slight brown, odor of carbolic acid. Two c.c.—0.041 residue or 2 5-100 per cent. Gives a slight precipitate with Mayer's reagent and gives test for albuminoids with Biuret test. Dose ten to eighty minims hypodermically as a non-poisonous germicide.

No. 3.—Colorless liquid, non-alcoholic. "Made from shad's roes." Two c.c.—0.005 residue,  $\frac{1}{4}$  of 1 per cent. No ppt. with Mayer's reagent but gives yellow color. Does not respond to test for albuminoids. Price \$2.50 per ounce.

*Natural Sodium Salicylate.*—"There is considerable variation in color, odor and taste of market products. What explanation can be offered?" When the salt is made by acting on the oil of wintergreen with solution of sodic hydroxid there is a possibility of the contact being insufficient or the temperature too low. In consequence a considerable quantity of sodium methyl salicylate is produced. This is a white powder, but neutralizing with an acid frees gaultheria oil and salicylic acid instead of salicylate acid only. We have seen samples that contained over 25 per cent. of sodium methyl salicylate.

The latest investigations of oils of gaultheria and birch by Dr. Fred. B. Power and Dr. Clemens Kleber demonstrate that the statement of many text-books that these oils contain 10 per cent. of a terpene  $C_{10}H_{16}$  is an error, and must have arisen from an examination of an oil adulterated with turpentine. Power and Kleber conclude that the true oil of wintergreen consists of 99 per cent. of methyl salicylate with fractions of 1 per cent. of a paraffin, an aldehyde or ketone, an apparently secondary alcohol and an ester. When *fresh* it has a left rotary power. Oil of sweet birch, commonly offered as gaultheria oil, consists of 99.8 per cent. of methyl salicylate, the remaining .2 per cent. being made up of the before-mentioned paraffin, an aldehyde or ketone and an ester, but does not contain any of the secondary alcohol. It is always optically inactive. The artificial oil of wintergreen is supposed to consist entirely of methyl salicylate.

It is said that the statement that natural oil separates at once in drops from water while artificial does not, is erroneous. It is doubtful if any ordinary observer can detect the presence of as much as 40 per cent. of synthetic oil added to the natural and the *natural* salicylate of sodium might possibly prove to have been made largely from an artificial oil. Why should any natural sodium salicylate made from oil of wintergreen completely converted possess any advantages over a pure product from any other source?

*Kola Nut and Kola Wine.*—Much has been written upon kola nut. It has been stated that the fresh nut does not contain caffeine but that this alkaloid and theobromin are produced by the decomposition of a natural glucoside by a proteid ferment having diastasic power. Kola red and glucose are said to be produced at the same time. Heckel and Schlagdenhauffer give as the constituents of kola: Starch 33 to 37 per cent., cellulose 29 to 30 per cent., water and inert matter 22 per cent., tannin  $1\frac{1}{2}$  per cent., kola red  $1\frac{1}{4}$  per cent., albuminoids 67 per cent. and caffeine 1 to  $2\frac{1}{2}$  per cent.

We have obtained from different lots of dry kola 1.2, 1.5, 1.48, 2.2, 1.48, 1.88, 1.91, 1.52, 1.32, 1.6, 1.76 per cent. of caffeine.

Fresh Jamaica kola nuts assayed .795 per cent. caffeine. They contained 61.19 per cent. of water, so that the dried should yield 2.05 per cent. caffeine. A portion of the fresh nuts dried rapidly at 60 degrees C. assayed, gave 2.16 per cent. caffeine.

Three of the market kola wines assay as follows:

No. 1. Twenty-ounce bottle, alcohol 13.22 per cent. by weight; 6 per cent. of extractive and 0.036 of 1 per cent. caffeine, equivalent to 2.25 per cent. of an average kola nut.

No. 2. Seventeen-ounce bottle, alcohol 13.81 per cent. by weight; 23 per cent. extractive including glycerin and 0.11 of 1 per cent. of caffeine, equivalent to about 7 per cent. of an average kola nut.

No. 3. Sixteen-ounce bottle, alcohol 16 per cent. by weight; 12 per cent. of extractive and 0.198 of 1 per cent. caffeine, equivalent to 12 per cent. of an average kola nut.

*Ether.*—Are the complaints frequently made concerning the value of ether due, as suggested by Dr. Squibb, to different methods of use or inefficiency in administration? The same lot that is pronounced by several operators as superior in every respect is derided by others as "watery," "half alcohol," "weak," etc.

We were requested to supply different grades of ether to a skillful operator for trial, the samples to include an ether as nearly pure as possible. The samples were numbered and consisted of the following products:

No. 1. Two 4-oz cans, the contents having a specific gravity of .7420 at 25 degrees C., equivalent to 74 per cent. of absolute ether, 26 per cent. alcohol and water.

No. 2. Two 4-oz cans of 1890 ether specific gravity .7163 at 25 degrees C., equivalent to about 95 per cent. absolute ether.

No. 3. A carefully distilled concentrated ether of specific gravity 0.7150 at 25 degrees C., was shaken repeatedly with distilled water during twenty-four hours, separated, added to 10 per cent. of its weight of quick lime and 10 per cent. of its weight of potassic carbonate recently dried at 125 degrees C., shaken frequently, decanted and fractioned by distillation, that fraction having a gravity of 0.7110 at 25 degrees C., and corresponding to over 98 per cent. of absolute ether being submitted for trial.

No. 4. A second lot prepared the same as No. 3 from Squibb's ether, of specific gravity 0.7146 at 25 degrees C., (95.35 per cent.) and giving a product testing the same as No. 3—about 92.06 per cent. absolute ether.

No. 5. Prepared as No. 3, using quicklime alone, and giving a product of specific gravity 0.7109 at 25 degrees C., equivalent to about 98.13 per cent. absolute ether.

No. 6. Prepared as No. 3, using dried potassic carbonate alone, and giving a product of specific gravity .7104 at 25 degrees C., equivalent to 98.51 per cent. absolute ether.

(A small amount of yellow liquid remaining after distilling each lot of ether, that evaporated from filter paper, left an unpleasant odor resembling that of cyanids or bitter almond.)

The surgeon reported: "No appreciable difference could be observed in the action of the different lots. In comparison with Squibb's ether, we were impressed that it was somewhat more bland, *i. e.*, seemed to have rather less irritating effect upon the respiratory-mucous membrane.

"Very careful records were kept of every patient upon whom we made the tests. I still have the feeling that ether of superior quality to anything now in the market may be produced by using chemically pure materials to start with. If I could have a sufficient supply to carry me through a year of surgical work, which would aggregate between two and three hundred anesthetizations, I think I could draw conclusions which would be of some value."

It is interesting to note the specific gravity accepted as correct for absolute ether at 25 degrees C. by different authorities:

Dumas and Boullay, 0.70737; Sassure and Thenard, 0.70987; Gay Lussac, 0.71190; Kopp, 0.7084; Watt and Wurtz, 0.70891; Mendeljiff, 0.70826; Allen, 0.71000; Roscoe and Schorlemmer, 0.70750; Dr. E. R. Squibb, 0.70842.

### MODERN METHODS OF TREATMENT OF TYPHOID FEVER CRITICALLY RE- VIEWED, WITH SUGGESTIONS FOR A RATIONAL THERAPEUSIS.

BY GUSTAVUS M. BLECH, A.B., M.D.

DETROIT, MICH.

Motto: Im Erkennen und Heilen der Krankheiten liegt die Aufgabe der Medizin. Das Erkennen allein ist Wissenschaft; das Heilen war bisher Empirie und wird es noch lange bleiben.—*Hyrth.*

There is hardly any other disease to which the above, written by the immortal Austrian anatomist, could be better applied than to typhoid fever. The dignity, the value of all scientific work and research, lies in the recognition of this malady and its pathology—not in its therapeutics. The more there is written to enlighten the profession in that respect, the better for us. The devising of new formulæ or new methods of treatment can never add much to the reputation of the prospective discoverer (?) Typhoid fever patients have recovered without any treatment whatever; others have died, and probably will die, under the most rational and scientific therapeutics.

Infallible methods exist only in the minds of their promoters and advocates. The number of methods, sub-methods and modifications is as large as that of bivalve vaginal specula which are baptized after their modifiers, the modification often consisting only in the different shape of an unimportant screw or handle. In this article only those methods will be considered which have acquired some popularity, or which have really a scientific value.

*A priori*, typhoid fever does not always appear as that dreadful constitutional disease described in textbooks; there are light forms of short duration. Individuals of regular habits will offer a good deal of resistance, the fight between the disease and the system being even, while others, especially alcoholic drinkers or those with prostrated or affected nervous systems, will succumb immediately. Again, the age, the previous history and the present status of the patient, all need to be considered, and will indicate the course of treatment that should be pursued. We should not treat diseases the same way the cook prepares a certain soup, after a receipt; we claim to be scientific physicians, and as such will have to use our own judgment in each individual case. A specific for typhoid fever has not been discovered as yet. However, we have made of late some advance in the knowledge of the treatment, and can truly assert that our methods

of to-day, if properly applied, are more scientific and more effective than the symptomatic treatment of ten or fifteen years ago.

We will first of all consider the treatment of typhoid fever with water.

*Balneo- and Hydro-therapy.*—This system, especially when carried out in the rigid manner advocated by Brand, who gave it to the profession, influences the entire course of the disease, reducing the mortality to a minimum, preventing complications (especially affections of the respiratory tract), and now stands ahead of all other therapeutic measures. Hydro-, especially balneo-therapy, has its opponents, one of the objections being that cold bathing is cruel, and can hardly be carried out in private practice. There is much truth in the criticism, and many general practitioners have often been compelled to let patients die from hyperpyrexia, owing to their prejudice or poverty. If the full cold baths be objected to, we can immerse the patient in lukewarm water and let the water gradually cool. Dr. L. E. Maire,<sup>1</sup> of this city, when a general practitioner, obtained good results from full baths with hot water. Where the procedure can not be carried out, the wet pack will prove of great help, although it is not as efficient as the full bath. But in no case of typhoid fever, should regular sponging of the body be neglected. I use in my practice a 10 to 20 per cent. aqueous solution of alcohol. Balneo-therapy will not only reduce the temperature but influence the entire nervous system. Strümpell<sup>2</sup> is right when he asserts that under balneo-therapeutic measures the grave "status typhosus" is much rarer than otherwise.

The details of bathing can not be given here; in fact, the condition of the patient and his surroundings will dictate to what extent and degree this method of treatment should be employed. In mild cases sponging of the whole body is sufficient.

*The Abortive Treatment.*—The theory that typhoid fever can be aborted is not of recent date. Wunderlich<sup>3</sup> believes that if at the onset of the disease a few large doses of calomel were administered, the disease could be aborted. His assertions, however, are very conservative, and he is not so sure of being able to abort every case as some modern writers are. *A priori*, typhoid fever aborts spontaneously in some cases, without any interference whatever. The so-called typhus levissimus runs a mild and short course. If such a case came under the care of the authors referred to, they would surely attribute the short course of the disease to the drugs they have "fired" into the stomach of their patient. When reviewing the statistics of their reports, this should always be borne in mind.

Dr. Aulde, of Philadelphia, editor of the *American Therapist*, asserts that he can abort typhoid fever with arsenite of copper. His paper was read only in part at the last meeting of the Mississippi Valley Medical Association. The writer has no experience with this drug. Dr. Aulde's assertions have not been verified by competent authorities in medical literature.

Dr. Woodbridge, of Youngstown, Ohio, has proclaimed himself a pioneer of the jugulant treatment of typhoid fever, and states that if he sees a case early he can undoubtedly abort it, and that death is a wholly unnecessary consequence, for which the physician is to be blamed. It is natural that such assertions must cause some excitement, although at the above mentioned meeting, his theories were received

by a large body of eminent physicians with disbelief and skepticism. He calls his system after his own name. It consists of tablets and soft elastic capsules containing small doses of calomel, thymol, menthol, guaiacol, podophyllin and eucalyptol, of which he administers one every fifteen minutes.

What is more startling is that he allows his patients to eat what they please and to attend to their business affairs while sick! His tablets and capsules are put up and sold by Messrs. Parke, Davis & Co., of Detroit, who send reprints of his various articles to every physician free of charge and distribute them "*en masse*" among students of medical colleges. Dr. Woodbridge could never have gained so much popularity, had it not been for the action taken by Messrs. Parke, Davis & Co., and it is for this reason that I beg the reader's pardon for dwelling somewhat at length on his treatment. It is well for every one to send for his pamphlet, so as to verify the following criticisms:

Dr. Woodbridge is not the first one who has claimed that typhoid fever could be aborted. His formulæ are nothing but a combination of antiseptics and aperients which have been used singly for years by different physicians; the combination forms no new chemical. It is nothing but a "shot-gun" prescription. Similar preparations are already on the market, the well-known antiseptics sold under the trade names listerin, borin, pasteurin, euthymol, etc. He is not original. If Dr. Woodbridge expects us to accept his statistics, he must first prove to be a man who adheres to facts even in little things. He states in his publication that the discussion, which took place after his paper was read at the Mississippi Valley Medical Association, Sept. 4, 1895, lasted three hours; while in fact, including my own criticism, which was also the concluding remarks for my own paper, the discussion lasted thirty-five minutes only.

As regards the value of the formulæ, as intestinal antiseptic treatment, I fully appreciate them. There is nothing bad about them, unless it be that it is very unwise to prescribe his ingredients in tablet form, owing to the pungent taste and the volatility of some ingredients. All his formulæ ought to be put up in soft elastic capsules. To bother a typhoid fever patient every fifteen minutes, is an outrage. Why not give usual doses every three or four hours? The effect is the same. But Dr. Woodbridge regards rest as unnecessary. I trust that no sane physician, for the sake of his patients and his own reputation, will accept this theory of the uselessness of rest and dietetic restriction.

Dr. Woodbridge points with pride to the reports sent him by other physicians. Without casting any reflections on the standing of the reporters, I will merely say that, considered carefully, the reports are inexact, unreliable and far from satisfying the scientific reader.

In most cases we are compelled to accept their statement that they treated cases of typhoid fever. If my criticism has been harsh, I will cite two of the reports which will amuse us:

One physician reports a case in which he observed the usual prodromes. Highest temperature 103.4 degrees; no delirium, no eruption; cure in seven days! *O tempora, O mores!* Another physician reports a case of two weeks' standing, after which he was called in. He gave one tablet and the patient improved immediately after the first dose. It must be borne in mind that the second dose had to be administered

fifteen minutes after the first one. The abortive treatment as such is valueless; the title antiseptic treatment, however, is justified.

*Antiseptic Treatment.*—According to modern views, typhoid fever is considered a microbial disease, caused probably by Eberth's bacillus typhosus. Most of these germs gain entrance into the human system, multiply in suitable soil and develop toxins, causing a general infection of the entire system.

By internal administration of antiseptics and chemicals the action of the germs is neutralized, their powers of multiplication and toxin production destroyed, thus giving the system an opportunity to eliminate the noxious toxins already produced. Pathology teaches that typhoid fever, as far as local lesions are concerned, is principally an intestinal affection, hence intestinal antiseptics are indicated. Bouchard<sup>6</sup> urges us to employ general as well as intestinal antiseptics.

This at best is theory only. The writer has practiced, and intends to practice, antiseptic therapeutics in affections now generally accepted as of microbial origin. But he frankly admits that he does so, not from blind belief in the correctness of the above quoted theory, but because it is the duty of every physician to leave nothing undone that might save the lives of his patients or prove of benefit to their sufferings, as no harm can follow from a judicious administration of antiseptics.

Trouessart<sup>3</sup> complains that antiseptics has not received general acceptance in internal medicine, while it is indispensable in all surgical procedures. That was so two or three years ago. To-day, chemic antiseptics is entirely discarded by modern surgeons. Even in septic wounds the antiseptic measures taken are not those formerly used. Modern surgeons state that wounds ought to be treated "aseptically." This is not the proper term.<sup>4</sup> Modern antiseptics in surgery does not consist of the employment of strong and toxic chemicals, but mild measures are used, such as sterilization, normal salt solution, peroxid of hydrogen, etc. The reason for this change is that carbolic acid, mercury, etc., in solutions usually employed, have been found to have very little influence on the microbes, and that wounds, even of a septic character, heal just as rapidly and just as nicely under a less rigorous antiseptics. If such is the case in surgery, the present fad for killing the germs through general counter-intoxication, will have to give place to a less serious medication.

In looking over the list of antiseptics one is impressed with the large number. Almost every drug, beginning with ordinary household coffee (in infusion) and ending with a saline cathartic has been found to be a direct or indirect antiseptic. And now the old-fashioned treatment of malaria with quinin, rheumatism with salicylates, and syphilis with mercury, has been found to be nothing but the antiseptic treatment of those affections. What is in a name? And now modern surgery has taught us that salicylate of soda has but a slight antiseptic power! If the typhoid fever bacillus is so easily neutralized by guaiacol carbonate, that Dr. Woodbridge, or others, have succeeded in bringing typhoid fever patients to an almost normal state, as far as the symptoms of a general intoxication are concerned, in twenty-four hours, why, I ask, does the same drug not kill the malaria organism or the as yet undiscovered and unbaptized but sure to exist bacillus rheumaticus?

That it does not I can testify from clinical experience. In several cases of malaria, for a few days, various antiseptics (guaiacol carbonate, carbolic acid, calomel, iodine) were tried with no effect. A hypodermic injection of the arsenite of quinin was sufficient to stop the chills.

In acute inflammatory rheumatism the salicylate of sodium, in spite of the fact that it has but slight, if any, antiseptic power, has proven of greater benefit than any of the above-mentioned antiseptics. Is rheumatism after all then a non-microbial disease? Colchicin has proven to have no antiseptic power whatever, and still one must be astonished to read in French literature the results obtained from its use in various rheumatic affections.

I have a large number of cases of chronic rheumatism, deforming and non-deforming under my care, and the administration of general antiseptics has produced no marked results within four weeks. Generally in private practice I can control chronic rheumatism with large doses of natrium salicylicum in about ten days.

If microbes are the cause of disease and they are destroyed by antiseptics, then consumption will soon be as much a curable disease as typhoid fever.

When such an eminent man as Osler, with his unusually large opportunities for observation in one of the largest hospitals in the world, testifies to the inefficiency of the antiseptic treatment of typhoid fever I must defer further discussions of "cause and treatment of microbial diseases" until further experiments can be carried out. It is to become my life study henceforth. The statement of the eminent Chicago surgeon, Nicholas Senn, at the last meeting of the AMERICAN MEDICAL ASSOCIATION that antiseptics fail when we mostly expect them to do the work, ought to have awakened the dormant thinking energy of many an intelligent practitioner.

It has been said that the antiseptic treatment influences considerably the typhoid fever curve. Most of the antiseptics are antipyretics and vice versa, and the fever could probably be controlled just as well by the continuous administration of small doses of quinin or acetanilid, which antipyretics have but slight depressing action on the heart. That the fever curve is considerably lowered by a systematic treatment with water is well known.

The hygienic and dietetic treatment of typhoid fever forms an essential part of the general management of such cases. It would be too much risk, however, to abandon all other means of treatment and to rely solely on the dietetic, as has been advocated by some believers in the *vis medicatrix naturee*. In mild cases it may be sufficient, but who can tell whether a given case is to remain as mild as it appears in the beginning? *Non medicamentis sed medica mentis* is a very good sophism, but I fail to see why it should be the motto solely of doctors, "à la Kneipp." It ought to be, and in fact is, the motto of every drug practitioner. As regards hygienic treatment it can be framed in four words: Rest, a good bed, ventilation and an intelligent nurse. The diet of typhoid fever should be light, liquid and nutritious. Meat, ordinary bread and raw fruits, especially apples and pears are to be strictly prohibited.

The patient should drink cold, fresh water freely. I allow my patients from ten to twenty glasses *pro die* and would give them more if they so desired. The water can be acidulated with hydrochloric acid,

lemon or peroxid of hydrogen (or hydrozone) alternately. Alcohol should be given early. I am surprised that most of the latest writers restrict its use to cases where direct stimulation only is indicated, as it is a medicine and food at the same time.

The key note of the dietetic treatment is nutrition. For more than a century plain cow's milk has been used. But plain cow's milk has many disadvantages, deranging the digestion and necessitating repeated macroscopic and microscopic examinations of the stools. These objections can be overcome by the addition of Mellin's food. This food, although hardly needing any further recommendation, has proven to me of incalculable benefit not only in typhoid fever but in a great many other acute and chronic affections of the gastro-intestinal tract. The effects this preparation has on milk can be summed up as follows:

1. Owing to its alkalinity it acts chemically upon the casein of the milk, converting it into soluble albuminates.

2. The dextrin present is a powerful peptogen and greatly increases the secretion of pepsin from the stomach glands, by its physiologic action.

3. Clinical observation as well as chemie experiments have proven beyond doubt that if the food be added to cow's milk it is rendered more easy of digestion and more nutritious.

4. If necessary Mellin's food can be given with water instead of milk, with similar results.

Light soups, preparations of beef juices, beer and coffee, can be given in small doses.

*Suggestions for a Rational Treatment.*—After considering the former methods together with my own experience, I think I can propose a treatment, that although far from being infallible, will recommend itself to the thinking physician, as one that promises the most satisfactory results.

I divide the disease, for practical purposes into three stages: 1, the time when owing to certain symptoms and phenomena, the disease can be suspected only; 2, the time from the definite diagnosis of typhoid fever until convalescence; 3, convalescence plus two weeks.

The treatment as long as the disease is only suspected, consists of attending to the symptoms as they appear. To produce diuresis, diaphoresis and catharsis is the most rational procedure.

But as soon as a diagnosis of typhoid fever is made, all energy should be awakened.

Hygienic and hydro-therapeutic treatment must be outlined for the entire course of the disease and systematically commenced at once.

No matter what the condition of the bowels, the first two days, the following prescription is given.

R. Calomel . . . . .	gr. iii	18
Salolis . . . . .	ʒss.	

Misce. F. pulv. No. vi. Sig.: One powder three times a day.

Then I commence with tonics, calculated not only to support vitality but to sustain the heart. Digitalis, strychnin, nitroglycerin are prescribed in suitable doses, and proper excipients administered at regular intervals. (Stearn's essence of pepsin is what I prefer.) For this reason I commence early with the administration of alcohol. French brandy (cognac) port or sherry wine are suitable. Recently I have obtained good results from the wine of fresh (undried) kola nuts, "kolavin-Stearns," which is not only a good tonic but a brain stimulant.

But one of the drugs on which I place much dependence is the peroxid of hydrogen. Care should be taken to obtain the strongest and best brand, as most of them sold in this country are poor imitations of even what the Pharmacopeia prescribes and that is weak enough. Hydrozone, as prepared by the New York chemist, Charles Marchand, is at this date recognized as the best in every respect being a 30 volume solution. It is best administered in teaspoonful doses (to be measured with a glass spoon only) in the water used as drink three or four times a day. I also add some hydrozone to the water used for washing the colon. The effects of hydrozone when administered in typhoid fever are these:

1. It oxygenates the blood, thus keeping the brains in activity. It is a brain tonic. If hydrozone be given properly all cerebral disturbances, delirium, that state of semi-unconsciousness which most of our patients pass through will be a "rara avis."
2. It improves digestion and checks abnormal fermentation.
3. It stimulates exertion.
4. Mechanically it cleanses the bowels, allays the hyperemia, prevents ulceration, and assists in "disinfecting" the contents of the gastro-intestinal tract.
5. It is as powerful an antiseptic as creosote and carbolic acid without possessing any of their disadvantages.

A useful procedure is irrigation of the colon, which should be practiced twice daily in cases of typhoid fever. It matters little whether the fluid passes beyond the ileo-cecal valve or not, for either through reflex action or through the aseptic state of the rec-

tum, the state of the bowels is greatly improved by the irrigation throughout the disease. It produces a natural catharsis. Only when an emaciating diarrhea exists (a case I never observed) I would substitute sugar of lead and opium and then would not irrigate but inject the fluid as a simple clysm. A stiff rectal rubber tube attached to a fountain syringe is the best means for irrigation. Soft rubber is not to be used as it lodges in the mucous folds of the rectal wall and bends over.

A metal sigmoid flexure irrigator has been devised by Dr. Cole. It is manufactured by Messrs. Halsey Bros. of Chicago, to whom I am indebted for the accompanying cut, which represents about one-third the actual size. On my suggestion they now manufacture smaller nozzles for children, which can be easily screwed on the instrument. This instrument has proved of great use in my hands, as it can be easily introduced into the sigmoid.

This treatment is routine in my practice. Depending on circumstances it is altered in minor points. Special symptoms call for special medication. This article is an incomplete pen sketch rather than a treatise on the treatment of typhoid fever. It is intended to cause the general practitioner to think, not to copy formulæ.

## TREATMENT OF TYPHOID FEVER.

BY F. M. GREENE, M.D.

LEXINGTON, KY.

Before continuing the discussion, on the disinfectant and eliminative treatment of typhoid fever, which was presented in a former paper, we wish to notice some criticisms upon this method read at the last meeting of the AMERICAN MEDICAL ASSOCIATION at Atlanta. The distinguished chairman of the section on general medicine, attacks rather severely, the advocates of the new method, calling them "heretics of the worst possible stamp," because they do not choose to "swim in his puddle with him." Being himself an advocate of hydrotherapy of most enthusiastic stamp, he takes issue with all those who differ from him, and triumphantly declares it "impossible to disinfect 25 feet of intestinal canal, with such remedies as Woodbridge recommends." He may find before getting through with the discussion of this important subject that there are "more things in heaven and earth than are dreamt of in his philosophy"; also that there are more than "two grains of wheat in his two bushels of chaff." His late work on the Practice of Medicine, lies on the table before us, and we venture the assertion that he will not spoil the next edition of his "jewel" by omitting a full description of the new method of treating typhoid fever. He may not then regard the papers which have hitherto appeared in the JOURNAL of the ASSOCIATION on the subject, as a "heterogeneous jumble, entirely unworthy

of the best traditions of the profession, and of a subject connected with the names of Bartlett, Gerhard, Jackson and Flint." He might have added also the name of George B. Wood, who first called attention to the value of oil of turpentine in this disease. We had the pleasure of listening to the clinic lectures of both Gerhard and Wood on typhoid fever, and believe that were they with us to-day, they would be found in the front ranks of antiseptic medicine. The latter had discovered an intravascular disinfectant of great value, without being able to explain its "modus operandi."

We agree with Dr. Osler that "all wisdom is not found in the professorial corps" and that "a good thing may come out of Nazareth." Professor Quine from the chair of the section on the Practice of Medicine, was more considerate of the new method and reports "twenty-one consecutive cases, covering his private practice during the last two years," and which were treated antiseptically. Under the same treatment, he gives an account of 275 cases and 6 deaths; a mortality rate of 2.2 per cent. He does not claim however that "the Woodbridge method was employed in one of them." The plan of treatment followed consisted in a general way of purgatives to the extent of from two to six evacuations daily. The antiseptics used were a mixture of guaiacol carbonate, thymol, menthol and eucalyptol—but not the Woodbridge formulæ. He declares: "Although no death occurred, the results, especially in the direction of aborting the malady, albeit, not discouraging to one who had not expected much, were less brilliant than those recorded by our friend from Ohio."

Again—"It is not assured that this inconsequential showing proves anything"!! Were "reasons as plenty as blackberries" we would not ask Professor Quine to give us "a reason upon compulsion." Finally he concludes: "No one has the right to condemn the method without proof." We think an impartial reader of these criticisms, might conclude that the one is highly prejudiced against, and the other favorably inclined toward it. The opponents of the method try to account for its success by saying that the observations of medical men everywhere go to show that the disease has existed in a mild form for the past two or three years, which is about equivalent to saying that a patient is threatened with typhoid fever. Physicians of experience know that it is one of the gravest maladies, and never threatens anyone; that in the same endemic, in the same section, and in the same family, the most severe and mild forms, frequently exist together. In these mild and so-called "walking cases" we may have grave complications, as hemorrhage and perforation. Both the etiology and pathology of this disease has been determined. The typhoid bacilli having entered the alimentary canal, find lodgement in the glands of the ileum, or are carried away in the excreta from the bowels. They have doubtless commenced their work when the physician is called, and there already exists hyperemia and congestion of the mucosa in this locality. Some time elapses before there is ulceration, erosion or necrosis. It is not the work of a day, but of many days before these changes take place. Neither are they confined to the lumen of the bowel, but through the absorbents they enter the blood, and are conveyed to the most distant parts of the system. They have been found in the liver, spleen and pancreas. It is some time, usually about the close of the second, or beginning of the third week, before a toxin is formed and nervous symptoms begin to appear, such as delirium, subsultus tendinum and picking at the bed-clothes. Now if we see the patient early, disinfect the bowel as soon as possible, and at the same time maintain free evacuation and elimination, it is not improbable that we may prevent these secondary symptoms, or that the disease may be aborted in its earlier stages. This is what some of its advocates claim, and the result seems to bear out the assertion. We have the testimony of many physicians that, under it, meteorism when present rapidly subsides; putrefactive changes are prevented, and the stools lose their peculiar odor. The most remarkable results are shown in fall of temperature, which sometimes reaches normal by the tenth or twelfth day of treatment. The patient now enters upon a favorable convalescence, asks for food, and it may be allowed much earlier than under the old régime. The bowel at any rate is the starting point of the bacilli, and if they are destroyed here, the intensity of the infection at least is modified, and the work of the phagocytes is lessened in proportion. It is more than probable that the essential oils of eucalyptol, menthol, thymol and turpentine act as intravascular disinfectants in the various organs and tissues of the body. Dr. George B. Wood introduced the latter many years ago, and it has maintained its reputation up to the present time. These remedies are absorbed before they reached the ileum, and are not supposed to act locally upon ulcerated surfaces.

The remedy which is perhaps the most important of all is the carbonate of guaiacol, which has been proved to be insoluble in the stomach. After it

leaves the stomach it is broken up into guaiacol and carbonic acid. The former is the active principle of creosote, and the odor of the latter is detected in the various excretions. Hoelscher and Seifert of Berlin and many other German physicians regard it as an intestinal antiseptic of much value, and especially useful in typhoid fever.

Creasote has gained reputation as a germicide in phthisis and is destructive both of the typhoid bacilli and other putrefactive bacteria which are found so abundantly in typhoid stools. We do not claim that it can repair damage already done or cure ulceration already existing, but when used early, is preventative of these, and other grave complications. Neither can the carbonate of guaiacol be regarded as an antipyretic, although rapid fall of temperature follows its administration. It is therefore the destruction of bacteria and consequent prevention of rapid metabolism, which, if not the cause, is always associated with the pyrexia of this disease. As the season approaches for the prevalence of this fever, physicians will have courage at any rate, to try the new method and decide for themselves its real merit or demerit.

So many new remedies have been foisted upon the profession lately, all claiming to be specifics, and when tried have proven worthless that it is difficult to call the serious attention of physicians to a new method which claims as much as this. We may undoubtedly control the high temperature of typhoid fever by the Brand method, but the disease is not subdued but only held in check and we have yet to contend with dangerous complications and sequelæ. There is some difficulty in carrying it out with hydrophobic children, and the poorer classes, among whom the disease is more prevalent. It is impossible for the physician to be present during the administration of the baths and there are required a number of intelligent assistants to carry it out properly.

There are sometimes contraindications to the use of cold baths in typhoid fever. In hemorrhage, whether active or passive, the exertion required in taking them is injurious, and the application of cold to the surface produces a greater determination of blood to the internal organs. So in hypostatic congestion of the lungs and in pneumonia; though in moderate attacks the application of cold water may be beneficial. In very great weakness of the heart's action, there would be danger from shock by the sudden immersion of the body in cold water. In country practice and among a large class of patients in our cities it is impracticable, unless, Diogenes-like we carry our tub around with us.

We allude to some of the difficulties of the Brand treatment not to influence any one against it, but to show that the new method is better adapted to patients of all classes and conditions.

26 North Mill Street.

## THE RATIONAL TREATMENT OF TYPHOID FEVER.

Abstract of paper read at the meeting of the Tennessee Medical Society in Chattanooga, April 14, 15 and 16, 1896.

BY J. A. CROOK, M.D.

JACKSON, TENN.

That the curative treatment of a disease so universally prevalent in all countries, latitudes and civilizations as typhoid fever, should engage the attention of lovers of science and the promoters of health, is most

natural and laudable. A disease whose preference is so great for young manhood and womanhood when active life, with its duties and pleasures is just unfolding a disease whose grave character and fatal issues, makes its consideration and the possibility of its abortion of great importance to the profession and to humanity, is certainly worthy of the attention of this honorable body, devoted, as it is, to the amelioration of suffering and the conquest of disease.

Typhoid fever is a disease, whose nature and pathology have long been known and often described, but whose etiology, until recently, has been but little understood. This has been left for late observers, with the aid of the microscope and much experimental research, to develop and determine.

While some observers were of the opinion that every one carried in the intestinal canal, waste products from the organism, material susceptible of putrid intoxication and the development of typhoid fever under favorable circumstances, later authorities, as Koch, Eberth and others, have demonstrated the bacillus typhosus to be the germ and cause on which this disease depends, and its origin otherwise impossible; that the disease is not contagious and these germs have to be introduced into the system from without in order to produce the disease, and that this is chiefly done through drinking water; that the habitat of these germs is chiefly the lower portion of the ileum and upper portion of the colon, where they rapidly grow and multiply till sufficient irritation and toxins are produced to develop the characteristic fever.

While every form of treatment that could be devised had been tried, none, until very recently, tended to cut short the disease, and typhoid fever had come to be regarded as a self-limited disease and had to run its usual course. Flint says: "It must be admitted that the known resources of therapeutics do not afford reliable means for the arrest, nor even shortening the febrile career." Loomis, says: "After the poison has once gained entrance into the system, no means have as yet been discovered by which it can be counteracted or neutralized so as to prevent the development of the disease. The duty of the physician is to guide the disease to a favorable issue, keeping in mind that a certain definite time must elapse before this result can be accomplished." Johns Hopkins Hospital report, Vol. 10, No. 1, says: "No known drug shortens by a day the fever. No method of specific treatment or of antiseptics of the bowel has passed beyond the stage of primary laudation."

While, until very recently, this represented the true status of medical knowledge, yet, if the consensus of professional opinion be true as to its cause, namely, a specific germ whose habitat is the small intestine, any remedy that will sterilize the entire alimentary canal, destroy this germ and neutralize its toxins effectually, that is not deleterious to the system, is certainly rational and worthy of trial.

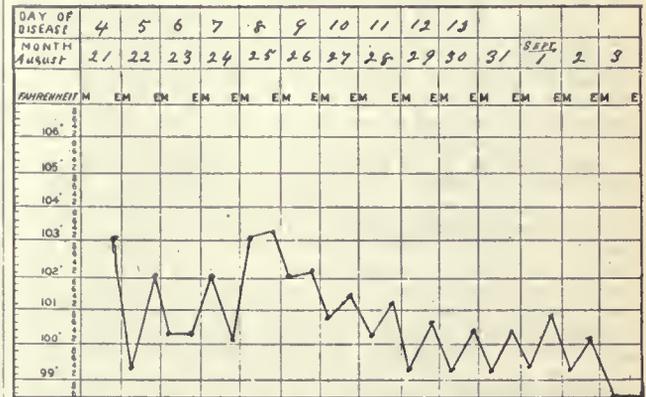

Flint again says: "It is not an unreasonable expectation that an antidote or parasiticide as effective in typhus and typhoid fever as quinia in malarial fever, may hereafter be discovered, and such a discovery is a proper aim for continued experimental observations."

This has been the teaching of nearly all authors. On this idea carbolic acid and iodine, sulpho-carbolate of zinc, salol, salicylate of ammonia, etc., have been used as intestinal antiseptics and germicides. Notwithstanding all these remedies, with the Brand

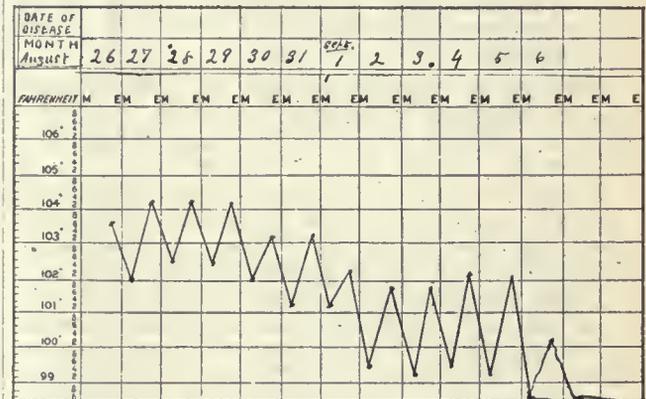

treatment, lessened the mortality and modified the course of the disease in some instances, it remained for John Eliot Woodbridge to discover and introduce to the profession the ideal intestinal antiseptic, and demonstrate with certainty, the success of his remedies, and render typhoid fever no longer one of the grave and much dreaded diseases.

I here report some of my cases:

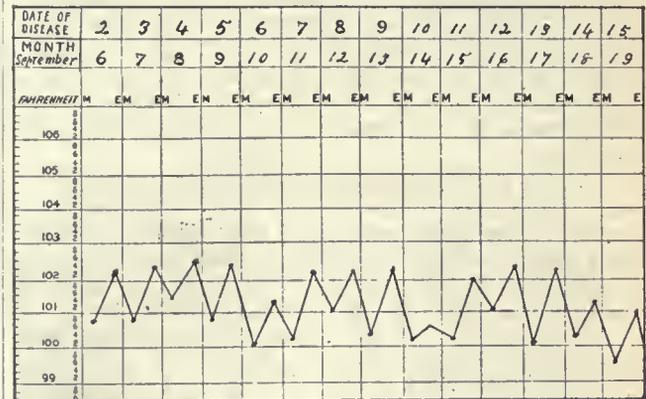

Case 1.—K. McC., male, age 17. I was called to see him on the fourth day of his sickness; temperature 103, tongue coated, and a feeling of malaise. I gave blue mass calomel and soda to move bowels, also phenacetin to reduce fever, and pressed

No. 1.—K. McC.

No. 2.—H. R.

No. 3.—L. M.

quinin. Next morning bowels had acted well; he had a free perspiration, temperature 99.4. In afternoon temperature was 102. Morning and evening temperature next day 100.4, free perspiration. Temperature next morning 102. Afternoon temperature 100.2, when I put him on Woodbridge tablets No. 2 every hour, but kept up quinin. Temperature next morning 103, and in afternoon 103.2; added phenacetin. Temperature next morning 102, and in the afternoon 102.2, I added Woodbridge No. 3 alternated with No. 2. From this time on the fever gradually declined, the yellow thin actions kept up from

bowels for a while, the nervousness grew less, and the patient's temperature reached normal on the seventeenth day of the disease, and the tenth day after the Woodbridge treatment was commenced, and he rapidly recovered. I may add that this young man was very despondent from the start, as he had a short time before lost his cousin with the same disease.

Case 2.—H. R., age 47, married. August 26, temperature 103.6, bowels tympanitic and three or four paint-like actions a day. I put him on Woodbridge treatment every hour, gave nothing else. Next morning temperature 102. No other change. I added Woodbridge No. 3 alternated with No. 2. The temperature continued as shown by the chart until the fifth day of treatment, when it reached normal. His recovery was uneventful except one of his legs swelled and remained swollen for some time during convalescence.

Case 3.—L. M., age 25. September 6, the second day after he had taken to his bed, morning temperature 100.8; put him on Woodbridge No. 2 every hour; afternoon temperature 102.2; added an occasional dose of quinin to satisfy patient; September 8 added Woodbridge No. 3, alternated with No. 2. The seventh day I noticed several rose spots on his chest and abdomen. September 20 his temperature reached normal.

Case 4.—Miss M., a young lady. October 2, temperature 105.5, tongue coated. I thought she had bilious fever. I gave blue mass, calomel and soda to move the bowels and put her on phenacetin and quinin. Next day bowels had moved well; she was perspiring freely but fever high. I pressed phenacetin and quinin. On the third day, as her fever kept up, I put her on Woodbridge No. 2 every hour, and kept up quinin. Next day no change. Next morning fever not so high and patient not so nervous. About 2 o'clock same day I found that she had had hemorrhage from the bowels three times, the chamber nearly filled with clotted blood and she was almost pulseless, temperature below normal. By the use of hypodermics of strychnia, stimulants and astringents, I was enabled to bring about reaction. As soon as I felt that she was sufficiently safe from another hemorrhage I put her on Woodbridge No. 3, alternated with No. 2 and kept it up.

When this hemorrhage occurred I thought that she had been sick longer than reported. It appeared she had been sick for two weeks or more, but had tried to wear the feeling off.

I might add reports of a dozen cases thus treated with like results, but I deem these sufficient, with the testimony other physicians who have had like results, to establish the fact that typhoid fever can be cured.

I have used only prescriptions Nos. 2 and 3. This I did purposely, as No. 2 contained the same amount of everything as No. 1, and four times as much carbonate of guaiacol and the addition of one-sixteenth grain of thymol. I am confident that the virtue of these prescriptions is increased, if not dependent on one or both of these drugs; and it seems more rational to give these at once, and get the patient earlier under the influence of these remedies. Besides it is contrary to my idea of treating a patient, to disturb him and his stomach every fifteen minutes with medicine.

I think that the success of this treatment is due to one or all of the components in No. 3, and that if this combination alone were used, with sufficient calomel and sodium tablets to keep the bowels open, the result would be the same as when Nos. 1 or 2, or both, are used, according to Dr. Woodbridge's directions.

In closing will say, that from the facts here adduced, in addition to statements published in Dr. Woodbridge's paper read at the meeting of the AMERICAN MEDICAL ASSOCIATION in Baltimore last May, the following conclusions may be drawn:

1. That the treatment given by Dr. Woodbridge for typhoid fever far surpasses in results any other treatment hitherto employed.

2. That it is entirely harmless, and it, or the anti-septics it contains, can and should be given without hesitation by any physician to any and all patients and under all circumstances when typhoid fever exists.

3. That if this treatment is begun early and persisted in, the disease will not only be materially shortened, but that all serious consequences and sequela, such as tympanites, glazed tongue, nervous prostration and delirium, will be prevented.

4. That if any reliability can be placed in this evidence, the Woodbridge treatment actually cures typhoid fever as certainly and surely as quinin does malaria, and that under this treatment there are but two stages of this formidable disease, first, that of rapid decline in temperature, and secondly, that of convalescence.

1796-1896.

## THE MEMORIALS OF EDWARD JENNER.

Address delivered at the Centennial Celebration held at Atlanta, Ga. May, 1896.

BY HORATIO R. STORER, M.D.

HON. PRES. NEWPORT MEDICAL SOCIETY, NEWPORT, R. I.

Upon the one hundredth anniversary of Jenner's discovery, anything connected with him becomes of unusual interest. There exist a number of medals, statues, busts, paintings, engravings, lithographs and wood cuts, purporting to represent him as he appeared in life.

*Medals.*—It was my intention to present to the ASSOCIATION a list, with descriptions, not merely of the personal medals of Jenner, but of those illustrating the history of smallpox and the physicians who have written thereon; inoculation, and those identified with its employment; and vaccination, with those, including Drs. N. S. Davis and J. M. Toner, who have been prominent, since Jenner's day, in its development. Quite a number of them were shown by me to the ASSOCIATION at its Newport meeting in 1889. A portion of the medals relating to the subject have been given by Dr. Charles Louis Hippolyte Klynkens' of Ghent, and a larger number still by Medicinal Rath Dr. L. Pfeiffer and Hof Rath C. Ruland<sup>2</sup> of Weimar. The first of these gentlemen has now deceased. His list of medals comprised twenty-nine, only of vaccination. To the others, Pfeiffer and Ruland, too much praise can not be given for their indefatigable labors. In their latest publication, 1882, they gave twelve medals of inoculation, and fifty-four of vaccination. That I have been able to materially add to these numbers, has been only through constant searching through several years, and a large amount of correspondence with numismatists. The list has been nearly finished, but ill health has pre-

<sup>1</sup> Numismatique Jennérienne. This first appeared in the Revue belge de numismatique for 1875, vol. xxxi, page 55, and was privately reprinted.

<sup>2</sup> Dr. Pfeiffer, who has been a prolific writer upon smallpox and vaccination, has been the collector of these medals, and Mr. Ruland, the curator of the Goethe Museum at Weimar, has been their collector. Dr. P. first published in 1876 "Die auf die Entdeckung und Ausbreitung der Impfung geschlagenen Denkmünzen" (*Deutsche Zeitschrift für prakt. Med.*, Leipzig, 1876, pp. 516-524). There then appeared anonymously but evidently from the hand of Mr. Ruland, "Beschreibendes Verzeichniss Der zu Ehren William (sic) Jenner's und Aloysio Sacco's sowie Auf Die Schutzpocken-Impfung und die Blattern-Inoculation Geprägten Medaillen" (*Archiv für path. Anatomie*, Berlin, 1877, LXXII, pp. 1-14). This was privately reprinted. There then came, also anonymously, "Pestilentia in Nummis. — Beschreibendes Verzeichniss der auf Epidemien von Pest, gelben Fieber, Cholera, auf Pocken-Erkrankungen und Inoculationen, auf Jenner, Sacco und die Vaccination, sowie der auf Hungersnöthe und andere Calamitäten geprägten Medaillen," Weimar, 1880; and finally, with the authors' names for the first time upon the title page, "Pestilentia in Nummis. | Geschichte | der Grossen Volkskrankheiten | in Numismatischen Documenten. | Ein Beitrag zur Geschichte der Medicin und der | Cultur." Tübingen, 1882.

[Since my paper was presented at the Atlanta meeting I have received still another and very interesting article upon the subject from Dr. Pfeiffer, entitled "Zur Jenner feier | des 14. Mai 1896 | Medaillen, Porträts und Abbildungen, | betreffend | E. Jenner, die Variolation, die Vaccination | und die Vaccine." | Tübingen, 1896. While it lacks a number of the memorials I had cited, it gives several that were new to me. These I shall enter, giving due credit for each with an asterisk.]

vented its completion, and indeed the hours of the present session have been so wisely parceled in advance that there would have been scant leisure for its consideration. I shall, therefore, now offer but a catalogue of the personal medals of Jenner alone.

## ENGLAND.

1. *Obverse*. Apollo presents a sailor who has been preserved by vaccination to Britannia, who holds a civic crown bearing: JENNER Legend: ALUA NAUTIS STELLA REFULSIT. 1801.

*Reverse*. An anchor. Above: GEORGIO TERTIO REGE. Below: SPENCER DUCE (Viscount Althorp, First Lord of the Admiralty and subsequently Earl Spencer.)

Gold.

Schlichtegroll, *Annalen der gesammten Numismatik*, I, p. 156; Rudolphi, *Recentioris Aevi Numismata de Rebus Medicis et Physicis Meritorum Memoriam Servantia*, Berlin, 1829 (3d edition), p. 81, No. 338; Kluyskens, *Des Hommes Célèbres dans les Sciences et les Arts, et des Médailles qui Consacrent leur Souvenir*, Ghent, 1859, II, p. 68, No. 1; *ibid.*, Numismatique Jennérienne, No. 1; Duisburg, C. A. Rudolphi, etc., *Denuo Edidit, Emendavit et Auxit C. L. D. D.*, Dantzig, 1862, p. 230, DCIX, 1; Pfeiffer and Ruland, 1882, p. 139, No. 385; Baron, *Life of Edward Jenner*, London, 1838, II, p. 456; Storer, *Sanitarian*, March, 1889, No. 926; *ibid.*, *American Journal of Numismatics*, July, 1894, p. 14, No. 747. [Pfeiffer, 1896, p. 3, No. 385.]

Presented to Jenner by the surgeons of the British Navy. Its locality is now unknown. It is not, as Pfeiffer has supposed, a portrait medal of Jenner.

2. *Obverse*. Bust, clothed, to left. Upon truncation: [T.R.] POOLE 1809 No inscription.

*Reverse*. Blank.

Of pink wax upon colorless transparent glass; 82 mm. (length of bust).

Storer, *loc. cit.*, April, 1895, p. 128, No. 880. [Not given by Pfeiffer, 1896.]

In the Library of Royal Medical and Chirurgical Society of London. I know of it through Dr. F. P. Weber of that city.

A gold medal was presented to Jenner by the Medical Society of London, at its anniversary dinner, March 4, 1804. It bore either upon its rim or the casket that contained it: E. JENNER M.—D. SOCIO SUO EXIMIO OB VACCINATIONEM

## EXPLORATAM

Biographie Médicale, V, p. 574; Rudolphi, p. 81, No. 339; Kluyskens, II, p. 68, No. 2; *ibid.*, Num. Jenn., No. 2; Duisburg, p. 230, DCIX, 2; P. and R., p. 139, No. 386; Storer, *Sanitarian*, March, 1889, No. 927; *ibid.*, *Amer. Jour. of Num.*, July, 1894, p. 14, No. 748; Baron, *loc. cit.*

Though mentioned by all these writers, its true character has remained undecided until it was lately ascertained by Dr. F. P. Weber of London that it was the John Fothergill medal of the society (Storer, *Am. Jour. of Num.*, Oct., 1893, p. 35, and July, 1895, p. 6, No. 645). Its present locality is unknown. If the inscription were upon its casket it is possible that it is the specimen now in the British Museum, as but one or two of these medals were struck in gold. [Pfeiffer, 1896, p. 3, No. 386, describes its bust as that of Jenner. It was not so, however, but of Dr. John Fothergill.]

There exists a medallion engraving, with bust in profile to right, by J. B. Drayton, from life, and Anker Smith. Though drawn for the purpose of a gold medal it was never struck.

A centennial medal has just been issued at Bristol.

3. *Obverse*. Bust, to right. Beneath: Fenwick, Sc.F. Birn'm. Inscription: Edward Jenner, M.D. LL.D. F.R.S. &c. Born 17 May 1749. Died 26 Jan. 1823. Berkeley, Glostersh.

*Reverse*. Within laurel wreath: May 14th, 1896. In commemoration of the centenary of Dr. Edward Jenner's First & Successful Experiment in Vaccination May 14th, 1796.

Silver. 38 mm.

Brettauer, *Mittheilungen des Clubs der Münz-und Medailen Freunde in Wien*, May, 1896, p. 55.

A medal in honor of Jenner has also been determined upon by the Epidemiological Society of London.

## HOLLAND.

4. *Obverse*. An allegorical group.

*Reverse*. EDUARD JENNER, DOCTOR IN DE GENEESKUNDE | GEBOREN DEN 17 MEY 1749 TE BERKLEY IN HET GRAAF | SCHAAP GLOCESTER IN ENGELAND EN ALDAAR OVERLEDEN | DEN 26 JAANUARIJ 1823. UITVINDER DER KOEPOKINENTING | IN HET JAAR 1775. DOCH EERST IN 1798 DOOR HEM | REKEND GEMAAKT.

Copper. By A. Bemme, at expense of H. Westhoff, Jr. Dirks, *Nederlandsche Penningen*, 1889, I, p. 169, No. 210; Storer, *Am. Jour. of Num.*, July, 1894, p. 14, No. 749. [Not given by Pfeiffer, 1896.]

## BELGIUM.

5. *Obverse*. Bust, upon an oval shield, between two females holding over it a crown. Beneath, an elongated shield, upon which a cow, to right.

*Reverse*. Blank.

Plaster of Paris. 37 mm. Unique. By Charles Wiener of Brussels.

Alvin, *Revue belge de numismatique*, April, 1888, p. 243; Storer, *Sanitarian*, March, 1889, p. 935; *ibid.*, *Am. Jour. of Num.*, July, 1894, p. 15, No. 757. [Not given by Pfeiffer, 1896.]

Reference to Jenner is also made upon a medal of Dr. Vrancken of Antwerp.

## FRANCE.

6\*. *Obverse*. Bust. Beneath: BARRE. Inscription: NAPOLEON III. EMPEREUR.

*Reverse*. Bust of Jenner, facing. At sides, a cloaked and a nude female figure, with laurel wreath. Beneath, a cow. Inscription: EDUARD JENNER. Upon rim: COMITÉ DE VACCINE DE LA SEINE INF. By Hamel.

Silver. 41 mm.

Pfeiffer, 1896, p. 6, No. 415c.

7. *Obverse*. Bust, facing, within palmleaves. Inscription: EDUARD JENNER. To left: HAMEL ET LECOMPTÉ Beneath, 1749 (the date of Jenner's birth).

*Reverse*. Between laurel branches: MEDAILLE DE 1RE CLASSE. Inscription: COMITÉ CENTRAL DE VACCINE DU DEPARTMENT DU NORD.

Silver. 40 mm.

Kluyskens, Num. Jenn., No. 9; Pfeiffer and Ruland, p. 145, No. 416; Storer, *Sanitarian*, March, 1889, No. 933; *ibid.*, *Am. Jour. of Num.*, July, 1894, p. 15, No. 755. [Pfeiffer, 1896, p. 7, No. 416.]

8. *Obverse*. As preceding, but bust somewhat toward left, and on pedestal, upon base of which the date.

*Reverse*. A laurel wreath, beneath which: MEDAILLE DE 2E CLASSE. Field vacant for name of recipient.

Silver. 36 mm.

Pfeiffer and Ruland, p. 146, No. 417, fig. of obv.; Storer, *Sanitarian*, March, 1889, No. 934; *ibid.*, *Am. Jour. of Num.*, July, 1894, p. 15, No. 756. [Pfeiffer, 1896, p. 7, No. 417.]

In the collection of Dr. Joseph Brettauer of Trieste.

9\*. *Obverse*. As preceding.

*Reverse*. Merely the wreath.

Silver. 36 mm.

Pfeiffer, 1896, p. 7, No 417 a.

## GERMANY.

10. *Obverse*. Beneath a rose bush and a cornucopia, an infant with rose in its hand points to its arm. At right of bush: L (oos) Inscription: EDUARD JENNER'S WOHLTHÄTIGE ENTDECKUNG Exergue: VOM 14 MAI | 1796

*Reverse*. ZUM | ÄNDENKEN | AN | ERHALTENEN | UND | MITGETHEILTEN | SCHUTZ | (a scroll) | GEREICHT VOM | DOCTOR (EDUARD) BREMER | IN BERLIN | 1803

Silver. 25 mm.

Rudolphi, p. 82, No. 340; Kluyskens, II, p. 68, No. 3; *ibid.*, Num. Jenn., No. 5; Duisburg, p. 230, DCIX, 3; P. and R., p. 141, No. 393; Baron, *loc. cit.*; Storer, *Sanitarian*, March, 1889, No. 928; *ibid.*, *Am. Jour. of Num.*, July, 1894, p. 14, No. 750. [Pfeiffer, 1896, p. 4, No. 393.]

In the Brettauer collection, that of the U. S. Army Medical Museum and my own.

11. *Obverse*. As preceding.

*Reverse*. As preceding, save that after SCHUTZ there is — —, and after BERLIN: 1811— | 8 L. 6 OR.

Silver. 25 mm.

Rudolphi, p. 82, No. 340; Kluyskens, Num. Jenn., No. 6; Duisburg, p. 230, DCIX, 3, note: Bremer, *Die Kuhpocken*, Berlin, fig.; P. and R., p. 142, No. 394; Storer, *Sanitarian*, March, 1889, No. 929; *ibid.*, *Am. Jour. of Num.*, July, 1894, p. 14, No. 751. [Pfeiffer, 1896, p. 4, No. 394.]

In the Brettauer collection and my own.

12. *Obverse*. Bust, to left. Beneath shoulder: F. LOOS Inscription: EDUARD JENNER ENTDECKER DER SCHUTZIMPfung D. 14 MAI 1796

*Reverse*. An angel from clouds, garlanding a cow, around which seven children are dancing. Legend: EHRE SEY GOTT— IN DER HÖHE Exergue: UND FREUDE | AUF ERDEN

Silver, bronze, Berlin iron. 36 mm. Thick and thin planchets.

Rudolphi, p. 82, No. 341; Kluyskens, II, p. 69, No. 4, fig.; *ibid.*, Num. Jenn., No. 7; Duisburg, p. 231, DCIX, 6; P. and R., p. 139, No. 387, fig.; Wroth, *Numismatic Chronicle*, 3d series, VI, 1886, p. 303; Storer, *Sanitarian*, March, 1889, No. 930; *ibid.*, *Am. Jour. of Num.*, July, 1894, p. 14, No. 752; Weber, *English Medals by Foreign Artists*, p. 50, No. 161. [Pfeiffer, 1896, p. 3, No. 387.]

In the Brettauer and U. S. Government collections, those of Prof. S. Oettinger of New York, Dr. W. S. Disbrow of Newark, N. J., and my own.

13. *Obverse*. As preceding, save that engraver's name is in exergue.

*Reverse*. Hygieia, with serpent upon her right arm, protects, by a shield bearing a cow, an infant against a flying demon. Legend: TRIUMPH! GETILGER IST DES SCHEUSALS LANGE WUTH

Silver, bronze, Berlin iron. 28 mm. With and without loop. Rudolphi, p. 82, No. 342; Kluyskens, II, p. 69, No. 5; *ibid.*, Num. Jenn., No. 13; Duisburg, p. 231, DCIX, 7; P. and R., p. 140, No. 388; Wroth, *Num. Chronicle*, 3d series, VI, 1886, p. 302; Storer, *Sanitarian*, March, 1889, No. 931; *ibid.*, *Am. Jour. of Num.*, July 1894, p. 15, No. 753; Weber, *loc. cit.* [Pfeiffer, 1896, p. 3, No. 388.]

In the Brettauer and U. S. Government collections and my own.

14. *Obverse*. A child, between a rose tree and the rising sun, exhibits its arm; at its feet a serpent. Legend: DANK DER GUTIGEN VORSEHUNG. Exergue: KRÜGER.

*Reverse*. Within a pearled octagon: WOHL | THATIGE | ENTDECKUNG | DER | SCHUTZPOCKEN | DURCH | ED: JENNER.

Silver. 30 mm. Kluyskens, Num. Jenn., No. 8; Duisburg, p. 231, DCIX, 8; P. and R., p. 142, No. 397; Storer, *Sanitarian*, March, 1889, No. 932; *ibid.*, *Am. Jour. of Num.*, July, 1894, p. 15, No. 754. [Pfeiffer, 1896, p. 4, No. 397.]

In the Brettauer collection.

15. A centennial medal is said to have been issued at Berlin, of which the details have not yet reached me.

#### RUSSIA.

16. There has also been a centennial medal struck at St. Petersburg, but its description has not been received.

#### ITALY.

Jenner's name appears upon the two medals of Dr. Sacco of Milan.

#### THE UNITED STATES.

A week after the meeting at Atlanta, the following medal was issued by the Medical Society of the County of Kings (Brooklyn, N. Y.), to commemorate its own very successful Jenner celebration. It is to be regretted that, through inadvertence, the locality of the society was omitted from the medal.

17. *Obverse*. Bust, with queue, to left. Inscription: VACCINATION, MAY 14TH | 1796—1896 | JENNER.

*Reverse*. Within a circle, the staff of Æsculapius, upright. Inscription: MEDICAL SOCIETY OF THE COUNTY OF KINGS | (Pointed rosette.) (This is a copy of the society's seal.)

Silver (but four struck), bronze. 33 mm. *Scientific American*, May 30, 1896, p. 344, fig. of obverse. In my collection, the gift of the Society.

#### PAINTINGS.<sup>3</sup>

I. Standing, facing and slightly to the left, leaning against tree; right arm upon branch, with hat, glove and cane in dependent left hand. Milkmaid with four cows and buildings at left.

Drawn from life. J. R. Smith, 1801. [Pfeiffer, 1896, p. 18.; not B. M. J.]

II. Three-quarter's length, in coat lined with fur, to right, seated at table upon which his work, "An Inquiry, etc." showing diagram of pustules, lies open. In background, figure of Hygieia and cast entitled "Sacred Cow."

By James Northcote, R. A. (For the Medical Society of Plymouth and Plymouth Dock.) [Pfeiffer, 1882; not mentioned by him in 1896; B. M. J.]

III. Older. Facing, with left forefinger upon brow. Northcote. This is preserved in the National Portrait Gallery at London.<sup>4</sup> [P., 1896; not B. M. J.]

IV. In easy chair. Bust turned to left, but looking forward, and showing portion of right hand.

Sir Thomas Lawrence, Pres't R. A. Owned by Royal College of Physicians. [P., 1896; B. M. J.]

V. Seated. Facing, and to left. At side, MS. with inkstand and pen. In background, reclining cow and buildings, at left.

J. Robinson.<sup>5</sup> [Not P., 1896; B. M. J.]

<sup>3</sup> While this paper is in press a list of Jenner memorials has appeared in the British Medical Journal for May 23. I gladly take the opportunity to add the few that had escaped me, distinguishing them by a cross, and also indicating by initials the others which were there mentioned. I also add four references to the *Revue Scientifique* for June.

<sup>4</sup> A copy of this in oil was at the Bristol (Eng'd) Industrial and Fine Arts Exhibition in 1893, examination of the catalogue of which, comprising the Meckler collection of Jenner relics, I owe to Dr. Joseph H. Hunt of Brooklyn, N. Y.

<sup>5</sup> A miniature of the above, on ivory, possibly the original, was at the Bristol Exhibition.

VI. Bust, to right; medallion.

Drawn from life by L. B. Drayton. [Not P., 1896; B. M. J.]

VII. Three-quarters length, in arm chair, with fur-collared robe. Left elbow resting on volume lettered at back: JOHN HUNTER.

Wm. Hobday. [Not P., 1896; B. M. J.]

VIII.† Aged, three-quarters length, seated, facing and slightly to left, with right arm resting on that of chair.

By Sir Thomas Lawrence. Owned by Mr. T. Malcolm Watson. [Not P., 1896.]

IX.† Artist unknown. At Royal College of Surgeons of England. [Not P., 1896.]

X.† There is said to exist an original portrait in the possession of Mr. William Smith of Chesterfield, a photograph of which is in the collection of the Royal Medico-Chirurgical Society. I have not as yet been able to identify this.

#### STATUES.

I. Marble statue, at west end of nave of Gloucester Cathedral, near his birth place. Erected in 1826.

By Siévier. [P., 1896; B. M. J.]

II. Bronze statue, in London. Erected in 1858 at Trafalgar Square, and thence transferred in 1862 to Kensington Gardens. In gown, face resting upon left hand, and right holding a scroll; seated in antique chair, upon whose side the staff of Æsculapius.

By W. C. Marshall. [P., 1896; B. M. J.]

III. Statue at Boulogne-sur-Mer. In standing position, left hand upon a pillar, and right flexed forward with lancet. Upon base: JENNER. Upon pedestal: A | EDUARD JENNER. | LA | FRANCE RECONNAISANTE | 11 SEPTEMBRE 1865.

By Eugène Paul. [P., 1896; not B. M. J.]

IV. Marble statuette, with rounded pedestal. Seated, and vaccinating a nude child, upon his knee.

By Giulio Monteverde. Exhibited at the Paris Exhibition of 1878. [P., 1896; B. M. J.]

#### BUSTS.

I. Looking to left and upward, draped, rounded and on rounded pedestal.

By C. Manning. [P., 1896; B. M. J.]

II. Looking forward and to right. Nude, squared, without pedestal.

[Not P., 1896; or B. M. J.]

III. At Brünn, Moravia. Within a temple dedicated to Jenner. Upon its pedestal: DIVO ANGLLO | EDUARDO JENNER, | LXV. | AETATIS EJUS ANNO | VACCINATA BRUNENSIS | MDCCCXIV. (Baron, *Life of Jenner*, II, p. 214.) [Not P., 1896; B. M. J.. which wrongly calls it a statue.]

IV. By Fujite Bunzo. Exhibited at the Centennial Vaccination Festival at Tokio, Japan.

#### ENGRAVINGS.<sup>6</sup>

I. From painting No. I:

a. With the milkmaid and four cows.

1. J. R. Smith, 1801. [P., 1896; B. M. J.]

2. Engraved by R. Page. No other inscription. Rectangular, 95x125 millimetres. In the J. H. Hunt collection. [Not P., 1896, or B. M. J.]

b. As preceding, but showing only a portion of hat and glove, and with but two cows and milkmaid.

3. D'Argent Sc., Edward Jenner (in script), M.D. F.R.S. Rect., 73x98 mm. At library of Surgeon-General's office. [P., 1896; not B. M. J.]

4. As preceding, but anonym. and without title. Rect., 73x98 mm. S. G. O.; N. Y. Academy of Medicine. [P., 1896; not B. M. J.]

c. As preceding, but not showing hat or glove, cows or milkmaid.

5. J. R. Smith pinxt., Londini—Dav. Weis sculps. Viennae | Dr. Jenner (in German script) | Zu finden in Wien bey Phil. Jos. Schalbacher. Oval, 98x120 mm. S. G. O.; J. H. H. [P., 1896; not B. M. J.]

d. As preceding, but less shown of left arm and waist.

6. Engraved by E. Scriven :- | JENNER | From a print engraved and coloured by J. R. Smith, in the possession of the late John Ring, Esq. Under the superintendence of the Society for the Diffusion of Useful Knowledge. London. Published by Charles Knight, Ludgate Street. (The Gallery of Portraits; with *Memoirs*, London, 1836.) Rect., 100x125 mm. S. G. O.; J. H.

<sup>6</sup> I am under the greatest obligations to Deputy Surgeon-General D. L. Huntington, U. S. A., Curator of the Army Medical Museum and Library, who, upon my request for information concerning several of the engravings of Jenner in his care, most generously sent to me at Newport for inspection the whole collection, over thirty in number. Dr. Joseph H. Hunt of Brooklyn, N. Y., with equal courtesy, forwarded to me for examination as many more, all different from the preceding, from his own magnificent collection. I have thus been able to perfect the list to an extent that would otherwise have been impossible.

H., and Redwood Library, Newport. [Not P., 1896, or B. M. J.]

7. J. R. SMITH pinx. E. SCRIVEN, Set | EDWARD JENNER, M.D. | WILLIAM MACKENZIE, GLASGOW, EDINBURGH, LONDON & NEW YORK. Rect., 105x130 mm. J. H. H. [Not P., 1896, or B. M. J.]

8. Mackenzie Sc. (in centre), Edward Jenner, M.D., F.R.S., &c. (in script). | Pub. July 1, 1802, by T. Hurst, Paternoster Row. Rect., 72x98 mm. J. H. H. [P., 1882, not 1896; not B. M. J.]

9. Mackenzie Sc. (in centre) | EDWARD JENNER M.D., F.R.S., &c. | Pub. Aug. 1, 1802, by T. Hurst, Paternoster Row. Oval, 83x102 mm. J. H. H. [Not P., 1896, or B. M. J.]

10. Mackenzie Sc. (to right) Edward Jenner (in script) M.D. F.R.S. Rect., 74x100 mm. J. H. H. [Not P., 1896, or B. M. J.]

11. P. Anderloni. [P., 1896; not B. M. J.]

12. R. Page, 1823. [P., 1882, not 1896; B. M. J.]

13. Engraved by G. Stodart. | JENNER. | Published by J. Mason, 14, City Road, & 66, Paternoster Row. Rect., 70x90 mm. J. H. H. [Not P., 1896, or B. M. J.]

II. From bust alone of Painting I.

14. Smith pinx. | Rahl Set. Dr. Jenner (in script). Oval, 65x74 mm. S. G. O. [P., 1896; not B. M. J.]

15. H. Lips sculp. | EDUARD JENNER, M.D. | Entdecker der Schutzblattern (in script, and both upon an oblong label). Oval, in rect. setting, 165x125 mm. S. G. O.; J. H. H. [P., 1896; not B. M. J.]

16. As preceding, but merely EDUARD JENNER, M.D., Entdecker der Schutzblattern (in script, and both upon an oblong label). Oval, in rect. setting, 165x125 mm. (*Scientific American*, May 30, 1896.) J. H. H. [Not P., 1896, or B. M. J.]

17. Jacquemot sc. | Jenner (in script). | durch Kunst-Verlag, W. Creuzbauer in Carlsruhe. Open, 78x75 mm. S. G. O.; J. H. H. [P., 1896; not B. M. J.]

18. As preceding, J. M. Fontaine | JENNER. Open, 78x75 mm. S. G. O.; J. H. H. [P., 1896; not B. M. J.]

19. As preceding, but head more elongated. Dessiné et Gravé par Ambroise Tardieu | EDUARDS (*sic*) JENNER. Open, 80x80 mm. S. G. O. [P., 1896; not B. M. J.]

20. J. R. Smith pinx. J. Hopwood sculp. | EDWARD JENNER, M.D. | Publish'd June 4, 1803 by W. Bent, London. Oval 73x90 mm. J. H. H. [P., 1882, not 1896, or B. M. J.]

21. EDWARD JENNER, M.D. | Painted by J. R. Smith—Engraved by Joseph Jenkins. | Published by James Robins & Co. Ivy Lane, London, Sep. 1, 1828. Open, 80x95 mm. J. H. H. [Not P., 1896; or B. M. J.]

III. From Painting I, but reversed.

a. Bust to right, with left arm on bough, and merely hat and glove in right hand; the hat shows two-thirds; milkmaid and but two cows, at right.

22. est. von Hoppe Leipzig 1804 | Dr: Edward Jenner; | Wohlthäter der Menschheit durch Erfindung | der Schutzpocken (all in script). Oval, 120x145 mm. S. G. O. [P., 1896; not B. M. J.]

b. As preceding, but body is shorter and but small portion of hat seen.

23. Anonym. Edward Jenner, M.D. F.R.S. &c. (in script) Engraved for the Hib. Mag. (1802.) Rect., 70x98 mm. J. H. H.; H. R. S. [Not P., 1896; or B. M. J.]

IV. From bust alone of Painting I, but reversed, to right.

24. J. R. Smith pinx. London | EDWARD JENNER, M.D. | Erfinder der Schutzpocken (in script) | —\*— | Zugeeignet dem eifrigen Beförderer dieses grossen | Wohlthat | für die Menschheit, seinem Freund (in script) Dr. Eichhorn | von Christoph Wilh. Bock sen. (in script.) Oval, 72x90 mm. S. G. O. [P., 1896; not B. M. J.]

25. Anonym. Oval, 55x65 mm. (Knight, Popular History of England, vii, opposite p. 475.) J. H. H. [Not P., 1896; not B. M. J.]

26. C. Böhme sc. | DR. EDWARD JENNER. Above, z. f. d. J.—No. 8 (in script). Oval, 75x93 mm. J. H. H. [P., 1896; but wrongly classed as lith.; not B. M. J.]

V. Seated upon a bank in top boots, to right and facing; left arm upon tree with its closed hand against temple, while right holds a scroll; behind, at left, two cows.

27. Bosio dis. F. Testadura inc. | Edoardo Jenner (in script). Rect., 115x163 mm. J. H. H. [Not P., 1896, or B. M. J.]

VI. From Painting II.

28. W. Say. Published January, 1803, by W. Say, No. 5 Quicksett Row, New Road, opposite Fitzroy Square, London, 270x275 mm.<sup>7</sup> [Not P., 1896; B. M. J.]

29. Anonym. [P., 1882, not 1896, or B. M. J.]

30. J. Northcote, Esqr., R.A.—Edw'd Finden | EDWARD JENNER, M.D. F.R.S., &c. &c. | Published by John Murray, Albemarle Street, 1830. Rect., 62x60 mm. (Lives of British Physicians, 1830.) S. G. O.; J. H. H.; H. R. S. [Not P., 1896; B. M. J.]

## VIII. From Painting III.

31. European Magazine (in script), (xcvi, 1804, p. 163.) Engraved by Ridley from an original Painting by Northcote. | EDWARD JENNER M.D. | Published by J. Asperna at the Bible, Crown and Constitution Cornhill 1 Oct 1804. Oval, 78x98 mm. J. H. H.; N. Y. Acad. of Med.; H. R. S. [P., 1896; B. M. J.]

32. Anonym. [P., 1882; not 1896, or B. M. J.]

See also at the end of this list.

## IX. From Painting IV.

33. Sir T. Lawrence, P.R.A.—W. H. Mote | Edw. Jenner (in facsimile script), M.D.—F.R.S. | FISHER, SON & CO. LONDON & PARIS. 1838 (Frontispiece to Vol. I, Baron's Life of Jenner; Pettigrew, Medical Portrait Gallery, II.) Rect., 100x112 mm. J. H. H.; N. Y. Acad. of Med. [P., 1896; B. M. J.]

## X. From Painting V.

34. J. Robinson pinxit.—R. M. Meadows sculp. | Edward Jenner (in script) M.D. | Published by M. Thomas, for the Analectic Magazine. 1817. Rect., 85x110 mm. S. G. O.; J. H. H.; H. R. S. [Not P., 1896; or B. M. J.]

35. As preceding, but without the Published, etc. Rect., 85x110 mm. J. H. H. [Not P., 1896; B. M. J.]

## XI. From Painting VI.

36. L. B. Drayton, ad. viv. del.—Anker Smith A.R.A., sculp. | EDWD. JENNER, M.D. L.L.D. F.R.S. &c. Circular, 47 mm. S. G. O. [P., 1882, not 1896, or B. M. J.]

37.† As preceding. Published February 1st, 1823, by J. B. Drayton, Cheltenham, Gloucestershire. [Not P., 1896.]

## XII. From Painting VII.

38. Wm. Skelton, "begun by the late William Sharp." Dedicated to the King, George IV by permission. Engraved from the Original, in the possession of Edward Davies. London: Published by R. Ackerman, 101 Strand, January 2d. 1826. 325x425 mm.<sup>8</sup> [Not P., 1896; B. M. J.]

XIII. Profile bust to left, seated, and with queue, arms folded.

39. Anonym. DR. JENNER within scrolls; above at left, Ms C L (Meyer's Conversations Lexicon) No. 1730. Rect., 84x96 mm. S. G. O. [P., 1896; not B. M. J.]

40. As preceding. DR. JENNER | EIGENTHUM & VERLAG DES BIBL. INSTITUTS IN HILBURGHAUSEN Above, WALHALLA—No. 38. Rect., 80x96. J. H. H. [P., 1896; not B. M. J.]

## XIV. Shortened bust of preceding.

41. W. Read sc. | Dr. Jenner (in script). Open, 40x50 mm. (Profess. Anecd. or Ana of Med. Lit., London, 1825, II, p. 74.) J. H. H.; H. R. S. [Not P., 1896, or B. M. J.]

## XV. Silhouette bust, to left, with queue.

42. Anonym. Dr. Jenner (in script). (Frontispiece to Vol. III, Lettsom, "Hints Designed to Promote Beneficence, Temperance and Med. Science," London, 1801 and 1816.) J. H. H.; Redwood Library. [Not P., 1896; B. M. J.]

43. As preceding. E. Jenner M.D., F.R.S., &c. (in script.) J. H. H. [Not P., 1896, or B. M. J.]

## XVI. Aged bust, facing.

44. W. Read sc. | EDWARD JENNER, M.D. Open, 65x55 mm. S. G. O.; J. H. H. [Not P., 1896, or B. M. J.]

## XVII. Bust facing, coat thrown open, shoulders truncated obliquely.

45. Anonym. EDWD. JENNER M.D. Open, 43x42 mm. J. H. H. [Not P., 1896, or B. M. J.]

XVIII. Erect, facing and slightly to left, with right arm resting upon pedestal of a pillar.

46. Anonym. DR. JENNER. | The Discoverer of Cow Pock Inoculation (in script). Published by J. Robins & Co. Ivy Lane, Paternoster Row, March 22, 1823. Open, 100x100 mm. J. H. H.; H. R. S. [Not P., 1896; or B. M. J.]

47. Anonym. JENNER. Rect., 53x40 mm. J. H. H. [Not P., 1896, or B. M. J.]

XIX. With cocked hat. (?)<sup>9</sup>

48†. Hicks sc. Published by Henry Fisher. Caxton. London: March 1st, 1823. [Not P., 1896.]

## XX.

49†. By Branwhite. Bust. In Medley's group of the Founders of the Medical Society of London. Not originally upon the plate, but subsequently introduced. I am not as yet certain as to its exact place in this list. [Not P., 1896.]

## XXI.

50†. J. Hazlitt jun. C. Turner, sculptor. London: Published October 20th, 1803, by J. Hazlitt, No. 109, Great Russell Street, Bloomsbury. I am also uncertain as to the exact classification of this. [Not P., 1896.]

## XXII.

<sup>8</sup> At the Bristol Exhibition.

<sup>9</sup> That this is of Jenner is denied by Dr. Hunt, who points out that it seems identical with that of Dr. Sims of London, in Medley's group of the Founders of the Medical Society of that city.

<sup>7</sup> At the Bristol Exhibition.

51†. Head, on large scale. H. E. Shrapnell. I am not sure as to its allotment. [Not P., 1896.]

XXIII. From Statue II (London). Front and to right. 52. Engraved by J. Moore, from a Daguerreotype by Beard. | DR. JENNER. Rect., 95x120 mm. S. G. O.; J. H. H. [P., 1896; not B. M. J.]

XXIV. From Statue II, left side. 53. JENNER. | ENGRAVED BY J. BROWN FROM THE STATUE BY W. C. MARSHALL, R.A. Open, 130x165 mm. J. H. H. [Not P., 1896; B. M. J.]

XXV. From bust of Statue I (Gloucester). Looking to right and slightly downward; draped, squared and on mounted pedestal.

54. \*Anonym. [P., 1896; not B. M. J.]

XXVI. From Bust I.

55. EDWARD JENNER, M.D. L.L.D. F.R.S. | Engraved by J. Dadley from a Bust by C. Manning [Esq.] (in script.) Open, 65x110 mm. S. G. O.; J. H. H. [P. 1896; not B. M. J.]

XXVII. From Bust IV. Japanese.

56. (Sei-i-Kwai Medical Journal, Tokio.)

XXVIII. There exists also an engraved portrait, of 1801, with this inscription in Spanish:

57. Edward Jenner, English physician, to whom the world is indebted for the discovery of vaccina, the wonderful and only preservative from the smallpox. It is prefixed to the dissertation upon cowpox published by the Royal Academy of Medicine. (Baron: Life, etc., I., p. 604.) [Not P., 1896, or B. M. J.]

In addition, there is an engraving of a cow with star above shoulder and crescent upon side. R. Reeve sc. Above; Sacred Cow. Circular. S. G. O.; J. H. H. I do not number it. It alludes to the cast represented upon Painting II, and refers to the "Sacred Cow of India," represented upon a medal of Dr. Guillaume Demanet of Ghent. [P. and R., 1882, p. 421.]

One of Northcote's paintings, II or III, is reproduced in the *Practitioner* for May, 1896.

#### LITHOGRAPHS.

- I. From bust of painting I.
  1. Th. Hosemann. [P., 1882; not 1896, or B. M. J.]
  2. Anonym. Lith. de Gregorie et Deneux, à Paris. | E. JENNER. Open, 195x190 mm. (Médecins et Chirurgiens célèbres. Paris, 1842.) J. H. H. [Not P., 1896, or B. M. J.]
  3. Anonym. Lith. rue Salle au—Comte, 10. | E. JENNER. Open, 200x190 mm. S. G. O. [Not P., 1896, or B. M. J.]

  5. \*As preceding. Engelmann. [P., 1896; not B. M. J.]
  6. †As preceding. Lithographed by C. de Lasteyrie, 1824. (Asclepiad, VI, p. 250.) [Not P., 1896.]
  7. \*As preceding. Villani. [P., 1896; not B. M. J.]
  8. As preceding. Steandriij van H. J. Backer, Dordt. | Edw'd Jenner (in fac-simile script). Open, 98x100 mm. S. G. O. [P., 1896; not B. M. J.]
  9. E. JENNER, M.D., F.R.S. &c. | Hart & Mapother, lith. Louisville, Ky. Open, 100x110 mm. S. G. O.; J. H. H. [Not P., 1896, or B. M. J.]
  10. Anonym. DR. EDWARD JENNER. | BORN 1749. DIED 1823. | AT BERKELEY, ENG., | &c. &c. DR. H. M. Alexander & Co., &c. Open, 40x40 mm. J. H. H. [Not P., 1896, or B. M. J.]
  - II. Anonym. Dr. Edw. Jenner (in script). | 1749—1823. within cartouche, over palm leaves: Dr. H. M. Alexander & Co., &c., 30x40 mm. J. H. H. [Not P., 1896, or B. M. J.]
  12. Anonym. JENNER. (Dr. H. M. Alexander & Co., Columbian Exposition.) Circular. Colored, 30x30 mm. J. H. H. [Not P., 1896, or B. M. J.]
  - II. From bust of painting I, but reversed, to right, and with smooth instead of wavy hair.
    13. Lagrand (in script)—Lith. de Ducarme. | E. JENNER, | Médecin Anglais. | 1er Observateur de la Vaccine, né en 1749, mort en 1823 (in script). Galerie Universelle—Publiée par Blaisot. | Place Vendôme, No. 24, | No. 353. Open, 150x135 mm. S. G. O. [Not P., 1896, or B. M. J.]
    - III. From bust of painting I, but reversed, to right, with left arm dependent, and right extending a MS. volume, upon cover of which a cow.
      14. Leon Noel (in script)—Lith., de Frey | EDOUARD JENNER. Open, 100x170 mm. S. G. O.; J. H. H. [P., 1896; not B. M. J.]
      - IV. From engraving XIII.
        15. Anonym. Dr. Jenner (in script). | Published by R. Phillips, No. 71, St. Paul's Churchyard, London. Open, 42x45 mm. J. H. H. [Not P., 1896, or B. M. J.]
        16. Anonym. EDWARD JENNER, M.D., LL.D., F.R.S., ETC., ETC. Open, 45x50 mm. (*Brooklyn Med. Jour.*, December, 1891.) J. H. H., H.R.S. [Not P., 1896, or B. M. J.]

17. As preceding. DR. JENNER. Open, 45x50 mm. (*Ibid.* April, 1896.) J. H. H.; H. R. S. [Not P., 1896, or B. M. J.]

18. As preceding. At sides: 1796—1896. (Jenner Centennial Festival, Med. Society of County of Kings, Brooklyn, N. Y.) Open, 45x50 mm. J. H. H.; H. R. S. [Not P., 1896, or B. M. J.]

V. From bust of Statue I (Gloucester). 19. EDWARD JENNER. M.D. | L.L.D. F.R.S., &c. &c. | Drawn from the bust by H. CORBOULD, and on stone by R. J. LANE. | Printed by C. Hullmandel. | Published March, 1827, by Henry Colburn, London. Open, 80x120 mm. (Frontispiece to Vol. II, Baron's Life.) S. G. O.; J. H. H. (P., 1896, B. M. J.)

20. As preceding. EDWARD JENNER, M.D. | L.L.D. F.R.S. &c. &c. Open, 95x140 mm. J. H. H. [Not P., 1896, or B. M. J.]

21. Anonym. (Variola and Vaccina. N. E. Vaccine Co.) J. H. H. [Not P., 1896, or B. M. J.]

VI. From Bust I.

22. M. Gauci, 1823. Published by N. Chater and Co., 33; Fleet Street, London, & Washburn & Sons Gloucester, August 10th, 1823. 225x300 mm. J. H. H. [P., 1882; not 1896; B. M. J.]

23. MÉTHODE DE DESSIN | PAR VIGNERON.—Pl. 49. | Edw. Jenner | Inventeur de la Vaccine. — | d'après une Gravure Anglaise (engraving No. 55 of this list). | Paris, Mon. Basset, 33, rue de Seine. Lith. de Thierry frères, Paris. Open, 294x420 mm. S. G. O. [Not P., 1896, or B. M. J.]

VII. From Bust II.

24. Anonym. Jenner (in script). Open, 68x95 mm. S. G. O. [Not P., 1896; or B. M. J.]

#### WOODCUTS.

- I. From bust of Painting I.
  1. Anonym. Edward Jenner, born May 1749, died February, 1823. (From an illustrated paper.) Open, 100x130 mm. J. H. H. [Not P., 1896, or B. M. J.]
  2. Anonym. (Russell, History and Heroes of Art of Medicine, London, 1861.) 60x65 mm. J. H. H. [Not P., 1896, or B. M. J.]
  - II. From bust of Painting I, but with a cow beneath.
    3. LES MÉDECINS ET LES ADMINISTRATIONS RECONNAISSANTS. | MONUMENT | A | JENNER. | W. BROWN DEL. & SC. Rect., with upper corners rounded; 195x245 mm. S. G. O. [Not P., 1896; or B. M. J.]

There are a number of caricatures of Jenner, and engravings of vaccination, vaccine farms, etc., but I have purposely omitted these.

During Jenner's life, as an offset to the innumerable insults and scurrilous attacks that he received, the Royal Jennerian Society was founded in 1803. In 1808, at his own request, it was merged in the National Vaccine Establishment. He was given a Parliamentary grant of £10,000 in 1802, another of £20,000 in 1807, and subsequently an additional £8,000 by India. He was also presented a service of plate by his country friends, and the freedom of the city of London, in a casket set with diamonds. There is a memorial window and tablet of him at the church in his native Berkeley.<sup>10</sup>

## THE SEMINARY METHOD IN TEACHING SURGERY.

Read before the American Academy of Medicine, Atlanta, May 4, 1896.

BY BAYARD HOLMES, B.S., M.D.

PROFESSOR OF SURGERY IN THE COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO.

I can best give an idea of this method by relating the history of an experiment which I made in teaching a few topics in surgery to a class of thirty students. A case of osteomyelitis of the tibia came to my clinic and was carefully studied by me with the help of the class. The history was outlined upon the blackboard, and the diagnosis, prognosis and indication for treatment were carefully discussed and our conclusions written down. When this had been done the students were instructed to bring into the class at the next recitation hour histories of three or more cases of osteomyelitis, which they had themselves observed or had copied from articles in the medical literature. The class had previously been instructed in the method of using the medical library, and cards had been placed in the card catalogue of the college library guiding the students to as many articles as the library contained bearing upon the subject of acute osteomyelitis. During the next clinic hour this patient was operated upon in the presence of the class, and a large sequestrum of bone removed. The involucrum was so cut down so as to allow the resulting concave surfaces to be covered with skin. At the next recitation hour the students came with some original and some copied histories of cases of osteomyelitis. One student with a good voice and prompt address was requested to read one of his cases aloud. This case had been selected by me because it was typical

and well recorded. As the reading progressed notes were placed upon the blackboard indicating the age of the patient, the predisposing causes of the disease, the immediate cause of the onset of the disease, the most prominent symptoms and the subsequent course and the treatment.

Opposite the age of this typical case was set down the age of the sixty-four other patients, whose histories were in the hands of the students in the class. In this way we discovered that nearly all the patients were between six and twenty-five years of age, one student was requested to make a statement, which would show the condition represented by the mass of figures. After a number of trials he wrote out the following sentence, which was accepted as expressing the facts: "Of the sixty-four cases presented by the class, 52 per cent. were between 5 and 20 years of age, 20 per cent. were between 20 and 30 years of age, and all of the remaining 28 per cent. were less than 46 years of age." In the same manner the previous condition of the patient and the predisposing causes of the disease were noted down upon the blackboard and afterward expressed in short sentences, thus: "Thirty per cent. of the sixty-five cases presented had suffered from some acute infectious disease immediately before the onset of osteomyelitis." In the same manner the other important points in the clinical history, in the pathology and in the treatment of the disease, was discussed. It required several hours for this work, and the intervening time was spent by the students in collecting new information and in exchanging histories of cases with one another. After every important point had been studied, the students were directed to make an abstract of the histories of ten or more cases, and then from these cases to prepare a generic history of the disease. Instructions had been given as to the size of the sheets of paper, the disposition of the manuscript on the page and the method of arranging and binding. Two weeks were then allowed for the completion of the thesis upon this disease. Thirty very excellent and satisfactory papers were written. One would naturally expect a great deal of sameness in these efforts, but contrary to my own expectation there was the greatest variety of treatment. One student of a judicial turn of mind numbered very carefully his cases and the pages of his manuscript, and then in the original portion of his thesis referred after each statement to the cases which authorized it. One man divided his histories up into fragments and quoted the fragments in full corroboration of each fact or conclusion stated. A few men copied outright from text books on surgery, but on the whole this was a most satisfactory exercise.

Various other subjects were studied in the same manner, all the class working upon the same subject at the same time. When familiarity with the method of work had thus been secured, separate topics were given each student, and he was directed to investigate the literature of the subject as represented in the college library, and then to prepare in the usual manner a complete account of the disease, its pathology and treatment, basing his remarks entirely upon the histories of the cases, which he had either observed himself in the clinics or on those he had abstracted from the literature, but best of all upon both. Care was of course taken to assign only such subjects as were adequately represented in the college library, and also so as to give each student one surgical disease of the head, one of the thorax, one of the abdo-

<sup>10</sup> They are figured in the *British Medical Journal* for May 23, 1896, p. 1253.

men, and one of the extremities. At first the work was reluctantly undertaken by the students, but after an examination at the County Hospital had been held in which, by chance, questions were asked involving a knowledge of two of the subjects which had been studied by this method, the value of this intensive teaching was recognized, and enthusiastically undertaken by nearly all the class ever afterward.

This method of study must be conducted in small classes of mature students, who understand the use of and have an adequate library at hand. It requires about six or eight hours preparation for each recitation hour, and it must be conducted by a teacher who fully understands the resources of the students and is wise enough to present at the start no insurmountable difficulties. Perhaps the ideal can only be attained when the teacher has previously studied each of the subjects he assigns in the library of the college and has taken care to have such cards put in the catalogue as will guide the student to all the literature without too much effort.

One of my students had assigned him a topic involving the repair of fractures in long bones. He took the trouble to study the specimens in the museum, and he also made a series of experiments on animals in which he made microscopic demonstrations and prepared large macroscopic sections sawed out near the seat of fracture. In the seminary method nothing should be neglected which will add to the concreteness and vividness of the conception of the student. He should be placed as far as possible in the position of an original investigator, with many of the difficulties which ordinarily beset the investigator removed.

This method is equally applicable to the study of any topic in the medical curriculum, but it should not be used to the exclusion of any other method, but rather as supplementary to any or all of them. It is especially adapted to students who have been trained in independent thought in colleges and universities, and it will be found an excellent preparation for such students as propose to contribute to medical literature.

## MALARIA.

BY ELLSWORTH D. WHITING, A.B.

AURORA, ILL.

(The L. P. C. Freer Prize Essay, Rush Medical College, 1896.)

(Concluded from page 269.)

The increase of connective tissue is first observed in the interlobular spaces, and later dips down into the lobules. The atrophy of liver cells follows this increase of interstitial connective tissue. (Plate vi.)

On gross examination the kidney is found to be larger and heavier than normal. In consistency it is either firm or soft and edematous, presenting a mottled surface, the result of infarction. The capsule strips readily or is thickened and adherent as in severe cases. The Malpighian bodies are either prominent and swollen or sunken and atrophied. These conditions are often present in the same specimen. On cut section the color of the kidney varies from the normal to a yellowish brown, marked by opaque, dark and minute hemorrhagic areas. The medullary rays are pale, showing between them dark, red lines of congested intertubular vessels. The cortex is generally thick and paler than normal. It is translucent and of yellowish appearance. (Plate iv.)

On microscopic examination the glomeruli may fill

their capsules, but they are often atrophied, the space between the glomerulus and Bowman's capsule being empty or filled with albumin, red corpuscles, disquamated epithelial cells or leucocytes. In some instances there seems to be a proliferation of the cells lining the capsule. Outside the capsule, at times, a space may be made out, filled with leucocytes and red corpuscles. Within the capillaries of the glomeruli are numerous leucocytes, parasites and microorganisms, which may completely fill up the lumen of the vessels. The leucocytes contain granular pigment and parasites. Parasites are also present in large numbers outside of the leucocytes. In the glomeruli macrophages are generally few.

Turning to the convoluted tubules, these appear dilated, the epithelial cells of which are swollen and show evidence of degeneration. Fringing these epithelial cells are small hyalin droplets. The tubules are often plugged with granular and hyalin casts, within the substance of which are blood corpuscles, degenerated epithelial cells, pigmented granules and yellowish urinary sediments or excretions. The intertubular capillaries are also dilated and crowded with the foreign materials found in the glomeruli. (Plates iii and v.)

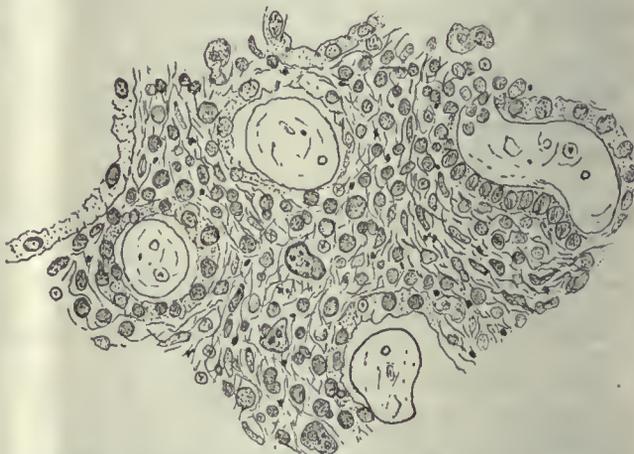

Plate III. KIDNEY.—Figure shows enormous increase of connective tissue which is infiltrated with round cells, macrophages, parasites and pigment granules. Tubules are filled with hyalin casts in which are seen pigment granules and leucocytes. Zeiss Obj. D D, Oc. 5. Draw tube 160 mm.

The changes in the interstitial tissue are usually slight. Here and there may be seen areas of round-cell infiltration, consisting of lymphocytes and large mononuclear leucocytes. In severe cases these changes may be great. (Plate iii.)

As a result of thrombosis extensive infarcts are present, embracing glomeruli, tubules, blood vessels and interstitial tissue. These infarcts are surrounded by a strongly marked margin of deeply staining round cells. It is in these thrombosed vessels, at the apices and margins of the infarcts, that the greatest number of parasites are found.

Fatty degeneration is present in the glomeruli, the lining membrane of Bowman's capsule and muscular coats of the arteries.

The heart on gross examination is practically normal in size and weight. The only constant pathologic change present is a brown pigmentation of the myocardium and a slight thickening of the endocardium. Calculus degeneration is commonly present in the valves, associated with atheromatous degeneration of great and coronary vessels.

On microscopic examination the only pathologic

picture to be seen is in the muscular fibers of the myocardium, where, at the poles of the nuclei of the muscle cells an excess of brown pigment may be observed.

Pathologic changes are common in the bone marrow. Macrophagi are present in great numbers and show contents similar to those found in the spleen and liver. Red corpuscles both nucleated, and degenerated may be seen in increased numbers, also leucocytes whose nuclei are fragmented and filled with pigment. The endothelial cells are also degenerate and filled with pigment.

On gross examination the lungs are either normal or emphysematous and non-collapsing. When non-emphysematous they are much darker than normal. On cut section edema of dependent parts is observed. Large and small bronchi are filled with a muco-purulent secretion, showing general bronchitis. In a great number of autopsies no lung lesions are present with the exception of a slight general bronchitis.

Plate IV. KIDNEY.—Figure shows atrophy of glomerulus, increase of interstitial tissue, infiltration with round cells, parasites and pigment granules. Epithelium of uriniferous tubules is swollen and granular. Zeiss Obj. D D, Oc. 5. Tube length 160 mm.

On microscopic examination the pleural and pulmonary veins are seen to be dilated. Here malarial organisms are present in great numbers, either enclosed in the red corpuscles, free in the plasma or in the leucocytes. Collections of pigment granules and phagocytes may exist in sufficient quantities to plug up the lumen of the vessels.

Pathologic changes in the brain are not numerous, but those present are of great importance from a clinical standpoint.

On gross examination an increase in the spinal fluid is observed. The dura is thickened and small pigmented and hemorrhagic areas can be made out, associated with turgescence of blood vessels.

On microscopic examination infected corpuscles and organisms are present in the phagocytes and endothelium lining the capillaries. In the cerebral tissue white infarcts with hemorrhagic margins are quite numerous.

In the supra-renal bodies many pathologic lesions are present which correspond closely with those described as associated with the kidney, liver and spleen.

Oligocythemia is always present in malarial fevers. It is caused by the direct destruction of the red corpuscles by the organisms and is in inverse ratio to the number of parasites present in the blood. A marked reduction of red corpuscles is noted after the paroxysm, from which point there is a gradual increase which continues to the beginning of the next paroxysm. In the mild tertian and quartan types during the apyretic stage complete restitution of corpuscles may be accomplished but in the severer form there may be an actual decrease during this period. It is quite a noticeable fact that restitution of red corpuscles takes place to a greater degree during the earlier days of the disease than in the later stages. As the disease lengthens in duration the decrease in red corpuscles may reach as low as one million corpuscles to the cubic millimeter. After protracted sieges of malaria the changes brought about in red corpuscles, are marked. In the blood stream may be found poikilocytes, degenerated and vacuolated red corpuscles, microcytes, macrocytes, normoblasts and megaloblasts. (Plate xvi.)

In regard to the leucocytes, their number follows

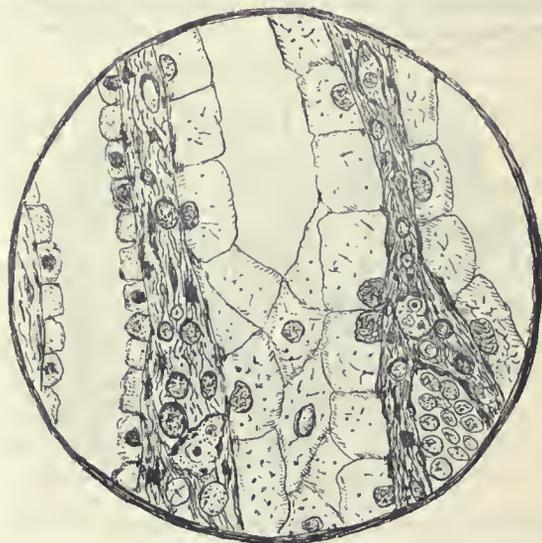

Plate V. KIDNEY.—Figure shows enlargement of epithelial cells lining tubules and increase of interstitial tissue, which is infiltrated with round cells, macrophages and pigment granules. Zeiss Obj. 1-12 oil. Oc. 3. Tube length 160 mm.

closely the changes noticed in the red corpuscles. Directly after the paroxysm there exists a marked leucocytolysis. At times the number may reach as low as one thousand per cubic millimeter. From this point an increase is observed until during the first hour of the paroxysm, when the count may be normal or an actual leucocytosis exist. The degree of leucocytolysis seems to depend greatly upon the size of the spleen. The greater the size of the spleen the greater is the leucocytolysis, a condition directly opposite to that found in splenic leukemia.

The recuperative power of the leucocyte is much less than that of the red corpuscle. In postmalarial conditions the red corpuscle generally gains its normal state long before the white, but in some cases of pernicious malaria a marked leucocytosis exists.

In regard to oligochromemia, its presence in malaria, as would be naturally expected, is marked and is generally in direct ratio to the oligocythemia. In some cases the lack of hemoglobin is greater than can be accounted for by the oligocythemia. No acute infection known has such a depleting action upon the

hemoglobin of the blood as malaria. Depending upon the severity of the underlying cause this condition may be brought about in a few days or be the result of a long infection. (Plate xvi.)

As in oligocythemia and leucocytolysis, oligochromemia increases after the paroxysm and diminishes gradually until the beginning of the following paroxysm. The rapidity and severity of the loss of hemoglobin affords a valuable diagnostic aid in differentiating malaria from pneumonia, typhoid fever and enteric fever.

The relative number of phagocytes present in the blood corresponds closely to that of the leucocytes. The ability of the leucocyte to cope with the parasite seems to increase with the age of the leucocyte. The small mononuclear leucocyte or lymphocyte which is supposed to be the first stage in the development of the adult form, possesses little or no phagocytic power. The large mononuclear has some phagocytic function, but is unable to cope with flagellate forms of the organism. The eosinophile has never shown any indications of phagocytic power. The greater portions of the work done by phagocytes is therefore accomplished by the large polynuclear leucocytes and macrophages aided by the cells lining the blood

vessels pursue. The paroxysms gradually increase in severity, a period of fluctuation, then spontaneous recovery followed in two or three weeks by a relapse. If the checking of the course of the disease depended upon the action of the phagocytes, the fever would be allayed in the first part of its course, for phagocytes are as numerous in this part of the course as in the later stages.

The theory of these latter investigators is that malaria is self-limiting and that at each period of segmentation a toxic substance is thrown into the blood stream, which becoming more and more virulent at each succeeding paroxysm, eventually becomes sufficiently potent to cause the death of the organisms, only a few spores protected by degenerate phagocytes surviving to be the source of a relapse.

Mannaberg claims that the temperature caused by the body in reacting against the toxic irritants in the blood, exerts also a deleterious influence upon the half and full grown organisms.

Thus in summing up causes which may bring about spontaneous cures we must take into consideration these three factors, phagocytosis, toxic excretions of the parasite and the temperature.

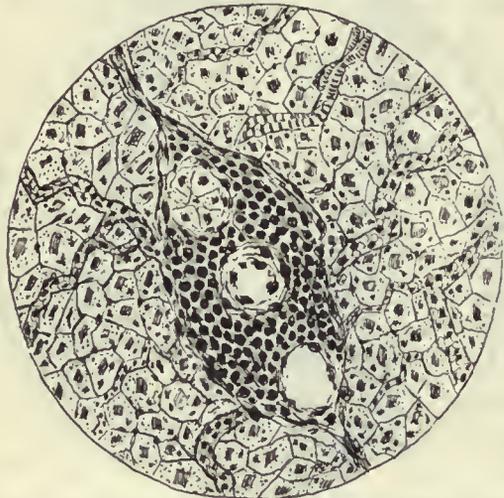

Plate VI. LIVER.—Figure shows interlobular space with portal vein, hepatic artery and bile duct and greatly increased connective tissue. Pigment granules are seen in and between hepatic cells. Capillaries are distended with many leucocytes. Connective tissue is infiltrated with round cells. Zeiss Obj. D D, Oc. 3. Tube length 160 mm.

vessels and endothelial cells of the liver and spleen.

As to the effect of the phagocytes upon the course of the disease there are two theories. The first, upheld by Golgi, Bignami and others, goes to prove that the spontaneous cure of malaria and the prevention of the mild forms from becoming pernicious is due to the action of the phagocytes in removing from the body spores, adult organisms and degenerated corpuscles. These men account for relapses by stating that when spores are contained in white corpuscles a struggle takes place between the two bodies, in which the phagocyte is finally worsted. On the other hand, Osler and others claim that phagocytes do not play the most important part in cutting short the course of malaria. To prove this statement these observers call attention to the fact, that in severe paroxysms phagocytosis is most apparent, and that in cases of spontaneous recovery there is no evidence of increased phagocytosis, but rather an increase in the number of degenerated organisms. They also call attention to the rhythmic course which untreated

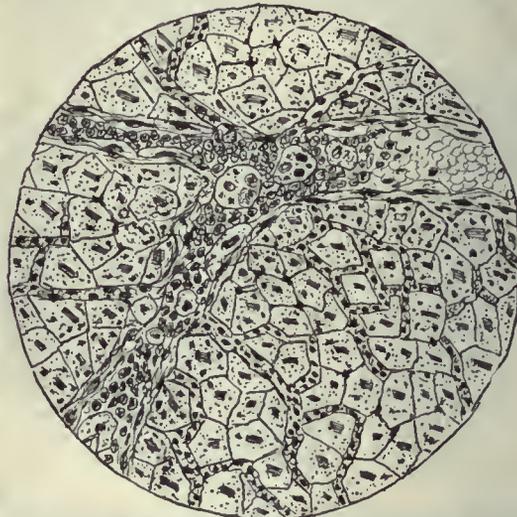

Plate VIII. LIVER.—The figure shows a thrombosed vessel containing red blood corpuscles, small round cells, macrophages, parasites and pigment granules. Pigment granules also in capillaries and in and between hepatic cells. Capillaries are dilated and contain many leucocytes. Zeiss Obj. D D, Oc. 3. Tube length 160 mm.

In consideration of malaria from a clinical standpoint, it may be divided into the following forms: 1, intermittent; 2, pernicious intermittent; 3, remittent; 4, pernicious remittent; 5, typho-malaria; 6, malarial cachexia and irregular forms. The clinical manifestations of malaria may also be classified in reference to the length of time between paroxysms: 1. Quotidian, produced by the segmentation of two groups of tertian organisms on successive days. 2. Tertian, produced by a single group of the tertian organisms. 3. Quartan, single, double and triple, produced by the quartan parasite. 4. Irregular or continuous, produced generally by estivo-autumnal parasites. The first classification, as proposed by Thompson, is much more complete and will be followed here.

Intermittent fever is caused generally by the tertian or quartan parasite, rarely by the estivo-autumnal. It is characterized by complete disappearance of symptoms between paroxysms. Its course may be divided into three distinct stages: 1, the cold stage; 2, the hot stage; 3, the sweating stage.

The first stage may appear suddenly or come on gradually. It is preceded by a headache and general malaise and is characterized by a subjective sensation of cold while the thermometer records a rise of internal temperature. The face is pale and pinched, the skin cold, clammy and of the goose quill appearance. The pulse is weak and rapid and respiration shallow. The patient complains of cold which abundant covers will not relieve, muscular pains and headache. Associated with the chill are often severe rigors in which the patient shakes violently from head to foot. The teeth chatter wildly and coherent speech is impossible. The superficial, sub-normal temperature is caused by the constriction of the peripheral vessels, resulting in great internal congestion. This fact explains the enteric, liver and splenic symptoms, evinced by frequent nausea and vomiting and tenderness. The paroxysm may be of varying duration. In some instances it may last for but a few moments, associated with simply a chilly sensation, or feeling of weakness, or it may last from two to four hours, accompanied with great rigors and intense pain. In children the chill may be replaced by a convulsion. There seems to be no relation between the severity of the chill and the following hot stage.

The second stage is characterized by a gradual rise in temperature which may reach as high as 106° F. The face is flushed; the skin of the mouth, throat and nasal passages hot and dry; the pulse full, rapid and strong and frequently dicrotic. The respiration is deeper; the headache and vomiting may continue, but disappear with the fever. When the fever runs exceedingly high the patient may sink into a comatose or delirious state.

The third or sweating stage follows the fall in temperature and is ushered in with a profuse perspiration. This commences upon the face and forehead, but soon the whole body is bathed in sweat, which often soaks the bed clothes. During this stage the patient experiences great relief. The headache, muscular pain, vomiting, tender abdomen and splenic tumor disappear. This is due in great part to the relaxation of the peripheral blood vessels, which relieves the internal congestion. After the perspiration has ceased the patient is greatly prostrated and may remain in this condition for many hours. This stage lasts from two to five hours and may continue from three to ten or twelve hours. During apyrexia the temperature is generally sub-normal.

The urine during and after the chill is increased in solids, although there is a relative decrease in the amount of urea excreted. Slight albuminuria and glycosuria have been noticed during paroxysms.

Intermittent fever at times assumes a grave and malignant aspect. It may be ushered by an ordinary paroxysm followed by a severe one which in turn is succeeded by a third and fatal one.

The following classification of intermittent pernicious fevers, based upon the most prominent symptoms, is given in the American Text Book of the Theory and Practice of Medicine: 1, bilious; 2, hemorrhagic; 3, algid; 4, asthenic; 5, comatose.

In the bilious form severe abdominal symptoms are present. There is generally flatulency and tenderness of the abdomen, associated with the vomiting of large quantities of bile, and watery discharges from the bowels. The liver and splenic areas of dullness are much increased. Jaundice may occur within a few hours after the paroxysm.

The hemorrhagic form is always grave. During the hot stage blood appears in the urine, which is decreased in quantity and contains albumin and casts. Soon there appear hemorrhages from the mouth, stomach, rectum and skin. Suppression of urine soon follows, with violent headache, delirium, coma, Cheyne-Stokes respiration, heart failure and pulmonary edema and death from uremic and malarial poisoning.

The algid form simulates closely the algid stage of cholera. Great prostration is present, associated with purging, vomiting, muscular pains, superficial sub-normal temperature and at times jaundice.

The asthenic form is accompanied by great nervousness, imperfect aeration and feeble heart.

In the comatose form the patient may immediately enter into the comatose state from which he can not be aroused. If this first attack be survived the second is certain to prove fatal. This form may be present in any of the preceding types, but it is rare.

The same stages characterize the remittent forms of malaria as the intermittent, with the exception that the temperature rarely falls below 100 degrees F. This form of the disease is associated especially with the second cycle of the estivo-autumnal organism. Remittent fevers may commence as intermittent or they may immediately assume this form after a severe initial paroxysm. The second stage is often prolonged, lasting from twelve to twenty-four hours. The third stage is not so prominent as in the intermittent. During the interval between paroxysms the patient is not as free from symptoms, complaining of fever, nausea, vomiting and muscular pains. The remission generally occurs during the night. The fever may subside gradually, retaining its remitting character or first become intermittent before disappearing.

Pernicious remittent fever is so nearly identical in symptomatology with pernicious intermittent fever that a separate description is not necessary.

Typho-malarial fever consists in a combination of the symptoms of malaria and typhoid fever. It begins with a chill followed by fever. The symptoms of this disorder may be most markedly those of either of these diseases; however, the typhoid symptoms are generally most prominent, the malaria being in evidence only by the variations in temperature. Typhoid fever, when associated with malaria is not as fatal as when existing alone.

Malarial cachexia is seen in persons who have had many attacks of malaria or in those who have lived for long periods in malarial districts. It is associated with a pale, muddy complexion. Anemia and indigestion are common. Circulation is poor and anasarca may be present. There is lassitude and mental depression. The temperature may be subnormal or slightly elevated. There is generally an enlargement of both liver and spleen.

Under the head of irregular forms are found many disorders of malarial origin which may escape the diagnostician. It is in these that the blood examination is of the greatest importance. In some instances the chill may be entirely absent. This is termed "dumb ague." In other cases the sweating stage is not present, and again both the foregoing may be absent. The entire paroxysm may be wanting, in the place of which malaise is noticed, headache, diarrhea or vomiting, with perhaps a very slight rise in temperature. Such patients are termed by the laity "bil-

ious." Again the malarial paroxysm may appear in the form of severe neuralgic pain associated with the fifth, sciatic, brachial or intercostal nerves.

The diagnosis of pure types of intermittent fever is readily accomplished without a blood examination, based upon the peculiar quotidian, tertian or quartan paroxysms and splenic tumor. These forms simulate closely, however, the onset of pneumonia which is later easily differentiated. Suppurative infection should be excluded by careful examination for infec-

These forms may be confused with typhoid fever, cholera, ulcerative endocarditis, pyemia, septicemia and meningitis. It is in these cases that the microscope is of invaluable aid to the physician and in many cases is the only means of arriving at an accurate diagnosis.

When rose-spots are absent in typhoid fever, a condition which often exists, it may be simulated very closely by the typho-malarial form of malaria. In yellow fever the characteristic symptoms, peculiar

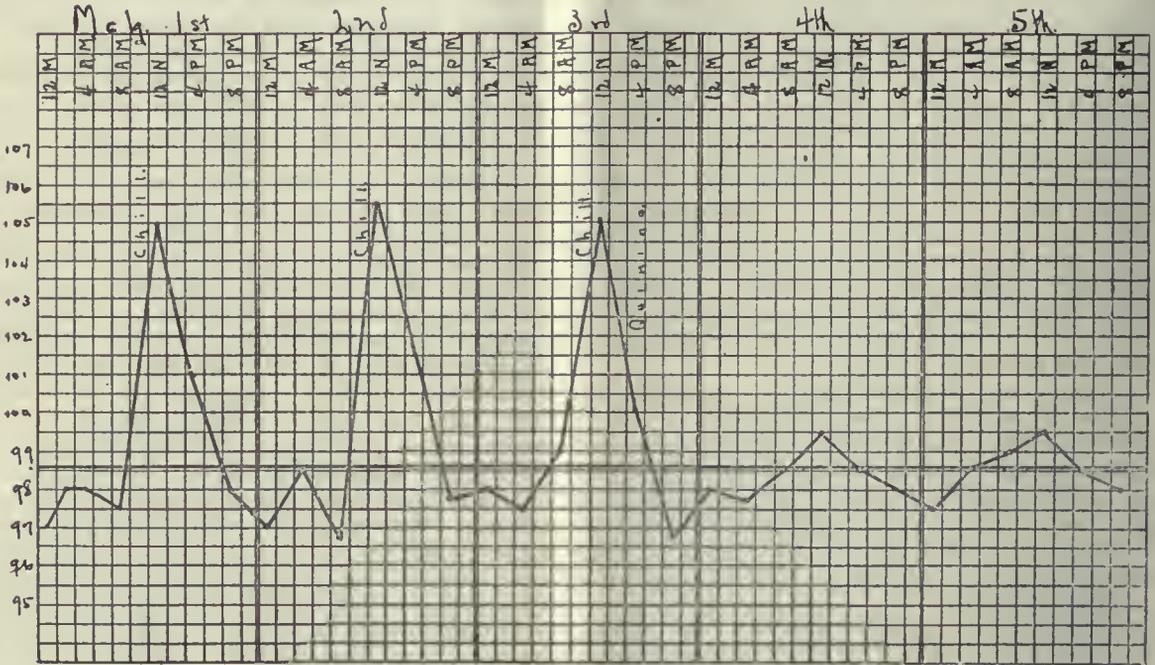

Plate XIII. INTERMITTENT QUOTIDIAN OR DOUBLE TERTIAN FEVER. TEMPERATURE CHART.

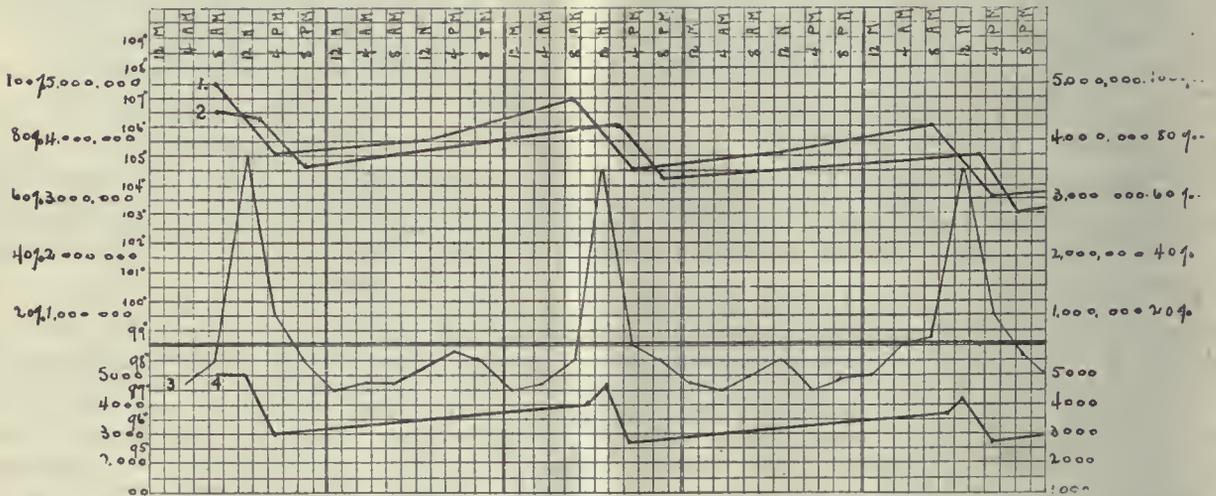

Plate XVI. DIAGRAM OF BLOOD CHANGES IN TERTIAN FEVER.—1, Red Blood Corpuscles; 2, Hemoglobin; 3, Temperature; 4, Leucocytes.

tion atrium and hidden foci. In these diseases the chills and fever are irregular and no splenic tumor exists. When suppurative processes are present with phthisis it is necessary to examine the sputum. Even in cases where the symptoms are pathognomonic, corroborative blood examinations should be made, if possible, in order to establish the type of organism present.

On the other hand, when it is necessary to contend with remittent and pernicious forms the diagnosis is at times very difficult from a clinical standpoint.

onset, black vomit, jaundice and suppression of urine, are all simulated by pernicious malaria. The diagnosis of the algid stage of yellow fever from the algid form of malaria is impossible without a blood examination. Ulcerative endocarditis can usually be differentiated from malaria by a physical examination of the heart, and pyemia by establishment of infection atrium. In differentiating uremia and meningitis from comatose pernicious malaria it should be remembered that coma comes on later in meningitis than in malaria, and that it is accompanied with

photophobia and lowered temperature. Pernicious malaria often merges into uremia and can be differentiated only by the microscope. It is in the differential diagnosis of malaria from the foregoing diseases that the discovery of the organism of malaria has worked its greatest benefit to the medical profession. This is especially true in the case of typhoid fever; and it is probably a fact that to-day many malarial patients are being treated for typhoid fever.

The prognosis of the milder forms of malaria is always good. In the pernicious types it is grave, the degree of mortality depending upon the vitality of the patient, the promptness of treatment and accuracy of diagnosis.

Prophylactic treatment is very efficient. Taken in connection with hygienic observations and pure water, quinin will in most instances establish immunity for a considerable length of time. Following this treatment travelers have invaded the most deadly malarial regions without serious results.

As to the treatment of malaria, quinin is the great panacea. Probably 95 per cent. of all cases succumb to its effects.

Most observers agree that quinin causes the death of the organism by direct contact when the parasite is in the sporulating form outside the corpuscle. This drug, when given two hours before the paroxysm, even in fifteen grain doses, will not stop the oncoming paroxysm but will prevent the spores from entering new corpuscles. This fact seems to prove that the adult segmenting organism is not affected by the drug while the free and growing spores constantly imbibing nourishment from the plasma of the blood are readily destroyed. When the spores have gained entrance into the corpuscles they are equally invulnerable as the adult organism. This goes to prove that the hyalin body lives to a great extent upon the protoplasm of the corpuscle.

As to the administration of quinin, two principal methods are in practice at the present time. The first consists in giving moderately large doses every four hours until the paroxysms are overcome and then gradually decreasing the size of the dose. The second method is to give small doses during apyrexia with very large doses from three to five hours before the anticipated paroxysms. As many as thirty grains may be given at one time. Good results follow both these methods.

In some instances quinin can not be given on account of individual idiosyncracies. But a few days ago the writer saw a young girl the skin of whose hands had completely peeled away as the results of taking a few grains of quinin. In other cases this drug in the minutest doses may produce distressing symptoms of cinchonism associated with nervousness and vomiting. In such cases the other alkaloids of cinchona must be tried. Marburg's tincture is often effective, and bone marrow and methylene blue have been used with a moderate degree of success. Arsenic is a powerful antiperiodic but is slower than quinin. During the paroxysm palative treatment should be used, as hot drinks and cloths during the chill and sponging during the fever if the temperature rise exceptionally high.

In pernicious cases quinin should be given hypodermically and with great promptness and the patient kept warm and quiet. The great object should be to tide the patient over the first paroxysm and abort the time of the second lest it should prove fatal. In

these cases the medicinal treatment, aside from the administration of quinin, cathartics and diuretics, should be largely symptomatic, and the symptoms combatted as they appear.

As convalescence approaches, a nourishing and easily digested diet should be arranged and the medical treatment consist of tonics and simple bitters with a moderate amount of healthful exercise.

## PRACTICAL NOTES.

**Keratitis Dendritica.**—Dr. Frank Allport says, that from experience with the last cases under his care, the application of absolute alcohol affords the most certain and rapid cure. He soaks a bit of lint in alcohol and scrubs the surface of the cornea with it. This may require to be repeated two or three times.—*Am. Jour. of Ophthalmology*, July.

**Loretin.**—Drs. Nichole and Gee state that, loretin has been used in the dispensary of the Medical College of Virginia for over a year under most careful and conscientious observation and with entire satisfaction. They have arrived at the definite conclusion that it not only equals, but surpasses, iodoform in its favorable action upon the processes of granulation and healing. As it is entirely odorless, it is obviously much more pleasant than iodoform to handle.—*Med. Bulletin*, July.

**Camphor in Strychnia Poisoning.**—Dr. A. K. P. Meserve reports the case of a child, 2½ years old, who was supposed to have taken 1-60 grain of strychnia. Characteristic symptoms of the poisonous action of the drug soon appeared. In the absence of a physician ten drops of tincture of camphor was given. The effect was almost instantaneous, the spasms relaxed and when a physician arrived, nearly an hour later, the danger seemed to be over, tannin and a larger dose of camphor, gtt. xx were administered, as a precautionary measure. The next day the child had fully recovered.—*Journal of Med. and Science*, July.

**Diagnosis between Diphtheria and Tonsillitis in Children.**—True diphtherial exudation may commence at the orifices of the crypts of the tonsil, but does not long remain limited to the tonsils and muco-lymphoid glands of the pharynx, as does the exudate of tonsillitis. The diphtherial membranes will extend within twenty to twenty-four hours to the pillars, velum or pharyngeal wall. The exudate of tonsillitis is thin and not materially raised above the surface. It is white, translucent and presents a living, clean aspect and no necrotic changes, while the exudate of diphtheria protrudes from the surface, is opaque and of a dirty yellow color. The exudate of tonsillitis is punctated, the spots corresponding to the follicular openings, and two or more puncta may join each other at their borders. In simple inflammation of the pharynx and in follicular tonsillitis as compared with diphtherial inflammation, the invasion is more sudden, the temperature higher and the redness of the throat more diffuse, and not confined to one side, as is frequently the case in commencing diphtheria. In follicular tonsillitis the yellowish-white spots can often be removed from the crypts which the secretion occupies, and the inflammation frequently ceases in thirty-six hours, whereas in diphtheria it

continues for a week or two. A doubtful looking layer of mucus is often removed by having the patient gargle the throat with some mild antiseptic or salt-water. The microscope of course clears up the diagnosis if the Kleb-Loeffler bacilli be present in large numbers.—Dr. Leo B. Auerbach in *Denver Med. Times*, July.

**Observations on Surgical Shock.**—Dr. W. N. MacArtney says: "In the human subject after crushing injuries of the limbs I have occasionally seen the pulse very slow and strong, but with a peculiar characteristic which should indicate to the careful observer that shock was present. It is a pulse difficult to describe, but which points unmistakably to a tendency to cardiac spasm. There is a prolongation of the systole, which encroaches upon and interferes with the diastole; cardiac spasm diminishing cardiac relaxation. This increase in the length of the systole once recognized in the pulse is not easily forgotten. This slow pulse indicates grave shock impending, and where I have observed it, when, in spite of protests, operation was done at once on the theory that with such a pulse no shock could be present, profound and sometimes fatal shock followed. It is a warning not to be lightly disregarded. In these cases do we have vaso-motor paralysis or does vaso-motor spasm precede the paralysis? The term vaso-motor paralysis, however, is so ambiguous that some uncertainty exists as to the exact meaning. There are vaso-constrictor and vaso-dilator fibers, and the term vaso-motor paralysis might be construed to mean either or both."—*Charlotte Med. Journal*, July.

**Acute Milk Infection.**—Dr. W. H. Wells says: One of the most fatal of diseases is cholera infantum. Its causes are always the same, namely, the poisons produced by various forms of pathogenic milk bacteria. It is always found in infants fed on artificial foods containing milk. It seems particularly virulent in infants fed continuously on condensed milk, or the various dextrinized foods which are intended to be used with milk. The child having once taken milk containing the germs no amount of subsequent feeding on sterilized or Pasteurized milk will prevent the continuation of the acute poisoning. The point in the treatment which is of the first importance is to take the child absolutely from a diet of milk and all substances containing it. The second indication is to free the system as quickly as possible from the milk poison with which it is already charged. The plan generally followed is to give the child no food at all for twenty-four hours and sometimes longer. During this time cold sterilized water into which fifteen or twenty drops of good brandy or whisky have been dropped, can be given to the child every hour.—*Philadelphia Polyclinic*, July.

**Suburethral Calculi in the Female.**—The *Rev. Int. de M. et de C.*, for June 25, remarks of an article on this subject in the April *Annales des Mal. des Org. Gen.-Ur.*, that it fills a gap in medical literature, as there is no other study of the calculi formed in the urethro-vaginal wall. These sub-urethral calculi are rare, and are different from the calculi of the urethra itself. The pocket forms in the anterior wall of the vagina, below the under surface of the urethra, into which it opens, one centimeter at least, above the meatus. The walls are usually composed of the vaginal mucous membrane, a layer of muscular tissue and of urethral mucous membrane, with a fibrous intergrowth and enlarged veins. The contents are a scanty yellowish liquid, sometimes sero-purulent, urine mixed with blood, with the calculi, generally ovoid in shape, but always of urinary origin. The symptoms are obscure; distress when seated, increased by walking and relieved or abolished, by reclining, with frequent and painful mictions, each followed by an involuntary discharge of a few drops of urine. Hematuria may also exist, with trouble in coitus. Investigation reveals a hard and painful tumor in the anterior wall of the vagina, with crep-

itation if there is more than one calculus. Certainty is attained by introducing a curved, grooved sound into the urethra, with the finger in the vagina. Spontaneous recovery is rare. The urethrocele sometimes discharges its contents into the urethra and heals, but new calculi are apt to form or a fistula persist. The best treatment is an urethro-vaginal incision, with resection of the pocket and complete suture on two separate planes.

**Strangulated Hernia.**—Dr. Alexander Hugh Ferguson says, that in a case of strangulated hernia, judicious and persistent taxis, carried out for five minutes, is long enough to tell of its inefficiency without an anesthetic. This being administered, taxis may be tried for five more minutes. At the expiration of this time, all preparations for herniotomy should be complete, and if taxis had failed, no time would be lost before liberating the strangulation. The dangers of prolonged taxis are: 1, ultimate failure and increased injury to the hernial contents; 2, rupture of the bowel; 3, the reduction of so traumatized and gangrenous a bowel as to cause peritonitis; 4, reduction en masse, *i.e.*, without liberating the bowel; 5, intraparietal reduction and reduction into the canal; 6, the non-detection of a second strangulation should it be present; 7, the rupturing of the sac and the forcing of the gut through the rent between the peritoneum and abdominal wall; 8, a diseased and perforated vermiform appendix may be reduced; 9, reduction en bissac, *i.e.*, the forcing of hernial contents into a congenital pouch or diverticulum; 10, bruising of the contents and hemorrhage into the sac is common. Most of these complications are rare, but they have all been encountered.—*Chicago Med. Recorder*, July.

**Simple Treatment of Chronic Catarrhal Deafness.**—Dr. B. Alex. Randall says, in the majority of cases, decided improvement will follow rational treatment, and though this may leave the patient possessed of only a remnant of hearing, it may be many times greater than before, and a most acceptable benefit to him. For the attainment of this result, no elaborate methods or apparatus are needed. "The naso-pharynx, from which the affection proceeded, must first be gotten into better condition. Only a small proportion of cases will present deformities or hypertrophies, which compel operative intervention to free the air passages. Vigorous spraying with an alkalin fluid in the hand atomizer, will generally suffice to cleanse the pharynx vault, but must be supplemented by mopping the region of the tube-mouths, and any parts to which the mucus clings, with the bent applicator, generally charged with glycerole of tannin or of iodine. An oil spray can usually advantageously follow, that of menthol-camphor, 1 to 2 per cent., for most cases. This gives a protecting coating to surfaces denuded of their usual covering of mucus, and about to be exposed to the outer air, while it medicates the cavities with a stimulating, disinfecting vapor, which will saturate every breath of air passing into the nose for a considerable while. It lubricates the nose, too, for the easy passage of the catheter." A good catheter is a very important factor. One of 3 millimeters external, and 2 millimeters internal diameter, 13 centimeters long, made of silver to secure pliability, serves in all but exceptional cases. The auscultation tube is very necessary. Only by its aid or the examination of the drum-head later can we determine that the tympanum is actually reached by the inflations. With the catheter properly placed it is easy to substitute the atomizer with its oily spray for the air bag and spray the fluid freely up the tube. Pure fluid petrolatum is recommended for this purpose, but probably more can be accomplished by medicating it, usually with from 1 to 2 per cent. menthol-camphor. Careful massage with the pneumatic speculum of Siegle or similar apparatus should complete the procedure. Without denouncing the "new" and "radical" procedures which are constantly being thrust into notice, better results can generally be secured by avoiding these innovations.—*University Med. Mag.*, July.

**Application of Gastric Juice in Therapeutics.**—Fremont announced at a recent meeting of the Académie de Médecine, that he had been very successful in relieving and curing gastric disturbances, such as enteritis, grippe with gastro-intestinal complications, aepsia, etc., by administering gastric juice obtained by isolating the stomach of dogs, according to his method previously communicated.

**Treatment with Serum from Convalescents.**—Weisbecker has been experimenting with serum from patients recovering from measles, with which he injected others in the incubatory stage. He considers the results quite satisfactory, as the incipient disease was very much modified, and cases of measles pneumonia cured. He urges others to continue these experiments with serum which nature herself has immunized, in scarlet fever, measles, etc.—*Therap. Wochenschrift*, June 28, from *Zeitschr. f. kl. Med.*, Nos. 3, 4.

**Tannigen in Diarrhea.**—Tannigen is a diacetyltannin, and like tannalbin (see *JOURNAL*, June 27) does not release its tannin until it reaches the lower alkaline secretions. Bachus reports marked success with it in seventy cases, and no unfavorable accompaniments. In some cases the improvement was surprisingly rapid. The dose for an adult was as much as could be taken up on the point of a knife, and for children 0.25 grams, three times a day. The only failures were in a few cases with ulcerous or tuberculous complications. The diarrhea ceased in two or three days in the forty-one cases of children treated. He preceded the tannigen with three powders of calomel, at 0.008 to 0.01 gram, in severe cases (*Munch. Med. Wochenschr.* Dec. 37). Schneider calls attention to the fact that tannigen becomes viscid at the temperature of the body when moist, and therefore he recommends mixing some insoluble substance with it (like silica one-half to one-tenth part), to prevent the adhesion of the particles of the tannigen.—*Nouveaux Remèdes*, June 8.

**Cardiac Therapeutics.**—A hypertrophied heart sometimes needs aconite or bromids to restrain an excess of effort. If bromids are used, that of potassium should be avoided on account of the especially toxic action which it has on muscle. Perhaps a conspectus of the drugs which have been commonly used to add to the heart's force, will aid in making a rational choice.

Tonic and sedative—Digitalis, tonic, slows pulse, cumulative, contracts arterioles, diuretic; spartein and convallamarin, similar, but not so powerful and not cumulative; squill, practically digitalis plus a nauseating but stimulating expectorant; strophanthus, digitalis minus cumulative action and with very little action on the arterioles; caffein, digitalis plus cerebral stimulant and with especial diuretic action, not cumulative but secondary depressing action liable to occur; cactina, not well understood. General supporter—strychnin. General regulator—atropin which is stimulant to arterioles in small dose, relaxing in large dose. Emergency class—ammonia, accelerator and stimulant; alcohol and ether, slightly accelerating and stimulant, vascular dilators, later depressing; amyl nitrite, nitro-glycerin, etc., vascular dilators, scarcely stimulant to heart muscle.—Dr. A. L. Benedict in *Am. Therapist*, July.

**Formalin in Dental Practice.**—Abraham, in *Zahnärztliches Wochenblatt* is quoted in the *London Therapist*, June, as follows: By the use of this substance he has been enabled to avoid that form of secondary periostitis that so often complicates the treatment of periodontitis. It is his belief that the vapors of formalin have a regenerative influence upon the diseased periodontium and promote restitutio ad integrum. The method of formalin treatment made use of by the author more recently is less complicated, and less likely to cause pain by the formalin accidentally overflowing on the surrounding tissue. He makes use of a powder, calc. sulphas., 200; hydrarg. bichlor. 4. These to be finely mixed, also a liquid form, acid sulphuric 32; formalin, 100; aq. destil. 100. A few drops of the liquid are rubbed on a glass plate together with sufficient of the powder to form a paste, which, introduced into the previously dried root canal, solidifies in a few minutes. The crown can be filled

with any stopping desired. The small quantity of corrosive sublimate and sulphuric acid in the paste, does not have any discoloring or corrosive effect on the tooth. The above proportions have been found to be the best as a result of numerous trials, and this formalin root cement may be employed safely after cautery of the pulp, etc., and for closing the foramen piacale. In a few cases, after employing this cement a slight periostitis without pain has appeared, continuing only one or two days.

**Morbus Basedowii a Neurosis.**—Hoesslin questions the rôle generally attributed to the thyroid gland in the evolution of this disease. He considers it a neurosis, and describes several unusual features in some cases he has had under observation for years (*Munch. Med. Woch.*, No. 2). One case (6 years) was distinguished by the marked rhythm of the pulse; it grew fast in the morning and slow at night. The attacks of tachycardia were also peculiar, beginning so suddenly that the pulse would jump from 130 to 250 in a minute, and ending as abruptly, with the phenomenon of a sudden violent contraction of the heart. These attacks lasted from an hour to weeks, and were most distressing. In another case the struma fluctuated in size, growing smaller as the tachycardia developed, and increasing as the latter subsided. A typical leucoplasia also formed on the tongue, forming a "lingua geographica" with painful cracks, as the disease reached its height, and subsiding with it, which Hoesslin attributes to sympathetic action of the vagus. In one case the patient ascribes his recovery to the vegetable diet which Hoesslin enforced for three years. He states that the attacks of tachycardia were much relieved or prevented by several successive rectal injections of opium, 20 to 30 drops of the ordinary tincture in a mucilaginous medium. All other treatment proved ineffectual.—*Deutsch. Med. Woch.*, June 25.

**Brenz-catechin Located in the Suprarenal Capsules.**—It is announced from the Path. Inst. at Berlin that the presence of brezn-catechin (pyrocatechin) in the suprarenal capsules has been definitely established. It has hitherto baffled investigators, as it did not respond to the usual tests, owing to its combination with a still unknown substance, from which it has finally been successfully separated. It is secreted in the medullary substance, and it is an interesting fact that the part of the medullary substance next the cortex is the deepest in color. Brenz-catechin is turned brown by contact with the air, and alkalies, which explains this fact, and is also probably the explanation of the bronze pigmentation in Addison's disease. As it is a poison, abnormal secretions of it may not only be responsible for the pigmentation, but also for the other symptoms of this disease. It has been much disputed whether it is to be attributed to abnormal functions of the suprarenal capsules or of the celiac ganglion. The present investigators consider it settled that the former secrete the brezn-catechin, while the latter or the suprarenal plexus, neutralize its toxic effects in normal conditions. The announcement in the *Deutsch. Med. Woch.* for June 25, is soon to be followed by a more comprehensive report in *Virchow's Archiv*.

**A Case of Antipyria Eruption.**—Dr. H. W. Webber of Plymouth, reports in the *London Lancet*, an interesting case of the above nature. The patient was a woman aged 53 years, who had two months previously undergone supravaginal amputation of the cervix uteri for cancer. "On Dec. 7, 1895, I found the entire surface of her body covered with a copious eruption exactly resembling in appearance that of a severe case of measles; the face and eyelids were also swollen. The temperature was 101.4 degrees F. and the pulse 102. She had been taking ten-grain powders of antipyrin twice daily for the previous three weeks for the relief of pain extending down the right thigh. These had produced no ill effects, but it appeared on the evening of December 5, she had eaten some unwhole-

some food, the results of which no doubt interfered with the proper elimination of the drug. Three grains of calomel and a mixture of ammonium acetate were prescribed, and the next morning the skin was almost free from eruption, the swelling of the face had subsided, and the temperature had fallen to 98 degrees. The antipyrin was omitted and pills containing a quarter of a grain of morphia were substituted. Finding, however, that these did not relieve the pain so well as the antipyrin had done, after a few days the patient recommenced taking the powders. After a second dose swelling and redness of the face came on and she had again to leave them off. No symptoms of cardiac depression appeared to be produced by the drug in this case."

**Colles' Fracture.**—Dr. J. B. Morgan (*Southern Medical Record*, July, 1896) says: "A great deal has been said and written about the diagnosis of this typical fracture; but two points only are necessary to observe, in order to arrive at a correct diagnosis. The marked displacement of the whole hand toward the radial side of the wrist, and the relative position of the styloid processes of the ulna and radius. In the natural condition of the parts with the arm hanging by the side, the styloid process of the radius is on a lower level than that of the ulna; that is to say, nearer the ground. After fracture, this process is on the same or higher level than that of the ulna. The first requirement in treatment is to effect exact reposition. The best way to effect this is with the patient's hand in pronation, you grasp his forearm with one hand, in such a way that while the radius is firmly held, your thumb rests just above the line of fracture. With the other hand, you grasp the hand of the patient, so that your thumb presses firmly upon the back of the lower fragment. The hand is now carried strongly back toward the dorsal aspect of the radius in forced and extreme dorsal flexion, until you feel by palpation that the lower fragment has become unlocked, and can be pushed into place by your thumbs, while at the same time, the patient's hand, under strong extension, is carried into the normal position. The best temporary and, in most cases, the best permanent dressing is Wyeth's modification of Pilcher's. It is applied as follows: Roll two pieces of a bandage, two inches and a half wide, into a compress about as thick as the little finger. After reduction is complete and the hand brought back into straight position, place one compress along the inner aspect of the ulna, extending from the anterior margin of the carpus upward, the other parallel with this, along the outer border of the radius, over the styloid process. Secure them by strips of adhesive plaster, one inch in width, wound around the wrist and arm, from the upper to the lower end of the compresses."

**Etiology and Diagnosis of Epidemic Cerebro-spinal Meningitis.**—Heubner announces in the *Deutsche Med. Woch.* for July 2, that he has succeeded in locating in the spinal fluids of patients suffering from epidemic cerebro-spinal meningitis, the microbe discovered not long ago by Jaeger, in necropsies after this disease. He has also established its pathogenic action by successfully inoculating with it a couple of goats, after failing with rabbits, guinea pigs and dogs. The microbe is found inside the pus cells, and is in the form of a diplo- or tetracoccus, not long nor lance shaped, but broad and arranged side to side, recalling the gonococcus in this respect. It develops luxuriantly on agar, dirty yellow in color, but shining like varnish. The experiments on animals showed that it is not a virulent microbe like the pneumococcus, which corresponds to the facts observed in epidemics of the disease. A pneumococcus meningitis ends fatally in a very few days. (Netter records sixty-one deaths in sixty-eight cases.) In epidemic meningitis on the other hand, only a half or third terminate fatally, and they frequently last weeks and even months. This also explains the relatively small number of cases in an epidemic. Heubner adds that when it is once accepted that this

meningococcus intracellularis is the factor in epidemic meningitis, then Quincke's "lumbar puncture" with aspiration of the spinal fluid, will become of still greater importance, enabling us to differentiate at once sporadic cerebro-spinal meningitis from isolated cases of epidemic cerebro-spinal meningitis.

**Hemostasis of the Bones with Shoe Nails.**—The *Semaine Méd.* of July 8 states that Professor Rapin of Lausanne controlled the hemorrhage during a Kraske operation by stopping the blood vessels in the bone with a small shoe nail which he inserted in each. They were left in place until the suture was to be made; no further hemorrhage occurred after their removal. Six of these little nails sufficed to arrest completely the hemorrhage across the surface of the sacrum.

**The American Blood Test for Cattle Tuberculosis.**—Dr. Ephraim Cutter compares the morphology of human blood in health with that of tuberculous subjects and says that consumption can be detected before there is any appreciable lesion in the lungs. He states the points of similarity of kine tuberculous blood to that of man are: White corpuscles enlarged often more than in man; the mycoderma aceti or vinegar yeast is present as in man. It is on this yeast the diagnosis is made. He summarizes the advantages of the blood morphologic test over that of tuberculin, in cattle, as follows: 1. It is simple, readily learned, easily applied. 2. It introduces no diseased matter into the blood to set up efforts to expel diseased tissues (not to stop causes), which efforts of expulsion cause fever. 3. It allows the diagnosis of the pretubercular stage and the cure of the cattle; tuberculin is of no value except when there is actual disease and breaking down of the lungs. 4. It does not involve the loss of the kine. 5. It is always good so long as pre-tuberculosis or tuberculosis exists; and as in man, is of immense value in making negative diagnoses when neither tuberculosis nor pre-tuberculosis exist. 6. The amount of the yeast spores present is a sort of measure of amount of the lesion; the more the disease the more the yeast. 7. It can be applied often and harmlessly. 8. It is common sense in principle, as it treats of causes, while tuberculin treats only with results, not influencing causes. 9. It is the best means of detecting tuberculosis and pre-tuberculosis in man and kine. He says that the evidence is overwhelming that tuberculosis comes from food, in excess and long-continued, which either before or after ingestion undergoes the acetic acid fermentation.—*New England Med. Monthly*, July.

**Lithium Preparations.**—The *New York Medical Journal* gives the following abstract, which states that the *Therapeutische Wochenschrift* for April 5, mentions in a list of new remedies, two preparations of lithium. The first is the American tartaralithin or lithium bitartrate. The *Wochenschrift* remarks that it is much employed by American physicians in the treatment of Riggs' disease (pyorrhoea alveolaris) on the theory that that form of suppurative gingivitis is of a gouty nature. The calcareous collections about the roots of the teeth are said to contain, beside the ordinary calcium carbonate and phosphate, a considerable amount of uric acid, calcium urate and sodium urate. Dr. E. C. Kirk is cited as having found tartaralithin a remarkably efficacious remedy in this affection, superior to any other lithium salt. Its diuretic action is manifest in many cases, but with some persons it acts as a laxative. Five grains may be given three times a day, dissolved in a glass of carbonic-acid water. The other preparation is lithium bromid, which is described as a grayish-white granular powder, soluble in water and in alcohol. The efficacy of this compound in gout is attributed by Mendelsohn to its diuretic effect rather than to any action as a solvent of uric acid. Polakow has employed lithium bromid in acute and chronic parenchymatous nephritis and found its diuretic action accompanied by diminution of the excretions of albumin and subsidence of edema, even when the patients were not on a milk diet or subjected to any other remedial measures. Polakow uses lithium bromid in the following prescription: Lithium bromid, 1 to 2 parts, sodium bicarbonate 4 parts, distilled water 200 parts. Mix. Sig.: Three or four tablespoonfuls to be taken in the course of twenty-four hours.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

## SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance . . . . . \$5.00  
Single Copies . . . . . 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

## MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

## INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, AUGUST 8, 1896.

## THE NOMENCLATURE OF DISEASES.

The want of an authoritative and uniform standard nomenclature of diseases, for the purposes of registration, has long been felt in this country by registration officers and scarcely less by medical writers.

The confusion that long existed in the materia medica nomenclature in the middle ages was measurably corrected by SIMON of Cordo, who was physician to Pope NICHOLAS IV and chaplain to Pope BONIFACE VIII, but no similar service was rendered the profession in regard to the nomenclature of diseases until the present century.

As nearly every reform in medical methods in this country has had its origin in the AMERICAN MEDICAL ASSOCIATION, so we find that as early as 1847 a system of classification was adopted by the ASSOCIATION, and in 1851 a Committee was appointed "to consider the subject of registration of births, marriages and deaths, and to use their influence to cause the same to be adopted by their respective legislatures." The Committee had no general meeting, but the chairman, Dr. EDWARD JARVIS, of Massachusetts, reported at the meeting held at Washington in 1858 in favor of the nomenclature prepared by Dr. WILLIAM FARR, of London, which had been adopted by the Registrar-General of England, and in this country by Massachusetts.

The report of Dr. JARVIS was not adopted at this meeting, but referred to a special Committee consisting

of W. L. SUTTON of Kentucky, EDWARD JARVIS, Massachusetts, EDWARD M. SNOW, Rhode Island, WILSON JEWELL, Pennsylvania and R. W. GIBBES, of South Carolina. The report of Dr. SUTTON the following year, signed by *all* the members, recommended adherence to the nomenclature adopted by the ASSOCIATION in 1847, because many of the States had subsequently adopted it and it was still in use. They made very few alterations, but left the twelve classes according to the original and added two, viz.: 1, zymotics; 2, diseases of general ulceration, or unlocalized seat; 3, diseases of the nervous system; 4, diseases of respiratory system; 5, diseases of the circulatory system; 6, diseases of the digestive system; 7, diseases of the urinary system; 8, diseases of the generative system; 9, diseases of the locomotive system; 10, diseases of the integumentary system; 11, old age; 12, from external causes; 13, from causes not specified; 14, stillborn.

No action was taken on the report except to refer it to a committee, and the minutes are silent as to any further action, but the meeting in New York City in 1864, on motion of Dr. CYRUS RAMSAY of New York, passed a resolution of thanks to Dr. APPLETON HOWE of Massachusetts and Dr. JOHNSON GARDNER of Rhode Island for having, while serving as State senators in 1842, secured the adoption of the (FARR) nomenclature. In 1867 Dr. CHRISTOPHER C. COX presented the ASSOCIATION with advance sheets of the "Provisional" nomenclature, proposed to be adopted by the Royal College of Physicians of London.

At the meeting held in 1869 a Committee was appointed "to determine what alterations, if any, are necessary to adopt the 'Provisional' nomenclature to general use in the United States." This committee consisted of FRANCIS GURNEY SMITH, GEORGE B. WOOD, S. H. DICKSON and ALFRED STILLÉ of Philadelphia, S. E. CHAILLE of New Orleans, J. J. WOODWARD and GEORGE A. OTIS, U. S. Army, W. S. W. RUSCHENBERGER and NINIAN PINKNEY, U. S. Navy, ALONZO CLARK of New York, EDWARD JARVIS of Massachusetts, WM. M. MCPHEETERS, of St. Louis, L. P. YANDELL of Louisville, A. B. PALMER of Ann Arbor, THEOPHILUS PARVIN of Indianapolis, and R. F. MICHEL, Alabama. Surely as strong a Committee intellectually as was ever appointed by the ASSOCIATION on any subject. This committee issued 1,000 printed copies of the English and Latin portion of the proposed nomenclature to the members of the ASSOCIATION for criticism and comment, but outside of the membership of the Committee, but three replies were received by the chairman; a majority and minority report resulted. The majority favored the adoption of the following resolution:

*Resolved*, That the AMERICAN MEDICAL ASSOCIATION be requested to appoint a committee to prepare a nomenclature of diseases which, on approval by the ASSOCIATION, shall be

submitted to the medical practitioners of the United States for adoption and observance.

Dr. AUSTIN FLINT and Dr. CHAILLE favored the adoption of the London nomenclature.

The Medical Society of New York sent a paper on the subject of the nomenclature, and through Dr. ALFRED UNDERHILL moved that it be substituted for the report of the Committee, but the majority report of the Committee was adopted.

In accordance therewith, at the meeting held in Philadelphia, 1872, the Committee reported the preparation of a nomenclature. They offered a system based upon the provisional nomenclature of the Royal College of Physicians, with some additions and modifications. They gave precedence to the English over the Latin names, an example which was followed when the London nomenclature was finally published. The Committee reported that they had held nearly fifty meetings in the two years. This report also had a majority and minority report, Drs. A. B. PALMER, AUSTIN FLINT, J. J. WOODWARD and GEORGE A. OTIS asserting that they had not attended the meetings of the Committee and had had no time to examine the report. The ASSOCIATION thereupon voted the distribution of the proposed nomenclature before final adoption. At the meeting at St. Louis in 1873, the "Philadelphia" nomenclature, as it was called by Dr. WOODWARD, was reported by a majority of the Committee. Dr. WOODWARD, representing the minority, asserted that the proposed nomenclature was inferior to that of the British, and that "as it was advisable to have some nomenclature which should be recognized wherever the English language was spoken, it would be advisable, until some definite plan was adopted, for that of England to be used, there being so many objections to that of Philadelphia as to render its adoption inexpedient." He then proposed the rejection of the majority report, and the appointment of a committee of three whose duty it should be to communicate with the Royal Physicians of London, and to negotiate for representation of the AMERICAN MEDICAL ASSOCIATION in the first decennial revision of their nomenclature. This was adopted, and the Committee consisted of Drs. WOODWARD, EDWARD JARVIS of Massachusetts, and ALFRED STILLÉ of Philadelphia. It was also resolved, on motion of Dr. TONER, that the occasion of the centennial celebration at Philadelphia was opportune for the consideration of plans for the adoption of an universal nomenclature for use by the profession throughout the world.

The action of the ASSOCIATION was in effect the adoption of the London nomenclature, and in October, 1873, the late Dr. JOHN M. WOODWORTH, the Supervising Surgeon-General of the Marine-Hospital Service, issued formal regulations adopting the provisional nomenclature of the Royal College of Physicians as the official nomenclature for the use of that Ser-

vice, and in 1874 and 1878 republished the nomenclature and distributed them to the Medical Corps, and to health officers generally. The American Public Health Association also indorsed the nomenclature in 1873.

The second edition of the nomenclature began to be considered by the Royal College in October, 1880, and to the Committee, Dr. CHAS. F. FOLSOM of Boston, and Dr. JOHN S. BILLINGS, U. S. Army, gave aid and suggestions. The revision was completed and the book issued late in 1885. This revision was adopted by the U. S. Marine-Hospital Service by a circular issued Nov. 7, 1885, by Surgeon-General HAMILTON.

The third edition of this nomenclature, being its second revision, has just been issued by Her Majesty's Stationery Office in London, and we regret to notice that no American representation was had in this revision. The Italian version which was included in the former editions has been very properly omitted from this. This revision necessarily has made many changes, for pathology has been greatly changed by the discovery of the microbic cause of many diseases; and the section relating to bacteria is entirely new.

There may well be question whether more frequent revisions are not required, for no sooner has a nomenclature been promulgated, than the progress of discovery and changes in art make portions of it behind its time, and by the end of the decade, the whole nomenclature is well-nigh obsolete, although, for the essential of uniformity, it must still be used until officially changed. The general plan of former editions has been retained in this, while many new terms have been introduced.

#### THE LEAST ATTRACTIVE DUTY OF THE SURGEON.

The specialized surgeon of the present has so many things in his favor, as compared with the surgeons of fifty and a hundred years ago, that it becomes necessary at intervals to "shake him up," and remind him of his full duty, a part of which is unwelcome to the minds of some of us. It is related of the late Professor ALFRED C. POST, of New York, that his sense of rectitude led him to unduly emphasize, before his classes in surgery, the fatalities that occurred in his practice. Dr. POST was a surgeon in every sense of the word; he was actuated always and only by the highest motives, and yet his formula, "But, gentlemen, the patient died," recurred so frequently in his prelections that the average student often wondered, what, after all, is the good of surgery? Both VON NUSSBAUM and Sir JAMES PAGET have recognized the less welcome side of surgery, its contretemps, its disasters. We quote the *British Medical Journal*, May 16, in further confirmation of this thought which is never far distant from, if never fully formulated in, the genuine surgeon's consciousness: "The ideal of the surgeon, as PLATO said of

his ideal republic, is laid up in paradise for him who will behold it and regulate his life according to it. And the recognition of all the slight defects of average surgery will surely help toward a clearer sight of our ideal. In every walk of life, the recognition of our demerits is essential to improvement of our practical work. An operation that is faultless is a wonder indeed, and most operations are far from faultless; the exquisite accuracy, fine touch, resource, insight, swift decision which the public attribute to the surgeon are seldom seen in practice. But if the surgeon will keep a daily record of his slightest faults he will find a sure way of improving his skill. 'Live in your own heart,' says PERSIUS, 'and you will then find how scanty your furniture is.' And if he desires the advancement of surgery, let him not be silent, or like an ostrich hide his head in the sand of success and think that nobody sees the tail feathers of failure. It would be a good rule for every hospital surgeon to point out to those round him at least one slight defect in each operation, and seldom to publish isolated cases; for these, as a rule, are of no great value unless they are ahead of what other men have done.

"Two suggestions are pertinent to him who wishes to fill the blank left in the literature of surgery by the want of any regular record of our faults. It is not proposed to set apart a confessional of surgeons, for that has been tried before, and commonly with the result that the confessions were loaded down with an unprofitable vicarious impleading of the *faults of others*. But there is a real need of a careful and complete statement of the defects of surgical work. VON NUSSBAUM'S essay, published in 1887, is only a sketch of what might be done. He begins with the dangers of the anesthetic; next, the general risks of operation, such as hemorrhage, septic absorption and traumatic delirium; then he considers the mistakes made in various operations, some of them belonging to minor surgery, such as tenotomy, circumcision, puncture of hydrocele, removal of tonsils; others being of a graver character, such as tracheotomy, ovariectomy and the operation for strangulated hernia. He gives examples of faults in all these operations and in many others; and indeed the ways of error in tracheotomy and herniotomy, to take these two only, are many and hard to avoid; each one of them might well afford a whole chapter of accidents. But his essay is short, incomplete and somewhat old fashioned; we want a full, careful, fresh account of the defects of surgery. Happily grave errors are rare; it is the trivial faults, the slight mistakes of skill or judgment, many of them so slight as to have the least influence on the result of the operation, that require to be set forth. The risks of the anesthetic, the drawbacks of this or that antiseptic lotion or dressing, the disadvantages that may attend the boiling of instruments, these might go toward the first chapters of the essay. But the essayist would find that his chief business lay apart from these subjects, in collecting, arranging and criticising all the small technical faults of operative surgery, and thus raising the standard which we desire to reach.

"Our second suggestion is that surgeons should publish less often isolated cases, and more often groups of cases, sets of consecutive operations, every example that has come under their care. This has been done by many surgeons—Sir SPENCER WELLS, Mr. KNOWSLEY THORNTON, Mr. HERBERT ALLINGHAM,

and others; the method may be studied in such works as BARDELEBEN'S Klinik, or in some of our hospital reports. This is the way to advance knowledge and to carry conviction; and we may be sure, for example, that Sir SPENCER WELLS would have had even greater difficulty in establishing the success of ovariectomy if he had published only selected cases; it was just because he published every case that he won the field for the operation and for himself a name that will not soon be forgotten."

It is as VON NUSSBAUM says, a single reverse has more teaching in it than ten successful cases. Students are quick to remember every criticism that the surgeon makes on himself, and trust him all the more for it; and they tend to distrust him who seems always satisfied, or finds fault in everybody and everything but himself. Again, the reports in the medical press and at medical societies of isolated successes, unless they mark some definite advance of surgery, do not teach much to those who read or hear them; they make us wish that the surgeon had published other cases where the result had been less pleasing to himself; they raise unkind doubts whether his experience is not in inverse ratio to his readiness to publish it. And it is certain that in the long run we hesitate to believe in the man who always believes in himself; and he who begins by publishing nothing but his success may end by having nothing to publish.

The confession and record of an imperfect work, and the publication of consecutive rather than isolated cases, are a sure way to improve the details of operative surgery; and unless we do these things we remain exposed to the reproach that the surgeon's art owes its high place in the minds of man not wholly to his own skill and insight, but in some degree also to the fact that he practices it on a fabric more frail and more precious than anything else in the world.

#### SHOULD GOVERNMENT ENCOURAGE MEDICINE, OR QUACKERY?

It is high time that the American medical profession should ask the American people if it is the proper function of our Government to enact and execute laws furthering the science of medicine, and therefore the health of the community and the progress of civilization, or whether it is much longer to ignore these noble purposes and continue to support downright quackery? A most striking instance of this pernicious result of legislation has lately come to light in the last Report of the Postmaster General, in which he shows that the Government annually carries 133,000 tons of mail matter costing at the rate of eight cents a pound, for which there is received in postage but one cent a pound; this results in a direct annual loss of about eighteen and one-half millions of dollars. It would be impossible to say what proportion of this second-class mail matter thus carried at so heavy a loss to the Government is nostrum and

"patent medicine" advertisements, but there can be no doubt that much more than half is this execrable trash. Hence we are deprived of one-cent postage on letters, a thing that long ago should have been brought about, in order that the nostrum vendors may make fortunes. Beside their larger direct profits wrung from the ignorant and poor, we give them an indirect Governmental bonus of ten or fifteen million dollars more out of the postal revenues. What insane folly!

But this was not intended. It is an unseen consequence of the mistaken policy that we should publicly encourage the diffusion of printed matter by lowering the postage upon second-class mail matter. Now, the reading of ink-marked white paper is *per se* no aid either to intelligence or to morality, and Government should very properly leave it to private enterprise. It has, as we see, got itself into a box by the mistaken aim, and a large part of the labor of the post-office officials is now expended in trying to exclude from the mails the filthy and injurious literature which the law permits the greedy advertiser to put there. We may reasonably hope for some remedial legislation which shall undo the blunder. But physicians should aid in bringing it about. It will hardly come of itself.

A still more powerful effect of laws, and one that is no unseen or unintended happening, is Governmental protection and encouragement of quackery by our patent or copyright laws. It may be that some of the so-called "patent" nostrums are comparatively harmless when considered in their direct effects. But, by encouraging reliance upon them instead of upon intelligent diagnosis and treatment, even these do incalculable harm. But what physician does not know that the majority of these vile concoctions are directly and positively injurious? In how many ways are they not directly injuring the poor in health and pocket, and indirectly preventing medical progress and sanitary civilization? If a cure-all can repair the damages of disease, why prevent the disease by sanitary legislation and a lowered death rate? What imaginable reason except this and allied facts is there for the difference between the English and the American death rate? If we were as wise as London in these matters, the number of our dying would each year be very many thousands less than it is.

How much longer are we to continue our hideous policy of protecting the nostrum vendors by United States laws and so-called patents? Why has the United Profession of Medicine had nothing to say to the United Quacks of America about this matter? Are we afraid of the silly gibe that we are acting simply from selfishness and for our "monopoly" of medicine? Let the answer be heard that they who unpaid carry on the free treatment of all comers in the thou-

sands of hospitals and dispensaries, may not be charged with selfishness by patent medicine vendors and syndicates!

Why do not our Congresses of medical men and our American Associations act to abate the disgrace? When the "homeopaths" meet in general convocation, a big proportion of their energies and time is spent in the consideration of public laws in their interests and in agitation concerning their public estimation and position. "And for that very reason we should not do the same," do we hear? For that very reason, we answer, we should—not do the same, but do better. The public does not understand or care about our technical questions, and somewhat justly concludes that if we care nothing about our own professional well-being and estimation, and especially about national medical questions, we are therefore more interested in fads and theories than in public health. In the one exceptional instance when we have spoken out—*re* vivisection—this mistaken idea of professional feeling on the part of the public is, unfortunately, likely to be increased. The public are opposed to what they call "vivisection." The "homeopaths" are, of course, with the public and against us. It therefore is doubly unfortunate that we are extremely likely to find an increased hostility toward medicine in the minds of the people and, rest assured, especially in a democracy like ours, this hostility will make itself disastrously felt in wretched laws and bitter agitation. We already have enough of this prejudice to bear in private, professional and public life, without having any further increase of it. In what way can we offset and neutralize it better than by showing interest in the public welfare, and by attempting to influence legislation on medical matters for the public good. The ignorant and the nostrum syndicates will for awhile roar at us all the more, but the leaders of public opinion, and indeed the great body of intelligent people, will be with us. Beside all this, it is wrong to longer permit this wrong to go on. "We must educate our masters," and if we would only collectively and thoroughly take the matter up, we could soon bring such influence to bear upon our Congress at Washington as to convince even that body that our contention is just. The copyrighting a name as a trade-mark of a nostrum, keeping constituents and method of manufacture secret, instead of being justified by our law-makers, should be made a crime. At present the Government stamps the crime with its hall-mark of favor, and the poor deluded public is encouraged in its stupidity by the very authority that should be its protector. There is no work, scientific or other, to which the AMERICAN MEDICAL ASSOCIATION could devote a tithe of its energies better than to this of abolishing the laws at present the very condition of quackery. Every physician should personally write his representatives in

the House and in the Senate, and petitions signed by every practicer of scientific medicine in the country should be presented to both bodies. A committee of leading members of the ASSOCIATION should also be appointed to effectualize the reform. Even the "homeopaths" should be willing to join in such a movement.

INSANITY AND DIVORCE.

"Modern Barbarism" is the title given by a well-known and well-edited New York religious weekly to the recent action of the German Reichstag in making incurable insanity a legitimate cause for divorce, and to the commendations of this legislation by an English paper, the *London Chronicle*. The latter had said, in effect, that in making this enactment the German legislature was in accord "with the common sense of civilized mankind," and that the existing law of England which does not recognize insanity as a cause for divorce, was only "a piece of barbarian bigotry."

From an alienist's medical point of view the stand taken by the religious journal can only be commended. Insanity acquired after marriage is a misfortune only comparable with other serious diseases, and it should therefore be no more considered as a cause for complete legal separation of husband and wife than should tuberculosis, organic heart disease or any other chronic and presumably incurable disorder. If the marriage relation were nothing more than a mere partnership for the purpose of keeping up the population, sterility would be a sufficient ground for divorce and insanity perhaps a still more valid one. But there are many other considerations to be taken into account, both ethical and social, and in a purely medical point of view divorce for insanity can not be considered justifiable. The subject was fully considered and discussed in France several years ago and the conclusion reached was much more creditable to the moral sense of the nation than appears to have been the case in Germany. While most cases of long-continued insanity are probably permanent or incurable, it is almost impossible to predicate this in any particular case with absolute certainty, and unexpected recoveries are constantly occurring amongst the chronic insane. The mere fact that the puerperal condition is one of the common causes of mental derangement in women is enough to affect the question; it would be manifestly wrong to make the wife suffer for what is partly at least the husband's doing. The chances of and temptations to actual wrong-doing that such a cause for divorce would afford are not to be ignored, but this is a sociologic rather than a purely medical consideration.

It is advisable, indeed, that the insane should not propagate their infirmity, and a legal restriction of the conjugal relations might be desirable. This, however, would apply in many conditions of mental disease that are not to be included under the form

that are proposed as a cause for divorce. Insanity is, of all disorders, the most liable to recur, and a single acute attack, as a rule, implies a cerebral weakness or instability that has a bad outlook as regards the inheritance transmitted to offspring, and should from this aspect be considered as valid a pretext for divorce as a chronic, so-called, incurable type of the disease.

There are other points that can be made against the admission of chronic insanity as a legal cause for divorce, but the above are enough, from a medical point of view, to condemn it. If incurable or transmissible disease of any kind is to be so considered, there are other affections that should precede insanity; the government itself should take the initiative and no more regard should be given to one side than the other; the elements of plaintiff or defendant should not be allowed to enter into the case. Our civilization, however, is not tending toward such a state of affairs, and the action of the German parliament is not in the line of progress any more in its medical than in its moral aspect. Perhaps "modern barbarism" is about as suitable a term to apply to it as any that can be suggested.

LOCATION OF THE JOURNAL.

The following is the result of the ballot cast on the permanent location of the JOURNAL, as counted by Trustees D. W. GRAHAM and JOSEPH EASTMAN:

Chicago . . . . .	2128
Washington . . . . .	810
New York . . . . .	24
Philadelphia . . . . .	48
St. Louis . . . . .	22
Baltimore . . . . .	4
Louisville . . . . .	3
Cincinnati . . . . .	3
Boston . . . . .	2
Atlanta . . . . .	2
Cleveland . . . . .	1
Columbus, Ohio . . . . .	1
Milwaukee . . . . .	1
Salt Lake City . . . . .	1
Hamilton, Ohio . . . . .	1
Pittsburg . . . . .	1
Elmira, N. Y. . . . .	1
Sedalia, Mo. . . . .	1
Little Rock . . . . .	1
Indianapolis . . . . .	1
San Francisco . . . . .	1
Camden, N. J. . . . .	1
Charleston, S. C. . . . .	1
Buffalo . . . . .	1

Total votes cast . . . . . 3061

Five thousand two hundred and sixty-five ballots were issued to members, 2,204 of whom did not vote. Several ballots were signed but no place specified, and several were filled out but not signed; these were necessarily thrown out.

**Chinese Graduates in Medicine.**—Two Chinese girls have been graduated from the University of Michigan, Department of Medicine and Surgery. They were sent to the university by Miss Charlotte Howe of the mission school at Kinglang, and are to act as medical missionaries in China.

## CORRESPONDENCE.

The Michigan Medical Legislation League.  
Open Letter No. 2 to the Members of the Medical Profession (regular) in Michigan.

DETROIT, MICH., Aug. 3, 1896.

In response to my brief, but earnest appeal to the adherents of regular medicine and the friends of suffering humanity in this State, published in the JOURNAL of the 23d ult., two letters appear in the issue of August 1, just received.

One of these letters is signed by the President of the so-called "League," and the other by his "alter ego," J. H. Carstens. Simmered down to their ultimate elements, these communications, with apparent politeness, charge me with "illiberality" and with Phariseism, and my attitude toward the question at issue as lacking in patriotic duty. To all such personal accusations the only answer that I have time or inclination to offer is written and can be plainly read in the quarter century record of my professional life in Michigan.

Neither do I propose to condescend to recriminations or "tu quoque" charges of any kind. Surely if the "Catholics and Lutherans and Presbyterians" can afford to be ranked with or compared to the indefinite, inglorious and mercenary sects which are so eager to grasp at any recognition by or association with true scientific unselfish regular medicine; surely, I say, if the friends of these three great branches of the Christian church can rest satisfied with the use which the president of the League has seen fit to make of their time honored names, it is not for a humble sinner like myself to undertake their vindication. But will the president kindly show us where we may be able to read and learn of the occasion when any one branch of the Christian church or the church as a whole ever formed or sought to form a coalition for the attainment of any great ecclesiastic undertaking, and in so doing asked its combined enemies to accept the controlling power and assume the honors which belong to the majority? While it is quite true that both religious and secular bodies have formed from motives of policy coalitions with other bodies more or less inimical to them, has the spectacle ever before been witnessed in the history of nations, of churches, or of professions of the party overwhelmingly in the majority, and possessing the greater power, humbly proposing that it be graciously and with humility accorded a position in the coalition inferior in point of numbers (and therefore of power) to that of its combined enemies?

I am not opposed to a Legislative Medical League as such, but I am opposed to any proposition which amounts to a confession of weakness on the part of the medical profession, of which I am a humble but a loyal member.

The president of the League says, and truly, that "our efforts at convincing the people and politicians of the wisdom of adopting measures which we alone promulgate have repeatedly failed, as the history of medical legislation, not only in this State, but in every other State in the Union, attests."

Does the president wish us to understand him to say that, "Because well known errors and weaknesses of human nature have in times past operated to prevent us from getting a good law, therefore, we have no resource but to turn round and labor for a *weak, inadequate and infamous law?*" "Half a loaf better than no bread" is a good old homely adage, but if that half is saturated with cold poison, how then? "*Better fast a little longer.*" Would it not, my friends, be better, wiser, more worthy the history and traditions of our noble profession to pause and study carefully the causes on our own part of failures in the past and wake up to a true and just sense of their nature, their magnitude and the means of avoiding and counteracting them in the future? Two or three lines in the very characteristic letter of my friend, Dr. Carstens,

to my mind, gives the whole case of the Michigan Medical League dead away. They are as follows: "It will give the young man a chance by preventing competition;" also the immediately succeeding lines as follows: "It makes no difference to Dr. Maclean or myself how many or how few quacks there are in this State, but it does make a difference to the new beginner." "*The public be damned!*" The letter and the spirit of these sentences are, so far as I am myself concerned, *absolutely repudiated*. If I had the strength and the opportunity to do ten times the amount of my present work, I should still take as great an interest in this legislative question as I now do, and I should still feel grieved and humiliated that in spite of my utmost exertions thousands of my fellow citizens are still medically, morally and financially writhing in the clutches of the omnivorous quack.

As to the young doctor himself, his interests have ever been a sacred and affectionate object of my most earnest consideration, and it is in the defence of his best and highest prosperity, and his good name that I protest against any such accusations of weakness on his part, no matter from what quarter they may come. I should pity and despise the young doctor, ambitious for professional distinction and usefulness, who should be willing to accept and endorse this cringing proffer of protection. *Protection from what?* May I be permitted to quote here a single sentence from my open letter No. 1. "Can it be possible that at this late date the regular profession in Michigan feels itself so feeble and unable to maintain itself that it stands ready to defy the public professional sentiment of this and all other lands in the hope of obtaining a milk and water degree of protection (*for themselves rather than their patients*), enter into a combination and unholy alliance with its most insidious and meanest foes and place the balance of power in the hands of the enemy?"

The president of the "League" complains of the term unholy alliance, and perhaps I should have used some other term, and I will leave it to the readers of the JOURNAL who have the instincts of honorable regular physicians to say what it shall be. One of the members of the executive board of this "Legislation League," with whom Dr. Shurly and others have formed an alliance, is Dr. C. Edson Covey, 6 Madison Ave., Detroit. The following is his advertisement, which appears daily in Detroit papers:

"Specialist in private or delicate and all chronic diseases. Confidential. Call or write Dr. Covey, 6 Madison Ave., Detroit."

When we consider the full significance of this advertisement, we do not envy Dr. Shurly any glory he may get from it, even though the profession generally do not consider it unholy. Quackery and charlatanism is condemnable in every field of human endeavor and in none more so than in the matter of "Medical Legislation."

If the regular profession in Michigan and in America hopes ever to assume and enjoy the regal and just position freely accorded the profession in other lands, we must study the history and emulate the example of the profession in these countries. Let us confess our manifold sins and transgressions, too numerous and too well known to require rehearsal here. Let us go back to fundamental principles. Let us study not merely the letter, but the spirit of the code of ethics of our National Association; let us live up to its teachings and laws, using them not as a cloak for Phariseism and disloyalty, but as a true living and ennobling inspiration and guide for all the duties and relations of professional life.

This may seem utopian and the expression of a forlorn hope, a vain aspiration in the direction of the unattainable. But is it not more worthy of our vocation to persevere in our efforts and die if necessary in our upward and onward struggle than to sell our birthright for a mess of pottage and barter all our hard earned power and honor for any such fictitious aid and comfort as this alliance could possibly promise?

The last two sentences of the "President's" letter charge me with error as to the statistics of the Executive Board of this "League." If so, all I have to say is that I am unable to read and understand plain English when I see it in plain print. But let that be as it may. Neither of these, mine, accusers have assailed the statistics upon which my main plea is based, namely, that the Board of registration provided for in the main clause of the bill, is by the request of the president and all his "League" to consist of nine members, *not more than four of whom shall be regulars, the other five to be just about any thing you please to call them.*

Before closing it is impossible for me to avoid calling attention to a most marvelous misstatement on the part of Dr. Carstens as follows:

"Dr. Maclean has been at the head of the Legislative Committee of the regular State Medical Society for twenty years, and has never accomplished anything." The facts are:

1. Dr. Maclean was chairman of that Committee for *one year and no more.*

2. No such thing as a Legislative Committee of the State Medical Society has existed except during occasional years and then by special appointment.

3. Dr. Maclean might have been successful in his earnest effort to secure a just law, but for three things, namely:

1. The dignified apathy and the masterly inactivity of the regular profession. 2. The beaverlike political activity, the wire pulling and the perfect consolidation of the quacks of every denomination. 3. Dr. Maclean's unalterable determination to stand true to that which he believes loyalty to the great science and art of medicine demanded and still demands of every individual who owes allegiance thereto. The tone and tenor of the two letters herein reviewed, together with the general "facial" characteristics of the Michigan Medical Legislation League, can hardly fail to excite the dread that the signification of the term "loyalty" as understood and interpreted by the fathers and friends of the *League* is in great danger of undergoing an unfortunate and degenerated form of metamorphosis, and being changed into "a something" utterly different from that which has always been accepted and approved by the fathers and friends of the regular profession of scientific medicine in this and all other countries from the dawn of civilization down to the date of the conception of the Michigan Medical Legislation League.

Dr. Carstens closes his very striking letter in these words: "I am happy to say that it is the overwhelming sentiment of all regular practitioners, of all so-called (*sic*) 'homeopaths' and of all the quacks of this State that the further influx of charlatans and quacks should be checked."

My friends, this is a truly wonderful sentence from a man in Dr. Carstens' position, and it will repay your careful dissection and analysis. His right to speak authoritatively for all the so-called "homeopaths" and quacks of this State, I have neither the right nor the desire to question, but by the authority of written letters and countless verbal declarations, I have not only the right, but equally the pleasure of giving here an absolute denial to the only statement contained in this never to be forgotten sentence, worthy of our attention, namely, that which in so wholesale a manner presumes to commit "the profession" to this preposterous scheme of abdication and degradation and evil association.

Finally, brethren, let me assure you that nothing could be further from my inclination than strife and dissension. If the accouchement of this anomalously begotten "League" *should* by any chance be successfully accomplished, and if by any chance the resulting progeny should after all prove to be a healthy, vigorous and noble infant, and if I should live long enough to see genuine signs and marks of "good breeding" with a promise of a life of usefulness and honor, I will be found ready to take my hat off to the youngster and wish

*him, her, or it* Godspeed. Not only so, but I will be found equally ready to pay all reasonable honor and respect to its strangely assorted progenitors and apologize for any "remarks" I may unadvisedly have made about them at the time of their courtship and marriage.

But if, on the other hand, to speak seriously, the effect shall prove to be, as I fear it will, to disgust and deter *desirable* and to attract *undesirable* persons to the ranks of the profession in this State, thereby leveling the profession down and the irregulars and charlatans up, I will at least, no matter how much such a result would inevitably grieve me, have the satisfaction of having done what little lay in my power to protect and defend science and humanity from so great a misfortune, and I will do my best to rest satisfied with the verdict of approval from what to the individual is the highest of all earthly tribunals, namely, the tribunal of *my own conscience.*

DONALD MACLEAN, M.D.

### Was Goldsmith a Physician?

SYDNEY, AUSTRALIA, JUNE 29, 1896.

*To the Editor:*—In your issue of May 16, Dr. John Morris publishes an extremely interesting and scholarly article under the above heading. There is great doubt concerning the dates of the various incidents in Goldsmith's life, and as I may be able to throw some light upon the matter, I send you a few remarks on the subject of the poet's life in Trinity College, Dublin.

Dr. Morris states that Goldsmith was born at Pallas, or Pallasmore, in 1728, that he entered Trinity College in 1745, and took his degree of B.A. in 1750. John Forster, in his "Life and Times of Goldsmith," gives these dates also, but they are not in agreement with the records of Trinity College.

The Rev. Dr. Stubbs, in his "History of the University of Dublin," published in 1889, gives in an appendix, some university records of well-known members of the college during the seventeenth and eighteenth centuries, from which I extract the following passages: "It may be interesting to inquire what the college records inform us as to the undergraduate career of the eminent men who were educated in Trinity College during the first two centuries of its university work. It must be remembered that no records of terms or examinations during the first century of the college have been preserved. The Senior Lecturer's books, which contain an account of the attendance of the students at the term examinations, and of their answering, were not kept until the middle of the eighteenth century. The old Senior Lecturers, however, filled up in their own handwriting a series of books in which were entered the names and the Christian names of all who were admitted into the college as students, the names and professions of their fathers, the place of their own birth, their own age at entrance, the date of their admission, the name of the schoolmaster who had educated them, and of their college tutors. The oldest of these books which remains begins in January, 1637-8, and continues to November, 1644. The entries then ceased, and they were not resumed until January, 1652, from which day to the present there is a continued record of the admission of students." Then follows a list of the most notable students of the college: "Goldsmith, Oliver, admitted as Sizar 1744, aged 14 years; son of the Rev. Charles Goldsmith; born in Westmeath; educated by Mr. Hughes; college tutor, Mr. Wilder. B.A. 1750." He was the celebrated poet, and the author of the "Vicar of Wakefield." As this entry was made during Goldsmith's stay in the college, there is every reason to believe that the statements it contains are correct. Therefore, Goldsmith was born in 1730 (not 1728), at Westmeath (not at Pallas, which is in the County Longford), he entered Trinity College in 1744 (not 1745), and took his degree of B.A. in 1750 (not 1749). The Catalogue of Graduates, published in 1869, gives the record, "Goldsmith, Oliver, B.A., *Vern.* 1750."

Now, Forster states that the Goldsmith family moved from Pallasmore in 1730, "to a respectable house and farm on the verge of the pretty little village of Lissoy, 'in the County of Westmeath, barony of Kilkenny West,' some six miles from Pallasmore, and about midway between the towns of Ballymahon and Athlone." From this it would appear that the poet was born after the removal from Pallas.

In my opinion, the dates given by Dr. Morris and other biographers of Goldsmith are not quite accurate.

Yours very truly, GEORGE LANE MULLINS, M.A., M.D.  
Trin. Coll., Dublin.

### Medical Grievances.

NEW YORK, July 18, 1896.

*To the Editor:*—I respectfully submit the prevailing grievances of the profession, as near as I have been enabled to collect them:

1. Medical appointments in free hospitals, dispensaries, maternities and other medical charities, lodges, societies or clubs, free visiting physicians of boards of health and daily newspapers, vaccination by boards of health, drug store charities, free advice in newspapers, etc., shall be made under the supervision of our medical associations. These associations should appoint committees or engage persons to investigate the financial responsibility of all recipients of charity and collect accordingly. These sums to be applied to a general fund, which should be devoted to the assistance of needy practitioners.

2. The duration of medical appointments in institutions to be so regulated that all applicants shall have equal opportunities to serve.

3. Charitable medical institutions should not have the power to make rules prohibitive as regards the profession in general or to employ offensive officers in their buildings.

4. Directors have no right to be overbearing toward attending physicians.

5. Physicians in hospitals or dispensaries, professors, lecturers and instructors should avoid making derogatory statements concerning other physicians.

6. There is a too prevalent disregard of our code of ethics. If members were disciplined for slight offences, graver ones would be avoided.

7. Many patients, who are in moderate circumstances, but not poor, prefer the skillful attendance obtained at our modern free institutions, with their perfect appointments, to that of the young medical beginner in private practice.

8. Hospital authorities have no right to refuse a patient admission because the diagnosis was made by a physician not connected with the institution. A physician does not wish his patient's case re-diagnosed and remarked on by any but the prospective operator or chief in the institution.

9. A physician, once given an appointment for an unlimited period, should not have his office vacated without the acquiescence of our medical associations.

10. Physicians having medical appointments should not be guilty of improper practices.

11. If a patient is temporarily in financial difficulties and visits a charitable institution, it is not proper to say that he or she is "nobody's patient" for that reason.

12. Physicians should not send patients to charitable institutions unnecessarily. Many operations can just as well be done at home, with proper assistance, and had better be accepted for a smaller fee, or referred to a neighbor who will.

13. Directors of free hospitals should be prohibited from making store-to-store canvasses for the purpose of soliciting members, and incidentally to laud the virtues of their institutions and their members. Women should be prohibited from making house-to-house visits for the purpose of collecting

charity for certain hospitals, and incidentally acting as solicitors for the institutions and their associated physicians.

14. Midwives should be prohibited from acting in any capacity beyond that of nurse, unless they have a complete obstetric education.

15. A physician dare not prescribe for the purpose of producing a criminal abortion; yet a druggist may sell "remedies" to his heart's content. Thousands of abortions are occurring annually.

16. Druggists sell therapeutic preparations for all ailments. When charged with prescribing, they contend that it was only for an emergency, which is legally allowable.

17. Patients with contagious disease are indiscriminately brought in contact with healthy customers in drug-store dispensaries.

18. It should be considered a breach of ethics for a physician to prescribe or recommend patent medicines, proprietary articles or drugs which have been untried in hospital or dispensary practice, or to recommend quacks or charlatans, or their remedies.

19. Physicians should not compound their own medicines or furnish tablets. These practices have a deteriorating influence.

20. Physicians should be discouraged from furnishing certificates of competence to midwives and nurses.

21. College appointments should be made solely for efficiency.

22. Association meetings should not be controlled by certain groups of members, to the exclusion of the remainder. All members should receive equal opportunities to address the meeting.

23. Associations should not devote all their energies to some professional offence affecting a few members, while ignoring the grievances of the mass of the profession.

24. The adoption of polyspecialism is not fair toward the mass of specialists. A professor on one subject should confine himself to that specialty alone.

25. "Indirect" professional advertising has been complained of.

26. The medical press should be freely accessible to the profession on all occasions and at all times.

*Audi alteram partem.*

S. B.

### The Oppenheimer Drink-cure in Bellevue Hospital and Gen. O'Beirne's Letter.

*To the Editor:*—Herewith is given *in extenso* the rejoinder of Charity Commissioner O'Beirne, in response to charges of collusion between the board, which he represents, and the new remedy for alcoholism.

The action of the Commissioners in this matter has been much the subject of two virulent attacks by the *Medical News* of July 18 and 24; but, after all, on cooler reflection, there does not seem to be any substantial ground for the charges made against the Commissioners. The medical profession should for once and all time, cast aside prejudices, and when a regular member of the profession, after proper testing and experimenting, offers a remedy for trial in a public hospital, before announcing it in general details to the profession at large, he should be permitted the fullest liberties in this direction. This was done in Paris, with Pasteur's attenuated virus for hydrophobia; with Roux's antitoxin serum in Charité and Koch's tuberculin in the Moabit Hospital and the Berlin Institute, for months, before its composition was revealed to the professional world. From what can be gathered from reliable and impartial sources, nothing further than this is being done at Bellevue, as the following communication from Commissioner Jas. R. O'Beirne in the *New York Herald*, July 20, clearly shows:

"The statements under caption of 'No Cure for Drink,' in your issue of to-day, are not true in point of fact. As I know the *Herald* aims to present only facts, I take occasion to say,

in correction of the article in question that, so far as it assumes to speak for the Board of Commissioners of Charities and 'the action they are to take to-day,' as to a specific for the cure of drunkenness—to 'saddle the city with several thousand dollars extra expense'—it is unfounded and unwarranted. So also is the case as to ignoring the Medical Board. The same is true as to taking the views of 'a young practitioner and Superintendent Murphy.' In making a trial of methods ascertained to be of value by a respectable practicing physician of standing in his profession, the object sought by the Board is to discover, with all proper safe-guards whether suffering humanity, in cases of misfortune and vicious habits, with apparently irresistible appetite for liquor; may not be further assisted and rescued in the domain of charity through the conscientious discharge of duty by the Board of Charities of New York city. If they can save the drunkard, the morphin fiend and the poor unfortunate conspiring against his own safety and that of the community, they believe it is their duty to do it, and that the charitable public of New York will approve it and rejoice if it shall be demonstrated a success. It is worth trying, at least, and, believing this to be their duty, they have acted accordingly, but do not think 'there is no cure for drink.' So far encouragement to warrant a reasonable doubt, without any expenditure of money. It is a misrepresentation to say that 'the Commissioners paid certain patients to undergo the treatment without expressing any opinion on the merits of the 'cure' as not one cent has been paid to any one by the Commissioners in connection with it, and the investigation as to its character and effectiveness having been assigned to me by the Board, it becomes imperative that I should make this denial. It will perhaps take months before a final conclusion will be reached in this investigation, which will be thorough, fearless and honest, but the result will be duly given to the public.

[Signed]

JAS. R. O'BEIRNE,

Commissioner of Charities, New York.

General O'Beirne, whom I am sure you know personally, is a high minded and scholarly gentleman, incapable of a mean act.

Faithfully yours,

JUSTITIA.

### Test for Albumin.

TRAVERSE CITY, MICH., July 28, 1896.

To the Editor:—On page 1094 of our JOURNAL of May 30, 1896, I find a test for the detection of albumin in urine. The reagent suggested contains sodium hypochlorite, a compound known only in solution, and one that I believe can not be obtained for use as indicated in the formula. If you know of any way of preparing the reagent, will you be kind enough to tell me how it is done? Yours very truly,

GUY L. NOYES, M.D.

### Resigned his Editorship.

CHICAGO, Aug. 1, 1896.

To the Editor:—Will you kindly notify your readers that in consequence of the intrusion of nostrum advertisements by the publishers on the *Medical Standard*, the attempt to convert this journal into a write up organ for nostrums and allied performances, I have severed my connection therewith after an editorial service of nearly ten years.

Very sincerely, JAS. G. KIERNAN, M.D.

We are sorry to see that our valiant colleague has been crowded out, but we hope to have an occasional article from his trenchant pen in our JOURNAL.—ED.

## PUBLIC HEALTH.

**Illinois State Board of Health.**—Governor Altgeld has accepted the resignation of Dr. William E. Quine of Chicago as member of the Illinois State Board of Health, and appointed Dr. Edgar P. Cook of Mendota to the vacancy.

**Special Tuberculosis Committee.**—The New York State Board of Health at its meeting in Jamestown July 13 appointed two of its members, the Hon. Owen Cassidy of Montour Falls and Dr. Frederick W. Smith of Syracuse, a special tuberculosis committee

**Double Entente.**—"Mike," said the superintendent, "there is

a dead dog reported in the alley between Illinois and Meridian streets. I want you to look after its disposition." An hour later the intelligent officer telephoned: "I have inquired about the dog, and find that he had a very savage disposition."—*Indianapolis Journal*.

**Delaware County (Pa.) League of Health Boards.**—The call which has been issued for a meeting at Chester July 16, of the various boards of health of Delaware County, was liberally responded to. An organization was effected to promote sociality and the interchange of views on sanitation. Dr. Isaac Crowther of Chester was elected president, Dr. D. M. McMaster of Ridley Park vice-president, and W. H. Flaville of Chester secretary and treasurer.

**The Monongahela Valley.**—The Monongahela valley of Pennsylvania is a complete wreck from Pittsburg to the head waters of the Monongahela River. All kinds of crops have been swept away, fences and outbuildings destroyed and scores of cattle and stock drowned. Fruit trees were blown bare and thousands of acres of oats, corn, etc., destroyed. To make the matter worse the contents of vaults have been swept over the low lands and will breed disease. Half-ripened fruit and all kinds of vegetables line the river banks. It is reported that the assistance of the State Board of Health will be asked to destroy decomposing matter.

**The Navy to Assist in Florida Quarantine.**—Governor Mitchell of Florida has appealed to the Navy Department for help in protecting his State against the introduction of smallpox from Cuba, where the disease is reported to be raging. Secretary Herbert has accordingly telegraphed instructions to Captain Crowninshield of the *Maine*, now at Key West, to aid the local health authorities in the work of boarding steamers and passing upon bills of health. The *Maine* will not long be kept at this work, as orders have been given to the cruiser *Montgomery*, now at Tompkinsville, S. I., detaching her from Admiral Bunce's squadron and sending her to Key West to take the *Maine's* place in looking after filibustering expeditions and enforcing observance of quarantine regulations.

**Ophthalmia Neonatorum in South Carolina.**—In the above-named State the following enactment was adopted and became law on Feb. 25, 1896, and is applicable to all towns having a population of one thousand or more: "Be it enacted by the General Assembly of the State of South Carolina, that should one or both eyes of an infant become reddened or inflamed at any time after birth, it shall be the duty of the midwife or nurse or person having charge of said infant to report the condition of the eyes at once to the local board of health of the city or town in which the parents of the infant reside; that the Secretary of State shall cause a sufficient number of copies of this act to be printed, and supply the same to health officers and health committees, whose duty it shall be to furnish a copy to each person who is known to act as midwife or nurse in the cities or towns for which they have been appointed; any failure to comply with the provisions of this act shall be punishable by a fine not to exceed \$25 or imprisonment not to exceed one month, or both."

**Advice to inmates of Public Institutions.**—Dr. John Morris, one of the Board of Managers of the Maryland Prisoners' Aid Association, has prepared a circular of advice to the inmates of public institutions, 3,000 copies of which have been printed and one placed in every prisoner's cell in the State, including reformatories male and female. The circular urges upon all prisoners the necessity for cleanliness, moderation in diet, and, above all, the avoidance of the practice of self-pollution. For cure of the habit it recommends cleanliness of the body, simple food, hard beds, abundance of fresh air and, more important than all else, occupation of mind in some elevating study or pursuit. Directions for the prevention and cure of many minor ailments to which persons in confinement are subject,

are given. Attention to the advice contained in the circular would add much to the bodily comfort and mental tranquility of the prisoners.

**Staff of the German Hospital, Chicago.**—The following are the names of the members of the new medical staff: Surgery—Christian Fenger, William Hessert, Weller Van Hook, E. H. Lee, Truman W. Miller consulting surgeon. Medicine—Gustav Fütterer, F. W. Rohr, J. H. Hoelscher, Otto T. Freer, Gustav Hessert consulting physician. Gynecology—Fernand Henrotin, William Doepf, Albert Goldspohn, Paul R. Welcker. Ophthalmology—H. C. Welcker, F. C. Harnish, Boerne Bettmann consulting ophthalmologist. Laryngology and Rhinology—Otto T. Freer. Obstetrics—P. R. Welcker.

**Sanitary Plumbing for Toledo, Ohio.**—Steps were taken at the special meeting of the health board July 23, which will result in a revolution in Toledo plumbing, sewerage and ventilation. A new board was created, which will look after all plumbing and see that it is done in accordance with the best sanitary precautions. A new inspectorship of plumbing was made and will be filled at an early date. The last Legislature provided for the creation of a board of plumbing directors, whose duty it is to examine all plumbers engaged in business in the city. The examination is to be conducted upon the lines of qualification in sanitary work and house ventilation. An inspector of plumbing is also to be appointed under the law, whose duty is to examine all work under construction and report violations of the plumbing ordinances to the board of health. He is supreme in his position, and no work can be done, except in repairs of leaks, without his permission. A penalty of from \$5 to \$50 is provided for all violations of the regulations, and a plumber's license can be revoked at any time for good cause.

**Prevention and Cure of Seasickness.**—Legrix has made a study of seasickness for the last twenty-seven years and asserts that all will be exempt if they follow his directions as given below. First, as a preventive, take one or two  $\frac{1}{2}$  milligram pills of strychnin (arsenate, sulphate or hyposulphite) every fifteen minutes for an hour before the boat starts, five to ten pills in all, and lie down. At the slightest symptom of uneasiness take every fifteen minutes the following combination: One strychnin pill as above, with two pills of  $\frac{1}{4}$  milligram hyoscinamin extractive and one pill of 1 milligram morphin (hydrobromate or hydroiodate). Twenty doses of this triple combination can be taken if necessary without danger. To establish the cure, take at night three 1 centigram podophyllin pills, with the triple combination above three times a day, for three or four days. Keep the horizontal position as much as possible; remain on deck in the open air; avoid pastry, acid candies and liquids. Brucin can be substituted for the strychnin in the case of children from 4 to 7 years, given every half hour, with no morphin and the hyoscinamin pills only three or four times a day. Calomel should replace the podophyllin.—Address at the Tunis Congress of the French A. A. S., April.

**Differentiation of Pathogenic Bacteria in Suspected Waters.**—Besson states that the difficulties so often experienced in locating pathogenic bacteria in waters supposed to contain them, are due to the presence of other interfering bacteria, which prevent their development, as the development of the cholera bacillus is retarded by the presence of certain other bacteria in the intestines and in cultures. In analyzing water this fact is of supreme importance, as the preventing bacteria conceal the presence of the pathogenic microbes. Cultures of waters near Tunis developed constantly and exclusively a red coccus, resembling the micrococcus prodigiosus, which produced trimethylamin and was fatal to rats and guinea pigs. But persevering with another medium, Metchnikoff's gelo-pepto-salt medium, at 100 degrees, three passages resulted in pure cultures of an unmistakable bacillus pyocyaneus, which never showed at all on the plate cultures. Further investigation

disclosed the prevalence of this bacillus everywhere around Tunis, which may explain the fact that this region has always been exempt from cholera although hygienic conditions certainly invite it, as Kitasato and Metchnikoff have stated that its presence retards the development of the cholera bacillus. Besson urges the adoption of Metchnikoff's medium in the analysis of waters; it retards the growth of saprophytes until the pathogenic bacteria have had time to develop. He also commended Elsner's method of differentiating typhoid bacilli as a valuable aid in analyzing waters. (See JOURNAL, March 7, page 493.)—From address at the Tunis Congress of the French, A. A. S.

**The Health of New York State in June.**—The *Bulletin* of the State Board of Health of New York reports the following statistics for the month of June, 1896: The reported mortality for the month is 200 less than that of the preceding month, but is 600 greater than that of June, 1895. The death rate for the month was 16.85, against 17.50 in May and 19.30 in April, that of June 1895, having been 16.10. The customary decrease in the mortality is less than usual, the average daily mortality for the month being in fact greater than in May, 311 against 308, that for June the past ten years having been 285. Of the 9,342 deaths 37.0 per cent. occurred under the age of 5 years, and 18.3 per cent. were from zymotic diseases. More than half of the deaths of this class, and nearly 10 per cent. of the total mortality were from diarrheal diseases. The diarrheal mortality of June is very variable, some years the number being less than 500 and others over 1,000, because of the varying earliness of commencement of the summer increase. This month there were 900 deaths, or about 250 more than the average. In the Maritime district 12.5 per cent. of the total mortality was from this cause, and in the Lake Ontario and Western districts 9.0 per cent., but in the more rural parts of the State it constituted but from 2.0 to 4.0 per cent. of the total mortality. From all other zymotic diseases respectively there were fewer deaths than in May. From consumption there were 1,100 deaths, which is above the average for the month. Acute respiratory diseases decreased one-half from May, a saving of 600 in the number of deaths, less than 10 per cent. of the total mortality being from this cause against 15.5 per cent. in May. There is an increase in the reported mortality from diseases of the digestive system, which always varies with the diarrheal mortality. Deaths from all other local diseases are less than in May. Next to November, June is the healthiest month of the year in this State. The average mean barometer was 29.96, the relative humidity 71 per cent. and the average temperature for the entire State 69 degrees, or 2 degrees above the normal; there was an average rainfall of 3 inches, a slight deficiency. The prevailing wind was southwest.

**Health Report.**—The following health reports have been received in the office of the Supervising Surgeon-General, Marine-Hospital Service:

SMALLPOX—FOREIGN.

Barcelona, June 1 to 30, 35 deaths.  
Bombay, June 23 to 30, 13 deaths.  
Buda-Pesth, July 8 to 15, 2 cases.  
Calcutta, June 13 to 20, 1 case.  
Callao, June 28 to July 5, 10 cases.  
Genoa, July 11 to 18, 1 case.  
Havanna, July 9 to 16, 23 deaths.  
Licata, July 4 to 11, 4 deaths.  
Madras, June 19 to 26, 3 deaths.  
Odessa, July 4 to 11, 11 cases, 3 deaths.  
St. Petersburg, July 4 to 11, 14 cases, 4 deaths.  
Warsaw, June 27 to July 4, 2 deaths.  
Yokohama, June 19 to 26, 2 cases, 1 death.

CHOLERA.

Bombay, June 23 to 30, 19 deaths.  
Calcutta, June 13 to 20, 29 deaths.

YELLOW FEVER.

Acapulco, July 11 to 18, 1 case.  
Havanna, July 9 to 23, 115 cases, 46 deaths.  
Matanzas, July 15 to 22, 100 cases, 54 deaths.  
Sagua la Grande, July 11 to 18, 65 cases, 8 deaths.

NOTE.—The report of 7 deaths each in Warsaw and St. Petersburg from yellow fever, in last week's JOURNAL, should read 7 deaths each from smallpox.

## NECROLOGY.

**SURGEON CHARLES S. D. FESSENDEN**, United States Marine Hospital Service died at Salem, Mass., July 23, aged 68. He was a great-grandson of the Rev. William Fessenden, and brother of Ex-Secretary William Pitt Fessenden, of Maine. He was born in Portland, Maine, Feb. 23, 1828, was graduated from Bowdoin College in 1848, from the Brunswick medical school in 1851, and settled in Portland, where he was for three years city physician. He was appointed to the Marine Hospital Service in 1861, and served at Portland, New York, Louisville and Mobile. In November 1895, he was placed on waiting orders on account of physical disability. Although not a frequent contributor to medical literature he possessed great ability in his profession, as an able operator and a profound scholar. He was greatly beloved by his fellow officers who deeply regret his loss. He was for many years a member of this ASSOCIATION.

**FRANK WHITMAN RING, M.D.**, of New York city, died July 17, in New Haven, Conn., at the home of his brother, Dr. Henry Wilson Ring, where he had been ill for nearly three months. Dr. Ring was born in Portland, Me., August 28, 1848. He graduated from Bowdoin College in the class of 1869, and from the Medical Department in 1878. He subsequently continued his medical studies in Paris and London, returning to New York city in 1883. He has since been well known as a most proficient eye and ear specialist. At the time of his death he was the Executive Surgeon of the Manhattan Eye and Ear Hospital of New York city, a member of the American Ophthalmological and Otolological Societies, the New York Ophthalmological Society, a Fellow of the New York Academy of Medicine and a member of the New York County Medical Society. He was the author of several important professional pamphlets relative to his specialties.

**A. C. MACKENZIE, M.D.** (Long Island College Hospital, Brooklyn, N. Y., 1868), of Negaunee, at Marquette, Mich, July 13.—**N. N. Patton, M.D.** (Jefferson Medical College, Philadelphia, 1873) at Monongahela City, Pa., of Bright's disease, July 14, aged 50 years.—**Phillip G. Corkins, M.D.** (Rush Medical College, Chicago, 1853) at Harwood, Mo. July 16, aged 70 years.—**W. B. McPheters, M.D.** (Medical Department of Western Reserve University, Columbus, 1870), at Hookstown, Pa., July 20, aged 45 years.—**G. M. Roberts, M.D.** (Hospital College of Medicine, Louisville, 1880) at Union Center, July 25.—**W. W. Walters, M.D.** (Pennsylvania Medical College, Philadelphia, 1853) at Johnstown, Pa. July 23, aged 73 years.—**J. M. Benedict, M.D.** (University of the City of New York Medical Department, 1867) at Salt Lake City, Utah, July 24, aged 52 years.—**John D. Dillon, M.D.** (Jefferson Medical College, Philadelphia, 1878), at Philadelphia, July 28, aged 40 years.

**WM. ROSE, M.D.**, aged 49 years, July 26, of apoplexy, at Columbia, Ill. He was born in Germany, where he received his early education. At the age of 17 years he came to this country. After graduating from the College of Physicians and Surgeons at Keokuk, Iowa, in 1878, he located in Columbia, where he practiced up to the time of his death.

**CUB. ISAACS, M.D.**, aged 40, a well known physician and politician, died at his home at Flat Fork, near Saylorsville, Ky., of general debility. He had been blind for several years and was confined to his room; his condition not improving he became despondent and his failure was rapid.

**SIMEON H. PEARCE, M.D.**, died at Friendship, N. Y., July 16, aged 66 years. He graduated from the Medical College of Castleton, Vt., in 1854. Has been a resident of Mt. Vernon, Ind., and in active practice of his profession since 1859. He was a member of the AMERICAN MEDICAL ASSOCIATION since 1875. Member of Indiana State Med. Association, Secretary of the Posey County Board of Health, and member of the Pension Examining Board, and Posey County Med. Association from its organization. He had gone East for his health.

## SOCIETY NEWS.

**Mississippi Valley Medical Association.**—St. LOUIS, July 30, 1896. *To the Editor*:—I desire to announce that the date of the meeting of the Mississippi Valley Medical Association has been changed to September 15, 16, 17 and 18, in order to permit the members and their families to take the opportunity accorded by this change to make a pleasant tour through the Yellowstone Park, so justly celebrated as the Wonderland of America. Prominent resident members of our Association in St. Paul and Minneapolis are formulating plans for the Special Yellowstone Park Excursion Trip, to leave on the evening of September 18, arriving in Mammoth Hot Springs in the Yellowstone Park about noon on the following Sunday, and devoting the following five days to the wonders of this remarkable region, returning to St. Paul Sunday, September 27. The cost of the trip, including all expenses west of St. Paul, will be announced in due season, but we are authorized to say that the figure will be a very favorable one, and we simply wish at this time to make the preliminary announcement of this most enjoyable feature of the St. Paul meeting, so as to give members the opportunity of making their plans in advance to join the party. It is desirable that there be a party of one hundred or more, in order to obtain the benefit of the special train service in both directions. It is urged that all members who desire to join the party should send their names to Dr. C. A. Wheaton, Chairman of the Committee of Arrangements, St. Paul, at as early a date as possible. If you desire to read a paper before the meeting, please send to me the title at once. Very truly yours, HANAU W. LOEB, Secretary.

**The Upper Peninsular (Mich.) Medical Association.**—This society held its first meeting at Marquette on July 20. Physicians from all parts of the peninsula were present. The election of officers held in the afternoon resulted as follows: President, Dr. J. Vandeventer, Ishpeming; Vice-President, Dr. O'Keefe, Menominee; Treasurer, Dr. B. D. Harison, Sault Ste. Marie; Secretary, Dr. H. J. Hornbogen, Marquette; Committee on Organization, Drs. O. G. Youngquist, O'Keefe, Felch, Harison, Crowell.

## MISCELLANY.

**Yale's Oldest Medical Graduate.**—Dr. Chauncey Ayer of Stamford, Conn., is said to be the oldest living graduate of the Yale medical school. He was a member of the class of 1831, and was born in 1808.

**Insane Asylum Appointment.**—Dr. C. T. Simpson, superintendent of the lunatic asylum located in Austin, Texas, tendered his resignation July 25, to take effect August 1 or as soon as his successor could be appointed. The Doctor leaves to take charge of the insane asylum of Oklahoma.

**Kentucky School of Medicine.**—A number of changes were made in the faculty July 28. The chair of anatomy was divided between C. W. Kelly and W. Ed Grant. Louis Frank was elected to the chair of clinical and operative gynecology; Henry E. Tuley, professor of obstetrics and also obstetrician to the Kentucky School of Medicine hospital; Carl Weidner to the chair of physiology. The chair of the practice of medicine was divided by the appointment of Ewing Marshall as professor of physical diagnosis. The chair of clinical ophthalmology, laryngology and otology will be filled by Thos. C. Evans.

**An Honest Newspaper.**—In a recent issue of the *Post*, published in Fort Dodge, Iowa, the editor of that paper declares that its advertisement pages can not hereafter be used by traveling doctors and medical fakirs. He says: "The *Post*, while not holding itself responsible for its advertising columns,

does feel this to be true, that it owes to the public who read it a duty, especially relating to advertising traveling doctors and medical fakirs, for the reason that no one is so liable to be imposed upon as a person in search of health, and such a one is deserving of the utmost good faith upon the part of every professional man who is called upon for advice or treatment. This, we are convinced, they are not apt to receive from the hands of traveling doctors and medical fakirs. In the future the advertisement of no such person will appear in the *Post* while it appears under its present management."—*Am. Med. Surg. Bulletin*.

**Dr. Henry T. Byford** of Chicago has gone to Geneva, Switzerland, to attend the International Congress of Gynecology and Obstetrics.

**Pregnancy Following Salpingo-oophorectomy.**—Dr. S. C. Gordon reports the following case: "March, 1894, I removed both ovaries and tubes from Mrs. R., aged 33, and so far as I know there were no fragments of the ovaries left; each was much enlarged and flabby, that on the right side being two and one-half inches long. She recovered promptly, but menstruated regularly each month after two or three months. In June, 1895, she became pregnant. The period of gestation was marked by no peculiar symptoms, and she was delivered of a healthy child March 12, 1896. In this case there must have been some stroma of ovarian tissue left, but the question of interest is, by what means did the ovum reach the uterine cavity? The only explanation is that the tube, after being ligated, must have opened at the stump, thus allowing it to pass through. I have seen the lumen of a varicose vein resume its normal caliber after having been ligated with catgut—absorption having taken place before the coats were destroyed. I presume the same may occur in the Fallopian tube."—*Jour. of Med. and Science*, July.

**Deciduoma Malignum.**—The Vienna letter to the London *Lancet*, July 11 contains the following note on Saenger's disease: At a meeting of the Vienna Medical Society Dr. Neumann read a paper on deciduoma malignum, a disease which was first described by Saenger in 1882. As a rule it occurs after delivery, abortion or cystic mole, and it may sometimes be observed even in childbed. It is characterized by obstinate hemorrhage which renders the sufferers too weak and anemic to undergo an operation. Metastatic deposits are formed in the vagina and lungs; in the latter case there is hemoptysis which may cause death by asphyxia. The initial symptoms are hemorrhage associated with enlargement and softening of the uterus; the disease may be distinguished from cystic mole by microscopic examination of portions removed by curetting. The general form of the tumor is like that of a polypus, its tissue has a reddish-gray color and shows hemorrhages, and in growth it resembles sarcoma.

**Lumbar Puncture of the Subarachnoid Space.**—Dr. A. H. Wentworth summarizes the results of some experimental work as follows: 1. The normal cerebro-spinal fluid contains neither cells nor fibrin, and is perfectly clear. 2. In cases of meningitis the cerebro-spinal fluid is invariably cloudy when withdrawn. The degree of cloudiness is to some extent proportionate to the amount and character of the exudation in the meninges. 3. The cloudiness is caused by cells. The character of these differs with the variety of the meningitis. After withdrawal, more or less fibrin is formed in the fluid. The presence of these cells and fibrin is pathognomonic of inflammation in the meninges. 4. The cloudiness is oftentimes so slight that close observation is necessary to detect it. 5. The operation is not difficult to perform on infants and children. It is not dangerous, if strict cleanliness is observed. 6. The differential diagnosis between the various kinds of meningitis can be made by microscopic examination of the sediment, by cultures taken from the fluid and by inoculation experiments.

7. Inoculation experiments afford the surest means of determining tubercular meningitis. It is of value to distinguish between the varieties of meningitis in order to determine if tubercular meningitis is recovered from. 8. In the normal fluid, a faint trace of albumin is usually present, about one-fiftieth of 1 per cent., or less, by quantitative analysis. In meningitis the amount of albumin is increased, and has varied from one-thirtieth to one-tenth of 1 per cent. 9. In one case a diagnosis of general infection with the staphylococcus pyogenes aureus was made from cultures taken from the cerebro-spinal fluid.—*Archives of Pediatrics*, August, 1896.

**"The Vildest of Crimes Against Dr. X."**—The following is an expurgated edition of the reportorial note in one of our daily contemporaries: "Dr. X. announced last fall that he had discovered a preparation which, if used in season, would in the majority of cases prove a cure for ——. He has recently discovered that the country has been flooded with spurious preparations, not only worthless, but full of danger as compared with his own. As a result of this discovery, Dr. X. has just brought suit against two prominent individuals, placing his damages in each case at many thousands of dollars, and additional suits will be brought as soon as the necessary evidence is obtained. 'This is not a question of money with me,' said the proprietor of the preparation, which for convenience may be called Assertolin, or Dogmatocin, 'for I freely published the formula, in the hope that the use of the remedy would receive the widest extension. Personally, I object to the use of my name in connection with these spurious compounds, the manufacture and sale of which is a crime of the vilest kind. I shall rigorously prosecute every person I find engaged in this infamous traffic.'" If the language applied by Dr. X. to his imitators is correctly reported, it is vigorous and pungent, to say the least. Does he really mean that the offense of which he writes is an "infamously vile crime?" Such conduct is admittedly tricky and of the nature of sharp practice, designed mainly to reduce the financial prosperity of the person imitated. The personality of the latter is indifferent to the imitators; to them Dr. X. is an unknown quantity and the name, whether that of Dr. A. or Dr. X., is chiefly valuable to them in proportion to the amount of notoriety through the press that has been previously attained.

**Dry Sterilized Catgut.**—Mr. Chas. Truax of Chicago has made some experiments on the tensile strength of sterilized catgut. He says: "I recently submitted specimens of catgut to the following tests: Ten pieces of German catgut, No. 6, each 6 feet in length were taken and numbered consecutively from one to ten, each being labeled at three points; at each end and in the center. These pieces were then each cut into three pieces, each 2 feet in length, resulting in three of each number. One set of sutures, those cut from the center of each piece, were then tested to ascertain their tensile strength by suspending with each a five gallon can and pouring water into the can until the suture broke. The breaking tensile strength was found to vary from 26 pounds to 32 pounds and 6 ounces, as shown by the following table:

		Raw.	Boeckmann.	Schimmelbusch.
No.	1	27 pounds	27 pounds, 12 oz.	27 pounds, 14 oz.
"	2	26 " 6 oz.	24 " "	26 " 12 "
"	3	28 " 10 "	23 " "	24 " 6 "
"	4	32 " 6 "	26 " 4 "	23 " "
"	5	27 " "	27 " 1 "	23 " 12 "
"	6	31 " 10 "	26 " 4 "	23 " 6 "
"	7	28 " 4 "	20 " "	23 " 6 "
"	8	26 " "	22 " 12 "	21 " 10 "
"	9	26 " 12 "	25 " 10 "	27 " "
"	10	30 " 18 "	23 " 12 "	24 " 12 "
		284 13-16	249 10-16	248 14-16

"The second set of pieces were then sterilized by the Schimmelbusch process, which in brief consists in immersing the ligatures in ether for twenty-four hours, after which they were transferred to the following solution:

Corrosive sublimate . . . . .	10
Absolute alcohol . . . . .	300
Aqua destillata . . . . .	200

where they were allowed to remain twenty-four hours, after which this solution was changed for a second lot of the same solution, and this process repeated until the catgut had successively passed through three like solutions, after which it was placed in absolute alcohol for forty-eight hours. The ten sutures were then subjected to the same test as above mentioned and the breaking tensile strength found to vary from 21 pounds and 10 ounces to 27 pounds and 14 ounces. The remaining ten pieces were subjected to the Boeckmann-Benckisser system of dry heat sterilization, after which the breaking tensile strength was found to vary from 20 pounds to 29 pounds and 4 ounces. It will be seen by consulting the above table that the combined weight sustained by the ten raw sutures was 284 13-16 pounds, or an average of about 28 5-10 pounds each. The ten sterilized by the Schimmelbusch process was 248 14-16 pounds, or nearly an average of 24 9-10 pounds each, while that subjected to the Boeckmann-Benckisser process was 249 10-16 pounds, or nearly an average of 25 pounds each. It is evident from this single experiment that the difference resulting from the use of the Schimmelbusch and Boeckmann-Benckisser systems is practically nothing, as a little variation in a single suture might have resulted in one or the other showing a slight advantage. It requires but little argument to demonstrate the superiority of the dry heat system. As the sutures require no vessels or containers in which to preserve them they can be stored or transported in a small space. Sealed in small sterilized envelopes they may be kept indefinitely without danger of infection. As no expensive chemicals are necessary either in the process of sterilization or storage the cost of preparation is reduced to a minimum. No expensive containers are required and no danger of loss by breaking of containers and spilling of contents is incurred in transportation. We trust that surgeons generally may be induced to make similar tests and satisfy themselves, for if these statements are verified by further actual tests and laboratory experiments still continue to demonstrate that catgut prepared by the Boeckmann-Benckisser method is surgically sterile the surgeon will have to exempt the catgut from blame if infection takes place."

#### Baltimore.

DR. EDWARD N. BRUSH, Superintendent of the Sheppard Asylum of this city, has been elected professor of psychiatry in the Woman's Medical College of Baltimore.

#### Indianapolis.

DR. JOSEPH R. EASTMAN of Indianapolis, the son of Dr. Joseph Eastman, has passed the examination at Berlin University, Germany, and received "Magna Cum Laude."

#### Cincinnati.

THE HEALTH REPORT for the week shows 132 deaths from all causes; annual rate per 1000, 19.61; below the age of 5 years 47; preceding week 111; corresponding week 1895, 114; 1894, 154; 1893, 108.

DR. CHARLES A. L. REED announces that the Mexican Central Railroad has made a single fare for the round trip to the Second Pan-American Medical Congress. It is expected that the American lines will make the same rate.

THE BOARD OF MEDICAL EXAMINERS have rejected one-third of the midwives who have applied for a license to practice. They have also notified a colored man by the name of Porter, who has been practicing medicine, that he must leave the State.

DR. J. B. BARKER of Piqua, Ohio, has been appointed U. S. Pension Examiner in his district.

AN ADVERTISING SPECIALIST of Cincinnati, Dr. W. I. Kelley, has been arrested and fined \$50 by the Kentucky courts upon a warrant sworn out by Dr. J. M. Mathews of Louisville, the

President of the State Board of Health, charging him with practicing medicine without a State license. It is alleged that Dr. Kelley applied for a license which was refused him. The Hon. W. C. P. Breckenridge defended him and he has given notice of an appeal.

MRS. ANNIE FLOREIN has again appeared in the coroner's court as a result of an alleged suspicious death occurring at her establishment. In this instance she presents the evidence of a young practitioner who attended the case and who denies any grounds for suspicion regarding the infant's death. The State Board of Examiners are somewhat handicapped in any attempt at prosecution in this case for the reason that Mrs. Florein claims that she does not practice medicine and therefore can not be governed by the Board. It is a particularly unfortunate matter that she can call to her assistance regular members of the profession to attend cases in which a fatal termination is expected, and then be able to present the physician's certificate as evidence of the fact that she is not practicing medicine.

A CASE OF UNUSUAL INTEREST to the neurologist and pathologist developed last week through a postmortem held on a man who had fallen out of a window and sustained a fracture of the frontal and occipital bones. An extensive adhesion of the dura and pia mater was found at the top of the brain and a suit for heavy damages is anticipated, as it is claimed that the diseased condition of the brain was responsible for the fall and that in turn the diseased condition was the result of an injury he received on the head some six months ago while working in a freight car at which time a quantity of ice fell upon him, an engine having forcibly struck the car.

DR. E. W. WALKER is again on duty after a serious illness.

#### Philadelphia.

DEATH OF INFANT FROM ACCIDENTAL ADMINISTRATION OF STRYCHNIA.—The danger of careless handling of medicine in the household was illustrated by a case investigated recently by the coroner, in which a fatal result in a colored child of 21 months was caused by eating some tablets administered by an older child who had taken them down from the mantel-piece. It was ascertained that they contained strychnin, which had been prescribed for the child's mother. A physician was brought in immediately, but was unable to save the child's life.

THE JEWISH MATERNITY ASSOCIATION of Philadelphia has greatly extended its usefulness by opening a Jewish seaside home for invalids at Atlantic City, the institution being now in its fourth season. Accommodations are also provided for sick infants and crippled children. It is purely charitable and no expense is borne by the patients. Dr. Boardman Reed of Atlantic City is the consultant and Drs. A. D. Cascaden and L. R. Souder are the attending physicians.

POLLUTION OF WATER.—In the annual report of the State Board of Health, Dr. Benjamin Lee, secretary, forcibly directs attention to the importance of the prevention of the pollution of water used for drinking purposes, and the great necessity of legislation upon this subject. He says:

"The fact that, during the past year, thirty-nine complaints have been made to the board of the pollution of water supplies, only serves to emphasize the misfortune to the State of the persistent refusal of the Legislature to accede to the request of the board to give it a special appropriation which would have enabled it to make a thorough investigation into the condition of the public waters of the Commonwealth. A pure water supply is the one great desideratum for building up a healthy, vigorous community. All other questions are dwarfed by it. The board will probably remember that early in the present year a communication was addressed to it by the health officer of Louisville, Ky., calling attention to the fact that a bill had been presented in Congress providing for the appointment of a commission to inquire into the pollution of such public streams as passed from one State to another, and requesting our Board to use its influence with the representatives of Pennsylvania in the national Legislature

in favor of the measure. A communication was also received from the State Board of Health of Missouri, enclosing a resolution adopted by that board endorsing the proposed law. At the meeting of the National Conference of State Boards of Health at Lansing, two years ago, your secretary, at the request of the board, made a report upon the subject, calling attention to the necessity of an investigation by the national government in consequence of the general inertness of State governments in dealing with this important question. A resolution was adopted at that time to memorialize Congress upon the subject, and the present movement was undoubtedly due to the action then taken. On receipt of the communication the board adopted a resolution approving the bill, and a copy of the same was forwarded to each of our representatives in the national Legislature, requesting him to give the measure his support. Inasmuch as many important streams pass both into and out of our territory from and to that of other States, such an investigation pursued by the thoroughness which characterizes work undertaken under national auspices could not but prove of the greatest benefit to us."

**A SENSATIONAL ROBBERY IN A HOSPITAL.**—A patient who occupied a private room in the St. Joseph's Hospital had his trunk forced open by an attendant, who carried off jewelry and bonds amounting to \$20,000 or more. The thief was soon afterward arrested in New York City, and with a female accomplice is now in custody. In such a case it might be asked whether there was not contributory negligence in carrying into a public institution such a large amount of valuables with such slight protection as is afforded by a trunk.

**ACCIDENT TO AN AMBULANCE.**—A trolley car last week struck an ambulance that was taking a boy to the Jefferson College Hospital to be operated upon there for appendicitis. The rear wheel was broken and the axle bent, and the boy's father was thrown violently upon the patient, greatly increasing the gravity of the condition. The operation was done soon afterward in the hospital and the lad, who was 12 years of age, died a few hours later. The coroner decided that the death had been accelerated by the accident, but had not been caused by it.

**DEATH FROM ACUTE INDIGESTION.**—On one of the warm days recently a man applied for treatment at the Episcopal Hospital, stating that he had eaten a great deal of cheese and thought that might be the cause of his illness. He grew rapidly worse and died a few hours later. He was a German, 49 years of age, and it was held that he died of heat stroke and acute indigestion or gastritis, from eating cheese.

**THE SAMARITAN HOSPITAL** on North Broad Street, which is under the fostering care of Grace Baptist Temple, is increasing its capacity by the erection of an additional wing to be devoted to isolation purposes.

**THE NEW CLINICAL AMPHITHEATER** of the Medico-Chirurgical Hospital is now under roof and presents a handsome appearance.

**THE MEDICO-CHIRURGICAL COLLEGE TRUSTEES**, it is announced, have in contemplation the creation of a faculty for a dental department as soon as the present arrangement with the Philadelphia Dental College is dissolved, which will be at the end of the next term. For a number of years the association of the two institutions in the same buildings was mutually advantageous, but the phenomenally rapid growth of the medical school has now placed it in position to occupy the buildings for its own purposes.

**A CASE OF DOUBLE PERSONALITY.**—At the Philadelphia Hospital a curious case of loss of memory has excited much interest, among the neurologists especially. The patient, a young man, after four months' stay in the hospital has been recognized by Dr. E. F. Robinson of the resident hospital staff as a former college companion named Spencer. The patient, however, did not recognize Dr. Robinson nor acknowledge the name. In fact, he did not remember his name at all and could not give any when admitted into the hospital, nor could he remember anything about his previous life or explain how he came to be in Philadelphia with nothing in his possession save some pawn tickets made out in the name of George Brandt, under which name he was received into the hospital.

Dr. Daniel E. Hughes, the superintendent, took great interest in the case and recently brought him before the Neurological Society. Dr. Lloyd was of the opinion that the young man might have been hypnotized. Dr. Hughes considers that it is a case of loss of personal identity, or of double personality of the Archibald Malmaison type. Mr. Spencer's home is in Lawrence, Kan., where his father resides. He was last heard of January 27 in Washington, but he can give no account of his wanderings before coming to Philadelphia. From his conversation, however, and replies to questions, Dr. Hughes believes that he has recently been in London and perhaps on the continent.

**COLLEGE NEWS.**—The State Board of Medical Examiners and Licensers of Pennsylvania met at Harrisburg last month, as directed by the statute creating this board, and the results have just been published. The examination comprised questions in anatomy, physiology, pathology, diagnosis, hygiene, surgery, obstetrics, chemistry, materia medica, therapeutics and practice of medicine, and requires four days to complete it. Out of a total of 381 candidates 340, or 89.24 per cent., were successful in obtaining the license to practice medicine in this State. The University of Pennsylvania sent up 48 candidates, all of whom passed the examination, and the 9 candidates sent by the Woman's College of Philadelphia were equally successful. Three out of 42 from the Medico-Chirurgical College were unable to pass, and 8 out of the 131 from the Jefferson were unsuccessful. It is proper to state that one of those rejected from the former college had failed to pass the board last year and had not attended lectures in the interval. The West Pennsylvania Medical College of Pittsburg was represented by 81 candidates, of whom 62 passed. There were 16 from the College of Physicians and Surgeons of Baltimore, of whom only one failed to obtain the license. Among the names of the successful candidates is that of Horation C. Wood, Jr.

## THE PUBLIC SERVICES.

**Army Changes.** Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from July 25 to July 31, 1896.

Major Henry McElderry, Surgeon (Ft. Robinson, Neb.), is granted leave of absence for one month, to take effect on or about Aug. 3, 1896.  
First Lieut. Isaac P. Ware, Asst. Surgeon (Madison Bks., N. Y.), is granted leave of absence for three months, on surgeon's certificate of disability.  
Capt. George E. Bushnell, Asst. Surgeon, is relieved from duty at Ft. Hamilton, N. Y., to take effect upon the expiration of his present leave of absence, and ordered to Ft. Assiniboine, Mont., for duty at that station, relieving Capt. Peter R. Egan, Asst. Surgeon. Capt. Egan, upon being thus relieved, is ordered to Ft. Hamilton, N. Y., for duty.

### Change of Address.

Dvorak, W. J., from 1620 to 1541 W. 22d St., Chicago.  
Judson, A. B., from 25 to 1 Madison Av., New York, N. Y.  
Kaunheimer, G., from 910 to 508 3d st., Milwaukee, Wis.  
Lawrence, G. H., from Chicago to 6 and 7 Kiltredge Bldg., Denver, Colo.  
Morrall, G. W., from Barnwell to Millettville, S. C.  
Martens, E. J., from St. Louis to Forsyth Junction, Mo.  
McMahan, C. Agnes, from Chicago Beach Hotel to 2970 Indiana Av., Chicago.  
McDaniel, E. B., from Cove to Rooms 306 and 307 Dekum Bldg., Portland, Ore.  
Oglesby, C. R., from Pensacola, Fla., to Kirkwood, Mo.  
Potts, J. S., from Los Angeles to San Jose, Cal.  
Percy, J. F., Galesburg, Ill., to Mantorville, Minn.  
Synon, G. C., from Cedar Rapids, Iowa, to 1557 W. Harrison St., Chicago, Ill.

## ORIGINAL ARTICLES.

### HEREDITY AS A SOCIAL BURDEN.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY A. W. WILMARTH, M.D.

FIRST ASSISTANT PHYSICIAN NORRISTOWN HOSPITAL FOR THE INSANE;  
LATE ASSISTANT SUPERINTENDENT PENNSYLVANIA INSTITUTE  
FOR FEEBLE MINDED CHILDREN,  
NORRISTOWN, PA.

It may appear a waste of time to place before you proofs of the existence of heredity as a large factor in the production of those nervous diseases on which I wish to speak briefly to-day. My reason for doing so is two-fold. The existence of heredity as such a factor has been occasionally denied by men of such position that their opinion must carry weight, even though they are opposed by the majority of the thinking men who have given this matter their attention. The existence of heredity appears thoroughly established by statistics which have been most carefully compiled and verified. Moreover, the great number of these defectives, and the vast, ever-increasing expense of their maintenance, as well as their harmful influence on society at large, can only be realized in this way.

The three forms of disease which are most liable to make their victims dependent on society by rendering self-support impossible, or their society dangerous, are epilepsy, insanity and imbecility. In dealing with heredity in connection with these three forms of nervous disturbance, it is not reasonable to expect each condition to exactly reproduce its kind. The law of heredity is that each characteristic in the parents *tends* to reproduce itself in the offspring. Characteristics derived from one parent may be overcome by the influence of the other, and may even reappear a generation farther on, or be permanently obliterated. The three above named conditions are all simply evidence of degenerative changes of the nervous centers, dependent for their form on the portion of the brain attacked, and the age at which they develop. Brain trouble occurring early in life occasions imbecility; later, insanity; while epilepsy may complicate either condition or, rarely, occur independently. Almost any lesion or trophic change in the brain may occasion one or more of these manifestations of disturbed nervous action.

Let us look first at epilepsy as an inherited neurosis. The statistics being more accurate than in the other two diseases, for the reason that its symptoms are unmistakable, and thus friends can neither deceive themselves or others in regard to its existence. Even in uncomplicated epilepsy, if the spasms are at all frequent, the sufferer's power of self support is lessened, if not entirely destroyed, and he becomes a burden on friends or the general public. Echeverria, after ten years' careful research in tracing the off-

spring of epileptics, has published the most valuable statistics on this subject that I have yet found. Excluding all cases which could not be fully verified, he found that 62 male and 74 female epileptics begot 553 children whose life histories were as follows: 22 were still born; 195 died in infancy from spasms; 78 lived as epileptics; 18 lived as idiots; 39 lived as paralytics; 45 lived as hysterical; 6 had chorea; 11 were insane; 7 had strabismus; 27 died young from other causes than nervous disease; 105 were healthy. Excluding the last three divisions we have 414 out of 553 who either died in utero or were affected with nervous disease. Could a more convincing story be told? He concludes that the marriage of epileptic women to non-epileptic men is more liable to result in neurotic offspring than when the conditions are reversed. He quotes one case when two epileptics married and out of five offspring two died of infantile convulsions, one from hydrocephalus, one lived an epileptic, and one was said to be bright. Of his 136 original cases 87 had parents with either insanity or epilepsy, while in forty-six cases epilepsy had existed through three generations. One woman had epilepsy from puberty to her marriage, which demonstrates that marriage may benefit epileptics, but of four children born afterward, two were epileptic and one paralytic. Dr. Knight of Lakeville, Conn., in an address before the American Conferences of Charities and Correction, quotes a case where an epileptic mother bore fifteen children. Eight died in infancy, two were fairly teachable imbeciles, two were epileptics and three had sufficient intelligence to secure husbands and thus risk the multiplication of their kind. Dr. Landon C. Gray tells of an epileptic woman who bore nine children, seven of which died of infantile convulsions.

I studied the records of 500 epileptics at the Elwyn (Pennsylvania) school for the feeble minded during my residence there as a medical officer. Of these 149 were very incomplete. In the remaining 351 I found neurotic disease in 108 families on the father's side; in 106 on the mother's side; in 22 instances on both sides, or 236 families in all. In 19 other families some neurosis existed in brothers or sisters, but was not acknowledged farther back. From my personal knowledge of some of the families, I am sure that strict truth and the power to see "themselves as others see them" would swell these figures considerably. Insanity, imbecility and epilepsy with 56, 58 and 71 cases respectively, figure most prominently in this array of epileptic inheritance, chorea, paralysis, etc., forming the remainder.

The heredity of insanity is not so evident, nor is it so certainly transmitted to offspring, especially in neurosis of the same form, as is epilepsy. The reason for this may be looked for in the fact that many cases of insanity are the direct result of excesses, or other causes occurring in adult life. The transmitted effect manifests itself more frequently in childhood

or infancy, and epilepsy or imbecility results. Or possibly we may find that incurable perversion of the moral nature, aptly termed "moral imbecility," which furnishes so much contention as to whether it should be regarded and punished as depravity or treated as a congenital absence of the faculty of moral control. A smaller number reach mature years before coming into their inheritance of misfortune and are classed as insane, and occasionally reproduce the parent malady with singular exactness. Savage, the eminent English authority, states the matter very concisely as follows: "Heredity produces some insanity, but is more likely to produce either mental defect or special and unusual forms of muscular, sensory mental or moral disorder." Nearly every systematic observer admits heredity as an etiologic factor in insanity, and while the most conservative statistics place the average from 20 to 25 per cent. of the cases observed, others place it higher and Kestevan says: "The most influential of causative conditions is heredity, and it is the most commonly suppressed by the friends." The truth of the last statement at least is indisputable. I wish to particularly emphasize the influence of heredity in imbecility and idiocy for the following reasons. They are the legitimate offspring of nearly every form of neurotic taint. Their extent and baneful influences are not realized by any one who has not given the subject very careful study. The census reports for 1890 and the natural increase would bring their number to between 90,000 and 100,000. This is far below the real number. So slow are parents to publish their children to strangers as feeble minded, that the late Dr. Kerlin of Elwyn, Pa., investigated the matter. Out of 295 applications for admission to his school in 1880, 178, or 60 per cent., could not be found on the census enumerators list. How far this may apply throughout the country we can only surmise, but mothers are much the same everywhere, and are not willing to publish their children's defects.

There are two conditions in parents which figure largely in the production of feeble mindedness in children, tendency to neurotic disease and inebriety. These conditions are associated with the greatest frequency. Dr. Beach of England states that drunkenness is found in the ancestry of 38 to 40 per cent. of the parents of idiots (using the term idiot in its broadest sense). The Fourth Conference for the Care of Idiots in Germany agreed that inebriety was the principal cause of idiocy. In this country the Association of Medical Officers engaged in the care of the feeble minded agreed unanimously that a large per cent. of imbecility is due to the transmitted effects of alcohol and counseled, as did the German conference, more stringent legal restriction of its sale. It is well to bear in mind, in regard to these conclusions, that we can not draw too close a line between the habitual inebriate and the neurotic, for one class merges into the other and makes the distinction between cause and effect a difficult study. A cloud of witnesses testify to the transmission of neurotic taint in one or more of its many forms, to produce the multitude of imbecile and idiot children whose large aggregate number and marked increase is shown by every census. The largest and most complete studies on this subject have been made by Dr. Barr in this country and Drs. Beach and Shuttleworth in England. The work of these gentlemen is too well known to make any doubt of the great care exercised in the preparation of their tables, or the accuracy of their results, possible.

	Barr.	Beach.	Shuttleworth.
Total cases . . . . .	1,044	1,080	1,200
	Per cent.	Per cent.	Per cent.
Insanity and imbecility.	38.02	22.71	20.08
Other neuroses . . . . .	21.55	36.85	Incomplete.
Total . . . . .	59.57	59.56	

If we accept the aggregate totals of Barr and Beach which are nearly alike we have nearly 60 per cent. of the families with more than one victim of nervous disease. These figures fairly illustrate the results of other observers. We can not go much into detailed cases, but I would like to quote Dr. Ireland in illustrating the persistence of this tendency to produce offspring of low grade in some cases. He cites an instance where four illegitimate feeble minded children were born to one defective woman from four different fathers. In another instance, under my own care, was a little idiot boy with the well-formed but lax and useless muscles in certain regions, which usually accompany the cerebral condition known as microgyria. His mother, a robust, high grade imbecile with no apparent physical defect, came to see him. She had married again and bore in her arms another idiot child very similar to his half-brother. A local physician assured me that they were certainly the children of different men, the second husband not having come to that region until after the birth of the first child.

Such is the evidence that tendency to nervous degeneration or instability descends from generation to generation, broken or interrupted perhaps by infusion of stronger elements, reappearing a generation farther on. What is their number and to what extent do they affect the welfare and progress of the public? Of epileptics, Dr. Knight, who has given their care much study, estimated that in 1892 there were, in this country, 19,000. They almost invariably drift into imbecility, dementia or other form of insanity, and are cared for, if cared for at all, under these heads. Some children recover, but adults very rarely. They are ever liable to injury, which prevents their following many forms of employment. They are free to marry if they can find a mate, and there are very few who set out earnestly on that quest and are not very particular, who do not succeed; and they leave as a legacy to the public more epileptics. When subject to attacks of epileptic mania no class of the insane are more dangerously violent.

The number of the insane in the country will hardly number less than one hundred thousand. Probably there are more. It would be difficult to ascertain the total cost of their support. We will look at the approximate cost in the two largest States which in 1890 contained about one sixth of the population of the country, which will furnish some guidance to the possible expense in the whole country. In Pennsylvania, in 1894, there were 8,616 insane in institutions of all kinds, of which number 6,342 were in the six State hospitals and the private hospitals at West Philadelphia and Frankford. These 6,342 insane represented an expenditure of nearly one and one-half million dollars. The care of less than one-eighth of the State's feeble minded added \$150,000 to this large total. New York spent in 1893 for the care of her insane in public hospitals and for a small proportion of her imbeciles, over two and a half millions of dollars. Carry out this ratio throughout the country and the amount would be startling. The bulk of the insane are in asylums, for public safety

demands this. Where are the feeble minded, who are found in European countries to outnumber the insane, and probably would here if properly enumerated? Not one-tenth are cared for in institutions. The remainder are in almshouses where their proper care is, in many cases, doubtful. Many are in homes where they monopolize their mothers' time and care, and elsewhere, where they are teased by children, abused by the vicious and live a strange life among their own people, with whom they have little in common. From the highest grades of imbeciles are recruited the ranks of petty criminals, prostitutes and tramps, who marry early and often, and who reproduce with the frequency of animals. Officers in reformatory institutions are becoming impressed with the idea that the majority of the younger criminals are permanently lacking in the higher mental traits, without which the development of moral character is difficult if not impossible. The growth of the burden on the industrious of supporting the helpless and the worthless may be better realized when we find that the New York State Board of Charities and Correction expended nearly eight and one-half millions of dollars in 1880 and nearly sixteen and one-half millions in 1890, although the population in that decade increased less than 20 per cent. Do you realize that the taxpayer may support, during a life of ordinary duration, members of three generations of these defectives? The remarkable increase in numbers in a family line of defectives and incapables may be best illustrated by quoting two instances. One, founded on the report of Miss Schuyler, President of the New York Charity Aid Society, of "Margaret the Mother of Criminals," and progenitor of a family of paupers, beggars, prostitutes and criminals, which finally became a race of 700. Their family vigor was largely preserved by intermarriage with fresh, vigorous families of ruffians, and some of the women bore at least twenty children, among which were numbered insane, epileptic and imbecile. I would quote briefly from Dr. Barr's exhaustive article on the influence of heredity on idiocy, the record of the family known as the "Tribe of Ishmael," where the descendants of one unclean, neurotic man traced through many years, "multiplied by consanguineous marriages into 250 families, numbering some 5,000 individuals, whose continuous criminal record has poured over the Northwest a flood of imbecility and crime." Nor do these instances stand alone. It is the salvation of society that at a certain stage of nervous retrogression nature appears to check further increase by making the most defective sterile and short lived.

The cost of human life through the insane each year is very large. Professor White, late of Cornell, places the number of homicides in the country last year at over 10,000. How many of these are due to insanity I will not pretend to say, but almost daily we read of suicides preceded too often by the death by violence of one, two, or even five or six people under circumstances which appear hardly consistent with normal mental balance. So frequent have such affairs become that only when some one of more than ordinary standing becomes the victim do they excite more than temporary local interest or arouse us to the danger which may be very near us.

The remedy for this state of affairs is a subject which demands earnest thought and radical measures for relief. The evil is so wide spread, so thoroughly grafted in the every day life of society that to think of its immediate or entire suppression would be folly.

It is time to attack the evil in some quarter. We can not expect relief from purely medical means. No more hopeless disease exists among the more common maladies than epilepsy in the adult. The relatively small number of "recoveries" in hospitals for the insane would be diminished if we subtracted the number who are committed to recover from alcohol, and other such cases who go out only to find their way back to some hospital later. Officers of institutions for imbeciles no longer look for restorations to normal brain power in large numbers, and even in such cases as leave the institutions there is a fear that their places may shortly be claimed by their children. He knows that the chief value of his work lies in the knowledge that the high grade imbecile is safer and the low grade and idiot more comfortable than he could be made at home. That he has relieved other children of association which would work harm and no good. He has relieved the family of an expense which deprived the other members of their due and the mother of a burden often too great for her. More than this, by enabling one person to care for perhaps five of these children, five families have been able to turn their entire efforts to ordinary social duties unhampered by such a burden as an imbecile child. Moreover, defective imbecile children should become the wards of the State until the danger of child-bearing is past. It is not so important with males. I need not explain why girls with strong animal passions and low mental or moral powers need such care.

It seems strange that our marriage laws should be so lax. The marriage of the unfit goes on unhindered. The epileptic may marry his kind and reproduce more of his kind. The drunkard, from a body thoroughly diseased, may cause any number of defective children to become public wards to be supported by the more self-respecting and industrious. There is no legal preventive against the man whose father and grandfather have been insane, and who has been, at some time, insane himself, from marrying a woman similarly afflicted and charging the bill to the public. The lunacy law of Pennsylvania expressly provides that a patient while still insane may go home for stated periods to resume all his family relations. It is time for a radical change in this condition of things. The excellent example of New York should be followed in other States and more accommodation provided for mentally and morally incapable women and girls. More stringent marriage laws should be enacted and enforced. The need of some such law was most strongly impressed upon my mind during my frequent observations of the mothers of feeble-minded children, so many of whom, though not feeble minded were surely close to the line. So many had a different name from their child's, from remarriage. Possibly, the fathers were the same, but this was not so evident. In one winter, out of five children who died consecutively, four of the mothers had contracted a second marriage. One woman who was said to be the mother of six microcephalic imbeciles, and had two of them in our care, once visited us and announced her intention of contracting another marriage. It is a well-established fact that a mother who has had a microcephalic child is liable to have any successive children similarly marked.

So long as this evil continues it is difficult to see how we can stop the constant increase of this class. Such marriages should be legally prohibited. While

women, in every way fitted to fill the post of wife and mother, hesitate before the responsibilities such a position entails, these women should not be allowed to assume such duties as they can never properly fill, at so great a public cost, for the mere gratification of animal instinct or a prospect of support. Such a law would not be unjust. The right of society to control all powers which militate against the general good ought not to be denied, and such a law judiciously applied would work no material hardship and interfere with no one's just rights. The marriage of an epileptic is a crime. It is almost absolutely sure to result in the birth of human beings foreordained to a lifetime of suffering.

On whom does the responsibility of righting these wrongs fall more heavily than upon ourselves. No one understands so well as we how surely the fruit follows the seed in these matters, and no one's word would have the same weight in molding public opinion to force proper legislation to this end. The marriage of the unfit should subject the perpetrator to punishment as surely as would any other offense against the public peace and morals. The whole body of the intelligent public would agree with us in this matter. The clergy would endorse such a move, perhaps excepting a few who are entirely unworthy of the vocation they have assumed, who disregard the divine warning that the consequence of the father's sins shall surely descend to the children and cheerfully assist, for a marriage fee, in perpetuating the evil.

These two measures, of providing safe and comfortable homes for the weak and preventing in some measure marriage among those who can only perpetuate and increase human suffering, poverty and crime, fall far short of fully solving the question, but they have the advantage of being practicable, and furnish, so far as I can see, the only radical method of presently reducing this class to its minimum number, for it truly attacks the evil at the root. We can not abolish human weakness and sin, but we can deprive it of the seal of the State and the Christian church.

### HYGIENE VERSUS DRUGS.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY C. F. ULRICH, A.M., M.D.

WHEELING, W. VA.

The American people have been called a medicine-taking nation. If the quantity of drugs prescribed by physicians, the masses of patent medicines, the barrels of so called home remedies, such as teas, decoctions, infusions and other monstrosities, swallowed by the American people, were ascertained, collated, arranged and published in a book, it would strike the reader dumb with astonishment. The fact that any human body can survive the injection of such an endless variety of vegetable, animal and mineral poisons as are poured into the patient and unresisting stomach and thence distributed throughout the various channels, acting upon the digestive organs, the circulation and the nervous system, proves that man is indeed "fearfully and wonderfully made," and has much greater powers of resistance than we would believe possible.

Let us suppose that an individual has what is commonly called a cold, which may be catarrh of the pharynx, the tonsils, the larynx, the trachea, the

bronchi; it may even be an incipient pneumonia. This person tells his or her suffering to a neighbor, the neighbor replies: "Oh, I had that, and I took such and such medicine." Immediately the article is procured and taken. Another one comes in, hears the tale of woe, and recommends something else, this also is duly swallowed. By the time the gauntlet of the whole neighborhood has been run, and the entire catalogue of the domestic and the proprietary pharmacopeia has been exhausted, the patient has either recovered by virtue of his good constitution in spite of the horrible dosing, or the disease has progressed to a dangerous stage. In the former case, the wisdom of the neighborhood gossips or the excellence of this or that patent medicine is lauded to the skies; in the latter case the doctor is called in and is told they have given the patient everything that everybody recommended and having failed, they now call him in to try his skill. Thrice happy is the poor doctor if these busybodies have left enough constitution and vitality in their unfortunate victim to give him even a faint prospect of working a cure. If, however, owing to the exhaustion of the vital powers, or the general subversion of all the functions of the body by the heavy, indiscriminate and absurd dosing to which the poor sufferer has been subjected, the doctor fails to cure him, all the vials of wrath will be poured upon his devoted head by the would be doctresses in the neighborhood. If he thinks the patient requires rest from drugs and gives nothing, he is promptly discharged and another one called in, who will come up to their standard of excellence by ordering some kind of medicine to be taken every hour, or oftener. I have frequently been told when presenting a bill that certain visits should not be charged for, because I did not make the patient take medicine on those days. My answer would be that it required as much medical knowledge to determine when medicine is unnecessary as to know what remedies are required. It has often been suggested to me by my patients, or their families, that it is not necessary to come every day, but to return about the time the medicine is exhausted, in order to prescribe more. It does not occur to these individuals that the physician's duty is to watch the course of the disease, note its changes, assist nature in her efforts to bring about recovery, prescribe suitable remedies against unfavorable tendencies; in short to act as a kind providence to watch over the patient and promote recovery. They imagining the physician's business is to pour all sorts of drugs down the poor patient's throat and keep him constantly saturated with medicine. While engaged on the preparation of this paper, I visited one of my patients in the afternoon, whose medicine was exhausted in the morning. I found the family in terrible trepidation because he had not been dosed for six hours. The fever having abated, the temperature normal, the pulse regular, the patient free from pain, he was all the better for getting a little rest from drugs; but the family had suffered agony on account of my coming so late, and were on the point of sending a messenger to my house to inquire what was to be done. It is often necessary to prescribe a placebo in order to retain the patient. The physician who studies nature carefully, who makes himself thoroughly acquainted with the physiologic and pathologic processes of the human organism, acquainting himself with all the changes that take place in the interior of the body, both in health and disease;

giving the proper remedy at the right time and refraining from the administration of drugs when nature is doing the work for him, will be successful where success is possible; although he may sometimes confront the prejudices or the dense ignorance of his clients, and thus lose caste with some of them; but in time, it will be better, not only for the patient, but for the physician himself.

I can call to mind very many families who had abandoned me for some new and more complaisant physician, who would prescribe large quantities of drugs, resort to a variety of mechanical methods, that he represented as new, convincing the family thereby that he possessed more knowledge and skill, who finally became disgusted with the meddlesome activity of the new man and returned to me, saying: "I like the old doctor best after all." Having said as much as is necessary about the pernicious abuse of drugs, let us see what we can offer as a substitute. Hygeia, in the ancient mythology, was the goddess of health. We call this divinity *Vis Medicatrix Naturæ*, the healing power of nature. To the diligent student of nature and of physiologic processes in the human body, this divinity, Hygeia, assumes a greater importance than is generally attributed to her by the young and inexperienced practitioner. In a paper read at San Francisco in 1894, entitled "Cleanliness the Chief Antiseptic," I endeavored to show that the earnest and continued effort to prevent the development of bacilli and their entrance into the human organism, is of much more value in promoting health than the effort to destroy them after they have been introduced, or to relieve the system of the disease caused by their presence. This is the first consideration in the study of hygiene, which was fully discussed in that paper. But, as every physiologist knows (and every physician should be a thorough physiologist), there is a very complete apparatus in the human system to carry off, not only the waste material in health, but to dispose of the results of abnormal processes and of disease caused by the introduction of malignant bacilli. This consists of the various emunctories, as the large intestine, assisted in part by the entire alimentary tract; the urinary apparatus, *i. e.*, the kidneys, the ureter, the bladder, the urethra; the skin with its system of transpiration, *i. e.*, the sudoriferous glands and ducts. Now, although physicians know all about these, the masses are ignorant of the importance of keeping these emunctories in order, and many physicians are inclined to be careless in this direction. Bacteriology, antiseptics and abdominal surgery have so engaged the attention and called forth the enthusiasm of our modern practitioners, that the good old custom of investigating the bowels, the kidneys and the skin is often lost sight of. How much misery and suffering might be avoided, what an enormous quantity of patent pills and other purgative drugs would be rendered useless, and the sums of money wasted on them might be devoted to making the family more comfortable, if proper attention were paid to keeping the intestinal tract in good condition, which could be done without taking pounds of pills or swallowing gallons of medicine, by simply adopting a sensible and hygienic system of diet, by observing proper times for attending to the calls of nature, by never allowing other avocations or a false notion of propriety to interfere with the performance of that most important function. How much kidney

stomach such liquids as contribute to the preservation of the proper relations between the solids and fluids of the body. Here some one asks the question: "Shall we live like the beasts of the fields, drinking nothing but water? Shall we not pay some attention to the taste which nature has bestowed upon us, and enjoy the pleasant beverages with which the world abounds?" I do not propose to be so severe; you may enjoy the pleasant beverages that nature, assisted by the art of man, furnishes you, but you must practice moderation; you must become acquainted with the capabilities of your organization; you must study the effect of these beverages, and stop before the point of deleterious influence is reached. When you see a man suffering from that deadly malady, Bright's disease of the kidneys, take it for granted that he has abused that great organ, whose function it is to rid the body of worn out and dead material. It is a very patient and long-suffering organ, that will submit to an immense amount of abuse; yet there is a limit to its endurance and it must eventually succumb. The skin, an important auxiliary to the kidney, can be kept in a healthy condition by attending to hygienic rules. If we promote perspiration by reasonable and moderate exercise, and by keeping the pores open through frequent ablutions, we will find much poisonous material carried off that the kidneys would fail to dispose of. If these two organs, the kidneys and the skin, are treated according to the rules of hygiene, much disease will be prevented and the taking of enormous quantities of drugs avoided. The stomach, that great work-shop, in which the first stage of converting food into tissue is accomplished, is as much abused as the kidneys and the skin. All kinds of incongruous, indigestible and injurious articles, under the false name of food, are forced into the long-suffering and much-enduring stomach; indigestion or dyspepsia, which brings in its train so many other ills, is the inevitable result. This was for many years the prevailing disease of the American people, causing them to be distinguished by their sallow complexions and pinched features. The consequence is that the sufferer, not knowing what is the matter with him, resorts to all kinds of absurd medication, throwing the entire machinery of the body out of gear, thereby damaging the intellectual faculties and ruining the disposition. There is not a more unfortunate creature in existence than the chronic dyspeptic, a source of misery to himself, to his family and to all who come in contact with him. Now, how is this to be prevented? Not by filling the stomach with drugs which, in many cases, act as a foreign body, or even as a poison. It can only be avoided by learning the requirements of the system, the ability of the stomach to dispose of the ingesta, and the peculiar characteristics of the food to be supplied. Another thing to be avoided is the unhealthy habit of bolting the food to gain time for business, neglecting mastication, an essential process in digestion, and swallowing the too often unhealthy food with such rapidity that it forms at first an inert mass and afterward ferments, producing gastralgia, acidity of the *primæ viæ*, with a long train of disastrous consequences. This is perhaps the most important branch of hygiene, and should be studied by every parent and by all the children old enough to understand it. The hygiene of drinking-water has been sufficiently discussed to require no mention here. Already intelligent housekeepers are filtering and boiling their drinking-water, and the

remarkable absence of typhoid fever in our city shows that this reform has borne good fruits. The hygiene of the lungs, the heart, the liver, etc., would require space enough for another paper; hence the examples given must suffice.

The question may be asked: "What has all this to do with State medicine?" The answer is plain: Give all your working men and women, your employes in stores, offices, factories, etc., ample time to consume their food leisurely; let none but healthy teachers be employed in your schools; require every teacher to be well versed in the elements of physiology and hygiene, and require them to teach these branches to the children who are old enough to understand them; devote a reasonable amount of time in the schools to physical culture; require the teachers to inculcate general rules of health into the minds of the pupils. Another thing I would recommend: Let schools for hygienic cooking be established at the public expense, to enable poor people to enjoy healthy food as well as the more prosperous. Much of this can be accomplished by intelligent legislation. If the rules barely hinted at in this paper be carried out by the more intelligent part of the community, and taught by precept and example to the masses, the unreasonable consumption of drugs will be reduced to a minimum, and the health, prosperity and happiness of our people will be more than doubled in a few years.

### PREVENTION OF SMALLPOX.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY ELMER LEE, A.M., M.D., Ph.B.

CHAIRMAN OF THE SECTION ON STATE MEDICINE, AMERICAN MEDICAL ASSOCIATION, VICE-PRESIDENT AM. ACADEMY OF MEDICINE, CHICAGO.

It is not my intention to rudely characterize the world-wide process instituted by Jenner just one century ago, as either inefficient or a failure. As there was more than one road which led to Rome, it may be that there is other than one method by which a given disease may be prevented. It was 100 years ago, on the 14th day of May, that the English physician perceived the effect of a slight accident and gave the world the deductions by which vaccination with cowpox, made his name forever to be remembered, and rendered universal aid to the people. It has not been in my power, personally, to inaugurate experiments for determination of the correctness of conclusions concerning prophylaxis by vaccination; indeed, it is the privilege of few physicians, to know the exact facts by personal knowledge. It is not my purpose to question the validity of the statistics which are prepared for our guidance on this subject. There are some physicians both in America and Europe who have expressed a doubt concerning the efficacy of prophylactic inoculation. Their sincerity and privileges of investigation have undoubtedly been equal to the majority of the physicians who may take an opposite view.

The reason that the paper on this subject was prepared for this occasion, was suggested by the near at hand centennial of our great confrère. This meeting of the ASSOCIATION is, practically, a memorial to one whom the world loves to cherish, and whom physicians are willing to honor. The first thought on the subject was to prepare an address relating to the treatment of smallpox, but owing to the relationship which

exists between this Section and myself, a paper suitable for that Section was suggested.

The origin of smallpox is unknown, at least, it is not recorded. The first recognition which is authentic, of the appearance of this disease dates only to the sixth century, in Europe. Undoubtedly it prevailed among nations during the earlier centuries, but owing to imperfect classification, as well as defective records, recognition is lost. The unwritten history of the disease is probably co-equal with the age of our race.

Its propagation is by two methods, namely, contagion and inoculation. The first is the most important and far reaching. Of what this contagion consists, our senses fail to grasp. The active principle by which the attack is produced is not able to be encircled by either scientific processes of detection, or the highest development of the senses. Whether the contagious influences are transmitted to the air passages or to some other vital organ, it is surpassing strange that, up to the present time there is no means of detection. We know full well the pathologic order of the symptoms of the body which has been invaded. Precision of the successive steps in the development of the disease marks the course of every smallpox patient. It has been my privilege to note the physical expressions of variola by clinical experience. It seems to me that there is no disease so exact in the regular order of symptoms as the one under consideration. Once having mastered the knowledge of the diagnosis of smallpox, it is an acquirement which is never lost. The fever and the characteristic pain in the lumbar region, or the back of the head, with the rapid appearance of the papules, the vesicles and pustules, make it a picture never to be forgotten. This much is certain, that smallpox is a systemic disease and whatever process leads toward prevention is necessarily that which best preserves the general economy.

Vaccination by the use of smallpox lymph creates some alteration in the animal body which is beyond the keenest sense of man to determine. Analysis of the fluids and solids, by the highest scientific processes reveals not the secret wrought. It eludes investigation, and is analogous to and the parallel of electric display. We do not know the condition, only the effect. There is no perceptible difference, except by a knowledge of the result between the wire carrying the electric influence and the uninfluenced wire.

Inoculation also produces smallpox. This is a rare form by which the disease is contracted. It is easy to understand the relationship between the introduction of the virus into the circulating fluid, and its effect, but it escapes our keenest perception to explain disease from contagion. As inoculation is rarely the actual cause in the production of smallpox, measures of prevention against it need not occupy our consideration.

Smallpox preys upon all races regardless of geographic separations, it does not spare the young or the old. There are some individuals, however, in whom there is some prevailing condition by which they are rendered insusceptible to the disease. Whether vaccinated or not, their exemption from attack is perfect. Could we but know with scientific accuracy the precise peculiarity and state of the powers of resistance in such presence, it would afford data upon which to base absolute measures of protection

for others. My own opinion as to what constitutes this immunity will be explained presently. Negroes, especially those who inhabit warm countries, are disastrously affected by this disease. Generally speaking, one attack of smallpox precludes a second; but the rule is not invariable.

Vaccination, as is known to all of us, is the introduction beneath the skin, of a minute portion of lymph from the vesicle which is produced by inoculation of some lower animal with the virus of smallpox. A disease similar to smallpox in man is natural to cattle. The origin of vaccination sprang from the incident by which the maid who milked the cow received into an abrasion some of the cowpox virus, and thus became immune to the disease which ravaged the community. It was Dr. Jenner's part in this drama of life to discover the relationship between cause and effect, and give a world-wide significance to the incident of the milkmaid, and the humane service which she performed. The protecting influence of vaccination is regarded as acting in two ways. The first assumption is, that to him who is inoculated, a protection against the disease is sure to follow. The second, that if the individual contracts smallpox, its duration and severity are lessened. These positions are reasonable and upon the same line of thought my plan for prevention of smallpox is now to be, for the first time, presented for your consideration. It is the desire at this moment to state that my preventive proposition is founded upon a process of reasoning from analogy. There are no cases reported by which the position is sustained, and it may be that there never will be; but in my own mind the conviction is established that whatever measures we are able to secure, to preserve a perfect health of the body, are necessarily, a prevention of disease, even the disease of smallpox. My views take two directions. First, the natural agent which is able to preserve immunity, and second, a method whereby, the prophylactic measures can be made practicable. It is sometimes a long step between that which is useful, and that which is able to be used. The distinction may be the insurmountable difficulty in the present instance, but it is certain that one step in the plan is sure to find a sympathetic response from modern sanitarians.

Uniform and stable health is maintained by preserving the quality and parity between the solids and fluids and between the supply of new material and removal of the old. This is the quadrangle and within its four sides the processes of life and health are protected. Water is the controlling factor of the organized human body. More than three-fourths of all the structures are water; 80 per cent. of the blood is water; seven-eighths of the brain and nervous structures are water. The preservation of the integrity of the soft structures depends upon water. Insufficient water results disastrously to the cellular tissue of the vital organs and to the physiologic function of those organs. It is a maxim of health, that impairment must precede invasion by disease. If it is possible by any universal agency such as water to practically prevent impairment of the system then it is able to say that water, when used rightly, may be a prevention of smallpox. The knowledge of the proper use of water is not generally understood or employed. A brief reference to physiology teaches, that two liters of water or its equivalent is required to maintain physiologic equilibrium each day. There

are but few people who are aware of this requirement and fewer still who practice it. My theoretic prevention of smallpox, other than by vaccination, is the physiologic use of water introduced into the system through the mouth. Does it not appear as a reasonable proposition that if water constitutes so large a portion of the tissues and of the fluids and solids of the body, then, according to the laws of nature if that relationship is persistently disturbed, a condition suitable for disease is established? Such is my conclusion based upon over four thousand clinical experiences in the use of hydriatics.

The second element of the proposition is how to make the first practicable. It would be my suggestion, first: that the United States government should speedily enact a law creating a bureau of public health, the commissioner of which shall be an officer of equal rank with those of the other present existing departments. Wise and sound measures of public health can be authoritatively disseminated among the people, only through a national department at Washington. As a direct means of prevention to the whole population, public baths for all classes and both sexes should be provided. At these public institutions there should be provisions made for supplying pure, soft water to drink. In each establishment permanently maintained printed instructions should adorn the walls concerning the physiologic daily uses of pure water. Circulars of information should emanate from the national department, plainly and in straightforward terms of simplicity, explaining to the people the value of water drinking, also the injury resulting from its neglect. The use of public baths should be included in the instructions. It is not the fault of the masses of the common people among whom smallpox principally prevails, that such measures of prevention are not employed.

Recently a private patient informed me that since his youth the average daily consumption of water had been so small that the quantity could not be remembered. As a result of his ignorance and neglect, while yet about 30 years old, his appearance resembled that of a man between 40 and 50. The stay of a month under treatment at the hospital revealed to him the value of the use of water internally, and gave him encouragement for improved and prolonged life. There is a wide difference between so-called hydropathy and true physiologic hydriatics. In formal treatises on hydropathy reference is especially made to external use of water, whereas, the essential principle underlying the views entertained and expressed by the author regards the internal use of the proper amount of the proper kind of water as of first importance. The use of the bath is a refinement and is to be encouraged by providing public establishments throughout the whole world, and in these public establishments may be easily and naturally taught the higher value of the internal use of water. At the same time the harmful and sad consequences of the abuse of alcoholic drinks could be successfully explained.

Finally, the prevention of smallpox, by other means than by vaccination, is by the physiologic uses of pure, soft water; and secondarily, the provision of a national bureau of public health and the construction of public baths for the use of the common people.

103 State Street.

DISCUSSION.

DR. COCHRAN—If a man were perfectly healthy would he be

equally resistant to the poison of scarlet fever, as the gentleman maintains he would be to the poison of smallpox or to the poison of diphtheria or strychnin, arsenic or any other poisons that we know of? I think not. I think water may be made to supply a very important part in the prevention of smallpox, but I think it is very hot water applied to the bedding and surroundings of the man who is sick, and not cold water taken internally. I expect if there is any attempt to celebrate Jenner's Day, there will be ample time to discuss this question. But I suppose from what I have heard that it is quite possible to prevent the spread of smallpox without vaccination or inoculation. Put a man under quarantine; smallpox does not fly through the air like a bird and attack people at a distance. It will not cross an ordinary street under ordinary circumstances, unless it is carried across. I have had large experience with smallpox. There is no doubt about the prophylactic efficacy of vaccination. You may vaccinate a number of men and place them in a smallpox hospital and if the vaccination is properly done none of them will have smallpox. It is a very curious thing, an item that went around among the papers a few weeks ago (among others the JOURNAL OF THE ASSOCIATION) stating that there had been a very considerable outbreak of smallpox in the town of Gloucester, the county town of Gloucestershire. It was the town in which Jenner lived and made his experiments. He did not live in the town of Gloucester, but in the town of Berkeley; but it is a little strange that in the town where he made his discoveries there is an Anti-Vaccination League with a large number of members, and owing to their systematic neglect of vaccination this disease has come on them.

DR. KOBER—One remark might be a trifle misleading. In my experience in treating smallpox, which has been considerable, I have never seen vaccination done without good effect. I believe if taken two or three weeks, or a month, before exposure one may then be exposed and not have smallpox; but if taken the same day of exposure, notwithstanding the fact that it runs its course, that patient is likely to have a modified form of smallpox.

DR. COCHRAN—My experience was not similar to that. We had an epidemic of smallpox in Mobile in 1874-5, and having made close observation of the disease, I concede the statement of the gentleman that the disease is checked in warm climates is correct. Along the Gulf coast during the summers smallpox will almost die out. When the weather turns cold in the fall the number of cases increase and continue to increase until the weather becomes warmer in the spring and then they diminish. At one time it prevailed continuously for ten years, and I made a table showing the mortality for three months; as the mercury fell in thermometer the smallpox increased among the people. Black races are very much more liable to smallpox than the white. Prior to this epidemic I speak of, very little had been done in the way of vaccination for many years. There were 450 cases when we took charge, and we had to work very energetically, and use a great many agents that had never had smallpox, nor had they been vaccinated, and we vaccinated them at the time. The general result was that those who were vaccinated nearly all escaped.

DR. MCDANIEL—We naturally are controversial, but when we try our best to agree it sometimes seems impossible. There was one remark made by Dr. Lee that I can not exactly understand. If I understand you, Doctor, you say that when we are healthy, perfect health would protect from smallpox. Do you take that stand?

DR. LEE—Yes sir.

DR. MCDANIEL—I desire to say that I appreciate his paper very much, but I believe that smallpox is a specific disease, and I believe that you will all agree with me. I believe that vaccination is a specific remedy for that disease, and if it be a specific remedy I do not see how it can confer a more perfect

health on the individual than he had before he was put under the effect of vaccination poison. For instance, the results from vaccinia virus are sometimes very severe. There has been a fatal case lately in our midst. In the convalescence from this extreme illness so produced, the patient is absolutely protected from an attack of smallpox. It can not surely be because he is on a higher plane of health at that time than before the vaccinia ordeal was encountered, because of his debility, and in that debilitated condition is perfectly immune from the smallpox. During the war I had charge of a Confederate recruiting camp; smallpox had been brought from Marietta, Ga., among our men, the raw recruits. There were 127 persons that were exposed to this case of smallpox brought from Marietta. In a few days it developed into an unmistakable case of smallpox; as Dr. Lee stated, the case was so characteristic that none could make a mistake after a few days. So I found on examination. All in camp were examined. Those who were unprotected, had no scar, were vaccinated. There were 118 out of the 127 who had the pitted mark; these I had disinfected, but of the nine others one had a scar that I could not approve; it had some signs of vaccination, but were not satisfactory. That man contracted varioloid, the other eight genuine smallpox. Out of the one thousand or more that I vaccinated, not one had smallpox.

DR. STONER, of Baltimore—During the past month a vessel came into port on which was a case of smallpox. The patient was put in quarantine on arrival at Baltimore, and everything thoroughly disinfected; after a few days' detention the immigrants were allowed to go. As an additional precaution the health officers were disinfected, and as a result there was no spread of the disease. The point I wish to make is simply this, that where a case is otherwise susceptible, if that person is vaccinated, the vaccination, if successful, would not be an absolute protection against smallpox. It would be modified to a very great degree, and might, in forty-nine out of fifty cases, prevent. My experience is that vaccination modifies to such an extent; that smallpox is not entirely prevented every time and varioloid occurs to a small extent. The point is that vaccination is not a preventive against it, still it is well enough to vaccinate to endeavor to keep a man from contracting it.

DR. QUIMBY—One word in reference to Dr. Lee's paper; it seems to me, as long as smallpox is a filth disease, if the caution is taken to destroy and put the surroundings in a good sanitary condition, then carrying out Dr. Lee's treatment, we certainly would have a preventive. Then use cold water inside and out and put everything in proper sanitary condition, because it is an insanitary disease, and if we dispose of the filth, we are freed from the germinating microbe that forms the disease.

DR. KOBER—I desire to be placed on record as opposing Dr. Lee. It seems to me, in the present state of our knowledge, that nothing short of vaccination and severe quarantine regulations can afford perfect immunity from this disease. In proof of this I will mention an epidemic which occurred two years ago in California, where the people enjoyed the best hygienic surroundings, in perfect health and blessed with the purest water and best food. The case of smallpox was introduced into the community from Chicago, a distance of over two thousand miles, and within a period of three weeks not less than fifty cases occurred in adjoining houses. All the hygienic conditions did not protect them from the disease, but as soon as sufficient quarantine and vaccination were resorted to the epidemic stopped.

DR. HIBBERD—He did not hold that the presence of pure water prevents, and if you do not use it, it is not a prophylactic.

DR. KOBER—But if they use the pure mountain water it should be considered a prophylactic.

## THE WELFARE OF THE COMMUNITY DEMANDS THAT MARRIAGE SHOULD BE REGULATED.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY DANIEL R. BROWER, M.D.

PROFESSOR MENTAL DISEASES AND THERAPEUTICS, RUSH MEDICAL COLLEGE; PROFESSOR MENTAL AND NERVOUS DISEASES, WOMAN'S MEDICAL COLLEGE.  
CHICAGO.

The closing hours of the nineteenth century are full of marvelous results in science and art, and of wonderful progress in medicine and surgery, but in the midst of these brilliant achievements may be seen on every side insanity, pauperism, criminality and the degenerating effects of various vices of nutrition so rapidly increasing that they will overwhelm the race unless they can be arrested. These melancholy effects are produced, at least in part, by the violation of the laws of heredity, constantly taking place in unregulated marriages. Under our higher civilization abnormal man, be he defective, dependent or delinquent, is propagated, cultivated and protected, his feeble and crippled offspring are nursed to manhood and sent forth to produce their kind. Under savage and semi-civilized conditions these abnormalities are speedily extinguished, the deformed and the weaklings have no place in their system, and some way or other are soon cut off.

The physicians, who have always been the advance guard of progress, ever watchful of the welfare of those entrusted to their care, must rise in their might, find the remedy and apply it to these defects of this brilliant age. The study of these defects of our civilization develop startling revelations.

First, consider the increase of insanity in Great Britain. In 1860 the proportion of insane to the population was 1 to 523, in 1870 1 to 411, in 1880 1 to 360, in 1890 1 to 320. The proportion of the insane to the population in New York to-day is 1 in 315. If this increase is to be stopped, it must be by the earnest efforts of such distinguished members of the profession as are gathered here.

Consider the question of crime. The census of 1890 places the criminals in prisons and reformatories at 82,329. If only one-third are incarcerated this gives a criminal population of about 250,000. Between the years 1850 and 1890 the population increased 170 per cent., the criminals increased 445 per cent. Between the years 1880 and 1890, the total population increased 24.5 per cent., the criminal population increased 45 per cent.

The statistics of pauperism show equally startling defects in our sociology. Dugdale, in his admirable study of the "Juke" family, shows how from one degenerate man, in seven generations there were developed 1,200 criminals and paupers. McCulloch, in his history of the "Ben Ishmael" family, showed as the offspring of this degenerate, 1,750 criminals and paupers. Maudsley says that an idiot is not an accident, nor an irreclaimable criminal an unaccountable casualty. Our mental and physical condition is an inheritance, an estate in trust received from our ancestors; we make it better or we make it worse, and we hand it down to our children. Heredity, according to Ribot, "that biological law by which all beings endowed with life tend to repeat themselves in their descendants," is the great underlying factor, and yet, while we are extremely careful to observe its

demands in the breeding of horses and cattle, we pay but little attention to it in laying the foundation for the physical, mental or moral condition of our children.

The laity need to be instructed on the subject; they should be taught that insanity, epilepsy, tuberculosis and drunkenness are all most certainly transmissible, and that he or she who possesses any one of these, or any other vice of nutrition, by marrying assumes a terrible responsibility in the suffering and misery they inflict upon their progeny.

Fortunately for the race these degenerates tend to extinction, and in the third and fourth generation, if not sooner, they have paid the penalty by annihilation, of their violation of the laws of nature.

Some of the laity are already deeply interested in this matter, and are seeking to find ways and means by which they may avoid these consequences; and the tendency to reversion furnishes us with the method by which the milder cases of hereditary taint may produce children who will but slightly inherit the abnormalities. We would, of course, advise such persons to unite in wedlock with those as far as possible removed from the vice of constitution which they possess, and then their progeny may be thrown back to the normal type.

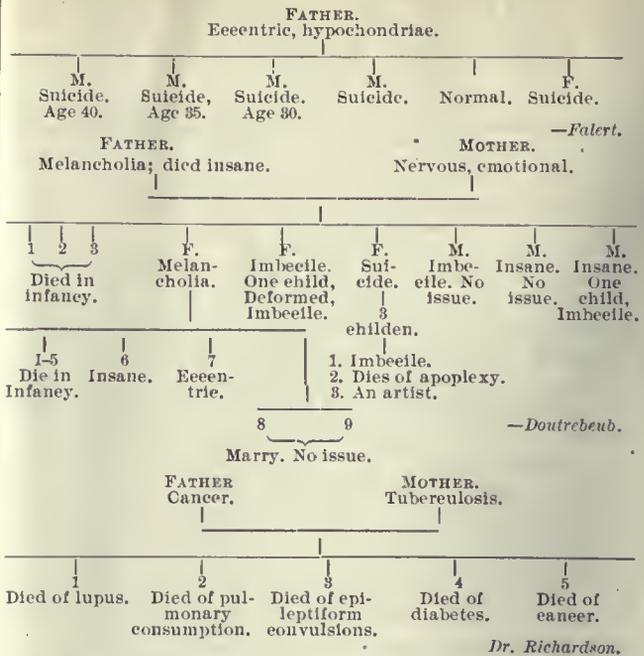

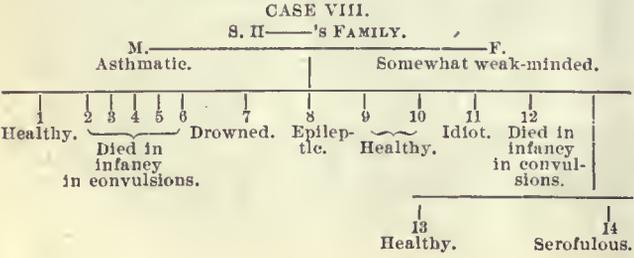

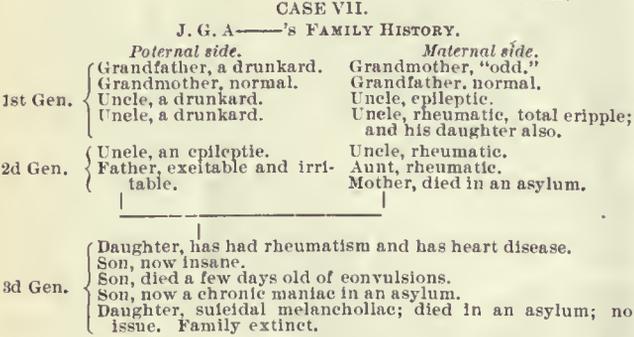

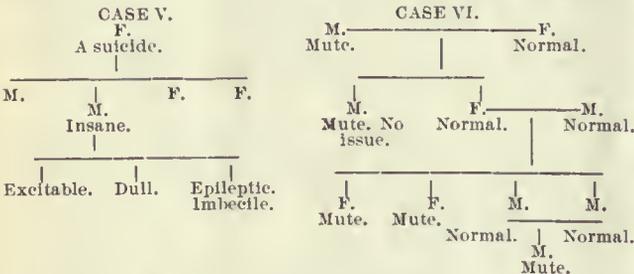

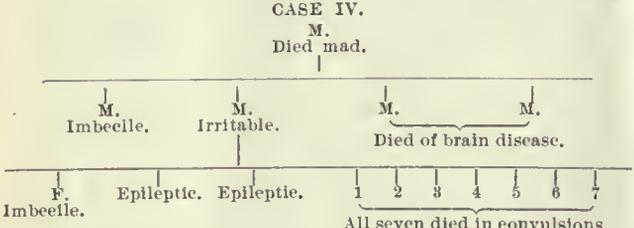

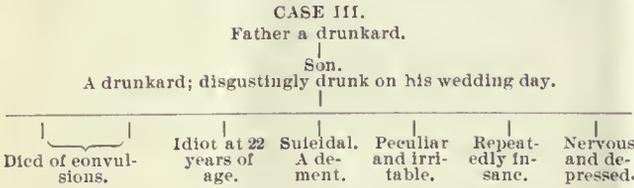

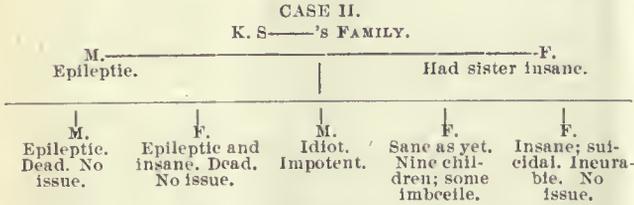

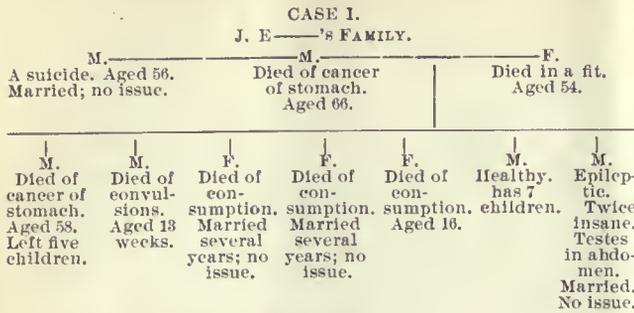

The most perplexing, as well as the most active factor in producing the defects of our civilization, is alcoholism. The appetite for alcohol may be acquired, but it can be transmitted to the children, and various diseases and degenerations follow. Echeverria collected the statistics of sixty-eight males and forty-seven females who were alcoholics. The number of children born to them was 476. Of these, 23 were stillborn, 107 died of convulsions in infancy, 3 suicided, 96 had epilepsy, 13 were idiots, 19 maniacal, 7 had general paresis, 5 had locomotor ataxia, 26 had hysteria, 23 paralysis, 19 deformed, 9 chorea, 7 strabismus, 3 were deaf, and 205 exhibited drinking tendencies.

Dr. Tarnavskin examined at St. Petersburg prostitutes who had been inmates not less than two years, and found eighty-two per cent had parents who were habitual drunkards.

Boies<sup>1</sup> makes the statement, "that the consumption of distilled spirits, per capita, has not materially changed even in fifty years in this country, but the consumption of malt liquors has increased 738.1 per cent. contemporaneously with an increase of 445 per cent. in criminals in fifty years. These statistics show very plainly that the temperance reformers have not reached the masses. While the decanter is no longer seen on the sideboard, and the consumption of wine among the well-to-do people has diminished, yet the saloons are multiplying on every side. Surely we can not permit this condition of things to continue longer, and must recognize the inadequacy of the forces that are contending with it. The physicians must educate the laity, must impress them with a knowledge of the disastrous effects of alcoholism, and through their coöperation secure such legislation as will remove the blot from our civilization.

The effect of marriages, in disregard of the laws of heredity, are well shown in the following life trees. They are taken from Dr. Strahan's admirable book on "Marriage and Disease," and other sources.

<sup>1</sup> Prisoners and Paupers.

In the midst of these overwhelming exhibits, surely the welfare of the community demands that marriage should be regulated. It is horrible to contemplate what will be the condition of the race in the future, and what will become of our social and political institutions if this wholesale production of abnormalities does not cease.

In most of the States of the Union a marriage license is necessary before the ceremony can be performed, but its requirements are insignificant. Let us agree that in addition, proper evidence must be furnished that both parties are in good health, that they are not insane, criminals, paupers, alcoholic nor narcotic inebriates, that they are not tuberculous, cancerous nor epileptic, and that they have not active venereal disease.

If the members of this great profession will unitedly advocate this great reform, they will succeed, and more than ever deserve the title of public benefactors.

**AGE AND SEX INCIDENCE OF MORTALITY IN MICHIGAN FROM DIPHTHERIA AND FROM CROUP DURING TWENTY-FIVE YEARS, 1870-94; A STATISTIC STUDY.**

Read by title in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY CRESSY L. WILBUR, M.D.

DIVISION OF VITAL STATISTICS, DEPARTMENT OF STATE, LANSING, MICH.

No apology is necessary at the present time for a statistic study bearing upon the history of diphtheria and croup in the United States during recent years. It is only a short time since the etiologic characteristics of the disease, or diseases, dependent chiefly upon the presence of the Klebs-Löffler bacillus and associated microorganisms, have been definitely ascertained, and a still briefer time has elapsed since the antitoxin treatment, based entirely upon modern bacteriologic research, has promised to revolutionize entirely the treatment, and to greatly reduce the mor-

tality of this, by far the most fatal acute infectious disease prevalent in this country, or at least its northern part.

It is of especial importance, therefore, in order that it may be known whether the claims of the new method of treatment are substantiated by experience, that reliable statistics of immediately preceding periods be available for comparison, and in case the employment of the serum therapy in any given locality appears to be attended with a reduction in the death rate from diphtheria, that it be known whether such reduction was probably caused by the special measures employed, or whether a reduction in mortality was reasonably to be expected as a consequence of the periodic fluctuations characteristic of the history of this and most other epidemic diseases.

Usually on the introduction of a new remedy, the appeal is primarily to the results of hospital treatment. This was necessarily so in the present instance, as the curative serum was costly and difficult to be obtained at first by general practitioners. Later, with increased facilities for its production and the undertaking of its preparation by official agencies, its use was more generally diffused, and an appeal could be fairly made to the testimony of the mortality statistics prepared by the general registry offices. Hospital statistics are notoriously unreliable, it being often impracticable to eliminate or fully describe the selective influences that determine the characters of patients and the results of treatment, as well as the preliminary diagnoses upon which the statistic conclusions largely depend. Small numbers are also usually employed, in themselves a frequent source of fallacy. In the deductions drawn from general mortality statistics, on the other hand, these minor sources of error tend to neutralize one another, so that any marked change from the usual course of a disease may, with considerable certainty, be ascribed to some extraneous influence.

*Purpose of the present paper.*—The data contained in the present paper are not presented in the interest of any particular method of restriction or prevention of diphtheria, nor, primarily, to illustrate the value of the antitoxin or any other method of treatment. If the serum therapy shall prove to be of as great usefulness as at present appears likely, valuable evidence as to its efficacy will probably be derived from the comparison of the incidence of mortality by sex and periods of age, as presented in this paper, for Michigan for the pre-antitoxin period, with corresponding data to be tabulated later for the "antitoxin era." If the antitoxin method goes the way of the Bergeon, Koch's tuberculin and other "fads," nevertheless the evidence here presented may be of special interest to the sanitarian and to all students of State medicine, from its bearing upon the history and success of the methods of prevention and restriction of diphtheria advocated and carried out by the Michigan State Board of Health under the able direction of Dr. Henry B. Baker. In any event it seemed to me that an impartial account of the prevalence of diphtheria in Michigan, and one as accurate as the available statistics would permit, would be of service in advancing our knowledge of this disease.

As indicated by the title, the discussion is confined entirely to the presentation of two features, with their inter-relations, of the mortality in Michigan from diphtheria and croup, viz., the distribution by ages in periods of years and by sexes of the decedents. It

will be necessary to preface the subject proper with some general account of the history of diphtheria in Michigan as a whole, and its relation to the recorded mortality from this cause in other States and countries, in order that the position of Michigan in reference to the disease may be understood. Other important features of the recorded mortality are purposely excluded from the present discussion, *e. g.*, the geographic distribution through the State,<sup>1</sup> relative death rates of rural and urban populations, and monthly and seasonal prevalence, with relations to meteorologic conditions.

The study will chiefly show: 1, the availability of mortality statistics known to be imperfect in certain directions for use in certain other directions, as evidenced by the constancy and clearness of their testimony; 2, the characteristic differences in the age and sex incidence of diphtheria and croup, and, inferentially, the inexpediency of confusing their statistics under the term "diphtheria and croup" from a statistic point of view; 3, the desirability of ascertaining the causes, and so far as practicable, of preventing the increased relative mortality from diphtheria of female children on reaching the age of five years and upward.

*Source and character of data.*—The Registration Reports of Michigan are utilized as the source of information. This series of annual reports began April 5, 1867, and is continued at the present time in substantially the same form that it originally assumed. The method of collection of data is imperfect, being nearly the same as that of the United States census in non-registration States, *i. e.*, an enumeration of the facts some time after their occurrence. Many deaths fail to be registered each year, and the deaths in months near the date of enumeration are more thoroughly collected than those of months more remote from it. The result is precisely as in the case of the United States census mortality statistics of non-registration States, that study of the monthly and seasonal prevalence of mortality is entirely misleading, unless a graduated "correction" be applied to the monthly returns, something nearly or quite impossible to satisfactorily accomplish;<sup>2</sup> and, secondly, that the absolute rates for the year, both of aggregate mortality and of individual causes, are considerably below the truth. For the latter imperfection it has been necessary to make an approximate estimate, since otherwise we should have no means of judging of the relative mortality of the State as compared with other States and countries. In the Registration Reports of successive years up to the year 1890, amounts of deficiency, different for each year, have been calculated, varying from 66.24 per cent. down to 9.92 per cent. of the original returns, and giving an average "correction" of about 40 per cent.<sup>3</sup> There has been, however, no evidence whatever to show that the accuracy of registration has been any greater in one year than in another; indeed, the only condition of usefulness of the data presented, as employed for comparison of mortality in successive years, involves the assumption that the degree of imperfection of registration remained substantially the same from year to year.

<sup>1</sup> For geographic distribution, see Michigan Registration Report for 1892, map opposite p. 195; the period is one of five years, 1888 to 1892, and diphtheria and croup are taken as one disease. See also the maps of diphtheria and croup (separately) in the Mortality and Vital Statistics Report of the Tenth Census, in which, however, percentages to total deaths, and not death rates, are shown.

<sup>2</sup> See Mortality and Vital Statistics of the Tenth U. S. Census, Part I, p. xi.

<sup>3</sup> Mich. Reg. Rep., 1891, p. 132.

This is the assumption under which the vital statistics of successive United States censuses are compared, and is, in fact, even more tenable as regards the Michigan statistics, since they have been collected under an unaltered law and by precisely the same registration machinery, at least since 1869. For this reason the writer has rejected the variable "correction" formerly employed in the reports, and has substituted since 1891, and employs in the present paper, an estimation—a mere guess, somewhat qualified by study of actual registered death rates of certain Michigan cities, and knowledge of the general rate of mortality of similar populations—that the returns of deaths in Michigan should be increased by about 60 per cent. to give the actual deaths that occurred. This estimate is probably sufficiently low, corresponding to an increase of the registered mortality from about 10 per 1,000 to an estimated actual mortality of about 16 per 1,000 population; is applied uniformly to successive years, and to the subdivisions of population, by sex, periods of age, etc.; and is only applied when the Michigan statistics are brought into relation with approximately correct rates of registration States or countries for direct comparison. For study of the *course of mortality*, the uncorrected rates, if only the assumption of their substantial uniformity of inaccuracy be granted, are as reliable as more complete ones.

Having stated the chief respects in which the Michigan statistics can not be taken at their face value, viz., monthly and seasonal distribution of mortality and absolute death rates, the following points upon which the results obtained from the Michigan returns are probably fully correct and reliable may be stated: 1, relative mortality from all causes and from special causes of death in successive years—the latter subject to the usual criticisms dependent upon defective diagnosis; 2, geographic distribution of mortality through the State; 3, proportions of deaths from specified causes to total mortality—this, however, a discredited ratio in vital statistics, although much used in the United States census reports in default of a better; 4, incidence of mortality by sex; 5, incidence of mortality by age. It is with the two latter features that the present paper is specially concerned, and it should be clearly understood that the admitted deficiency of Michigan registration in certain particulars in no wise affects the indications drawn from a large and fully representative mass of returns in regard to the facts of age and sex incidence of mortality from diphtheria and croup.

*Statistic nomenclature and classification of diphtheria and croup.*—The statistic study of a disease is necessarily secondary, in point of time, to its clinical study. It follows that uncertainty in diagnosis, confusion as to the true clinical and etiologic characters of a disease, or confusion of one disease with another, will be reflected in the vital statistics subsequently collected. The advances of knowledge in methods of exact diagnosis are shared, first, by the most progressive members of the medical profession, or possibly, by specialists in certain fields of investigation, in whose particular lines of research the advances were made; second, the rank and file of the profession adopt the discovery and it becomes a part of ordinary professional opinion; and lastly, the new knowledge filters through medical opinion and is more or less rapidly and thoroughly disseminated by the press until it finally becomes a part of the common belief of the people. It is from the people themselves, as a

rule without the immediate intervention of professional opinion, that the data in regard to causes of death are collected in Michigan, and the foregoing considerations are given in explanation of the facts that they are apt to be somewhat indefinite in character and, further, that the returns of any year do not correspond to the latest professional knowledge of the time. There is in this an advantage, however, that the returns are not affected by the more transient waves of medical thought, but only by those deeper currents representing well-grounded changes in medical belief.

The vital statistics of Michigan do not extend back, by about ten years, to the time of the first general recognition of diphtheria in this country. It is probable that substantially the same clinical distinctions between diphtheria and croup have existed during the entire twenty-five-year period. The early confusion between diphtheria and croup, prior to the recognition of the "new disease," such as appears in plain evidence in the death rates of Chicago (Table 2), had been outgrown, and the recent tendency to report deaths from what would have formerly been considered "croup" or "membranous croup," as diphtheria pure and simple, has probably not affected the statistics to a very great extent, although it may be expected to show a marked influence in the next few years.

Bacteriologic analysis, by its proof of the Klebs-Löffler bacillus as the cause of true diphtheria, has laid the foundation of future exact statistics of this and related diseases. But we should not allow our statistic methods to outrun the actual advance of knowledge. While on the one hand, there is undoubted evidence that many cases of croup are diphtheritic in character and due to the infection of the Klebs-Löffler bacillus, it is equally positive that a certain proportion of them are not diphtheritic. Indeed, a certain fairly large proportion of cases of clinical diphtheria is found to be lacking in the presence of the essential germ, under our present methods of recognition, while in the undoubted cases of true diphtheria the action of the Klebs-Löffler bacillus is modified so largely by the presence of other species of microorganisms that the tendency is undoubtedly, at present, in the direction of a more minute analysis of true diphtheria, rather than to the inconsiderate consolidation of diseases possessing quite distinctive clinical, etiologic and statistic characters. Professor Novy of the University of Michigan well remarks, "That which for clinical or anatomic reasons is described as a definite disease, may in reality be far from be an entirety. . . . What was called a disease becomes, through the study of its etiology, a group of diseases. The old typhoid fever has passed through such a history, and we may say in advance that diphtheria has recently experienced a similar development."<sup>4</sup>

In the older Farrean classification of causes of death, as employed at present in the Massachusetts and Rhode Island Registration Reports, and in the Michigan Registration Reports up to the year 1892, diphtheria and croup are placed together, but separately, among the zymotic diseases. In the later classification adopted by the Registrar-General of England, and which is in use in most of the English colonies and in certain States of this country, croup

<sup>4</sup> Etiology of Diphtheria, Trans. Mich. State Med. Soc., 1894, p. 396.

is removed from its position in conjunction with diphtheria, and placed among the diseases of the respiratory system under the class of local diseases. This was undoubtedly a mistake, although made with the sanction of the Royal College of Physicians at the time (1883), for recent bacteriologic evidence makes it clear that a large proportion, perhaps at least 75 per cent., of cases of croup is in reality diphtheritic. The distinction made by the Italian reports<sup>5</sup>, which place "difterite (crup difteritico ed altre forme difteriche)" under the head of infectious diseases, while "crup non difteritico" is put under the head of diseases of the respiratory organs, would be valuable, were it not certain, in the light of our present bacteriologic knowledge, that the practical distinction of non-diphtheritic from diphtheritic croup must have been quite impossible at the time this classification was adopted. The tendency at present, as evidenced by many European (continental) reports, and some in this country, is to combine the mortality reported from diphtheria and croup under one title, namely, diphtheria and croup, or simply diphtheria. Bertillon says, referring to his proposed statistic nomenclature of causes of death, which was presented to the International Statistical Institute, Chicago, 1893:<sup>6</sup> "It is very important for exactness of international comparison that the titles 'diphtheria' and 'croup' should always be placed side by side to facilitate adding the numbers; we prefer to combine them under a single title." This latter preference I can not but regard as unfortunate for the reason that such statistics of diphtheria and croup cease to be comparable with those of diphtheria and croup stated separately, as found in all reports following the present Registrar-General's classification. An even worse method, considered statistically, however justifiable it may be from the present bacteriologic and from a sanitary point of view, is the plan boldly adopted in the Chicago report for the year 1894, of adding bodily 80 per cent. of the reported deaths from croup to diphtheria. The rates thus changed become wholly incomparable with those of previous years, which should have been either changed in a similar manner, or, better, an additional column showing the aggregate mortality from diphtheria and supposed diphtheritic croup might have been given. "It is not the duty of a statistic office to interpret diagnosis (that is to say, to guess at what has been left incomplete). It can only register facts as they are formulated." (Bertillon.)

In the provisional classification of causes of death employed in the Michigan Registration Reports since 1892, I have placed the returns of diphtheria, croup and membranous croup side by side, in order that the summation or total deaths from diphtheria and croup, might be readily obtained, while at the same time the statistic integrity of each cause of death, as returned, remained unimpaired. The aggregate number of deaths registered during the twenty-five years from diphtheria and croup was 28,088, of which number there were 21,095 deaths reported as diphtheria, 5,897 as croup (otherwise unspecified) and only 1,096 as membranous croup. The very few cases returned as spasmodic croup are included under simple croup, while a few returned as diphtheritic croup have been

compiled under diphtheria. So also are included under the latter head a few cases of "putrid sore throat" occurring during the early years of registration.

*General prevalence of diphtheria and croup in Michigan.*—Two tables are given in illustration of this subject, which show respectively the general importance of diphtheria as a cause of death during recent periods of years in certain European countries, Australasian colonies, and in the United States; and the course of diphtheria and croup as registered year by year in Michigan, compared with Chicago, Massachusetts, England and Wales, and the colony of Queensland.

TABLE 1.—Comparison of death rates per 100,000 population from diphtheria, and from diphtheria and croup in certain countries, states and cities during recent periods of years.

Country, State or City.	Years.	Rate per 100,000 population.	
		Diphtheria.	Diphtheria and Croup.

Michigan, as estimated . . . . .	1890-94	73.0	94.9

NOTE.—The data for Europe are from the *Statistica delle Cause di Morte*, Rome, 1894, and have been kindly revised by Prof. Richmond Mayo-Smith of Columbia College, from whose work, *Statistics and Sociology*, they were taken. The rates for Australasia are as given in the Victorian Year Book, 1894. The rates for the American cities during the six-year period, 1885-90, are from the special investigations of the Eleventh U. S. Census. The rates from diphtheria for Chicago are the means of the rates stated for the five-year periods in the valuable "Chronological Summary of Chicago Mortality, 1851-1894," forming a part of the *Annual Report of the Department of Health for the year 1894*. In obtaining the rates for croup from this Summary the writer nearly fell into error from the fact that the column in the statistics of this disease (p. 250) corresponding in position to the column of death rates per 10,000 population in all of the other tables, does not contain death rates, as stated by the general heading, but instead contains "percentages of total deaths;" it was necessary to calculate all of the rates given for croup in Table 2, and from these annual rates the means given above were obtained. For the Michigan cities, Detroit and Grand Rapids, reference was made to the table in the *Michigan Registration Report, 1893*, p. 248, the rates in which were based upon the deaths actually registered by the city health officers, and recorded in their monthly or annual reports.

Table 1 indicates the world-wide extension and universal importance of diphtheria as a cause of death.<sup>7</sup> Incidentally it shows the inconvenience in

<sup>7</sup> Cape Colony has only just adopted a general registration system (Act of 13th July, 1894), so that data representative of Africa are not available. It may be noted, however, for certain cities and towns of Cape Colony the death rates from "diphtheria and croup" in 1894 were extremely high: Cape Town, 80.4; King William's Town, 83.0; Worcester, 92.5; Malmesbury, 162.5; Beaufort West, 179.1; Murraysburg, 382.8; Aberdeen, 398.4, all rates per 100,000 population. The antitoxin treatment has come into general use, serum being supplied to medical men free of cost.—*Cape of Good Hope Reports on the Public Health, 1894*, p. xxiv.

<sup>5</sup> *Elenco sistematico delle cause di Morte, Statistica delle cause di Morte, 1885*, p. LIII.  
<sup>6</sup> Translated and appended to Report of Committee on Nomenclature and Forms of Vital Statistics made to the American Public Health Association, Montreal, 1894.

making comparisons arising from the fact that for some countries and cities rates for diphtheria only, in others for diphtheria and croup only, could be obtained. We notice that England and Wales, Ireland, Holland and Switzerland, show a low mortality as compared with other countries of Europe, that the prevalence in Australasia is light compared with Europe and America, and that the mortality in America is very high as a rule. The rates for the twenty-eight largest cities of the United States, Germany and England, are from the report made to the Eighth International Congress of Hygiene and Demography, Budapest, 1894, by the American Committee on Diphtheria, whose chairman was Dr. J. S. Billings, ex-Deputy Surgeon-General U. S. Army, editor of the "Vital Statistics Reports of the Tenth and Eleventh U. S. Censuses," and the foremost American authority on the subject.

In Table 2 the fluctuations, but not the absolute rates, of the mortality in Michigan from diphtheria and croup may be compared with corresponding rates for Chicago, Massachusetts, England and Wales, and Queensland for successive years. These comparative data are chosen for their special significance. The course of the disease in Chicago, from its geographic proximity, may be taken as corresponding fairly closely to that in Michigan, but it extends over a longer series of years, in fact from beyond the first recognition of the disease diphtheria as such during the present period of prevalence. The high death rate from "croup" in 1858 and 1859, during which years practically no "diphtheria" was reported, together with the high death rate from diphtheria in 1860 attended with some decline of the rate from

croup, are indicative of the confusion between these diseases which was present at its first outbreak. Until about 1875 croup had caused a larger annual mortality in Chicago than diphtheria as a rule, but since that time diphtheria has been the more fatal. It should be remembered that for 1894 the compiler of the Chicago statistics has taken 80 per cent. of the registered mortality from croup and added it to diphtheria, thus disturbing the true relations of these causes of death as returned.

Massachusetts was selected as a State fairly representative of the East, and because her system of registration is the oldest and probably the most perfect of any in this country. The data are from the Registration Report of 1890, the rates having unfortunately not been continued in later reports.

Besides the rates given for England and Wales as representative of European statistics of diphtheria, it would have been desirable to present a corresponding series for Germany or some other continental country, in which the disease is far more prevalent, as a rule, than in England. Unfortunately statistics were not at hand for this comparison, so that the general relations indicated in Table 1 can only be referred to as illustrative of the general European mortality from this disease.

The data for Queensland, which colony was taken as fairly representative of Australasian experience, do not extend back as far as would be desirable in order to show the early development of diphtheria as a cause of death in the Southern Hemisphere. They were, however, the longest series of death rates accessible to the writer, and have been taken directly from the annual reports of the Registrar-General of that colony. A complete file of the annual reports of New South Wales, beginning with the year 1857, completely covers the history of the disease, but, unfortunately, for the early years of registration the zymotic diseases are all grouped together, without stating separately the number of deaths due to each cause. The first mention of diphtheria occurs in the Report for the year 1864, but the disease had occurred to some extent during previous years, and had been tabulated as quinsy. An interesting table is given in the 9th Annual Report for 1865 showing the deaths annually registered from certain diseases during previous years, part of which is here given:

Deaths registered in New South Wales, 1856-64.

Year.	Scarlatina.	Quinsy.	Diphtheria.	Croup.
1856 . . . . .	81	4		61
1857 . . . . .	53	4		38
1858 . . . . .	105	6		69
1859 . . . . .	120	50		85
1860 . . . . .	89	115		52
1861 . . . . .	70	153		74
1862 . . . . .	103	309		35
1863 . . . . .	95	51	239	142
1864 . . . . .	350	32	162	85

General age and sex incidence of diphtheria and croup in Michigan during the twenty-five-year period, 1870-94.—In Table 3 are given the condensed results of registration for twenty-five years as regards these particulars. About 85 per cent. of all decedents from croup were under five years of age, and about 13 per cent. were aged from 5 to 9 years. The proportions at more advanced age periods were insignificant. From diphtheria a smaller percentage of deaths occurred under 5 years of age (46.3 per cent. for males, 42.1 per cent. for females), about one-third of the total deaths was at the period of 5 to 9 years,

while the period 10 to 14 showed about the same proportion of deaths from diphtheria as the preceding quinquennial period did from croup. Nearly 8 per cent. of all deaths from diphtheria were of persons over 15 years of age.

The death rates per 100,000 mean population from croup are much less than those from diphtheria at every period of age except the first (0-4); the greater concentration of deaths from croup into this period raises the rate of mortality from croup to over 50 per cent. of that from diphtheria.

As regards sex, the marked distinction will be noted that croup causes more deaths of males, diphtheria more deaths of females. Comparing the death rates at each age period by sex (and thus eliminating the unequal distribution of the sexes in the population, which would affect the results if the numbers of deaths of each sex were only compared), we find that the proportion of death rates of males is higher than that of females for croup at all ages and during the quinquennial age periods, 0-4, 5-9, 15-19. For the period 10 to 14 a lower rate appears for males, while for ages over 20 years the rates are equal. There were only 102 deaths returned from croup over 10 years of age, so that the proportions above the first two periods of age should probably be rejected from insufficiency of data. Except for the first five-year period, during which the death rates of each sex are nearly the same, with a slight excess of males, diphtheria shows a markedly greater fatality among females. From 5 to 9 years of age about eighteen males die for every twenty females; from 10 to 19 about seventeen males to every twenty females, and above 20 years of age the disproportion is still greater, being at the rate of only about thirteen males to twenty females.

In both age and sex incidence, membranous croup is seen to occupy an intermediate position between croup, returned only as such, and diphtheria. Contrary to what might have been expected, the proportions, both by sex and age, appear to stand in somewhat closer relation to those of croup than to those recorded for diphtheria. It is therefore obvious that in the statistic treatment of deaths returned from "membranous croup," consolidation with croup is more desirable than consolidation with diphtheria, provided the apparent distinction between these two latter forms of return is to be maintained. This position leaves open the question as to whether all deaths from croup are not largely diphtheritic, the peculiar age and sex incidence of the former being due to clinical distinctions not borne out by bacteriologic criteria.

In any case, from the small number of deaths reported from membranous croup, we shall be justified in neglecting this item, and referring chiefly to the deaths reported as croup and diphtheria in the following comparisons. Also, for convenience, the series of five consecutive quinquennial periods from 1870 to 1894 is generally employed rather than single years. Rates of the average deaths in each period, carefully computed from the mean population, are used, not the means of the annual rates. Since only .4 per cent. of decedents from croup were over 20 years of age, and only about 3.5 per cent. of those from diphtheria exceeded 20 years, we shall be justified in grouping all decedents aged 20 years or over together, analysis by quinquennial periods of age being confined to decedents under 20 years of age.

We accordingly have four consecutive five-year periods, viz., 0-4, 5-9, 10-14, and 15-19, the study of which is practically exhaustive for the causes of death under consideration. Indeed, it will be found that so few deaths are reported for croup above the age of 10 years, that only the data referring to the first two quinquennial periods are of value in the discussion of this disease.

TABLE 3.—Showing, for the twenty-five-year period, 1870-94, in Michigan: 1. the percentage of deaths, by sex, at certain periods of age, as returned from croup, membranous croup and diphtheria; 2. the death rates per 100,000 population of same age and sex from each disease; 3. the ratios of death rates of males to death rates of females at each period of age.

*Sex incidence of diphtheria and of croup by years and quinquennial periods.*—Sex incidence at all ages is shown in Table 4 for diphtheria, croup and membranous croup. Individual years are given as well as the results for quinquennial periods. With the exception of a single year, 1873, the death rates of males from diphtheria are lower than those of females; with five exceptions, 1874, 1884, 1889, 1893 and 1894, the contrary is true for croup. From the small numbers involved, the relations of the mortality of the sexes from membranous croup may be expected to present less uniformity, but on the whole the death rates of males are greater, as with croup reported without further specification.

In the last two columns of this table the ratios of death rates of males to death rates of females from diphtheria and from croup are stated, the death rates of the females being taken as a basis (100.0 per cent.) in each case. This form of expression, which eliminates the error incident to comparison of deaths of males and deaths of females as returned without allowance for relative numbers of each sex in the population, will also be used in Table 5 for comparing the relative mortality of the sexes from each disease at the different age periods. It will be called, for convenience of reference, the *relative male mortality*. (See upper part of diagram.)

The relative male mortality from croup was slightly higher during the last quinquennial period than during the first; it rose rapidly from 1870-74 to 1875-79, declined nearly as quickly as it rose for the next two periods, and rose again from 1885-89 to 1890-94. The relative male mortality from diphtheria fell slightly from 1870-74 to 1875-79, but has risen since that time. It must be remembered that these statements refer solely to the quinquennial periods as a whole; within these periods are many minor oscillations in the opposite direction to that of the general tendency of the ratios.

By age periods, it will be noted that the curve of croup, 0-4, corresponds very closely to the relative male mortality of croup at all ages, as should evidently be the case, since about 85 per cent. of all decedents from croup were under 5 years of age. The relative male mortality of decedents from croup aged 5-9 may be said to exaggerate the variations of the group 0-5, rising and sinking more rapidly than the latter, but moving in the same general direction.

The relative male mortality of diphtheria for the two periods, 5-9, 10-14, corresponds closely to the relative male mortality of diphtheria at all ages. That of decedents under 5 years of age moves in the opposite direction to that of the two following periods, but on the whole shows little variation. The age period, 15-19, as is generally the case when the aggregate number of deaths is becoming too small for reliable inferences, shows the most violent changes. The relative male mortality from diphtheria between the ages of 15 and 19, during the period 1885-89, exceeded the relative male mortality from croup at any age, something quite the reverse of the usual experience.

TABLE 4.—Death rates by sex, from diphtheria, membranous croup and croup, as returned in Michigan for each of the years, 1870-94; with rates for the quinquennial periods included, and for the twenty-five-year period. Also per cent. of death rates of males from diphtheria and from croup to corresponding death rates of females.

Years and periods.	Death rates per 100,000 population, by sex.						Per cent. of death rates of males to death rates of females.

*Age incidence of diphtheria and of croup by quinquennial periods.*—In the first part of Table 5 the ratios of deaths by sex, to total deaths at all ages from diphtheria and from croup are shown, for each of the quinquennial age periods studied, at each of the five-year periods of registration lying between 1870 and 1894. (See second part of diagram.) It will be observed that the lines representing the sexes are nearly parallel, thus showing that the influence exerted by the factor of sex at each age period is very nearly constant. The only exceptions to this rule are croup, 0-4, for the period 1875-79, and diphtheria, 5-9, during the last quinquennial period of registration, 1890-94.

The ratio of mortality from croup under 5 years of age to total mortality from croup at all ages is nearly double that from diphtheria at the same or at any other age period. Its course is nearly uniform, and averages about 85 per cent. for both sexes.

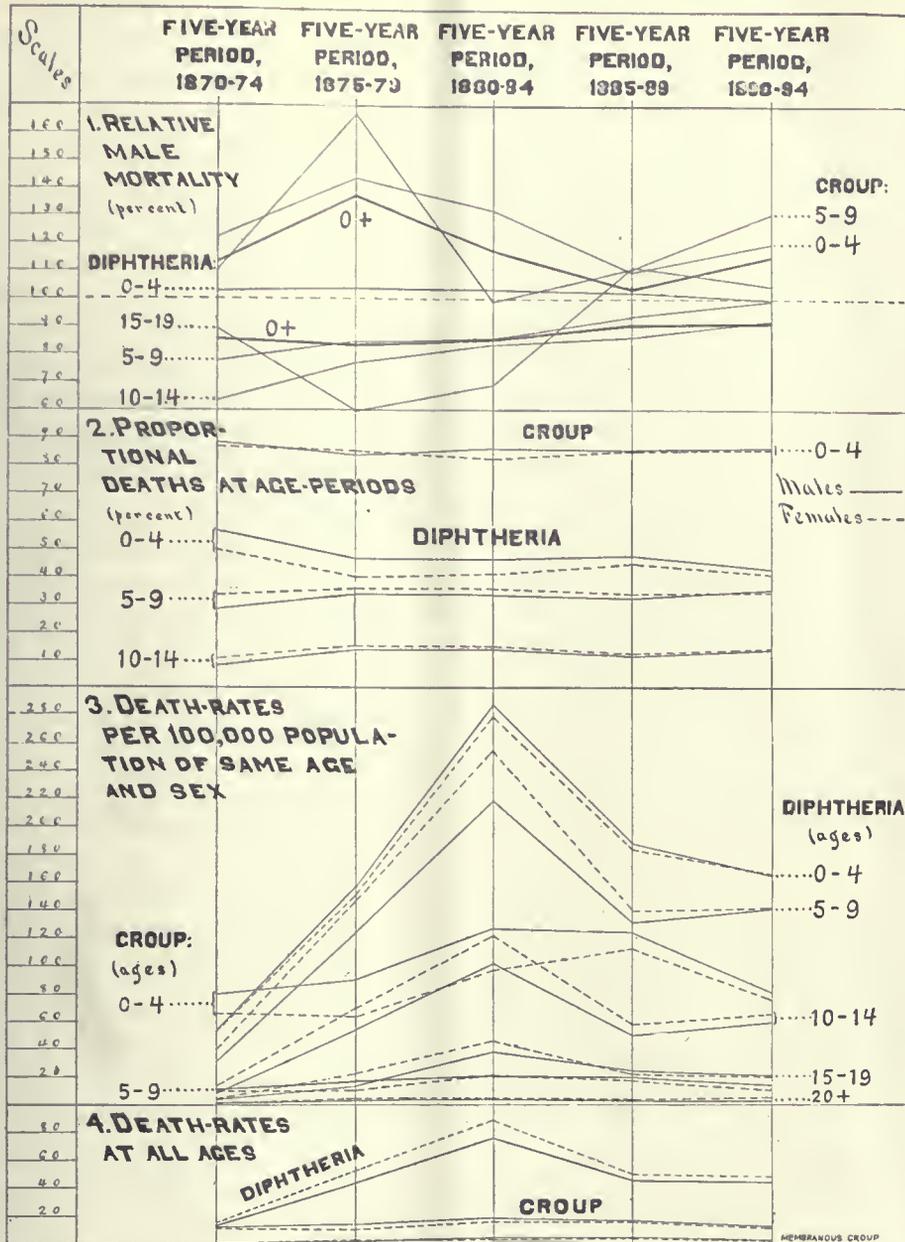

The curves representing the proportional mortality from diphtheria at the periods 5-9 and 10-14 are nearly parallel, and show a slight increase between the two most recent quinquennial periods. Both rose from 1870-74 to 1875-79, continued nearly stationary from 1875-79 to 1880-84, and declined together from 1880-84 to 1885-89. It is evident that the curve representing the proportional mortality from diphtheria in children under 5 years of age must exhibit changes of a compensatory character, that is to say, as appears after examination of the figures, the ratio of decedents from diphtheria aged 0-4 fell from 1870-74 to 1875-79, remained nearly stationary from 1875-79 to 1880-84, rose from 1880-84 to 1885-89, and fell again from 1885-89 to 1890-94.

TABLE 5.—Showing, by sex, the proportional deaths, death rates per 100,000 like population and ratios of death rates of males to death rates of females, at certain periods of age, from diphtheria and from croup, according to the returns in Michigan during five quinquennial periods, 1870-94.

*Relations of age and sex incidence of diphtheria and croup to their epidemic prevalence in Michigan.*—Having considered separately the principal features of the changes in age incidence and sex incidence of diphtheria and of croup as manifested in the statistics of successive quinquennial periods of years, it will be

GRAPHIC ANALYSIS OF MORTALITY IN MICHIGAN AS RETURNED FROM DIPHTHERIA AND FROM CROUP, BY QUINQUENNIAL PERIODS, 1870-94, WITH REFERENCE TO AGE AND SEX INCIDENCE.

NOTE.—Males are indicated by a continuous line, —————, and females by broken line, - - - - - , in all cases. Ages are both inclusive: thus 0-4 represents the five-year group aged under 5; 0+ represents all ages, etc. Beginning at the lower part of the diagram (4), death rates at all ages per 100,000 population are shown for each cause of death. These rates are further analyzed by age-periods in the part above (3), and the relations indicated in this portion of the diagram are more clearly shown with reference to sex and periods of age in parts 1 and 2 respectively. In part 1 the basis of comparison is female mortality (death-rate) taken as 100 per cent.

of interest to see what relations these changes bear to the variations in the death rates. For this purpose the death rates from diphtheria and from croup at the most important periods of age, and from diphtheria, croup, and membranous croup at all ages, are represented in the diagram, by sex, and may be directly compared with the curves showing relative male mortality from each disease at specified age-periods, and with the curves showing the per cents of deaths at each period of age.

The death rates per 100,000 population according to the returns are, of course, too low in their absolute values for purposes of comparison with corresponding

statistics of States or countries having accurate systems of registration; for this reason a supplementary scale making an estimated correction (addition) of 60 per cent. might properly have been added to the diagram on the hypothesis that the percentage of deficiency for these diseases, and for the several age periods included in them, is substantially the same as the estimated percentage of deficiency in the returns of deaths from all causes and at all ages. So far as the variations in mortality are concerned, ratios of the sexes, etc., the figures represented in the diagram are probably perfectly comparable among themselves, without correction. A constant error in statistic

data, affecting various elements uniformly, may be entirely disregarded for purposes of intrinsic comparison.

A characteristic feature of the curves representing the death rates from diphtheria is the high mortality for the period 1880-84. In the statement by single years (Table 2) it will be seen that the maximum year was 1881, the great epidemic year for diphtheria in Michigan, for which year the number of deaths registered from this cause (2,063) was greater than from any other cause of death, even consumption (1,954) being exceeded. The rise from the first period of registration, 1870-74, to the period 1875-79, and from the latter the period of maximum prevalence, 1880-84, was very rapid, being especially so for children at the age periods 0-4, 5-9. From 1880-84 the death rate as a whole declined, somewhat faster than it rose, to the next period, 1885-89, and continued nearly stationary from that to the present time. The ages 5-9 and 10-14 showed a somewhat more rapid decline from 1880-84 to 1885-89 than other ages, and have somewhat increased since 1885-89.

In marked contrast with diphtheria is the uniform and moderate course of croup. A slight amount of variation may, however, be noted, which is mostly in the same direction as the variations of diphtheria for the same time. Taking the age period 0-4 as especially characteristic, we see that croup increased very slightly from 1870-74 to 1875-79; somewhat more rapidly, but not at all approaching the virulence of diphtheria at this period, from 1875-79 to 1880-84; and, instead of rapidly declining like diphtheria, remained nearly stationary from 1880-84 to 1885-89. From 1885-89 to 1890-94 the death rate from croup has diminished.

The relative male mortality from croup appears to sustain a somewhat inverse relation to the general movement of the mortality from that disease. Taking the period 0-4 years of age as typical, the relative male mortality rose noticeably from 1870-74 to 1875-79 while the death rate increased in less degree; from 1875-79 to 1880-84 and 1885-89, the relative male mortality decreased while the death rate increased; from 1885-89 to 1890-94, the relative male mortality again rose while the death rate fell to about the same extent. Nothing very definite appears in regard to the proportional deaths from croup at this age, since the curves representing the ratios of male and female decedents move in opposite directions, and nearly neutralize each other.

The regular and nearly uniform rise of the relative male mortality of diphtheria at all ages, especially at the ages 5-9, 10-14, and the slight decline in the relative male mortality of decedents under 5 years of age, when compared with the very similar mortality curves at all of these ages would seem to indicate that sex has not been an appreciable factor in the epidemic history of the disease; that is to say, variations in the extension and fatality of diphtheria have not been attended with simultaneous special increase of mortality in one sex. The change in sex incidence seems to be a general one, advancing throughout the entire history of the disease, as included in the quarter century of statistics, in a determinate direction, and perhaps dependent upon some general social change or development in the treatment of male or female children.

Age incidence, unlike sex incidence, appears to sustain a certain relation to the degree of epidemic

prevalence of diphtheria. This relation is direct for the age periods 5-9, 10-14, and inverse for the period 0-4. That is to say, when an increase in the general mortality from diphtheria and croup occurs, there is an increased percentage of deaths of children over 5 years of age and a decreased percentage of deaths of children under 5 years of age, as compared with the total mortality.

Dr. H. B. Baker, in a report to the Michigan State Board of Health on "The Present Comparative Immunity of Adults from Diphtheria," found that "when the reported deaths from diphtheria are over five-tenths of one death per thousand inhabitants, the average per cent. of diphtheria decedents over ten years of age is 22.55, and when the reported deaths from diphtheria are less than five-tenths of one death per thousand inhabitants, the average per cent. of diphtheria decedents over ten years of age is 19.27." This observation covered the statistics of Michigan during twenty-one years, 1868-88, for which period the mean per cent. of diphtheria decedents aged over ten years was 20.68.<sup>9</sup>

Mr. Arthur Shirley, President of the Epidemiological Society, makes the following statements in regard to the changes in age incidence in England and Wales:<sup>10</sup>

"There has been throughout England and Wales relating to the diphtheria mortality at all ages a considerably augmented incidence of the disease upon the population aged above 3 and under 10 years in the decennium 1871-80, compared with that in the decennium immediately preceding. And in the case of England and Wales as a whole, that increase has been maintained throughout the succeeding decennium 1881-90.

"When croup and diphtheria are taken together it is found that in both the periods 1871-80 and 1881-90 there was a relative increase of the disease at school ages (3 to 10) as compared with 1861-70."

Diphtheria declined in England and Wales from 1861-70 to 1871-80, and rose from 1871-80 to 1881-90. Between the two latter periods, therefore, the variation agrees with the tendency in Michigan, but the increased age incidence at older ages from 1861-70 to 1871-80, with a decreasing death rate, differs from the observation in this State. It is possible that the difference in the exact age periods taken may in part cause this discrepancy; and that it may be due, in part, to the increased proportion of children exposed at school in England under the Education act, which went into operation in 1870.

*General conclusions.*—It may be well to summarize the principal indications, statistic and otherwise, which may be drawn from the study of these statistics and which are clearly shown in the accompanying diagram. It is understood that such general conclusions have reference entirely to the history of the disease in Michigan, and are of wider application only so far as confirmed by the study of the statistics of other States and countries. As there are no other statistics, however, for any State west of New England embracing the time included in the Michigan statistics, together with statements of ages of decedents from individual causes of deaths, the results presented

<sup>9</sup> Rep. Mich. State Board of Health, 1891, p. xx.

<sup>10</sup> Quoted by Edward Seaton, M.D., in a "Report on the Present State of Knowledge Respecting the Etiology and Prevention of Diphtheria," presented on behalf of the English Committee at the Eighth International Congress of Hygiene and Demography, Budapest, 1894. British Medical Journal, Sept. 15, 1894.

in the Michigan Registration Reports will ever remain the only exact history of the course of diphtheria over any State area in the Western part of the United States during the onset and most fatal period of prevalence of the great epidemic, and as such are deserving of special study.

1. Statistically, the line of demarcation between diphtheria and croup is clearly defined. Their age incidence, their sex incidence, and, I might add, although the subject has not been studied in the present paper, their monthly and seasonal prevalence are distinct. This statistic difference is the expression of an equally well-marked clinical distinction. Even though bacteriology should decide with more certain voice than at present, that diphtheria and (nearly all) croup are identical, would it not still be advisable to keep separate the statistics of such a definitely distinguished portion of the diphtheria returns as are the deaths from "croup?" And if not the mere presence, but the predominance, of the Klebs-Löffler bacillus shall come in future to be the distinguishing characteristic of true diphtheria, statisticians may awake to the fact that a great mistake has been committed in confusing the statistics of two diseases.

2. If the statistic distinction between diphtheria and croup be maintained, the return of "membranous croup," providing it be not given a separate place as in the Michigan reports, belongs rather to croup than to diphtheria.

3. The fact that the death rates are higher for males under 5 years of age from diphtheria, and that after that age the mortality of females from this disease is greater, is of interest, and accords with English observation. From this change in the relative mortalities, it would seem possible to derive therapeutic or prophylactic suggestions of value. What is there in the conditions attending the development of girls after the fifth year that is more favorable to fatality from diphtheria? They start out with a relative immunity, the death rate of female children under 5 years being markedly lower than that of male children at that age. Why does not this relation persist, and what causes the disease to bear more heavily upon girls than boys at the usual school age?

This question is discussed by Dr. T. W. Thompson in the article on "The Natural History of Infectious Diseases," *Stevenson and Murphy's Hygiene*, vol. ii. p. 298, but the reasons given are not intended to be considered conclusive. As embodying further the opinions of Dr. Downes and Dr. Thorne Thorne, I present his remarks in full:

"The excess of female mortality, at certain ages, at least, is no doubt largely due to greater exposure to infection—that is, to the closer and more continuous contact with the sick to which females are exposed as compared with males; but Dr. Arthur Downes has pointed to the very early ages at which the excess of female mortality is discernible as perhaps indicating that some further explanation is required. As regards this, Dr. Thorne remarks that 'the excess of diphtheria death which attaches to females over males from 3 to 15 years of age, increases precisely as the age advances which fits them more and more to take some share in the care of home, and of relations during the periods of sickness.' And he further remarks that 'something may depend upon the full significance of the term 'domesticity,' and upon its taking account of those acts of affection and tenderness which, in

their relation to the sick characterize females during the period of girlhood, as well as in mature womanhood.' Both these considerations are deserving of considerable weight, especially as regards a disease such as diphtheria, in the dissemination of which close contact is known to play a conspicuous part; but it still appears to remain doubtful whether increased exposure to infection can be regarded as entirely accounting for the excess of female mortality, especially in the very early years of life."

It is probable that the greater docility, affectionateness and domesticity of girls render their share of the mortality from diphtheria greater than that of boys. A larger proportion of girls may be found in regular school attendance, owing to less temptation to truancy and less liability to employment during school age. Among children girls tend, as a rule, to come into more intimate personal contact with one another. Boys naturally isolate themselves after an early age, and repulse kisses, embraces and other demonstrations of affection, as unbecoming the manly character. Besides boys indulge much more persistently in outdoor sports and occupations, and thus "toughen" themselves to resist the initial lesions of the mucous membranes, resulting, perhaps, from atmospheric irritation, which often afford a point of entrance for the diphtheria germ. Speaking of croup, but with equal application to diphtheria, Hirsch remarks:<sup>9</sup>

"Something wrong in the upbringing of the family, particularly in the way of too much tenderness and coddling, has been the real cause of the family liability. The susceptibility which predisposes to this disease would seem to be bred in those children who are kept most from the effects of the weather, sheltered from every wind, and during the cold season anxiously detained whole days and even weeks indoors, and that too, in heated and not always well-ventilated nurseries."

Whatever the cause of the greater relative female mortality from diphtheria above the age of five years, it is a cause that has been undergoing progressive amelioration during nearly the whole history of the disease in Michigan. Should the change continue at approximately the same rate, the relative death rates of the sexes will become nearly the same after the lapse of a few years. Does this indicate that the "new woman" of the future is already foreshadowed in a more masculine type of education for girlhood? At least, then, one favorable result will have to be placed to the credit of the female renaissance, if it tends to prevent diphtheria.

4. The increased proportion of mortality at ages over five years coincident with a general increased prevalence of diphtheria, has already been sufficiently pointed out. Facts of this class have an important bearing upon our knowledge of immunity, and the self-limitation of infectious diseases, but the limits of the present paper preclude any special reference to this subject.

5. Incidentally the importance of stating death rates from diphtheria and from croup in the terms of the susceptible population has been suggested. It is only in this way that the real prevalence of these diseases in countries or States with various age-distributions of population can be accurately compared. For diphtheria the number of inhabitants under 15 years of age, or if this basis were not generally obtainable,

<sup>9</sup> Handbook of Geographical and Historical Pathology, iii, 65.

the number under the age of 21 years, would give fairly accurate results; for croup, the rates should be based on the population under five years of age. In the same way that the standard distribution of ages suggested by Kőrösi has been adopted by the International Statistical Institute for the computation of mortality indices, instead of the unreliable death rates, for international comparisons, so should certain standard ages be selected as bases for stating all mortality rates of children's diseases; and whenever a higher mortality is shown to belong to either sex, the standard population should be stated by sex.

6. Lastly, if this paper has any predominant purpose, it is to emphasize the necessity of statistic study of diseases, and to maintain that clear-cut statistic distinctions are equally cogent with clinical or bacteriologic arguments in determining nosologic classifications. Statistics may be likened to the brake that serves to restrain the plunges of the wild horses of medical theorizing, and prevent their dragging the car of true medical science through devious ways, and to final wreck amidst a chaos of unsupported opinions. It may not be the noblest office, but it is a necessary one; and a knowledge of statistic technique should be regarded as a fundamental part of the equipment of the medical reasoner just as fully as equipment in chemic, bacteriologic, pathologic and clinical methods is deemed essential at present. Vital statistics is historically and practically the basis of an enlightened sanitary science. The statistic pictures are to be considered, in their place, equally with the clinical pictures in making up our concepts of diseases; yet from the paucity of data, especially in this country, this is very seldom done. There are very few medical colleges in the United States that give any systematic instruction in the treatment of medical statistics. The hope for the improvement of this condition lies in the spreading of a higher opinion of the services of the medical statistician among the ranks of the profession at large, and through the profession to the people. As a result of such enlightenment, accurate systems of registration will gradually come into existence in this country in all of the states whose density of population and advanced civilization may warrant them; medical schools will adequately treat the subject in their curricula, and health officers, graduated therefrom, will be able to make intelligent practical use of registration data in limiting and preventing the spread of disease; finally a vast body of the most essential facts concerning the constitution and destiny of our people will be accumulated, whose full import, vast, social significance, and practical beneficence can not be estimated in advance, but, judging from the triumphs of sanitary science based upon an exact knowledge of vital statistics in the past, will prove a potent factor in the elevation of the human race.

### PREVENTIVE MEDICINE IN APOPLEXY.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY EPHRAIM CUTTER, LL.D., M.D.

HARVARD, 1856; UNIVERSITY OF PENNSYLVANIA, 1857.  
NEW YORK.

Presuming that the Section I have the honor to address is a board of medical police whose business it is to detect the pre-stages of diseases and to procure their prevention, if not their birth, the subject is then

legitimately up for thought and has an ever-present living importance. The press rarely appears without some reference to apoplexy. To-day it is Baron de Hirsch's death cabled across the Atlantic in thousands of words and eagerly read by the public who love and appreciate such wealthy nature's noblemen. The press also, with the confidence conferred by its position, affirms that champagne freely drank caused his apoplexy within a few hours. But it must have had pre-stages longer than these few hours. This idea was expressed by the late Dr. F. A. Sawyer, Vice-President Massachusetts Medical Society, who told his son that his death would be from apoplexy, as it was. My cousin, the late Dr. Calvin Cutter, author of Cutter's Physiologies, after he had experienced apoplexy accurately predicted to his son, Dr. J. Clarence Cutter, the two succeeding "strokes" he should sustain and that he would die from the third and last, which he did. If I am correctly informed, Prof. Joseph Jones, M.D., LL.D., late member of our ASSOCIATION, and one of the brightest medical lights of the South, if not of the age, died from apoplexy. So also died Job S. Crane of New Jersey, another A. M. A. member whose character was like pure gold, and whose presence in our meetings has added the charms of delightful friendship and genial personality in the past. If they do these things in a green tree what shall be done in the dry? If such medical men are destroyed what will be done with the laity? The high esteem of these distinguished gentlemen impels me to tell what I know personally about their disease as a grateful tribute to the loveliness and glory of their characters.

*What is Apoplexy Clinically and Conventionally?*  
—It means "sudden loss or diminution of sensation and power of voluntary motion, usually resulting from inter-cranial hemorrhage." Simple or nervous apoplexy is where no lesion is discovered. Reference is here confined to apoplexy from clot or serum pressure on or in the cerebral substance or ventricles. The chief agency lies in the rupture of an artery, usually the basilar. No rupture, no apoplexy. A normal artery will not rupture with ordinary or extraordinary heart pressure. It must be weakened beforehand. Or, in other words, there is a *weakening of the artery before it ruptures*.

This weakening is not due to violence of puncture by a weapon; we are not considering traumatic cases. For years it has been taught and it has been found true that this weakening comes from a substitution of the circular muscular fibers of the arteries and of the fibrous coats of capillaries, sometimes by fats or fat acids, as oil, cholesterin, lardacein, stearin and margerin, with gravelly matters as atheroma, etc. The fats have not the tensile strength of muscular and fibrous tissues and hence the damage comes the moment the artery is not strong enough to resist the arterial pressure, normal or abnormal. Indeed, the artery becomes fragile like a worn-out rubber hose, which gives out where the interstitial molecular changes of the mechanical mixture of rubber and sulphur are most rapid.

*The Clinical Lesion is the Fatty Degeneration.*—The results of the clot pressure vary from instant death to protracted paralysis more or less complete as the site of hemorrhage is nearer to or more remote from vital nerve centers. *Hemorrhagic apoplexy, then, is merely a masquerade and local manifestation of fatty degeneration in the cerebral arteries and*

this is the line on which our medical police have to work.

*Clues Macroscopic, i. e., with Unaided Observation.*—1, 50 years of age and over, though apoplexy sometimes comes in younger persons from severe sickness or bodily abuse by food, drink and otherwise; 2, arcus senilis; 3, cataract; 4, amaurosis; 5, apoplexy of retina; 6, obesity, though strictly speaking it is not a fatty degeneration; it is an abnormal accumulation in normal localities; 7, waxy and lardaceous countenance; 8, edema or thickening of eyelids; 9, hebetude; 10, neuralgia sometimes; tic douloureux; 11, muscular weakness; 12, flabbiness of tissues; 13, atheromatous radial and temporal arteries; 14, senile gangrene; 15, defective vision; 16, the urine shows albumin; often necessary to examine seven specimens from voidings of seven successive days; 17, glaucoma.

*Clues Microscopic.*—1, casts of kidney, tubes; 2, fatty epithelia; 3, amyloid bodies in blood and urine; 4, free oil in blood and urine; 5, pigments blue, bronze, anilin blue, emerald green in urine and blood. 6, fat globules in leucocytes; 7, cholesterin in blood (credit should be given Dr. Jas. H. Salisbury for first noting 3, 4, 6 and 7 in his writings); 8, protoplasmic, filamentous or Indian club catarrh, one or all alternating with albumin, casts and fatty epithelia. This catarrh is very common in neurasthenia and should not be overlooked. A recent case under my son's care had been diagnosticated gout because of painful shoulder by another physician. Use on urine work for above clues, first, a good inch objective. All clues are not present in every case.

*Causes General.*—1, impeded or retarded languid functions; 2, fat food in excess; 3, carbohydrate foods in excess, producing paralyzing gasses by fermentation in alimentary canal; 4, want of exercise; 5, old age; 6, disuse of organs; 7, lack of motions and emotions; 8, abnormal metabolism or transformation (Dunghlison); 9, loss of vital force or dynamos by work or pleasure, etc.

*The general prophylactic treatment is to stop causes, restore normal metabolism, fully sustain nature and then she will restore healthy in place of fattily degenerated tissues.*

*Particular Treatment.*—1, restore languid, impeded or retarded function by removing all mechanical, physiologic, chemic or pathologic restraints; 2, avoid fat foods; 3, avoid carbohydrates including alcohol entirely till signs are gone, and thus stop the gases which paralyze parts near and remote, thereby impeding the functions of life. Dr. Joseph Jones, in 1856, reported through the Smithsonian Institute that carnivorous turtles fed on parsley had fatty degeneration. Sir B. W. Richardson of London and S. Weir Mitchell of Philadelphia produced cataracts in ten minutes by injecting under the skin of a guinea pig or a frog 1 dram of a saturated watery solution of sugar. 4, exercise in some labor that has the psychologic stimulus of doing good to others; work is healthy. 5, avoid premature old age. Obliteration of the caliber of arteries, more or less complete, by peripheral deposits usually of a calcareous, atheromatous character, blocks in the aged the circulation of blood, osmosis, secretion, etc. But there is no reason for having old age come prematurely and people should live longer than they do now. In olden times there were some 900 years old, showing what the human race is capable of! 6, organs should be used as far as possible consistent with common sense. Unused horses, overfed, fattily degenerate in muscles.

7, when the list of motions and emotions that the limited knowledge of the writer can trace in normal human life reaches forty-three in number, it is plain that life is made up of motions and that it is important these motions should be normal. If they are languid one indication is to quicken them by forms of motion biologically penetrating. Music is one such form of harmonious motion now proved by Dogiel of Kazan, Russia, to dilate the capillaries, increase the flow of blood, remove congestions, calm the nervous system revive memory, promote excretion of carbonic acid from the lungs, promote digestion and confer vital force. Hence music means much good to those predisposed to apoplexy and should be had by them either as listeners or performers. The Hon. J. G. Blaine, in his final fatty ills, is said to have allowed hand-organ music under his windows. The late Czar of Russia, it is said, in his last illness had the trombone played at midnight. There was good reason for this. Electricity (specially the *galvanic*, as Althaus says that the *induced will of itself produce fatty degeneration of the muscles*) is an effective form of motion, biologically penetrating. Hence the favorable use of galvanism in fibroids—the writer has seen cases standing cured for twenty-one years. Fibroids, probably, are caused by impeded or hindered functions as fatty ills are. On this principle galvanic electricity is useful in the pre-apoplectic. Trolley car rides do good also, by the induced electricity.

8, Normal *transformation* or the laying down and taking up of tissues all the time going on—or *metabolism*, if the Greek word is preferred, is aided greatly by drinking distilled hot water one hour before meals and on going to bed. It may be taken cold, not iced, as there is no easier way of retarding or impeding functions than by a temperature below 32 degrees F. One argument is, as there must be from 100,000 miles or more of capillaries in an average human adult, it follows that in normal conditions there must be considerable force expended to maintain the blood circulation and all the functions dependent upon normal circulations. Now, if this capillary circulation is impeded by lack of water in the system (which is too generally the case) the way to relieve it is to supply more water. Spring waters heavily charged with salts are interdicted. They produce evil by blocking. *Again*, the drinking of hot water washes out the stomach of slime and yeast, promotes peristalsis, carries off undigested and unfermented foods and thus removes the gases which are causes of apoplexy. In this clinical light, flatulence, which is tabooed by society ethics everywhere, is a means of relief. Pre-apoplectics would, there is evidence to believe, prolong their lives by allowing flatulence to have free evacuations. Hot water and sometimes cold wonderfully promotes beneficial flatulence by causing the unstriped muscular fibers to contract. The proper treatment to stop flatulence is by cutting off foods that ferment. Hot water also washes out the liver, kidneys, skin, keeping the primæ viæ clear of gas, wonderfully quickening retarded and impeded functions and promoting normal metabolism.

9, Loss of dynamos by work, worry or pleasure. Life is very much a question of expenditure of vital force. It takes a certain amount to "run," so to speak, the body systemic and the reserve should be used for work, worry or pleasure. If one has no reserve he is like Sam Small's steamboat that every time it blew its

whistle it stopped! Of course this is overdrawn, as stopping the body means death, immediate; but many pre-apoplectics are using so much steam to blow their whistle in work, worry or pleasure, there is not steam enough left to run the body healthily; hence a retardation and impeding of function, and hence follow fatty ill's we are considering. Allow an illustration. A woman of 65 years with an enlarged and fatty heart showed signs of pre-apoplexy. Under treatment on these principles the signs had nearly disappeared on a certain visit. The next day the free oil in the blood and the fat in the white corpuscles were greatly increased. The cause lay in a sudden removal from one room to another in her boarding house, the patient being mentally worried and tired out by the discharge of womanly duties which she would not entrust to others. On resting these signs soon diminished but did not entirely disappear. Rest is a remedy approved by all practitioners of medicine, and cures are due to rest that sometimes are credited to schools of medicine and medicinal measures. Other ways of treating loss of force are by plenty of fresh air (air is food) by a diet for pre-apoplexy of two-thirds animal to one-third vegetable food, or better by beef, mutton, lamb, whites of eggs, all suitably cooked, not raw, for animal food; wheat, rye, potatoes, sage, hominy, tapioca (celery as a relish), choosing not all but few of these foods at a meal, and watching their digestion and assimilation by the condition of the blood, feces and urine, not depending upon the patient's feelings or opinions. Force is also to be conferred in massage or the imposition of hands. The masseur must not be tired; I have known such to deplete patients of strength given them by resting and food. Massage is an old measure dating, it is said, 2,600 B. C. The blind have been masseurs from time immemorial in Japan. Force can be conferred by contact with horses riding, driving and handling. Force may be conferred by the stimulus of ideas, of well-deserved praise, by trust in God, by calmness, moderation and temperance, by not pulling oneself up by the roots daily to observe progress, by crushing out all envy, malice, hatred, by following out the golden rule; force may then be saved by not wasting what one has. These are little things. David Copperfield said when his wife was dying, "Life is the sum of little things." The successful prevention of pre-apoplexy means the intelligent study of little things, and nothing that touches the patient is too small; these are the days when the medical heavens are illuminated (?) by the lights of pathologic experts, that is, dead men's doctors. Would it not be just as well to practice medicine for the living? Text books of medicine are silent on this great subject of pre-apoplexy.

The result to be expected is that nature will restore to health the diseased cerebral arteries; space does not permit the adding of the clinical evidence of cases on which this communication is based.

## A NEW TREATMENT OF PHTHISIS.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY HUBBARD WINSLOW MITCHELL, M.D.

NEW YORK.

Pulmonary phthisis or pulmonary tuberculosis is perhaps one of the most widespread diseases to which mankind is subject. It occurs in persons of all ages

and in every country, and in all conditions of life.

While tuberculosis occurs in nearly every organ of the body, the scope of this paper is confined to that form of the disease which attacks the lungs, and that form also which is known as acute tuberculosis.

*Cause.*—The cause of phthisis pulmonalis is due to the introduction into the lungs of the microörganism known as the tubercle bacillus. The existence of this bacillus was suspected by many, but it was left for Koch to demonstrate its existence, and its invariable association with this special disease.

The tubercle bacillus is a short, fine rod, slightly bent or curved, and hence the name often applied to it of the "bent rod." Its average length is from one-half to one diameter of a red blood globule. When stained with carbohc fuchsin it assumes a bright red color and presents under the microscope a well-defined body which contains from two to five vacuoles. These vacuoles give it a sort of beaded appearance, and some observer has attributed this appearance to the presence of spores, but it is probable that these vacuoles are the nuclei of new bacilli which are formed by the fission and subdivision of the parent bacillus. It is undoubtedly the case that these bacilli multiply by a rapid subdivision of themselves.

When the bacillus is treated with anilin dye or carbohc fuchsin it stains slowly of a bright red color, and retains this color permanently after treatment with acids, and this characterizes it from all other known forms of bacteria, with possibly the exception of the bacillus of leprosy. It can be cultivated in blood serum and on the potato, most readily in the former, and the cultures must be kept at blood heat. They grow slowly and appear about the end of the second week. The colonies of bacilli form thin grayish-white masses on the surface of the culture medium, and but little is known yet of the chemie composition of the tubercle bacillus. They are found in all tubercular lesions throughout the body, and in every organ where tuberculous disease is present, but, as above stated, they will be studied solely in connection with pulmonary tuberculosis.

The bacilli multiply with great rapidity in lung tissue, and a patient suffering with pulmonary consumption discharges them in the sputum in considerable numbers. When they are so expectorated, if great care is not taken to destroy their virulence, they become a focus of danger to others wherever they are discharged, and this shows the great danger associated with the sputum of phthisis unless it is most carefully disposed of.

In the dust collected from the walls and bedsteads of hospital wards, in asylums and prisons, bacilli have been found, sometimes in great numbers, showing that in these places the sputum was carelessly distributed and new foci of infection were thus formed.

The tubercle bacillus is thus a widespread and dangerous organism in all places frequented by patients suffering from phthisis.

*Mode of infection.*—It is not altogether satisfactory to say that phthisis is hereditary. Life insurance companies reject applicants for insurance whose parents or brothers or sisters have died of phthisis, even when the applicant himself was in perfect health. How far the theory of heredity is true is a disputed question, but from my own observation and studies, I believe that the ancestors of such persons did not confer a taint sufficient to warrant his rejection.

If a woman suffering with phthisis becomes preg-

nant it is not true, certainly in many cases, that she confers a phthisical taint upon her child, and the same may be said of a man suffering with phthisis, the woman whom he impregnates can not, through the venereal act, contract the disease, so that heredity is of less value to-day, in the line of modern researches, than it formerly was.

*Contagiousness of phthisis.*—If we accept the theory that phthisis pulmonalis depends for its existence upon the introduction into the lung of the tubercle bacillus, then that microbe must be introduced from without, and from some source where the bacillus has retained its activity and virulence, and when we remember that the sputum from phthisis patients contains vast numbers of these bacilli, which are distributed widely through dust and carelessness with which the sputum is voided, it will be seen that the danger from contagion is very evident, and the acquirement of this disease by contagion directly from a patient, or indirectly through his dried sputum which is inhaled elsewhere, forms the most common source from which this disease is acquired.

It has been very justly remarked by many observers that it is important to draw a line always between hereditary and accidental tuberculosis, for cases present themselves to the practitioner that have a very incomplete history, although by careful examination a conclusion can be reached upon which we can base our opinion as to its source.

Cases have been noted where phthisis has been acquired through inoculation, as from persons washing the clothes of phthisis patients, or the bite of a tuberculous person, or inoculation from a cut or abrasion where the sputum has been brought in contact with this traumatism. The expired air from the lungs of a tuberculous patient does not convey the disease, and a person coming in close contact with the patient will not necessarily acquire the disease from his breath, but kissing a tuberculous patient will undoubtedly produce the disease in some cases.

Infection by milk, by meat, and by water and food need not be touched upon here. The danger from these sources exists and must not be lost sight of, but space prevents my speaking of them in detail.

*Influence of age.*—Tuberculosis occurs at all periods of life. It is met with in the nursing infant, as well as in those tottering upon the edge of the grave. No age is immune from the disease. In the young we find the lymphatic glands very frequently affected, while in the old, the lungs seem to be especially prone to the disease.

In my judgment, *soil and locality* play an unimportant part, and the association of other diseases is to me of less importance than has been ascribed to them.

It is interesting to note the changes produced in the pulmonary tissue from the introduction of the tubercle bacillus. When a bacillus enters the tissue of the lung, it is believed to cause in the first place a proliferation of epithelioid and giant cells, followed by an inflammatory reaction and the formation of masses which are termed tubercle, and when these tubercle masses are once formed they quickly undergo caseation. This caseation, which is undoubtedly caused by the bacillus, is a process of coagulation going on in the cells, which lose their outline, become irregular, and are finally converted into a structureless substance. The tubercle may gradually be converted into a yellowish-gray pus in

which the bacilli are abundant, and when this matter infiltrates the inflamed lung tissue it is loosened more or less by inspired air, escapes into the smaller bronchi, and finally is coughed up by the patient in the form of a thick yellowish or grayish sputum containing the bacilli in greater or less numbers.

When the bacilli are introduced into the lungs two processes may go on, the first, caseation and ulceration which is destructive and dangerous, the other, sclerosis, which is conservative and healing, and the ultimate result in a given case depends upon the capabilities of the body to restore the tissues, and limit the growth of the bacillus, or to permit the process to go on to a dangerous and finally fatal termination.

There are some cases where the bacilli are introduced into the pulmonary tissue and are for some reason destroyed at once, and in these we say sclerosis has taken place. The bacilli have gained a lodgment and have done some damage, but finally the victory is with the conservative forces of the body. In other cases the bacilli grow luxuriantly, caseation and softening occur, and victory is with the invading bacilli and a fatal result follows.

*Symptoms of pulmonary phthisis.*—After the bacillus has invaded the lung tissue, the symptoms are very soon manifest. The patient develops a cough which at first seems to be of a broncho-pneumonic type, and is marked with expectoration of a mucopurulent character. Dyspnea is a striking feature and is more or less severe. The respiration rises from twenty to fifty per minute and there is frequently cyanosis of the lips and finger-tips. The early physical signs are those of bronchitis.

Percussion teaches us but little in the early stages. On the contrary, auscultation is of the utmost importance. Rales are nearly always heard, either sibilant or sonorous, or they may be crepitant. We may, rarely, have crepitation from the presence of tubercle on the pleura. As the disease advances the rales become larger and more mucous in character, and we have a fine or coarse bubbling rale according to the intensity and extent of the disease. As the disease advances cavities may form in the lung tissue.

When the disease is confined to one lung the physical signs just described are present more or less, and the opposite lung is very frequently congested, and auscultation on that side reveals a harsh, rasping respiration.

The temperature rises sometimes as high as 103 degrees and is always a symptom of severity. The pulse is rapid and feeble in proportion to the extent and severity of the disease.

I will not touch upon the symptoms caused by the invasion of other organs by this disease. It is sufficient for this paper to deal only with the pulmonary type.

*Duration of the disease.*—Cases have been noted where the disease ran a rapid course and caused death in a few weeks. I have not myself met with cases terminating in so short a time. It is usually of a slower development and continues for a much longer period. In my own experience many months elapse before death takes place, and under the treatment which will be described later in this paper, no deaths have occurred up to this time, so that it is impossible to tell the exact duration of the disease. But without treatment of any kind the disease will terminate fatally in from four to twelve months.

*Diagnosis.*—The diagnosis of pulmonary phthisis is not difficult. The presence of cough, emaciation, night sweats, diarrhea, anorexia, thirst and general anemia, are nearly always present and point to the nature of the difficulty. But the unfailing test in the diagnosis is the presence of the bacillus in the sputum. As it is believed that this microorganism is the direct cause of phthisis, its presence is proof positive that the disease is pulmonary tuberculosis. If the sputum contains no bacilli, then the disease is not pulmonary tuberculosis *per se*.

It is not necessary here to touch upon the morbid anatomy of the disease, nor of the many lesser symptoms which are present in any given case, nor is it necessary to divide the disease into clinical groups, as some writers have done. This paper deals with pulmonary phthisis induced by the bacilli reaching the lung through the bronchi, termed by some writers "inhalation tuberculosis," the ulcerative tuberculosis which we are now considering.

*Prognosis.*—The prognosis of pulmonary phthisis, when not modified by treatment, is extremely fatal. Various percentages of death are given, and while these percentages differ with many writers, and perhaps no accurate percentage can be given, it is true, as every practitioner will testify, that the death rate is extremely high.

The mode of death may be by asthenia, or gradual failing of strength. Here the end is usually peaceful and quiet, disturbed perhaps by cough, but rarely by pain, and consciousness often is retained until near the end. Or by asphyxia. This occurs in the acute cases which run a rapid course, but rarely in the chronic, even of great severity. Syncope is also a mode of death, but not common. It occurs when patients in a very advanced stage of the disease insist upon going about, and if organic cardiac disease be present, as it often is, then syncope may occur.

Hemorrhage also may be a mode of death in chronic phthisis, and is due to the erosion and rupture of a large blood vessel or of an aneurysm in a pulmonary cavity. Coma may occur, due to meningitis, but this I believe is rare.

The most common mode of death is by asthenia, where the vital powers slowly succumb to the onslaughts of the disease.

*Treatment.*—The treatment of pulmonary phthisis is the special point to which I desire to call attention.

About three years ago I began to experiment in my private laboratory with a group of chemic salts known as the halogen group, and I found that these salts, when combined in definite proportions, formed a fluid having remarkable antiseptic powers. To this group I subsequently added the hypochlorites of sodium and potassium, as will be seen in the formula below. The resultant fluid was a chemic combination of the above named salts, and for want of a better name has been called after me, namely, "Mitchell's Fluid." It is with some diffidence that I use this name, but no better one appears to be available, and I will in this paper term it "fluid."

I first used the "fluid" in a large number of cases of ulcerative and suppurative processes occurring upon the external surface of the body, and through the courtesy of Drs. Taylor, Sturgis, Phelps, McGuire, Burchard, and the very able house staff at Charity Hospital, in the wards of which I was allowed to experiment freely, I obtained satisfactory results in ulcers of a syphilitic, traumatic and varicose nature,

and in many of the lesions of syphilis and chancreoid, the sores were healed in a very short time.

I conducted these experiments through a period of two years, treating 375 cases. I also used the "fluid" extensively in my own private practice, but up to this point it had been used externally only.

It occurred to me that if the "fluid" acted so well upon the outside of the body, it might be that it would act well upon phthisis, which is an ulcerative process in the lung tissue due to the presence of the tubercle bacilli, if the "fluid" could be brought in contact with the lung tissue, and I reasoned thus:

As the gastric juice is of hydrochloric acid reaction, and this "fluid" being of the same reaction, I thought if it could be introduced into the stomach when that organ was perfectly empty, it might be carried by the blood into the lung and there modify the course of the disease, and perhaps destroy the bacillus. This reasoning was acted upon immediately and with flattering success.

My first case was that of a young man 21 years old, who had a cavity in his right lung. He had had hemorrhages weekly of considerable severity, and when I first saw him he raised blood at each effort of coughing. His sputum contained pus cells and the characteristic bacilli. He had night sweats, anorexia, loss of flesh, and began to show the signs of phthisis cachexia.

I gave him the "fluid" in 2 dram doses, always on an empty stomach, that is, half an hour before each meal, and at bed time. The "fluid" was given full strength; no other remedy was employed. His diet was ordered to be rich and nutritious. Treatment was begun on June 1, 1894. On the third day his night sweats ceased, he stopped spitting blood and immediately his cough began to lessen. The treatment was continued steadily, and on July 31 his sputum contained few bacilli and few pus cells, and his general symptoms were much improved. On October 1, auscultation showed the lung had healed, and the sputum was free from bacilli and pus cells. He was completely cured.

I immediately selected eight cases, all women and all having the typical symptoms of phthisis pulmonalis. The treatment was the same as in the first case, and in periods varying from four to seven months they all recovered.

At this time I have in my private practice 130 cases of true phthisis pulmonalis. In every case there are present all the characteristic symptoms. Forty of these are now practically well, and this opinion is based upon the fact that the sputum is entirely free from bacilli and pus cells. Thirty of the above 130 cases are absolutely hopeless. The destruction of the lung tissue is too extensive to be restored, yet severe as they are, all of the symptoms are considerably modified. The diarrhea which so often accompanies severe cases is quickly checked, the night sweats cease, and very soon the respiration becomes more normal, and a degree of comfort given which was not hoped for, and when death comes, it will come largely robbed of its terrors through an amelioration of these distressing symptoms.

The remaining sixty cases, while they are all severe, I have every reason to believe that most of them will ultimately recover.

*Treatment in detail.*—I give the "fluid" in from 2 to 3 dram doses, clear, four times daily, always upon an empty stomach. This is absolutely a *sine qua non*.

I use a glass to measure the fluid, not a metal spoon. In all cases whisky is given, 1 to 2 ounces at a dose, two to three times per day.

The cough is somewhat lessened by adding essence of peppermint to the whisky in the proportion of half a dram to each dose. The diet must be nutritious and liberal.

In every case of phthisis in my practice the sputum is examined once in ten days or two weeks. These examinations are made by Dr. John Hoch of this city. His method of examining the sputum is as follows:

He stains the fresh sputum with carbohc fuchsin and methylene blue; the former stains the bacilli of a bright red, while the pus cells and other ingredients of the sputum are stained blue by the methylenè. The sputum thus stained is mounted on glass slides, and a permanent record made of each case and of each examination, so that they can be referred to at any time.

Dr. Hoch uses a one-twelfth inch objective oil immersion lens, which gives a diameter of 925 times. This high power makes it possible to count every bacillus in each specimen of sputum, so that errors are absolutely eliminated. As the treatment progresses these microscopic examinations are made at short intervals, and the diminution in the number of bacilli are accurately observed.

When a case of phthisis presents itself for treatment I make a complete and careful examination of the patient, keeping a permanent record of each case with the history of all symptoms noted, and this with the record of the sputum made by Dr. Hoch, places the treatment of phthisis upon a firm, careful and scientific basis. This, so far as I am aware, is the first attempt made in this country to treat the disease in this scientific and methodic manner, and the results obtained have shown that it is of the highest possible value.

In addition to the above I enjoin every patient to keep as quiet as possible, remaining in bed and in doors when necessary, and I rely upon rest as an important adjunct of the treatment.

In the severe cases, where the cough is incessant and distressing and the fever high, I often give a pill at night, containing 3 grains of sulphate of quinin and  $\frac{1}{2}$  grain of powdered opium, omitting it as soon as possible for fear of disturbing the stomach.

The composition of the "fluid" is as follows:

Sodic hypochlorite . . . . .	7	grams.
Potassic hypochlorite . . . . .	7	"
Magnesian chlorid . . . . .	1.5	"
Calcic chlorid . . . . .	2	"
Hydric chlorid . . . . .	2	"
Chlorin . . . . .	5	"
Potassic sulphate . . . . .	1.5	"
Magnesian sulphate . . . . .	.5	"
Aquæ . . . . .	1,000	"

Sodic carbonate, potassic carbonate, equal parts added in sufficient quantity to bring the solution to the proper degree of acidity.

**Hemorrhage into the Pons and Opium Poisoning.**—A special interest is attached to the symptomatology of hemorrhage into the pons Varolii, because lesions here sometimes very closely simulate narcotic poisoning. The slowing of respiration, the pinpoint contraction of the pupils, the unconsciousness, all give to some cases of pons hemorrhage a similarity to opium poisoning, and mistakes in diagnosis have been made even by men of large experience.—Dr. Dana in *Post-Graduate*, July.

THE EXPERIENCE OF SEVERAL PHYSICIANS WITH SERO-THERAPY IN TUBERCULOSIS.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association held at Atlanta, Ga., May 8-8, 1896.

BY PAUL PAQUIN, M.D.  
ST. LOUIS, MO.

One year ago, I was honored by the courtesy of this ASSOCIATION when I presented the results of my humble laboratory and clinical work in the domain of sero-therapy, as applied to tuberculosis. I had had then only six months of experience in the application of immunized horse blood serum in man. Preceding work had been in animals. Notwithstanding the many decided improvements I then reported and the apparent recoveries, it was yet too early to arrive at a reliable conclusion as to the merits of this form of treatment and the remedy itself. Since then, I have enlisted the aid of many physicians throughout the country, and will take pleasure to-day in reporting, in part, the results of their work, and my own, in proper cases, as well as indicate the failures, unavoidable in many instances by any and all forms of treatment. Many of these physicians have been persistent even in desperate cases of their tests of anti-tubercle serum, and some have been rewarded with results unlooked for.

Although I shall have the pleasure to present another paper on this serum to this ASSOCIATION, *i.e.*, before the Section of Pharmacy and Therapeutics, a preface to this report, by way of explanation of certain disputed questions concerning the rationale and utility of serum in tuberculosis will not be amiss.

I am facing some who have failed in treating consumption with serum; physicians who have doubts as to its value in therapeutics except as may be due to inherent conditions dependent on the relative immunity of the horse against tuberculosis; doctors who doubt the qualifications of private laboratories and their delvers and of a general practitioner's ability, opportunities and time to investigate, experiment scientifically, safely and successfully.

Since presenting my report last year Maragliano, of Genoa, reported recoveries of consumption by the use of the serum of the ass, to the British Medical Society; Behring, Winternitch, Foa, Roux and others write on the efficiency of immunized serum produced by themselves, either on experiment animals or man. Their labors are in the line of my own, and possibly some of their work antedated mine, although my researches on tuberculosis and its general treatment, which led to the production of serum and its application in medicine in 1894, date back many years, when I was connected with the State University of Missouri. While these foreign scientists of world repute, used serum from various animals, particularly the ass, the horse blood serum was immunized first in this country by myself.

The anti-tubercle serum, like the anti-toxin for diphtheria, rests on the biologic laws governing the defensive forces of an organism to oppose the encroachment of microbes and their products on the tissues and blood. Tuberculous individuals sometimes recover without remedy. This is due to nature's own efforts, *viz.*: exalted phagocytosis, with all that this interesting physiologic phenomenon implies. A complex being, such as man or the horse, is a republic of small animated subjects, the cells, with distinctive individual properties and obligated to co-operative functions for the sustenance of the whole. The brain

and nerve cells constitute the governing power; the phagocytes constitute the soldiers of the country. Their arms consist of their individual annihilating power in a physical sense and the antitoxin elements they produce, capable (probably by a digestive or diastatic property) of neutralizing the poisons thrown amidst them by the armies of microbes constantly attacking the wonderful aggregations which they defend. What occurs in a case of consumption cured by nature occurs in a horse properly subjected to the influence of the consumption poison. Either a natural antidote is increased in power, or a new one created, and this is what exists in the serum I use in man. Man suffering from tuberculosis is under the influence of a certain amount of tuberculin, a poison, and nature produces in his system an antitoxin to counteract this noxious agent. But usually the army of invaders win the fight after a more or less prolonged and painful conflict. What the laboratory is expected to do is, to supply man with this defensive force, the antitoxin, produced at the expense of the horse's system rather than his own.

One must not be too sanguine. Little hope can be offered to the unfortunate who suffers from advanced tuberculosis, with extensive destruction of tissue; general tuberculous intoxication; general debility; pronounced dyspepsia, deficient assimilation and disimilation, difficult and perverted secretions and excretions, and the hopelessness of such cases is emphasized, more or less, according to the more or less pronounced microbial complications which may exist. These complications are influenced only secondarily, by virtue of nature having recovered some strength after the bacilli of tuberculosis are arrested in their development and devastation. I have confidence that early cases of tuberculosis can nearly all be arrested by serum administered under proper conditions, and that were it the policy of the laity to submit to constant observations and repeated analysis the moment a lung or bronchial irritation manifests itself, the diagnosis of incipient phthisis would be made early enough to diminish the death rate due to consumption 90 per cent. by the action of serum.

While I would take pleasure in quoting from all the reports of more than sixty physicians, who have used the serum, more or less successfully, the time at my command will not permit it. Consequently, I will limit myself to cases that have not yet been reported, or reported in the past to a limited degree, and are now in a different or more improved condition.

I shall call attention first to a case of J. R. Lemen, M.D., St. Louis (reported in the *New York Medical Journal* for Sept. 21, 1895) in which the Doctor claims to have effected the recovery of an acute case of tuberculosis, in the person of R. C. G., a real estate agent; age 60. I am personally acquainted with the patient and saw him when he was prostrated in bed, weighing less than 160 pounds. The symptoms were clearly those of acute tuberculous pneumonia. The bacilli were present in profusion. He has now recovered and to-day attends to his business as usual and weighs 224 pounds.

Case under care of Geo. W. Cale, M.D., St. Louis, Mo.: B. McG., age 18 years, 2 months, has been suffering with joint and bone tuberculosis for seven years and had had ten operations performed on different parts of his body to open abscesses and to remove necrosed bones. The seat of the primary trouble was

the right hip joint but it was giving him trouble in every limb. The left tibia was much involved, having at one time eight openings, discharging a tubercular pus. The hip had three openings that would heal and open alternately and one that was open continually for seven years. He had an abscess on each arm, one of the sternum, one of the index finger of the right hand, a tubercular nodule in the scrotum, an abscess near the apex of the left scapula and two on the lower jaw. The patient says that after the continued efforts of Dr. J., of Waverly, Ky., who had four consultants, Drs. H., of Henderson, Ky., and A. J., of Sturgis, Ky., had failed to cure the patient; it was decided to let nature take its course. He was without medical aid for two years. In the fall of 1894, he was put in charge of Dr. Broome, St. Louis, who performed an operation to remove necrosed bone from thigh and tibia, thinking that these openings would heal. This having failed, he decided to try the serum treatment and the case was taken in charge by Dr. Cale. He began the treatment in March, 1895, at which time he had four abscesses discharging a characteristic tuberculous pus and two others that afterward opened. He had daily injections of 20 to 30 ms., and at the close of six months treatment, five of these abscesses had healed, he had gained ten pounds and temperature was normal. He is working steadily and is still gaining in weight. The last and only opening, a very slight one, is in the thigh, and dead bone has been located which is the cause of it remaining open. Up to the present date he has gained sixteen pounds, and is enjoying good health.

Dr. L. L. Shropshire, of San Antonio, Texas, reports in the *New York Medical Journal*, of January, 1896, the case of a brakeman 25 years old, who had had hemorrhage of the left lung, followed by fever, purulent expectoration, loss of weight, and generally declining health. The physical examination had revealed dullness over upper lobe of the left lung, moist râles and a gurgling sound; violent cough; abnormal temperature reached as high as 103 F. Had had night sweats; could retain but little food, losing flesh rapidly, weighing at the time 125 pounds. Microscopic examination revealed bacilli of tuberculosis. After two or three weeks of daily injections of serum, night sweats grew less, appetite returned and digestion improved. Four months after the beginning of treatment he is practically well, and to-day, about seven months after the beginning of the treatment, he is reported as recovered and attending to his duties as a brakeman.

He reports another case, a shoemaker, age 51, who had contracted tuberculosis. The diagnosis was made from physical signs and microscopic analysis. He had declined in health and strength very rapidly, weighing at the time 131 pounds. At the time of the report, he had returned to work and had gained 18 pounds, and to-day he is reported as having recovered.

He reports two other cases with positive improvement and gain in flesh and mentions twenty-five cases, treated up to that time with improvement in all of them.

A. M. Hayden, M.D., Surgeon, St. Mary's Hospital, Evansville, Ind., reports cases as follows (In the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*):

My first case was one with large cavities in left lung, hepatization of the lower portion of right lung; had a great many hemorrhages; sputum contained large quantities of bacilli; weight 120 pounds. Treatment commenced May 10, 1895. In

three months tubercular bacilli disappeared from sputum entirely, and it has remained free from them ever since. The cavities in left lung healed up, with great contraction of the left chest, three or four inches. It has remained so. The patient ceased to expectorate heavy sputum, and now expectorates a light frothy sputum. Has had no hemorrhages since treatment began; he has weighed 140 pounds for the last six months; ridden a bicycle; eats well, and commences his duties as assessor to-morrow. After the first three months, I gave him one to two ounces only at intervals of one and two months. I am satisfied that he would have been dead long before this had he not had the serum.

*Case 2.*—A young man, 25 years old. Family history was that of tuberculosis. His sputum contained quantities of tubercular bacilli; weighed 110 pounds; had been west without benefit; had night sweats, fever and all symptoms of the dread disease. I commenced his treatment September 8, 1895. I gave him 58 daily injections of 35 ms. each. Tubercular bacilli disappeared from sputum; gained 10 pounds. January 20 I commenced and gave him 16 more injections, during which time he gained five pounds, which is more than he ever weighed in his life. He is still in splendid health and says he is feeling better than he ever did in his life. To-day I advised him to take another ounce of serum to guard against relapse.

*Case 3.*—A young man with long standing hip-joint disease. I gave him an ounce in January, 1896, during which time he gained sixteen pounds in flesh and general health much improved. He then stopped two weeks, during which time he ceased to gain flesh. He then commenced again and took one ounce more and gained ten pounds. His health has been much improved since.

*Case 4.*—A man aged 40 years. Several brothers had died of tuberculosis; was taken sick in November with a cough, night sweats and fever. His family physician treated him until January, 1896, when I was called. He was much emaciated, no appetite, night sweats, fever, etc. While he coughed almost incessantly, he did not expectorate. I failed to find any lesions of the lungs in physical examination. His liver failed to act (chalky evacuation, etc.) His family physician had treated him faithfully without results, and he was satisfied that patient was suffering with tuberculosis of liver and other glands. I advised him to use serum, stating to patient that if his trouble was tuberculosis he would be benefited, if not cured. He consented and started the treatment. The improvement commenced at once. In sixteen days he gained sufficient to get up and walk a square to a grocery and get weighed, and found that he weighed his usual weight, 150 pounds. We then stopped the treatment for ten days. Patient requested me to begin again, saying that his appetite was not so good and that he was having night sweats again. I ordered another ounce; had him weighed, and found he weighed 150 pounds still. I gave him one more ounce, which covered sixteen days, and again had him weighed, and found he weighed 170 pounds, a gain of twenty pounds in sixteen days. He is now at work and says the serum saved his life, and will not hear to anything else. After I commenced the treatment I stopped all other medication.

I have a case of laryngeal tuberculosis that has just finished her second ounce, of thirty-two days' treatment, and she has gained one pound; has a better color and says she feels much better; and Dr. Lehardy, a throat specialist, who has been examining her throat, says the ulcers on vocal cords are improved.

I have one lady patient with acute tuberculosis of lungs that has taken two ounces, thirty-two days' treatment; was benefited during the first two weeks, since which time she has lost, and at present her condition is not any better than when she commenced her treatment. However, she has a mixed infection.

I am also treating another lady that has pulmonary tuberculosis. She has taken 1½ ounces, twenty-four days' treatment. She is improving very rapidly, and I am satisfied that she will recover. All my cases have been diagnosed by presence of tubercular bacilli in the sputum, as well as by physical examination, except the one with tuberculosis of the liver. Diagnosis in that case was based on family history and physical signs, together with the fact that he went from bad to worse in spite of the best medical treatment.

Dr. J. A. Dunwoody, Cripple Creek, Colo., April 23, 1895, reports: I will begin first with my own case.

*Case 1.*—J. A. D., male, white, age 30. On July 26, 1895, upon physical examination, the upper two thirds of the left lung was found to be infiltrated; numerous moist râles could be heard throughout this portion. Expectoration of a mucopurulent character; about two ounces during the twenty-four hours. Weight 125 pounds. Microscopic examination showed

tubercle bacilli. Range of temperature was from 99 to 100 degrees in afternoon, which continued until August 2, when I was attacked with acute pleurisy on the left side, which confined me to bed ten days. The temperature ranging then from 100 to 102.5 degrees for a week, after which time it fell to 99 to 100 degrees; until September 18, when it became 98.5 degrees. The injection of serum was begun July 26, 1895, with 10 m. and rapidly increased to 45 m.; then went back to 30 m., which was maintained continuously, notwithstanding the attack of pleurisy, until Dec. 24, 1895, at which time there was a small abscess produced, through want of proper care of the physician giving the injection. Weight at the time (December 24) had increased to 143 pounds; expectoration had ceased, not being able to collect enough for microscopical examination. Physical examination revealed the absence of all râles; clear vesicular respiration throughout the affected portion of the lung, though somewhat weak in character. Right lung not affected at all. March 24 was attacked with la grippe, during which time weight was reduced to 134 pounds, and cough returned for a short time, loss of appetite, etc. April 13, I resumed the daily injection of 30 ms. of serum with an increase in weight of two pounds, and cessation of cough. Have used no other treatment at all, the ingestion of serum alone. This point in my case proves conclusively the great mistake of stopping the serum before the lung tissue has been restored to its full strength and vitality.

*Case 2.*—H. H., white, female age 4. Weight 27 pounds. Date of examination Jan. 3, 1896. Left lung almost completely consolidated; no vesicular respiration, bronchophony quite distinct, cough quite distressing at times; range of temperature 99 to 100 degrees in the afternoon. Began the use of serum Jan. 3, 1896, with a dose of 4 ms. and rapidly increased to 12 ms. daily. Right lung no lesion. During the first six weeks; of sero-therapy patient increased in weight four and one-half pounds and has maintained this weight (31½ pounds) until the present time. Upon physical examination, April 8, find that there is some vesicular respiration throughout the affected lung; cough has almost entirely ceased. During the last three weeks the injections have been somewhat irregular as the little patient was in another city two miles distant from my office, having had a mild attack of scarlet fever.

*Case 3.*—Mr. S., white, male, age 46; weight 135 pounds. Date of examination March 16, 1896. Left lung almost completely consolidated; no vesicular respiration; quite dull and flat upon percussion; small tubercular ulcer upon the epiglottis and vocal chord, affecting the voice. Expectoration about four ounces daily. Patient states that he was first affected with tuberculosis in October, 1894. Daily injections of 30 m. were begun on date of examination. There was considerable erythema in this case which gradually disappeared, though the serum was given daily. Examination, April 21, find that there has been wonderful improvement in the condition of the lungs. There is already some slight vesicular respiration throughout the lung. Expectoration has diminished about one-half. Has increased four pounds in weight. When this patient commenced the daily injections of serum, he could only walk a very short distance without extreme fatigue; now he can walk at least half a mile, without any discomfort at all.

*Case 4.*—J. B., male, white, age 21 years. Date of examination Feb. 15, 1896. Patient states that he has had tuberculosis since the spring of 1893. His normal weight was formerly 143 pounds. Left lung at time of examination was in the same condition as the preceding case; no vesicular respiration; dull and flat upon percussion. Present weight 115 pounds; very much emaciated. Patient difficult to control and comes at irregular intervals for the injections. There is evidence that this patient practices the disgusting habit of masturbation. Upon examination April 21, can find little or no improvement and there is little hope of his ever being relieved.

Dr. A. D. McIntyre, Union Grove, Wis., reports having used the serum, with very flattering results, in a case of ovarian tuberculosis, the history of which I failed to receive in time to embody in this paper, but which will be published.

Dr. William Miller, Boerne, Texas, reports a case of pulmonary tuberculosis in the second stage absolutely recovered. I had an opportunity to examine this case about a month ago and there existed then no physical signs of tuberculosis, nor in the expectoration by microscopic analysis. After several months of treatment, on March 19, 1896, Dr. Miller reports as follows concerning this case: "Examination of Mr.

Malloy, at Boerne, Texas, March 19, 1896: Pulse, 72, full and strong; respiration 18; temperature 98½; weight 152 pounds. This gentleman has gained 20 pounds since he came under treatment. Chest measure: expiration, 35½; inspiration, 37¾. Respiratory murmur clear and distinct over both lungs; no cough or expectoration."

Dr. Miller claims "specific improvement in 40 per cent. of the cases treated; 30 per cent. received some benefit, and 20 per cent. did not improve." In his explanation of the failures he says: "Nearly all the cases I have treated were in the third stage, and 30 per cent. of these at the end of their rope."

Dr. Hoell Tyler, Mentone, Cal., himself a tuberculous patient, states that he took the serum for five months through the kindness of Dr. C. C. Browning, Highlands, Cal., and that he had on Jan. 2, 1896, no symptoms of the disease in his lungs, and to-day he is attending to his usual duties as a physician.

Dr. J. L. Wiggins, East St. Louis, Ill., had the following case in June, 1895:

Miss V. Z., East St. Louis, Ill.—Had been ill several months and prostrated in bed with a complete history of acute, pulmonary tuberculosis for some weeks. Temperature 103 to 104 degrees F. almost continually; microscopical analysis demonstrated the bacilli of tuberculosis. Three physicians consulted and diagnosed acute tuberculous pneumonia. Every ordinary method of treatment was pursued, and the fever remained at 104 F., even reached 105 F., with symptoms of delirium, etc. The lungs were both largely involved, consolidation nearly complete in one. Dispnea excessively pronounced, weakness extreme; prognosis fatal. Everything having failed, the serum which I produce was tried. The treatment began early in June, 1895. Doses ranged between 20 and 40 ms. daily, and were continued some six weeks more or less regularly. The result was that the temperature decreased gradually and steadily after the first seven days' treatment to normal temperature, which was reached on the 22 of June, or thirteen days after the first injection. Injections were continued until the end of July. The patient gradually gained strength and flesh and is again at work. She weighs 132 lbs; was emaciated to at least 80 lbs before treatment. The germs of tuberculosis have disappeared entirely and all previous symptoms of lung disease are absent. Case recovered. The diagnosis of this case, which seemed clear to all the physicians, was questioned by one man because recovery had occurred, and here is the reply of Dr. Wiggins: "In answer to your query, 'Did you consider the case of Miss V. Z. acute tuberculosis,' I will answer unqualifiedly, yes. At the time of treatment with serum I had no hopes that the case would recover, either with or without serum. But as the temperature began to fall, diarrhea, which was before uncontrollable by medication, was controlled without medication, and the cough and hemorrhage became lessened and gradually disappeared. I concluded that these marks of improvement were more than a mere coincidence. The diagnosis was clear, outside of microscopic analysis. This in the beginning was clouded. I would have filled out a death certificate, had she died, as being the result of tuberculosis."

Among my own cases I may report:

Mr. E. D., St. Louis, Mo., age 36 years; occupation, shipping clerk. History of glandular tuberculosis, dating back about eleven years. Had pneumonia four years previous to examination in my office, May 16, 1895; had been declining six months; had night sweats and fever; pain in left lung, back and front. Pulse at 108 degrees at the time of examination; abnormal temperature ranged from 99.35 to 101 degrees; cough chiefly in the morning; expectorated a yellowish matter. Bacilli present. Slept fairly well on the right side but could not sleep on the left; was too weak to attend to his duties properly. Dullness in the left lower lobe and crepitus of the left apex over a lateral area of four inches, extending about three inches downward; interrupted breathing both sides. All these symptoms disappeared in four months of treatment consisting of 15 to 30 ms. of serum a day. Several examinations of sputum made since revealed no bacilli. Mr. D. is at work from twelve to fifteen hours a day, Sundays included, and feels strong and in good health. He did not bear the injection of serum well, but he was persistent and recovered.

Mrs. H. R., St. Louis, Mo., consulted me in February, 1895. Had been ill for two years. Had had slight hemorrhages; was coughing very severely and expectorated a yellowish, mucopurulent material, occasionally tinged with blood. The sputum was full of bacilli of tuberculosis and largely loaded with different forms of pus germs. There was infiltration in the apex of the right lung between the third and fifth rib, covering an area of about four inches, laterally, and penetrating the lung more or less. There were mucous râles about the middle of this area, very pronounced, and interrupted breathing on both sides. The circulation was exceedingly rapid and the fever ranged from 99 to 101 degrees F.; it rarely went above that. Patient had lost much flesh, being reduced from 130 to 90 pounds. At the regular dose of 30 ms. three days for four months and then irregular treatment three or four times a week, and with a loss of three weeks at one time, the whole treatment covering a period of six months, Mrs. R. increased in weight to 132 pounds, and became strong accordingly; developed a splendid appetite, and for the last three months the sputum was exceedingly scarce and comes now only when she is affected by cold. It exhibits no bacilli of tuberculosis. She suffered a miscarriage and six weeks' illness recently, but her lungs remained apparently sound. The consumption symptoms which existed at the beginning have disappeared.

Mr. F. S., St. Louis, Mo., was examined in February, 1895. He weighed about 145 pounds at the time. He had had very profuse hemorrhages at Hot Springs, and was sent home considered hopeless; had lost about fifty-five pounds from his regular weight which was above the normal for his size; coughed a great deal at night and day; expectorated a thick, yellowish matter loaded with the bacilli of tuberculosis and other microbes and was gradually losing ground. He was unable to perform his duties as a groceryman. Physical condition evidenced tuberculous affection in both lungs, particularly in the right, over the whole of which interrupted breathing was very marked. The lower half of the lung exhibited moist râles and softening. Symptoms after seven months of more or less regular treatment, which consisted of 20 ms. daily in the beginning, and was increased to 40, and once in a while to 60 ms., almost entirely disappeared, with the exception of a slight interrupted breathing. Flesh was regained to the amount of 170 pounds, and now strength is as good as ever. Mr. S. has been for four months without treatment, attending to his usual duties, working hard every day. He expresses the opinion that he is free from disease. The bacilli are now absent, but there is still a slight catarrhal condition of the bronchi, with micrococci. His condition of health is continually improving. Active tuberculosis, at least, has been arrested by the serum.

Mr. G. N. F., St. Louis, Mo., was examined April 29, 1895. Age, 45 years; occupation, bookbinder. Had had a dry, hacking cough two years; had had pneumonia at the age of 18, congestion of the lungs, so-called, two years previous to his examination. February 7, 1895, he had severe hemorrhages, and at the beginning of treatment he weighed 130 pounds. Expectoration thick and yellowish. Bacilli of tuberculosis numerous. Temperature increased at times; infiltration of the left apex below the second rib, about three inches downward and four inches across, evidenced both anteriorly and posteriorly, dullness over same region; crepitus over some of the area, and râles and crackling on deep inspiration extending below left breast, anteriorly. Mr. F. was treated with tubercle antitoxin from the beginning of May until October, almost every day, at the dose of 30 to 40 ms. Since then several examinations have been made and no germs of consumption are to be found. Physical symptoms have now disappeared and the patient is at his work, feeling strong and well and considers himself cured. He weighs 143 pounds, which is more than his normal weight before his illness.

Mr. F. B. M., St. Louis, Mo., age 20; occupation, railroad clerk working at night. He had bronchitis at the age of 14; had suffered from night emissions of early puberty; previous health feeble; cough slight; pain in the lower lobe of the left lung; temperature 99 to 100 F. Physical examination evidenced dullness of the lower left lobe, beginning at a line drawn below the nipple and extending toward the base. Microscopic examination revealed the bacilli of tuberculosis; not in large numbers. Mr. M. was treated from May 27, 1895, to the middle of September, practically four months. All physical symptoms and evidences of tuberculosis have disappeared. He is now at work as before in good health. No bacilli have been found in examinations made since September.

Miss G. A., St. Louis, Mo., age 19 years; occupation, music and vocal student; had influenza in Memphis six years before; dry cough for a year; weighed 123 pounds. Hemorrhages four years previous to examination Sept. 26, 1895, larynx infiltrated; temperature from 99.5 to 101; coughing much and expectora-

tion in the morning of a yellowish matter. Bacilli of tuberculosis quite numerous. Heart disease evidenced regurgitation. Treatment began the last day of September, 1895; injected very small doses on account of her heart condition, that is, 10 to 25 ms. daily. At this time Miss A. weighs 136 pounds; the bacilli of tuberculosis are now absent and for two months there has been but one or two in the field of bi-monthly examination. Cough has almost entirely disappeared. Strength has been regained and appetite is splendid, and the patient is considered as having almost, if not quite, recovered, as there exists no longer the physical signs of infiltration nor any signs of breaking down. There is still expectoration with micrococci.

Miss S., Nashville, Tenn., began treatment in May, 1895, and remained under its influence for some three months. She came with a written diagnosis of pulmonary tuberculosis from her family physician, which was substantiated by microscopic and physical examination. The bacilli of tuberculosis were found in large numbers and the patient was rapidly losing ground both in weight and strength; coughing considerably, particularly at night; expectorated occasionally a yellow greenish matter. Night sweats had existed and fever ranged at times from 99 to 102 F. She was treated with serum at doses ranging from 20 to 30 ms. daily. After three months she had gained ten pounds. She then removed to Las Vegas, N. M., where she resumed the treatment and her improvement continued. She had first lost flesh, but again increased in weight and every symptom seems to have disappeared, if I may judge from the reports sent me. Bacilli have not been present for two months.

Mrs. A. C., age 26 years, married, has had three children and two miscarriages, one recently. At the age of 14 she received a blow in the chest, at which point pain appeared frequently whenever the patient contracted cold. On examination infiltration was discovered, covering an area of about three inches in diameter, on the right side below the breast; also a dullness in the left lung between the second and third ribs, extending about two inches downward and two inches laterally. She had had various symptoms of tuberculosis for some years and dated the accidental incipency of it fourteen years previously when she had received the injury mentioned. She has had several hemorrhages. The active development of the disease dated three years before my examination, which occurred June 7, 1895. At that time she weighed 115 pounds. To-day she weighs 135 pounds. She had dyspnea; expectorated a great deal; coughed very much and had a poor appetite. Now all these symptoms have disappeared and her strength has increased so that she is able to perform her duties; comes to my office daily and expresses herself as improving continually. The physical signs above mentioned have disappeared almost completely. A few bacilli were found in the last three months.

Mr. V. (employed at our institution) a patient under the charge of Dr. Hanau W. Loeb, had laryngeal and pulmonary tuberculosis. His condition had been declared hopeless by a number of specialists in St. Louis. He has been treated under the special care of Dr. L. and myself, occasionally, for a period of about ten months, having received from 30 to 120 ms. daily. At the beginning of his treatment there existed infiltrations of the larynx and other lesions. He had lost his voice, weight and strength. He was in a hospital, unable to perform any work. He was, at the writing of this report, assisting in the care of some twenty-two horses, working many hours every day in water and dust. His appetite had improved and his strength good. He is susceptible to colds, but under the treatment with serum he had gained a condition which permits him to do all the menial labor that can be asked of any man. Rarely have we found the bacilli in the scant expectoration of the last four months. I report him because he was incidentally and indirectly under my supervision some months, and the injections were done by my assistants or myself. The case is surely under control at present. Some physicians pronounce him practically cured.

John H., aged 48. Pulmonary tuberculosis two years; prostrated in bed at city hospital; cavity, contracted lung, bacilli numerous; mother died of phthisis; cough aggravating. Injections 30 ms. daily, begun Dec. 1, 1894; continued for three months regularly. Weight increased 6½ pounds first two months. Has since been under treatment irregularly. Has been at work for over a year, grooming from twelve to twenty horses, ploughing and farming generally part of the time. Bacilli absent.

Miss Y., age 18; pulmonary tuberculosis, first stage. Lost ten pounds; infiltration in and dullness over area of three inches in diameter between second and sixth ribs, in right lung; cough persistent at night and expectoration profuse in morning; bacilli present. Miss Y. was treated over four

months almost daily, at a dose of 30 ms. hypodermically. To-day she has more than gained her normal weight, is absolutely free from cough, and the last symptom of pulmonary tuberculosis has disappeared; bacilli absent.

Dr. S. B. Hall, Rock Island, Ill., reports as follows, April 28, 1896:

*Case 1.*—Age 27; has been coughing since January, 1895; normal weight, 160 pounds. Weight at commencement of treatment (Dec. 20, 1895) 132 pounds; present weight 136 pounds. Average dose 25 to 30 ms. Have had to suspend treatment several times. Coughs and raises very little at present; sleeps well; has a good appetite, has moist râles in upper lobe of left lung. Right lung normal. Have suspended treatment for a while. This was a charity case; lived in a poor damp house and had barely the necessaries of life. I think he has made a wonderful improvement.

*Case 2.*—Male, age 40; sick one year, given up by several doctors, is a carpenter by trade; was confined to bed three months prior to the beginning of treatment June 25, 1896; no cavities, but the upper lobe of the left lung and the middle lobe of the right lung were the most affected. Cough was incessant—coughed two-thirds of the night. Maximum dose 45 m. average 30 m. Cough is markedly diminished and he sleeps and eats fairly well. His greatest trouble now is a soreness in the trachea and bronchial tubes. He says they seem raw. Both of these patients refused any additional treatment and they have both improved wonderfully.

Dr. C. E. Bauer, St. Louis, Mo., writes on April 28, 1896:

*Case 1.*—Age 40 years; weight 140 pounds; height 5 feet 10 inches. I was called the latter part of October, 1895, while he had a hemorrhage. I was told that he had two hemorrhages before this last one, about three or four months apart. He coughed a great deal and expectorated a thick greenish sputum. On percussion I found a dullness of the left side extending from the supraclavicular space to three or four inches below clavicle. On auscultation, I could hear nothing but a blowing murmur; after coughing, moist râles. Very profuse perspiration at night. Temperature in the morning 99; in the evening 100 and 101. I commenced with injections of 10 ms. of serum and gradually increased to 50 ms. daily. After injecting about two months, I had to reduce the amount to 30 or 35 ms. on account of sudden rise in temperature. I have used the serum in this case from Nov. 2, 1895, until April 1. Since then I am only making two injections a week. The patient has increased in weight from 140 to 156 pounds. He coughs very little and there is not any sputum at present. The sputum before treatment showed a great number of tubercle bacilli and streptococci. Night sweats have ceased entirely. On auscultation, I hear a blowing murmur, but no moist râles. He has returned to his occupation as fruit peddler.

*Case 2.*—Miss L., age 22 years; height 5 feet, 4 inches; weight 110 pounds before treatment. Had a cough for some months and was losing flesh, expectorating a great deal; respiration increased to about 35; temperature in the morning 99; in the evening 102 and sometimes 103 degrees; perspires considerably when sleeping; face becomes flushed toward evening. Sputum was examined before treatment and showed a great number of tubercle bacilli, also streptococci. On percussion I found dullness on the right side from the clavicle down about four inches, also over suprascapular space; on auscultation, I could hear moist râles. I have been injecting serum in this case since November 3, daily, up to two weeks ago, and intend to continue. This case did not get along very well but we have been rewarded at last. The temperature does not go above 99; she coughs and expectorates very little. I do not hear moist râles on auscultation. Her weight has increased from 110 to 118 pounds; respiration is not so frequent and she does not perspire at night. When she came to me she could not speak above a whisper. I examined the larynx and found the vocal cords red. On the left cord was a small ulcer; since the treatment with serum her voice has been entirely restored; the ulcer cicatrized. I have treated this case with Paquin's anti-tubercle serum, commencing with 10 and increasing to 50 ms., but had to reduce it to 25 ms., on account of palpitation of the heart. I think it very advisable to discontinue the injections for about two weeks in cases where patients have been injected daily for three or four months.

Dr. Elizabeth McLaughry, New Castle, Pa., in one of her recent reports states:

Patient, a young woman, age 32, had been ill for two years,

gradually growing weaker. When I first called, found her prostrated with a temperature of 104, pulse 120. Cavity in left lung and dullness in apex of right, dyspnea, huskiness of voice, night sweats, cough, which prevented her from sleeping; sputum, muco-purulent, often streaked with blood. No appetite, throwing up what food she did take, and diarrhea. Weight 84 pounds. Bacilli very abundant in sputum. Began treatment by injecting five minims of serum—increasing to thirty daily. She began to improve at once; temperature gradually went down to normal in less than two weeks, night sweats ceased, coughed much less, slept soundly all night, appetite became good and diarrhea ceased. Now after two months treatment, she has grown quite strong; gained four pounds.

Dr. Richard Fricke, Fort Wayne, Ind., April 28, 1896:

*Case 1.*—Mr. S., a man 37 years of age, was taken sick January 4 with typhoid malaria. About the beginning of February the fever had disappeared, and there were no symptoms, except weakness. But after about one week's time a hacking cough set in, with but little expectoration, and at the same time, he began to get asthmatic, losing flesh and having night sweats. I learned that several members of the family had died of consumption. By examination, I find the apices dull and contracted. The microscopic examination was negative. March 4 I began to inject the Paul Paquin anti-tubercle serum. After about one week's treatment he began to feel better, his appetite improved, his night sweats grew less and at the end of the second week he had gained four pounds. From that time he improved rapidly in every respect and gained an average of three pounds a week. He lost his night sweats, his asthma, got strong and robust and is now at work again. During the treatment he did not take any medicine except the injections of serum.

Ed. W., St. Louis, Mo. Examined July 9, 1895, complained of sore lungs, both sides for two years. Dullness in left apex; cough slight; expectorated, thick yellow sputum, containing bacilli of tuberculosis. Dyspeptic. Bowels irregular; had lost seven pounds in preceding three months. Was treated with an average dose of 30 ms. almost daily since examination, and to-day is absolutely free from tuberculous phenomena, although he has a slight catarrhal discharge with micrococci. He has regained lost strength and weight.

It is useless to say that the improvements in cases in very advanced disorganization and prostration have not been of long duration. Nothing will reconstitute a lost tissue to its former condition, nor will anything cure moribunds.

#### DISCUSSION.

Replying to the interrogatories by Dr. William Dougal, and others, Dr. Paquin said the serum would not kill germs outside the body as a chemic germicide; that the horse from which it was obtained was treated with tuberculin, or the toxins of the germs of tuberculosis, in a manner similar to that followed in producing diphtheria antitoxin. The horses were first kept under observation three or four weeks, and if there were the least indication of illness they were not used. The tuberculin injections in the animals were continued as long as they produced any reaction. It was usually three months before reaction ceased. The subsequent steps taken insured a very clear serum. The living germs of tuberculosis were not injected into the horse. Moreover, the horse was naturally relatively immune to tuberculosis, for out of many attempts to infect the animal he had succeeded only twice in producing even local tuberculosis, and this failed to become generalized. The immunized horse serum injected into tuberculous man did not kill the germs of tuberculosis, but, as with diphtheria antitoxin, simply stimulated the forces within us to neutralize their products. In diphtheria we found germs three or four weeks after the use of antitoxin. It was not at all due to chemic action.

Dr. A. M. HAYDEN of Indiana—I have obtained the very best results in eight cases out of ten. The question most important to settle at the present time is, what cases will be benefited, and under what circumstances, and how to distinguish between cases which will be benefited and those which will not, I have been unable at the commencement to decide. A case in mind was that of a patient having an immense cavity

in the left lung. Apparently he got no benefit from the treatment the first three weeks, but had the flushed face, disturbance of circulation, and seemed to lose ground for a month. But on examining the sputum we found the tubercle bacilli were diminishing. After thirty days the tubercle bacilli were very much diminished in the sputum, and he began to gain in strength, appetite, flesh, etc. In three months the tubercle bacilli had disappeared from the sputum, although they had been very numerous on the microscopic slide at the first. He had had hundreds of hemorrhages, and could not go out of the house alone. The other lung has cleared up, the chest wall has contracted over the cavity, he is at work and enjoying life. In one or two other cases there was improvement the first two or three weeks. Then it ceased and they lost ground. In 80 per cent. of my cases the results obtained have been better than those I have ever succeeded in getting from any other therapeutic agent. I discontinued all other treatment in these cases in order to give the serum a fair trial. One man whose condition was regarded as hopeless would take no other treatment, and the result was so favorable that I abandoned all other measures while using the serum. The man whose history was sent Dr. Paquin, and who had tuberculosis of the glandular system, coughed, was emaciated, had swollen feet, pulse 140, night sweats and insomnia. Everything else was stopped and he was given the serum. At the end of sixteen days he had improved sufficiently to get out of bed and had gained a number of pounds. The treatment was discontinued ten days or two weeks; he began to feel badly again, and another ounce of serum was sent for; soon afterward his weight increased to 170 pounds, and since then he has gained five pounds more, being heavier than he had ever weighed before. One of my patients who did not improve had mixed infection, and I believe it will be found that such cases are less likely to be benefited than those with purely tubercular infection. The other case which apparently improved at first, but relapsed afterward, was one of laryngeal tuberculosis. It is a peculiar fact that most of the cases in which I got good results did not seem to improve at first, whereas the two which at first showed improvement of appetite and some gain in flesh, afterward relapsed.

Dr. RICHARDS and Dr. WEBSTER of Illinois, inquired whether the serum had been used in local tuberculosis by injection.

Dr. PAQUIN knew of only one case of lupus in which it was used, the report coming from the State of Washington. The physician stated that the disease had disappeared.

Dr. WILLIAM DOUGAL of Illinois—It seems to me that by this treatment we are stimulating the natural forces within us to throw off and annihilate tuberculosis within the system.

## THE SURGICAL TREATMENT OF UTERINE FIBRO-MYOMATA.

Read before the Minnesota State Medical Society, June 18, 1896.

BY E. C. DUDLEY, M.D.

PROFESSOR OF GYNECOLOGY, NORTHWESTERN UNIVERSITY  
MEDICAL SCHOOL.  
CHICAGO.

The object of this paper is not to enlarge upon a great variety of procedures which have become or seem destined to become obsolete, but rather to present briefly the more useful operations for the treatment of fibro-myomata of the uterus. The subject will be divided as follows: 1, palliative operations. 2, radical vaginal operations. 3, radical abdominal operations.

### I. PALLIATIVE OPERATIONS.

The palliative operations are, *a*, curettage, *b*, electrolysis, *c*, ligature of the uterine arteries and broad ligaments, *d*, removal of the uterine appendages.

*a. Curettage.*—The irritating presence of the tumor often gives rise to hemorrhagic endometritis. Curettage is therefore indicated precisely as it would be in hemorrhagic endometritis from any other cause. The operation is generally followed by a degree of relief from the menorrhagia, is seldom permanent in its results and must usually therefore be repeated again and again. It is especially useful in connection with intrauterine gauze tamponade to control hemorrhage until an exhausted patient can gain blood and strength for a more radical operation, or in cases of small tumors until the menopause has passed. Curettage of the myomatous uterus gives increased danger of sepsis, hence the necessity for great anti-septic and aseptic care.

*b. Electrolysis,* especially electro-puncture, must be taken as a surgical procedure; even the simple intrauterine electrode is powerfully caustic and therefore surgical. Undoubtedly this agent may in a limited number of selected cases be capable of producing a more or less permanent symptomatic cure, and may occasionally result in the disappearance or reduction of the tumor. The earlier promise of its enthusiastic supporters however has not been fulfilled. Its immediate dangers also are considerable. The survival of this method depends chiefly upon the patient's ignorance of its inadequacy and dangers, upon her worship of the mysterious, upon an unreasoning dread of operative measures and upon a desire to grasp any other promising means of relief.

*c. Ligature of the Uterine Arteries and Broad Ligaments.*—The purpose of these measures is to shut off the blood supply to the uterus and by this means to induce atrophy of the growth. Gottschalk of Berlin reports cases of multiple myoma in which he has ligatured the uterine arteries with good results. Martin ligatures the whole base of the broad ligament so as to include not only the uterine artery but its branches and certain uterine nerves. He even goes so far in desperate cases as to ligature also the ovarian artery on one side. Robinson reports successful cases in which he has ligatured the Fallopian tubes and broad ligaments, including the ovarian and uterine arteries on both sides. The method has hitherto failed to elicit much discussion. Even its authors of late preserve on this subject an ominous silence.

*d. Removal of the Uterine Appendages.*—This procedure, which suggests the names of Battey, Hegar and Tait, when properly carried out—*i. e.*, when the ligatures are placed close to the uterus so as to include a large part of the broad ligament—usually stops the hemorrhage and reduces the tumor, sometimes even causes it to disappear. Its dangers however, are nearly if not quite as great as those of the more radical operations. This is especially true since the technique of the latter has been perfected. Removal of the uterine appendages for fibro-myomata is becoming an obsolete operation. At least it will be done only in rare cases of small tumors in which for some special reason the hysterectomy and myomec- tomy are inadvisable.

## II. RADICAL VAGINAL OPERATIONS.

The vaginal operation is preferable when the tumor can be readily reached by that route. All cervical fibroids, all intrauterine pedunculated fibroids and some of the more accessible submucous fibroids have usually been removed by the vagina. In their removal the *ecraseur* and galvano-cautery so often used for hemostasis are unnecessary, because hemorrhage is

either not feared or can be readily controlled by the uterine gauze tampon. This route has usually been reserved for the smaller tumors of a size not larger than the capacity of the small pelvis. Latterly however the vaginal method has been often and successfully used by certain French surgeons for the removal of much larger tumors. Their removal is accomplished by repeatedly seizing the presenting part of the tumor with vulsellum forceps and cutting away as large a piece as possible with the scissors, one piece after another, until the whole tumor has been removed. I refer to the operation by traction and morcellation. This method, although generally supposed to be of more recent origin, was really described by Dr. T. A. Emmet more than thirty years ago and has been constantly advocated and practiced by him ever since. It is applicable to those cases in which the tumor is accessible through the vagina but too large to be enucleated and delivered entire.

The operation of traction and morcellation when its technique is more generally understood and its advantages more appreciated will undoubtedly become more and more a procedure of election in place of hysterectomy. Many large submucous or mural tumors for which the abdomen is now opened and the uterus sacrificed may be rapidly, safely and effectually managed by this method. One strong contraindication to the vaginal route for large tumors must always be, however, the constant possibility of pus tubes or ovarian abscesses, so often unrecognized or unrecognizable when they occur in connection with large irregular fibro-myomata. Many a fatal result has followed the rupture of an unsuspected small pus tube caused by most careful enucleation or morcellation through the vagina. The vaginal route then should be avoided if there be any reason to suspect purulent disease of the uterine appendages. The tumor is usually made more accessible and its enucleation or morcellation is facilitated either by dilatation or more frequently by deep lateral incisions of the cervix even to the internal os. These incisions having been made, the anterior and posterior lips of the cervix are drawn well down to the vulva and held widely apart by means of strong double-tooth forceps in the hands of an assistant. The operator then seizes the presenting part of the tumor with strong tooth forceps and removes it, either by enucleation or by morcellation. If the tumor be of mural origin it may be necessary to divide the mucous membrane and submucous muscular tissue before commencing the enucleation. This incision should be parallel to the uterine canal.

I now propose a possible improvement upon the two lateral incisions. It is a simple median incision through the anterior wall of the uterus, as follows:

1. Make a circular incision in front of the uterus which shall separate the vaginal wall from the cervix at the utero-vaginal attachment in the line CD, Figure 1.

2. Incise the anterior vaginal wall from the point at the middle of the first incision for a distance of one-half to three-fourths of an inch, line AB, Figure 1, taking care not to invade the bladder and to avoid the ureters on either side.

3. Separate the bladder from the uterus by means of the finger or some other blunt instrument, keeping close to the uterus until the peritoneum is reached but not divided. Then expose with retractors the anterior wall of the uterus. (Figure 2.)

4. Divide the anterior wall of the uterus longitudinally in the median line by means of scissors to whatever extent may be necessary to render the tumor accessible. (Figure 2.) If necessary, the peritoneum may be opened and the incision carried high up into the corpus uteri.

This simple anterior incision would permit wide separation of the lateral fragments of the anterior uterine wall and thereby expose the endometrium and in selected cases would render accessible a myoma in any part of the uterine wall. It would probably have the following advantages over the lateral incisions:

1. Less traumatism, one incision instead of two.
2. The parametria are not opened and exposed to possible sepsis.

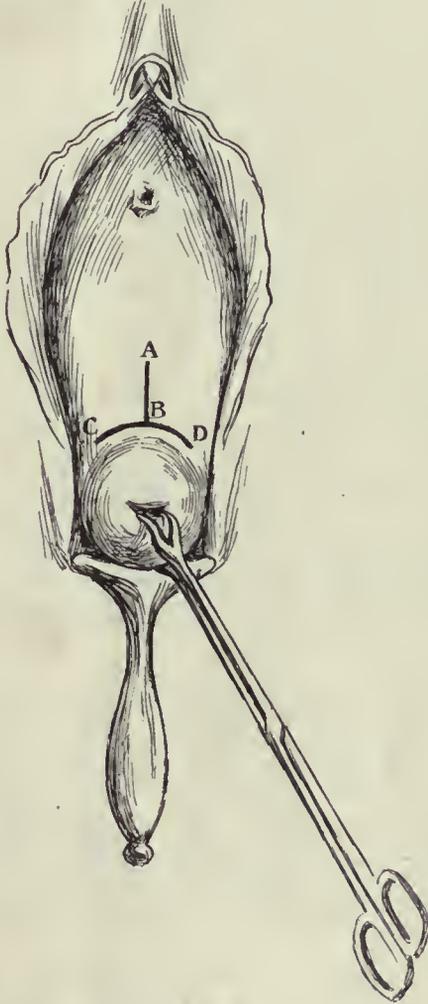

FIGURE 1.

3. The tumor would be more accessible because the anterior uterine wall would be out of the way instead of being between the operator and his field of operation.

4. A much longer incision may be made if necessary, because the broad ligaments are not involved.

5. Less hemorrhage.

6. The pelvic cavity may be easily reached for any accessory operation on the uterine appendages or peritoneum. Even a small pedunculated or subperitoneal tumor could be removed.

### III.—RADICAL ABDOMINAL OPERATIONS.

The radical abdominal operation includes the following subjects:

1. The extraperitoneal versus the intraperitoneal treatment of the stump, *i. e.*, the clamp versus the ligature.

2. The removal of the tumor together with the whole or a part of the uterus and its appendages.

3. The removal of the tumor, leaving the uterus and its appendages intact, so as to preserve their reproductive functions.

The question of intraperitoneal versus extraperitoneal hemostasis recalls the old contest between the clamp and the intraperitoneal ligature in the treatment of the pedicle in ovariectomy; a contest which resulted in a complete victory for the ligature and necessarily established the general principle that the extraperitoneal method is relatively dangerous and consequently, whenever perfect hemostasis by the intraperitoneal method is practicable, should be avoided. Undoubtedly this general principle should apply with some force to the removal of other abdom-

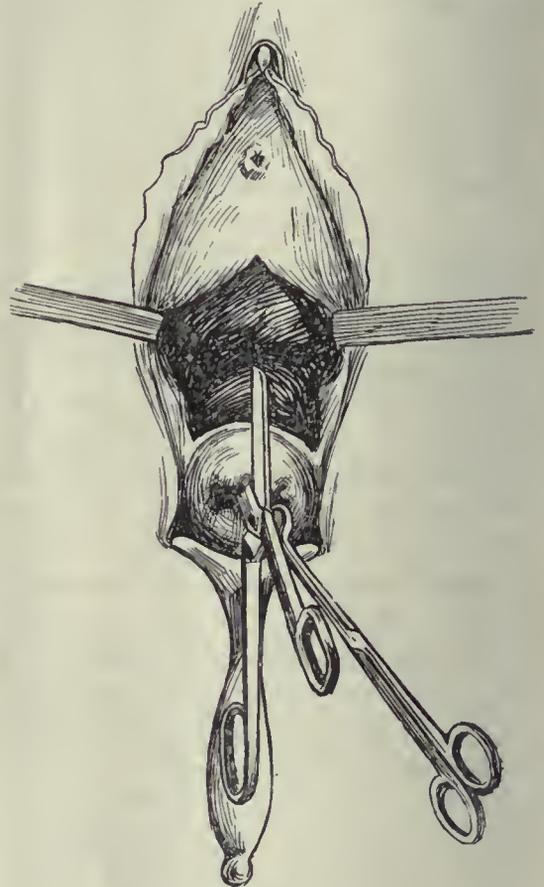

FIGURE 2.

inal tumors. Nevertheless the earlier statistics in myomectomy and hysterectomy show that the dangers which necessarily belonged to the clamp were more than balanced by the insufficiency of any means then known of intraperitoneal hemostasis. The advocates of the clamp based their objections to the ligature upon the supposition that the moist soft uterine stump when ligatured and returned to the abdomen would at once become a source of danger from hemorrhage and decomposition, with consequent peritonitis and sepsis. However tightly the ligature was drawn around the uterine stump, however carefully the flaps of the stump were stitched together, however perfect the hemostasis may have appeared upon the completion of the operation, the fact

remained that shrinkage of the stump within a few hours with consequent loosening of the ligatures almost invariably occurred from the escape of serum, and fatal hemorrhage or sepsis often followed. The extraperitoneal treatment therefore became for a time almost universal, and with improved technique gave promise of becoming the established method. In the hands of Keith and a few other extraordinary surgeons it gave a singular freedom from mortality; but in the hands of the average operator the mortality was unfortunately too great. This was so because of the extreme difficulty in keeping the stump aseptic. It would suppurate in many cases and become the medium of deep peritoneal infection.

In myomectomy the history of ovariectomy has repeated itself—first, the intraperitoneal treatment of the stump; second, the extraperitoneal treatment, rendered necessary on account of the difficulty of intraperitoneal hemostasis. Now, finally, the intraperitoneal treatment has become the established method in myomectomy.

The great condition hitherto wanting is now supplied by ligaturing the uterine and ovarian vessels, thereby shutting off the blood supply from the field of operation. This not only renders the operation bloodless, but prevents secondary hemorrhage. It now seems extraordinary that the very first men who ever attempted myomectomy did not realize the surgical necessity of first shutting off the blood current by ligaturing these vessels. Instead of using this simple, direct, natural procedure, we have been for a quarter of a century, groping about in the dark, searching in and out of the way places for a method by which we could secure intraperitoneal hemostasis. Just as soon as Baer and others began to ligature these vessels the whole procedure became simple. It is the old story of Columbus and the egg over again.

It would be unprofitable here to continue the discussion of the clamp against the ligature in the surgical treatment of uterine fibroids. The subject is rapidly passing out of the field of discussion and becoming a matter of history. There is, however, a limited class of cases in which the very much constricted stump may readily be brought into the abdominal wound, and fixed there by means of the clamp, in a much shorter time than would be required to secure hemostasis by ligature of the uterine and ovarian vessels, and to complete the operation by the intraperitoneal method. In such a case, if the condition of the patient is precarious, the clamp will always be useful, because it will enable the surgeon to complete the removal of the tumor with the minimum of operating. It will then fulfill a most important indication—the saving of time.

Nearly eight years ago I reported to the Chicago Gynecological Society a case<sup>1</sup> operated upon in St. Luke's Hospital, in which the abdomen was opened, the tumor enucleated, and the cavity from which the tumor had been taken stitched into the abdominal wound by means of catgut sutures. By this means the uterine wound made by enucleating the tumor was rendered extraperitoneal. The tumor cavity was then tightly packed with a continuous strip of gauze to control hemorrhage and to drain through the abdominal wound.

This operation differs from the so-called "peritoneal cuff operation" recently introduced by Dr. Senn

somewhat in detail, but not at all in principle. I have recently, however, learned that Dr. Polk, of New York, described substantially the same operation before the New York Obstetrical Society in January, 1888, thus anticipating me by a few months, but he soon abandoned it for hysterectomy. When I first described this operation I regarded it, for selected cases, as a great advance in the surgical treatment of uterine myomata, because it saved the reproductive organs. In about fifty cases it gave me a mortality of only 2 or 3 per cent. Now, however, I would usually prefer one of the modern intraperitoneal operations soon to be outlined.

The grounds upon which the extraperitoneal method, whether by clamp, elastic ligature or suture, should for the most part be discarded, may be given as follows:

1. No greater safety in the extraperitoneal method.
2. Fixation of the whole or a part of the uterus to the anterior abdominal wall is objectionable from an anatomic standpoint, and often gives the patient great inconvenience from traction and from other mechanical causes.
3. Extraperitoneal hemostasis in any form is apt to cause unnecessary adhesions. It usually makes a longer and more tedious convalescence.
4. Greater danger from ventral hernia.

#### OPERATIONS WITH INTRAPERITONEAL HEMOSTASIS.

To illustrate the various operations which may be performed with intraperitoneal hemostasis, I will briefly present from my note books the histories of three operations performed at St. Luke's Hospital on three consecutive days, Nov. 4, 5 and 6, 1895.

*Case 1* was of many years' standing. Electrolysis—electropuncture—had been repeatedly used. This treatment had been followed by extensive, almost fatal pelvic peritonitis. There had been so much inflammation of the tumor itself that it could not be easily shelled out of its capsule. On account of extensive adhesions to the abdominal viscera, the inaccessibility of the field of operation and the bad condition of the patient, the operation presented unusual difficulties. After ligating the uterine and ovarian vessels, the tumor, weighing about ten pounds, and the entire uterus with its diseased appendages, was removed. The operation necessitated great traumatism in the pelvis, and large surfaces were left uncovered by peritoneum. The pelvic cavity was therefore packed with gauze. This gauze was continued into the vagina and left as a capillary drain. The abdominal wound was closed without abdominal drainage.

*Case 2.*—The next case was very much like the preceding one, but the tumor was somewhat smaller and there were no adhesions. Both tubes were distended with fluid. Each ovary was as large as the double fist. The tumor, the entire uterus and its appendages were removed, as in Case 1. The broad ligament stumps were drawn down into the vagina and held there by sutures. The vaginal and abdominal wounds were both completely closed, the latter with catgut sutures. No drainage.

*Case 3.*—On the following day the third case presented itself, with a perfectly round, globular tumor as large as the double fist springing from the anterior wall of the uterus. This tumor was removed by an incision through the corpus uteri, precisely such as would be made in a Cesarean section. Temporary hemostasis was secured by a rubber ligature. This was removed before closing the abdominal wound. The tumor having been enucleated, the cervix dilated and the granulations curetted out of the endometrium, the cavity of the uterus, which communicated with the uterine wound, and the vagina were packed with a gauze drain. The uterine wound from which the tumor had been enucleated was then closed. As in Cesarean section, the entire uterus was dropped back into the pelvic cavity and the abdominal wound closed without drainage. The Fallopian tubes and ovaries were preserved intact.

The method adopted in this last case is undoubtedly applicable to the treatment of a much larger

<sup>1</sup> Reported before the Chicago Gynecological Society, May, 1889, and published in the *Am. Jour. of Obstetrics*, September, 1889.

number of tumors than is generally supposed. I desire to emphasize the statement that any surgeon who is constantly alert to enucleate the tumor and preserve the reproductive organs will be surprised at the number of cases in which this is entirely feasible. The mutilating operation of hysterectomy for fibro-myoma is often necessary, but not so often as the statistics of the present time would indicate. In the vast majority of cases the uterine appendages will be found normal, and in a large proportion of this majority the tumor may be enucleated from the uterus and the wound successfully closed precisely as would be required for the removal of such a tumor in any other part of the body. Cases of very large tumors and cases in which many small tumors are scattered through the uterine wall may require hysterectomy. The conservative operation of simple enucleation will apply in many cases when the tumor is even larger than the fetal head, and in cases of multiple myomata when there are not too many tumors.

If the tumor is subperitoneal, and especially if pedunculated, the uterine traumatism is superficial and easily treated with catgut sutures. In mural tumors large numbers of buried catgut sutures may be used in bringing the surfaces of the uterine wound together, and then some modification of the Lembert suture may be used in closing the peritoneal margins. If the tumor is submucous and the uterine cavity is invaded in its removal, the same method of buried suture applies. In these cases it is well to tampon the uterine canal and vagina for drainage with a continuous strip of sterilized gauze. The question has been raised whether the wound made by enucleation of a mural tumor without entering the endometrium should be simply closed with buried catgut sutures and left without drainage into the uterine canal, or whether an opening should be made into the endometrium for that purpose. I have operated several times in both ways, and always with success. I recall one case, however, of large tumor, the enucleation of which made a very large wound in the uterine wall. This was closed with buried catgut sutures without establishing any drainage into the uterine cavity. The patient recovered, but only after a period of high temperature and rapid pulse which lasted for about two weeks. During this time the uterus was enormously swollen and I feared suppuration in the uterine wound. Nothing, however, was done in the way of a secondary operation for drainage. The experience of this case indicates that drainage into the uterine cavity is desirable for large uterine wounds. In the introduction of the gauze tampon I always dilate the uterine canal from the abdominal side, the temporary elastic ligature being in place around the cervix, and then force a continuous strip of gauze three or four inches wide down into the vagina, packing the vagina first and then the uterine cavity. All of the gauze may be removed in forty-eight hours by traction from the vagina. If not removed within two or three days it is apt to produce high temperature and rapid pulse, which usually subside promptly upon its removal.

I have presented these three cases, all of which recovered, to illustrate the fact that there can be no stereotyped operation for uterine myoma. Each case must furnish its own indications for the particular operation which applies to it. Sometimes the entire uterus and its appendages must be sacrificed; often they may all be preserved and their functions restored;

sometimes the cervix uteri alone may be left, after the method of Baer. Often, as in Case 1, the injury to the pelvic peritoneum is so great that gauze packing is necessary for drainage and hemostasis. In other cases the injury is so slight that when the ligated stumps are drawn down into the vagina and the vaginal and abdominal wounds are closed there is no peritoneal traumatism save the united wounds, and therefore no need for gauze packing. The modern tendency is properly on the side of the vaginal drain as against drainage through the abdominal wound. When no opening has been made into the vagina in the course of the operation proper, and drainage is necessary, I would favor as a general proposition that such an opening be made there, posterior to the cervix, for the purpose of drainage. The advantages of this are, 1, better drainage; 2, complete closure of the abdominal wound; 3, consequent rapid convalescence; 4, minimum risk of ventral hernia.

In myomectomy the uterus should, if possible, be saved when the tubes and ovaries are healthy. When the appendages have to be removed, the uterus may as well go with them, especially if its removal facilitates drainage or in any way renders the operation more simple. I do not, however, share a certain modern prejudice against the uterus, which would prompt one to remove it simply for the purpose of getting it out of the way.

## NOTES ON TAKA-DIASTASE.

BY T. H. ALLEN, M.D.

NEW YORK.

I have been using taka-diastrase recently in a large number of cases, my attention having been called to it some time since by a physician whom I met in consultation.

It has been efficacious in such cases of amyaceous indigestion as are so frequently met with in gynecologic practice, and which seem dependent on irritation of the sympathetic governing digestion. The following case best illustrates its effect:

Mrs. H., aged 38, had chronic ovaritis with intense pain in left inguinal region, flatulency, headache, colic occasionally. The ovaritis had been treated in the usual way, but the intestinal pains depending upon the flatulency and headache, resisted all remedies until I administered the taka-diastrase in three grain doses after each meal. The result was remarkable in its promptness; at the end of three days the tympanites and pain had completely disappeared. I continued to use the remedy during two weeks, after which time there was no return of the symptoms. The ovaritis is yet being treated.

Instead of giving in detail a report of the cases in which I have seen so much benefit derived from the use of taka-diastrase, I will only mention one other case. Mrs. X., aged 26; fibroid of the uterus. Owing to the continued loss of blood she was very anemic and very much run down generally. She suffered from flatulence and digested starchy foods poorly. The relief of her intestinal symptoms and increase in weight was marked soon after she began to take the remedy.

In treating cases of this kind, where there is an abnormal degree of acidity in the stomach, I have in some cases given a dose of bi-carbonate of soda or lithia immediately before eating, thinking that by

lessening the degree of acidity the digestive properties of the diastase were less apt to be interfered with.

I consider taka-diastase a valuable addition to our newer remedies and do not hesitate to recommend it most cordially for the various forms of amylaceous indigestion. I might add that a very large proportion perhaps more than half, of the cases of indigestion we meet with are of the amylaceous variety, and the reason why we are so often disappointed in the use of pepsin is that we give it in cases needing a ferment to aid in the digestion of starches and not proteids.

52 West Forty-fifth Street.

## SOCIETY PROCEEDINGS.

### British Medical Association.

*Sixty-fourth Annual Meeting held at Carlisle, Eng., July 28-31, 1896, under the Presidency of William Barnes, M.D., F.R.C.S., J.P., of Carlisle.*

[Reported for the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.]

The proceedings began with a meeting of the Council, and was followed by a general meeting in the new Public Hall. Subsequently a special service was held in the Cathedral, it being attended by a considerable number of medical men and their friends. The Bishop's sermon was appropriate to the occasion.

At the second general session the report of the Council was presented and adopted. It showed the Association to be in a satisfactory condition, both as to its finances and membership. Last year the number of members on the books was 15,669. During the past year 1,240 had been elected, 145 had died and 442 had resigned, leaving on the books 16,332.

Reports of various committees were also presented and adopted.

DR. CHARLES PARSONS of Dover was elected Treasurer of the Association.

A resolution was introduced and adopted, requesting the Ethical Committee to draw up a Code of Professional Ethics to be submitted to the Association for discussion and ratification.

PRESIDENT BARNES then delivered his address, an abstract of which we give herewith:

#### THE PRESIDENT'S ADDRESS.

He selected for his subject "The Medical History of Carlisle." At the outset he stated that it was assuredly a distinction of no common kind to be elected President of the British Medical Association, the largest and most powerful medical association which the world has ever known. Having its origin in a small provincial city sixty-four years ago, it had grown and prospered, and now numbered among its members all that was most distinguished and eminent in the profession. When he looked back to the long list of distinguished men who had preceded him in this position, his mind was filled with misgivings, for the list included names of men distinguished alike for their high literary and professional attainments. The only claim which he could advance was that he had worked for the Association for nearly thirty years.

After a brief sketch of the general history of Carlisle, the speaker passed on to matters of medical interest and importance. He spoke of those eminent Cumbrians who had contributed to the advance of medical science, and of the conditions of life which existed at various periods. The question as to whether the Roman armies were provided with medical officers was one which had not received much attention from archeologists. In many of the works on Roman antiquities there was no allusion whatever to it. The practice of medicine was not much encouraged in the early days of Roman power, and its professors were not held in high esteem. The surgical treatment of disabled Greek warriors was minutely described in many parts of the Iliad, and in Xenophon and other Greek writers reference was made to the services rendered by surgeons in times of warfare. But neither in the Roman classics nor among the writings of the Greek physicians who practiced in

Rome are there any direct notices relating to the medical and surgical care of the numerous and scattered armies employed by Rome in different parts of the world. Celsus, it is true, lays down very distinct and practical precepts for the extraction of war weapons from the bodies of the wounded; but neither he nor Paulus Ægineta make any allusion to the appointment of physicians and surgeons as a part of the regular army. Bitter military experience, however, proved in ancient times, as it has often done in modern times, the necessity of having an efficient medical staff in connection with the armies in the field, and in no part of the world was this more clearly shown than in this part of Britain. Some modern discoveries in this part of Great Britain and elsewhere have demonstrated that in the time of the Empire, at all events, the armies of Rome were provided with a medical staff. Among the many monumental tablets which have been discovered along the course of the great Roman wall there is surely none more interesting than one which was discovered a few years ago at Housesteads. The inscription shows that it was erected by the first cohort of the Tungrians to the memory of their "medicus ordinarius." This cohort distinguished itself under Agricola at the battle of Mons Grampius, and was afterward engaged in the erection of a portion of the more northern Roman wall of Antoninus.

Another point in connection with the early history of Carlisle is deserving of notice. One of the earliest institutions established for the reception of cases of leprosy in this country was placed just outside the city walls. It is not quite certain at what period leprosy was first introduced into England, but it must have been fairly common before the date of the Norman conquest, as he finds it the subject of legislation in the codes of a Welsh king, Hoela Dha, or Hoel the good, who died about the year 950. In the laws relating to married women, it is enacted that a wife may leave her husband without losing her dower if the husband become a leper. It is reported that Lanfranc, Bishop of Canterbury, who died in 1080, founded two hospitals at Canterbury, one for general diseases and one for leprosy. Some years ago the speaker investigated the records of the leper hospitals connected with the counties of Cumberland and Westmoreland. These were three in number, but the Hospital of St. Nicholas at Carlisle was the wealthiest and most important. The earliest records of which he could find any notice date back to the year 1180. There is a general concurrence of opinion that it had a royal foundation, and some historians believe that it was founded by William Rufus. If this be so, it was one of the earliest institutions of the kind in this country. Leprosy seems to have been a fairly common disease in this part of England, there being several hospitals for lepers in the adjoining counties of Cumberland, Westmoreland and Northumberland, three of which provided accommodation for ninety-one lepers.

At the close of the thirteenth and in the early part of the fourteenth centuries the city of Carlisle was the scene of many events in the history of England. Here within our walls three parliaments were summoned by Edward I, the father of parliaments. Here, in this remote corner of the English kingdom, probably for the first time in the world's history, the question of river pollution was brought under the consideration of a parliament. The Earl of Lincoln came to the Carlisle Parliament to seek redress for the restriction of the channel of the river Thames and its general condition, being so restricted by filth and refuse. The Earl prayed that "the Mayor, Sheriffs and discreet Aldermen of London may inspect the river Thames, and restore it to its former condition." The matter having been considered, orders were given by Parliament that impediments to the course of the river caused by filth and the refuse of barnyards be removed. This early recognition of the evils of river pollution by a parliament met to consider the general business of the country is a striking testimony to the value attached to sanitary legislation by our ancestors, and the prompt action which was taken contrasts strongly with the tardy legislation of modern times.

During the dark period of the Middle Ages there is little medical progress to record in connection with the history of the district. In common with other parts of the country medicine was here under a cloud, and we find abundant evidence of the faith in charms, witchcraft and the miraculous gift of healing supposed to be the special attribute of the reigning monarch. Several persons suffering from the king's evil were certified by the clergy and church wardens, or by the local justices, and sent to obtain the royal touch in order that they might obtain that restoration to health which the physicians of the day were powerless to give. Much of the ordinary medical practice was in the hands of irregular practitioners, and apparently a good deal of domestic doctoring was done by the heads of families. A few extracts from the account books of Sir Daniel Fleming of Rydal, shows the value which attached to

the services of regular and irregular practitioners. Under date of Aug. 10, 1658, there is an entry, "Given unto George Brown of Troutbeck, a bonesetter, when Will was hurt, 00 02 06. August 11. Given unto William Story of Seadgewicke, near Oe Sighser, bonesetter, for lookeing at Will's thigh, 00 07 06. August 12. Given unto John Rawling, a bonesetter for Will, 00 01 0." The services of these three irregular practitioners do not seem to have been of much avail, for the account book shows that a certain Dr. Dykes obtained "for comeing and laying plasters unto Will, 00 10 0;" and at a later date, "for his plaisters and paines contributed towards the cure of Will, the sum of 05 00 00." The same account books also show the value of the services of a midwife. Under date July 30, 1659, there is this entry: "Given unto Daniel Harrison's wife for being my wife's midwife, 00 05 00."

In the eventful history of Carlisle the visitations of the plague have at times caused serious calamities; occasionally the disease has swept away such multitudes that the living were scarcely sufficient to bury the dead. One of the most notable epidemics was the great plague of 1598, which is alleged to have caused a mortality of 2,260 at Penrith, 2,500 at Kendal, 2,200 at Richmond and 1,196 at Carlisle. These figures, which are taken from an inscription on a stone in the chancel of Penrith Church, have given rise to considerable controversy. The Carlisle parish registers do not go so far back, and the Penrith registers only record the deaths of 583 persons from plague at this period. It is therefore now believed that the numbers refer to the mortality in the rural deaneries bearing the above-mentioned names. Another great plague occurred in many parts of the country in 1623, and a third occurred in 1646. Of the former we find evidence in many local parish registers, but of the latter we have few particulars. The historic MSS. of the mayor and corporation of Carlisle, under date 1649, contain the following reference: "It is ordered that John Diffecke, bellman, shall have forthwith paid to him . . . the sume of forty shillings in consideration of his labour and paines during the time the heavy judgement of Plague continued in this place in the year 1646." The circumstances of the town about this period were such as to make an outbreak of the plague exceedingly probable. The citizens had suffered much from wars for a series of years. In July, 1644, it was seized by Royalists, and was besieged by Lesley in October, the siege lasting many months. It had a garrison of about 700. About the end of February all the corn was seized to be served out on short allowance. On June 5 "hempseed, dogs and rats were eaten." All Cumberland was in such a state of destitution that Parliament ordered a collection for its relief; numbers of the poor are said to have died in the highways, and 30,000 families were in want of bread.

In the evolution of its sanitary administration, progress has been somewhat slow in Carlisle. During the Middle Ages, the government of the town was first vested in the free merchants' guild, which in later times became the town council. The Governor or Dormont Book, which bears the date of 1651, contains a code of by-laws for the government of the city, and among them are many useful sanitary edicts. It is ordained that, "If any person or persons hereafter caste any manner of corruption as deyd dogs, cattis, nolt hornes, or any other thinge corrupte in any of the common wells of the city, or do place any midden or dunghill towards any of the said wells or within twelve feet thereof, he is to be fined for every offence 6s. 8d. to be levied of his goods, or else to be extremely punished by the Mayr as of the pillorie or otherwise." Swine are not allowed on the common streets; for the first offence the penalty is 6d., for the second 12d., and for the third the swine are to be forfeit to the "Mayr and balif." Penalties are also ordained against inhabitants who fail to keep the forefront clean to the middle of the pavement, and middens and dunghills are to be cleared away within eight days.

The Chamberlain's accounts of the city contain several items of expenditure for cleaning the town dykes, removing dead animals, etc., and during times of pestilence special precautions were taken to prevent the introduction of the disease. The following is the heading of one of the accounts: "Disbursements in attending the gaittes in the time of the seakness being at Newcastle beginning the iiii of August, 1603."

In 1874, however, voluntary agencies were superseded and a regular sanitary administration established. A medical officer of health was appointed, who has since published annual reports of the health of the city. From these reports it is possible to judge of the results to some extent of sanitary administration by comparing them with previous periods. The earliest data upon which any reliance can be placed are the bills of mortality drawn up by Dr. Heysham. In the eight years between 1779 and 1787 there were 1,615 deaths, being at the rate of 24.9 per 1,000. In 1788 to 1795 the rate rose to 26 per

1,000, while from 1796 to 1800 it was only 23.3. In the ten years from 1800 to 1810 with the average population at 12,660, the death rate was again 23.3 per 1,000. It was upon these tables that the Carlisle tables of mortality were founded, which afterward became so much used by life insurance offices. The complete tables of the first period are the only ones to which he had access. The most fatal disease in the list is smallpox, which caused 238 deaths. Consumption was the cause of 214 deaths, 204 deaths were due to the weakness of infancy, and 226 are set down to the decay of old age. There were 493 deaths due to what we should now classify as zymotic diseases. Between 1842 and 1848, with an average population of 24,000, the death rate varied from 24.25 to 43.92 per 1,000. Since the publication of the reports of the medical officer of health there has been a steady fall in the death rate. In 1874 it was 32.6; in 1875 it was 29.2; and in 1889 it had fallen to 18.1. In 1874 the zymotic rate was 11.3; last year it was only 0.8.

Dr. Barnes closes by saying that the question of the improvement, training and restriction of midwives was one to which much attention had been devoted, and it was one which called for a speedy settlement on a satisfactory basis as much in the interest of the public as of the medical profession.

The present unsatisfactory state of the law relating to Certificates of death and Coroner's Inquests had often been under consideration and steps must soon be taken for its amendment.

The compulsory registration of stillbirths was another matter of urgent necessity. These were all matters in which the public was as much, or even more concerned, than the profession. Free discussion in meetings like the present would lead to more definite views of public and professional requirements, and he concluded with the hope that the deliberations at this meeting would help to further a settlement of some of these questions.

Sir DYCE DUCKWORTH, M.D., LL.D., F.R.C.P., delivered

#### THE ADDRESS IN MEDICINE.

He selected for his subject "The Importance of Prognosis of Disease." The first part of the address was largely historic. In recent times the literature relating to prognostics had been far to seek, and the speaker knew of no work purely relating to the subject which had been published in this century. He dwelt at length upon acute specific diseases, after which he discussed chronic infectious diseases.

The prognostics respecting syphilis relate largely to individual peculiarities, habits and environment, to the adequacy of treatment, and the degree and virulence of primary impregnation. It is certain that the greater number of persons so infected ultimately recover satisfactorily if they have been properly treated from the outset. It is equally certain that the character of the primary lesion does not enable us to prognosticate the ultimate evolution of the malady.

Pyemia and septicemia.—If organisms be present in the blood of the patient, and capable of cultivation from it, the prognosis, according to Kanthack, is bad.

Prognosis in relation to tuberculosis is a large question. The factors on which determination has to be made vary greatly with the individual and his environment. Without doubt the prognosis of all disorders of a tuberculous nature admits of a more hopeful view than formerly.

Cancer of the stomach commonly proves fatal within a year from the time a certain diagnosis is made. Those cases last longest and have less suffering in which neither orifice is involved.

In cirrhosis of the liver, if signs of toxemia set in, life will not be prolonged many days. Tapping of ascitic fluid may aggravate the nervous symptoms of such toxemia. If a free collateral circulation is gradually established between the portal and systemic veins, life may be prolonged for some years. A recurrence of either copious hematemesis or melena is generally fatal.

Cancer of the liver is usually fatal within twelve or fifteen months, but rapidly growing tumors sometimes in a few weeks. Cancerous growths of the peritoneum commonly kill within a year.

Gallstones.—The prognosis of cases in which gallstones are believed or proved to exist in the gall bladder is always uncertain. Many may be present for years and give rise to no or few symptoms; or a few may be present and cause serious attacks of biliary colic. Continued irritation from them may induce cancer of the gall duct, the gall bladder and the liver. Obstruction of the small intestine, commonly the ileum, is sometimes a grave complication due to plugging by a biliary calculus. A calculus may be removed from the bowel and the gall bladder emptied of calculi with complete relief of all untoward symptoms. Although unaware of any treatment by diet or by drugs which can cause removal of calculi already formed, their

further formation can certainly be prevented by appropriate medical procedures.

**Typhlitis.**—Many cases recover under judicious medical treatment. Perityphlitic abscess, if opened carefully about the ninth or tenth day, and the peritoneal cavity escape contamination with its contents, may generally heal favorably. Earlier surgical interference is very apt to lead to a fatal issue by toxic peritonitis. A gangrenous state of the vermiform appendix, if diagnosed, demands an early operation.

In diseases of the heart the outlook is generally better than it was half a century ago. Pericarditis of rheumatic nature is very rarely fatal *per se*. In Bright's disease pericarditis is commonly fatal, and septic pericarditis is uniformly so. With the practice of aseptic surgery purulent pericarditis is no longer necessarily fatal. Tuberculous pericarditis may be rather protracted, but is beyond recovery. Pneumo-pericardium is commonly fatal within two days. Rupture of the heart is generally promptly fatal, whether from injury or as a result of muscular degeneration. Tachycardia demands a very cautious prognosis. The outlook in Grave's disease is uncertain. One case in three may recover. In the viable class of congenital malformed heart life is rarely prolonged over puberty. A better prognosis for longevity attaches to lesions of the aortic orifice, which are however rarely encountered. Life may be prolonged to the third decade in these cases. Ulcerative endocarditis is almost always fatal.

**Aortic aneurysm.**—No certain prognostics can be laid down in cases of this disease. Sacculated aneurysms of the ascending part of the thoracic arch, pressing forward, are commonly very chronic and cause least interference with vital structures, but they may vary in the direction they take. In aneurysm of the abdominal aorta the prognosis is always grave.

**Arcus senilis** is perhaps more generally recognized as a diagnostic than as a prognostic sign of a degenerated vascular system.

**Diseases of the blood and ductless glands.**—Simple anemia in young women is apt to recur, but most cases will recover if vigorously treated at intervals for three years. Pernicious anemia admits now of less grave prognosis than formerly owing to treatment with arsenic and marrow. Examination of the blood may help us in prognosis. Kanthack considers a steady diminution of leucocytes a bad sign and no less grave is an increase of the nucleated red corpuscles with a progressive diminution of hemoglobin. Leukemia generally proves fatal within two or three years. The pure lymphatic form is the gravest. Hemorrhagic tendency is of evil augury. In Hodgkin's disease recovery is rare, most patients die within two years. A fatal result is usual in Addison's disease within two or three years, but life may be prolonged for six or eight years.

**Diseases of the kidneys.**—Anuria of the obstructive variety, unless relieved by surgical measures, generally proves fatal within two weeks. The prognosis in respect of albuminuria is only to be framed by full consideration of all the features of each case. Chyluria of the non-parasitic variety may last for many years without disturbance of health. Chronic nephritis, tubal, interstitial or tubulo-interstitial often runs a protracted course. Prognosis can be framed only by a consideration of all the personal and diathetic factors in each case.

**Diseases of the nervous system.**—Taking the whole group of conditions due to neuritis, we may affirm that our prognosis is guided by consideration of the etiology and personal factors in each case. Early recognition of the nature of the disorder and of the peccant matter which has induced it is no less important than early treatment. The cases often last for years, but the results are quite remarkable if treatment be persisted in.

The prognosis in Ménière's disease is always uncertain. Recovery may occur, but deafness is the most frequent result. The symptoms may persist through life. In torticollis complete recovery is rare. In essential paralysis of children the outlook is certainly less grave than formerly if assiduous electric treatment be long carried out from the outset. In locomotor ataxia no absolute cure is to be expected. Cases setting in violently are often devoid of the characteristic later symptoms, and an arrest of the disease may ensue. This is especially noted after the occurrence of early optic atrophy. In aphasia the prognosis is only hopeful in the young, who may be educated again in the right cerebral hemisphere.

**Cerebral apoplexy.**—Prognosis in this condition chiefly relates to the particular locality involved and the size of the blood clot. Pontine hemorrhage is uniformly fatal, generally within a few hours, and so is that into the ventricles. The gravest indications are deepening coma, rising temperature two days after the hemorrhage and Cheyne-Stokes respiration.

**Chorea.**—Cases of this disease admit of a generally favorable prognosis at any age below puberty. At that period, and after, the outlook is much more grave. Chorea insaniens is

a very dangerous form. The average duration of the disease is ten weeks and three days.

**Epilepsy.**—The truth of Hippocrates' aphorism respecting this malady is still attested: "Epilepsy supervening before puberty may undergo a change, those cases arising after the age of 25 for the most part terminate in death."

RODERICK MACLAREN, M.D., of Carlisle, delivered

#### THE ADDRESS IN SURGERY.

His subject was "Preventive Surgery." He claimed that it was a product of modern times, the outcome of recent advances in the knowledge of the intimate causes of disease, of the introduction of anesthetics, and of perfected methods of wound treatment.

The conditions which render preventive operations justifiable were next considered at some length. Passing on to anesthetics, the speaker said that surgeons no longer inflicted pain during any operation. This had been a solved question for fifty years; and in this, the jubilee year of anesthesia, he thought it not inappropriate to call attention to a development of surgery which hangs entirely on its use. There are still, however, longings after the perfect anesthetic, which should be as portable, manageable and pleasant to take as chloroform; as capable of long use as either chloroform or ether, and yet as safe and free from after-effects as nitrous oxid.

For minimizing after-pain, much rests with the individual surgeon. If he avoids by direction of incisions all unnecessary injury to nerves, if he manipulates as gently as possible, if he leaves his wound free from tension either by tight sutures or contained blood-clot, secures the most restful position, and ensures for his wounds a normal healing, he may do extensive operations with exceedingly little after-pain.

A large amount of preventive operative surgery has a casual connection with the throat and naso-pharynx—diseased conditions, to which are given different names, branch in various directions from this locality as a common center. They are conditioned by the various tissues and localities they subsequently affect, by their rate of spread and by their surroundings, and they give rise to appearances entirely different and which often seem to be separate diseases till we go back to their essential nature and cause. Under ordinary circumstances the inspired air entering the body is free from organisms by the time it reaches the back of the nose. But when highly charged with impurities this is altered, and as the air there turns at angle and meets with a moist surface organisms and their spores are deposited. There are crypts, gland openings, and channels in which they find a home; if their nature be infective only a delicate and easily injured epithelium separates them from lymphatics and veins, ready to carry them to new fields. Even if this region remains their home they may cause tissue growth in the form of enlarged tonsils and adenoids.

The inflammatory swelling set up by organisms may hinder the exit of natural secretions from cavities, as, for instance, from the Eustachian tubes, giving rise to their distension with fluid and admirably fitting them to promote the further growth of microorganisms. These start a chain of changes which has often grave consequences. With the preventive surgery of this region there is no small risk of overlooking the original cause. Hypertrophied tonsils, adenoid growths, suppurating ears and glands are all so obvious that further investigation is apt to stop, leaving out of consideration the behind cause, though it should be removed as well as the visible lesions attended to.

Enlarged tonsils and adenoid growths produce some slight local discomfort, but the chief evil they do is in checking growth and nutrition. Children who are affected with them are generally small for their age, anemic, and ill-developed; their chests contracted and drawn in along the line of the rib cartilages. It is often striking to see the growth and development which follow the removal of large tonsils and the scraping away of adenoids. The guillotine operation for tonsils is wanting in precision, and very given to miss the lower portion of the tonsil, which may be much hypertrophied just out of sight. It fails moreover in those cases in which the enlarged tonsil is contained and hidden between the pillars of the fauces. The imperfect results which it so often gives have brought the operation into a certain degree of undeserved discredit from the frequency with which the portion left increases again. It is much more satisfactory to give the patient a deep anesthetic and deliberately cut out—or, still better, with a blunt director tease out—the whole structure, doing an operation of precision.

Adenoid growths in the naso-pharynx produce similar remote effects to those of enlarged tonsils; their nature is presumably the same, and most commonly they exist together. So, generally speaking, the removal of tonsils is not a com-

plete operation without a scraping away of all growths. Few operations give so good results with so little trouble. In the throat is the common starting point of another set of conditions in which preventive surgery has given assured and brilliant results. From diseased and swollen mucous membrane, from secretions bottled up and cultivating organisms powerful for evil, a train of sequences is set up which may ultimately result in brain abscess or purulent meningitis. The middle ear may be converted by the blocking of the Eustachian tube into a full cavity with complicated recesses and chambers. These become the dwelling of many organisms, which set up suppuration and destruction of tissue, the ear drum gives way and opens a new channel of contamination, or it may be that an independent opening to the surface is formed behind the ear, and pus escapes there. Every case of suppurating ear should not be made the subject of operation, for many are amenable to treatment and are permanently cured. With many, however, treatment fails, and everybody who has a chronic suppurating ear goes about in deadly peril. It should be a rule to operate on every discharging ear which does not get right by treatment. The mastoid cavities should be laid open and converted into hollow cones; all diseased bone should be removed, all unwholesome structures scraped away and everything made suitable for speedy healing, not for the sake of the ear as an organ, not even for the sole purpose of removing the local trouble, but for the avoidance of the grave secondary risks which are always present.

He believed the view generally held by surgeons was that so long as hernia could be steadily kept up by a truss, which does not much incommode nor prevent the patient following his occupation, there was no necessity for operative interference. But if trusses fail for any reason to keep up the gut, if the truss is painful to bear and excites repeated inflammations of the sac, or if the patient's occupation requires exceptional activity, the time has come to operate. Perfect results can be got from almost all the present so-called operations. Whatever secures good closure of the rings effects a cure. The peritoneum is of hardly any value in aiding the integrity of the abdominal wall. If left in the ring it is undoubtedly a source of weakness by keeping open a channel and preventing a union of the stronger structures, but in itself it is a mere slack distensible membrane with little resistant capacity. It is on the union of the aponeurotic and tendinous structures, and oblique that we rely for real strength, and the more thoroughly we get these together, and the more they form a uniform sheet the less likely is the rupture to recur.

Among the miseries which may make long life a burden to its possessor there are none greater than those resulting from an enlarged prostate. It is much better to advise early operation than to wait for a desperate state of matters. We have a certain latitude of choice in operations. Supra-pubic cystotomy may be combined with perineal removal of portions of the prostate, or with perineal drainage, and finally we have castration.

Suprapubic cystotomy with removal of enlarged prostate, whether central or lateral, and the establishment of a clean low-level canal into the urethra, is at present the operation to be first considered, though every surgeon should be prepared to deviate from it should local circumstances show that this would be of advantage. The resulting mortality is small, perhaps not more than 1 in 10, and it must be kept in mind that the condition itself is a very fatal one. The mechanic result is that in at least 40 per cent. the bladder recovers its function, and in the remainder suprapubic drainage establishes a state of greatly increased comfort. Within the last three years a new operation has been introduced for enlarged prostate. Relying on the observed fact that atrophy of the organ follows removal of the testes, surgeons have performed castration. The operation is too new and the cases too few to allow of any decided opinion of its merits; the results, however, have been sufficiently good to justify its further employment. Cases in which the urine was offensive and loaded with mucus and requiring removal at frequent intervals are reported as, after operation, passing a healthy urine spontaneously, and as having no detectable enlargement of the prostate. In other cases, though complete cure has not followed, a large improvement has. From one or other method we have the possibility of preventing one of the most prominent terrors of old age.

Twenty or thirty years ago a physician or surgeon attending a patient with an acute condition of distended tympanitic and painful abdomen, a quick and small pulse, and drawn-up legs thought that he had fulfilled the whole duty of man when he had diagnosed peritonitis and excluded perforation of the stomach and obstruction. Who is content with such a diagnosis now? It has gradually become apparent to our minds that peritonitis has almost always its cause in some other lesion

and that our investigation is not complete till we have localized that cause. We know also that the origin is very often indeed situated in the appendix vermiformis, that this tube is subject to several morbid states; it may be strictured, and the part distant from the bowel may distend with septic contents; it may ulcerate through; it may be the seat of tuberculous disease; foreign bodies may lie in it or concretions form; the whole thing may go gangrenous. As consequences of these we may have at one end of the scale a mere local disturbance passing away after a few days' discomfort or at the other a general rapid peritonitis followed by death. Between these extremes we find many degrees of severity of attack. Thus if a slow perforation occurs we have an abscess in the peritoneum, but shut off from the general cavity by adhesions. We probably hardly yet know the whole pathology of the appendix, but we know enough to form a good clinical idea in most cases of the essential state of matters.

A general peritonitis following perforation or a local abscess round the appendix demands immediate surgical interference; the stage is past when prevention can come in. The class of cases which falls within the domain of preventive surgery is that in which the appendix has not perforated, but in which it is subject to repeated attacks of distension, in which it inflames from retained concretions; indeed, when from any cause it is the subject of one or more inflammatory attacks of a severity short of immediate danger to life. Three views of surgical duty prevail. Some surgeons hold that the appendix should never be removed; that the probability of a putrid infection of the peritoneum during the necessary manipulations makes it an operation of unjustifiable risk, and that the prospect of natural cure is a more hopeful outlook. He believes this view is held by an ever-narrowing circle.

Another opinion strongly held both here and in America by men whose surgical work entitles their views to the highest possible respect, is that every appendix which has given rise to morbid symptoms should be cut down on and removed when in a quiescent state. The third view is that only after a repeated appendicitis and the failure of careful dieting does there exist the necessity for a preventive operation. The following arguments are adduced in favor of this view: The great majority of attacks are not repeated, after one all clears up, and no further disturbance occurs. Most instances of perforation are first attacks; an evidence that one seizure does not increase the probability of perforation in the case of recurrence and, lastly, that a milk and farinaceous diet and mild aperients are often successful in preventing return.

Another disease holds out the prospect of a wide field for the extension of the preventive principle, namely, carcinoma. There is much to learn about its nature. In the absence of knowledge we may use our reasoning faculties and make some effort to infer the unknown from the known. In cancer of the lip and in Paget's nipple are two instances in which the life-history is well made out.

Let us investigate the small and early changes. If we can find out the antecedent or even the first symptoms of carcinoma, we may then know how to prevent it. The recent developments of surgery in cancer have been in the direction of extensive operations and wide-reaching removal of tissue—wider than we dreamed of some years ago, for we are now aware that the visible disease is but a fraction of the total, and if we have far-spreading disease we must have sweeping removal. He thinks and hopes that there is in the future a preventive surgery founded on fuller knowledge, which will anticipate these great operations by small ones or, it may be, by such preventive measures as will do for cancer what we are steadily doing for so many other diseases—compress it within narrowing limits.

(To be continued.)

## SELECTIONS.

**Chloroform and Ether in Parturition.**—Bukoemsky, of St. Petersburg, in *Monatschrift für Geburtshülfe und Gynekologie*, March, has given comparative research to the use of ether and chloroform in normal labor. He remarks that while many observers have studied the action of chloroform, but comparatively little has been done for ether. Bukoemsky carried out a series of experiments to determine whether ether or chloroform render labor painless and why they do so; what effect they have upon the contractile power of the uterus, upon the strength and frequency of the pains and the interval between them, upon the dilation of the os, and the abdominal

pressure. He looked also for the irritative symptoms due to ether and chloroform, examining their action upon the kidneys, respiratory function, pulse, temperature and general condition. In the puerperal period he examined the loss of blood, the involution of the uterus, the lochia and the secretion of milk, and finally noted the effects on the child and the frequency and degree of icterus neonatorum. The following conclusions are drawn: 1. Ether undoubtedly diminishes the painfulness of uterine contractions in all cases and generally makes painless the actual birth of the child. Its anesthetic effect is most marked during the expulsive period, if the patient has been already partially under its influence. It does not prolong labor, but on the contrary seems to shorten it about one hour in primiparæ. It increases the force of the uterine contractions as shown by the toko-dynamometer. It does not lessen the length of the pains, but shorten the intervals between. "In respect of the secretion of milk, its effects were not unfavorable; in some cases the quantity seemed to be increased. Even in larger doses ether had no unfavorable effect on the fetus, which was in no case dull or narcotized when born. Icterus was less common and severe and the loss of weight was less during the first week. The best time for the administration of ether seemed to be when the os was dilated to the width of three finger-breadths; it seemed to have no effect upon the early dilation of the os. 2. Chloroform in small doses do not diminish the contractile power of the uterus. In the majority of cases examined the pains were shortened eight seconds, but in a few they were lengthened eight seconds. The intervals between the pains were generally lengthened 13 to 49 seconds. Although chloroform generally protects labor somewhat; it seems to have no ill effect on the mother when given in small doses. It is pleasanter than ether, but in a few cases slight irritative symptoms were noticed at the commencement of chloroform narcosis. It had no unfavorable effect upon the puerperal period, and in no case did hemorrhage occur when it was used in small doses. The children seemed unaffected by it, and a mild icterus occurred in about half the cases. The best time for administration is the same as for ether. In comparing the action of ether and chloroform it seems that ether is generally preferable, because it has less toxic effect upon the organism and does not produce such ill effects as chloroform if it has to be given in a relatively large quantity or for a length of time. Moreover, it shortens labor and has a more favorable effect upon the puerperal period and upon the fetus. As most of these patients were delivered at night, and a common coal-oil lamp was used in the room, there need be no fear of ether taking fire or exploding if ordinary precautions are used. From these observations it seems clear that either anesthetic may be used in ordinary cases of labor, if given carefully and in small doses, without injuring mother or child and without causing hemorrhage during the puerperal period. It is equally certain that chloroform may predispose to hemorrhage and injure both mother and child if given in too large doses or for too long a time. Chloroform should be selected when complete relaxation of the soft parts is required or when there is much spasm to overcome. Ether is preferable when deep anesthesia has to be maintained for some time, or when there is severe cardiac trouble, or when some operation has to be done after the conclusion of labor, such as the repair of perineal laceration or the removal of an adherent placenta. When chloroform has been given for some length of time during labor, the child is apt to be lethargic when born and does not begin to cry without considerable stimulation."

**The Strychnia Cure of Alcoholism and Opium Habit.**—A certain proportion of the submerged 4,000 who pass yearly through the alcohol wards of Bellevue Hospital distinctly and seriously wish to have a treatment given them which will take away

their tendency to periodical sprees. Consequently the use of strychnia and the solanaceæ, with certain adjuvant tonics and moral influences, is employed in these cases. The technique of the treatment as arranged by myself has been carried out most skillfully and improved in its details by my house physician in charge of the alcohol cells, Dr. J. D. Brown. I am greatly indebted to him for the intelligence and faithfulness shown in his work among this class. The drugs selected for use in this "cure" are those which the experience of ten years in the care of these cases has shown me to be most useful. The suggestive and moral influences thrown about the "cure" are borrowed, I freely admit, from the Keeley and other alcohol cures of the country. Selected patients, after having passed through an attack of acute alcoholism, and are convalescent, are allowed to remain two days and take the "cure." The wards of the hospital are not large enough to permit of a longer stay. Only persons who have reasonable intelligence and who show real evidence of sincerity are chosen. The following solutions are used:

- I. R. Strychnia nitrat . . . . . gr. 1-15.  
Atropiæ sulph . . . . . gr. 1-300.  
Aquæ distilled . . . . . m. x.  
Misce. Sig. Inject t.i.d., first day injection.
- II. R. Strychnia nitrat . . . . . gr. 1-20.  
Atropiæ sulph . . . . . gr. 1-200.  
Aquæ . . . . . ℥x.  
Misce. Sig. Inject t.i.d., second day injection.
- III. R. Tinct. cinchon. comp . . . . . m. xv.  
" capsici . . . . . m. ½ to m i.  
" solan. carolineus . . . . . m. ii.  
Vini ferri amari . . . . . ad ℥i.  
Misce. Sig. Mistur. stomachic., ʒi t.i.d. Shake.
- III. Order: ½ to 1 glass of milk (hot or peptonized), alternating with hot beef tea or broth, every two hours.
- IV. First and second nights, if needed.  
R. Potas. bromid . . . . . gr. xxxii.  
Chloral hydrat . . . . . gr. xvi.  
Tinct. valerian. . . . . ʒi.  
Aquæ . . . . . ad ʒiv.  
Misce. Sig. ʒi dose, repeated once, if needed.  
Shake. Mistur. sedativ.

The patients are given the injections I. and II. and "stomachic," III., three times a day, with abundant nourishment, washing out the stomach if necessary, to help any catarrhal disturbance. The patient, during the treatment, is made to understand distinctly that he is taking a "cure" with all that that implies, but no mystery is made of its character or of the means used. After the second day he is perforce discharged. In most cases his craving is gone, but this generally occurs after a debauch. In fact, the natural history of many cases of periodic alcoholism is that craving ceases after the spree for from one to nine months. On being discharged, the patient is given:

- IV. R. Tinct. columbo . . . . . ʒi.  
" capsici . . . . . m. xv.  
" nucis vomic . . . . . ʒi to ʒiiss.  
Apomorphinæ . . . . . gr. ½.  
Tinct. cinchon. co . . . . . ad ʒiv.  
Misce. Sig. ʒi t.i.d. in water after meals.

The patient is told to take this and report weekly. After a month he reports monthly, and is kept supplied with the bottle, which he is told to take the minute any craving develops, and report at once. By the application of this method to alcoholics, we are able to send out many patients with hope in the future, confidence in themselves, and a staff upon which to lean in this weakness. The same treatment, when applied to patients with the morphin habit, has to be given much longer, and sometimes must be modified by adding bromids or gradually reducing the morphin. Dr. Brown was able in one case to stop immediately the use of morphin taken to the extent of 30 grains a day. The patient did not suffer in the least.—CHARLES L. DANA, M.D., in *Post-Graduate*, July, 1896.

**Operative Treatment of Entropion and Trichiasis.**—The lid is split in the ordinary manner along the whole border of the eyelid, or only a short distance if the in-curving of the lashes is but partial. The incision is placed well behind the roots of the cilia and is carried up into the substance of the lid a distance of from 4 to 6 mm. A second incision is then made through the skin on the outer surface of the lid, at a distance of from 2 to 4 mm. from the point of emergence of the lashes. This incision is continued parallel with the edge of the lid so far as the in-curving extends and carried down to meet the other, so that the edge of the lid from which the lashes are growing is then completely detached, except at its ends. But the incision is not taken horizontally backward; it is carried upward and backward, so that it joins the other at an acute angle. We have, then, the portion of lid containing the lashes attached only at its ends, but with its upper margin wedge-shaped. The next step consists in the rotation of this piece so that the edge from which the lashes spring is applied to the upper lip of the skin incision, the lower lip being pushed backward into the wound. This rotation can easily be effected by sutures passed from the lower margin of the detached portion to the upper margin of the skin incision. The sutures are tied and the operation is complete.—James W. Barrelet, M.D., F.R.C.S., in *Ophthalmic Review*, May.

**Injections of Gray Oil in the Treatment of Syphilis.**—Dr. James Galloway writes in the *Practitioner* that a much greater measure of success has followed the renewed trial of this treatment since an improved technique has been adopted. The preparations made use of are the gray oil and a suspension of calomel, as before; but it has been found advantageous to use vaselin oil in the manufacture of the fluids, in preference to other vehicles. (The gray oil formulæ are mercury, 3; lanolin, 3; olive oil, 4; or, mercury 39; mercurial ointment, 2; vaselin oil, 59. Martindale and Westcott.) But preferably Milliet and Thibierge's formula (*Vide Annat. de Derm. et de Syphil.*, 1894, p. 943, which is itself a modification of that employed by Professor Neisser). Three and a half drops of the gray oil and 1 gram of the calomel oil, containing 0.05 gram of the pure salt, are the doses now used instead of the much larger doses formerly employed. The injections are given weekly over periods of six or eight weeks, or at longer intervals as circumstances direct, and between each course of treatment is a period of repose, according to the rules formulated by Professor Fournier. The fluid is injected deeply into the muscles of the buttock, taking care to avoid the vessels and nerves of this region, and, in order to secure that the injection shall be placed at a sufficient depth, the syringe is armed with a needle of from 5 to 6 centimeters in length. Great care must also be taken to prevent any of the fluid from coming in contact with the skin or subcutaneous tissue of the part. A rigid antiseptis of the fluid, of the apparatus and of the skin is essential. With these precautions, the painful swellings, the abscesses, the severe mercurialism, which formerly gave the treatment "a black eye" are evaded. The advantages claimed for the method are: 1. the certainty and convenience of the treatment, so that, as a rule, the patient's occupation is in no way interfered with. The patient comes once a week for his injection, nothing interferes with his dose, and then he goes about his daily occupation, whether of pleasure or of business. 2. The secrecy which is characteristic of the treatment is much appreciated by patients, and can not be obtained so completely by any other means. 3. Its non-interference with the digestive apparatus and the liver—an important consideration when one recollects the evidence showing that structural alterations are produced not infrequently in the mucous membranes of the stomach and intestine, and in the liver by courses of mercury administered by the mouth. 4. The inability of certain patients to take mercury, owing to

the immediate irritation caused in the alimentary tract. 5. Its powerful effect and rapid action when compared with the other methods of administration—a fact of the utmost moment when syphilitic lesions of vital organs have to be treated.

The efficacy of the method has never been in doubt, and now many cases are on record of inveterate syphilis treated and completely cured by these injections, after having resisted all other forms of treatment. We will quote one only, given by M. Thibierge, which has the additional authority of Professor Fournier himself. The patient was a cachectic and chronic syphilitic of eighteen years' standing, and suffered from severe headache associated with the formation of exostoses from the cranial bones. Very little result had been obtained by Fournier with the ordinary methods of treatment, and the patient was sent to Aix-la-Chapelle, where he was subjected to courses of inunction, which had given much pain and inconvenience, but did no good. He then had the good fortune, as Fournier puts it, to consult Thibierge, and was treated by injections of the gray oil; he rapidly lost the headache, and at the same time the exostoses diminished in size, while his health rapidly improved.

As to the relative merits of the gray oil and calomel, it appears that the effect produced by the calomel is more rapid and powerful, while the gray oil acts somewhat more slowly, but causes little or none of the characteristic pain; so that, as Thibierge remarks, in the case of calomel we have a remedy producing its effect *cito*, while the gray oil has the advantage of acting *tuto et jucunde*. The only inconvenience is the pain which seems to be so often the result of the injection. At the actual time of the injection nothing is complained of, but on the third or fourth day a certain amount of pain resembling that caused by a bruise is felt at the spot where the operation has been performed; it reaches its maximum on the fifth or sixth, and subsides by the eighth day. In the majority of cases the pain is not severe, in many it is altogether absent, but in a small proportion it is so acute as to render the method intolerable. Even in the last group of cases the pain does not always occur, and thus it is suggested that the very severe pain is an accidental circumstance, and may in the future be eliminated.

## PRACTICAL NOTES.

**Cause and Treatment of a Volvulus.**—Prioleau states that a frequent cause of volvulus is defecation deferred when the desire is imperious, on account of the conflict between the peristaltic and antiperistaltic movements. Mucous enteritis and sigmoiditis may also produce the same result. The most important diagnostic indications are the absence or tardy appearance of vomiting and a sharp localized pain accompanied by local meteorism. Treatment recommended: Forced injections of 3, 4, or 5 liters, administered with an Esmarch douche, and glycerined water at 100 per cent.; supplemented by puncture of the distended intestine and abdominal massage.—*Bulletin Méd.*, April 26.

**Efficacy of Thyroid Treatment for Fibroma of the Uterus.**—It was by accident that Jouin discovered the value of this treatment. He had a patient with a voluminous fibroma, and as she was painfully obese he administered thyroid extract to relieve her of her obesity, when he found that the fibroma shrank rapidly to one-quarter of its former size. He reported at the Tunis Congress that he had used it since in twenty-four cases, finding that thyroid medication certainly reduces the fibroid growth, and has also a most favorable effect on the attendant symptoms, local neuralgias, debility and depression, but it is especially valuable for its power to arrest the tendency to hemorrhage. It is very effective in uterine hemorrhages due to the menopause, with or without fibroid growths. He suggested

that as the fibroma is really only a sarcoma in a certain stage, thyroid medication may yet be found useful as a preventive. He suggested also a possible connection between the atrophy of the thyroid gland with increasing adult age, and the atrophy of the genital organs at the menopause, generalizing that lack of function may perhaps be the cause of the tendency of the tissues to return to their original embryonic fibroid state, of which the fibroma is an extreme instance.

**Low Temperature Pasteurization of Milk.**—Dr. Rowland G. Freeman recommends the Pasteurization at a temperature between 65 and 70 degrees C., for the following reasons: It destroys almost all the ordinary air bacteria which occur in milk. It destroys the bacillus tuberculosis, the bacillus typhosus, the bacillus diphtheria and many other pathogenic bacteria. It causes no change in the taste of the milk and avoids those chemical changes which are produced by higher temperatures.—*Archives of Pediatrics*, August.

**Results from Antidiphtherial Serum at Edinburgh.**—In the *Glasgow Medical Journal*, Dr. Ernest L. Marsh publishes a carefully prepared set statistic tables showing the influence of the antitoxin treatment on the cases of diphtheria admitted to the Belvidere Fever Hospital during 1895. The admissions numbered 179, and of these 137 were treated by antidiphtherial serum, the remaining 42 cases were not brought under the treatment, as being mild and not requiring it, or as being moribund on admission. Of the mild cases, the number was 38, and of the moribund there were 4 cases. The fatal cases numbered 25, giving on the admissions a percentage of 14 deaths. In the five years previous to 1895 the cases of diphtheria had never given a less percentage than 35.5 deaths in any one year, so that the improvement is a very impressive one. Of the 179 patients in 1895 tracheotomy was needed in 29, and of these 10 died, giving a mortality of 34.5 per cent. The author draws special attention to these cases and contrasts the low death rate with the high mortality of the tracheotomy cases in previous years, viz., 76.2 per cent. (42 cases) in 1893 and 86.9 per cent. (23 cases) in 1894.

**Diphtheritic Laryngeal Stenosis "Cured" with Behring's Serum.**—The *Deutsch. Med. Woch.* for July 9 describes a severe case of diphtheritic stenosis in which the parents refused to allow tracheotomy, as they had lost another child previously where it had been performed (non-serum treatment). The physician considered the case hopeless, but still administered a dose of Behring's serum (1,000 immunity units) with the usual local treatment. The case continued growing worse for thirty hours, when a sudden change for the better became apparent, and rapid improvement and recovery ensued. Bornemann adds that if other cases confirm this experience, that serum treatment promptly administered will cure diphtheria in spite of laryngeal stenosis (if it is of short duration and the heart still vigorous), new fame will accrue to its inventor and many children now considered past hope will be saved. All of which, to use an old phrase, "is important if true."

**Tuberculosis of the Lungs in its Inciency.**—The microscope, when it demonstrates the existence of tubercle, confirms the diagnosis of tuberculosis, but its failure to demonstrate their presence does not imply that the disease does not exist, because the germs of consumption appear in the sputum only when the tubercles open and the germs are liberated and this occurs not in the incipiency of the development but in the second, third and fourth stages. Pulmonary tuberculosis may present at first the slightest pigmented catarrhal secretion, which gradually changes to a more yellowish substance, and finally becomes thicker and more profuse. The first discharge may contain no bacilli. This seems to be the result of limited inflammation, provoked by the development of tubercle foci, and not until some of the foci rupture do we find pus in its true nature and germs of consumption. Catarrhal conditions of the lungs then

should always be considered suspicious, and only good can result from a treatment based on this ground.—DR. PAUL PAQUIN in *Medical Herald*, July.

**Tic Douloureux.**—Dr. Danas's method of treatment consists in the following procedures: 1. Strychnia is given in single daily doses, hypodermically. He usually begins with gr. 1-30, and this is very slowly increased until by the fifteenth or twentieth day gr. 1-6 to 1-4 is given. Most patients can not take over gr. 1-5, an excess being shown by stiffness in jaws and legs, trembling and nervousness. Sometimes the largest doses are not well borne and are not advisable, but this is rare. After receiving the maximum dose it should be continued for a week or ten days and then gradually reduced, so that by the end of five to six weeks the beginning dose is reached. The drug is then stopped and is replaced by others. 2. The patient is now placed on potas. iodid, gr. v, *ter in die* increased to gr. xx; and tincture of iron m. v, increased, if possible, m. xxx, and well diluted. In some cases salicylate of potassium replaces the iodid, or nitroglycerin is added to the iodid or iron. 3. Rest in bed, with light diet and diuretics.—*The Post-Graduate*, July.

**Thyroid Medication in Goitre.**—Pharm. Institute of Budapest, has been making a special study of this subject. The investigations are described in detail in the *Deutsch. Med. Woch.* for July 9. The results briefly stated are: 1. The goitre in every case decreased in size. 2. The patients lost in weight, some as much as one to two kilograms. 3. The amount of urine increased. 4. The elimination of nitrogen, especially, in the urine, increased. 5. Increased elimination of ClNa and of P<sub>2</sub>O<sub>5</sub>. 6. The amount of uric acid excreted was much increased, especially in the first days of the treatment. We know that the amount of uric acid excreted increases with increased numbers of leucocytes. The latest researches have established the fact that thyroid medication increases the number of leucocytes, which accounts for the increased amount of uric acid. Until we are better acquainted with the chemic structure of the thyroid gland, it is not sufficient to explain this increase in the amount of uric acid by the assumption that it corresponds to the amount of deterioration of the nuclein bases (xanthin, hypoxanthin) in the thyroid gland. It is interesting to note that Baumann does not consider it settled that the thyroïdin he discovered may not be some product of a nuclein acid.

**Operation for Appendicitis.**—Dr. A. J. Bloch describes his method of operation, in acute and gangrenous forms, as follows: "An incision four inches long was made in the right linea semilunaris, and the cecum exposed. This was drawn into the abdominal incision and the appendix located. The appendix was detached from the abdominal viscera, to which it was adherent and brought out at the wound, the cavity of the abdomen being shut off with sterilized gauze. With two pairs of long forceps I seized the appendix, placing one pair three-fourths of an inch from the cecum and the other a little nearer the distal end, dividing the appendix between them. Cleansing the surface, two long straight needles threaded with fine silk, were passed, one into the anterior, the other into the posterior lip of the remaining appendix, tied and given to an assistant to hold, the needles and sutures being left in place. The forceps were now removed, a small uterine dilator passed through the lumen of the divided appendix into the cecum, and both dilated to the extent of from one half to three-fourths of an inch. The needles were then both together passed through the dilated lumen of the appendix and cecum, into and out of the cecum at its posterior surface, making but one puncture. Pulling now upon the sutures the appendix became invaginated into the cecum, and healthy tissue approximated, three rows of Lembert sutures were then passed through the cecum, completely closing off the invaginated appendix, the traction sutures

cut and allowed to drop into the bowel, and needle puncture closed by one or two sutures. The abdominal wound was closed with silkworm gut without drainage and sterilized dressings applied.—*New Orleans Med. and Surg. Jour.*, August.

**The Technique of Suprapubic Puncture.**—In the *Wiener klin. Wochenschrift*, Dr. Von Dittel state that he has tapped the bladder above the pubes considerably more than one hundred times. He washes it out by means of a two-way cannula, and and then introduces a Jacques catheter (No, 8), the caoutchouc of which has the property of swelling up and so effectually preventing any escape of urine. The catheter must be changed at least once in eight days; its stopper is to be removed whenever the necessity for micturition is felt, once at least every four or five hours. When introduced in this way the foreign body seems much less likely to induce vesical catarrh than if inserted *per vias naturales*; this is probably due to the absence of the bacteria of the urethra. The puncture has a great tendency to spontaneous closure, which is a manifest advantage when the indications for its employment have been obviated. Von Dittel has always operated in the mid line, but of late Schopf has conceived the ingenious notion of a lateral puncture, whereby the rectus or pyramidalis is used as sphincter and the permanent catheter done away with. One disadvantage of this method is that the puncture requires keeping open by the nightly passage of a sound or drain. Furthermore, Von Dittel has shown that the depth of the peritoneal pouches inclosed by the urachus, obliterated hypogastric arteries and the epigastric arteries is very variable, so that in some cases but a very small portion of the anterior wall of the bladder is free from peritoneum. In such instances lateral puncture may lead to perforative peritonitis, and of this he records one fatal case. He has therefore abandoned Schopf's procedure, and reverted to his own former method. He has found, however, that the poorness in vessels of the linea alba sometimes leads to necrotic changes round the puncture, and therefore now adopts the plan, particularly in old people, the operating just at the edge of this tendon.

**Improper Performance of Caesarean Section.**—We are indebted to the *New York Medical Journal* for an analysis of a discussion of the above named operation, that has appeared in the *Centralblatt für Gynäkologie*. It appears that Dr. J. Esser reported a case of that operation, the sole indication of which was an enlarged fetal trunk (the head had been detached by the use of forceps); this distension was later found to be due to the presence of a large quantity of clear fluid in both chest and abdomen. He reported his case in the *Centralblatt* for March 21, defending his employment of Caesarean section rather than embryotomy. The woman made a good recovery. In the same journal for April 4, however, Dr. F. Ahlfeld criticises Dr. Esser's course very severely. "It may happen, he says, that in the conduct of a case harrowing to both mind and body, in which one resource after another fails, an obstetrician at last loses his head and subjects both mother and child to danger by resorting to a wholly unsuitable procedure, and under the circumstances he may be pardoned, or at least the circumstances may be pleaded in extenuation. But in the whole history of obstetrics it has not been recorded before that a practitioner calling himself 'Frauenarzt, and having a 'Klinik,' presumably, therefore, having served for some time as assistant in a hospital, when called to a well-built woman in labor in the sixth month, has applied and reapplied the forceps, then explored the interior of the uterus up to the fundus on the right and on the left, whereby he has ascertained that the obstacle to delivery lay in abnormal distension of the child's body, and finally sent the woman into his 'Klinik' and performed the Caesarean operation on her. The climax is capped when Herr Esser has the heart to publish such a case and main-

tain that his conduct of it was proper. Dr. Ahlfeld goes on to declare that, if Dr. Esser had followed the precepts laid down in the text-books, his course would have been as follows: When an hour or two had elapsed after full dilatation of the os uteri, and the little head, lying deep in the roomy pelvis, failed to advance, he would have suspected at once that the trouble was due to immense distension of the fetal trunk. An examination with four fingers, or at all events with the whole hand, would easily have cleared up the point, and then he would have simply opened the distended trunk with the perforator, after which the child would soon have been expelled without further medical intervention. Dr. Esser has no ground for alleging that his case possessed extraordinary features; on the contrary, that particular cause of dystocia is a typical one, occurs over and over again, and is always to be met in the same way. Ludwig's case, which Esser unjustly adduces, showed real difficulties; the child was gigantic, and a young physician might well have been perplexed as to his choice of resource. But even in this case the Caesarean operation was unnecessary. Neither case can be regarded as legitimately extending the field of usefulness of the Caesarean section; on the contrary, each of them should serve as a warning to young physicians."

**New Method of Diagnosing Typhoid Fever with Serum from Patient.**—Recent investigations by Pfeiffer, Koll and Gruber have shown that the serum of persons convalescing from typhoid fever, the same as the serum of animals immunized against typhoid infection, will produce a distinct and specific reaction when added to a culture of Eberth's bacillus *in vitro*. They found the same phenomena with the cholera spirillum and Escherich's bacillus. The process is so clearly defined that it promptly differentiates the disease, while it is so simple that it requires nothing but a tube culture of Eberth's bacillus (which keeps for weeks) and a drop of blood to complete it. If a few drops of immunized serum are added to a culture of the coli bacillus they produce a noticeable cloudiness, with decided motility of the microbes. The effect is entirely different if they are added to a tube culture of Eberth's bacillus. There is no cloudiness, but the reverse; the microbes cluster in masses, forming agglomerations and a precipitate at the bottom of the tube, with limpidity instead of cloudiness. This agglutination is the point in differentiating, and the higher the serum is immunized, the more rapid the effect, sometimes occurring as rapidly as a chemic process. Widal announces that he has been testing the serum from patients in various stages of the disease, and has found the reaction unmistakable in each. He drew the blood from the vein in the bend of the elbow, with a syringe, after antiseptic precautions, or from the hand of the patient, hanging over the edge of the bed, after slightly massaging the finger from the root to the point, when a prick with the lancet will draw enough blood ( $\frac{1}{2}$  to 2 c.c.), which should be caught in a thimble or test tube first passed through a flame. After corking and waiting a few minutes for the serum to separate, add one drop of the serum to ten drops bouillon culture of Eberth's bacillus, and in a very short time the agglomeration commences, if it is a case of typhoid. Between the characteristic agglutinations a few scattered and motile microbes are still to be seen, growing less in number until, in a few hours, they have all been absorbed into the clustered masses. The drop of blood can be drawn directly into the culture, but no time is gained, as the serum has still to separate. Widal also made the test with serum from normal persons and also from numerous patients suffering from different diseases, as well as from persons who had recovered from typhoid fever from one to fourteen years previously. In each of these cases there was none of the specific typhoid reaction, the agglomeration, but the Eberth bacillus kept on the even tenor of its way, isolated and motile.—*Bulletin Médical*, June 28.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance . . . . . \$5.00  
Single Copies . . . . . 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, AUGUST 15, 1896.

THE WICKED HOUSE FLY.

I'll hide my master from the flies as deep as these poor pickaxes can dig.—*Cymbelene*.

At the August season when the summer dog-days are with us, the mighty insect *Diptera*, of the noble family *muscida*, particularly the *musca domestica* or the *musca harpya*, commonly mentioned in the vernacular as the house fly, makes his presence seen and felt. From the earliest times, the ancestors of this species were known to be most malicious, and at the same time as a plague most unaccountable.

When the LORD threatened PHARAOH that he would send "swarms of flies upon him," PHARAOH was probably not aware that the mere presence of the fly, insured the planting of plenty of pathogenic microbes, and it is probable that the corruption of the land by reason of the swarm of flies (Psalms cxv. 21), had a great deal to do with the death of the first-born in the plague next succeeding.

"Dead flies cause the ointment of the apothecary to give forth a stinking savor," says the good book (Eccles. x, 1) and it is morally certain that in these bacteriologic days, not only *dead* flies, but flies of all kinds are known to be carriers of contagion.

"The proboscis of the house fly" says one of our popular encyclopedias "is a very interesting object," a remark almost paralleled by that attributed to the late ARTEMUS WARD concerning the kangaroo. "The kangaroo" remarked ARTEMUS reflectively, is an

"amoosin cuss." "The proboscis of the fly is the greatly developed 'tonguelet' or lingula, the upper part of the under lip, but with these are combined lancets formed of the metamorphosed maxillæ" (CHAMBERS). Not only may this weapon infect the tiny wound made in the skin, but bacteria themselves develop in the intestinal canal of the insect, and are ejected on every accessible object of food or furniture. This is the well known "fly speck" abhorrent to the good housewife. But the measure of the iniquity of the house fly does not end here. As he has a decided preference for a diet of decaying garbage, putrid sores or rotten carcasses he alights upon them and without stopping to sterilize his feet afterward he flies to madame's kitchen where he dips his feet jauntily into the iced tea, deposits a "speck" or two on cut bread just as it goes to the table, or annoys madame herself by maliciously alighting near the corner of her eye.

It needs no philosopher, no PASTEUR or TYNDALL to show the infinite capability of the fly as a carrier of infection. Bacteriologists have traced the infection carried by flies until there is no longer any question of the fact (see this JOURNAL, June 25, 1892, Vol. xviii, p. 818). LUCIEN HOWE remarked the frequency with which the fly is the most probable source of contagion in the Egyptian ophthalmias. When flies walk over a gelatin culture, bacteria develop in their tracks (see this JOURNAL Sept. 22, 1894, Vol. xxxiii, p. 479). It is proper to say that the constant irritation of the lid produced by fine particles of sand, predisposes to the development of the bacteria when once deposited. The observation of Dr. HOWE, however, is not new, for M. SONNINI, years ago in speaking of Egypt, said: "Of insects there the most troublesome are the flies. Both man and beast are cruelly tormented with them. No idea can be formed of their obstinate rapacity when they wish to fix upon some part of the body. It is in vain to drive them away; they return again in the self-same moment, and their perseverance wears out the most patient spirit. They like to fasten themselves in preference on the corners of the eyes and on the edge of the eyelid. . . . The Egyptians paid a superstitious worship to several sorts of flies and insects. If then such was the superstitious homage of this people, nothing could be more determinate than the judgment brought upon them by Moses. They were punished by the very things they revered, and though they boasted of spells and charms, yet they could not ward off the evil. How intolerable a plague of flies can prove is evident from the fact that whole districts have been laid waste by them. Such was the fate of Myuns in Ionia and of Alarnæ. The inhabitants were forced to quit these cities, not being able to stand against the flies and gnats with which they were pestered. TRAJAN was obliged to raise the siege of a city in Arabia, being driven away by the swarms of flies. Hence different peoples had deities whose office it was to

defend them against flies. Among these may be reckoned BAALZEBUB, the fly-god of Ekron, *Hercules Muscarum Abactor*, and hence JUPITER had the titles of *apomnios*, *muigros*, *muiochoros*, because he was supposed to expel flies and especially to clear his temples of these insects."<sup>1</sup>

The Hebrews also had the same superstition as appears from JOSEPHUS, who narrates that "AHAZIAH, as he was coming down from the top of his house, fell down from it, and in his sickness sent to the Fly, which was the god of Ekron, for that was this god's name, to inquire about his recovery."<sup>2</sup> A footnote states that the "God of flies seems to have been so called, as was the like god among the Greeks, from his supposed power over flies in driving them away from the flesh of their sacrifices, which otherwise would have been very troublesome to them." In literature the fly has been execrated from time immemorial. Persons who forced themselves into other men's entertainments were called flies, as a term of reproach, and "in PLAUTUS an entertainment free from unwelcome guests is called *hospitium sine muscis*, an entertainment without flies; and in another place of the same author, an inquisitive and busy man, who pries and insinuates himself into the secrets of others, is termed *musca*. We are likewise informed by HORUS APOLLO that in Egypt a fly was the hieroglyphic of an impudent man, because that insect being beaten away still returns again; on which account it is made by HOMER an emblem of courage."<sup>3</sup>

But the wicked fly notwithstanding his demoniac doings has had his defenders, some from pure benevolence, as Tristram Shandy's Uncle Toby: "So," says he, one day at dinner, to an overgrown one which had buzzed about his nose and tormented him cruelly all dinner-time, and which, after indefinite attempts, he caught at last, as it flew by him, "I'll not hurt thee," says my Uncle Toby, rising from his chair and going across the room with the fly in his hand, "I'll not hurt a hair of thy head; go!" says he, lifting up the sash and opening his hand as he spoke, to let it escape. "Go, poor devil, get thee gone, why should I hurt thee? This world, surely, is wide enough to hold both thee and me."<sup>4</sup>

Another defender was OLDYS, whose two stanzas, according to D'ISRAELI,<sup>5</sup> were occasioned by a fly drinking from a cup of ale, the favorite potion of poor OLDYS:

Busy, curious, thirsty fly!  
Drink with me, and drink as I.  
Freely welcome to my cup  
Couldst thou sip and sip it up;  
Make the most of life you may,  
Life is short and wears away.

Both alike are mine and thine,  
Hastening quick to their decline,  
Thine's a summer. Mine no more,  
Though repeated to three score!  
Three score summers when they're gone  
Will appear as shortas one.

But however sweet and delicate the strain of OLDYS, we can not forget that this is not the age of sentiment, and we must therefore insist in the interest of public health and suffering humanity, that the fly must be excluded from our houses by every possible barrier; he must be kept away from our food supplies by every possible means, and if he persist he must be destroyed with no less sternness than is displayed by

Boys pursuing summer butterflies  
Or butchers killing flies. CORIOLANUS.

#### BICYCLING—PRO AND CON.

If every smoothly paved thoroughfare, crowded, especially at night, with men, women and children bestriding a bar suspended between two wheels, were not alone evidence of a *furor populi*, the facts that large establishments exclusively devoted to the supply of bicycles and their numerous appurtenances have sprung into existence in every quarter, that piano stores include among their offerings for sale more varieties of the silent wheel than musical instruments, and that even little narrow "holes in the wall," where thread and needles or candies and newspapers once modestly bid for buyers, now exhibit their half dozen apparatus, betoken a craze that has possessed the people wilder than the magnetic syrup or any other fad of forty years ago or the silver *folie* of to-day.

It is, perhaps, injudiciously soon to cry "halt" to the maddened crowd of riders, and so many physicians, themselves victims, have sanctioned the practice by precept and example, that the criticising medical men, who do not ride, are sought to be discredited because they have not ridden. As for the clerical advocates who have hastened into print with their indorsement of this new sanitary device for developing the muscles and at the same time encouraging innocent diversion at the expense of roof-gardens and rum-shops, MRS. CHARLOTTE SMITH has spiked their guns by suggesting that the grateful recognition of an acceptable gift has unfitted them for unprejudiced judgment.

If medical men and medical journals ought to interest themselves in the every-day affairs of life, there is good reason why they should give most serious consideration to this bicycle question, which has grown to such incredible proportions within so short a time. Its only parallel is the jinriksha of Japan (the two-wheeled buggy with a man between the shafts), which wholly unknown thirty years ago, has now almost completely supplanted all other modes of travel. Inasmuch as no inconsiderable number of the members of the profession themselves bestride the double wheel, the case so far as they are concerned has been prejudged, and it may be assumed that others, whose families and friends have acquired the habit, are in the same category.

Enthusiasts do not kindly brook criticism. If you

<sup>1</sup> Edwards' Encyclopedia of Religious Knowledge, 1852.  
<sup>2</sup> Josephus' Antiquities of the Jews. Book IX, Chap. II.  
<sup>3</sup> Potter on the Miscellany Customs of Greece.  
<sup>4</sup> Sterne: Tristram Shandy, Vol. II, Chap. 12.  
<sup>5</sup> Curiosities of Literature.

have not eaten raw fish with the Japanese or limaçons with the French, you are apt to be challenged with: "What do you know about a diet of uncooked salmon or slimy slugs anyhow?" Admitting the palatability of the dish, it is still possible for the looker-on to argue its wholesomeness. A moment of impartial inquiry, therefore, may be permitted the physician, who is seriously concerned with the welfare of the people among whom he lives.

At the first view, it seems plausible that anything which impels individuals to pass so many hours a day at exercise in the open air should be beneficial, and undoubtedly the abstract statement is incontrovertible. One startling revelation for which the bicycle is responsible is the amazing number of spindle-shanks among the feminine part of the population. Notwithstanding the aid of leather leggins and worsted stockings, the cruel fact is evident to the on-looker that Mary Ann and Eliza Jane, as well as Birdie and Rosie, Maud, Ginevra and plain Susan have unsubstantial understandings that bespeak lack of exercise and poor nutrition, and the pedaling action required to propel the machine ought, *prima facie*, be the indicated means of repairing attenuated calves. It is true that the same amount of exercise afoot would be equally salutary, but the inducements to walk are so much less that the outdoor recreation is not obtained. The mere purpose of improving the health has never been sufficient to impel either young or old to do anything that will accomplish this end, as the admitted fact of downright harmfulness has never deterred even the intelligent, wise and cultured from some gratifying indulgence. The novelty of the bicycle, the delusion that one is sitting down and gliding without personal effort, the element of fashion, the contagiousness of example influence all classes to mount and away, when the suggestion or advice or invitation or command to "put on your hat and take a brisk walk" is resolutely ignored or defiantly opposed.

Granted then, that the congregation of men, women and children in the open air, on broad avenues, upon country roads, in park-ways and by river-banks rather than sitting in crowded, ill-ventilated theaters, saloons, billiard-rooms and beer-gardens is a sanitary gain, shall it be denied that this alone commends the practice? Not—were this the whole truth and nothing but the truth.

Watching the swiftly moving throng on a city boulevard the observer notes the fact that the posture of the majority of male riders involves a curious contortion of the body, by which the head is lowered and the face lifted, thus curving the neck anteriorly, while the back and shoulders are elevated into a hump, the chest and abdomen forming a hollow corresponding to the dorsal convexity. The legs are bent at an acute angle upon the trunk, the whole weight of this being

thrown upon that portion of the body which in the normal act of walking is absolutely free from strain and pressure. Medical bicyclists admit that the posture of most wheelmen causes injurious pressure upon the parts around the neck of the bladder, developing irritability of the latter, increased desire to urinate, congestion and hypertrophy of the prostate, narrowing of the canal of the membranous and prostatic urethra, and ultimately atrophy of the testes. The last might not be an unmitigated evil in the conditions of modern civilization. The others are sure to enlarge the clientèle of the genito-urinary specialists of a few years hence. It is fair to say that a minimum only of bicyclists, including, of course, all medical men, sit upright, as upon a horse and are content to amble along with gentle effort. In their case, the ischial tuberosities support the body, provided the saddle is broad and without the anterior horn (pommel), relieving the genital region of the pressure inevitable in the hideous hump-backed caricatures which professional wheelmen and their multitudes of imitators make of themselves.

Great as the physical injury to men, it is small beside that suffered by young women. Surmounted upon the edge of a wedge, their very erect posture forces this wedge up between the tuberosities, the yielding soft parts of the perineum resting upon the narrow rigid fulcrum. The tendency consequently is to diminish the outlet of the plastic pelvis by approximating the ischial extremities instead of spreading them apart as in the normal exercise of walking, when the weight of the body is borne upon the widely separated heads of the femurs. It is a sorry sight to watch the young girl enamoured of her wheel, devoting every hour she can spare to the novel, exhilarating occupation, obtuse to the soreness and pain so many of them experience, bruised and excoriated by the prolonged friction, weary and worn, but with the determination of the ballroom belle who dances when ready to fall from fatigue and blistered feet. There are hygienic seats, in two parts, fitted to receive the tuberosities, but they are not in common use, and the majority bestride the narrow saddle with its prominent anterior horn, which presses into the vulva in resisting the tendency to slide forward, especially in ascents.

The esthetics and morality of bicycling do not come within the professional ken of the physician. A costume and posture which make ninety women in a hundred absurd spectacles, will not long be popular with the thousands and tens of thousands of the fair sex as to-day. Slim legs operating like a steamer's walking-beam, and generous buttocks, whose contour is alarmingly delineated, are not pleasing displays; and we leave to the philanthropic lady who is President of the *Women's Rescue League* to show that the promiscuous commingling of respectable young women on the

same roads with the cocotte class, for whom the wheel has such fascination that all ride who can borrow the money to hire a vehicle, and that the accentuation of the leg as the feature of the girl who has learned to swagger in bloomers or short skirts into crowded public restaurants for the much needed refreshment, can only have a demoralizing effect. It is enough for us to declare that a woman, especially an adolescent girl, can not be suspended on the summit of a wedge without injury to the structures above, and deformation of the pelvis; and that the bruising of the flesh, which some riders unwillingly admit, and the craving for stimulants after a fatiguing ride, ought to restrain the prevailing indiscriminate and intemperate use of the vehicle. If exercise be the object, we commend a pair of sturdy human legs as a motor of unsurpassed fitness for every sanitary purpose. Assuredly, the pedestrian's features will not wear that intently anxious expression, which has already been given the designation of the "bicycle face."

#### ROENTGEN RAYS IN DIAGNOSIS.

The surgical utility of the ROENTGEN rays is now a well-established fact, and every day adds to the evidence in its favor. Their therapeutic value is, on the other hand, a dubious quantity and, as yet, only a few enthusiasts, mostly outside of the ranks of the regular profession, have seriously expressed their faith in it. Experiments conducted under scientific conditions have so far led at best to only unsatisfactory results.

There is, however, in the latest developments of skiagraphy more or less suggestiveness of possible extra-surgical uses of these rays, and it does not seem altogether unreasonable to look forward to their future employment in medical as well as in surgical diagnosis. The methods have already improved to such an extent that it appears even probable that before long we may be able to detect diseased conditions in the viscera by the fluoroscope and thus throw a light also on various pathologic questions. There is a whole field of research in determining the permeability of the various organic and inorganic compounds in these rays, which has thus far only just been touched upon, here and there, in medical literature, notwithstanding its suggestiveness from a medical point of view.

In the latest issue received in this country of the *Deutsche medicinische Wochenschrift*, that of July 23, there is an important paper by Dr. E. SEHRWALD of Freiburg i. B., on the action of the halogens, chlorin, bromin and iodine, on the ROENTGEN rays. He finds them in a pure state to give an almost complete shadow, and in chemie combination producing a shadow proportional to the percentage of the element contained. Solutions and compounds that are almost or absolutely transparent, like hydrochloric acid and

bromoform and chloroform, show this peculiarity very plainly, as they give a shadow as dense as that of the metals. The transparency to these rays of organic substances generally is due to the fact that the four chief component elements, carbon, hydrogen, oxygen and nitrogen, present to them very little, if any, obstruction. The shadows that are cast in a skiagraph by the soft parts of the organism are due to the proportion of iron in the blood and the alkaline metals, but especially to the chlorin contained in the tissues.

Such facts as these and others that will undoubtedly be developed along these lines, will suggestively supplement our existing data in regard to the physiologic and pathologic chemistry of the animal tissues. Their practical value will, of course, remain to be determined by future investigations.

#### A REGRETTABLE OVERSIGHT.

National medical associations are becoming so numerous that it requires considerable watchfulness to avoid conflict of their several dates of meeting. This has led bodies like the American Academy of Medicine, the Medical College Association, the Association of Medical Examining and Licensing Boards and others, to assemble coincidentally with the AMERICAN MEDICAL ASSOCIATION, that as many as possible might be able to attend two or more. The circular issued on July 20 by the Secretary of the Mississippi Valley Medical Association, announcing the change of date of the annual meeting of that body from October 20-23 to September 15-18, is in probably unintentional, but very regrettable, conflict with the date of the next meeting of the American Public Health Association, which long ago announced its forthcoming annual session at Buffalo, N. Y., on these very days. While the latter is not technically a medical body, since any one who is interested in public sanitation may belong to it, its membership is so largely composed of prominent medical men, that it has a quasi-professional character, and the enthusiastic devotion of its members to their work, which has made it the leading sanitary body in the world, is so great that its claims to consideration can not justly be ignored.

While it will be difficult for such as are earnest members of both organizations to decide which to sacrifice, a very little forethought would have obviated any necessity for it. Giving the right of priority to the American Public Health Association, not only on account of its longer existence and greater membership, but because of its antecedent selection of the date, considerations which have operated in the case of the AMERICAN MEDICAL ASSOCIATION and its attendant correlated bodies, the Mississippi Valley Medical Association might readily select the week following the adjournment of the older and larger organization, for its own re-amended date of meeting and we earnestly hope that the president, Dr. H. O. WALKER of Detroit,

in deference to the wishes and convenience of those who belong to both bodies, may authorize this change.

#### THE BRITISH MEDICAL ASSOCIATION.

The very complete abstract of the annual meeting of the British Medical Association, which we have received from our special correspondent, is too voluminous to publish entire this week. We are sure that our members will be pleased to know that the JOURNAL representative received great courtesy at the hands of Mr. ERNEST HART, the editor of the *British Medical Journal*, and every facility was afforded our correspondent for the accurate abstract of the papers read at the meeting, which we shall present in this and succeeding issues. It will be noticed that the next meeting will be held in Montreal.

### CORRESPONDENCE.

#### The Michigan Medical Legislation League.

DETROIT, MICH., Aug. 10, 1896.

*To the Editor:*—I hope you will permit me to occupy a little more space in the JOURNAL for a few remarks concerning the Michigan Medical Legislation League. Of course, there is no use of continuing a controversy upon a subject when the participants are so widely apart in their premises; but I can not see wherein the "Regular" members of the League merit any censure! On the contrary, they deserve commendation for their patriotism and liberality of spirit in putting aside, for the moment, special ethical scruples for a broader code of human ethics which embraces the welfare, not only of the craft, but of all their fellow human beings. As already pointed out, the Michigan Medical Legislation League is merely a political organization. This controversy illustrates curiously the romance of history. Twenty years ago Dr. Donald Maclean and his colleagues of the Faculty of the Medical Department of Michigan University were arraigned before the State Medical Society and, later, before the AMERICAN MEDICAL ASSOCIATION, for associating with, and assisting in the teaching of, the "despised" "homeopath." At that time, I am ashamed to say, I was one of the multitude who shouted at them epithets of derision. They were accused, as this League is now by Dr. Maclean, of degrading our noble profession, assisting in the prostitution of medical science, bringing the quack and the fraud (for as such homeopaths were then denounced) up to the level of honorable recognition with scientific medicine. They were called feeble, cowardly, treacherous! Such was our bigotry, then, that even the eloquence of Maclean, Frothingham and Dunster could not broaden our narrow disposition, and we persisted in persecuting the Ann Arbor Faculty with a spirit of intolerance for some time. Their position, however, in the light of a broader intelligence, was right! although we were honest in allowing our action to be governed by a belief born of tradition, instead of reason and benevolence. I am sorry that one of those defenders of righteous expediency and equity, has changed so that to-day he is attacking the principles which he formerly assisted to defend! It is a pity that Dr. Maclean did not bring his objections forward at the meeting which adopted the constitution, and formally organized "The League." He was present at that meeting and took an active part in its proceedings, and if he had thus voiced his sentiments, the regular profession might have been spared the appearance (so ludicrous in the eyes of the laity) of dissension and lack of public spirit on matters of

public interest. Personally, I would be glad to turn over the "glory" of my office as President of the League to Dr. Maclean, for I do not enjoy the unpleasant duties of official life, while he unquestionably does. However, I feel that the League is engaged in a highly beneficent undertaking, and hope that its members, one and all, may display a courage and fortitude in the coming battle for humanity, which may equal in glory and results the magnificent campaign against bigotry and intolerance which the Ann Arbor Faculty of 1876 achieved.

Regarding my statement pertaining to the composition of the Executive Committee of the League, I should have explained, had I not supposed that Dr. Maclean was aware of the fact, that the Executive Committee included the officers of the League.

E. L. SHURLY, M.D.

#### Congress of Leprologists.

NEW YORK, Aug. 4, 1896.

*To the Editor:*—It has seemed desirable to publish all over the world the fact that the government of Norway will next year probably convoke a congress of leprologists, and delegates from all civilized countries, especially from those which, by the suffering of their own people, are especially interested in the question of leprosy. Hansen, the discoverer of the bacillus, suggested that this congress should be held at Bergen, Norway, and out of compliment to him we suppose that there will be no opposition to this proposition. Dr. Goldschmidt, a Paris physician who has practiced among lepers during twenty-six years in Madeira, has originated the scheme. You will find inclosed my correspondence with this eminent leprologist which I hereby authorize you to publish. The American, Mexican, Japanese and Chinese governments, also all the Republics of South America, who are evidently and considerably interested in the question of the suppression and prevention of leprosy, have been appealed to, to join their efforts in this philanthropic undertaking. Norway and Hawaii have already expressed their willingness to send their delegates. The American, English and French governments will assuredly support the movement. The delegates of the different governments will form an international committee, to be permanently active. Funds will be raised by that committee in all civilized countries, and applied to the support of leper asylums in those countries where either the willingness or the capacity to help those institutions is wanting or insufficient. All problems concerning leprosy will be submitted to that international committee.

It is hoped that by this common and universal effort against the dreadful scourge it may, in a comparatively short time, be wiped off from the surface of the world. It is certainly worth the while to fight some years for such a tremendous result. Mankind certainly at no time of history has fought for a greater object. Such a momentous matter can not help to appeal to the sympathies of so important a medical journal as yours, published in a country which suffers more than even China from the terror, against which we mean to begin this fight.

May we hope that you will use the influence of your paper to obtain an expression of opinion from the principal leprologists of India as to this matter. Should some of them, as we fervently hope, be willing to join our congress, will you ask them to communicate their intentions to me, as now and for a little time to come I shall have the foreign correspondence on my hands.

Yours respectfully,

ALBERT S. ASHMEAD, M.D.

#### A Crusade of Education.

BURLINGTON, IOWA, Aug 10, 1896.

*To the Editor:*—The controversy now going on in the JOURNAL between Dr. Maclean and the Michigan Medical Legisla-

tive League reminds some of us of the struggle some years ago to get a medical law in Iowa; and some of us perhaps sympathize with Dr. Maclean even if we have such a law and the Regulars have a majority on the Board.

Specialists in general, and eye and ear men in particular, have not infrequently been accused of tendencies to lax methods in practice; and the specific charge commonly made is that of consulting or desiring to consult with homeopaths, etc. Some of our brethren in New York (and they are not all specialists), on account of their liberal declaration on this subject have been denied fellowship in the AMERICAN MEDICAL ASSOCIATION.

But here in Iowa (and it may have been so in other States) we had the spectacle of a "joint legislative committee," composed of committees from the regular, homeopathic and eclectic State Medical Societies, who consulted together, moved unitedly upon our legislature, and secured the law we now have.

To some of us I fear that the consultation with a homeopath or eclectic for the welfare of the individual, and a consultation with the same for the welfare of the State, is a distinction without a difference; and we must be pardoned for holding to the belief that the end no more justifies the means in one case than in the other.

No wonder that, under these circumstances the public disregards our denials that medical legislation is intended to benefit the profession more than the public. The public only sees what it esteems *factions*, always warring against each other on everything else, but all in harmony on just this one point; and the conclusion is inevitable. So what sort of a law on the average, do we get? Is it really worth the time and labor spent upon it by the profession?

The Iowa law does not prevent quackery in Iowa. It makes a great show, but the quack who is not ingenious enough to dodge its provisions is too dull to be dangerous; and the dangerous fellows continue to dodge it successfully—as the records will show.

It may be considered rank heresy to entertain such a thought, but after as complete a survey of the situation as I am capable of making, the question arises—is *law* a proper remedy in the physicians' armamentarium? In other words, would it not be better to wait until public sentiment crystallizes into a demand for a medical practice law, the profession confining itself meanwhile to a *crusade of education* in this direction? Let no physician degrade his time honored title by appearing as a lobbyist.

Truly yours,

H. B. Young, M.D.

## PUBLIC HEALTH.

**Examination of Milk Cows.**—Secretary Briggs of the Scranton (Pa.) Board of Health has sent out a circular to wholesale milk dealers requesting them to have their cattle examined for tuberculosis.

**Epidemic of Sore Eyes Among Boys at Newark, N. J.**—A number of physicians have complained that sore eyes were epidemic among the small boys who bathe at one of the public baths, and it was thought the contamination was carried through the water. A number of the cases have been reported to the board of health by the physicians connected with the eye and ear department of St. Michael's Hospital. Measures for disinfection were taken.

**New Jersey Law as to Bread and Bakeries.**—Chapter 178 of New Jersey Laws, session of 1896, is an act to regulate the sale of bread, which will take effect Aug. 1, 1896. It provides that bread shall be sold by weight, and that all bread sold shall be free from all impure or foreign substances or any material injurious to health. Chapter 181 is to regulate the manufacture of flour and meal food products. It provides how biscuit, bread

or cake bakeries shall be drained, plumbed and ventilated; how rooms for manufacture are to be constructed and what to contain; how flour is to be kept; that there shall be washrooms, and that closets and sleeping places shall be kept separate from the work and storage rooms.

**To Prevent Illegal Practice in New York City.**—At the request of the New York County Medical Society, Chief of Police Conlin ordered every policeman to take the census of the physicians—not including surgeons—found on his post July 29. The Medical Society has inaugurated a war upon bogus doctors, and the enumeration of the medical men is the first step tending toward a vigorous ousting out of practice of all who are not regularly and legally entitled to recognition.

**A Sanitary Examination in England.**—Some questions and queer answers are reported as having lately been exchanged at a test-examination lately held in England for itinerant inspectors. A question having been asked about the wilful exposure of a person suffering from an infectious disease, the examinee promptly answered: "He must not ride in any conveyance except a hearse without first informing the driver," while another answered: "A person dying of an infectious disease must give notice to the local authority within twenty-four hours." Another candidate said: "Members of a family where small-pox has broken out must be sent to the hospital and well boiled;" while still another said that milk is the best food for children, because it does not require any chewing; and his notion that food builds up the "waist" of the body would seem an error in spelling rather than in idea.

**Consumption and Typhoid Fever.**—Prof. V. C. Vaughan lectured to the summer school students at Ann Arbor, Mich., July 28. He talked for the most part on typhoid fever and consumption. Dr. Vaughan ventured the assertion that one out of every seven of those present would die of consumption, that 3,000 die of it every year in Michigan, and that 50,000 people annually die of typhoid fever. Both diseases, he said, were easily prevented. He claims that the medical profession of to-day is fully a century ahead of the politicians and others who are in control over municipalities. In Berlin and Hamburg people are compelled to disinfect their sputa, thus retarding the spread of tuberculosis. The death rate in those cities has decreased rapidly. He believes that in time cities will be held responsible for typhoid fever outbreaks as much as they are for defective sidewalks. To prevent typhoid fever, he says, boil your water. To prevent consumption use a cheap paper cuspidor and burn it twice a day.

**Danger of Leprosy from Russian Immigrants.**—According to reports from Germany the commissioners of immigration and quarantine physicians of this country should be especially vigilant in the examination of Russians who come to the United States. The famous Berlin physician, Prof. von Bergmann, who was recently consulted by the officials of the German health department, declares that a large number of the Russians who enter Germany with the intention of proceeding to America are afflicted with leprosy. The increase of the loathsome malady in the western provinces of Russia has become so alarming that the German government has ordered the immediate establishment of lazarettos at various points along the Russian frontier.

**New Jersey Backs Up Health Codes as to Sewers.**—A law was passed in New Jersey in May, 1896, providing that in all cities, townships and other municipalities of that State, wherein there are now or hereafter may be sewers constructed for the purpose of carrying off the sewage of such cities, towns, townships and other municipalities, or in streets or sections of such cities, towns, townships and other municipalities, the owners of property along the line of any such sewers shall be compelled to connect their houses and other buildings therewith, in compliance with the ordinances, rules and regulations of any local

board of health now or hereafter to be made for that purpose. The provisions of this act shall be enforced by the local boards of health, by a fine of \$25 against any delinquent who shall not comply with the terms of any such ordinance, by-law or regulation within thirty days after notification to make the prescribed connection or connections by the proper officer of the local boards of health, and an additional fine of \$10 for each and every day after such thirty days in which the provisions of this act and of such notice shall not be complied with.

**New Departures in the Massachusetts State Board of Health in Diphtheria and Tuberculosis.**—The State Board of Health of Massachusetts has recently issued circulars stating that it is prepared to examine cultures taken from the throat for the bacilli of diphtheria, sending out the necessary tubes and swabs, and reporting to the physicians or local boards of health who may send cultures for examination. The circulars explain in detail the proper methods of taking cultures, and explain their value both in the diagnosis of doubtful cases and in determining the length of time the isolation of convalescent cases shall be continued. This circular is accompanied by another which explains in detail the methods of administering the antitoxin furnished by the State Board of Health, and of caring for the syringe, etc. The Board also offers to make examinations of sputum for tubercle bacilli, the object being, as stated in their circular, not so much to enable the physician to make an early diagnosis as to protect the public from manifestly infective sputum. Examinations of cover-glass preparations of blood for the malarial organism will also be made by the Board. The opportunities offered by the Board to physicians and local boards of health for having such examinations made without charge can not fail to be of great value to the promotion of public health by the prevention of infectious diseases, especially in our smaller communities, where absolutely no facilities for having this work done have existed. The State Board of Health furnishes an example well worthy of imitation by other boards in Massachusetts et al., or elsewhere, in the thoroughness and efficiency which they have shown in making available to all who may need them, the best modern scientific methods in the diagnosis, prevention and cure of infectious disease.

**Havoc by Measles in London.**—The *London Lancet* for July 18 sounds the alarm regarding measles as a form of child murder. It says that the mortality for measles has proportions that call for more attention from sanitary authorities than it receives. There is this most significant difference between this mortality in different classes of the community; in the better sort of practice the mortality from measles is almost *nil*. "Some practitioners with well-to-do patients have possibly never seen a fatal case of measles in their practice, though the disease is often highly pyrexial. But the number of deaths from it now in the large towns of England and Wales and of Scotland exceed greatly the number from scarlet fever or diphtheria, or from both of these put together. This mortality has been described lately by writers in the nineteenth century as a form of murder. It is sufficiently illustrated in our issue of last week. Our monthly analysis of London sickness and mortality gives a mortality in June from scarlet fever of 67 and from diphtheria 173, and from both of 240, whereas the mortality from measles was 412. In thirty-three of the largest English towns during the week ending July 4, of 720 deaths due to the principal zymotic diseases, 175 were from measles and 100 from scarlet fever (36) and diphtheria (64) combined. The case of Scotland is not much better. Of 548 deaths in eight Scotch towns, 109 were caused by the principal zymotic diseases; of these, 38 were referred to measles. Glasgow—whose physicians, notably Dr. Gairdner and Dr. Russell, have directed attention to this infanticidal disease—has a bad preëminence in this respect, and

measles is responsible for 33 of the 38 zymotic deaths." Such havoc of infant life can not be much longer continued without scandal and discredit to sanitary authorities. The remedy is not so easy as in the case of the other two diseases, as the infectiousness is greater and has time to act before quite declaring itself. Nevertheless, ways must be found for improving the hygienic environment of the little patients and for anticipating the diagnosis under suspicious circumstances.

**New Regulations in New York City Concerning Garbage Collection.**—After August 1, the householders of that city will be obliged, under penalty of a fine of \$50, to observe the new regulations of the health department directing the separation of kitchen garbage. They can not allege, however, that they have not had timely notice, for on June 23 the Mayor issued a proclamation and the health department sent out these notices: Please take notice that section 95 of the sanitary code, which requires that a suitable and sufficient receptacle be provided on every premises for receiving and holding garbage without leakage, and that a separate receptacle, made of or lined with some suitable metal, shall be provided for ashes, and that ashes and garbage shall not be placed and kept in the same receptacle, will be enforced by the board of health on and after Aug. 1, 1896. The department of street cleaning will collect ashes and garbage in separate carts on and after Aug. 1, 1896, at each house. It has also been decided that householders shall provide a third receptacle for refuse of such a character as would come under the head of broken furniture, bottles, rags, old shoes, clothing, etc. The street cleaning department is not obliged to remove articles of that description from houses, as they do not properly come under the head of garbage, but it does so as a matter of convenience to the householder, and also with a view to the preservation of the public health. The third receptacle may be a basket, box or a similar article. The occupants of flat houses may in some cases seek to avoid complying with the order. In such cases the owner of the building will be held responsible. The police department has been instructed to coöperate with the health and street cleaning departments to secure a thorough enforcement of the law. Twenty-two policemen were detailed by Acting Chief Cortright to assist in the work. Only one collection of garbage will be made daily, and that in the forenoon. The city has entered into a contract with the New York Sanitary Utilization Company, which has established a large plant at Barren Island for the purpose of disposing of garbage. All garbage except ashes will be taken charge of by the company after it has been delivered by the street cleaning department at the dump. The city is considering the advisability of entering into a contract with a contractor who is willing to buy the ashes and use them for filling purposes.

**Health Report.**—The following reports of mortality from smallpox, yellow fever and cholera have been received in the office of the Supervising Surgeon-General U. S. Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Ohio: Dayton, July 1 to 31, 1 death.  
Louisiana: New Orleans, July 25 to August 1, 4 cases, 1 death.  
Florida: Key West, August 3, 3 cases, 1 death.  
Tennessee: July 1 to 31, Tipton County, 8 cases; Shelby County, 5 cases, 2 deaths.

SMALLPOX—FOREIGN.

St. Petersburg, July 11 to 18, 2 cases, 6 deaths  
Gibraltar, July 12 to 19, 1 case.  
Licata, July 11 to 18, 2 deaths.  
Königsberg, July 18 to 25, 1 case.  
Osaka and Hiogo, June 28 to July 4, 45 cases, 12 deaths.  
Kanagawa, July 3 to 10, 3 cases.  
Madras, July 18 to 25, 1 death.  
Odessa, July 11 to 18, 13 cases, 1 death.  
Calcutta, June 20 to 27, 3 deaths.  
London, July 18 to 25, 37 cases.  
Cairo, May 28 to June 3, 7 deaths.

Alexandria, May 28 to June 3, 4 deaths.  
Warsaw, July 11 to 18, 4 deaths.  
Bologna, July 18 to 25, 2 cases.

## CHOLERA.

India: Calcutta, June 10 to 27, 38 deaths.  
Egypt: Cairo, May 28 to June 3, 175 deaths; Alexandria, May 28 to June 3, 54 deaths.  
Japan: July 2 to 11, Tokio Tu, 12 cases, 1 death; Cheba Ken, 1 case; Tukung Ken, 8 cases; Hiogo Ken, 2 cases; Iboraki Ken, 2 cases, 1 death; Kagawa Ken, 1 case; Kanagawa Ken, 2 cases; Migayaki Ken, 1 case, 1 death; Okayama Ken, 3 cases; Shidzuoka Ken, 1 case, 1 death; Toehigi Ken, 1 case; Tamanashi Ken, 2 cases; Jehime Ken, 1 case.

## YELLOW FEVER.

Vera Cruz, July 23 to 30, 3 cases.  
Matanzas, July 22 to 29, 35 deaths.  
Santiago, July 25 to August 1, 21 deaths.  
Havana, July 23 to 30, 90 cases, 40 deaths.

## NECROLOGY.

DR. JOSEPH MEREDITH TONER, of Washington, D. C., died at Cresson Springs, Pa., August 1. He had practiced medicine in that city over forty years, and his death will be keenly felt in medical and scientific circles. He took an active inter-

JOSEPH MEREDITH TONER, M.D.

est in all public-spirited and charitable institutions and societies for scientific investigation. In 1871 he founded the Toner Lectures by placing the sum of \$3,000 in the hands of trustees charged with the duty of securing two lectures annually on some original research. The interest of the fund with the exception of 10 per cent., is paid to the authors of the lectures. The balance is added to the regular fund which has thus been increased to \$5,000. In 1875, and for three subsequent years, he offered the Toner medal at Jefferson Medical College for the best thesis on the results of original investigation. In 1882 he gave his library, consisting of 28,000 books and 18,000 pamphlets, to the Congressional Library and this collection is kept separate from the other books. This collection is specially rich in American medical writings prior to 1800. Dr. Toner possessed a large collection of the writings of Washington, which is also

deposited in the Congressional Library and will be of great historic value. He was born in Pittsburg, April 30, 1825, and received his academic education at the Western University and the Mount St. Mary's College. His medical studies were pursued at the Vermont Academy of Medicine and at the Jefferson Medical College, from which he was graduated in 1853. He practiced in Summit and Pittsburg, Pa., and Harper's Ferry, Va., and established himself in the city of Washington in 1855. He was president of the AMERICAN MEDICAL ASSOCIATION in 1853, and was subsequently a member of the Board of Trustees. He was a member of the Medical Association and Medical Society of the District of Columbia, and at various times filled leading offices in both organizations; of the American Public Health Association; a delegate to, and one of the vice-presidents of the International Medical Congress at Philadelphia in 1876; an honorary member of the New York and California State Medical Societies, of the Boston Gynecological Society, He was the founder of the "Rocky Mountain Medical Society," an organization composed of members of the AMERICAN MEDICAL ASSOCIATION that attended the meeting at San Francisco, in 1871. Among his many writings may be mentioned: "Abortion in a Medical and Moral Aspect," in 1861; "Arrest of Development of the Cranial Bones; Epilepsy," in 1861; "Maternal Instinct or Love," 1864; "Propriety and Necessity on Compelling Vaccination," 1865; "Anniversary Oration before the Medical Society of the District of Columbia," 1866; "The Portability of Cholera and Necessity of Quarantine," 1866, joint paper with Charles A. Lee, M.D.; "History of Inoculation in Massachusetts," 1867; "Medical Register of the District of Columbia," 1867; "Address at the Dedication of Medical Hall, Washington," 1869; "Statistics of Representation in the AMERICAN MEDICAL ASSOCIATION," 1870; "Necrology of the Physicians of the Late War," 1870; Prepared "Medical Register of the United States," 1871; "Sketch of the Life of Dr. Charles A. Lee," 1872; "Statistics of the Board of Health in the United States," 1873; "Free Parks or Camping Grounds, or Sanitariums for Sick Children of the Poor in Cities," 1873; "Facts of Vital Statistics in the United States, with Diagrams," 1872; "Statistic Sketch of the Medical Profession of the United States," 1873; "Statistics of the Medical Associations and Hospitals of the United States, 1873; "Address as President before the AMERICAN MEDICAL ASSOCIATION," 1874; "Dictionary of Elevations and Climatic Register," 1874; "Annals of Medical Progress and Education in America," 1874; "Contributions to the Study of Yellow Fever in the United States: Its Distribution, with Weather Maps," 1874; "Annual Oration before the Medical and Chirurgical Faculty of Maryland," 1875; "Biographic Sketch of Dr. John D. Jackson," 1876; "Medical Men of the Revolution; an Address before the Alumni of Jefferson Medical College," 1876; "Sketch of the Life of Dr. T. M. Logan," 1876; "Biography of Dr. John Morgan of Philadelphia," 1876; "Address on Biography before the International Medical Congress," 1876; "Water Supply of Cities; Public Health Association," 1876; "Notes on the Burning of Theaters and Public Halls," 1876; etc. During his whole life he was one of the most industrious members of the profession, and as he always verified every quotation, he liked to be known as the "fact hunter." His card indexes were prepared mostly by himself. Socially, Dr. Toner was more prominent than any other member of his profession in Washington, and his influence in shaping scientific and medico-political matters at the capital was very great. His handsome, genial countenance will be greatly missed, and he will have no more sincere mourners than those of his colleagues who have met him at the annual meetings for over a third of a century, and who will remember his fraternal hand grasp and his kindly smile with deep regret at the loss of a faithful friend and colleague.

WILLIAM MORRIS HOLT, M.D., of Anchorage, Ky., died at

the St. Joseph Infirmary, Louisville, Ky., of appendicitis, on the 4th inst. He was operated on the day before he died, but the abscess was general and the operation was too late. Dr. Holt was born fifty-six years ago in Henderson, Ky., and graduated at the Louisville Medical College, beginning practice soon after at Lebanon, Ky., where he remained until about fifteen years ago, when he removed to Anchorage where he enjoyed a large and lucrative practice up to the time of his death. He was of a kind and jovial disposition and his death is a great loss, not only to the profession, but to the community in which he lived.

LAWRENCE C. CORTELYOU, M.D. (Bellevue Hospital Medical College, New York City, 1864) at New York, August 5, aged 50 years.

## SOCIETY NEWS.

**American Public Health Association.**—The Twenty-fourth Annual Meeting of the American Public Health Association will be held at Buffalo, N. Y., Sept. 15-18, 1896. The Executive Committee have selected the following topics for consideration: "The Pollution of Water-Supplies;" "The Disposal of Garbage and Refuse;" "Animal Diseases and Animal Food;" "The Nomenclature of Diseases and Forms of Statistics;" "Protective Inoculations in Infectious Diseases;" "National Health Legislation;" "The Cause and Prevention of Diphtheria;" Causes and Prevention of Infant Mortality;" "Car Sanitation;" "The Prevention of the Spread of Yellow Fever;" "Steamship and Steamboat Sanitation;" "The Transportation and Disposal of the Dead;" "The Use of Alcoholic Drinks from a Sanitary Standpoint;" "The Centennial of Vaccination;" "The Relation of Forestry to Public Health;" "Transportation of Diseased Tissues by Mail;" "River Conservancy Boards of Supervision." Upon all the above subjects special committees have been appointed. Papers will be received upon other sanitary and hygienic subjects.

**Officers, 1895-96:**—President, Dr. Eduardo Licéaga, Mexico, Mex.; first vice-president, Lieut.-Col. Alfred A. Woodhull, Medical Dept., U. S. A., Denver, Col.; second vice-president, Dr. Henry Sewall, Denver, Col.; secretary, Dr. Irving A. Watson, Concord, N. H.; treasurer, Dr. Henry D. Holton, Brattleboro, Vt.

**The Canadian Medical Association.**—This Association will hold its twenty-ninth annual meeting at Montreal, Aug. 26-28, 1896. The following papers will be read: "Hemorrhagic Pancreatitis," A. McPhedran, Toronto; Title to be announced, Wm. Osler, Baltimore; "100 cases of Retroversion of the Uterus, treated by Ventrifixation and Alexander's Operation, with subsequent results," A. Laphorn Smith, Montreal; "The Influence of Mitral Lesions on the Existence of Pulmonary Tuberculosis," J. E. Graham, Toronto; "A Note on Amputation at the Hip Joint in Tubercular Disease," A. Primrose, Toronto; "Tetanus following Scarlatina," J. B. McConnell, Montreal; "Etiology and Treatment of Acne Vulgaris," A. R. Robinson, New York; "The Foot, its Architecture and Clothing," B. E. McKenzie, Toronto; "Ophthalmia Neonatorum," R. Ferguson, London; "Observations on the Relation between Leuchemia and Pseudo-leuchemia," C. F. Martin, G. H. Mathewson, Montreal; "Thyroidectomy," D. Marcell, St. Eustace, Q.; "Some Observations on the Heredity of Carcinoma," T. T. S. Harrison, Selkirk; "Some Applications of Entomology in Legal Medicine," Wyatt Johnston, George Villeneuve, Montreal; "Physiologic Demonstrations of Interest to Medical Men," Wesley Mills, Montreal; "The Theory of the Eliminative Treatment of Typhoid Fever," W. B. Thistle, Toronto; "Oral Surgery," G. Lenox Curtis, New York; "Vaginal Fixation of the round Ligaments for Backward Displacements of the Uterus," Hiram N. Tineberg, New York; "Clergyman's Sore Throat(?)," J. Price-Brown, Toronto; "Non-malignant Tumors of the Tonsil, with report of a case," H. D. Hamilton, Montreal; "Sinus Thrombosis, associated with acute Suppurative Otitis Media, occurring during Scarlet Fever," J. W.

Sterling, Montreal; "(a) Exhibition of an Artificial Nose-bridge, (b) Some cases of Foreign Bodies in the Eye, in which the Electro-magnet was used successfully," F. Buller, Montreal; "Remarks on Cold Air in the Treatment of Pulmonary Tuberculosis," Edward Playter, Ottawa; "Hereditary Cerebellar Ataxia (with patient), D. Campbell Myers, Toronto; "A report of three cases of Abdominal Section for Conditions Comparatively Rare," H. Meek, London; "Early Atrophy of Muscles in Cerebral Disease," Frederick G. Finley, Montreal; Title to be announced, F. J. Shepherd, Montreal; "Electric Baths and Dyspepsia," A. L. de Martigny, Montreal; Title to be announced, J. C. Webster, Edinburgh; "Militia Medical Reorganization," W. Tobin, Halifax;

## MISCELLANY.

**Name of South Carolina Asylum Changed.**—The South Carolina institution formerly known as the "State Lunatic Asylum" has had its name changed by law to the more euphonious one of "State Hospital for the Insane."

**Appropriation for Vaccin and Antitoxin.**—The Chicago city council has appropriated \$25,000 for the purchase of vaccin, antitoxin and the employment of physicians to prevent the spread of smallpox and diphtheria.

**Date of Meeting of South Carolina Examiners.**—The general assembly of South Carolina has changed the date of the regular meeting of the State board of medical examiners, at Columbia, S. C., from the fourth Tuesday in April to the third Tuesday in May, each year.

**Medical Heroes.**—A hall has been established in the Val de Grace Hospital in Paris, where the names of French medical men who died in the performance of their duty are inscribed on marble tablets. A list of 143 practitioners has just been placed on its walls, all of whom perished in the yellow fever epidemic in San Domingo, 1801-1803.

**The Old "Faculte de Medecine."**—This structure has been bought by the city of Paris as a historic monument. There is great rejoicing in medical circles that the municipality has purchased this superb specimen of fifteenth and eighteenth century architecture, around which cluster so many memories, as the "cradle of medicine." It will probably be devoted to a scientific museum.

**Age of Consent Advanced in South Carolina.**—Section 2460 of the general statutes of South Carolina of 1882, defining the crime of having carnal knowledge of a woman child has been amended by changing the age from ten to fourteen years, and providing that where the woman or child is over ten years of age the jury may recommend mercy and the penalty shall be reduced to imprisonment for a term not exceeding fourteen years.

**Fees for Examinations for Life Insurance.**—The Equitable Life Insurance Company of New York has issued the following circular to medical examiners: "Please take notice that for medical examinations for new insurance in this society made in the United States, the Canadian provinces and Newfoundland on and after July 1, 1896, compensation will be by the uniform fee of \$5 for each case of a completed examination report and opinion of the risk, rendered according to the society's standard blank form for a medical examination report. The cost of an examination for the restoration of a lapsed policy is to be borne by the subject, and not by the society. The fee in such cases is accordingly a matter of private arrangement between the examiner and the examinee."—*Med. Exam.*, July.

**Vacancies in South Carolina Boards of Health.**—The South Carolina statute approved Jan. 5, 1895, entitled "An act to establish local boards of health in the cities and incorporated towns of the State and to define the powers thereof," has been amended, by act of 1896, providing that in all cases of vacancies on said board occurring from any cause at any time, said

vacancies shall be filled by appointment for the unexpired term or terms. The city as well as town council is also now expressly authorized to impose or collect the \$25 fine provided for failure of any member after accepting and being duly elected, to qualify and serve on the board.

**Medical Service at the Paris Exposition of 1900.**—It is amusing to note in the discussions of this subject that the medical service at our Columbian Exposition seems to be regarded by the Parisians as an unattainable ideal, absolutely beyond realization. Baudouin in the *Progrès Méd.* remarks that he actually had to lie down on one of the beds in the hospital *inside the grounds* at Chicago, to convince himself that he was not dreaming.

**To prevent Adulteration of South Carolina Candy.**—A law was passed at the recent session of the general assembly of South Carolina prohibiting, under penalty of not less than \$50 nor more than 100, the manufacture for sale, knowingly selling, or offering for sale, of any candy adulterated by the admixture of terra alba, barytes, talc, or any other mineral substance, or by poisonous colors or flavors or other ingredients deleterious or detrimental to health. The candy so adulterated shall be forfeited and destroyed under direction of the court.

**The "American Suture" the Invention of Chassaignac.**—The intradermic suture was much admired by Pozzi as he saw it employed at the Johns Hopkins Hospital in Baltimore on his visit to this country. He introduced it into France, where it has been quite generally adopted, and called the "American suture." It has now been found that it was originally the invention of Chassaignac, and is described by him in full in the *Bulletin de thérapeutique* in 1852. Hereafter the French will call it the Chassaignac suture. As the little knots to hold the thread are hard to make, some surgeons use a small piece of lead for the purpose, and others a small roll of iodoform gauze, which is always ready and requires no further sterilization.—*Union Méd.*, July 11.

**The Silver Craze.**—As a foretaste of what may be a common occurrence, we print the following from one of our advertisers, a very shrewd business man, who writes us as follows: "Referring to the way of advertising which you suggest, I already submitted to our board a proposition of this kind, which you made to me, at the time I had the pleasure of seeing you in Chicago, but they don't like to advertise in this way, and just now, they requested me to limit the advertising expenses as much as possible, because we don't know how the anarchists of the Windy City will turn out in November, at the time of the elections. You will understand quite well, that if we have to pay for our goods in gold and get 53 cents in silver for \$1.00 of gold, we will be in such a bad fix that we will have to reduce still more our advertising expenses in order to meet all emergencies. I don't believe that we will do anything new in the way of advertising between now and the end of this year. We are cautious people and we never do anything which we are not sure we can carry out."

**Cessation of a Medical Journal in Havana.**—The *Revista de Ciencias Médicas*, of Havana, closes its eleventh and last year with the June number. The farewell editorial pathetically states that the management is compelled to this decision by "the circumstances through which the country is passing, the general scarcity of resources, the dispersion of the noble medical family . . . the absence of beloved friends whose coöperation has been so valuable to us, but especially as the immediate cause, by the assessment levied upon a periodical devoted exclusively to the publication of scientific matters. . . .  
"Stronger and more solid structures have fallen, men of prominence have been overwhelmed, family after family ruined, and happy hearths deserted; the disappearance of the *Revista* is merely an incident in the general ruin and desolation on all sides."

**Fees for Postmortem Examinations in South Carolina.**—By law passed in 1896, physicians in South Carolina shall be paid the following fees for postmortem examinations and testifying at coroner's inquests: For a postmortem examination and testifying, when no dissection is required \$5; when dissection is necessary and the body not interred, if requested, by the coroner's jury, \$10; for same after interment for three days or more, \$15; for chemic analysis, a sum not exceeding \$40 and expenses for such analysis; and when chemic analysis has been made the chemist who makes it must furnish to the county board of commissioners, with his account a full statement of the analysis. The clerk of the county board of commissioners shall verify and file with the clerk of court of general sessions a copy of such statement of analysis and account. Provided, that nothing contained in this act shall apply to counties of Barnwell and Williamsburg. The account of claim for the services herein named shall be certified to by the coroner, and if dissection is made it shall be certified that it was done at the request of the jury.

**Progress in the Preventive Treatment of Cholera.**—The May number of *Annales Pasteur*, reports another forward stride in our knowledge of cholera, and the methods of preventing it. Roux, Metchnikoff and Taurelli announce that they have established the fact that cholera is an intoxication, and to combat it an *antitoxic* serum is required and not an *antimicrobial* as Pfeiffer asserts. This serum they have succeeded in producing for experimental purposes. Animals injected with it before they are inoculated with the comma bacilli, resist the action of the latter in most cases, while animals inoculated without it almost all succumb. The same favorable results are obtained if the serum is administered simultaneously with the bacilli culture. But the results are negative if it is administered after the inoculation. The serum therefore is not curative, but it is preventive, which is, however a great advance. The experimenters hope to secure better results when they have obtained a stronger serum.—*Annales de la Soc. Méd. Chir. de Liège*, June.

**Liquid Salol in Surgery.**—Salol becomes liquid at a temperature of 108 degrees and remains fluid for fifteen to twenty minutes. In this state it is slightly syrupy, but much less than glycerin and will pass through a Pravaz syringe without the slightest difficulty. While fluid, different antiseptics can be mixed with it, and as it solidifies the two substances become intimately blended. Salol thus combined with iodoform or aristol has many uses in surgery, especially in cases of osseous cavities from tuberculosis, osteomyelitis, etc. After trephining it can be used in the place of iodoform gauze, with the advantage that the suture can be made directly on the injection, and union by first intention thus secured. It can be prepared at a moment's notice at the bedside, by heating the salol and the other substances together in a test tube over a lamp. It has also proved very effective in tuberculous adenitis. Two or three drops of the iodoform-salol injected into the tumor will either abort it or else render it much more benign in its development.—Reynier in the *Jour. de M. et de C. Prat.* Quoted by the *Annales de la Soc. Méd.-Chir. de Liège*, June.

**Sudden Death after Puncture of a Hydatid Cyst.**—Chauffard reports a case of almost immediate death with symptoms of a triple reaction, cutaneous, cerebro-spinal and myocardiac, following a simple exploratory puncture with a Pravaz syringe, of the anterior surface of the liver, below the ribs. Ten centimeters of a characteristic limpid fluid were withdrawn, confirming the diagnosis of hydatid cyst. The subject was a vigorous man, 38, with traces of old benign syphilis, malarial attacks in 1887, at which time he was drinking absinthe to excess, but not since. The necropsy showed marked compensation in the liver; the sound lobe weighing 1,205 grams, and the other 1,245. The liver with the cyst weighed 6,500 grams. The

other organs were apparently normal; death occurred in systole, and the heart was found empty. The hydatid fluid was tested both chemically and by inoculating guinea pigs, with negative results. No alkaloids were discovered in it, but there were traces of an albuminoid, apparently belonging to the mucin group. Chauffard attributes the fatal result to the escape of some of the hydatid fluid into the peritoneum, as the puncture had been completed several minutes before the disturbances began. The intense toxic effect can only be due to some individual reaction or idiosyncrasy, "to use the old term which expresses in so many instances, the limits of the knowable." He adds the warning that owing to the possibility of such an idiosyncrasy, which it is impossible to foresee, this operation is one to be approached with caution in cases of hydatid cyst. His report includes a review of the literature on the subject.—*Semaine Médicale*, July 8.

**Retirement of Dr. I. N. Love from Marion-Sims College, St. Louis.**—Dr. Love, who has been for many years connected with medical college circles of St. Louis, has tendered his resignation, owing to the fact that his private practice and his *Medical Mirror* work require his undivided attention. The *Alienist and Neurologist* of St. Louis for July says: "The resignation of Dr. I. N. Love from the chair of Clinical Medicine and Diseases of Children in Marion-Sims College of Medicine leaves a void in the faculty of this institution that will not be easily filled. Love's lectures are fluent and instructive, and so entertaining as to always hold his class in rapt attention while he speaks, a desideratum in the teaching corps of a medical college too often overlooked. In many medical schools no style of speaking and teaching is considered too dry for the medical student, a plain-speaking knowledge of the English language not always being regarded as requisite. Love taught the science of his chair in entertaining phrase and never made a student tired to listen to him." Dr. Love's large acquaintance and great popularity in the medical profession of America as well as abroad, together with his ability as a teacher, should make his place hard to fill in any college. A special committee appointed by the faculty, composed of Drs. B. M. Hypes, R. C. Atkinson and C. Borek, expressed full appreciation for past services of Dr. Love and kindest hopes for future pleasure and profit in all his relations.

**The Etiology of Appendicitis.**—There has been much discussion of Dieulafoy's statement that appendicitis is invariably caused by a calculus or some accumulation of fecal or foreign matters, which obstruct the appendix and transform it into a closed cavity. It is confirmed by Klecki and Roger, who have proved that the bacilli circulating harmlessly through the intestines, acquire extreme virulence when arrested and forced to stagnate in a closed cavity. In this virulent state they soon find their way through the enclosing walls and produce infection, even before there is actual perforation. Dieulafoy ascribes the obstruction of the appendix in many cases to the formation of a calculus and states that the appendix makes a trio with the renal and biliary systems in the formation of calculi. He classes appendicitis with the arthritic family, in which the French include all forms of rheumatism and rheumatic neuralgia, gout, obesity, and the tendency to the formation of biliary and renal calculi, as also asthma and migraine. These diseases are not contagious, but they are all hereditary, that is they can be transmitted from parent to offspring, either directly or by the inheritance of the tendency, so that although the offspring may not inherit the same disease, he is liable to any one of the group, as they are chronic conditions of imperfect chemic or organic transformations in the organism. The Germans are not so fond of grouping diseases as the French, and the arthritic tendency is neither so frequent nor so pronounced with them as in the countries farther west, consequently Dieulafoy's classification has not been accepted in Germany.—*Deutsche Med. Woch.*, July 2.

**Etiology of Hysteria.**—An article with this title by Sigm. Freud has just been concluded in the *Wien. Klin. Rundsch.*, Nos. 22 to 26. He makes the grave assertion that hysteria, hysteric parasthesia or paraplegia, hysteric sensations, etc., and probably also paranoia, "compulsory ideas" and various psychoses, are all traceable to one cause, viz., conscious or unconscious memories of sexual occurrences in early childhood, and that the character of the neurosis is directly determined by the character of the sexual actions. The hysteria commences with an effort of the will to throw off some haunting idea; this idea is connected either logically or by association with some unconscious memory; this unconscious memory is invariably of one or more sexual occurrences dating perhaps from the earliest childhood. The hysteria usually develops after puberty, but in the severest cases it commences with unflinching regularity at the eighth year. The sexual events that preceded it date therefore, from a still earlier age, in some cases from the fourth, third or even the second year. In the eighth year, the period following the second dentition, the sexual system probably passes into another stage of development, as the same sexual events commencing or continuing after this period, have none of this pathogenic effect. Freud believes that the original instigation always proceeds from an adult. His statements are based on extensive clinical experience, and scrupulously careful investigations. He expects to meet with opposition and incredulity, until the pathogenic power of unconscious memories is more fully recognized than at present.

**On the Indecency of Patent Medicine Announcements.**—The *Medical and Surgical Reporter* commends the conductors of the *Ladies' Home Journal* for their avoidance of those advertisements, so largely addressed to suffering mankind, and for taking the ground that as the better portion of the medical profession will not advertise, they the conductors of the *Journal* will not cater to those not in good standing in their profession and yet willing to publish their wares. It further says: "The patent medicine monger has recently awakened to the fact that young girls have not been sufficiently instructed in the psychic and physical phenomena of puberty and menstruation. Here, as in modern fiction, the worst sinners are women who first catch the eye of the victim with some such complaint as that "only a woman can understand woman's woes." Frequently we encounter the picture of a miss of 18 writhing with dysmenorrhœa, and the latest abomination is a novelette in which some phase of female weakness stands between the heroine and marital bliss, and in which sexual restoration, a vegetable compound, and marriage bells are artistically mingled. *The purpose of such advertisements is manifestly to direct the attention of the young woman to her sexual organs, to exaggerate the importance of trifling abnormalities incident to civilized life, to awaken the sexual instinct, and at the same time to arouse forebodings as to the existence of some physical obstacle to marriage and reproduction, so that a sale of remedies may be effected. Although actual indecency of phraseology is studiously avoided, the moral and mental tendencies of such literature are decidedly injurious. We grant that the ideal of the last generation of ignorance as innocence was not a wise one, and that the girl should be instructed in the physiology and hygiene of the pelvic organs. But the instructor should be the mother, teacher, or some other intimate and mature female friend, and we would prefer ignorance to the obtaining of knowledge from a mercenary charlatan, while false modesty is better than no modesty at all.*

The climax of indecency is reached with the proclamation of the abortifacient nostrum. Pennyroyal seems to be the favorite catch-word, and women are informed that the pill or powder in question is prompt, sure and safe, and this statement is often coupled with the sly intimation that it should not be taken by women who are pregnant, since it will produce abortion. In many, if not most cases, the women who buy these

nostrums desire the discharge of something more than blood from the uterus, and the advertiser, without direct allusion to criminal therapeutics, is calculating not on the patronage of women already in trouble, but on those who will yield more readily to temptation if the danger of pregnancy is eliminated."

**A Sneer from Merck's "American Medico-Surgical Bulletin."**—The shrinking modesty characteristic of a trade organ, believed to be operated by and for an importing branch of a foreign drug house in New York city, induces it to print the following ill-mannered slur. This is the sheet that has heretofore omitted no opportunity to print unkind and discourteous words of the ASSOCIATION and its membership:

"THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—Our most esteemed friend in spirit, the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, appears to be having a wofully hard time in selecting a permanent abode. The atmosphere of Chicago does not appear to agree with it, and it thinks a little of testing the National capital. So far no voice seems to have been raised in favor of New York, and yet, since this is the center of medicine, why should it not come to our welcoming arms—JOURNAL, Editor, Code and all. It can fight our very much esteemed contemporary, the *Medical Record*, to better advantage here than from a distance, and we can assure it that it will find the editor of the *Record* a much better and milder and every way more acceptable individual than he appears to be from a distance. We think it might sleep in the same bed with equanimity as that which another great friend of ours occupies—the *New York Medical Journal*; and we are satisfied from personal contact that the *News* (late of Philadelphia and now of New York) is overflowing with the spirit of brotherly love. As for ourselves it would please us greatly to look at this great organ from close quarters, and we may without loss of modesty say that we think we could teach it something along the line of fearless, independent, scientific journalism. Further still, personal contact would make the JOURNAL love the *Bulletin* a little more and a little long, so that from every point of view we trust that our suggestion will prove acceptable, and that New York may become still more the headquarters of peace and good will in medical journalism."

**The Proof of Insanity.**—In the April number of the *Physician and Surgeon*, Professor Frank T. Lodge of the Michigan College of Medicine, contributes a paper on insanity in its relations to crimes, contracts and wills, inclusive of the spirit of the laws of his State as to the proof of mental alienation. On the latter branch of his subject he writes, "In nearly every case where insanity is set up, physicians are called as witnesses. The law does not recognize expert testimony in these cases as being of any greater value than that of ordinary persons. The credibility of each person's testimony, be it laymen or doctor, is to be weighed and determined by the jury. Nevertheless, if the testimony of a physician, called as an expert witness, is properly given, it must and should have great weight with the jury. As a rule, the physician will be called to testify with reference to the particular person whose sanity is under consideration. His testimony should be based upon a previous examination. The subtle essence of the mind can not be subjected to ocular and visual examination. Its quality must be determined from close observation of the acts and conversation of its owner. Most physicians testify from a short conversation with the person, and we all know how unsatisfactory such an examination is. Nervous persons of perfectly sound mind may appear almost insane under certain conditions, while the wildest lunatic frequently converses for hours rationally and intelligently. In many cases it is only when his particular hobby happens to be touched upon that he manifests his mental bias, and in the absence of previous knowledge, how can the examiner know toward what point to direct his inquiry?

In my opinion, the sanity of no person should be decided until he has been under close observation by competent physicians for a considerable period, say from one to two months, under all the circumstances most favorable to the examination. The examiner should be furnished with the life history of the patient, the history of his family for the preceding two or three generations, the mental condition of his ancestors with relation to possible hereditary taints, and the many other details which will readily occur to all of you. Without this opportunity for a careful and thorough examination, there will always be abundant opportunity for punishing innocent persons for crime, for setting clever and unscrupulous scoundrels at large and for depriving imbecile and incapable persons of large property interests by the clever machinations of designing villains."

**Birch Agaric in Cancerous and Non-cancerous Gastro-intestinal Disturbances.**—The belief is current in Russia that the polyporus betulinus will cure cancer. Smirnow has been testing it and finds that it is highly efficacious in chronic gastro-intestinal troubles accompanying cancer and other inflammatory conditions of the stomach and intestines. The cancer itself continues its course, but great relief is experienced even in a couple of days after imbibing the strong decoction. The pain subsides; the food can be retained and the inflammation heals, if not cancerous.—*Semaine Médicale*, July 8.

**A Powerful Emetic.**—A foreign contemporary states that Dr. Kraus, privat-docent in the Medical University of Berlin, having been called upon by the faculty to explain why his name appeared in a testimonial of the alleged virtues of a certain soap, "declined to do so, or even to express regret, and when the faculty, justly indignant, inflicted upon him the severest reprimand at its disposal, he threw up his appointment."

**Notes on the British Medical Association Meeting.**—At a general meeting of the second day, Dr. Robert Saundby of Birmingham, was elected President of the Council for the next three years, and on motion it was resolved to accept an invitation of the Montreal Branch to visit Canada next year and hold the annual meeting at Montreal in August. An amendment in favor of Portsmouth was lost. Professor Roddick, President of the Montreal Branch of the British Medical Association, was appointed President elect. The business part of next year's meeting will be transacted in London, and only the scientific meetings will be held in the Dominion. The British Association will hold its annual meeting in Toronto next year, and it is hoped that arrangements may be made so that members may attend both.

The Council of the Association decided to present a gold medal to Captain Whitchurch for gallantry in connection with the Chitral expedition, and it was presented by Dr. Barnes, the President. This medal is rarely given, and is consequently greatly prized by those who may be considered worthy of it. The same medal was presented to Dr. Ormrod of Workington, who distinguished himself in connection with the St. Helene colliery explosion.

At the meeting of the Association last year, held in London, there were 3,000 members in attendance; at Bristol the year before 897 members were present, while at Carlisle this year, up to Wednesday evening, the second day of the meeting, only 600 had registered, showing a very small attendance in view of the fact that the Association now has a membership of 16,332.

The scientific work of the Association is divided into nine Sections, as follows: Medicine, Surgery, Obstetrics and Gynecology, Public Medicine, Psychology, Pathology and Bacteriology, Ophthalmology, Diseases of Children, and Ethics.

Speeches at the general sessions are limited to ten minutes. At the sectional meetings no paper is allowed to exceed fifteen minutes, and participators in discussions are allowed ten minutes each.

The discussions in the various Sections are not reported stenographically, but each speaker is furnished with a writing pad at the close of his remarks and asked to write them for publication. Neither are the remarks on motions in the general meetings reported *in extenso*. The members of the Association are beginning to see the absolute necessity and importance of having their proceedings taken down by an expert shorthand writer, because there is a movement on foot to the effect that a volume of Transactions be published as soon as possible after each annual meeting, giving full or well-condensed reports of all papers prepared for the meeting, with the discussions that followed, and also verbatim reports of the general meetings.

**Duty to Sick Passengers.**—A girl of 18 was the only passenger on a certain street car. While there, she became sick and, going to the door, she told the conductor that she was sick, and asked him to stop the car, so that she might get off. He told her to sit down, and she would feel better after a while. She sat down, but felt worse all the time. Presently the conductor passed through the car, and she again appealed to him to stop; but he looked at her, smiled, went to the front of the car, and began talking to the motorman. She then felt dizzy and sick at the stomach, became frightened and dazed, got up from her seat, and staggered toward the rear door for the purpose, she said, of seeing whether she could not get some one on the street to stop the car, and fell unconscious through the door, remaining unconscious for several weeks. The car had then 670 feet to go before reaching the end of the electric route, at which point the girl was to be transferred to a horse car for carriage about a mile further, to her destination. An action was brought against the street car company for damages. June 15, 1896, the court of errors and appeals of New Jersey affirmed a judgment for the plaintiff. *McCann v. Newark & S. O. Ry. Co.* The court says that in view of the plaintiff's youth, her illness, and her mental disorder, it can not say, as matter of law, that she was bound to exercise the same degree of care and forethought as persons of mature years in the full possession of their faculties would ordinarily exercise; and that it was for the jury to determine whether, under the peculiar conditions then existing, she had used such prudence as it was reasonable to require. The court also holds that it was lawful for the jury to find that, when the plaintiff made her second appeal to the conductor, he was apprised of her serious illness, or, at least, should have inquired further as to her condition. The jury also had the right, the court says, to conclude that, on perceiving or informing himself of the extent of her sickness, it became his duty either to stop the car, so that she might alight as she requested, or else to afford her such reasonable attention as would save her from harm in the moving vehicle. He did none of these things, but passed her by heedlessly, and left her utterly uncared for, when there was no other person at hand to render her assistance. Such conduct would not fulfill the duty of the defendant as a carrier of passengers. It is but a corollary from the principle which enjoins upon these carriers reasonable care for the security of their passengers that when, through sudden illness, a passenger becomes less able to look after his own safety, and that fact is made known to the proper agent of the carrier, the latter must exercise toward the passenger a greater degree of care than is demanded in ordinary circumstances.

#### Louisville.

**PURE WATER.**—The filter tests, a reference to which was made in these columns some time ago, have at last been completed and the reports of the experts will be made to the Water Company in the near future. A year ago the Louisville Water Company invited all representatives of water filters in the country to compete in a test of efficiency, making very liberal propositions in regard to the conduct of the tests. The result

was that four companies erected filters on the ground at the pumping station, the water and steam power being furnished by the water company from the pumps at work. The contest has attracted not only local interest but has attracted the attention of the scientific world, and the success of the test means the adoption of the filter by all the principle towns of the Ohio and Mississippi Valley. The question of a wholesome water supply has agitated the minds of the people of this community for some time, for with every freshet and flood the Ohio becomes a rushing stream of mud, carrying along the drainage from five States at least. The public has not as yet benefited by these tests, for the water pumped into the filters has been allowed to run back at once to the river, but we live in hopes that there will be at least one of the filters represented accepted. The water company had as its representative in the laboratory specially erected, Mr. George W. Fuller, from the Lawrence Experimental Station in Massachusetts, a man of ability and experience. Throughout the test the character of the water from the river, filtered and unfiltered, and the action of the filters had to be carefully recorded and the report is a most thorough and exhaustive one. Three of the filters use alum and the fourth is an electric one. The company has been unusually fortunate in having such a protracted muddy spell as they have had while the tests were in progress, for it has not been equaled since 1875.

**SMALLPOX.**—Seven cases of smallpox have developed near Paducah, supposed to have been contracted from the pest-house, which is located near one of the most frequented pikes near the city. There has already been a lawsuit in regard to this building, which is regarded as a menace to the community on account of its location.

#### Medico-Literary Notes.

**GUY'S HOSPITAL GAZETTE.**—The editors of this journal have, with that energy and acumen which characterizes them, issued a special Festival Number. It gives a full account of the great festival dinner and an interesting sketch of the history of the hospital.

IN A RECENT WORK published in Paris by the *Société d'Éditions Scientifiques*, Dr. A. Calmette gives in epitome the result of his investigations into the nature of snake poison and the best way of treating envenomed bites. The only drugs he has found beneficial are the hypochlorite of lime and the chlorid of gold, the use of the latter having been recommended by him in 1892; but he maintains that in the serum of immunized horses there exists a perfect antidote against snake poison. The serum is now prepared in a bulk at the Pasteur Institute in Lille, of which Dr. Calmette is the director. The price of the book is 3 francs.

**A MEDICAL MAN'S EXPERIENCE AT SEDAN.**—Dr. Charles E. Ryan, now of Glenlara, Ireland, has written quite an elaborate account of his services with an ambulance during the Franco-German War, and his personal experiences and adventures with both of the opposing armies in 1870-1871. This book may be best described as a series of photographs of the tragic side of a most tragic war. A simple record of what the author or his comrades saw, it constitutes nevertheless an impressive word-painting, and affords a painful view of the ghastly scenes which form the background of the romances of battle. Dr. Ryan was a member of an Anglo-American ambulance in the Franco-German War, and by force of circumstances was brought into close contact with both French and Germans. He does not conceal the fact that he felt great enthusiasm for France at the first, and that his sympathies were throughout with her. Yet he is an honest and just man, and did not fail to note the shortcomings of the French and to recognize the merits of the Germans.

**THE STANDARD BIOGRAPHY OF DR. O. W. HOLMES**, "the genial Autocrat," has appeared in admirable form under the title of "Life and Letters of Oliver Wendell Holmes." The

*Book News*, June, contained the following points of information interesting to the medical profession: "We have before us one of the most delightful biographies ever produced in the United States, in these two volumes. The author, Mr. John T. Morse, Jr., has every qualification for his task, including that of relationship, as he was a nephew of the subject of the book. All the material obtainable in the form of letters and autobiographic notes has been placed at his disposal, but these are less copious than may have been expected. It appears that letter writing was irksome to Dr. Holmes, and consequently his letters were comparatively few. A report has been current that Dr. Holmes for some time before his death was engaged upon an autobiography. It turns out, however, that he left only some disjointed memoranda in which he had not advanced beyond the period of youth, and had not even covered that period consecutively and thoroughly. Instead of weaving these notes into his text, the biographer has thought it better to print most of them collectively in a separate chapter.

**MEDICAL JOURNAL ENTERPRISE IN PARIS.**—The publishers of one of the medical papers of Paris, it is said, have hired a large shop almost opposite the School of Medicine on the Boulevard St. Germain, and transformed it into a reading room, free to all the physicians and medical students of Paris, to each of whom a card of admission was sent. The front part of the establishment opens directly on the street, and on one side contains notices of anything which may be interesting from a medical point of view, such as courses of lectures, etc.; the other side is devoted to the latest reports from various news agencies. In the rear of the establishment are found numerous desks, paper and ink, and a case containing several hundred medical papers from various parts of the world. The reading room opens into a small garden where the visitor may smoke.—*Boston Med. Journal.*

**A CHOLERA TRACT FROM INDIA.**—A most useful little pamphlet on "The Cause and Prevention of Cholera" has been written by Mr. E. H. Hankin, chemical examiner and bacteriologist to the Northwest Provinces and Oudh. It is intended for the people of India, showing how they can easily mitigate the prevalence of cholera by strict attention to the purity of their water supply. Mr. Hankin says that twenty-four cholera epidemics, of which he knows, were stopped on the disinfection of the wells with permanganate. He advises that the permanganate should be added at sunset, so that it may have all the night to settle. In this way the sediment has time to fall to the bottom, and on the following morning the water is fit to drink. The theory being that the permanganate removes the organic matter, consequently the microbes cease to thrive.

## THE PUBLIC SERVICES.

**Army Changes.** Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from Aug. 1 to Aug. 7, 1896.

Capt. William D. Crosby, Asst. Surgeon (Ft. Missoula, Mont.), is granted leave of absence for one month.

Major James C. Worthington, Surgeon, leave of absence granted on account of sickness is further extended one month on account of sickness.

**Navy Changes.** Changes in the Medical Corps of the U. S. Navy for the week ending Aug. 8, 1896.

P. A. Surgeon G. H. Barber, detached from the "New York," ordered home and granted two months' leave.

P. A. Surgeon V. C. B. Means, detached from the "Maine" and ordered to the "New York."

**Marine-Hospital Changes.** Official list of changes of station, and duties of Medical Officers of the U. S. Marine-Hospital Service, for the sixteen days ended July 31, 1896.

Surgeon H. R. Carter, directed to inspect Marine-Hospital Service at Tampa, Fla., July 28, 1896.

P. A. Surgeon C. T. Peckham, directed to report to Surgeon Godfrey, chairman of board for physical examination, July 24, 1896.

P. A. Surgeon B. W. Brown, granted leave of absence for six days, July 23, 1896.

P. A. Surgeon W. J. S. Stewart, granted leave of absence for four days, July 17, 1896.

Asst. Surgeon C. E. Decker, to proceed from Battle Creek, Mich., to St. Louis, Mo., for duty, July 21, 1896.

Asst. Surgeon Emil Prochazka, granted leave of absence for twenty days, July 23, 1896.

### BOARD CONVENED.

Board convened to meet at Port Townsend, Wash., for the physical examination of P. A. Surgeon C. T. Peckham; Surgeon John Godfrey, chairman; W. G. Stimpson, recorder, July 21, 1896.

### PROMOTION.

P. A. Surgeon C. E. Banks, commissioned as Surgeon, July 27, 1896.

### DEATH.

Surgeon C. S. D. Fessenden, died at Salem, Mass., July 23, 1896.

### Circular Letter.

TREASURY DEPARTMENT,  
OFFICE OF THE SUPERVISING SURGEON-GENERAL M.-H. SERVICE,  
WASHINGTON, D. C., July 31, 1896.

To the Medical Officers of the U. S. Marine-Hospital Service:—It is with regret that I have to announce to the medical officers of the Service the death, on the 23d inst., from a complication of heart and kidney affections, of Surgeon Charles Stewart Davis Fessenden. Surgeon Fessenden was the senior surgeon of the corps, having served since April 4, 1861—a period of more than thirty-five years. He was born in Portland, Maine, Feb. 23, 1828, and was of a family noted in the annals of his native State and the nation. His father, General Samuel Fessenden, was for many years a leader at the bar of Maine, and his eldest brother, William Pitt Fessenden, was the distinguished senator of that State, and during the administration of President Lincoln became Secretary of the Treasury. Two nephews of Surgeon Fessenden rose to the rank of Brigadier General during the Civil War, and others have been prominent in private life, two of them in the profession of medicine.

Surgeon Fessenden was fitted for college at Portland Academy, and in 1844 entered Harvard University, where he pursued his studies for one year; leaving Harvard he became a student at Bowdoin College, from whence he was graduated in 1848.

He studied medicine under Charles W. Thomas, M.D., of Portland, Maine, and attending medical lectures at the Medical School of Maine and also in New York, was graduated in 1851 from the Medical School of Maine. From 1853 to 1856 he was physician in charge of the Portland City Hospital, after which date he became a private practitioner until his appointment as surgeon in the Marine-Hospital Service in 1861.

During the period of his membership in the corps, he served as commanding officer at the ports of Portland, Maine, New York, N. Y., St. Louis, Mo., Norfolk, Va., Louisville, Ky., and Mobile, Ala. During this period he was also a member of three boards of medical officers convened for the examination of applicants for the Service, and of eight boards convened for the physical examination of candidates for admission to the revenue cutter service, beside serving on various special details as inspector.

On account of the failure of his health in the fall of 1895, he was ordered to appear before a board of medical officers for physical examination, and in accordance with the report of the board was placed on waiting orders Nov. 22, 1895.

During the few months which intervened between this date and his demise, Surgeon Fessenden resided at Salem, Mass., at which place his death occurred.

Respectfully yours,  
WALTER WYMAN,  
Supervising Surgeon-General, M.-H. S.

### Change of Address.

Dunne, A. J., from Springfield to Pittsfield, Mass.

Johnson, C. W., Litchfield, Ill., to 625 Locust Street, St. Louis, Mo.  
Kober, G. M., Washington, D. C., to Box 277 Winchester, Va. (care of Mr. Spangler); Klebs, E., from 422 Center Street, to Hotel Majestic Chicago.

Stanley, F. A., from Mobile, Ala., to Julien Hotel, cor. 63d street and Stewart Avenue, Chicago, Ill.

## ORIGINAL ARTICLES.

### ABSCESS OF THE LUNG, WITH REPORT OF SEVEN CASES.

Read before the Detroit Medical and Library Association and the  
Cook County Hospital Alumni Association,  
January and June, 1896.

BY E. FLETCHER INGALS, M.D.

CHICAGO.

The subject to which I invite your attention is one of peculiar interest on account of the difficulties surrounding its diagnosis and the brilliant results that not infrequently follow its proper treatment. Abscesses of this variety are either primary or secondary; primary when the direct result of injury or exposure, as for example the entrance of foreign bodies into the air passages or such exposures as often eventuate in pneumonia; secondary when the direct result of some antecedent disease, as for example tuberculosis, pyemia or embolism.

An abscess of the lung may be described as a circumscribed collection of pus within the pulmonary parenchyma. It is usually characterized by pain at times very severe, by chills and fever, and later by the expectoration of a small amount of blood, followed shortly afterward by a considerable quantity of pus which usually escapes within a few hours. As a result of the inflammation a small or a considerable mass of lung tissue may be destroyed, but usually in the primary abscess the tissues are crowded before the collection of pus, and only a limited part becomes necrotic. Primary abscesses (in which we are chiefly interested), are comparatively rare, but secondary pulmonary abscesses, especially those of tubercular origin, are very frequent; the latter, however, I do not wish to consider at this time, because the symptoms and signs which they produce are quite different from those produced by the primary affection and also because the treatment and the results of treatment are not like those of the primary disease.

*Etiology.*—Primary abscesses usually result from exposure, from the entrance of foreign bodies into the air passages, from injury and for our present purpose I will say from pneumonia. Secondary abscesses result from pyemia, embolism, syphilis, the pressure of tumors upon the bronchi, suppuration of bronchial glands, and from perforating abscesses below the diaphragm, or within the mediastinum. Although my remarks apply to the secondary abscesses that are not tubercular, and to a limited extent even to the latter, they are mainly applicable to primary abscess and to abscesses resulting from acute pneumonia which present the same symptoms and demand similar treatment.

*Symptomatology.*—The primary pulmonary abscess usually speedily follows some exposure or accident which causes acute inflammation of the lung, the inception being marked by a chill and fever, very

similar to that of croupous pneumonia, though commonly neither are quite so severe as in the latter disease; however, the abscess may not occur until sometime after the acute stage of the pneumonia has subsided. In either case the formation of pus is attended by repeated rigors followed by hectic fever similar to the symptoms indicative of suppuration in other parts of the body. Pain, sometimes very severe, is usually present in the beginning of the disease. The temperature fluctuates two or three degrees during the day corresponding to the irregular chills and fever. In the milder cases although the pulse is rapid the fever is not pronounced; but in most instances the constitutional symptoms are very like these of croupous pneumonia, and they are apt to continue for two or three weeks. In favorable cases spontaneous opening of the abscess and convalescence may be expected within twenty or thirty days and in most of them the pus will escape within ten or twenty days. The abscess may open into the bronchi, mediastinum, pericardium or pleura, or through intervening adhesions may discharge its pus into the abdominal cavity or externally. The discharge of the contents of the abscess is usually preceded by a few drops of blood or bloody pus which is followed by the expectoration of from a few ounces to a pint or more of yellowish or greenish pus. The pus is apt to be brownish when there is considerable necrosis of lung tissue. The contents will escape freely for a short time, or possibly for several hours, until the abscess is emptied, when the opening is liable to close for two or three days; it may then be reopened and give vent to a copious discharge. The pus is not usually offensive except when it has been long retained or gangrene has occurred. The sputum generally contains small yellowish or dark pieces of lung tissue visible to the naked eye that upon microscopic examination are found to consist of elastic lung tissue.

The essential signs of the disease are: dullness with feebleness of respiration or absence of the respiratory murmur over the abscess combined with indistinct râles in the lung tissues immediately about it and sometimes with bronchial breathing. After escape of the pus the well-known signs of a cavity may be present for a short time, though in the primary affection the lung is apt to contract speedily so that cavernous respiration is present for only a few hours; or refilling of the cavity with pus may prevent the respiratory and vocal sounds common over a vomica.

*Diagnosis.*—The affection is liable to be mistaken for bronchitis, pneumonia and acute or chronic pleurisy. The most important features in the diagnosis are the occurrence of symptoms similar to those of acute croupous pneumonia, but followed by irregular chills and hectic fever indicative of the formation of pus and dullness more or less circumscribed that is apt to be more distinct over a small region than that of pneumonia but less distinct than in pleurisy.

Atypic respiratory and vocal signs unlike those we expect to find either in pneumonia, pleurisy or bronchitis, are a most important element in the diagnosis and finally the sudden expectoration of a considerable quantity of pus containing elastic lung fiber reveals the true nature of the disease.

**Bronchitis.**—Bronchitis is to be distinguished from pulmonary abscess by absence of the irregular chills and fever common in the latter disease, by the comparatively slight fever in bronchitis; absence of dullness on percussion and the presence of bilateral mucous râles; by frothy and subsequently mucopurulent expectoration instead of the purulent expectoration of abscess, and by the quantity and time of occurrence of this expectoration. The sputum in bronchitis is at first frothy and subsequently gradually becomes muco-purulent; whereas in abscess of the lung there is usually little or no expectoration at first, but finally a large quantity of pus preceded by a few drops or drams of blood.

**Pneumonia.**—In pneumonia the symptoms and signs are much like those of pulmonary abscess, indeed this disease is very liable to obscure the signs of abscess, but a careful review of the symptoms and signs will generally enable us to make a correct diagnosis, except in cases where the abscess results from a primary croupous inflammation. In the beginning of pneumonia we have a severe chill instead of the irregular chills and fever indicating suppuration; yet abscess of the lung may have been preceded for a few days by all the symptoms of pneumonia. In pneumonia there is usually more or less distinct dullness over the greater portion of one lobe or more, of one lung, slight in the beginning but well marked later on. In abscess of the lung the dullness is apt to be circumscribed at the middle or upper part of the lower lobe and the area smaller than in croupous pneumonia. The dullness may be more pronounced than in pneumonia, when the abscess is close to the surface, or scarcely discernible when the collection of pus is deeply seated and a considerable quantity of healthy lung tissue intervenes between it and the chest wall; but in most cases of abscess the dullness eventually becomes pronounced and distinctly circumscribed and it is liable to be surrounded in every direction by fair pulmonary resonance.

Upon auscultation in pneumonia, distinct crepitant râles are heard in the beginning, distinct bronchial breathing later on and still later the subcrepitant râles of resolution; but in pulmonary abscess the respiratory sounds are atypic and commonly very confusing. At first over the abscess there may be no sign excepting a feeble respiratory murmur, though if the abscess is near the surface there may be entire absence of respiratory sounds due to occlusion of the air vesicles and smaller bronchi, by compression. Usually, however, there are a few subcrepitant and larger bronchial râles in a zone two or three inches wide about the abscess and there may also be a few crepitant râles; but these signs are much less numerous and less distinct than in typical pneumonia. It will be readily understood that location of the abscess near the surface, or deeply seated would necessarily change the character of the respiratory sounds over it.

To me the most important elements in the diagnosis of this affection consist of the indistinctness of the respiratory murmur and the irregularity and confusing character of the râles all of which are very different from the typical signs of pneumonia or pleurisy.

The signs are such that the physician, even though an expert, after having made a thorough physical examination is inclined to admit (to himself at least) that he does not know what is the matter. A careful consideration of the history of such a case including all predisposing and exciting causes together with a study of the early symptoms, taken in connection with the atypic signs will generally lead to a correct diagnosis.

**Acute Pleurisy.**—In pleurisy as in abscess of the lungs there are apt to be irregular chills and fever, but the chills and fever of pleurisy occur in the beginning and are not followed after three or four days by rigors and hectic indicative of suppuration. In pleurisy the discovery of friction sounds and fremitus in the beginning is important in differentiating it from abscess, but frequently these signs are not very different from the irregular râles which are heard in the latter disease. After the effusion of fluid in an acute pleurisy the dullness necessarily extends to the lower limit of the pleura and becomes more pronounced than in an abscess. There is also a change in the level of the fluid on changes in the patient's position, and absence of vocal fremitus when the patient speaks; signs which do not occur in abscess. Contrary to the usual teaching, the respiratory and vocal signs though feeble, are not entirely lost over the upper part of a pleuritic effusion, but they are usually less distinct than over an abscess. In acute pleurisy the fever commonly subsides from the third to the fifth day and after this time we do not have irregular chills and hectic fever such as indicate the formation of pus. In pleurisy the displacement of the heart to the opposite side is an important sign which does not occur in the abscess of the lung. In acute pleurisy we do not get the expectoration characteristic of the disease under consideration.

**Chronic Pleurisy.**—In this disease we are apt to find a very different history from that of pulmonary abscess. Empyema, when involving a large part of the pleural cavity may be easily distinguished from abscess of the lung by the well-known signs of a pleuritic effusion, but when circumscribed the signs are not characteristic. In a case coming to us several weeks after the inception of the disease a physical examination may reveal only a limited area of distinctly circumscribed dullness; the cavity may have opened into a bronchus and the patient may be raising large quantities of pus so that neither by the physical signs nor symptoms could we distinguish between the two affections with accuracy. In such cases a microscopic examination of the pus may reveal the true nature of the disease by discovering elastic pulmonary fiber in the case of abscess, but none in empyema.

**Prognosis.**—Pulmonary abscess may prove fatal within four or five days, but usually even fatal cases extend over two or three weeks or sometimes many months. When an abscess opens spontaneously it usually does so within three weeks. In unfavorable cases, especially of secondary abscesses, many of the patients die of exhaustion or as the result of infection of some other part, and others succumbed to repeated inflammation of the lung tissue about the pus cavity. Abscesses of the lung resulting from pyemia, gangrene, tuberculosis, embolism or the infectious diseases are necessarily very grave. Those that we have classed as primary are much more likely to recover.

**Treatment.**—The treatment of abscess of the lungs

when of secondary origin must be that appropriate for the primary disease with such tonics and stimulants as appear necessary and ample nourishment. The early treatment of primary pulmonary abscess is very similar to that of lobar pneumonia. In practically all cases the expectant form of treatment is the best in the beginning, but when an abscess can be distinctly located, especially if near the chest wall, the question of surgical interference must be considered. Remembering the natural tendency of this disease and the possible dangers of an operation, I believe that the greatest good to by far the greatest number of patients will be obtained by pursuing the expectant plan for at least three or four weeks. I know that some cases may be shortened by an earlier opening, but I am satisfied that some lives would be lost by this procedure which might be saved by waiting. After three or four weeks if the abscess does not open spontaneously and an accurate diagnosis can be made surgical measures should be adopted. The comparative safety with which surgical operations may be made under antiseptic precautions and the glamour surrounding extensive and showy operations strongly tempt the surgeon to cut down at once, resect one or more ribs and perforate the lung to allow the escape of pus. That this operation is proper and desirable, in certain cases we do not deny but that it should be held as a dernier ressort seems to me to have been demonstrated by common experience and by the records of a few cases in my own practice, brief histories of which I will presently give.

Aspiration alone is competent to effect a cure in many cases where necrosis of lung tissue is small, even though the collection of pus may be large. Aspiration combined with washing out of the cavity by disinfectant solutions would be effective in others, but where there is a considerable necrosis of lung tissue or where aspiration has been tried and failed, the more radical operation of cutting down and resecting a rib and then perforating the lung by the thermo-cautery should be adopted. When we have decided that an abscess of the lung is present, or when after a thorough examination by a competent diagnostician we are led to believe that one exists, exploration to discover the pus should be made, in several places if necessary, with a fine clean needle at least three inches in length. Having in this way located the abscess, aspiration may be done by any of the common instruments and a comparatively large needle. It has always been my custom to disinfect the aspirator needle by dipping it into a solution of equal parts of carbolic acid and olive oil or oil of almonds, and it has seemed to me that this strong solution is especially beneficial in cauterizing the tract of the wound and thus preventing absorption of purulent matter. The pus cavity should be emptied by the aspirator and the operation repeated at the end of five or ten days if it refills, and again and again if necessary. The question of washing out the abscess will have to be determined by the individual operator; but usually it is not best unless the pus is very offensive, when there is reason for believing that a considerable mass of gangrenous lung tissue is present within the abscess cavity.

When an abscess results from gangrene or from any other cause that leads us to believe free drainage necessary, and after aspiration has been tried and failed we should resect a rib in the ordinary method.

If the pulmonary pleura is found adherent to the costal pleura we may at once open the lung with the thermo-cautery; if not, the two should be stitched together and fifteen or twenty-four hours allowed for adhesion to take place before the lung is opened, in order to prevent the escape of pus into the pleural sac. Preliminary aspirations as already recommended will usually excite adhesive inflammation if the latter has not already occurred in the natural course of the disease so that the stitching will be unnecessary. Having made a free opening and secured adhesion of the two pleural surfaces it only remains to open through the lung tissue and introduce a large sized drainage tube, or tubes, after which it is managed in the same manner as other large abscess cavities, the patient being supported by tonics and nutritious diet.

In illustration, I have to record briefly a few cases that have come under my own observation in private practice. Of the first case I have no notes, of the second a brief record, of the third case I have complete notes regarding the laryngeal condition, but only a very concise history of the pulmonary abscess though it occurred so recently that I have the features of the case clearly in my mind. Of the fourth case I have no notes, of the last three I have good records.

*Case 1.*—About ten years ago I was called to see a physician between 50 and 60 years of age, who had been hunting a few days previously and returned with the symptoms of acute pneumonia. Upon examination of the chest I found signs suggestive of pulmonary abscess, but a positive diagnosis was not made until a few days later when the abscess opened spontaneously and the pus was evacuated. In this case the cavity rapidly contracted and the man made a speedy recovery; the whole duration of the disease probably not occupying more than four weeks.

*Case 2.*—Mrs. D. F., aged about 40. This patient I first saw in July, 1894. She presented obscure symptoms pointing to inflammation in the region of the diaphragm involving the liver and later apparently involving the pleura and lung. She had suffered from the disease for many months when I first saw her, and was in a low condition when she came under my constant care a few weeks later. It was impossible to make a positive diagnosis, but about six weeks later I became satisfied there was an abscess in the lower outer corner of the right mammary region; this I aspirated and withdrew a few ounces of pus; subsequently it refilled, and eventually a small quantity of pus continually escaped from the wound made by the needle. She had been expectorating purulent material at times, and every few days had been evacuating several drams of pus from the bowels. Early in November, I resected portions of two ribs, and penetrating about half an inch of lung tissue came upon a pulmonary abscess which communicated through the diaphragm with an abscess cavity of the liver, and by an obscure opening with the bronchial tubes. Large drainage tubes were inserted and the wound treated in the most approved manner; but she failed more rapidly after the operation and died in about three weeks. What the result in this case would have been if the operation had been made sooner can never be known, but from the patient's history and symptoms I believe that had the abscess been opened earlier death would have been correspondingly early.

*Case 3.*—Mrs. W. G., aged 28, came under my care March 17, 1894, suffering from stenosis of the larynx. She had great difficulty in breathing and was much emaciated. The history and appearance of the larynx convinced me that the obstruction was due to the contraction of syphilitic cicatrices. The cords were adherent nearly to their posterior extremities and the caliber of the glottis was reduced 80 per cent. I opened the glottis with Whistler's cutting dilator and subsequently kept it dilated with O'Dwyer's large tubes until healing had occurred. The patient improved greatly in flesh and general condition, and was about to be discharged when I was sent for to visit her at her lodgings. I found her suffering with severe pain in the right side and dyspnea, with all the symptoms of a sharp attack of acute pleurisy. The room was cold and conditions were such that a careful examination of the chest could not be made without too much exposure, therefore I contented myself with a diagnosis of acute pleurisy and prescribed accordingly. The pain was relieved by

anodynes; but four days later the abscess ruptured and the patient expectorated large quantities of offensive pus with a little blood. The pus was also aspirated into the surrounding bronchi and greatly increased the dyspnea; secondary infection and inflammation speedily followed so that she rapidly failed and succumbed to the disease about thirty-six hours after the opening of the abscess. This case illustrates a syphilitic origin and a rapidly fatal course.

*Case 4.*—Mr. X., about 22 years of age, was seen by me in consultation some three years ago. I found him with what might be called typical signs of pulmonary abscess, because they were so much like, yet not typical of, pneumonia or pleurisy. There was dullness on percussion, and a feeble respiratory murmur with indeterminate râles over and about the abscess. I found a valvular lesion of the heart that explained the origin of the disease. The history showed that the inflammation had come on suddenly and that after a few days the pus had escaped, but the abscess cavity had subsequently closed to reopen again in about forty-eight hours. This opening and closing continued for some days, but the man eventually died. This case illustrates the origin, course and termination of embolic abscesses.

*Case 5.*—S. J., aged 36, came under my care Jan. 8, 1884. He stated that eight months previously he had an acute attack of inflammation in the left lung and that thirteen days later he had expectorated about a quart of offensive matter. With the attack he was confined to his bed about four months, since that time he had been expectorating pus at irregular intervals. He had formerly weighed 168, but had lost 44 pounds. At the time of my first examination the pulse was 110 and irregular, but the temperature normal; the appetite was poor and the digestion imperfect. He suffered very much from dyspnea upon exertion, had a spasmodic morning and evening cough and said that he expectorated about a pint of purulent offensive matter daily. About ten weeks previously on two occasions after a particularly hard coughing spell he had expectorated a few drops of blood. A careful physical examination revealed a little flatness in the left infra clavicular region. The left side measured sixteen and one-half inches, the right sixteen and three-fourths to seventeen and one-half just below the nipple. The heart was in its normal position. The respiratory sounds were feeble at the upper part of the left lung and lost below, but there was slight vocal fremitus. The right side was normal. I introduced an aspirator needle between the seventh and eighth ribs near the angle and drew off four ounces of very offensive pus; as the last of it came away he felt like coughing and the pus became bloody. That night he slept all night which was the first time since the beginning of his illness. Six days later it was noted that he had coughed about as much the preceding night as before the aspiration. Another aspiration was made, but at this time only about one ounce of pus escaped followed by blood. Fourteen days later the aspirator needle was again introduced but no pus was obtained. He was given tonics consisting of iron, quinin and strychnia and also the chlorid of calcium. One month after the first operation he had gained eleven pounds, and ten days later it was noted that he weighed twenty-five pounds more than at the first operation. He continued to improve rapidly in weight though he was still annoyed by a cough for several weeks. The dullness over the lung subsided slowly, and I did not consider him perfectly well until about four months after he first visited me. He is still living in good health and has had no recurrence of the pulmonary trouble or any indication of tuberculosis.

*Case 6.*—Mr. W. W. G., aged 19, came under my care first in Sept. 1888, complaining of cough and loss of strength. Four months previously he had suffered from an attack of what appeared to be pneumonia from which he had recovered except that the lung did not fully clear up. About four weeks before I saw him he began to feel ill again, having slight chills and fever which continued for about twenty days. He had been better for some ten days just before I saw him, and the fever had mostly disappeared, but the cough was very troublesome. Physical examination revealed circumscribed dullness over the lower part of the right lung. I aspirated and withdrew twelve ounces of pus which was not offensive in odor. Five days later I aspirated again and withdrew ten ounces of pus when it became necessary to desist because of cough and pain. About a week later I again aspirated and withdrew a smaller quantity of pus. Three weeks later the dullness over the lung continuing, I thought it would be necessary to introduce drainage tubes, but making explorations in several places no pus was discovered. The young man continued to improve and shortly after went to Colorado where he has remained since. About a year later, happening in Colorado Springs, I made a careful examination of his lungs and found them in perfect condition except a scar from the old disease. He still

continues in perfect health. In this instance there was apparently abscess of the lung as a sequel to pneumonia. There was at first some question as to the diagnosis in this case, but the pus was so distinctly circumscribed and so deeply seated, and the respiratory murmur in other portions of the lung was so distinct that after aspirating I felt confident that it was an abscess though I did not make microscopic examination.

*Case 7.*—C. A., aged 16, came to me in July, 1895. His history showed that the previous April he had suffered from inflammation of the lung and that subsequently he had frequent chills and fevers, with cough and free expectoration of pus. The boy was pale and sallow, and had lost considerable flesh, but he had no fever at the time I first saw him, although his pulse was 132 per minute. Physical examination showed the heart in normal position and revealed considerable dullness at the lower part of the right lung, more pronounced over a limited area a little below the spine of the right scapula. A feeble respiratory murmur could be heard about this spot, vocal resonance was diminished and vocal fremitus absent over some parts of the lung in the vicinity, but the signs could not be satisfactorily accounted for by the hypothesis of either pneumonia or pleurisy. This case was first examined by my associate, Dr. John Edwin Rhodes, who pronounced it empyema. He introduced a hypodermic needle in the region indicated just below the angle of the right scapula, and withdrew a small quantity of pus, and sent the patient to me for operation. When the boy came to me I could easily see the point of puncture that had been made with the hypodermic needle. Having Dr. Rhodes' letter before me, without careful examination, I introduced the aspirator needle at the same point and withdrew about twelve ounces of pus. The boy was sent to his home, a few miles distant, and a few days later I saw him again in consultation with his former physician. At this time I explored the chest in two or three places about an inch from the former point of puncture, but was unable to find pus. I found also that the respiratory and vocal sounds were distinct over portions of the lung, above, below and laterally of the area of dullness. Finally, upon entering my needle at the site of the old puncture and passing it in about an inch and a half, I again found the abscess and withdrew ten or twelve ounces of bloody pus. At the first operation I supposed I had to deal with a circumscribed empyema, but after obtaining a more definite history of the boy's case from the physician who had him first in charge, and after my explorations and deep aspiration, I became convinced that it was an abscess of the lung following pneumonia. I left word with the doctor that in case the cavity refilled it should be again aspirated, but a recent letter from him informs me that the boy continues to improve and has gained twenty pounds in weight. The cough did not return and the abscess did not refill.

These last three cases all resulted from pneumonia, they were all deep seated and chronic in character. In each there were distinct signs of a collection of fluid and a preliminary diagnosis of empyema, but in every case the pus was so sharply circumscribed and deeply seated that I feel sure of the diagnosis, even though I did not use the microscope to detect elastic lung fiber. These last cases are of special interest in showing what may be accomplished by simple aspiration in chronic, deeply seated abscesses of simple inflammatory origin.

36 Washington Street, Chicago.

#### DISCUSSION.

DR. McARTHUR.—In reviewing the literature of the subject I have been greatly surprised that men of such wide-spread experience and acuteness of observation as Trousseau or Chomel had in twenty-five years experience seen but two cases each of pulmonary abscess. It has been my fortune to see at least ten or a dozen, most of which have been operated upon. The large proportion of cases occurring subsequent to a pneumonia, is striking and worthy of emphasis. In these cases the consolidation instead of liquefying and being absorbed or expectorated, breaks down into pus, together with the pulmonary tissues involved. This frequently does so at the time when termination of the pneumonia should occur, but does not. A diagnosis of pulmonary abscess being made (and in addition to the physical and microscopic examination we might recall with advantage the fact that the pus being expectorated from a

pulmonary abscess if shaken up with water will separate, on standing, into three layers; the *upper* mucous, *middle* water, *lower* pus, as in purulent urine), I believe the general plan a good one to empty them surgically; though Dr. Ingals has had such good results by the conservative treatment in selected cases. Dr. Fenger has emphasized: 1, the point that if we desire to determine the presence or absence of adhesions, that this can best be done by inserting a hypodermic needle deeply, when if the surface of the lung be not adherent the needle will move with each respiration; 2, that thickened, diseased lung tissues bear surgical interferences very well, and do not retract as do the healthy lungs. In the absence of adhesions in the lower portion of the pleural cavity (three hepatic abscess cases) I have been able to protect the pleura against a septic pleurisy by simply packing off with iodoform gauze strips the small area necessary for perforation of the diaphragm, and since in this situation it was possible in one very putrid echinococcus cyst. I have no doubt the same means might be employed to advantage in pulmonary abscess without adhesions, thus obviating the extremely difficult though sometimes successful suture of parietal and pulmonary pleura.

DR. FRANK BILLINGS—I agree fully with Drs. Ingals and McArthur, that the most common cause of abscess of the lung is croupous pneumonia. Of the cases I have seen, pneumonia preceded the abscess in all but three. In one case, an ordinary copper cent lodged in the right bronchus and caused abscess of the lung near the foreign body. A postmortem revealed the abscess and the cause. In two cases, stricture of the esophagus was the cause; in both carcinoma of the esophagus near the cardia, with consequent dilatation and perforation of the esophagus above the stricture, allowed infection of the tissues and abscess of the lung. Postmortem examination was made in these cases also. In one case of chronic abscess of the right lung which was successfully operated upon at Mercy Hospital there was a history of pneumonia, which occurred two years before. Cough continued after the pneumonia, with the expectoration of decomposing pus. The abscess cavity was reached by resection of a piece of rib just below the scapula, and after a needle exploration, by cutting through the lung and pleural adhesions, the operation was made simple. Thorough drainage resulted in a cure. This case returned to the hospital a month ago, more than a year after the operation, suffering with cerebral syphilis. A full history of syphilitic infection several years before the occurrence of the pneumonia was obtained. It is therefore possible that syphilis had some causative relation to the abscess of the lung in this case. In my experience, abscess of the lung following pneumonia, occurs most often in the lower lobes, contrary to what the books state. In abscess following pneumonia the crisis may occur and the temperature fall to normal. If the temperature falls it will rise again in what seems a prolonged convalescence. Hectic usually occurs. The physical signs of consolidation of a part of the lung remain with, however, as a rule, diminished respiratory sounds. I think it is not possible to make a positive diagnosis until the presence of pus is shown by aspiration or by spontaneous rupture of the abscess into a bronchus or other outlet. The differentiation of circumscribed or encysted empyema from abscess of lung would be difficult without the discovery of lung tissue in the pus aspirated or discharged. From an empyema involving the whole pleural cavity, the usual signs of fluid in a pleural cavity and especially the displacement, by pressure, of neighboring organs would make a diagnosis easy. The diagnosis, therefore, in abscess of lung must depend, I think, upon the visible presence of pus, usually containing formed elements from the lung. The clinical history and physical signs furnish rational or presumptive evidence only. The treatment resolves itself into palliative, expectant medical treatment and curative surgical measures. If in an acute case,

the patient is anemic and emaciated as a result of pneumonia or other causative disease, operative interference should be postponed until the patient may be strengthened by restorative iron and other tonics, good food, etc. One may cause a cavity to drain by placing the patient in a position to allow the pus to run into a communicating bronchus. I have had patients lung, head downward, over the bed for a few minutes at a time, a few times a day, or in certain cases a recumbent posture, on one side, or the back or face, for a time. A cavity may be so drained that recovery will take place without surgical interference. In acute cases, when drainage by posture can not be obtained, and in all chronic abscesses, chronic because drainage has not been good, surgical interference is indicated.

DR. SHURLY—It is often exceedingly difficult to make out abscesses of the lung when deeply seated. This seems to be one of the things over which we fail. A great many of these cases presenting obscure physical signs are abscess of the lung following pleuro-pneumonia. Some of them, however, present so little constitutional disturbance that we are apt to let nature alone. Others present such constitutional symptoms that our attention and aid are required at once. I have had three cases in which inflammation of the brain came on after the development of abscess in the lung and chest. I might have saved these patients perhaps if I had operated early. Even in cases of ordinary empyema it is not uncommon, whether they have been operated upon or not, for an attack of meningitis to follow, the exact cause of which we are unable to determine even under our modern doctrines. I think many cases where only the pleura seems to be involved are really cases of abscess of the lung thus presenting the most complex features to us, and requiring the most careful treatment. If the contents of the cavity be so imprisoned by fibrous walls that there be little absorption we may have little or no temperature or other constitutional disturbance; but if these barriers break away a sudden infection of surrounding pulmonary tissues takes place and we have septicemia, which may end life in a few days. Some of the most virulent cases of septicemia follow upon abscess of the lung. Sometimes making an opening will not avert it; for in the cases I opened, the abscess of the lung all died of septicemia. It was probably because I opened two inches of lung to reach the abscess. I am not surprised at the result, for I thus exposed a field of capillaries and lymph spaces such as does not exist anywhere else in the body outside of the generative organs. It is a wonder that one does not observe septicemia in every case. I have thus been warned from sad experience to refrain from cutting into lung abscesses which are deep seated, unless I can see some sign of invasion of some other part of the body, and if the cases seem to be improving ever so little I content myself with waiting. I have two cases on hand now which are recovering slowly of abscess of the lung, in which I did not feel warranted in attempting any operation. We should be extremely cautious if we can not positively distinguish the location of the abscess. A few years ago I had a case of abscess of the lung, following croupous pneumonia, sent to me for operation. The man was in a very low condition, his temperature fluctuating between 105 and 97 degrees. I thought the operation must be done at once and advised the man accordingly, but a brother telegraphed requesting that nothing should be done until his arrival. As he persistently refused to have it done we were forced to wait and when the brother came the man was somewhat better. Later in consultation with his physicians we concluded that we would be justified in continued waiting, and the result was that the man finally recovered without an operation. If I had operated he might have died.

DR. SAMSON—I have had the opportunity within the last twenty-four hours of seeing one of the most interesting cases of abscess of the lung in existence at the present time. The

patient six years ago swallowed a boring of maple. He began to suffer in health and was sent to Denver and other health resorts. Specialists tried to reach the abscess by passing a trocar in some distance below the scapula. They did not find any pus. Just now the case is a typical one of abscess of the lung, coughing up fully a pint of pus every day. Very much can be done in a surgical way for the relief of this trouble, and I believe we should operate in all cases where we are able to make a correct diagnosis.

DR. FLINTERMAN—I would like to inquire of author if where there was a pulmonary abscess was there not sometimes a pleuritic effusion in the pleural cavity?

DR. INGALS—I have not seen the condition referred to by the last speaker. I was much interested in the statement made by Dr. Shurly, that inflammation of the brain was a common occurrence with abscess of the lung. Dr. Shurly's experience seems to correspond with my impression, viz., that as a rule the earlier we operate the sooner the funeral. The early evacuation of a pulmonary abscess does not seem to me as safe as tentative treatment, at least for a few weeks.

### PURE WATER.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1895.

BY FRANK W. EPLEY, M.D.

NEW RICHMOND, WIS.

In the beginning God created the Heavens and the Earth, and he filled the Earth with pure water and surrounded it with pure air.

Then he made man and put him on the earth. And for a time he also was pure. Then he began to be restless and to invent. He has sought out many inventions.

The Allwise Creator provided means whereby all filth should be purified and resolved into its ultimate elements. Man has sought out many cunning devices for defeating God's plan of purification. The most potent purifying agents are heat, light and air. The most potent factors in the development of poisonous germs and gases are warmth, moisture and darkness. The offal of all living things except man is deposited upon the *surface* of the earth. The bird deposits his while flying through the air; the ox and horse upon the dry grass, or in the dry dust. The dog is wont to place his upon the top of a stump or stone, and all are left in the best possible condition for the action of nature's disintegrating elements heat, light, air, etc. Man alone, whom God made upright and in the image of Himself, has invented a *hole*. Two holes in the earth; nearly always close together, at least relatively, so that both shall be convenient. One he makes comparatively shallow but deep enough to accommodate himself and family for many years. In this he deposits his offal both liquid and solid and says, "Soul take thine ease," in this hole thou shalt lay up much goods for many years, "eat, drink and be merry," and if thou hast any other unclean thing which offends thy sight or smell, cast that also into this *hole* and it shall sink away into the earth out of our sight. Even so the rain falls upon the surface of the earth and sinks away out of sight, finding its way into the other hole which man has invented, and from this he supplies his family with pure (?) water.

If he, this Lord of creation, lives in a modern city which is embellished with all the improvements of our advanced civilization (?) he has a much handier method. He has a bottomless bowl, or one having one side wanting and with a small quantity of water

in the bottom into which his offal is deposited and which is washed away by a dash of water; *most* of it, out of his sight and into a tube which leads down into a subterranean passage, this passage communicating with a like tube from his neighbor's bath room and receiving the contents of tubes leading to thousands of other bath rooms until the filth of the whole city is coursing through it and is finally deposited into a pond of pure (?) water just without the city; or what is more likely, within the city.

I said *most* of the offal was washed off the smooth polished surface of the bowl in his bath room; some small quantity, however, frequently requires a vigorous rub to be displaced. When it reaches the inner surface of the tube below, it does not get this vigorous rub and remains stuck to the sides until the whole tube is, many times, full. From this a gas is found to arise finding its way in six out of ten cases directly into the living apartments, and when it has any odor, is very frequently termed the "smell of aristocracy." But pardon this digression, we were to speak of pure (?) water. However, we were very close to it when we left the end of the tube leading down from the bath rooms into the pond. We have now only to go a short distance further out into this pond to obtain an abundance of pure (?) water. Then we lay another tube along side of the first one, which leads up to the kitchen faucet. Will any one attempt to give us the chemic formula for the water obtained from this faucet? It is H<sub>2</sub> offal; contemplation. Can we reasonably expect to obtain pure water to drink from our abundant natural resources when we resort to such civilized (?), shall we say such outrageous, systematic methods of wholesale pollution. Can we while we do this lay any reasonable claims to rationality? I say "no."

Gentlemen of the AMERICAN MEDICAL ASSOCIATION: We are the logical keepers of the public health. We all know these two systems of disposal of filth are abominable. Shall we sit quietly down, fold our white clean hands, and say, this is too dirty a subject to handle? They are wrong, but they are old established customs and it is too great a task to undertake such a revolution. For shame! There is no task too great for Saxons to undertake.

There is no wrong, however grievous, too great for Americans to try at least to rectify.

The *death knell* of our American vault and sewage systems should be sounded, and it is incumbent upon *this ASSOCIATION* to hurl the fatal shaft.

#### DISCUSSION.

DR. HIBBERD—I desire only to call attention to the inference that I think might be drawn from the verbiage of the paper—that man made all that is bad on the earth in spite of the Beneficent Providence, which created it pure and good in the early arrangement of the universe. All I want to say is, so far as my knowledge concerns, everything of the kind takes place in the world as precisely according to the laws of the Creator, as though they were made in the beginning; therefore, man did not invent them, and if they are not salutary in their effect, it is simply because there is a lack of observation of what is good, as the Creator intended. I think God is good, and that He has made the world good. I think the laws by which we grow, and progress are all good, and if we fail in recognizing what we should do to maintain the operation of these laws in a sanitary direction it is a failure, but not on the part of the Creator. All I want to do is to raise the idea that God is Supreme and has made everything good primarily; and that if we do not obey

His laws and receive the benefits which He intended us to derive, then we are at fault and should not throw the blame on Him.

DR. MCINTYRE—Of course we can not all see the value of the paper and appreciate the ideas brought forth therein regarding pure water; and while there may be mistakes contained in it I will simply speak on the line suggested by the author, rather than suggest any corrections. It seems hard to suggest anything that will take the place of our present sewage system, or exactly meet the requirements; but will the correction of the evil be found in purification? I think that is being done. I think the demands of modern civilization require two things: First, thorough purification of sewage before it contaminates the streams and lakes, and secondly, thorough purification of the water itself before it is pumped into the mains to be distributed into the city. The manner in which this is done at Lawrence, Mass., has demonstrated that as the solution of the difficulty. The experiments tried in the last cholera epidemic at Hamburg show the difference between filtered and unfiltered water. These experiments all show that this can be done and at the same time that the sewage of the city can be cared for in the convenient manner in which it is generally disposed of. And then, by proper ventilation, there is no odor in the house, and the water in the house is kept clean.

DR. JEROME COCHRAN, Montgomery, Ala.—Having something to do with practical sanitation, I am naturally interested in it. Filth, doubtless, is a very undesirable thing to have about a place, and it is especially undesirable to have it in the water supply; but I would like to emphasize that there is a great deal of filth that is offensive to the senses that is not detrimental to health. I would insist that that filth which is detrimental is a sort that is not offensive to the sight or taste. The things which produce diseases in water supplies are bacteria. We have disclosed the filth so far without reference to its organism. The fecal matter in itself, when it is not filled with the bacilli of typhoid fever, is perfectly innocuous to health. I think the remedy is to purify the sewage before it enters the waters, and purify the water after it is taken away from the lakes; fortunately for us nature has shown us how to purify water. The great method of purification is by filtration. That is the way nature purifies water, but there are practical difficulties in the way of getting rid of those pyogenic organisms that do not seem to have attracted the attention of sanitarians. The city of Lawrence, Mass., has made a study of the filtration of water, but you find that all the bacteria are not eliminated in that way nor all the organic matter. It is this matter going to any water—these pyogenic bacteria already taken out of it that will soon multiply again. You can not thoroughly purify by filtration. It is in a very much better condition than before so that if you want to get water that is practically free from bacteria there is only one way, and that is to re-filter it.

DR. EPLEY—I only hinted at the subject to call attention to the disposition of filth and the obtaining of what is termed "pure water."

We have all of us recognized the difficulty in the disposition of human offal. As I said, man has invented a hole, and for that reason I have for many years been endeavoring to create a disposition among people where they have no sewerage to dispose of offal in a dry condition. But they say "I have dug a vault, and it will last me a great many years. I shall never have any more trouble." I have for years advocated the keeping the human offal dry and letting the water fall off on the top of the ground. It is very easy to do that when a system of closets are used. I have seen them used for eighteen years without any trouble at all. I have encouraged their use in the community where I live, where they had no sewerage. In fact I have encouraged it where they have sewerage. The sewerage system has many faults, and it must sometime be cor-

rected. We have no right as intelligent beings to deposit our offal in all conditions, whether benign in its character or filled with diseased germs, into running water, our pure sources of running water that we must have for our sustenance. So far as the purification of water before it reaches our streams is concerned, I am not conversant with any system which promises anything substantial or reliable in this line that can purify water that is one-third or one-fourth or 10 per cent., or 5 per cent. fecal matter, while it is still in the sewer and before it reaches the water course. It seems to me to be an impracticable plan. I do not understand how it can be done.

DR. MCINTYRE—It is done by filtration at sewage farms, by the use of the lime and iron process.

DR. EPLEY—It is purified, but at what expense? The disposition of it as a fertilizer is right, and should be used, but at the same time it is truly impracticable to attempt to dispose of offal in the current of water and have so much more to destroy; it is much harder to destroy a quantity of water that is one-half or a very large percentage solid matter, than it is to have the solid matter and the water separate. But this process would not exclude sewer gas; and if I understand the gentleman who spoke of sewer gas correctly, he said proper ventilation would prevent it from entering the house. I was investigating this matter in Milwaukee a few days ago, and I asked an inspector, who was testing for sewer gas (and his test responded beautifully, in a large percentage of houses in Milwaukee, a well ventilated and well sewered city) what percentage of houses would respond to that test, and he said nine out of ten. The gas was entirely without smell, but it was deleterious in its effect upon the inmates of the household.

The method of filtration is satisfactory, if it is executed as it should be; but what I state is that to keep the solid matter separate from the liquid matter is much easier and can be done with much less expense than purifying the whole mass after it has become thoroughly mixed.

DR. KOBER—I would like to ask how he considers it feasible in a large city. The plan he speaks of is very applicable to small communities and is, perhaps, the best method of disposition; but the dry earth system is scarcely applicable to a town of over twenty-five thousand inhabitants. Indeed, it has been considered quite expensive in every way, and if he has any data on the subject I would be glad to hear it read.

DR. EPLEY—I have not a thoroughly matured plan, indeed, I do not profess to be an inventor or civil engineer; but I believe that it is an evil to which our inventors and civil engineers should turn their attention, and I have no doubt but that a system can be provided whereby this solid matter can be kept from the lake by a system of dry closets, or keeping the offal dry in some way.

DR. MCINTYRE—I think, in parts of Birmingham and Glasgow there is no sewage system. There are places where the pail system prevails. My impression is that the cost per capita of removing the pails in this way is larger than the system of purification. It is in small towns where it has been used on a small scale.

DR. EPLEY—You have not disposed of the sewer gas.

DR. MCINTYRE—I refer you to the report of the committee appointed by the London Commissioners of General Works on the air of sewers, where it is shown that the air of the sewer is better than the outside air.

**New Jersey County Hospital Law Amendment.**—The law passed in New Jersey in 1886, entitled "An act to enable counties which have no free county hospital to assist in maintaining hospitals located in such county," was amended in May, 1896, making it lawful for the board of chosen freeholders of any such county to make an appropriation therefor of a sum not exceeding \$8,000 a year, instead of \$1,000 as heretofore, and providing that the act shall not apply to counties of the first class.

## EVIL RESULTS OF OVERSTUDY IN THE YOUNG.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association at Atlanta, Ga., May 5-8, 1906.

BY W. THORNTON PARKER, M.D.

MEMBER OF THE MASSACHUSETTS MEDICAL SOCIETY, MEMBER OF THE AMERICAN MEDICAL ASSOCIATION.  
GROVELAND, MASS.

In the early days of our Republic, it was the unwritten law that the youth must work first, and study afterward.

The children of the wealthy could be sent to school or college, but for the average American book learning formed a small part of life.

The picture of Abraham Lincoln lying on his stomach, in front of the open fire, with a piece of charcoal ciphering on a broad wooden shovel, represents the man who afterward became President of the United States. This is not an extraordinary picture in early American life. Garfield, as well as hundreds of other prominent men, won his education by a struggle. And up to the present moment, there are countless young men throughout our country who are earning their way through college, just as there are many other young men who are squandering their way through. These two classes suffer from the evil effects of overstudy; the former being obliged to work with the mind when the body is weary, the latter recklessly wasting time in pleasure and dissipation, struggle in the process of cramming to make up for lost time in order that they may retain their class membership.

The American public school has been the pride and glory of American institutions, not because the standard of learning is any higher, but because it represents liberty, equality, fraternity. In this nation of ours, the humblest can, if he will, acquire a good education. We are inclined as a nation to have a rather exalted opinion of ourselves in everyway. Our waterfalls are the biggest, and everything else is in noticeable proportion. The recent rumors of war illustrate the fact that we are becoming rather reckless. The victory of the American athletes in the recent Olympic games, is likely to create a popular idea that our students are the strongest in the world, and that our educational system is therefore all right.

A recent paper by T. S. Waters, D.D.S., in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, concerning "The Public School, and its Defects in Relation to Health," is particularly instructive in this connection. The writer being a dentist emphasizes the fact that inferior teeth demonstrate the existence of abnormal constitutional conditions. He says: "School crowding and cramming impairs the health and lessens the appetite, which causes imperfect nutrition, bad assimilation of food and of ideas. This therefore lessens appropriations of good amounts of food which should consist of a proper amount of phosphates, with lime salts for the growing child, the very want of which retards and impairs the development of the second growth of teeth, of hair, nails and bones." This is the sum and substance of the matter in a nutshell. "The overtaxed student immediately suffers from physical as well as mental harm. We often hear it said that some young cripple possesses an extraordinary amount of brain to compensate for the weakness of body. I believe that physiologists are quite agreed that during our sleeping hours there is less blood in the brain than during our waking moments.

It is unreasonable to suppose that because a man's circulatory fluid is diminished in quantity, he will be able to compete mentally with a man whose mental and physical vigor is as near normal as possible. But it is reasonable to suppose that the student who is mentally and physically overworked, and who does not receive suitable nourishment, who is deprived of needed rest and sleep, and whose circulatory fluid is below par, is not in a fit condition for physical or mental work. He is unable to stand the pressure. Unusual mental activity is apt to result in speedy bodily derangement amounting to more or less serious illness. The illness may be so profound that the nervous system is permanently disabled, and this injury may range all the way from simple nervousness to hopeless insanity.

I will quote from a paper which I have published in the March number of the *Dietetic and Hygienic Gazette*: "The nervous strain laid upon our young students is inexcusably wrong. Generally speaking they are too young to understand the full meaning of the condition which this youthful rush, miscalled energy, inflicts upon them. Later on in adult life, if they survive the terrible strain, they recognize the injury they have sustained when it is practically too late to undo the harm which has resulted. The strain of study and the effort to acquire a high standing in the class is encouraged by the teachers and directors. The tension of modern schooling must necessarily create nervous disorders, of which heart disease is one of the most easily recognized manifestations. The trouble is present in the rudimentary errors of modern life, which we can see all about us, and which to the onlooker appear very much like morbid restlessness. The loads we place upon the shoulders of our children should shame us. We would never place physical loads in proportion to the mental burdens we force them to assume, because if we did public justice would cry out against us. The physical burdens are not so injurious or far reaching in harmful influence as the mental strain. Our children go to school and labor mentally to please us, as well as to gratify their own ambition. We stand by and witness this outrage on our own flesh and blood without making any active effort to save them."

It is not intended that these remarks shall apply to our young men only; unfortunately the outlook for our young women in this respect is even more serious.

Dr. Waters, and other writers, have called attention to the nervous injuries which overstudy inflicts upon our girls. "Neurasthenia saps the nervous energy that should be devoted toward fitting her for motherhood within the next few years, when her greatest development in mind and body should be perfected. Hysteria is the most prolific source of domestic infelicity."

The new woman craze endeavors to teach the daughters of Eve that they can study as well as men, and can accomplish as much if they endeavor to do so. There is a partial confession that, although physically inferior in strength and not suited for war, agriculture, or mining, in every other respect they are man's equal, and it is essential that the girl of thirteen should go to school with the boy of the same age and continue her studies by his side. The fact that she is about to ripen into young womanhood, that every twenty-eight days she should menstruate regularly, seems to suggest no mitigation of the amount of toil which is placed upon her. She bravely attends to

household duties at home, hurries off to school whether head or back aches or whether she should be in bed, and tries to keep up in the unequal contest with the boys. That she appears to win and graduates with higher honors, gives us little idea of what the struggle has cost her, and of what the sum and substance of the struggles of all these girls will cost our nation later on. These little misses ought to be at home learning from their mothers, if their mothers know enough to teach them, lessons in domesticity. The noble women who had so much to do in shaping the fortunes of this Republic in its early days would be disappointed in their descendants, in spite of the incongruous cap and gown, of this fin-de-siècle age.

This interesting, artificial young creature so unlike the women of a century ago, abnormal in her bodily functions and very much given to neurasthenia and hysteria, intends to marry some day; but many of them do not intend to have children if they can prevent it, and if they survive the birth of one child, it is doubtful if they could properly nourish it. When a little school girl, clothing was given her irrationally made; it mattered not if it pressed on the breasts and retarded their growth, or if its pressure on the pelvic organs pushed them out of their natural position until pelvic disease was almost a certainty. The object of her existence seemed to be that she hold her own with the boys of her age; that would be her glory! The fact that such artificial women are likely to know something of divorce laws later on makes no difference, she must be educated no matter what happens. The result of all this is most excellently shown in an editorial in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of April 25. "The Despised Office of Motherhood."

The fault therefore in American student life is to be charged to the educators and to the parents of children, rather than to the youths themselves. In an article published in the December number of the *Dietetic and Hygienic Gazette*: "Most parents think that the studies of their sons and daughters at high school are altogether too numerous and too severe. We are apt to suppose that it is the particular high school to which our young people go that is at fault; but a little inquiry shows that our neighboring academies are just as bad, or even worse, in this respect. Who are to blame for this? Certainly not the parents? The teachers disclaim the responsibility, and many of them even regret it. Therefore in our municipality at least, we are forced to conclude that it must be either the supervisors or else that august body of irresponsible, tyrannical solons called the *school committee*. We desire no worse punishment for such supervisors and committees than that they should be obliged to swallow the mental food which they have prescribed for the young people. This would give them a mental dyspepsia for the remainder of their days that would surely keep them from doing any more harm of this kind."

Dr. Dujardin-Beaumez has also called attention to these evil effects of overstudy. He says: "These students are badly developed, pale blooded, exhibiting an excitability of the nervous system which results from mental overwork depriving them of sleep." Insufficient sleep is one of the most noticeable evils of modern civilization; the nervous system, as well as the brain, suffers severely from this want of sleep. Both mind and body are seriously and oftentimes permanently injured. Mental exhaustion, irritability,

and brain fag are the result, the sleeplessness causing neurasthenia. So many of our students are ignorant concerning the requirements of health, or if not ignorant, are forced to continue their studies far into the night, reserving only four or five hours for sleep when they should have eight or nine. These hours of repose should be passed in rooms where the best sanitary conditions obtain, and this is what almost never happens. One of the most frequent causes of heart disease, is the want of proper rest. There are many influences provocative of heart disease in the young, which we can readily understand if we give the matter attention.

With the bars of our ancient puritanic austerity thrown down, in an age of the sharpest competition, and when great things are expected in every department of life, it is no wonder that the sands are strewn with many a noble wreck. In the rush of student life, the meals are eaten with too much haste, the quality is apt to be inferior, mastication improperly performed, and indigestion the invariable result. These diseases of the nervous system, of the heart and the digestive apparatus, are the exciting cause of melancholia. Our daily papers chronicle from time to time the extraordinary suicides of our youths. This fact alone should call for a radical reform in our educational system.

A very grave responsibility rests upon the managers of our institutions of learning. They desire to satisfy the public as to their faithfulness; the public demands that these educators shall exhibit a good showing for the large sums of money invested; and all this great burden rests at last upon the shoulders of our children. The manly vigor of the Republic is robbed of its strength for the sake of creating an artificial condition which does not contain the elements of future national prosperity.

## THE PREVENTION OF INFECTIOUS DISEASES.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association held at Atlanta, Ga., May 5-8, 1896.

BY J. M. G. CARTER, M.D., Sc.D., Ph.D.

Professor Preventive and Clinical Medicine, College of Physicians and Surgeons, Chicago; Fellow of the American Academy of Medicine, the American Association for the Advancement of Science, the American Academy of Political and Social Science, Etc.

WAUKEGAN, ILL.

Perhaps no branch of medicine occupies so much of the thought of the medical profession to-day as infectious diseases. The manner of dealing with these has undergone great changes during the last few years.

The treatment is more satisfactory, and the prophylactic and preventive phases of treatment are most prominent. Since Jenner discovered the importance of vaccination as a preventive measure against small-pox the belief has prevailed in many minds, and hope in all, that some means might be discovered to reduce the terrors if not prevent the prevalence of all the diseases commonly known as infectious. Under improved hygienic precautions and more scientific methods of treatment this hope is beginning to be realized. Typhoid and malarial fevers are almost conquered, the specters of tuberculosis and diphtheria are beginning to pale and show evidences of vanishing, the terrible cases of scarlet fever are not so frequent, measles *et al.* are not so frightful.

The object of this paper is to offer some sugges-

tions upon certain points in this field of medicine, but a full discussion can not be undertaken in the brief time allowed to this subject.

The most successful methods in bringing about these results in the past are the means which should be pushed under wise supervision in the future until they assist us in conquering all these diseases or discover better methods which will help us to attain this end. The principles upon which these methods as practiced at present are based may be given as: 1. Systematic cleanliness. 2. Prevention of individual contact. 3. Fortifying the system against an invasion of the disease.

1. Systematic cleanliness is of the utmost importance and includes the whole field of asepsis and antiseptics, a subject which can not be discussed in this paper.

2. The prevention of individual contact with persons who have an infectious disease, or who have been exposed to one, has been attempted ever since the infectious and contagious nature of certain affections was discovered. These attempts have been conducted in various ways, however, and frequently with very meager knowledge of what is required to make them efficacious.

Without stopping to explain the terms infectious and contagion I will observe that the only difference between them is one of degree, not of kind; that all bacterial diseases are conveyed from one person to another chiefly through the medium of the atmosphere, or water and other liquids; that those cases occurring from the immediate application of the poison, as in instances where particles of diphtheritic membrane have been coughed into the mouth or eyes of attendants, or scarlet fever has been carried by fomites, are not exceptions to this statement. The virulence of the poison depends upon its degree of attenuation. A few of the bacteria which produce a given disease may not infect a person while an invasion by a large number may be irresistible. The atmosphere and water (liquids) while serving as media for the conveyance of these disease germs, at the same time cause an attenuation of the poison by dilution. There is a difference in resisting force to this dilution manifested by different bacteria which helps some to remain concentrated while others are rapidly separated. This enables us to explain the well-known fact that whooping-cough, diphtheria, measles, etc., are conveyed only by an immediate or almost an immediate contact usually; as soon as the germs reach the atmosphere they are in most instances widely and rapidly diffused, concentration is quickly overcome, and their virulence soon destroyed. The bacteria of scarlet fever and typhoid are more resistant to diffusion, perhaps their poison is more malignant or possibly they are more tenacious of life; hence these bacteria may be conveyed through air or water (liquids) to a greater distance. Still other diseases, like influenza and cholera, are caused by bacilli which are not so much affected by separation in the atmosphere, in fact frequently seem to have greater opportunities for growth by such diffusion under certain favorable conditions of moisture and temperature. In all these cases, however, sufficient attenuation of the poison by atmospheric dilution will destroy the virulence of the bacteria and put an end to the spread of the disease. This principle is the basis of judicious efforts at isolation, segregation and quarantine; but it will also convince us that these means alone may prove futile in many instances.

It is well known that bacteria inhabit the soil in large numbers, non-pathogenic in the superficial and pathogenic in the lower layers. More air is found in the superficial than in the lower layers; so that the principle of atmospheric attenuation seems to apply here also. Water which filters through the soil and enters a well may poison the water with pathogenic bacteria. In like manner ground water which enters a cellar may fill the space with the germs of some infectious disease. It is to the latter point that I desire to direct especial attention. In order to avoid some of the dangers and prevent the occurrence of infectious diseases in houses otherwise in good hygienic condition it is necessary to have good ventilation of the cellar or basement. Where this precaution is not taken even in homes otherwise above reproach, frequently ravaging outbreaks of measles, scarlatina, diphtheria and the like are held to be mysterious dealings of an inscrutable Providence, when it is but the misdoings or shortcomings of unwise men, and one of the least mysterious matters in preventive medicine. If such disastrous results may be experienced in houses of the well-to-do and of the rich, what shall we say of those farm, village and city houses of the poor where, to keep out the cold, the entire foundation is banked with dirt or manure, thus preventing any access of fresh air under the floor during a long winter? The effect of such exclusion of the air is to make a favorable culture medium for the bacteria of diphtheria and scarlatina, and it is the experience of many practitioners that their most frightful cases are met under such circumstances. Architects and officials should direct especial attention to this matter and prevent the erection of buildings which can not be easily and thoroughly ventilated from cellar to garret.

3. Fortifying the system against the invasion of these diseases is a legitimate undertaking and although some of the methods which have been adopted may be of doubtful efficacy, every earnest effort in this line should be encouraged. Vaccination and inoculation have been resorted to with such satisfactory results that in smallpox and hydrophobia they may be said to have passed beyond the stage of discussion. Serum therapy has promised brilliant results and the most hopeful have great confidence in this new form of attempting to strengthen the cells of the body to enable them to destroy, or at least resist, the evil influences of pathogenic bacteria.

The condition of immunity which is said to be established by these antitoxins is subject to variations in the time limit, and in some instances the influence seems to be negative. A friend and neighboring practitioner who had immunized many cases told me lately that of the cases in which he had given the injections of Behring's serum for immunizing purposes some of the patients had suffered from diphtheria in three or four days after exposure to the disease and the administration of the immunizing agent. The time limit of immunity varies after vaccination also, but the virus has a more prolonged effect than the serum upon the human system. It must be remembered, however, that the serum treatment is scarcely fully understood yet, while the value of vaccination has been firmly established. We may ardently hope that this new method may lead to discoveries of means which will enable us to rescue humanity from the blight of infectious diseases. While we are waiting for the realization of this hope

many will still prescribe belladonna to prevent scarlet fever and iron to ward off diphtheria; but I wish to emphasize what I consider a more rational process, particularly with diphtheria, typhoid fever and other exhausting diseases. It is known as a physiologic fact that certain fluids of the body, as blood, serum and the gastric juice, when in a normal condition are germicides. They kill bacteria. For our present purpose it does not matter how they accomplish this result. Such being the case, whatever helps to keep these fluids in a healthy condition will serve to fortify the system against the bacterial or infectious diseases. In view of the fact that the human body has the power within itself to battle with these enemies it may be suggested that most if not all cases of infectious diseases are results of neglect of some hygienic law or of the transgression of some other. The individual should not reduce his vitality or derange his digestion by eating too much or too little, or by submitting to fear or excitement, or any other condition which will diminish the normal resisting power. He should not permit work, pleasure nor social relations to interfere with his physical well being. He should be well clothed as well as properly fed and comfortably housed. This opens up a question which is too broad for just consideration in this paper, a social and political question. It is our duty, however, to call sufficient attention to this phase of our subject to make it a matter of thought. It is a cardinal fact that infectious diseases are prone to prey upon if not to originate among the poorer classes of society. To avoid this occurrence, to prevent these diseases from arising thus, requires that the poor should be well housed, well clothed, well fed, well bathed and properly exercised. How is this to be done? I do not discuss the method, I only desire to suggest whose duty it is to remove the condition. The poor can not do it. No man so thoroughly realizes as the physician that he is to a degree his brother's keeper. If a man has no right to do anything which may bring disaster to his neighbor, he has no right to go dirty, to live slovenly, to breed disease. If children are unable to accomplish results, to perform duties, which the rights of men lay upon them, the father's duty to aid them is paramount. We, and the poor with us, are but children of the State. The question then remains with us, how shall we as physicians, humanitarians, socialists, politicians, statesmen, provide the unfortunate with proper food, proper clothing, comfortable houses, opportunities for bathing and sufficient work to help them keep the grim monster from threatening our doors by invading the homes of the poor in the form of an infectious disease? Until something can be done in this direction, infectious diseases will still dwell in our land, although improved prophylactic or preventive agents may reduce their mortality.

Believing that the plan of supporting the ultimate tissues of the body by general hygienic procedures and proper feeding is the best means given to us for preventing the group of infectious diseases, it may be admitted that some good may be accomplished by the administration of certain drugs. If belladonna is of any value as a preventive of scarlet fever, it must be so because it has some modifying effect upon the cells of the body, not because it produces a rash. So far as I am aware no experiments have determined this point. Still I use this remedy for the purpose here suggested and in many instances have thought it

seemed to have some virtues as a preventive. The use of iron to prevent diphtheria is in direct accord with the ideas advanced in this paper, and without doubt serves an excellent purpose. Hydralactin, protonuclein and other proprietary preparations like the antitoxins have not enough reliable evidence in their favor to make their use as preventives general, but we are encouraged to hope that further reports and improved methods of production and administration will justify the high expectations which have been excited by the introduction of these agents, especially the antitoxins. A remarkable claim has lately been made for a specific action for jaborandi or its alkaloid, pilocarpin, upon the white blood cells. It is said to increase their phagocytic power or function. If this should be confirmed pilocarpin will be of great value in the treatment, as well as in the prevention, of all bacterial diseases. In two cases of tuberculosis in the earlier stages I have observed a favorable modification of the symptoms when administering this remedy and in several cases of chronic bronchitis the improvement has been marked. I shall conclude this paper with the following résumé:

1. Systematic cleanliness should be practiced, (a) by thorough disinfection of the patient, the sick room, all instruments, vessels, and other apparatus or clothing in use; (b) by allowing no unclean or infected fabric or vessel to be taken from the room until rendered aseptic.

2. Prevent individual contact (a) by isolation, segregation or quarantine; (b) by prohibiting communication between the infected and uninfected except under strict surveillance of the physician or in accordance with his explicit directions.

3. Provide thorough and systematic ventilation of cellars and basements as well as all other rooms in houses used for dwellings, and give free access of air under floors of houses which have no cellars or basements, and supply complete drainage.

4. Fortify the system against pathogenic bacteria (a) by abundant and suitable nourishment; (b) by insisting upon the observance of the laws of hygiene relating to clothing, eating, exercise and bathing; (c) by the administration of certain drugs, among which belladonna, iron and pilocarpine are prominent; (d) by the conservative use of vaccination, inoculation, the serums or antitoxins and perhaps protonuclein.

5. The State or city should see that the poor have work, food, clothing, good shelter, public baths and fresh air.

6. Health inspection officers should keep their wards in good sanitary condition, and see that the water and food supplies are uncontaminated.

## PHYSICIANS AS PAUPERIZING AGENTS.

Read in the Section on State Medicine at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 6-8, 1896.

BY DOUGLAS H. STEWART, M.D.

NEW YORK.

The writer has no desire to indorse any doctrine of socialism, communism or the like, but he wishes to call attention to two axioms which, though trite in themselves, are ever new in their application and abuses: 1, capital requires labor; 2, competition compels capital to lower wages. Without labor, capital may neither be accumulated nor maintained. Any sum of money must be dissipated eventually unless it brings interest, and interest, directly or indi-

rectly, means the earnings of hand workers. The fundamental laws of progress, and of animal life itself, seem to begin at toil with the hand or its substitute. Thus we see large communities of brainless beings, and the descending scale brings us to the jelly-fish which presents only a stomach and tentacles—a perfect type of absorption and accumulation. The brain may be essential to civilization, but without the hand existence would be impossible.

Lower wages may be obtained by reduction, regardless of employes or their needs. Business is without sentiment, and this direct method has been tried and has called forth the denunciations of organized unions from Maine to California. United labor has become capable of such independence and reckless readiness in asserting real or fancied rights that capital is cautious of unnecessarily antagonizing it. Constant attempts at making the hire unworthy the laborer arouse feelings quite different from the plaintive protests of a few individual sufferers, and if persisted in could only end in a chaotic condition of society. The Government Reports for the last seven years show a total loss to the community from strikes of \$64,000,000; fully 25 per cent. being due solely to attempted reduction of wages. Another method of decreasing compensation would be the importation of men under contract for a remuneration which may seem fair in Italy but, owing to the radical difference in the purchasing power of money, is starvation's limit here. Hordes of such immigrants would glut the market and force the American to compete with foreigners who can and do exist on food found in the garbage barrels. This danger was dissipated by labor's voting power and its effect on the legislative bodies. Laws were passed cutting off the contract-labor supply from too economical employers, and the capitalist is now between two fires—the stubborn resistance of labor and keen competition, with a possible removal of protective duties. From a business standpoint he can not be condemned for managing any industrial investment with the sole idea of "product as low and market as high" as circumstances will permit. Economical machinery has enabled one man to do the work of ten, and quality is made secondary to quantity. But despite all this, the element of expense in the cultivation, collection and conversion of raw material remains the price of labor.

The laborer will not adopt a cheaper mode of life without a protracted struggle; therefore, if his earnings are to be lessened, his living expenses must be cut down and his money made to go farther. The leading items of his disbursements are rent, clothing, food and professional services. Overcrowding will lower the value of rent and clothes, but labor is united on the plan of: "One for all, all for one," and the packed tenement and the "sweaters'" pittance press hardest on the poor toiler. This objection, backed by solid votes, has caused a law to be passed forbidding the "double-decker" house and the erection of any structure occupying more than 65 per cent. of the lot. The present "sweat-shop" investigation is presumably only preliminary to prohibitory legislation.

Food, mostly farm products, can go no lower. Many farmers are now abandoning the farms and seeking a livelihood in the city. Those who do remain in the country are organizing for protection from ruin.

Professional services are rendered by the lawyer, the clergyman and the physician. The lawyer may

be called perhaps but once in a lifetime. He does no public charity work and all attempts at starting legal dispensaries have come to naught. He can be a help if employed or a hindrance if opposed. He is in command of the legal machinery from the White House to the "Tombs" prison. He and his professional brethren are so united in their interests that a malpractice suit against him must fail for lack of expert testimony. Capital can not reduce his fees, for he is a most dangerous adversary when attacked through the pocket.

The sums paid to church and clergy may be great or small, but an attempt to diminish them would cause such an upheaval as has not been since the Crusaders. The owners of wealth are growing old. The grave and the chances of a leveling process beyond make awkward thoughts for quiet hours. Capital sleeps lightly and if a millionaire is timid a multi-millionaire is often hysterical. Conscience does make cowards and the man of the cloth is let alone. He even receives "offerings" instead of fees, but he uses his influence for what he mistakenly believes is a good cause, and has collections in his church for charity falsely so called.

The doctor is an urgent necessity to the working-man. Exposure incident to toil, low vitality from lack of sunshine and from malaria and other diseases consequent upon meagre air space and indifferent plumbing—all these make the physician a frequent visitor upon the tenement families. The doctor's charity toward laymen is unlimited, but toward his colleagues he holds the simple faith of "Holy Willie" in Robert Burn's satire: "God bless me and damn my neighbors."

The farmer and the physician are ground very fine—but with this difference, the farmer is organizing but the physician is disorganizing. The workman does not yet realize that the cheapening process means lower wages later on. It is not sufficient to give the work people free medical attendance, but everyone must be furnished as well, so that the shop-keeper can decrease the pay of his employes, as the banker can his bookkeeper's salary. To lower the cost of living everybody but the very rich must become paupers—so far as the medical man is concerned.

What must we think of any citizen quietly submitting to such imposition and becoming part of a great wedge which is to split up the manhood and self-esteem of our whole community? Is any one willing to inculcate the doctrine of non-payment for value received? Is this not the very teaching most opposed to all political economy, and the plan of action which makes the counterfeiter the most dangerous foe to the Government? There is such a man. He comes to the city a student, advertised for and welcomed by the medical colleges. They extend promises, either real or implied, of a livelihood after his diploma is secured. The demand and depend upon high fees and have many extras. The advertised multitude of patients available for teaching purposes is a very tempting bait. The victim does not appreciate the fact that if one institution attends 10 per cent. of the whole population there are, within a mile, ten other dispensaries all depending on a portion of the remaining 90 per cent. He may at this stage of his life have fine ideas of elevating the poor and of the dignity of charity, and has not yet learned that pauperizing processes are not conducive to high

mindfulness and that charity is not the "benevolence business." He goes through his whole course, supported by hope and a fund contributed by the self-denial of his whole family, till he gives his graduation fee of \$30, and exits from college life in a blaze of gas and glory. He becomes a practitioner, puts up his sign and finds himself penniless. He discovers that he has been deceived—that his most pitiless enemy is the alma mater who received him so smilingly and relieved him of his last \$30 with the ease and grace of a confidence queen. He realizes now that of the 10 per cent. of the population wrongfully under free treatment, two out of three individuals might pay him a small fee and one in three could recompense him handsomely. This year he learns that the clinic is to attend all the students of Columbia University in their own homes. Some of these pupils are the sons of wealthy parents and neither deserve nor need alms. The question of deserving poor or alms-receiving rich does not enter into the plans of the dispensary. The whole population must be able to save at the expense of the doctor in order that labor shall be cheap. So the young man becomes a member of the dispensary staff in order that he may obtain a few dollars by clandestinely sending patients from the "free" classes to his office—thus, by his aid in perpetuating the evil, the medical profession finds its charities, the viper warmed in its bosom which is stinging it again and again. The charitable and the taxpayer pay the expense. No medical union, on the plan of the laborers is contemplated. Personal jealousies are fostered by interested outsiders—the very governing boards actually think they do a physician a great service by allowing him to work for nothing. No position of trust is open to him; even the office of president of the health board is closed by law. He is not wanted as a commissioner of charity, yet the whole public service must cease without his gratuitous services in the hospitals. Membership upon the trustee boards of both hospital and the dispensary is denied him. The trustees themselves endeavor to arouse enmity between the specialist and general practitioner and are primarily responsible for the fact that worthless patients so crowd the institution that, for lack of time, the worthy can not receive proper attention. They promulgate the doctrine that the specialist has created the hospital and dispensary because he must have material to study and experiment upon. This is plausible reasoning, but its casuistry is made evident by the fact that any man can learn more from ten cases carefully mastered than from a hundred cases crowded in so fast that the most superficial diagnosis is all that is possible. The woeful daily mistakes resulting from such snap-shot methods is a significant proof of this.

The large sums spent out of public taxes for private institutions are wasteful and unnecessary. One-half this expenditure placed in the hands of a powerful charity organization society, could do all the work required and perhaps leave a surplus, simply by the exclusion of unworthy objects of charity, which deplete the treasury and burden the taxpayer. All private contributions for medical charity are superfluous if the thronging of public and private clinics by would-be paupers was stopped. At present the city is giving \$1,500,000 per annum to establishments not under its control, and private persons in mistaken kindness are donating a great deal more. Including the excise fund of more than \$60,000 a month and

the four and a half millions requested by the Charity Commissioners, the city of New York, at a rough estimate, expends \$5 per capita per year for charity alone.

What is the local effect of promiscuous beneficence? "a prostituting charity." John Stuart Mill expresses the idea thus: "A charity which makes twenty beggars while pretending to relieve one is a condition of affairs which makes it possible for some one to grow rich by administering the funds for the poor." We all know a neighborhood where the people were thrifty and contented before a medical college and its appurtenances appeared on the scene and initiated free treatment for all comers. The laborers, especially the younger ones, have become idlers; policy shops and loan offices have been opened; gamblers, dissolute women and opium "fiends" have appeared in such numbers that the locality is now named the "New Tenderloin." I have asked those addicted to morphin and loose women why they congregated near the dispensary, and their answers are appalling. The first say they can always "procure a jab" (hypodermic) when out of money. The second reply, "the female department is so crowded and the gynecologist so rushed that they can fool him and 'get a free abortion on tap.'" The speaker claimed personal experience; whether this be true or false, it is evident that the self-respect of the entire community has been undermined and the decent element is moving elsewhere. *Post hoc* if not *propter hoc*. The druggists know the status of the people and every apothecary can name many who are shameless in their abuses of charity. All classes are drifting to the dispensary, even the agricultural population. The country doctors inform me that only their richest patients can afford the time and money to take the journey to the city and stop at a hotel while obtaining free advice at the clinic. Surely the efforts at pauper-making may be said to be very successful.

The two parties most to blame are the millionaire and the medical man. The first enters the benevolence business for what it is worth to him; he may even think his contributions are doing good, though the smallest investigation by disinterested parties would prove the incalculable harm he is working to the very class he believes himself relieving. The medical attendants are only flies in the spider's web. They are engaged without salary and discharged without a hearing. On the first of November the visiting boards of six or eight hospitals were removed without any charges being preferred, and "reorganized" by a man who was "not impressed" by maggots in the patients' food.

You can not compel the capitalist to cease his donations, you can not obtain his ear against those who flatter his soul and place his name in the prospectus; the only remedy lies in the profession. That should demand that the poor should be treated like men and not like "clinical material."

In the public mind the doctors are all "good fellows," who are to give much and to get what they can. This is characteristic, as there is no human being lower in the social scale than the good fellow. The good fellow of the saloon "treats the crowd" and spends money for liquor that should buy his children's clothing, while his whole family depends in sickness upon the dispensary. The good fellow is the prey of the gambler and blackmailer. Goodness and weakness seem to be synonymous, and the final end of all good

fellows is they are cast into outer darkness after giving their best to the bad fellows; their course and termination is the same with the saloon hero, the Wall Street lamb, the card sharper's prey, and the physician at the hands of the trustee boards of the dispensary and of the commissioner of charity. The saloon, the gambling hell and the hospital can get plenty more good fellows to fill the places of those who now attend.

The people who formerly went to a consultant's office, now have a plain dispensary dress and consult him at a charitable institution. I have myself sent patients to well-known men, and have received an opinion written on a dispensary blank—the gratuitous advice having been obtained by deception. A certain specialist charges \$10 for an office fee; sometimes the patient demurs and is sent at once to the dispensary, regardless of the fact that many a younger man in the same line, and possibly a more careful worker, would be glad to obtain \$5 for the same case.

The public can not believe that the profession is so imbecile as to seek positions which pay nothing, and consider that the places are sought for advertising purposes and for self-protection.

The fees for the specialist come, in most instances, from the general practitioner, but the practitioner is fast becoming an all-round specialist. Thus, through unquestioning charity, the specialist crushes the general man and he retaliates by sending cases to the dispensary rather than have a consultation. In the Manhattan Eye and Ear Hospital this is a common occurrence, and if an outrageous case is turned away, he proceeds immediately to the Vanderbilt, where no question as to length of pocket-book appears to be asked.

There is honor even among thieves—but the specialist and the practitioner, by suicidal and foolish bickerings, seem determined to prove that honor has fled from the grandest profession that ever shed luster on humanity. The medical "pirate" and the dishonest consultant appear with the lofty brow and amiable mien of the true philosopher, while they do deeds and participate in actions that even a bunco steerer would blush to contemplate toward his pals. The code is no longer the "Golden Rule," it has become the commandment of the Golden Calf. It is not "do as you would be done by," but "do or you will be done." Is it not evident that the whole profession is a most applicable tool, when pauperization is the work?

What is the remedy? The present condition is unjust to the tax-payer, and if the physician is a decent citizen he will stop enlarging our tramp class. In London I found many who would not work, because physicians and the charitable had made it easier for the pauper than for the laborer. Is it wonderful that the unemployed exceed a million in that city? In New York the dispensaries make it comfortable for those who wish to save the doctor's fee and spend it in the grog shop. I am now studying the transformation of men from clerks to rum soakers and then to tramps and I know that some of these men took their first step in pauperism in the clinics. I am convinced that some might be good citizens to-day had they not known the influence of such a family physician as came to my father's house when I was a lad. The institution crowds are maddening and confusing; they are only "clinical material" to the attendant, who becomes a doctor of medicine and not of humanity. He may say

hastily to some miserable wreck, "you are a bum" or some equally helpful remark, but the words are very different in effect from a man-to-man statement, "your heart is damaged; if you do not stop whisky you are a dead man." All physicians know that the hospital builders are no friends to the poor, that the service as now conducted is no more charity than stone is bread. If the money required to found these great places was meant for the benefit of the laborer it would have been spent for better homes and hygienic tenement houses and then the working-man's medical requirements would have been very few.

Let the physicians resolve not to attend undeserving dispensary cases, the trustees will ask for resignation, let the outside members of the profession refuse to fill vacancies produced by removals without cause; the matter will be remedied. To the honor of Philadelphia be it spoken that a position vacated by such a condition of affairs was not filled, and the trustees became humble. In New York a whole hospital staff was dismissed without a notification of charges or discharges. The nominating committees of three medical colleges, the Mayor and the Commissioners were written to and a hearing requested by a committee representing 1,000 physicians; not one of those written to had the courtesy to reply. This is mentioned to show how little the authorities care for any stand the medical profession may take, short of a point-blank refusal to fill the vacancies.

Boston has adopted a system of cards which requires some investigation into the qualifications of each applicant for free treatment. Some physicians have started their own dispensaries under the hope that they can reduce the material of the teaching clinics, so as to bring them to reason and give the physician a chance to say who shall or shall not be paupers. Some of the brightest young minds in the profession are seriously contemplating entering on an advertising career, arguing that the hospital attendants only hold their positions for advertising purposes, and printers' ink is much quicker. The physicians of New York can have all the institutions put under the care of the Charity Organization Society; they could have the powers of that body enlarged to those of the "Gerry" and "Berg" corporations, and make the *sine qua non* of free service that every dispensary should be under the supervision of a capable and disinterested investigating body. A committee sent to the Legislature with a petition signed by the majority of those practicing under the laws of the State of New York could obtain all the power necessary.

The profession has a duty to the public of our city, and as no medical man has ever been deaf to the cry of "Give, give," let him not stop his ears to the demand of "Withhold." Let him always help "God's poor and the poor devils," but let him stop making or unmaking the "devil's poor." And let him ever set his face against any and all means used for increasing the awful burden of pauperism which our city is already called upon to bear.

#### POINTS BROUGHT OUT IN DISCUSSION.

The writer of the essay has not suffered by the action of the Commissioners and colleges and is simply interested as anyone might be in an act of contemptible injustice toward the profession of which he is a member.

The Commissioners pretend to have consulted only

the interests of patients; if so why did they not secure the best physicians by making the hospitals over to the Civil Service Board and fill vacancies by competitive examinations?

Were the Commissioners legally justified in turning public hospitals over to three close corporations, *i. e.*, the colleges?

Is the medical profession at large "riff raff," in contradistinction to about one hundred men connected with the teaching faculties?

Had there been a medical union as firm in resisting injustice as the Hod-Carriers' Assembly, would the Commissioners have dared to ignore its request for a hearing?

Why were homeopaths not molested? For political reasons and pull?

Was not the whole so-called "hospital deal" a transaction by which an ex-commissioner was to be re-appointed by the influence of certain men, to whom he turned over all the hospitals of the department of Public Charities of New York City?

### THE TURKISH BATH IN MENTAL DISORDERS.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY L. FORBES WINSLOW,

M. B. CAMPB., M. R. C. P. LONDON, D. C. L. OXON.

Senior Physician to the British Hospital for Mental Disorders, London  
Physician to the Mount Vernon Hospital, London. Late Lecturer  
on Psychologic Medicine at Charing Cross Hospital Medical  
School, London; and Physician to the Hospital for Epilepsy and Paralysis, London.

The treatment of disease at the present day is not based on "guesses" or "surmises" whatever might have been the case many years ago. This is the language of the empiric, not that of the man of science. There are intelligent men in our profession at the present time, who are now able to diagnose with extraordinary accuracy the pathologic changes going on in the brain, so wonderful has this knowledge become that it is not to be wondered at that we should gradually, but surely progress in the investigation of the treatment of those complaints. We learn from our experience that by opening the flood-gates of the skin from time to time, and submitting ourselves to the manipulation of the shampooer, in the oriental fashion, we may attain unblemished health under certain circumstances, both in mental and bodily complaints. During a long experience in diseases of the brain and nervous system I have had frequently to resort to the use of the Turkish bath as a remedial agent. I allude especially to cases of what is known as "brain fag." Where the victim to that complaint is reduced to a very low degree of vitality, I have found that after a systematic course of Turkish baths, that in many instances the mind recovers its wonted conditions and the brain exhaustion from which the patient suffers has diminished, if not entirely disappeared. The use of cold shower baths in the treatment of mental disorders has been known to the profession for a great many years. I have also found the Turkish bath beneficial in the treatment of some cases of acute mania. A patient is brought to the asylum in a state verging on cerebritis, and exhibiting all the well-recognized symptoms of sanguinous congestion of the brain. He is wildly delirious, the scalp burning hot, the skin dry and parched, the conjunctivæ injected, the pulse rapid; it has been found in such a case that material improvement has taken place, even after

the first Turkish bath has been used; but in such a case I would not advise a prolonged one, but of short duration, each alternate bath to be of increasing length in gradations. In the treatment of acute brain disease I would suggest that the whole process should not exceed half an hour for the first bath.

"Without principles," says the great Dr. Cullen, "deduced from analytical reasoning, experience is a useless and a blind guide." Appreciating the truth of this *dictum* we are naturally led to ask ourselves the question as to the rationale of this treatment in acute brain diseases; the answer plainly is the gradual and general lowering of the vital powers causing a certain nervous prostration, by means of which the cerebral vessels become relieved, and the system calm and quieted. In insanity, the *vis vitæ* is often reduced to the lowest possible condition. In the great mass of acute cases of disordered mind which the physician is called upon to treat, particularly in our public institutions, the nervous system is in a state of positive exhaustion and debility.

The furor, the violence, the maniacal excitement; the muscular resistance, so often associated with insanity, are generally symptomatic of profound nervous and vascular depression. The excitement of the insane is an excitement without power, and it must be left to the discretion and experience of the physician versed in the practical use of the Turkish bath to discriminate as to in what acute cases it may be used beneficially, for we must recognize this important pathologic fact that in some cases it is our duty to conserve and husband the flagging and ebbing vitality of the patient until the mind recovers its equilibrium. If in the treatment of acute brain diseases the Turkish bath is prolonged in the first instance fatal results may follow; of this there is abundance of proof; therefore in its use, in such acute diseases, much discretion must be used. Insanity does not result from active inflammation of the brain, and if such were its origin no physician would be justified in attempting to prostrate the system of those mentally disordered. In cases of profound cerebral excitement, the patient often recovers under the combined influence of a tonic and stimulant treatment. I have known violent mental perturbation considerably mitigated and often cured by the administration of stimulants combined with iron and quinin. Here is an instance where it would not do to prostrate the patient but to stimulate him; so in dealing with the use of the Turkish bath in such cases it becomes the imperative duty to consult one versed in its use. I wish seriously to draw your attention to what I have just stated, and also to further say than an excited patient may be made manageable and docile for the time being, but it will be quietness and docility gained at the expense of his reason and perhaps of his life, if the inexperienced in its use allow its adoption to be prolonged in such mental cases as I have just described.

Treatment of insanity by baths of various description has long been in vogue in various countries. Esquirol, the first to find fault with and denounce many of the abuses found in the treatment of the insane, freely used the cold douche shower bath in the treatment of insanity and to the use of which he attributed the cure of many of his patients. In his "Maladies Mentales" he records cases where the cold affusion was followed by tranquility in the first instance and a repetition of it by a complete recovery. A second case is mentioned where the use of the bath

was followed by shivering, and a slow weak pulse and ultimately by sleep. The latter lasted for four hours during which period copious sweating took place but on awakening the delirium had passed away and reason had returned. Esquirol concludes from his experiments. "That the douche on the head has a sedative physical action, on account of the cold and a moral action as a means of repression. The generality of convalescents declare that they have experienced benefit from its use and some patients ask for it; *il ne faut pas en abuser.*"

The danger, however, of too frequent use of the cold shower bath came to be recognized, and to prevent a misuse of it, the Commissioners of Lunacy in England framed a series of laws to regulate its use. It is now but rarely made use of except in neurasthenia and in hysteric subjects, in both of which cases it exercises good beneficial results, especially when it has been preserved in, and in some cases of melancholia the duration of the bath lasting from fifteen seconds to half a minute. The warm bath is a wonderful remedial agent in tranquilizing the nervous system and acts frequently as a powerful soporific and allays mental irritation.

The Turkish bath has also been used in alcoholic cravings, and with a certain amount of success. The functions of the skin are two-fold, that of secretion and absorption; by it we perspire and by it we may be said to breathe. It is a well known physiologic fact that the oxygen absorbed by the skin through its seven millions of pores has the same effect as that taken in by the lungs, the purification of the blood, and the supply of caloric to the body. The Turkish bath causing profuse perspiration, and so opening and cleaning the seven millions of pores renders them permeable in an increased degree to the oxygen which burns off the effete matter left by the stimulants; increased vigor and vitality are thus given to the system and the alcoholic craving is diminished.

The Turkish bath may be used beneficially in certain cases of melancholia of a recent nature, without any possible risk ensuing; it often calms the nervous system and often reduces the mental depression. Also in cases of threatened recurrent mania, it sometimes cuts short the attack if used immediately the symptoms are returning. At one epoch in medical science depletion was freely used in cases of insanity; this then for a time disappeared altogether but it is now coming into use again with some physicians. The idea used to be that the depressing, lowering and overpowering plan of treatment of the insane was most disastrous in its results. It was then considered by all practical and sagacious psychologists experienced in the care of the insane that in the morbid affections of the mind a condition of brain existed which would not tolerate a depressing and prostrating mode of treatment. There is a vast difference between the use of the cold shower bath in the treatment of insanity and the use of the Turkish bath. In the former there is an immediate depression and prostration of all the vital energies and the effects sometimes prove rapidly fatal. Consider for one moment what would be the effect of using a prolonged shower bath in the treatment of delirium tremens, or in a case of puerperal mania, or the insanity following such a condition. In this class of cases we often witness extreme excitement and violence associated with profound vascular and nervous depression. How dangerous then must be the cold shower bath in such a condition, entirely

overlooking the pathologic state of the patient. If the treatment of the insane be a rapid reduction of the physical and mental powers of the patient to the minimum standard; if it be all important to make a noisy, excited, destructive lunatic tractable and quiet so as to preclude the necessity for the use of mechanical restraint, then continue the shower bath; but if it be the intention to carry out a proper curative mode of treatment by some form of ablation then the Turkish bath has proved itself to be the remedy needed in such a case. I have known many instances of death resulting from the unwise use of the prolonged cold shower bath in the treatment of mental disorders, but I know of no instance where such has resulted from the Turkish bath.

Let us ask ourselves what would be the result on a patient suffering from a depressing and exhausting disease, and insanity is especially of this type, on whose head was allowed to fall a continuous volume of cold water for a period varying from a quarter to half an hour, as was formerly practiced in some large asylums. He emerges from such a bath with the powers of life reduced to the *minimum*. I have records of thirty-two cases of acute insanity treated by the prolonged use of the cold shower bath, with the following results: Fourteen recoveries, one death, the others remaining in the asylum. I might mention that in these cases it was used periodically, as occasion required, and was prolonged for the time I have previously mentioned. It is specially fatal in the earliest stage of acute mania and may be called an heroic treatment. In many cases it was apparently made use of in instances of insubordination as a means of quieting the patient and with effect. The plunge bath was formerly and sometimes is now substituted for the cold shower bath. But this appears to me to be the old story of *Scylla and Charybdis*. I do not know whether any of my audience can realize exactly what I mean by a plunge bath in the sense I am now using it. A violent and excited patient is forcibly taken by his legs and plunged head foremost into an ordinary swimming bath. He is not permitted the use of his limbs when in the water, but is detained there, or taken out and plunged again into the bath, until the required effect of tranquility is produced.

Quietness, submission to authority, docility and freedom from excitement and violence are the natural consequences of this gentle soothing treatment. I say most emphatically that both the prolonged cold shower bath and the cold plunge bath, if used at all, are generally made use of for obstructive patients, and not as a remedial agency. In cases of neurasthenia or hysteria such a treatment is often very beneficial, but not in dealing with insanity pure and simple, especially in chronic violent cases.

Now the Turkish bath is used entirely as a remedial agency, not a means of unwarrantably controlling the individual. Its use has been generally adopted in England since 1861, when it was first introduced into my country and used extensively but Dr. Lockhart Robertson, the late Lord Chancellor's Visitor of Lunatics in England, and Dr. Power of Cork, were the two first to introduce the Turkish bath into the treatment of insanity. The first asylum for lunatics where a Turkish bath was constructed, was the Devon County Asylum. It was here found useful in certain cases of melancholia, where the skin was hard and dry, and in some cases of dementia. At the time of

which I speak the use of it was in its infancy. I was requested at the opening of the second series of Turkish baths in London to preside as chairman: this was about twenty-five years ago. While in your country last year I derived much pleasure from a visit to Dr. Shepard's Turkish baths at Brooklyn; I found them in every way perfect and quite up to date in every possible requirement. When the Turkish bath was first introduced into my own country it was said by some that so long as we diligently and regularly had recourse to the Oriental bath neither malaria nor miasma nor infection nor the poison of fever could find a lodgment in us. All that was hurtful would be swept away in the health-giving, health-preserving perspiration which streams forth. The mind and the brain, nay the whole of the nervous system, central and peripheral, would hold their own against the deteriorating influences which haunt our daily life. Man may indeed confront the world, armed in proof at all points against every danger which may assail his frame, whether wholly or in detail, from morbid agencies, if he can only be persuaded to habituate himself to the use of the Turkish bath. Its chief action is depuration by the skin, but it also acts by diuresis and its effects as a narcotic and tonic are well known. It may be considered, in fact, to be a complete materia medica in itself. I think that all those physicians who have advocated its use in the treatment of disease and especially of insanity, will never regret so doing. It has been left, however, to the wisdom of the nineteenth century to unveil the therapeutic use of the Turkish bath, and I trust that the few remarks I have to-day made may further its continuous use for the benefit of humanity in general.

### THE THERAPEUTIC ACTION OF THE TURKISH BATH.

Read in the Section on State Medicine at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY VICTOR JAGIELSKI, M.D. (BERLIN), M.R.C.P. (LON.)  
Consulting Physician to the Royal York Bath, London, N. W. Physician in Ordinary to Infirmary for Diseases of Consumption, Diseases of the Chest and Throat, London, W., etc.

LONDON, ENG.

My long experience with the Turkish bath prompts me as most essential, before going into the therapeutic aspect of the question, to make you first acquainted with the tools with which you have to work in order to obtain good results. All Turkish baths do not correspond to the requirements of modern science and vary so greatly in this respect that many of them now in existence should cease to exist on this ground. We doctors try to do the best we can for the public and ought to direct the patients only to baths which we have ourselves examined so that we can recommend them conscientiously for curative purposes. But, alas, how many bathers do consult doctors, and how many doctors have taken the trouble of studying balneologic details; hence bathers go to any Turkish bath they hear of without any previous or proper instruction. From my experience of the Turkish bath, I must greatly impress upon your consciences as doctors the necessity of going and examining personally each Turkish bath and better still to have personal experience of the bath before advising your patient. I acquired this knowledge theoretically and practically when I rebuilt in 1883, with my good friend Mr. Thomas Duarans, the eminent architect in Lon-

don, the Turkish bath at the Royal York Bath, York Terrace, London, N. W. We studied together the subject of building a Turkish bath according to the requirements of modern scientific principles. When we considered the architectural plans, we based them first on sanitary principles, and adopted the beautiful Moorish architecture for secondary reasons; but the drainage system and the ventilation claimed our first attention. We gave the drainage a good fall for the rapid off-flow of the water and erected the plunge bath that holds over 5,000 gallons of water at the end of the whole drainage system, so that a thorough washing out of all the pipes is obtained by giving the necessary speed and power to the stream and therefore cleanliness and freedom from all dirt and bad smells. A fall of 1 foot in 15 feet within the length of 120 feet between the plunge and the sewers was adopted. The diameter of pipes six inches. Equidistant manholes enable us to open the entire system for the inspection at any time with convenience and to brush the pipes out in case of stoppage by accident and to observe if the sediment pass down. This is essential. At the deepest manhole, and that nearest to the sewers in the street, an air-shaft is built to admit the fresh air which is drawn through the pipes by means of exhaust shafts at the top end of the drains. Thus, the air flows in the reverse direction to that of the water. The waste pipes from the bath and the rain pipes are separated from the main pipe-drains discharging into a side inlet gulley which has an open gridiron top for the admission of fresh air and passage of the cleansing brushes or rods.

The next point was the ventilation of the suite of rooms of the Turkish bath. This was attained by building a tunnel 75 feet in length, 5 feet in width and 7 feet in height tapering toward the furthest end where the furnace is situated beneath the hottest room. In this way the fresh outside air is forced toward and into the space around the convoluted iron furnace, and with such a velocity that the draught on the candle flame visibly indicates the constant current of fresh air to be heated and finally enters the hottest room above through the open grating. In this room which is a vault of glazed white bricks with an ornamental colored skylight in the roof, a temperature of 250 to 300 degrees Fahrenheit can be obtained as required, but 230 or even 210 degrees are sufficient to produce perspiration with ease in the shortest time possible in the habitual bather. The second hot room is between 170 and 180 deg. F., and the communicating first hot room is about 130 F., and the next communicating shampooing room is 110 F., and the douche room 90 F. and so on. The plunge room and the cooling room are about 65 F. All these rooms have large colored skylights to admit sunshine or daylight, and when dark gas-burners within large white and ornamental globes of 20 inches diameter, are arranged so that the products of combustion do not mix with the air of the rooms. At the bottom of the seats around the rooms are "hit and miss" exhaust grates by which the vitiated air, from perspiration and exhalation being heavier in specific gravity and accumulating nearest the floor, is drawn off through upcast shafts outside the roof. This principle of ventilation ensures a constant stream of hot air through all the rooms, and so great is its effect on the Mosaic floor, through the created friction caused by its uninterrupted flow from above downward and out through the upcast shafts, that the floor appears to a new-comer

to be heated from underneath; slippers are required when walking on the floor, and sheets when lying down on the marble plates around the walls. I need not describe the shampooing methods, nor need I speak of the shampooers who work according to my system, and make use of the soap and brush, showers, needle-bath, douches, etc.; but this description I think will show you sufficiently in an abstract way, that the first essentials of a good Turkish bath are a free circulation of pure air with plenty of oxygen, sufficient heat and good light. The dryness of the air in the hot rooms is most strikingly proved in a foggy London day, when the bather enjoys this beautiful change of pure air, free of mist, and feels contented in this clear, hot atmosphere within the Turkish bath as nowhere else. It is evident that this artificial dry, hot air is a happy imitation and substitution for the natural hot dry climatic resorts where patients are sent to by their medical advisers, like Madeira, Egypt, Algeria, Australia, India, etc., especially for lung and kidney complaints. Under certain conditions and circumstances many patients are unable to leave their homes and are bound to remain in this country and do the best they can for their health. For these the Turkish bath proves a great boon, and you will understand with what safety you can recommend your patients to avail themselves of what constitutes a good sanitary Turkish bath. Oxygen is the great want in a hot air bath, particularly for weak people or weak lungs. It is true we have also in England excellent places for consumptives at the South Sea Coast and the Channel Islands; but when patients have to return to their homes in sooty, foggy towns, it is frequently the case, that their improvement vanishes, the air being too polluted; for these the Turkish baths are a delightful change. Advanced cases, to be sure, ought not to be sent away to distant countries, which deprives them of the comforts of their home, their friends, their relatives, their native language. I have made it my principle not to send patients away unless they are wealthy enough to procure for themselves the utmost comforts possible, and when they have improved in health I do not allow them to leave the security of their new homes for the risks they run in a wet and cold climate.

The literature on the Turkish bath is not very great, particularly by men of science and learning. On the physiology of these baths we find besides Urquart and Sir Erasmus Wilson only exceptional papers like those of Dr. Bucknill in the *Lancet* of 1876, of Dr. Cameron in 1877 and of Dr. W. J. Fleming, Lecturer on Physiology, Glasgow, 1879; the latter investigated the effects of immersion in hot dry air, and his conclusions are:

1. That a very large quantity of material can be eliminated from the body in a comparatively short time and, although the greater part of this is water, still solids are present in quantity sufficient to render this a valuable emunctory process.

2. The temperature of the body and 3, the pulse rate are markedly raised.

4. The respiration falls at first but afterward is less influenced.

5. The urine is increased in density and deprived of a large portion of its chlorids, while, if anything, an increase in the amount of urea is produced.

6. The sweat was found to have an average specific gravity of 1006.3; faintly alkaline, or neutral; the collection of the sweat, its determination and analysis require further experiments.

7. The principal effect upon the arterial tension seems to be an increase produced by the greater rapidity of the heart's action combined with a dilated, we may almost say, gorged condition of the capillary circulation.

Dr. Fleming's deductions from these conclusions as to the use of the Turkish bath in medicine are: Its most important effect is the stimulation of the emunctory action of the skin. By this means we are enabled to wash, as it were, the solid and fluid tissues, and especially the blood and skin by passing water through them from within outward. Hence, in practice, one of the most essential requisites is copious drinking of water during the sweating. Persons of sedentary habit or suffering from disease interfering with fluid excretion will, therefore, benefit very greatly by the use of these baths which produce such a reaction of the skin, and by its means considerable elimination of morbid matter may also be brought about. On this point there is but one opinion of all the writers, who also agree that sweating in these baths relieves the internal congestion on the same principle and with much greater certainty than the usual diaphoretics; besides it softens the skin, relaxes the muscles and permits more readily of passive movements called rubbing or shampooing, which follows systematically and enhances the process of perspiration during the manipulations. The shampooers who work so many hours a day in this hot air perspire very freely and enjoy the best of health, although they constantly pass from hot into cold and vice versa. So every one can harden his skin and accustom it to these changes by taking a Turkish bath twice a week; it will then be difficult for people to "catch a cold." Should a shampooer get one he will cure it by the next following copious perspiration followed by a shower of cold water or a cold douche. This may appear alarming to the inexperienced, but in practice it proves grateful to the sensations and is wholly free from even a shadow of danger. In fact, immunity from colds is thus acquired by persevering in Turkish bathing; the triple faculty of preservation of health, of prevention of disease and of curing the same is thus exercised by the action of the skin, which repels the depressing effects of cold by its intrinsic power of generating heat, and it also expels miasmatic poisons by its emunctory power. The malaria is eliminated from the body in this simple way; the chill passes into heat and the hot fit is transformed into perspiration. Gouty and rheumatic poison in the form of uric acid and urea is constantly eliminated by perspiration in the Turkish bath, and a man who has taken too much alcohol can with proper care expel it rapidly by the lungs and skin during the stay in the bath. What is eliminated by the Turkish bath is the excess of effete matter, which the weak body or degenerate organs can not excrete and which if retained by the inefficient action of the skin, liver and kidneys, is the prime cause of chronic disease. It is, however, not only the action of dry heat in the bath, but of hot, dry oxygenated air in the internal organs through the lungs and circulation, as well as on the skin which is so beneficial. The bath not only cleanses the skin, but purifies the whole circulation and blood, effecting a thorough cleansing of the system. A deficiency of oxygen and an excess of carbonic acid gas is the first cause of bad health, whatever form the symptoms may take. Ignorant people, and I am sorry to say many medical men, have an idea that the

Turkish bath is weakening or that its only immediate effect is "to bring down fat." Sweating, it is true, under abnormal conditions—in the fetid workshop or crowded assembly rooms for instance—is weakening, but it is far different when perspiration is naturally and beneficially induced in and by a thermo-oxygenated atmosphere. Here the life-giving oxygen replaces during the action of the bath the impurities of the blood. People who suffer from eruptions of the skin which indicate the too rich or too poor blood, or in fact, an impurity of the blood, by appearing on the surface of the skin in the form of pimples, boils, carbuncles and abscesses, eczema, herpes, etc., see these unpleasant and painful manifestations disappear after the first Turkish bath. They may expect if they persistently use this purifying process twice or three times a week that they will never see these complaints return again. In the Turkish bath we learn to distinguish by the eye and the touch the weak and the strong, the healthy and the unhealthy skin. In the bath there are no wrinkles and no decrepid age; the skin becomes firm and elastic, recovers color and smoothness and even upon the scalp of the bald, I have seen the hair return. The skin may have a deficient and imperfect circulation of the blood and a deteriorated sensibility, a defective cell-formation and secretion, and exhausted tone and vigor, but you may take it for granted that the habit of the bath will reverse these unnatural conditions. I remember how greatly it impressed me when taking my first Turkish bath. I placed my quickly heated hand on any part of my skin and felt a sensation of coldness; soon, however, the whole skin became warm and dry, then moist and soft, and finally I saw the pores opening, the humidity on the chest and arms gathering into drops like the dew on flowers or grass when garnished with crystal beads; the beads running into little rills, and the rills trickling down in small streams so that the whole body admitted of being washed by means of the water that issues from the blood.

Believe me, the bath is a preservative of health, a prevention of disease, and it will cure most chronic diseases when persevered with. How many cases could I describe from my practice that have lost their chronic bronchitis, their asthma, their inclination to catching cold in the nose, the pharynx, the Eustachian tubes, their larynx and vocal cords, who had crackling in their joints when moving them, even in the jaw joints so that bystanders could hear the masticating movements. All this rheumatic, gouty, scrofulous and other constitutional dyscrasias which so easily cause local deposits, show their evil existence and manifestation of sufferings in headache, earaches, neuralgias, giddiness, deafness, ringing in the ears, etc.; all these inherited or acquired weaknesses of constitution and illness are curable and preventable, but the baths must be persevered with during the time you are apparently free from disease. I mean you must not only take the baths when you are ill or suffering but during the intervals when you are seemingly well and healthy; then you will preserve your health and prevent any development of a cold, because it is the first cold that has the tendency to localize somewhere and produce mischief of longer duration. Shampooers always enjoy remarkable health because they at once cure their cold. If you want to know what regular perspiration in a Turkish bath can do, you must watch others and watch yourself most scrupulously and you will soon learn how true it is that per-

spiration in hot and well oxygenated air with all the manipulations of the Turkish bath will prevent congestion of the internal organs like the brain, spine and nerves as well as the organs lying in the thoracic and abdominal cavities. These congestions and inflammations from colds in certain constitutions with proclivities and inclinations of localizing in the periosteum, the muscles, the fibers, mucous, serous and all other tissues of our body may become very serious and dangerous, but the perspiration drives the blood from the internal parts to the peripheries or skin and frees the internal organs. When cold has chilled the skin, driven the blood inwardly producing shivering, headaches, etc., a weak spot exists *locus minoris resistentie*. To drive it out again you must go to the Turkish bath at once and get rid of the first attack; then you prevent disease and cure it at once at its start. It represents the whole principle of balneology and should be had recourse to by everyone, immediately he is seized with disease whenever and wherever possible. It is useless merely to treat a cold when it appears; the proper and effectual way is to persevere with the bath, even when in apparent health. It is very curious to hear how often you find the Turkish bath praised, by doctors, for its effect in reducing the bulk of fat people, and how difficult it is to bring them to acknowledge how wonderful Turkish baths are in restoring, for instance, a weak heart and circulation to strength. The heart is naturally a very powerful muscle which does an enormous amount of work in twenty-four hours, in order to pump the blood by each pulsation into all the arteries of the body. The innervation of the heart is frequently disturbed and its muscular power impeded so that the blood vessels of the skin do not sufficiently dilate and keep the circulation free. Most nervous complaints produce palpitations, but indigestion is frequently the first cause. Through over-feeding fatty degeneration is induced as well as through alcoholic intemperance. I advise abstinence, regular walking exercise and a Turkish bath in such cases with excellent results. They stimulate the skin, deplete the blood, relieve internal organs of congestion, relax spasms, improve digestion and assimilation and restore vigor to the body even when exhausted by bodily or mental labor. The hot-air bath has a quieting effect on the heart, especially, as all shock is avoided in undergoing the sweating process. Patients suffering from disease of the heart obtain instant relief in the bath, although the number of pulsations is increased. The more the pores are opened and the perspiration enhanced, the greater is the relief and the gradual improvement in the health of the patient. Cool ablutions and drinking of pure water must not be neglected. Persons can avail themselves of the benefits of the Turkish bath with less risk than attends ordinary medicinal treatment in nearly all forms of heart disease, because the skin becomes very inactive in heart disease, and the oppression in breathing increases; immediately, however, the skin becomes moist and active, the oppression subsides and the patient is relieved. A hot drink before entering the bath, and deep quiet breathing when extended on the back, or reclining in the chair accelerates perspiration and soothes nervous irritability, giving a happy feeling of relief. Directly the skin is active the internal conditions are relieved and the improved condition of the circulation through the body is reëstablished. It is simply marvelous how in this way the

action of heat affects beneficially all organic complaints not only of the heart, but also of the liver, the lungs, etc., immediately the skin acts. Thus, even in incurable complaints, the Turkish bath proves a source of comfort when all other means have failed, as in dropsy, anasarca, edema, etc.; the intelligent administration of the Turkish bath is the great desideratum if it is to be used as a medicinal or curative agent and not merely for nettoyage. The competency of the people who have the direction of the Turkish bath establishment is a *conditio sine qua non* and doctors should sometimes take the first bath or two together with their patients to give them confidence; but notwithstanding all the blundering managements in Turkish baths without doctors, there have been fewer accidents and more good results from their use than one would reasonably expect under such conditions. People with hypertrophy of the heart and a very powerful pulse have to be careful in taking the Turkish bath and must follow special advice, particularly if giddiness and headaches complicate the complaint; but people of what we call an "apoplectic" build will do well to take the Turkish bath regularly, and to accustom themselves to the change of hot air and cold ablutions. In very hot summers when apoplectic fits are frequent, habitual Turkish bathers will not be likely to stand in fear of these but will find a great advantage and comfort when leaving the bath to find that 80 degrees F. in the shade feels agreeable. We never hear of a death from syncope in a Turkish bath. Sunstroke never occurs in people who perspire copiously from the head and neck. Cold hands and feet, biliousness, stitches in the sides, lumbago, sciaticas and neuralgias of all kinds are indications for habitual Turkish bathing. Predisposition to fainting, palpitation, sinking feeling give way entirely to the gradual use of the Turkish bath. People who can endure a heat of 200 degrees F. with comfort and afterward take a plunge of 60 degrees F. or less are sure to remain in a strong and good condition of health, unless they commit excesses in eating and drinking, or contract influenza or malaria, etc.

I know bathers who have been living now comfortably for over twenty years with symptoms of softening of the brain, chronic alcoholic poisoning or nervous tremor, and constantly speaking of themselves as improving, and others who complained of restlessness and sleeplessness at night were entirely cured and slept as well as ever after every Turkish bath. The supposed danger of a Turkish bath to elderly people is quite a fallacy. Physiologically, pure air and exercise are as necessary in old people to keep up health as in young ones. Indeed, they want these more to restore a certain amount of lost vitality. In fact, the bath is of great value in prolonging life in the aged as well as in the diseased, and I know many old gentlemen between 65 and 85 who keep in vigor by taking their Turkish bath regularly once a week.

As to our brains and nerves, the close connection and reaction between the mind and body are indisputable proofs that the right action of the mind greatly depends upon the health of the body and consequently of the senses, for they are inseparable in life while the nerves are capable of their functions. If we possess pure blood disease is baffled, blood being the material out of which all the organs repair themselves its deficiency in quality and quantity lessens the energy of the brain's functions. A stimulant—be it alcohol, tea or

coffee—accelerates the circulation and increases the vascular supply. I always recommend a stimulant in a weak heart before the bath for weak persons until they can do without. I never recommend it after the bath; rest and a good meal must take its place after the Turkish bath. One writer fears the bad reaction of the stimulant; I have never observed it in practice; but I always try as soon as the patient is accustomed to the Turkish bathing to recommend cold water in place of the stimulants in the bath. Another writer uses stimulants and says people require a stimulant before they feel "fit," I suppose, for brainwork. Now, before I used the Turkish bath for sleeplessness I always had a good result from a stimulant for sleeplessness in people with a weak circulation and with mental worry and over-fatigue, and the dose must be a full one, for a small dose would produce mental excitement. To excite rapidity and intensity of thought one writer recommends the Turkish bath, "If," he says, "I require to think out a knotty point, I take a Turkish bath; my mind is clear, my judgment more keen and my loftiest and purest thoughts come to me during the process of blood arterialization."

There is not the slightest doubt that for the brain, the spine and the nerves the Turkish bath is excellent, and even noises in the ears and head may be cured or mitigated; but should the complaint want additional help in order to rectify and bring it to normal conditions of health, I always give the preference to the natural means of treatment, among which massage and electricity form the principal ones.

I have cured several cases of deafness which were given up as incurable by specialists. One of them, Mr. R. A., had to retire and take his pension—half-pay—at the Trinity House, when nine years later I unexpectedly restored his hearing by massage and Turkish and electric baths. "What a pity," the patient then said, "had I known of you before I spent all my money with specialists on the continent and in England, I would still have been in office to-day with full pay." However, let us hope that others will profit by this experience. He is now 74 and takes his Turkish bath frequently, being mentally very active, and, I am happy to say, useful to his family and to society.

I have not said anything about febrile diseases with high temperature, nor have I given opinions about treatment of hydrophobia by Turkish and vapor baths, the paper being already too long, but I repeat my warning, that a Turkish bath establishment which does not invite the doctors and the public to inspect their drainage and ventilation systems, or which refuses to show these must be looked upon with great diffidence and had better be avoided; there can be no mystery-pleading in these things, and the public has a right to see all. Therefore, allow me to impress, let the public constitute themselves their own inspectors and fearlessly demand of each Turkish bath proprietor a display of the ventilating arrangements before entering the bath.

---

**Military Hospitals Thrown Open to the Civilian.**—The German authorities have decided that civilians residing near military hospitals can be received and tended in them whenever the physician considers that transport to another hospital might be injurious. A decree in France also opens the military hospital in places without hotel accommodations, to civilians who apply to the chief of the department. The prices are to be the same in both countries as for the lower military ranks. The *Bulletin Méd.* July 12, strongly deprecates this transformation of the little hospitals in the colonies into boarding houses.

## PUBLIC TURKISH BATHS NEEDED.

Read in the Section on State Medicine, at the forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY CHAS. H. SHEPARD, M.D.

BROOKLYN, N. Y.

The action of the New York Board of Health in appropriating \$30,000 for applying the discovery of antitoxin in the treatment of diphtheria, encourages the hope that in the near future the public mind may be quickened to recognize its opportunities and its necessities in other and broader fields. It is time to appreciate the fact that we are our "brother's keeper," and that whatever works harm to him reacts upon ourselves. This action of the Health Board also indicates a growth in public sentiment that will encourage and sustain important measures for the public welfare. It is a moral duty as well as a principle of public polity, in all civilized countries, to protect the people from the invasion of infectious disease, and it would be very short-sighted to stop at mere infection. The use of antitoxin is only to supply a temporary exigency. It does not purify the homes of the people or teach them to take better care of their bodies or sanitary surroundings. We need something to uproot the cause of the disease, and when this is secured, it will be found that many other diseases have disappeared.

The Romans understood and perfected public sanitary works on a most stupendous scale, as is witnessed, among other things, by their aqueducts for bringing pure water to the city of Rome. Magnificent ruins of many of them are standing to-day, and some of them are in use at the present time.

It is known that in India, the home of cholera, the city of Calcutta is now protected from epidemics of that fearful scourge by the supply of comparatively pure water that has recently been furnished the city.

When the community can be assured of pure water to drink and pure food to eat, with proper bathing facilities, the enjoyment of life will be much enhanced and its length prolonged.

In a recent report of the Committee on National Quarantine of the New York Academy of Medicine, it was stated that "the most certain protection of this or any other country against the ravages of infectious disease, lay in the practice of internal sanitation." What is true of the State is also true of the individual. The more cleanly a man's habits, and the purer his food and drink, the less liable he is to disease, because his body is thereby rendered naturally immune to disease. Whatever our theories as to prophylactic measures in the prevention of disease, the production of a barren soil for the growth and development of pathogenic germs is of greater importance than the destruction of the germs themselves, though efforts should be made in every direction for the elimination of all diseases. Various theories have been offered by different authorities concerning the processes and changes that take place in the body in consequence of artificial immunization, but the scientific controversy regarding it has not yet been settled. Suffice it to say, that the more pure and active the fluids of the normal living body, the more powerful are the bactericidal properties thereof.

There is at present a revival of a favorite practice of the ancients, and that is their system of bathing. The old Roman baths, which are identical with the Turkish baths of the present day, were prominent features of the daily life of the Romans and were

counted among their choicest privileges, and so continued during the period of their greatest prosperity. They were then carried to a scale of perfection never surpassed. The baths of Diocletian, which were the largest ever built in the world, were capable of accommodating 18,000 bathers at one time.

We have heretofore maintained, and would reiterate, that as one of the great sanitary necessities of the day, it is most desirable that large public Turkish baths, as a preventive of disease, should be established throughout our cities at public expense, placed under medical supervision, with admission at nominal rates, so that the poorest individual could partake of their advantages with a feeling of self-respect in paying something for the help and comfort to be derived therefrom. They should be made attractive, and thus draw people from demoralizing enjoyments. This would react on the social life of the community, and by purifying the people would purify their homes.

We support public schools, and compel our children to attend them. With more propriety could we furnish public Turkish baths, and insist upon every man, woman and child availing themselves of their luxuries at least once a week. The physical is of greater importance than the mental; indeed, it is of the first importance to the State.

Herein would wealth have a royal opportunity to consecrate itself to the service of mankind. The endowment of public baths was among the most noble actions of the Roman Emperors. Eight hundred of those institutions adorned the capital of the empire, and they supplied, during many eventful years, almost the only medicine to a people distinguished for their corporeal and mental vigor.

Among the important results that are brought about by the use of the Turkish bath may be mentioned: 1, a perfect cleansing of the external body, and relief from any undesirable odor, replacing therefor the beauty and fragrance of health; 2, a purification of the blood by the elimination of its impurities through the surface of the body; 3, an equalization of the circulation and perfect distribution to and through every organ and tissue of the body, however remote; 4, the speedy elimination of blood poison, laying the foundation for; 5, increased nutritive changes throughout the whole body; 6, a relaxation by heat of the tissues of the body, and thereby relief of congestion, whether located in the lungs, bowels or other organs of the body, or in the muscular tissues, as shown in the relief from rheumatism, malaria, etc.; 7, absorption of exudates and inflammatory products; 8, better ventilation of the lungs, and the placing of climatic treatment on a scientific basis; 9, greater activity of the secretions and excretions; 10, the prevention and the eradication of the predisposition to disease; 11, strengthening of every vital organ, and therefore an increase of vital capacity.

The arguments in favor of public Turkish baths are both manifold and important. To enumerate but a few of them:

They would be comparatively inexpensive.

They would lessen the cost of medication.

They would prevent the spread of epidemics.

They would render extinct many classes of diseases.

They would lessen the demand for stimulants of every kind and render the police force less necessary.

They would be more powerful than any law of prohibition, because they would be more attractive than the saloons.

They would reduce the expenses of hospitals and asylums.

They would shorten the time necessary for patients to remain in such institutions.

They would reduce the demand for hospitals, so that what are already built would be sufficient for a generation to come.

They would help toward the refinement of the community.

They would vastly prolong the average of the life of the people.

They would add to the enjoyment of life, by making everybody healthier and happier.

They would tend to render the cities that adopted the bath preëminent among all the cities of the world, and be an example for all other cities to follow.

They would redound to the honor, and conduce to the growth of such cities, and continually increase the numbers of the better elements of their citizens.

They would uplift the community and tend to develop a superior race of mankind, as handsome as were the Greek models, and as powerful as ever were the Romans.

To the individual the Turkish bath is the perfection of sanitary science, and to the nation it is the coming blessing.

These few reasons but imperfectly state the great need and many advantages that would accrue to the community adopting the practice of public Turkish baths.

#### DISCUSSION.

DR. KELLOGG—This subject is one of very great importance. I am sure that there is nothing so valuable, as a health measure, as public baths. In different parts of Europe I have noticed that where there are public baths the cities possess a superior class of people. On the streets of Stockholm I saw some very fine looking men, stalwart and ruddy-faced. There you can get a public bath for five cents. There are several in the city; for twenty-five to fifty cents you can get a better bath. There are different grades, so that all classes are accommodated. Connected with these baths are laundries also, so that poor women can wash their clothing.

Three years ago I attempted some missionary work in the way of establishing free baths in Chicago. I wanted to find the wickedest men in the city. For this purpose I consulted the chief of police, who told me which was the worst place in the city. There I put in fourteen free baths. There was a gospel mission next door. I asked the superintendent of the mission what he thought of the idea. He did not think it amounted to much, but I nevertheless determined to proceed with it. There was but one place where a man could get a bath without paying for it, and that was by falling into the lake, and there was a law against that. Two or three weeks afterward this same gentleman came to me and said that he wanted to shake my hand; that the baths had changed the complexion of many of the people as well as of the community. The baths were patronized by men who were so black you could not tell to what race they belonged. I was astonished to see how anxious the lower classes were to be clean. I spent Sunday there until within the last three years; I found one December morning, when the temperature was a little below zero, 180 men in line, the nearest one against the door, waiting to wash their bodies and clothes. There was not a man who had an overcoat or gloves. Their collars were turned up and they were shivering in the cold. They had been there since 6 o'clock in the morning. It was really a pathetic sight. It is the rule to find a line like that there now every morning. Sometimes 200 men come and wait their turn in line. I was glad to see that the city authorities, two years later, estab-

lished as a memorial of the Mayor, Mr. Harrison, their own free baths.

THE CHAIRMAN—Were your baths entirely free?

DR. KELLOGG—Yes sir, entirely free; we are still carrying it on. We find the men are still ever ready to patronize these baths. I think it is a means of free grace that is better than preaching.

Another thing I have noticed, in studying this question, is that those people who give attention to public cleanliness, are the most advanced in civilization. To illustrate that, I remember an anecdote that I heard at the expense of Spain. An Englishman was traveling in Spain some time ago. He went to a hotel and called for a bath. The proprietor was astonished, and could not fully understand what was wanted. Finally the traveler learned that his host did not possess such a thing as a tub. After considerable delay he brought two large butcher's trays, and the traveler was enabled to take his bath, presenting the appearance of a miniature Colossus of Rhodes. The result was that the water leaked through the floor upon the people below, which caused the traveler considerable trouble.

I think what is called bogus Christianity is chargeable with the degeneration of the baths. One of the first things the Christians did in Rome was to try to tear down the baths and convert them into unnecessary churches. You will find in Rome at the present time scarcely such a thing as a public bath, only two or three floating arrangements, but several hundred unnecessary churches. They have been built almost entirely from unused public baths. The baths have been torn down and to day serve as churches or convents.

I was reading regarding one of the early fathers who was supposed to be very eminent in piety and canonized because of his little regard of appearances. He was filthy and had three hundred patches on his pantaloons, and was canonized because it was believed that the purest souls were found in the dirtiest bodies. What this country needs is the promulgation of the gospel of life, and I do not know of anything more conducive to pure minds than ample facilities for personal cleanliness. The Turkish bath is one of the best ways by which it can be promulgated.

A celebrated doctor in Vienna called attention to the fact that a hot, followed by a cold, shower bath caused the blood corpuscles to be increased in number from 35 to nearly 50 per cent. That seems unreasonable, but I have repeated his experiments, and while I have found no instance in which the increase was so great as 50 per cent., I have frequently found an increase of from 10 to 20 per cent. But that is considerable when we have an area of nearly two thousand square yards in the body.

I think we must consider this bath as one of great value. It is not that the corpuscles are originated, but simply brought out of their lurking places. They accumulate in the spleen, viscera and liver, whereas by the circulation they are brought into the stream of the blood, whereas before they were stagnating. So that the Turkish bath becomes the means of increasing the general vitality, and at the same time preserves the corpuscles from destruction. I do not think anything can be of greater benefit than the Turkish bath.

#### MESSAGE IN CASE OF APPENDICITIS.

Read before the Scandinavian Society of Teachers of Gymnastics, Stockholm.<sup>1</sup>

BY ASLEY LEVIN, M.D.

All authors on internal medicine whom I have studied on this subject (Niemeyer, Eichhorst, Strümpell, Kunze, etc.) regard it unanimously to be the first rule in the treatment of appendicitis, to let

<sup>1</sup> Translated by Hugo Oldenborg, Central Music Hall, Chicago.

the patient have complete immobility, not even allowing examination with palpation. In all the papers on gymnastics which I have perused, I have not found a single word mentioning the benefit or even the possibility of a gymnastic treatment for the disease in question. As far as I know, the only publication on the subject to be found is in the report from the Swedish Medical Congress in Norrköping, 1887, where Dr. A. Wide reports about four cases which he has treated. During the last years some masseurs have made use of massage in this disease, regarding the treatment as often very serviceable, although always more or less dangerous. I wish to present my experience on the subject. It may first be necessary to distinguish the meaning of the word appendicitis.

Authors on medicine speak of three different diseases, all of which may be included under the name of appendicitis. They are typhlitis, perityphlitis, and paratyphlitis. Typhlitis is an inflammation of the intestinal wall; perityphlitis of its serous membrane, and paratyphlitis means an inflammation of the porous connective tissue behind the appendix, between that and the rear abdominal wall. The difference between these three is often difficult to determine, especially as they often pass into each other and may be found simultaneously.

The disease usually commences as a typhlitis or a perityphlitis and may remain in this stage, or later on develop into paratyphlitis. During the course of the disease we can plainly distinguish two stages. The first stage, the acute, is characterized by fever, pain and great soreness. The second begins when the fever has subsided, the pain decreased and the bowels moved. The most marked symptom is soreness, localized in a circumscribed place. It is observed when the patient makes a stronger contraction of the muscles of the abdomen or of the lower extremities. It is also felt on pressure.

The treatment is quite different during the different stages. In the acute stage complete immobility, ice, opium, etc., are prescribed, and only in the second stage of the disease has massage, as far as I know, been applied by some masseurs.

In the manual method of treatment the rule is, and in some respects even more than when treating the disease by medicines, *tentare licet* (hasten slowly). Without trying something new, without testing the adaptability of the method on new regions of the body, we would here, no more than elsewhere, not be able to make any progress. Furthermore, with the means which one has, literally speaking, in one's own hand, there is less danger attached to experimentation than with many other methods. All of us have been happy to witness how the therapeutic gymnastics continually enlarges its field of work and takes possession of additional diseases for treatment. May I then be permitted to describe the method I have followed, and which may be an example of many other methods that are pursued by other masseurs.

*Case 1.*—A man, 40 years of age, who was treated by me in 1884. Seven years previously he had suffered from appendicitis, having had fourteen relapses, several of which were quite serious. Seven or eight months have intervened since the last attack. The patient consulted me for a stubborn constipation, which had followed as a result of the disease, and probably the constipation was the cause of the many relapses. There was also a moderate soreness in the fossa ileo-cecalis. I started the treatment with much cautiousness and a feeling of respect for the dreaded disease. The treatment consisted of bowel-massage, given in the beginning with great precau-

tion, on the right side; but as the soreness gradually disappeared the strength of the treatment was increased, and finally all the soreness having gone, this side was especially worked upon. The stools became more and more regular, and there was no need of any more treatment. The patient had then been treated during four or five months. Perhaps the function of the intestines varied after that and occasionally required repeated treatment, but in the mean time there has been an absence of relapses. The last effect of the treatment was, so to say, added to the bargain, because it was not expected from the beginning, as I could hardly have hoped to obtain such a result.

*Case 2.*—Encouraged by the result secured in the first case, I eagerly started in with my second case in 1885. Mrs. K., of 20 and some years, was taken ill with appendicitis (typhlitis, peri- and paratyphlitis) after a cold. She was attended by a colleague here, and after consultation with him I commenced the treatment about five weeks after the disease had set in, and three weeks after the patient had left the bed. There still remained a rather considerable resistancy along the cecum with moderate soreness, except on one single spot, the size of a finger tip, located about the middle between the navel and the right anterior superior spine of the ilium, which point was very sore. The treatment now consisted of gentle massage of the resistant part, avoiding the tender spot. After a couple of months there was nothing to be found of the resistancy. The circumscribed soreness, however, still remained, although it had somewhat decreased in severity. The stools were always normal.

These two cases are to be regarded only as results from the appendicitis, or, at least, as such cases in which the acute stage has already passed. All of the cases treated by other masseurs have been similar.

*Case 3.*—Contemporary with the above mentioned case, I received a third one for treatment. The patient was a man, 37 years old, who accidentally slipped down on his right leg from the last step of a staircase, and landed on the heel with straight knee. He felt a sudden pain in the right side of his abdomen, and eight days later noticed soreness in the side. On the eleventh or twelfth day I was called and found the patient suffering from pains and great soreness over the lower part of the right side of the abdomen. Constipation had been present for three days, and there was slight fever. The usual treatment was carried out, immobility, ice and opium. The pains soon subsided; the soreness disappeared, and the temperature became normal. On the ninth day I tried to effect evacuation by means of an injection, but did not succeed. I ordered another injection for the evening and returned the following day in company with a colleague. No stools. Two great injections did not have any effect, but as there was no soreness I gave a common bowel-kneading, beginning with great care, but by and by, as no pain was felt and gases began to leave the patient, a matter that had not occurred before, I increased the vigor of the treatment. The patient soon felt an inclination to move the bowels, and a small injection had the desired effect. As the patient lived some six miles distant from me out in the country, I was only able to treat him irregularly with massage during one month. The soreness in his right side disappeared, however, entirely during this time; the stools became normal, and since then he has had no relapses.

In this case the treatment was begun nearer the acute stage; but all fever having disappeared and the soreness already much reduced, we considered the acute stage as being passed, although the patient had not yet had any stools, when the treatment was started.

During the winter 1887 I spent a month in London in order to pursue at the very place the so much spoken of "method" of Mr. G. H. Kellgren. In my opinion it does not decidedly differ from the method of Ling, upon which method it was admitted to have been based; but in some cases it was carried out quite differently. For instance, a couple of manipulations were used, already mentioned by Ling, and also in our gymnastic institutes. Kellgren, however, practiced them a good deal more and had technically improved them. These were nerve-friction (our nerve pressure) and vibration (a very slight and fine shaking or trembling motion). Beside that, the whole gymnastic treatment was given during a much

longer time and with more energy than is generally the case here.

The above mentioned manipulations were also used in several acute diseases, such as fevers, etc., which generally have been regarded as unsuitable for mechano-therapeutics. I am sorry to say I had not the opportunity of following up such a case, but judging by from what I heard and regarding the splendid technique that was displayed and which I also tried to practically learn, I decided to try this kind of treatment as soon as an opportunity presented itself. I thought especially of the appendicitis which Kellgren said he had treated during the acute stage and with good results.

*Case 4.*—It was not before 1888 that I had an opportunity of trying the method on a more acute case. It was when the same lady whom I had treated before (Case 2) had a relapse. I started treatment on the fourth day, while there was still a great deal of soreness and fever (38 to 39 degrees C.) existed. It consisted then of extremely fine vibrations just over the most sore place. I argued like this: Here is a stasis; if I were now able to produce a motion which on one side is strong enough to cause an excitation of the debilitated tissues, especially in the vessels, but, on the other hand, is not so vigorous as to tear possibly existing adhesions, the effects must be beneficial. I regarded the vibrations to be such movements, if they were carried out, that the trembling of the arm and hand is transferred to the underlying parts without so great a motion being produced, that no rubbing or dislodgment of adjacent tissues could take place. I would not, even now, begin the very first day. The treatment with ice and opium was resorted to as before. The exceedingly sore abdomen could not only stand my treatment, but the patient felt relieved; it had even a soothing effect upon her. The first day the treatment only lasted for five minutes; the second it was increased to fifteen and it then relieved the pain and decreased the pressure in the abdomen by causing gases to escape for the first time. So also the following day and when on the seventh the fever had disappeared and an injection of water was given with good result, the attack was over. Massage and vibrations were then continued. One week later all resistancy was gone, but the old sore point still remained.

*Case 5.*—In the summer of the same year, 1888, there came to the watering place of Bie, a 17 year girl, Miss A. In the spring of 1887 she had a slight attack in the ileo-cecal region, which, however, by her physician was not regarded as a real inflammation, until the patient in the spring of 1888 had a strongly marked appendicitis, leaving a soreness in a small place, also the one localized about midway between the navel and spine of the ilium, anterior superior dextra. There were also found so-called cellulites (infiltrations) in the subcutaneous connective tissues of the abdomen, which possibly started after the long lasting cold compressions that were used during the attack in the spring. There was no resistancy to be observed except in the sore spot, the size of a finger tip. The treatment consisted of general abdominal massage, directed partly against the subcutaneous infiltrations, partly against the slowly acting intestines, and especially against the sore point. The patient was getting along all right, when one day I saw her in a running race down a long steep hill. Being below, I immediately stopped her, but it was too late. The following morning I received notice that she had been taken ill during the night with pains in the right side and very much increased soreness, slight aching, but no fever. The patient, as well as her mother, who was along with her, were convinced that it was a relapse, because the previous attack had begun under the very same circumstances and with the same symptoms. Treatment was immediately commenced, and as the usual massage could by no means be endured, I resorted to vibrations during half an hour and repeated this treatment twice the same day with a constant diminution of the pain. There was slight fever in the evening. The following morning no fever was present; the pain had nearly disappeared, and the soreness decreased. After the first treatment this day the patient felt entirely well and wanted to leave the bed. She remained in bed that day, however, received one more treatment, and felt completely well the next day. The massage treatment was continued with the result that the patient did not feel anything but a little soreness on pressure at the above mentioned point.

In December of the same year she came back again in order to get this soreness, which had now somewhat increased,

worked away. I had hardly treated the patient a week before she happened to slip on the floor and fell, and, as she expressed it, sprained her right side. She immediately felt pain again in the old place. The pain and soreness increased, so that at my visit the following day they were pretty severe and did not permit of the usual kind of massage. I took up the vibrations at once and after half an hour of treatment the pain disappeared, and the soreness was not worse than before. The following day the condition was as usual. After that, I treated the patient occasionally without being able to entirely remove the soreness in the above mentioned point.

*Case 6.*—The same year I had at the Central Gymnastic Institute another patient with recurrent appendicitis. Miss T. was 19 years of age. She suffered in February, 1886, from appendicitis. In May, the same year she had a relapse after an improvement. Since that time she has had soreness in the ileo-cecal region, which later spread over the groin and the whole hip, with pain in the small of the back and the whole right leg, attended with increased difficulty in walking. Nov. 22, 1888, she came to me for treatment at the Central Gymnastic Institute. During the first month her condition was unchanged, with considerable pain in the small of her back, right hip and groin, and a great deal of hardship in walking. Great soreness in the ileo-cecal region, with the resistancy spreading in the right side of the abdomen. During the stop at Christmas time the patient had a relapse without known cause, Jan. 9, 1889. I was called the 10th, when the patient had pain in her right side which had considerably increased in severity, accompanied with soreness and slight fever (38 to 39 degrees C.). I immediately gave the treatment with vibrations and afterward ordered ice and morphin. The treatment was repeated two or three times this day, also the following day for from fifteen to twenty minutes each time. As the patient felt greatly relieved and pain and soreness had materially decreased after every treatment, ice, as well as morphin, was discontinued after the second day. On the 15th the temperature was normal; an injection was given with the desired result. A couple of days later she was up, and after a fortnight more she appeared again at the Institute, to which place she had quite a distance to walk. This case showed what a different effect the treatment has when the vibrations are properly given. As my time in the beginning of the term was so much occupied that I could not possibly visit the patient more than once a day, I desired to let some of the pupils from the Institute (now in their second year) try the treatment in such a delicate case. Consequently I let the pupil which had previously treated the patient at the Institute, who had given very good movements, and when giving the abdominal massage to the patient (which she had done for a month previously) displayed marked ability in moderating the strength of the movements, again accompany me and give treatment with vibrations. The patient, however, had marked soreness during the whole treatment which lasted quite a while after the treatment was discontinued. Treatment was again tried, but with the same result. My own treatment gave, as before, relief. I did not dare let this pupil continue the treatment, but took another, whom I had found previously to give the best vibrations, although she had not before treated this patient, and had not even had a case resembling it. Her treatment was tolerated very well from the start and afforded relief. I might remark here that the patient did not like to change the masseuse she once had become accustomed to. When she returned to the Institute she was treated once daily with massage and light passive movements. As the soreness passed away the strength of the movements was increased, with the result that when the patient stopped May 15, the soreness was very nearly gone, and the resistancy could hardly be felt. She could walk without any trouble, and her bowels moved regularly, daily. Since that time she has had no relapse.

*Case 7.*—Mrs. D., 33 years of age, came April 1, 1889, to the Central Gymnastic Institute. She had had perityphlitis December, 1883, a relapse during the summer, 1884, since which time there was soreness in the right side. The patient felt "tired and weak"; the slightest exertion produced additional soreness and even pain for a couple of days. She suffered from another relapse in January, 1889. During the last two weeks she has been treated with massage by a colleague in this city and has improved. Now she gave evidence of slight pain, a great deal of soreness on pressure in the cecal region, especially at a point a little below the middle between the navel and the right superior spine of the ilium; pain in the sore region when bending or turning the trunk; also in case of longer and more rapid walks. Stools fairly regular. After a month of treatment with massage and light movements, her strength was considerably increased; there was no pain experienced

while walking or in moving the body. The soreness on pressure remained, though very slight. Her bowles moved regularly.

*Case 8.*—In April, 1889, Mrs. Y. (See cases 2 and 4) had another relapse. This time, as before, she suddenly complained of pain and great soreness which came on at once; later a high fever developed (38.3 to 40.1 C.). The same colleague was called who treated her before and the treatment consisted of ice, morphin and opium. I began the following day to give vibrations and my colleague, who had been very doubtful as to the benefit of this treatment, had to acknowledge its good effect. It gave more relief than the ice. The treatment was given twice a day, and at the end of seven days the attack subsided. The after-treatment, which was continued for some time, could not even now remove the soreness in the old place.

*Case 9.*—In October of the same year another relapse occurred in the same patient, which was just as sudden and severe. This time I had the opportunity of giving two treatments the first day, which afforded so much relief that neither ice nor opium was used. The temperature ranged from 38 to 39 degrees C.

A brother of Director Kellgren in London, Dr. Arvid Kellgren (also from London), who happened to be in the city, was kind enough, at my request, to accompany me the following day and give the treatment, which in manner was the same as I had previously given, but in execution undoubtedly much better, as his technique was exceptionally good. After his first treatment, which was kept up for half an hour, the pain decreased very much. We then both continued the treatment for half an hour each daily until the fifth day, when the patient was able to leave the bed. After that I gave a long after treatment, following which she felt less of her sore spot than ever after the first attack. But the soreness did not disappear entirely. This lady was pregnant in 1887 and 1888 which condition normally progressed without any influence upon the soreness in her right side. During none of the relapses was there any soreness to be found in the pelvic regions, which were always examined.

My opinion as to the use of therapeutic gymnastics in the treatment of the above-mentioned disease, judging from the experience I have had, and what I have found out from other masseurs, is that the indications are quite different in different stages of the disease. My opinion is decided about the later stage, the so-called "after stage," which, as above mentioned, has hitherto been the only stage where mechano-therapeutics have been used. I regard the treatment in this stage, as a rule, both useful and beneficial. The anatomic alterations consist in most cases of effects that are left after the inflammation has subsided. These effects consist sometimes of adhesion between the cecum and the surrounding tissues, as the abdominal wall, other intestines, etc., resulting from the inflammation of the serous membrane of the intestine. It is very natural that in proportion to the degree that these adhesions are short and broad, they will obstruct and limit the peristaltic action and to the same degree, when they are lengthened, this hindrance will decrease. A strong bowel kneading which will make the intestines move about each other, helps to extend and lengthen those adhesions, without tearing the intestinal walls, because of the now well organized condition of the results of the inflammation. Such a movement must consequently be very beneficial and there is no reason to suspect any danger.

Another effect depending upon the inflammatory process in the intestinal wall is a remaining edema, which renders the intestinal wall thicker, its muscles less powerful, and consequently the whole action of

the intestine is lessened. From this there results an inclination for constipation, and the constipation on its side is generally the cause of the relapse. It is, of course, analogous to the effect of the kneading upon any other part of the body, that the direct kneading of the intestine will promote the circulation, remove the products of the disease, and consequently bring the tissues back to their normal stage. If there are no other changes in the intestinal wall we can not suppose that such a kneading would be of any danger. Had there been paratyphlitis, that is, an exudation of pus behind the cecum, the amount of pus would regulate our action. If the amount is rather limited, an infiltration, it is often absorbed without any interference from the outside. Careful massage or, perhaps better, vibrations will then increase the tissues' power of resorption, distribute the pus, and prevent it from accumulating and forming an abscess. If, on the other hand, the amount of pus is so great that an abscess really exists there, it is very doubtful if any kind of manual treatment would be beneficial. It might be a source of danger in producing a rupture and, above all, we can sometimes do more harm than good by this kind of treatment, by deferring what in such a case would be more beneficial—a surgical operation.

In still other cases (cases of real typhlitis) a sore may be developed in the intestinal wall and perforation thus threatened. Such cases are frequent when the disease begins in the vermiform appendix. In most cases such a perforation is prevented by a previously circumscribed peritonitis which solders the threatened place together with the adjacent part of the peritoneum. In this way an adhesion will be developed, which will always be in great danger of breaking before the intestinal wall has healed up again.

All manual treatment during this stage is, of course, dangerous and as the benefit it might produce in promoting resorption does not exceed the danger to which we subject the patient, we must say that this kind of treatment under such circumstances is decidedly contraindicated. If pus is encapsulated somewhere we must think of the possibility that by manipulating the same we might cause an acute inflammation, which will be followed by perforation.

With reference to the acute stage, our experience as yet is so little regarding the treatment, that we would hardly dare pronounce an opinion. So much might be said, however, that the treatment seems to give the patient relief without causing any annoyance or danger; so consequently we are justified in continuing the experiments, observing the greatest caution and possessing as complete a knowledge as possible about the case. It is not advisable for any masseur to try such treatment without being closely controlled by a physician.

In case of relapse I regard it of great benefit to immediately make use of the treatment, because we might be able to abort the attacks in some cases, a matter which, will always be difficult to prove.

Finally, I would again call attention to the fact that the manner in which the movement is given is of the greatest importance, and should be given in such a manner that the hand of the masseur will not injure, but rather have a decidedly beneficial effect. Any other movement would really do harm. Only a good operator in consultation with an expert diagnostician ought to try the manual method of treatment. In

the same degree as more practitioners try this method, our experience will be proportionately increased, and then I hope better methods will be devised and more decided indications given.

### ENCHONDROSIS.

Read by Title in the Section on Surgery at the Forty-seventh Annual Meeting of the American Medical Association held at Atlanta, Ga., May 5-8, 1896.

BY MERRILL RICKETTS, PH.B., M.D.  
CINCINNATI, OHIO.

While this disease is one of the rarest affecting the human skeleton, it has many interesting features and causes. The literature pertaining to it is indeed scarce, but few cases being reported, and those by Berg of Stockholm within the last year.

The principal causes assigned in the twenty-one cases referred to were syphilis, tuberculosis, typhoid

brought to my office by Dr. J. K. Brammer, his attending physician. Cocain was injected and an incision made about two and a half inches long. It was found that the cartilage was diseased, necessitating a thorough curetting. He returned November 1, no improvement having taken place. Two inches of the seventh cartilage was removed at this time. On December 1 the sternum was thoroughly curetted and a portion of the seventh, eighth and ninth cartilages removed. Still there was no improvement, the disease gradually extending. Feb. 4, 1896, another portion of the seventh, eighth and ninth cartilages on the left side, allowing the space from which it was taken to granulate. A drainage tube was passed beneath the entire flap. He made a rapid and uninterrupted recovery and is now able to perform work of any kind.

In conclusion I would offer the following suggestions:

FIGURE 1.—H. McK. Aged 37 years. Injured June 29, 1895. Abscess upon. Opening Sept. 29, 1895. October 19, curetted. November 1, removed two inches seventh cartilage. December 1 curetted sternum and removed part of cartilage of seventh, eighth and ninth. February 4, removed part of cartilage of seventh, eighth and ninth cartilage. March 11, 1896, removed cartilage and three-quarters of an inch of bone of the sixth, seventh, eighth, ninth and tenth; also curetted sternum and removed double pedunculated flap from left side to cover entire granulating surface. Recovery. "Traumatic chondritis."

fever and trauma. When once the cartilage becomes diseased there seems to be no remedy but complete removal and also a portion of its bony attachment.

The accompanying report of a case of traumatic enchondrosis illustrates the amount of destruction which may result from an injury to the perichondrium: H. M., age 37, white, American, received an injury to the right seventh costal cartilage on June 7, 1895. An indurated mass appeared about one and a half inches to the right of the median line over the seventh costal cartilage. An abscess appeared which was opened on the 20th day of September following; this continued to discharge pus until October 19, when he was

FIGURE 2.

1. None but the most radical operations should be made at the onset of the disease.
2. At least one half inch of the bony attachment of the cartilages should be removed.
3. Great care should be exercised to prevent puncturing the pleura.
4. Surgical anesthesia should always be resorted to, as it is difficult to determine the extent of the disease before operating.
5. If the sternum be diseased a portion of the normal should be removed with the diseased tissue.
6. Unless bone is removed with the cartilages, the wound should be allowed to heal by granulation and not by flaps, as fistulæ indicate the diseased tissue.
7. Flaps should be resorted to when possible.
8. There is no evidence that medication is of any avail.

The Trinidad, 415 Broadway.

REPORT OF FIVE HUNDRED CASES OF INTUBATION OF THE LARYNX.

Read before the Colorado State Medical Society, June 17, 1896.

BY F. E. WAXHAM, M.D.

PROFESSOR OF DISEASES OF THE CHEST, LARYNGOLOGY AND RHINOLOGY, GROSS MEDICAL COLLEGE; ATTENDING PHYSICIAN NOSE, THROAT AND CHEST DEPARTMENT, ST. JOSEPH'S HOSPITAL, DENVER, COLO.

It has been my pleasure to have reported, on a previous occasion, 466 cases of intubation. To this number I can now add 37, making a total of 503. Of these thirty-seven cases there were seventeen recoveries, or 46.64 per cent. Many of these cases were beyond all hope when the operation was performed. Several were complicated with scarlet fever and some with measles, and in these cases the operation was simply performed for euthanasia, much to the detriment of a good record. In nine cases antitoxin was administered with six recoveries, or 66.66 per cent. In order to complete the record I desire to publish the following cases:

Case 467.—Diphtheria of pharynx and larynx; age 6 years. Wore tube seven days; complete recovery.

Case 468.—Diphtheria of nasal cavities, pharynx and larynx; age 18 months; patient died within thirty-six hours.

Case 469.—A case of malignant diphtheria with larynx involved. Great relief from dyspnea afforded by the operation, but patient died within twenty-four hours from exhaustion; age 7 years.

Case 470.—Semi-malignant diphtheria of nasal cavities, pharynx and larynx; patient died three days after the operation from exhaustion; age 3 years.

Case 471.—The case was considered to be one of membranous croup, as no membrane was visible in nasal cavities or pharynx. Patient wore tube nine days, making a good recovery; age 3 years; other children in the family developed pharyngeal diphtheria.

Case 472.—Patient died on third day after operation from extension of membrane to the finer bronchi; age 4 years.

Case 473.—Diphtheria of nasal cavities, pharynx and larynx; wore tube ten days; complete recovery; age 16 months.

Case 474.—Patient dying from suffocation when operation was performed; wore the tube four days; perfect recovery; age 20 months.

Case 475.—A case of laryngeal obstruction complicating measles. Operation gave relief to the urgent dyspnea, but patient died from exhaustion within twenty-four hours; age 20 months.

Case 476.—A case of laryngeal diphtheria. Operation gave relief for twenty-four hours, when obstruction occurred below the tube which could not be expelled on removal of the tube. Tracheotomy was done and a membranous cast of trachea and larger bronchial tubes was removed. Patient died forty-eight hours later from bronchial obstruction due to the reformation and extension of the membrane. Age 13 years.

Case 477.—Diphtheria of pharynx and larynx; wore tube four days; uneventful recovery; age 3 years.

Case 478.—A bad case of diphtheria involving the larynx; wore the tube ten days before it could be dispensed with. General paralysis occurred, involving muscles of throat; necessary to feed through stomach tube; slow but complete recovery; age 3 years.

Case 479.—Operation gave relief, but patient died twenty-four hours later from extension of membrane. Age 5 years.

Case 480.—Operation gave relief for forty-eight hours, when obstruction occurred below the tube. The tube was removed, but the patient was unable to expel the offending membrane and immediately became asphyxiated. Tracheotomy was quickly done after respiration had ceased and the patient resuscitated. A membranous cast of trachea and bronchial tubes was removed. The case did well for thirty-six hours, when reformation and extension of the membrane occurred and the patient died; age 5 years.

Case 481.—A case of malignant diphtheria terminating fatally twenty-four hours after operation; age 3 years.

Case 482.—A sister of the previous case; malignant and fatal within twenty-four hours; age 4 years.

Case 483.—Diphtheritic case; wore tube four days; recovery; age 4 years.

Case 484.—Wore tube five days; recovery; age 3 years.

Case 485.—Diphtheritic; died three days after operation from extension of membrane to the finer bronchi; age 11 mos.

Case 486.—Wore tube five days; uneventful recovery; age 8 years.

Case 487.—A diphtheritic case; prompt relief was given, but case terminated fatally within thirty-six hours from extension of membrane; age 12 years.

Case 488.—The case was one of edema of the larynx associated with very severe form of scarlet fever. The patient died from edema of the lungs within twenty-four hours after the operation; age 17 years.

Case 489.—A case of scarlet fever attended with laryngeal obstruction. The case was hopeless when operated upon and died within twenty-four hours; age 3 years.

Case 490.—Wore the tube six days; uneventful recovery; age 5 years.

Case 491.—Wore tube six days; antitoxin administered; good recovery, although slow; a secondary attack of pharyngeal diphtheria occurring within three weeks; age 3 years.

Case 492.—Wore the tube nine days, making a good recovery; age 7 years.

Case 493.—Patient very low with scarlet fever accompanied with laryngeal obstruction. There was but little relief from the operation and the child died within a few hours; age 2½ years.

Case 494.—The patient was very feeble and died within thirty-six hours; age 3 years.

Case 495.—Antitoxin used; patient nearly moribund from asphyxiation; wore the tube four days; recovery.

Case 496.—Patient died within twenty-four hours after the operation; age 3 years.

Case 497.—Diphtheritic case; patient greatly exhausted from difficulty of respiration; antitoxin employed; wore tube five days; good recovery; age 2 years.

Case 498.—Wore tube nine days before it could be dispensed with; antitoxin used; recovery; age 3 years.

Case 499.—A very bad diphtheritic case; patient nearly dead and lower trachea and bronchial tubes already invaded; intubation gave no relief on account of obstruction in trachea and bronchial tubes which could not be expelled; tracheotomy performed and patient died within twenty-four hours; age 2 years.

Case 500.—A bad diphtheritic case, nose, throat and larynx being involved; four other bad cases of diphtheria in the family; antitoxin used; wore tube five days; recovery; age 2 years.

Case 501.—A case of pharyngeal and laryngeal diphtheria and patient greatly exhausted from long continued dyspnea; antitoxin used; wore tube five days; recovery; age 3 years.

Case 502.—A case of laryngeal diphtheria, no membrane being visible in pharynx; child suffering from intense dyspnea; case terminated fatally within thirty-six hours from extension of membrane; age 7 years.

Case 503.—The patient did well for four days, when the tube was removed. Within a few hours the stenosis returned and before reaching the patient death had occurred from suffocation; antitoxin used; age 3 years.

In conclusion, arranging my cases in series of 100 consecutive cases the record to date is as follows:

FIRST ONE HUNDRED CASES.

Age.	No. Cases.	Recoveries.	Percentage.
Under 1 year . . . . .	5	1	20.00
1 year . . . . .	13	2	15.38
2 " . . . . .	22	4	18.18
3 " . . . . .	17	2	17.76

I can not close this paper without emphasizing the importance of the use of antitoxin in cases of laryngeal diphtheria. I am fully convinced that antitoxin limits the extension of diphtheritic exudation as does no other remedy that we possess and as the danger lies chiefly in the extension of this membrane it is apparent that the remedy should be employed early before the membrane has extended to the lower trachea and to the bronchial tubes. In a case of diphtheria, the very moment that it is evident from the slightly embarrassed respiration and croupy cough, that the larynx has become invaded the remedy should be used. By the early use of antitoxin in these cases not only will many operations be avoided but many cases requiring operation will be saved that would otherwise perish. In corroboration of this statement I would say that since the general use of this remedy in Denver I have been called much less frequently by my confrères to operate than formerly, and in those cases operated upon a much larger percentage have been saved.

THE EMINENTLY SCIENTIFIC NATURE OF OUR PATENT AND COPYRIGHT LAWS.

THE KLEBS ANTIPHTHISIN CASE.

BY F. E. STEWART, M.D., PH.G.

DETROIT, MICH.

For the purpose of promoting progress in science and the useful arts the Constitution of the United States gives Congress the power to grant to authors and inventors for limited times the exclusive use of their respective writings and discoveries. On the clause in the Constitution referred to, our patent and copyright laws are based. The question at issue is the right to copy. The copy right law refers to the right to copy the writings of others; while the patent laws refer to the right to copy the inventions of others. Now I propose to show that it is just as equitable for the medical profession to endorse the patent as applied to medicine, as it is to endorse the copyright as applied to literature. At the same time I hope to make it clear that so-called "Patent" medicine business is a misnomer; and I hope to show that what is generally known as the "Proprietary" medicine business possesses no property in medicines whatever, and is a misnomer likewise.

All will admit that the promotion of science and the useful arts is of great benefit to society at large, and any fair minded man will agree that capital invested in business should be properly protected. If, therefore, there is a law which will protect both science and commerce at the same time such a law must be truly beneficent. Such exists in our patent law, which, if properly applied is capable of effecting that most desirable end.

"A patent is a contract between the inventor and the government representing the public at large. The consideration moving from the inventor is the production of a new and useful thing, and the giving to the public a full knowledge thereof by means of a proper application for a patent, whereby the public is enabled to practice the invention when the patent expires. The consideration moving from the government is the grant of an exclusive right for a limited time, and this grant the government protects and enforces through its courts." Simond's Manual of Patent Law, p. 11.

The patent office at Washington is a great bureau of archives representing progress in science and the arts in the United States. Any one who wishes to post himself in regard to inventions in any special line of work can obtain full knowledge of everything patented in that line by applying at the patent office. Models, drawings, descriptions, working formulas, are all there for inspection; and he can secure, at small cost, copies if he so desire.

Many useful arts of the ancients have been lost to the world for lack of publication which would have been preserved if patent laws similar to those devised by our law makers had been in force. The necessity of securing the publication of the art of manufacture of every medicine must be apparent to every one. In case of a patented medicine such publication is secured. Moreover, the inventor, to whom the world is indebted for the discovery of a new and useful thing receives well merited reward for his labor.

The patent law provides "That any person who has invented or discovered any new and useful art,

machine, manufacture, or composition of matter, or any new and useful improvement thereof, not known or used by others in this country, and not patented or described in any printed publication in this or any foreign country, before his invention or discovery thereof, and not in public use or on sale for more than two years prior to his application, unless the same is proved to have been abandoned, may upon payment of the duty required by law, and other due proceedings had, obtain a patent therefor." Sect. 24, Act of July 8, 1870.

It may be observed, first, that an invention for which a patent is sought must be original with the applicant; second, it must be new and useful; third, full knowledge of it must be filed at the patent office; fourth, the grant is limited to a term of years at the end of which the monopoly ceases, and the invention becomes common property.

If all these requirements are not complied with the patent is invalid, even if granted, and the courts owe it to the public not to protect inventions when the demands of the patent law are ignored. Now I contend that the enforcement of these demands, when patents for medicines are applied for, would do much to correct the abuses which are throwing our laws into disrepute in their relation to medicinal preparations.

The inventions specified as patentable are:

1. An art or an improvement of an art.
2. A machine or an improvement of a machine.
3. A manufacture or an improvement of a manufacture.
4. A composition of matter or an improvement thereof.

To define what constitutes a new art, machine or manufacture, or an improvement thereof is sometimes a difficult task. But it is far more difficult for courts to define what constitutes new and useful compositions of matter or compositions thereof. The law requires that an invention to be patentable, must be "*new and useful*." To define what are new and useful compositions of matter may require the most profound knowledge of chemistry; and when referred to therapeutic inventions, a score of expert physicians and chemists might be required to settle it. Yet patents have been granted without any attempt being made worthy of the name to ascertain whether the alleged inventions conformed to the demands of the patent law or not. More care should be taken to carry out the wise provisions of the Constitution in this connection, so that the patent law shall promote and not hinder progress in the science of therapy and pharmacy. Surely no patents should be granted for medical compounds unless the applications are first submitted to a commission of physicians and chemists to pass thereon; and the courts should not attempt to decide questions of infringement without first consulting such a commission.

Another point of great importance in the application of patent law to medicine is the question of naming new compositions of matter. Mistaking the nature of the patent privilege some inventors have registered the names of their inventions as trade-marks for the purpose of continuing the monopoly after the patents expire, and thereby defeating the patent law. Now it is certainly true that if the only name by which a compound is known may be legally used as a trade mark, it is equally true that its use as a trade mark may be continued indefinitely after the patent has expired, so that the trade mark law may

render the patent law ineffective so far as promoting progress in science and the arts is concerned. But when the patent expires the article, according to the contract between the inventor and the government, becomes common property. Surely, under the contract, it is not fair to permit the inventor to exercise a perpetual control over the name of the article and thus exclude the public from an equal chance in its manufacture and sale. Moreover, the name by use becomes descriptive of the article, and it is an axiom of law that a descriptive name can not be made a trade mark.

Mr. George H. Lothrop of Detroit, one of the most eminent patent lawyers in America, in a conversation recently used an illustration which seems to make clear the absurdity of claiming the only name of an article as a trade mark. He said: "When a baby is born into the world, a name is given it. Does the name of the baby belong to the baby or to the one who gave the baby its name?" Every new thing born into the world must have a name; and that name belongs to the thing, not to the one who named it. While the patent is in force the use of the name is restricted to the patentee along with the invention, but when the patent expires both should, and I hold that they do, become common property.

Now, as we have no law in this country granting the exclusive use of articles of trade to individuals except the patent law, and as every article not patented in which the world is trading is free to the public to manufacture and sell, it follows that there is no property in a medicine unless it is patented. The majority of medicinal compounds on the market are not patented. The reasons for this are various. First, only a few of them are patentable, being mere aggregations of old and well-known drugs. Next, the manufacturers had rather rely on secrecy and semi-secrecy for protection than expose their trade secrets by an application for a patent. Then the monopoly permitted by the patent law is limited, and it is possible to monopolize a medicinal compound indefinitely by secrecy as to its true or working formula. But it is hardly a correct definition to call these unpatented compounds proprietary medicines, for it inculcates the idea that there is property in them (which there is not), and that any one except the introducer who may desire to manufacture and sell them is guilty of piracy. As well might every manufacturer of pens, ink, paper, silk and woolen goods, and of every article of commerce not patented be called a pirate. Competition is the life of trade, and it is this mistaken idea that every manufacturer of unpatented articles except the introducers are pirates, imitators and infringers of the rights of others that is throttling the entire manufacturing interests of the United States as far as medicine is concerned.

If the medical profession and the pharmacists of this country would combine on this one thing and demand that every medicinal composition shall be published and provided with a name under which it may be manufactured and sold by all, it would do more than anything else to blot out that great misnomer, the so-called "patent medicine" business. It is a wise and just policy that rewards the inventor of a new and useful composition of matter with a patent. But let no patents be granted for medicines unless there are reasonable grounds for believing that they are new and useful inventions, and then see to it that the scientific and beneficent ends of the patent law

are carried into practice. The protection of labels' trade marks and packages is indispensable to the existence of trade and a great protection to the public, but let it be known that there is no legal warrant in the use of the only name of an article as a trade mark. Such a use of it creates a perpetual monopoly, protects secrecy, kills all competition and is an open door to fraud.

Another very important point in this connection is the right possessed by the government representing the public at large to refuse a patent to an inventor when public policy demands it. The granting of a patent that will hinder progress in science and useful arts is contrary to the policy of the patent law. "The policy of the patent law is, primarily, a selfish one on the part of the public, and only secondarily intended for the benefit of inventors, and then as a means to an end only." Simond's Manual. The same author states that the United States Supreme Court has, twice at least, decided that a principle can not be patented, "and this in one instance when one of the most important of all inventions of all ages was under consideration—that of the electric telegraph." The Government thought that by giving the inventor a monopoly it would delay the development of that most useful discovery, and so refused the application. In the same manner the government has a right to refuse a patent upon a chemical, such as *phenacetin*, for example. A patent on a process or machinery for making the chemical might not be objectionable, but the granting of a patent upon the chemical itself, and thus cutting off all opportunity for developing new and improved methods for its production does not seem wise public policy and compatible with the end in view, viz., the promotion of progress in science and the arts. Especially does the policy seem a foolish one when the manufacture of the chemical is conducted in Germany, and results in the enrichment of a foreign corporation. Still more foolish does it seem when it is considered that Germany will grant no such privileges to American inventors manufacturing in this country and exporting to Germany. But the height of unfairness is reached when our laws are so construed that *phenacetin* is protected in this country so that it costs at wholesale \$16 a pound, when, according to the *Chemist and Druggist*, it can be purchased under its chemical name (paracetphenetidin) in England for about \$1.25 per pound.

Now for the practical application of all this to the "Antiphthisin" case. Dr. C. P. Ambler, Associate Medical Director and Laryngologist, Winyah Sanitarium, Ashville, N. C., an institution where that preparation is being exploited, asked the privilege of reading a paper on the subject of "Antiphthisin" before the Section on Materia Medica, Pharmacy and Therapeutics of the AMERICAN MEDICAL ASSOCIATION. As chairman of the Section I gave my consent. This I was justified in doing, as "Antiphthisin" is the invention of the famous scientist, Klebs, of Klebs-Löffler bacillus fame, and Prof. Klebs was present in person to discuss the subject. In the discussion it developed that the product known as "Antiphthisin" is patented in Germany and a patent applied for it in this country. The name "Antiphthisin" is also registered as a trade mark in the Patent Office at Washington. "Antiphthisin" will not be made in this country, but will bear a stamp "Made in Germany." As the Code of Ethics of the AMERICAN MEDICAL

ASSOCIATION forbids physicians prescribing patented medicines it is not surprising that there were members present who seriously objected to permitting Dr. Ambler's paper to go unchallenged. Accordingly a resolution was passed and referred to the Business Committee of the ASSOCIATION in condemnation of "Antiphthisin." The Business Committee is composed of conservative gentlemen who will doubtless decide the question on its merits, yet it would be a very unfair thing to affix any serious penalty on Dr. Ambler for reading his paper, or to take any action under the circumstances that might injure the good name and reputation of Dr. Klebs.

When it is considered that probably 25 per cent. of the medicines prescribed by the members of the AMERICAN MEDICAL ASSOCIATION are claimed as proprietary by their manufacturers is it any wonder that Dr. Klebs considered the rule against proprietary medicines of no binding force, even if he knew of its existence? Was it any more objectionable for Dr. Ambler to read a paper before the Section on "Antiphthisin" than it would have been if he had made the subject "The Comparative Merits of *Phenacetin*, *Antipyrin* and *Salol*"? All these substances are patented, and their names are registered as trade marks.

Now is the time for the AMERICAN MEDICAL ASSOCIATION to take definite action in relation to the subject of patented medicines. Something must be done. The ASSOCIATION will not be satisfied with any compromise measures. The patenting of medicines is right or it is wrong. Personally I believe it is right if the scientific demands of the patent law are complied with. Now that the matter is brought clearly before the ASSOCIATION by the Klebs case let the matter be carefully considered, and acted on in a manner fair to all concerned. If the Code is to be sustained in this instance then let it be enforced all along the line and dismiss every member of the ASSOCIATION who prescribes *phenacetin*, *antipyrin* and *salol*. The Code can not be enforced in this matter. What then shall we do? Shall we indorse the use of patented medicines without qualification, and thereby indorse the nostrum trade *in toto*, to the utter ruin of scientific pharmacy? Shall we repudiate those manufacturing houses who have sacrificed many opportunities of making money by standing by the profession and throw our influence in favor of those who leave no stone unturned to throw the profession into disrepute by advertising to cure incurable diseases and jeering at the medical profession because of its admitted impotence in such cases? These are serious questions that demand an answer and the nostrum trade will not be slow to seize the opportunity to use it for the advancement of the nostrum business unless we answer these questions in such a manner that it will leave no doubt in the minds of the public in regard to our true position. We can not afford to fight the patent law, founded as it is on the Constitution of the United States, as it is eminently scientific and just, but we can demand that it shall be so enforced as to promote progress in the science of medicine and the useful arts of pharmacy and therapy, and not be a hindrance to all progress by patenting principles, protecting secrecy, killing competition and throttling trade under the guise of law.

**Ichthyol in Orchitis.**—Dr. Leedom Sharp recommends enveloping the inflamed testicle and cord in a 30 per cent. ichthyol ointment.—*Univ. Med. Mag.*, August.

## A CASE OF SUPPURATING MASTOIDITIS CURED WITHOUT CHISELING.

BY ALFRED HINDE, M.D.

SENIOR SURGEON EYE AND EAR DEPARTMENT, CENTRAL FREE DISPENSARY;  
OPHTHALMOLOGIST TO THE NEUROLOGIC CLINIC IN RUSH  
MEDICAL COLLEGE,  
CHICAGO, ILL.

N. McG., a robust Irish girl aged 17, about ten days in the United States, applied on May 8, 1891, for treatment on account of a severe earache of the right ear that had commenced twenty-four hours before and had become progressively worse since its onset. She gave a history of "catching cold" about three weeks previously, adding to it during the voyage across the Atlantic and on the cars to Chicago. On examination marked tenderness was elicited on pressure over the tragus and downward behind the ramus as far as the angle of the inferior maxilla. The drum membrane was intensely reddened, thickened, and its landmarks buried. The adjacent soft parts of the external auditory canal were swollen and injected, especially those of upper posterior wall. The mucous membrane of the nasal cavities was hypertrophic, and it and that of the naso-pharynx was still inflamed and discharging. The Eustachian openings were red and swollen. The ear disease was evidently an extension of the naso-pharyngeal catarrh, and the grade of the inflammation was such that an accumulation of pus was expected in the tympanum as soon as sufficient time had elapsed for its formation. The symptomatic treatment consisted in syringing with hot boric acid solution in large amount, and in a continuous stream into the external auditory canal; hot fomentations of the same solution applied to the region of the affected ear. In the absence of leeches, a fly blister was applied over the tragus. Saline derivatives to move the bowels were advised, and for the usually increased nocturnal pain pills of camphor and opium were ordered to be taken one every four hours as needed. Nasal cleansing with warm salt solution was ordered. The nose and naso-pharynx were daily sprayed with Dobell's solution and an eucalyptol-menthol-vaselin mixture. Beside every second day, after cleansing the naso-pharynx, a dram solution of nitrate of silver to the ounce was applied. Gentle inflation of the Eustachian tube was resorted to after a few days.

Ear pain continued, deafness increased, and a profuse serum-like discharge appeared at the external meatus; then the sufferings ceased. The discharge became muco-purulent and lastly purulent and lessened in amount under the above treatment, and the perforation of the drum-membrane decreased in size. The membrana flaccida was now seen to be bulging and of yellowish-red color and on this, the thirteenth day of the disease, it was freely opened under cocain, but the pain produced by its incision was so severe that the patient did not return for treatment for sixteen days following. During the latter time no treatment was had. She returned, however, with a complete relapse of all the inflammatory ear symptoms and a slight ear discharge. Beside, there was some headache on the right side, and slight tenderness on firm pressure over the right mastoid.

A free incision of the membrana tympani was advised, and a crucial incision was made in its posterior half and much sanguinous pus was evacuated, and a thorough cleansing, with the peroxid of hydrogen and the other solutions, was resorted to. At this period of the disease the Eustachian tube could not

be opened by any means whatever. The urgent symptoms decreased rapidly and the case did well for eight days, when another relapse occurred.

The patient became pale and looked sick, the ear discharge continued, the headache and mastoid tenderness returned and increased. A slight edema and redness of the soft parts over the mastoid appeared and a Wilde's incision was suggested but objected to, so that the foregoing treatment was continued. The symptoms increased in severity. The mastoid tissues became more swollen and painful and pyrexia (101 degrees F.) supervened, upon which latter quinin had little effect. She sickened still further and was unable to attend to her domestic duties. During two days she vomited at intervals and was nauseated all the time, and could not eat or sleep. An incision of the mastoid process was urged, but permission was only given to cut through the soft tissues and this was done freely, close to the pinna, through the periosteum, and an inch in length. A small amount of thick, creamy pus was evacuated from beneath the edematous tissues, the wound was irrigated, and the bone was found to be sound and without any opening into it, and permission to open it was positively refused by the patient and her friends. The drum membrane was again incised and the parts thoroughly irrigated. After this the symptoms rapidly decreased and the patient was quite comfortable again for a week. The mastoid swelling and tenderness disappeared so long as the wound remained open, but when it had almost closed she again became ill with a complete recurrence of all the ear, mastoid, head and stomach symptoms and fever. An opening into the affected mastoid was urgently advised but more positively refused. A second incision through the soft tissues over the mastoid was done and a slight amount of pus again let out. The bone was not osteo-porotic but perfectly healthy. No sinus was visible in the exposed field, but after a protracted search in all possible directions with a No. 6 Bowman's probe the latter sunk into the bone through a normal canal to the depth of three-quarters of an inch, and in the upper posterior part of the mastoid process. The incision through the soft parts was now made to expose this opening into the bone. The bone was laid bare and found to be perfectly normal, and undoubtedly the passage-way was a physiologic canal giving exit most probably to an emissary mastoidal vein (the emissarium mastoideum of Santorini). The membrana tympani was again freely incised. Into the newly found opening in the mastoid was inserted the tip of a finely-pointed, tightly-tied medicine dropper whose point diameter was one-sixteenth of an inch. It snugly fitted the entrance and through it was injected a dropper full of sterilized water—the drum perforation being watched at the same time—and pus was seen to ooze from the tympanum into the external auditory canal as the water disappeared from the large bulb of the medicine dropper under extreme pressure into the mastoid cavity.

This was repeated until the external auditory canal was filled with a watery pus and the patient felt fluid running into the throat and coughed it out. An open way was thus demonstrated between the mastoid process and the tympanum and through the Eustachian tube, and seeing that we had no choice, we decided to try and drain the abscess through existent openings. Irrigation was continued until clear water escaped from the ear. The relief of symptoms was almost

immediate and the patient slept well the first night and next day was much improved in appearance, and said she felt almost well—the head and stomach symptoms were all gone. The ear was discharging freely, and we injected a solution of peroxid of hydrogen and watched the bubbles escape through the perforated drum membrane, and the entire external canal became filled with the same, and the patient coughed the froth out of her throat and blew it out of her nose. Afterward a one-half per cent. warm solution of carbolic acid was injected and last of all an alcoholic solution of boric acid was used and the latter caused considerable temporary pain. The mastoid wound was dressed in the usual way and the nose and throat treatment was continued. So rapid and marked an improvement resulted from the daily treatments that at the end of four days the ear discharge had almost ceased and what little was still present was thin, pale and watery, and seen only in the neighborhood of the perforation in the drum membrane. At the end of one week from the initial injection of the mastoid a mere speck of watery moisture at the site of the drum perforation was mopped up on cotton, and on examination, per microscope, was seen to consist of detritus, with a few granular, breaking down, and fissured pus cells. Ear treatment was now discontinued. A plug of cotton was kept in the external auditory canal, and the mastoidal wound was allowed to close. In another week the tympanic perforation and the wound of the mastoid had healed and the case was dismissed with the request that the nasal douchings be continued. The cure was complete, and it proved to be permanent as no relapse has since occurred. One year later the hearing distance for the watch was 11-40, whereas for the left ear it was 40-40, and the tuning fork was heard in all positions, better in the right ear. In all, the diseased process had lasted about fifty-eight days in the right ear, but a complete and thorough drainage and antisepsis of the infected cavities had been instituted for only four to seven days before a perfect and permanent cure resulted. This is the indication in all suppurative processes, but it is notably difficult to accomplish in aural surgery without opening up freely the suppurating cavities. This case shows, however, that, even as dangerous as conservative surgery is in such ominous cases, very occasionally a cure may result from simple methods.

16 Laffin Street, Chicago, Ill.

## THE CHURCH OF ROME AND THE LEPERS OF COLOMBIA.

BY ALBERT S. ASHMEAD, M.D.  
NEW YORK.

I send you an appeal of the order of St. Lazarus for help to the unfortunate lepers of Colombia. Formerly the grand master of this order had to be a leper himself. His Grace, the Archbishop of New York, informs me that this manner of qualification for the grandmastership was abolished by the Holy See in 1253.

### LECTURE.

Lecture given by the Reverend Father (Salesian) Evasio Rabagliati, in the Solemn Session of the Society of St. Lazarus (Bogota, Colombia) on July 7, 1895. (Exordio—Et occurrerunt ei decem viri leprosi, qui steterunt a longe et levaiverunt vocem suam dicentes: Jesu preceptor, miserere nostri—and there met him ten men that were lepers, which stood afar off; and

they lifted up their voice and said: "Jesus, Master, have mercy on us.")

The first thing we should observe in this story is the great and exquisite kindness of Jesus, etc.

Brethren, not far from here, not one, not ten, lepers lift their voices, there are many more. In Agua de Dios there are 850, in Contratacion (Santander) I left, a few months ago, 700 and more; and all these lift their voices, in order that you may hear them. And what do they say? What is their plea? The same as that of the gospel, *miserere nostri*, have pity on us. . . .

Until to-day, according to data gathered in a private manner, I believed that the number of lepers of Colombia did not exceed 15,000 or 16,000. Now, I see that I was mistaken. Before I ascended this pulpit one of our physicians, Dr. Carlos E. Putnam, member of the Academy of Medicine, Bogota, assured me that I was; for he, after asking from all the departments the precise number of the patients, obtained this result: That the number of lepers in the whole Republic of Colombia on July 6, 1895, amounts to 27,250! Is there an error in this account? Who knows? For my part, I will admit an exaggeration; I will suppose that there is an error in the figures; I will try to believe that the number does not reach 20,000, even less; that there are not more than 15,000. Do you think that if we can abate a few thousands of the official account, this is an argument that ought to quiet us? Even thus, do you not believe that the calamity is great, and that the consequences for the future would be serious and baneful. . . .

During fifteen years which I passed in the Argentine Republic, in Uruguay and in Chili, I did not see one leper. If anyone should take the time and patience to gather precise data on this subject, "Leprosy in the World," the result would be, that the Republic of Colombia alone has more people attacked by leprosy in its different manifestations than all the other nations of the universe. Really such a thing is amazing and terrible. . . . Let us ask the men of science, the physicians; they all, unanimously, will tell us that the principal causes of this disease are heredity and contagion. As to heredity, there is not the least doubt; the Lazarinos themselves acknowledge that either the children or the grandchildren inherit the disease; the germ remains. Who is able to say what enormous proportions the disease must assume through this cause? As to the contagiousness, not being competent I shall give no opinion. All the Lazarinos say that the disease is not contagious. Almost all the physicians say that it is; and I have said almost all because in the medical congress held at Bogota about two years ago, of more than one hundred physicians called upon to give an opinion on the matter, only two said, No. All the others answered in the affirmative. Who was mistaken? The two or the ninety-eight? But I give my opinion, whatever its value. I believe there are climates unfavorable to the disease, and that others favor it. In the first place there will be no contagion, or it will be very slight; in the other case there will

<sup>1</sup> And it came to pass, as he went to Jerusalem, that he passed through the midst of Samaria and Galilee. And as he entered into a certain village, there met him ten men that were lepers, which stood afar off. And they lifted up their voices and said: "Jesus, Master, have mercy on us." And when he saw them, he said unto them: "Go show yourselves unto the priests." And it came to pass that as they went they were cleansed. And one of them when he saw that he was healed turned back, and with a loud voice glorified God. And fell down on his face at his feet, giving him thanks; and he was a Samaritan. And Jesus answering, said: "Were there not ten cleansed, but where are the nine? There are not found that returned to give glory to God save this stranger." And he said unto him: "Arise, go thy way, thy faith hath made thee whole." St. Luke, xvii: 11-19.

be contagion and it will manifest itself rapidly and energetically.

One fact most evident is that the evil increases every year. In the year 1888, according to the statistics of the Lazarinos of the Department of Santander, which were made conscientiously by one of the most distinguished physicians of that Department, the number of patients in that year did not reach 1,500; in October of the next year, I think, I met from 5,000 to 6,000; I have since heard from persons of competent authority that I had been very much mistaken, for in the department in question there are not less than 10,000 lepers. There is another fact which is evident. A few years ago this disease was totally unknown in Antioquia; now it is frequently seen there. In the Cauca we hear the same story; the number of the lepers can not be very small, when we consider that the authorities of that department have decided to establish a lazaretto for their exclusive use.

Allow me to speak with entire frankness. The public in general believe that isolation exists, because we have a large lazaretto a few leagues from the capital, in Agua de Dios, and another lazaretto in Santander. That is true; but these lazarettos have only the name of a hospital, and I may say without the least exaggeration there might be written over the entrance of both, "Fabrication of Lazarines." I can tell you, even now, that in both these leper houses the healthy are much more numerous than the diseased; two healthy ones to one sick; this is the proportion of the population of the lazarettos. But what are the healthy people doing there? Some, the smaller number, probably attend to the patients; it is the healthy daughter who accompanies and attends her mother, or *vice versa*; it is a brother, some relative who does not want to forsake a sick brother or relative; to that there is nothing to say, it is a laudable act of charity which these healthy persons are performing, and God will not leave this work of love without reward. But, on the other hand, there are other healthy persons, the greater number, probably, who are there for other reasons. Some for the purpose of doing business, others with the infamous object of exploiting the poor lepers. On this subject, I have been told in the Lazaretto of Contratacion of incidents that were really scandalous. Moreover, in both lazarettos he enters who will, and remains as long as he likes; he may even establish his residence there if the whim takes him to do so, without anyone having the right to interfere. . . . The attendants are generally healthy persons, who have to live in intimate contact with the diseased, eat at the same table, perhaps from the same plate, sleep under the same roof, use the same garments.

And now, tell me frankly your opinion, are these lazarettos just as we see them, places of danger, or are they not? You must consider, that from these houses the lepers may go to other places and establish themselves in the villages with the greatest facility. Any pretext is good; if there is none, one is invented. It is not the President of the Republic who gives these permissions, not even the *alcalde* of Tocaima, which is the nearest place to the lazaretto. They may be given simply by the administrator or a person delegated for that purpose.

We recognize the necessity for a large and unique lazaretto; but where? The prospect of the island of Coiba, in the Pacific ocean, as a place of isolation has entirely failed for many reasons; and the most forcible

of these, in my opinion, was the obstinate resistance of the lepers. They have told me over and over again, on all occasions, "We shall flee to the woods, Father, we shall hide in the mountain caves, we prefer starving here; but to the island we shall not go." I have consulted reliable persons on this matter, and they have pointed out to me the plains of Casanare, or of San Martin. The idea of taking Casanare could not be considered, because it is a region very little adapted; 1, because these plains have a large population; 2, because the inundations are frequent during many months of the year. In San Martin it is very different; the rivers are not so numerous nor so rapid; we can find with exceptionally favorable conditions, a great plain, surrounded by the Meta and Nare Rivers, which form a very beautiful peninsula several leagues in extent, the elevation rendering flooding impossible, however rainy the winter may be; and it has other advantages not necessary to enumerate here. As to population we may say it has none; it is a desert pure and simple.

The successor of Don Bosco, the present superior of the Salesian order, Don Miguel Rua, long ago solemnly promised the representative of Colombia in Rome, the most excellent Dr. D. Joaquin Vélez, to send as many monks to Colombia as was necessary to execute this project. In one of his last letters, dated from Bogota, he approved and blessed it and encouraged us to begin to execute that great idea. The friend and father of the Lazarines, Father Miguel Unia, also approved the project, and thinks it feasible; he, who is speaking to you, has received from his superiors of Turin all the means necessary to consecrate himself exclusively to this mission, and after the feasts of Our Lady of Carmen he will be entirely at the disposition of the public. He will fulfill his promise and begin his journey from place to place through the whole extent of the republic to ask for the mite of Colombian charity; if this shall be the decision of this conference. I wish before starting, to speak to you again; in order to further elucidate these ideas, and answer the objections which may be made. In the meanwhile, to the intelligent, distinguished and charitable people of the capital, I intrust the project. To all, without distinction of opinion, either religious or political, I recommend it most seriously; study it, discuss it, amend it also, if you see fit. What is important to all is to arrive at satisfactory and feasible solution. Especially do I intrust it to you, men of science and of arts, to the physicians and publicists; adopt this project, make it your own, and let your valuable opinion be spread to the last confines of the republic, in order to fill with hope the heart of all lepers, and with charity and generosity the hearts of all Colombians.

My last word is for you, virtuous and devoted Sisters of the Society of San Lazaro. May God bless you for all the good you have done during the four years of existence of your beloved society. Forward, with perseverance, you have done much; but there remains immeasurably more to do; enlarge the sphere of your activity, increase your ranks; every Colombian whose heart beats with love of religion and fatherland must enter them. Your work is a work of redemption above all others. Do not be discouraged by the difficulties which you will meet; remember that every great and holy work must bear the seal divine, the seal of contradiction and struggle. Once passed through the crucible, the work will prosper

and triumph. God certainly has blessed and is blessing us now, for his Vicar on earth, the Sovereign Pontiff Leo XIII, has blessed you and blesses you now. You find the proof of that in the treasure of indulgences, partial and plenary, which he sent you last year. Be ye all enthusiastic propagandists for the project which I have announced; and with your fervent and constant prayers help the work which we undertake.

In the name of God, in the name of your wards, the lepers of Agua de Dios, in the name of religion and fatherland, I send you the most sincere thanks. And for all you have done, and all you may do in the future, all the glory will be solely for God and the salvation of souls.

*Ad Majorem Dei Gloriam.* I have said.

#### PASTORAL.

We, Bernardo Herrera Restrepo, by the grace of God and of the Holy Apostolic See, Archbishop of Bogota, to the clergy and to the faithful of the Archdiocese:

All the good sons of Colombia who are animated with Christian charity toward their fellow men, are deeply concerned by the sad situation in which are placed so many of our brethren, who suffer this terrible disease of leprosy and its painful and inevitable consequences of isolation and perhaps of abandonment and utter want.

The church could not do less than take part in that general solicitude; and, therefore, if in other times and in similar circumstances, men especially called to help the poor diseased arose from among her ministers, now, too, by means of the sons of Don Bosco,<sup>2</sup> she gives examples of love for the unfortunate lepers. They with the spirit of sacrifice which is above all praise, live among these unfortunates, nursing them as a father would, and offering them in life and death the consolations of religion.

Now the great work of the founding of the national lazaretto having been begun with the object of insuring to the lepers habitation and means of subsistence to make their lives less bitter and of opposing the spread of the contagion, the Salesian Fathers will announce and propagate this grand work in the whole republic. With that object, the Reverend Father Evasio Rabagliati prepares to journey about in the republic in order to persuade all to coöperate according to their means and to contribute with their alms and voluntary donations.

It is our duty to support this holy and charitable enterprise; and for that purpose, we appeal to the clergy and to the people of the republic, and especially of the city of the archdiocese entrusted to us, and we request everyone to give a hearing to the Christian sentiments of his heart, and to contribute as largely as he can to the founding of the national lazaretto, delivering into the hands of the Rev. Father D. Evasio Rabagliati the alms which he destines for that purpose.

Our Lord, God, will reward all those who help in this work of Christian love which we recommend; they will return an hundred-fold to the giver the goods which will be offered for the relief of those who cry like Job:<sup>3</sup> "Have pity upon me, have pity upon me, O ye, my friends; for the hand of God hath touched me."

This pastoral shall be read twice in all the churches in the archdiocese. Given in Bogota, Aug. 4, 1895.

BERNARDO,  
SALUSTIANO GÓMEZ RIAÑO, Archbishop of Bogota,  
Canonical Secretary.

## CONGENITAL ABSENCE OF THE ESOPHAGUS.

BY DANIEL LICHTY, M.D.

MEMBER OF THE AMERICAN MEDICAL ASSOCIATION,  
ROCKFORD, ILL.

A writer in a late issue of the *JOURNAL*, in an article on a subject remote from this, made the statement that "malformations of the *internal* organs of the fetus are still more rare than the various orthopedic lesions of the exterior body." In confirmation of this, a case of the above title came to my notice, whose rarity then impressed me, and it is here given to add to the peculiarities and mysteries of tissue growth in pre-natal life. If those who have the *Index Medicus* can find similar cases recorded in it, it would be interesting to know of them.

There was born in Rockford Hospital July 24, 1895, after a quite natural and easy labor, of a healthy Swedish mother aged 25, her third child, a male weighing six and three-fourths pounds, well formed and fully developed in all its external parts. After birth there was some of the obstructive mucous respiration often observed, which usually passes away after wiping the mouth, a drink of water, inverting the child and such like procedure. In this case, however, it persisted from day to day; it could nurse and seemingly swallow. There was nasal regurgitation, though the hard and soft palate and pharynx were perfectly normal; the gurgling respiration continued in spite of all efforts to relieve it, and on the eighth day the child died of inanition.

The privilege of a postmortem examination was obtained from the grieved but sensible parents. Exploration began by removing the sternum, dissecting through the thyroid isthmus, exposing and inspecting the larynx and trachea, which were each found normal except being filled with the ingested milk; a soft catheter was passed into the pharynx and esophagus which met obstruction that resisted further advance. Deeper dissection brought to light the esophagus ending in a distinct cul-de-sac, in which the tip of the catheter was engaged at the second dorsal vertebra. The lumen of the gullet was normal to this abrupt terminal, being about one centimeter in diameter, easily admitting a No. 12 catheter. Two centimeters below this and a little to the left, as would follow the normal course of the esophagus, began a fibrous impermeable cord one millimeter in diameter, very gradually increasing in size, in its passage through the diaphragm, until the natural dilatation of the stomach was attained, where its permeability was reestablished, and the remainder of the alimentary tract was of normal form and function throughout. No other malformation was discovered.

**Minnesota Coroner's Fees.**—Where the coroner on the same day makes two separate examinations of two different dead bodies, or holds an inquest on one body and makes an examination of the other, the supreme court of Minnesota holds, in *Kistler vs. Board of Commissioners of Hennepin County*, decided June 24, 1896, that, under section 5554, General Statutes 1894, he is not entitled to a fee of five dollars for each examination and each inquest, or to anything more than five dollars per day "for the time actually spent."

## SOCIETY PROCEEDINGS.

## British Medical Association.

*Sixty-fourth Annual Meeting held at Carlisle, Eng., July 28-31, 1896, under the Presidency of William Barnes, M.D., F.R.C.S., J.P., of Carlisle.*

(Continued from page 378.)

[Reported for the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.]

Dr. W. F. ROBERTSON, of Edinburgh, gave in the Section on Psychology, a microscopic demonstration upon the pathology of hematomata auris. The sections illustrated the various stages of the degenerated lesion in the ear cartilage, which, as had already been contended by Fischer, Pareidt and others, prepared the way for the occurrence of the hemorrhage. Typically this took place from new vessels in the wall of an intra-cartilaginous cyst. It was shown that these vessels were specially prone to a degenerative change, which must render them liable to rupture from slight violence, or even spontaneously. The blood was slowly effused into the cyst, which tended gradually to enlarge by separation of the perichondrium.

In the same section, Dr. A. Robertson of Glasgow read a paper on "The Treatment of Mental and Nervous Diseases by Animal Extracts." He first drew attention to other special methods of treatment which he had used in his practice, before considering the group of therapeutic agents which were the subject of the paper. These special methods were:

1. Heat and cold to the head at graduated temperatures. In some cases of insanity recovery was at least largely due to this mode of treatment.

2. Mechanical stimulation of the brain and membranes by percussion of the skull. This has conduced to the recovery of some patients.

3. By electrization of the brain through the medulla. One electrode passed along the floor of the nostril, rests on the cervical spine, the other is moved slowly over the convexity of the head. He had not yet used it in the insane, but is now recording a case of diabetes insipidus cured under this mode of application.

4. Psychical, combined emotion and suggestion. The rapid recovery of a patient after mental shock is referred to, and the fact that it has been tried by the writer as a mode of treatment is mentioned.

5. Hypnotism should not be discarded. Its power over the nervous system is illustrated by the intermediate and confirmed recovery of a patient recently in the Royal Infirmary suffering from hemianesthesia, after other treatment had failed.

He then proceeded to record his experience with organic extracts, and also his impressions of their value. He had made observations on the effects of the following preparations: The fresh brain of the sheep; cerebrinin, an extract of the cortex; thyroid extract; Brown-Séguard's testicular liquid; the thymus gland. These preparations were then discussed in their order.

The author closed with the remark, that in the thyroid and cerebral extracts, as well as the other special methods of treatment referred to at the outset, we have additional remedial measures, and it is the duty of the physician in charge of the insane to have recourse to them in suitable cases.

Dr. RUTHERFORD MACPHAIL made some remarks on

## POST-INFLUENZA INSANITY.

In which he presented an analysis of twenty cases admitted under his care into the Derby Borough Asylum in the five years ending Dec. 31, 1895. He included only cases among the recent admissions whose insanity was attributed to influenza, or who were reported to have had an attack of influenza a few months previously. This represented 4.8 per cent. of the admissions.

Of the twenty cases, nine were men and eleven women. The youngest patient was a lad aged 18, the oldest a man aged 71. The average ages were, for men, 37.6; for women 39.2. The largest number of cases (eight) occurred in the fifth decade. Hereditary predisposition to insanity was admitted in six of the twenty cases. In all except two the attack of insanity was an initial one. As to the form of mental disease, melancholia occurred in the cases of three men and seven women, mania in five men and four women, and one man was a general paralytic. Fifty per cent. of the cases were therefore melancholics, a larger proportion of melancholia than usual, for the records of the asylum during the five years in question show only a percentage of twenty melancholics to all admissions. The type of melancholia varied from simple depression to the acute forms, with well-marked delusions. The delusions most common in the maniacal cases were those of suspicion and of poisoning.

Four of the cases were actively suicidal and had made attempts on their lives at home.

The results were as follows: Among the men, four recovered, two were relieved, one died and two are still under treatment and are chronic. Of the women, eight recovered, one died and two have become chronic. All the melancholics recovered except one woman who died. The average residence in the asylum of those who recovered was three months for men and four months for women. These numbers are too small to permit of any definite conclusions, and accordingly no attempt was made to dogmatize. It was, however, worthy of note that in the cases under review the average percentage of recoveries to the total admissions was higher than usually obtains in public asylums, while the average period of asylum residence was considerably lower.

In the section on public medicine Mr. GORDON SHARP, of Leeds, contributed a paper entitled:

## THE SOIL IN RELATION TO DIPHThERIA AND ITS ORGANISM.

He drew the following conclusions:

1. Diphtheria would appear to be endemic in certain districts. Soils organically laden are dangerous, but much may depend on the nature of the subsoil. Where the subsoil is porous a neighborhood may be free. Where the subsoil is impervious the surface at certain seasons of the year may be a favorable breeding ground.

2. I think I am justified in deducing that soils which would otherwise be sources of the spread of diphtheria are rendered innocuous by deep drainage.

3. The presence of a large quantity of air in the surface soil appears to be salutary and the contrary holds. However, this may be an accidental circumstance.

The close connection between enteric fever, scarlatina and diphtheria has often been remarked, and Bond has especially called attention to the close relationship between scarlatina and diphtheria, and formerly the connection seems to have been even more marked. Thorne has called attention to the fact that as authorities have improved their water supply, enteric fever has declined in frequency, while under the same conditions and with improved sewerage systems diphtheria has increased. Immersion in water for a short time seems fatal to the microbe of diphtheria, while the contrary holds with regard to the organism of enteric fever; both seem to live in sewage. A moist rather than a water-laden soil seems to be the home of the organism of diphtheria.

Mr. JAMES NIVEN, of Manchester, followed with a contribution entitled:

## THE PUBLIC HEALTH ASPECTS OF TUBERCULOUS DISEASES.

He said that preventive action in this affection should take something like the following shape:

1. Information as to the precautions needed to be taken should be distributed to every home from time to time, until a sufficient body of opinion was created on the subject.

2. Tuberculosis, attended with discharge, should be made a notifiable disease. This would entail additions to the sanitary staff, including probably a qualified medical assistant. The objects of notification would be: (1) To gather precise clinical knowledge as to the various conditions under which individuals contract tuberculosis. During such an inquiry in Oldham in 1889 I found that more than half the deaths from tuberculosis investigated were of people who had previously been in intimate and prolonged intercourse with previous cases. (2) To ascertain and remove insanitary conditions about the house as speedily as possible, so as to give a chance to the patient of recovery, and so as to diminish the risk to the other members of the household. (3) To distribute printed information on the preventive measures required, and to bring about an understanding with medical practitioners as to their giving systematic personal instruction to the patient and attendant.

3. Hospitals for consumptives are at present foci whence a practical knowledge of preventive measures radiates. It may be doubted whether the time is ripe for the establishment of such hospitals at the public expense. If this becomes possible, such hospitals would greatly aid in reducing the amount of infective material in circulation.

4. To prevent the milk from tuberculous cows remaining the source of danger which it now is we require a systematic examination of in all cowsheds by competent veterinary inspectors. Two assistant veterinary surgeons have recently been appointed in Manchester for this purpose, and already five cows have been slaughtered as tuberculous and found to be so. This appointment is one which I have had much at heart. The milk of suspected cows will also be examined bacteriologically where the grounds for condemnation are otherwise not perfectly clear. The veterinary surgeon is now authorized by the corporation to examine suspicious cows with tuberculin. Under new reg-

ulations an effort will be made to bring the cowsheds into a tolerably sanitary condition—at least those which can be so amended. If the cowsheds are cleansed with water twice a day and the cows kept clean, and if in addition the cowsheds are kept well lighted and well ventilated, then there will not be much risk of infection between cows and human beings or from cow to cow.

5. All meat and pork should be thoroughly examined; hence no meat should be taken direct from a private slaughterhouse for sale. The presence of tuberculous glands in meat or pork should suffice to condemn it. In the case of animals killed at the public abattoir this criterion is not required. It is the more necessary that it should be rigorously applied in other cases.

6. Cats certainly, and fowls possibly, are a serious source of danger. More attention should be given to the diseases of which cats have died—and, indeed, the cause of death of all our domestic animals should be fully investigated.

DR. F. A. DIXEY of Oxford, read an interesting paper on

#### VITAL STATISTICS OF DIPHTHERIA IN LONDON.

The most interesting question in the paper was that of the effect of the antitoxin treatment of this affection. On this point the general conclusion reached by the author in a former paper was fully maintained, and he asserted that the diphtheria mortality of the metropolis had received a considerable check which it was difficult to attribute to any other cause than the introduction of the serum treatment. We quote *verbatim* from the paper the following:

"Comparing together the average weekly number of deaths for the last five years, we find that after rising from 26.2 in 1891 to 36.2 in 1892 and 62.8 in 1893, it fell to 51.4 in 1894 and 44.5 in 1895. It is true that the opening months of 1895 promised a greater diminution than that exhibited by the figures for the whole year, and that the intensity of the rise last autumn seems to show that some other factor than the antitoxin treatment must have been concerned in the diminished mortality at the end of 1894; but notwithstanding these facts, which are freely admitted, it would seem that the general run even of these figures suggests a conclusion favorable to the efficacy of the treatment. This conclusion becomes strengthened if, in place of the actual number of deaths, we consider what is of course a truer test of the matter at issue—namely, the case mortality, or relation of deaths to notifications. Under this head the main facts are as follows: The number of cases notified during 1893 was 13,694; of deaths during the same year 3,264; giving a case mortality of 23.8 per cent. In 1894 the corresponding figures were 11,190 and 2,674; the case mortality stood, therefore, at 23.9. In 1895, however, while the notifications rose to 11,229, the number of fatal cases fell to 2,289, and the case mortality was therefore only 20.4 per cent., the lowest rate for the whole year yet recorded. The numbers for the first half of the present year are respectively 6,193 cases notified, and 1,239 deaths, which work out to a case mortality of 20.2 per cent. In view of the fact that quite irrespective of the number of cases, the case mortality of the last half of the year is invariably below that of the first, it may fairly be anticipated that by the end of 1896 the year's case mortality will for the first time on record have sunk below 20 per cent. This diminution in case mortality, which appears to be still in progress, represents the annual saving of some hundreds of lives, and I may be allowed, in conclusion, once more to repeat that it is difficult to see what cause can have been at work during the last two years in producing so marked a result, unless it be the treatment by antitoxin."

DR. A. SHERIDAN DELEPINE of Manchester, in his opening address as chairman of the Section of Pathology, dwelt on the place of pathology in medical education, saying that it formed such an important part of medical science that any question touching medical education necessarily concerns teachers of pathology, who should do their utmost to make their subject useful and not a stumbling block to the medical student. This is all the more important as pathology has only of late been recognized in our universities or colleges as a subject worthy of a special chair.

To quote Professor Hamilton's words: "It will, I think, be granted that the pathology of to-day is not delimitable merely as a matter of pure morbid anatomy, pathologic histology, pathologic physiology, pathologic chemistry or clinical medicine, but that these are simply the members of a great body, and that they are indissolubly bound together."

He first considered how the subject is taught in schools thus:

1. Under the name of clinical medicine, that part of pathology which deals with symptoms, diagnosis, prognosis, is taught at the bedside with applied therapeutics.

2. The same subjects are also usually dealt with in system-

atic lectures on medicine and surgery, lectures which are also very often made to cover a considerable portion of other branches of pathology.

3. Pathologic anatomy is taught in systematic lectures and demonstrations, and practically in the postmortem room.

4. Pathologic chemistry and histology are taught by means of lectures and demonstrations, and of practical classes.

5. Etiology and pathogenesis are taught by means of lectures, which are sometimes complemented by a practical course in bacteriology.

6. Experimental pathology is reserved for advanced students, and does not form a regular part of any curriculum.

If all these subjects were taught by the same man, he would certainly not require to say in systematic lectures what he had already clearly explained at the bedside or in the postmortem room, or in the laboratory; he would as much as possible try to save his own time as well as that of his pupils by not repeating himself. He would reserve for lectures those subjects that can not be easily and better taught by actual demonstration.

Is it possible for three or four men teaching the various branches of the same subject so to combine their efforts as to give students the benefit of advantages which they would derive from being taught by a single man? He believes that, within certain limits, such a thing is possible on condition that the following principles be kept in mind by all teachers:

1. Every fact capable of simple actual demonstration should be taught by means of demonstration whenever this method does not involve excessive loss of time, considerable expense, wanton cruelty or a knowledge of methods unknown to the student.

2. In each department the teacher should, as much as is compatible with clearness, confine his teaching to the demonstration and exposition of those facts which fall within the natural sphere and the actual work of his department.

3. It seemed to him also important that the time devoted to the study of each branch of medicine should be proportional to the relative importance of the facts and principles taught, rather than to the number of details which have erroneously been thought to be necessary elements of certain studies. And in determining the relative value of scientific courses from an educational point of view, he would feel inclined to give the preference to those in which it is possible to make the student see and judge for himself. Lectures should be reduced to the smallest number compatible with a clear exposition of those principles which would otherwise have to be constantly repeated in the course of practical demonstrations, or to those subjects which are not capable of demonstration at all.

In order to give a more concrete form to his ideas, he asked the members to suppose that they follow a student desirous of gaining personal knowledge in his study of cases, medical or surgical.

1. In the wards of the hospital he is shown how to recognize the presence of certain symptoms, and from this to establish a diagnosis; he then sees various modes of treatment, surgical or medical, applied, and is made to note the course of events that follow, being thus initiated to the art of prognosis. Here the only means he has to test the accuracy of the views expressed to him by his teachers are the effects of treatment and the correctness of the prognosis.

2. In the postmortem room he has an opportunity to see for himself what gross lesions correspond to some of the symptoms to which his attention has been attracted during life. The meaning of the appearances due to alteration of size, shape, color, etc., have to be explained to him as far as it is safe to do so from a naked-eye examination. The teaching in the post-mortem room can not go further, and is necessarily fragmentary.

3. It must therefore be supplemented by demonstrations of museum specimens by which complete series of lesions, some of which occur rarely in the postmortem room can be made to illustrate the coarse anatomic changes produced in the body by disease. Such specimens being provided with short clinic histories, there should be as little room for speculation as possible regarding the nature of the symptoms associated with the lesions. This general study of morbid anatomy is specially useful in directing the mind to the parts of the body which are most generally affected by disease, and to the way in which certain symptoms are mechanically produced. Naked-eye anatomy, however, gives very little information regarding the nature of the reactions of the organism to morbid agents; it seldom gives the means of finding the actual cause of diseases, and it must be admitted that many of the naked-eye appearances are so ambiguous that even an experienced morbid

anatomist is often mistaken as to the meaning of lesions observed in the postmortem room or in the museum.

4. In the histologic laboratory the student sees the changes of structure which give rise to the appearances observed in the postmortem room, and here he begins to be on firmer ground and better able to acquire a knowledge which will depend less on an extensive practical experience than on well-trained powers of observation. The reasons for this are: 1, that all the organs of the body are composed of a few elementary tissues; 2, that these tissues are composed of cells which have many properties in common; 3, that the morphologic changes indicating the reaction of these cells to pathogenic agents are very comparatively few. It is, therefore, possible for a teacher to impart within a limited space of time and by means of actual demonstrations a tolerably complete and accurate notion of the anatomic changes produced in the organism by disease. It is to these advantages and not to any special fancy for microscopic work that pathologic histology has taken such a leading part in the study of disease.

5. We now come to the most difficult part of pathology. So far, we have had to deal only with the objective parts of the subject, with facts which necessitated chiefly powers of accurate observation, and which could all be easily demonstrated. When we come to deal with causes of disease and with the way in which lesions are produced we must necessarily introduce into our work induction, deduction and experimentation. When a number of facts seem to indicate that two or more phenomena are correlated and due to the action of a certain cause, we feel generally, when dealing with biologic problems, that we may have overlooked many factors, and therefore we have to test our views by experimentation. Experimentation is not, however, always guided by direct observation, for it often happens that the causation of certain lesions is inferred from what we know of the causation of other more or less analogous lesions.

The conclusion which the speaker drew from the above considerations was that students could obtain a more useful knowledge of medicine if they had fewer lectures and more practical courses. They should be made to attend thorough practical courses on: 1, pathologic anatomy, histology and chemistry; 2, bacteriology as applied to the study of infectious diseases; 3, general clinical medicine and surgery, with special courses in special branches of clinical work, such as diseases of women and obstetrics, diseases of children, infectious diseases, mental diseases, diseases of the eye, of the ear, of the throat, etc.

Systematic lectures should be confined to courses on: 1, etiology of disease and pathogenesis; 2, general considerations regarding the practice of medicine and surgery. These courses should be as short as is compatible with a clear exposition of those principles which but very few students would be able to formulate for themselves from the study of facts.

SIR JOSEPH EWART of Brighton in opening the public medical section, delivered an address upon the lowering of the general death rate. He said that in time typhoid fever, consumption, scarlet fever and many other diseases would come to be prevented with as much success as had attended the warfare against scurvy, the plague, leprosy, cholera, etc., and to assist in securing that end our scientific machinery should be perfected.

One of the subjects discussed in the section was vaccination and revaccination, and a resolution was passed that it is desirable that calf lymph should be made universally available by the State.

The section on ethics discussed the abuse of the out-patient system in hospitals. MR. LOCH, secretary of the Charity Organization Society, read a paper in which he said, that while there were 87,000 in-patients in London hospitals, there were over a million and a quarter out-patients. Millions of out-patients at hospitals must mean large numbers of patients withdrawn from the general practitioner. He suggested that the number of out-patients should be limited to as many as could be fully and fairly dealt with in the allotted time, and that there should be a well-trained almoner at a hospital able to make proper inquiry or insure its being made.

DR. NELSON HARDY challenged anyone to say that the out-patient departments were carried on by assistant physicians out of charity and benevolence. The appointments were accepted by them with a view to their own advancement and ultimate profit.

DR. G. H. BROADBENT of Manchester read a paper on "Provident Dispensaries," cautioning medical men against such institutions.

DR. MAJOR GREENWOOD of London said the cheapening of medical services through the outdoor departments of hospitals was doing an appalling amount of mischief to the medical profession, and the time had come to secure radical reform. Other members spoke on the same line.

DR. ALEX. OGSTON of Aberdeen presided over the Section of Surgery.

An interesting discussion on

#### PROSTATIC HYPERTROPHY

was opened by DR. DAVID MAC EWEN of Dundee, who said that as long ago as 1856 Mercier had suggested the operative treatment of an enlarged prostate which was causing obstruction to the outflow of urine. The method proposed was to remove part of the enlarged gland through the urethra—in other words, to perform urethral prostatectomy. Following Mercier, Sir Henry Thompson and Reginald Harrison had urged perineal section and drainage. Later, Dr. Wm. T. Belfield of Chicago employed the "combined method," as did also Dr. Nicoll of Glasgow and Dr. Alexander of New York. But whatever form of prostatectomy was employed, the mortality was still high, and even now reached 20 per cent. In 1893, Dr. J. W. White of Philadelphia suggested that the testes had an influence on the nutrition of the prostate similar to that exercised by the ovaries on the uterus, and that just as oophorectomy leads to a diminution in size of the fibroids of the uterus, so would castration lead to atrophy of an hypertrophied prostate. In May, 1895, White reported the results of 111 cases in which orchectomy had been performed for the purpose of causing atrophy of an hypertrophied prostate. Of this number, in 82 per cent. rapid atrophy is said to have taken place, in 52 per cent. cystitis had either disappeared or had been materially lessened, in 66 per cent. there was a return of vesical contractility, in 83 per cent. there was marked amelioration of troublesome symptoms, and in 46.4 per cent. there was a return to the normal conditions. Dr. MacEwen said he had collected fifty-two cases of orchectomy operated on since White read his paper; of these forty-two were said to have resulted more or less successfully; of the ten unsuccessful cases, in four there was no improvement, and six died. The speaker had himself operated in five cases. Of these, three were treated by double orchectomy, and two by resection of the vas deferens. Orchectomy is sometimes followed by marked mental disturbance, but this is never seen when the testis is removed for disease. The essayist had had no experience with unilateral orchectomy. The results of resection of the vas deferens are divergent. He had done it twice. The first patient died within a week from uræmia. The second case was 65 years of age and for seven years had been troubled with micturition. Dr. MacEwen drew the following conclusions:

1. In many cases castration causes more or less atrophy of the prostate.
2. Atrophy occurs most commonly when the prostate is soft.
3. It is of most value when the enlargement is general.
4. Cystitis may be relieved or cured.
5. In marked cystitis drainage is better.
6. It may do away with the necessity of the use of the catheter.
7. Or the catheter may be required less frequently.
8. Resection of the vas deferens acts more slowly, but the effect is similar.

MR. REGINALD HARRISON of London, read a paper on VASECTOMY, OR DIVISION OF THE VAS DEFERENS FOR PROSTATIC HYPERTROPHY.

He stated that cases of vasectomy could be divided into two groups: 1, where only one vas has been divided; and 2, where both have been operated upon. He had performed unilateral vasectomy in twelve cases. Of these seven obtained permanent benefit, and in five negative results were secured or the patient could not be traced.

One patient was 69 years old. He had a large prostate. Micturition occurred hourly, but no catheter was necessary. The right lobe was distinctly larger than the left. The right vas was divided, the patient was able to retain urine much longer, and the right lobe atrophied. In the second group of cases there were ten; of these, five were much benefited. In two cases there was no improvement, two disappeared, and one is too recent to be considered a success. This case was that of a man 70 years of age, who had a suprapubic fistula after lithotomy. Micturition was attended with considerable difficulty. Double vasectomy was performed, and he was able to abandon the use of the catheter. In the five successful cases the points gained were diminished frequency of urination, improved condition of urine and less suffering from vesical spasm. No fatal cases, and no cases with mental disturbance.

Lastly, both by castration and by resection much good could be done. It should be remembered, however, that some cases were not benefited by either method.

MR. C. MANSELL MOULLIN, of London, looked upon statistics as almost valueless, and said he relied on his individual experience. He would include prostatectomy as one of the methods

of treatment of enlargement of the prostate; while the mortality was very high, it had of late been materially reduced. For instance, of eleven cases reported by Mayo Robson, there was only one death, and Mr. Moullin himself had operated on five cases with no deaths. He urged the importance of operating on cases before the urine was ammoniacal and before cystitis and pyelonephritis had supervened. The operations of castration and vasectomy should be reserved for cases unsuited for prostatectomy. In eleven cases he had done bilateral orchectomy, but he did not think any benefit would follow from the unilateral operation. Of the eleven cases, three died. In six of the eight cases which survived the relief was great.

PROF. JOHN CHIENE of Edinburgh, held that castration should only be performed when all other means had failed to afford relief in prostatic enlargement. Suprapubic cystotomy should be first tried in cases in which an operation was needed, and then if there was enlargement of the third lobe, and if the urine was aseptic, the third lobe might be removed. In case the urine was septic, the surgeon should wait for six weeks, if no relief occurred even then perineal drainage should be tried, and a tube inserted, which might be worn with comfort for years.

MR. F. A. SOUTHAM of Manchester, took the ground that an operation was required in only a limited number of cases. He urged the early use of the catheter. If the urine is septic, the bladder should be washed out and antiseptics, such as salol given by the mouth. These failing, suprapubic cystotomy should be done. In some cases in which he had resorted to double orchectomy, a complete cure had resulted.

MR. C. A. MORTON of Bristol, had done double orchectomy in one case, the man being 70 years of age, who had much enlargement of the prostate, and frequent micturition. A trophy followed gradually, but the patient had improved.

PROFESSOR I. H. CAMERON of Toronto, had done double orchectomy in twenty cases, with one death from suppression of urine.

DR. MAC EWEN, in closing, said he did not wish to be understood as implying in his previous remarks that orchectomy should supersede prostatectomy. He should try resection of the vas deferens, after listening to the remarks of Mr. Reginald Harrison. Intra-vesical growths should be treated by prostatectomy, but that general enlargement of the prostate requires orchectomy. Drainage was simply palliative and may be used in very weak or aged patients.

#### THE GENERAL MEDICAL COUNCIL.

The probability of an animated discussion in reference to the General Medical Council—which, as is well known, is a Government institution created by the medical act of 1858— attracted an unusually large number of medical men to the section of Ethics. Nor were they disappointed for the discussion, though one-sided, was certainly vigorous. The attack was led by DR. A. G. WELSFORD, who opened with a very outspoken criticism of the General Medical Council. "The history of the Council," said Dr. Welsford, "is one long story of wasted opportunities and neglected duties. Although by pressure from without it has been forced into a semblance of activity, the work has been done unwillingly, and when possible, difficulties have been created. The Council is a great stumbling block to reform. Its failure is mainly due to its non-representative character, which places it beyond the control of the medical profession. The Council is mainly composed of nominees of universities and colleges, and the net result is that whether the Council originally was intended to protect the public or the profession, it actually is concerned only with the interests of these bodies. The General Medical Council is an anachronism. It is out of date in the nineteenth century. Its very constitution embodies the opposite of the principle 'No taxation without representation.' The medical profession has to pay for a governing council which it does not elect, over which it has no control, but which has arbitrary and absolute power of legislation upon matters affecting general practice of which the members of the Council are profoundly ignorant. A new spirit has appeared in our profession. We long ago lost respect for the impotent and vacillating coterie of university and corporation nominees, called the General Medical Council.

"We recognize its callous indifference to all other interests than its own, and we object to continue to pay for the maintenance of this nineteenth century medievalism. When we obtain a new medical act, as we shall succeed in doing by union and organization, a new council will be created, and this council must be one representative of the profession. Combined attack is being made on all sides upon institutions which maintain and protect vested interests, and the Council will not

escape deserved censure. Apologists may assert that the Council is the best possible in this best of all possible worlds, may whittle down these duties to vanishing point, and then claim that the Council performs these duties most ably, but the medical profession can not any longer be hoodwinked as to the real nature of the General Medical Council and will with united voice demand reform."

PROF. VICTOR HORSLEY of London pointed out the great danger to which the profession is liable in consequence of the standing orders of the General Medical Council in regard to "condemnation of infamous conduct" and "the protection of the honest practitioner from exploitations of quackery." He complained, among other things, that the president of the council was endowed with a degree of autocracy which was dangerous to the safety, honor and welfare of the members of the profession. The profession ought to memorialize the Council to appoint a president who was capable and scrupulous, and to actively urge reform upon its very imperfect procedure.

DR. LOVELL DRAGE of London agreed that the great fault of the General Medical Council was that the president had absolute power under the standing orders, which should be radically reformed. The medical profession, he said, was given over to the hands of its enemies, and it was exceedingly difficult for the five direct representatives to use moral suasion. What could five votes do against twenty-five when those twenty-five were the votes of men who had common interests and common monopolies to defend? The cornerstone of the whole edifice of reform must be an increase in the direct representation.

It happened that a member of the General Medical Council was present in the Section. DR. GLOVER of London, who is a "direct representative" on the censured body, but is not a member of the British Medical Association, was invited to say a word in defense of the General Medical Council. Dr. Glover admitted that there was great force in the complaints that had been made as to the way in which the disciplinary work of the Council had been carried on and as to the powers of the Penal Committee. At the last meeting of the Medical Council there was a strong feeling that a change was necessary in the conduct of penal cases and in the way in which evidence was to be laid before the Committee and the Council, and he thought he could encourage them to believe that in the future the investigations and the evidence would be much more complete than it had been in the past. He hoped this Association would not lend its sanction to the idea of relieving the qualifying bodies of their disciplinary functions, for it was explicitly stated in their charters that they should not only qualify men but take note of their conduct.

DR. W. DOUGLAS (Leamington Spa) considered that Dr. Glover had only confirmed the very unfavorable view entertained with regard to the General Medical Council. It was difficult to move that Council, and he suggested that instead of going to them they present a petition to Parliament, showing how inefficiently the Council performed their duty, keeping neither the spirit nor the letter of the laws which they had to administer. If by that means they did not get a new Act which would give better representation to the profession on the General Medical Council, they would, at least, bring such pressure to bear on the Council as would compel them to act in the interests of the profession.

Much merriment was provoked by the suggestion of DR. BROADBENT of Manchester that a new element in "moral suasion" might be introduced by appointing on the General Medical Council a lady doctor, who might have some power over the gentlemen in that body.

DR. JAMES MYRTLE of Harrogate believed the root of the whole difficulty was that the Council was an antique and insufficient body. He agreed that if they could put pressure upon their representatives in Parliament they would secure an alteration of the Council and a greater share of direct representation.

#### SELECTIONS.

**The Curative Serum of Hydrotherapy.**—It is a fact long since known that the pathogenic microorganisms and their products possess poisonous properties. Experiments and observations have taught us that the system reacts against these poisons by producing antipoisons and other preventatives which are only known to us to a minor degree. From the endeavor to antagonize the poisonous products of infection by their antipoisons, serum therapy has emanated. Like every other organic func-

tion the resisting power which the system possesses in order to keep off injurious influences, can be strengthened by methodic rote. As we can gradually make ourselves unsusceptible to mineral and vegetable poisons, like arsenic and morphin, we can also to those poisons produced by microorganisms.

Upon such a systematic strengthening of the natural resisting powers of the system against a certain poison immunization seems to be based. It is now said that the blood serum of the immunized animal contains those antitoxins which, when injected into a person who is afflicted with the same infection are able to assist the patient in overcoming the disease.

As, however, the sovereign antitoxin for any and every infection has not yet been discovered, a certain serum must be prepared for every species of disease. After the readily prepared antitoxins have been injected into the blood, they must be converted by the system in such a way as the healing process requires.

Yet it is doubtful, if the serum injected is equivalent to the one produced by the diseased system itself; it is also doubtful, if the entire process of reaction against the disease consists exclusively in the serum and the antitoxins. It is more likely that the whole system and all its functions participate in the process of reaction, that in the cells themselves and their assimilation, in the nervous system, etc., auxiliary powers are put in motion. We must also consider that the injection of the blood serum of one animal into the blood of another species undoubtedly involves dangers. Serum therapy tends to substitute in an artificial way a substance which the system is unable to produce, at least not to a sufficient amount. It may not be timely to criticize the new treatment, still we must admit that we know but very little of the biology of so-called internal secretion and that the substitution of living or morbid tissue or serum can not at all be held for an actual substitution of the missing or imperfect function. The various physiologic and pathologic proceedings can be explained by physic and chemic laws only partially, which is the reason diseases can not always be treated in the same way and why equally competent physicians often disagree entirely as to the same remedy. From quite a different standpoint I believe in antitoxic powers of the living organism and in the more or less complete substitution of a missing function by the system itself, or in other words, I believe in an "auto-serum" and "autoorgano-therapy" and in the possibility to improve this "autotreatment" by physic agents. It is no longer doubtful that numerous infectious diseases, often the most severe and dangerous types, convalesce without any medical aid whatever. If, therefore, the power of the system to overcome the infection, intoxication or autointoxication, consists in the blood and its serum, as is supposed to-day, the system itself must produce the antitoxins required to defeat the infection. "Gradually," says Buchner, "we have come to the conclusion, and this has since been proven by experimental investigations, that the system is possessed of natural auxiliaries against the producers of disease." I have occasionally controverted the belief that this conclusion is of a late date. Since Hippocrates and since there are medical schools, the physicians were forced to come to this conclusion from the observation of the undisturbed course of various diseases.

Could we now prove that there are agents by which we are able to improve or even call in action the natural powers of the system to resist the producers of disease, or in other words, to assist the system in its fight against the injurious influences, we would have to call this treatment a rational and physiologic one. And we would have to consider, if such a treatment which is based upon the action and functions of the system, was not less dangerous, and yet, not less efficacious than any other artificial treatment. It would lead me too far to prove this for the effects of all physic agents. This has been done repeatedly by numerous investigators, also by myself, and it has been shown

that there is no function of any organ or any system of organs which can not be altered, invigorated or labeled by thermic and mechanic agents. As to hydrotherapy, I only want to say that it is first of all a therapy of oxidation, as is shown by Pospichil's and my own investigations on respiration, and by Strasser's and others' investigations on the chemism under thermic influences; it is a therapy which increases internal oxidation, leucocytosis and the alkalinescence of the blood. We not only command the distribution and circulation of the blood by thermic agents, but also its morphologic and chemic composition, as I have shown years ago. In the first place, I found, at the same time as Rovighi did—that upon the employment of cold, leucocytosis sets in, a fact which is of fundamental importance for the explanation of the effects of thermic applications in infectious diseases. I knew long ago, and have mentioned this repeatedly, that the decrease of temperature could only partially explain the favorable effects of the water treatment in infectious diseases. We have long been familiar with the favorable symptomatic effects which an improvement of innervation, circulation and tone of blood vessels and tissue caused by the water treatment has upon the feverish process. But we could not explain how the treatment could affect the pathogenic microorganisms and their toxins. If, however, the leucocytes are the real phagocytes in the meaning of Metschnikoff and, as Buchner says, the transporters of the alexins, the destroyers of the toxins, we understand why we can affect the infection by means of hydriatics which enable us to produce leucocytosis at any time we desire. Further investigations taught us that under the cold water treatment, also the red blood corpuscles, the specific weight of the blood and the amount of hemoglobin increase considerably. If we further consider that we can stimulate or modify the circulation in the whole body and the locus morbi by hydriatics, we have a good explanation for the value of the water treatment in infectious diseases.

Further we must consider that numerous secretions and excretions can be affected considerably by hydriatics. I called attention to their diuretic effect in infectious diseases long ago, a fact of great value in regard to prognosis. Rogue and Weil saw the urotoxic coefficient of the urin increase in typhoid fever under the hydriatic treatment, and proved that under this treatment six to eight times as many toxins were eliminated as under any other treatment. Thus we know also that the elimination of the noxæ and their products by the kidneys, the skin, the bowels, the salivary glands and probably most of the excretions belong to the reaction of the system against the infection, which reaction can be greatly invigorated by hydrotherapy.

Even the chemic composition of the blood can be changed by cold applications, as has been shown by Strasser's investigations. The alkaline blood is of great importance not only as a vehicle of the phagocytes, but also because of its chemic condition. Numerous investigators observed that the alkaline reaction of the blood decreased considerably in infectious diseases. Tassinari found from experiments on rabbits, that upon a septic infection the index of alkalinity decreased from 3.6 to 1.58 within two days. It could hardly be doubted any more that the intensity of the bactericide power of the blood and, probably also the neutralization of various acid products of the microorganisms, depend upon the degree of the alkalinescence of the blood. Strasser by his investigations has made this presumption a certainty, and has shown that cold baths increase the alkalinity of the blood. This fact forms an exact basis for Buchner's presumption that "the cold water treatment very probably acts as a direct destroyer of the producers of infection."

Thus we can call the hydriatic treatment a true auto-serum, and autoorgano-therapy by which the blood and its serum obtain a stronger bactericide power and by which we have a perfect control of the circulation of the blood in the whole system, at

large, and in the locus morbi, in special. It is a treatment by which the functions of all organs and also the internal oxidations are increased and improved considerably, and which is a natural stimulus to vital energy.—PROF. W. WINTERNITZ, Vienna. Translated by Dr. Carl Struëh, Chicago.

**Organ Extract Therapeutics of Female Genital Organs.**—The *Therap. Woch.* of July 12 contains an article by Bell of Glasgow, describing his success in the treatment of carcinomas, fibromas, etc., of the female genital organs with extracts of the thyroid, parotid and lacteal glands. The parotid gland seems to have an important effect on ovarian troubles, and the lacteal on uterine. He describes fourteen cases taken at random. The patients applied to have the neoplasms extirpated, but this soon became unnecessary after taking a teaspoonful three times a day of one of these extracts, with ichthyol or iodophenol tampons applied locally. The neoplasm rapidly diminished in size, while the general health improved, and the patients were dismissed practically cured, with no further pains or discomforts, and in some cases no trace left of the neoplasm after a few months of this treatment. Knauer has succeeded in implanting an ovary in the uterus of four rabbits, which became incorporated with the tissues and resumed their functions, reproduction of ova. Mainzer reports various climacteric troubles cured by two 5 gram pastilles a day of freshly dried ovarian tissue, increasing the dose to three pastilles a day, returning to a smaller dose as the troubles disappeared. In two cases menstruation was produced in women who had never menstruated before. The most favorable results were obtained in troubles of a vasomotor nature; next came primary or secondary amenorrhea, while purely nervous or hysteric patients were not affected by it except suggestively. These facts may be found useful in differentiating. Jayle has successfully treated the troubles consequent to castration with dry ovarian extract or an ovarian fluid prepared in the same way as the Brown-Séquad extracts. He considers himself justified in advocating ovarian therapy in amenorrhea or dysmenorrhea caused by ovarian disorders, as it may render castration unnecessary.

**Gymnastics in Heart Disease.**—The *Boston Medical and Surgical Journal*, June 18, contains an elaborate report of the discussion, before the Society for Medical Improvement, of the above subject. Some interesting observations by Dr. Folsom were the following:

"When I was in Munich in 1879 I had considerable talk with Ziemssen about the treatment of organic heart disease by muscular exercise, to which Oertel had called the attention of the profession several years before. Ziemssen was using it pretty generally in his practice, and I asked him to see an American gentleman who had seen a number of specialists in this country and in London and had been advised not to take vigorous exercise. Ziemssen immediately put him on Oertel's treatment, and that very afternoon this gentlemen walked a number of miles over the hills in the vicinity of Munich. He has kept up that treatment, more or less, under suitable guidance. He now walks, rows, walks over hills, rides horseback and has absolutely no symptoms so far as his heart is concerned. The valvular murmur is pronounced and the heart is larger than it was then. The compensation is perfect, and it seemed to me an extremely good result. It was not one of the cases to which allusion has been made, of beef-eating, beer-drinking Englishmen. He was very temperate in all respects, and did not materially change his course of life. Five or six years ago a highly accomplished Swedish medical gymnast came to this country. She had a large practice after graduation, and was so proficient in her work that she had been the assistant of the professor in charge in Stockholm. She came into the wards in my service at the City Hospital and did some work to show me what she could do. Since then I have used gymnastic exercise very largely in my practice. . . . There were three things with regard to the Swedish medical gymnastics which struck me: In the first place, the very complicated system; secondly, their apparent simplicity, and thirdly, their great power for good or for evil according to the judgment and skill of the operator. I think in the whole system which Ling

introduced there are something like one thousand different movements. I was also struck with the extreme simplicity of them. One would hardly think their physiologic effect would amount to so much. As regards the very great power of these movements, the movements to correct slight scoliosis may defer menstruation one, two, three or four weeks. On the other hand, in the absence of menstruation it can be brought on with great rapidity. It is the most efficient means of correcting metrorrhagia without organic trouble that I have seen. I have had a number of cases of organic disease of the heart treated in this way. I have four at present. One is a lady who five years ago had valvular disease of the heart, dilated heart, weak, irregular, intermittent pulse, and had had complete hemiplegia of one side, including the face. She has continued that treatment more or less all this time, and it has constituted one of the chief means of treatment. The pulse is regular, a little above seventy. She considers herself in perfect health. Another is a lady with a marked arterio-sclerosis and dilated heart. She has been under my care about two years, and that has been the chief method of treatment. The benefit in that case has been striking. . . . My belief is that the best way of using physical exercise, if the person is able to do it, is some out-of-door, regular, general exercise. Of course a very large number of patients can not do that, and the medical gymnastics which would be required in valvular disease of the heart where there is compensation or hypertrophy, would be entirely different from the movements which would be required in a dilated heart where the walls are weak, and especially where there is arterio-sclerosis. It seems to me that while there are people in this community who are sufficiently accomplished and can be trusted in these cases, and who have demonstrated the very great value of this treatment, there is also a large number who call themselves Swedish medical gymnasts who have certificates or diplomas of varying value, and whose knowledge is so imperfect that they are dangerous persons to set to work on any important or difficult case."

## PRACTICAL NOTES.

**Eliminative Treatment of Typhoid Fever.**—M. Gottman, M.D., gives the following synopsis of the treatment: 1. Eliminate the poison by the free use of saline cathartics, as they are best and safest. 2. Give baths of ten or twenty minutes' duration, beginning with the temperature of the patient, for their tonic and sedative effect, as well as their eliminative action. 3. Dilute the poison freely by imbibing largely of good, cold water. 4. Avoid food, unless peptonized (and sometimes even this will not agree), until you know it can be digested, and this applies especially to milk and lime water. The mental and physical condition of the patient is the best index to the exhibition of food.—*Memphis Med. Mo.*, August.

**Bekarewitsch Treatment of Varicose Ulcers.**—After the spot is thoroughly disinfected, a piece of gauze smeared with a 10 per cent. boric vaselin is laid over it, through which it is delicately massaged for five to ten minutes, and then more energetically. It is then dried and dusted with iodoform and wrapped in an antiseptic bandage covered with the following: Zinc oxid and gelatin equal parts; glycerin and dist. water, four times the quantity, equal parts. The whole is then enclosed in a starch bandage and left undisturbed for two or three days, during which time the patient can go about and do light work.—*Therap. Woch.*, July 12 from *Wratsch*, No. 1.

**Improved Method of Narcosis.**—Gräfe has found that the sensitiveness of the nasal membrane is of far more importance in terminating narcosis than is generally supposed, owing to its reflex action on the vagus region. If the nose can be kept closed, the narcosis proceeds far more readily and rapidly, and lasts much longer, with less of the anesthetic required. He has therefore invented a light spring pad with which he stops the nostrils before the operation, and does not remove it until the patient is completely aroused. (Schütz, Leipsic, Windmuhlenstrasse, 30.) It has rendered surprising service in the narcosis of persons with pronounced heart troubles, with the minimum of after effects.—*Cbl. f. Chir.*, July 18.

**Somatose increases the Lactal Secretions and improves the Blood.**

—Drews reports from his experience in twenty-five cases that somatose has a direct specific effect on the lactal glands, promptly and efficiently increasing their secretions. He urges its use in all cases of deficient or decreasing lactal supply, recommending one teaspoonful three to four times a day, in a cup of warm milk, soup, cocoa, etc. Owing to its tastelessness, the use of it can be kept up indefinitely as long as it may be needed (*Cbl. f. inn. Med.* No. 23). Seonamiglio has been making a study of the blood of patients taking it with no other medication. He found that the erythroblasts gradually increased in number, while the microcytes and poikilocytes decreased. The amount of hemoglobin was increased from 8.9 per cent. to normal, 13.5 to 14.5 per cent.—*Therap. Woch.*, July 12.

**Chronic Otorrhea Permanently Cured with Trichloroacetic Acid.**

Halasz confirms Okuneff's announcement of the value of this treatment, and recommends the following *modus operandi*: As the pain is severe, five to eight drops of a 10 per cent. solution of cocain should be held in the ear for three minutes. During this time a syringe of tepid water should be used to melt the crystals of the acid on the specially constructed sound. The inner ear is then lighted and the sound introduced into the middle ear through a rubber ear speculum. Every spot to be cauterized should then be touched lightly but effectively with the acid, especially the edges of the perforation and the mucous membrane of the middle ear. The ear should then be rapidly rinsed out with one or two syringes of water and after it is dry, dusted with aristol or powdered borax blown in. The operation should be rapid and repeated once or twice a week, when the otorrhea soon disappears, the perforation in the drum closes, and the hearing is completely restored.—*Therap. Woch.* July 1 from *Orvosi Hetil.* No. 17.

**Sodium Hyposulphite Antidote for Malonic Nitrite.**

—Heymans of Ghent reports that "nitrite malonique" (dinitrite malonique,  $CN, CH_2, CN$ ) is fatal at a dose of .006 milligram per kilogram (rabbit), with symptoms resembling intoxication by hydrocyanic acid. Animal succumbing to this intoxication can be recalled to life at any moment, even when in convulsions, by an intravenous injection of sodium hyposulphite, and if the latter is injected at the same time as the nitrite there are no toxic accidents. The interesting point is that the antidote follows and neutralizes the poison in the inmost nerve cells, instead of its action being restricted to the poison in the blood or the alimentary canal.—*Bulletin de l'Académie de Méd.*, July 22.

**Lewaschew Method of Substituting Salt Solution for the Effusion in Pleurisy.**

—Requests have been received by the JOURNAL for further information in regard to this method. We refer those interested to the *Deutsche Med. Wochenschrift*, No. 52, 1890 (G. Thieme, Leipsic, Seeburgstrasse, 31), and to the *Therap. Woch.* of June 28 (Vienna, XIX, Döblinger Hauptstrasse 36). Lewaschew states in the former: "I first, with extreme care and very slowly, withdraw a certain amount of the effusion from the pleural cavity, stopping at the first indication of pain. Then with a syringe I very carefully introduce the same amount or a trifle less of the 7 to 10 per cent. sterilized chlorinated soda solution, warmed to about 86 degrees. Again I withdraw the effusion from the cavity until slight pain is experienced, when I stop and again introduce a corresponding amount of the salt solution. I repeat this procedure from two to six times as may be necessary, which depends upon the character of the effusion and the peculiarities of individual cases." (See this JOURNAL, page 214, July 25.)

**Early and Intensive Method of Curing Syphilis.**—Manino reports the highly successful results of eight years' experience with

this treatment (*Giorn. It. delle Mal. Ven.*, p. 50). Instead of waiting for the usual symptoms to appear, the initial chancre is excised or thermo-cauterized and calomel injected every fortnight for ten to twelve months (10 centigrams calomel to 1 gram glycerin and one drop water). After this the injections are made every twenty days for three or four months; then one in sixty days for two months more, when potassium iodid is administered for two months; then two months more of mercury injections, this time the sublimate. The patient then rests for a couple of months, when the iodid is recommenced for a while, followed by a protoiodid, which is kept up till the end of the second year. The initial chancre soon subsides, and no secondary or tertiary phenomena have appeared in any of the cases treated during the eight years. The inconveniences of this treatment, the painful injections, the temporary loss of appetite and weight, are far more than compensated by the victory over the disease, which is arrested before it becomes constitutional.—*Bulletin Méd.*, July 22.

**The New Celluloid Mull Bandage.**—It has been found that celluloid will dissolve in acetone into a thick gelatin, which can be used for casts, as it hardens sufficiently in an hour and a half, and becomes absolutely solid in three to four hours. The sheet of celluloid is cut with a pair of scissors into scraps and placed in a wide-mouthed bottle, filling it a quarter full. The rest of the bottle is then filled with the acetone and the contents stirred with a stick occasionally. When rubbed on the mull bandage it forms the cleanest, hardest, and by far the lightest substance known for this purpose, while it is not affected by the secretions of the body. It has been used at Strasburg with great success, and is warmly recommended as a most valuable bandage on account of its cheapness, durability, solidity and elasticity, especially for use in policlinics. It is not necessary to have as many layers of the bandage as with other substances, and the celluloid rubbed in for the outer layer forms a handsome finish. As it is very sticky and can only be dissolved with acetone, it is best to wear leather gloves while handling it. It is especially adapted for permanent removable casts, with or without splints. In some cases a cast or model of the limb or part has to be made, and the celluloid cast modelled on this.—*Cbl. f. Chir.* July 18.

**Oxycyanid of Mercury; Ophthalmia Neonatorum.**—Von Sicherer, in the *Münchener Med. Wochenschrift*, recommends the use of mercury in the treatment of ophthalmia neonatorum. The advantages of this drug were first brought to the attention of ophthalmologists by Schlosser in 1893, at the meeting of the Ophthalmological Society in Heidelberg. Schlosser demonstrated that this preparation presented antiseptic properties equal to those of the bichlorid of mercury, but caused much less local irritation and much less power of coagulating the albumin than the corrosive sublimate. Generally in acute affections of the conjunctiva 1 or 2 per cent. solutions were used. In ophthalmia neonatorum a solution of 1 to 500 has proved most effectual, and has been used exclusively in this affection in the University clinic for several years past. The application is extremely simple: After eversion of the lids they are rinsed thoroughly with this solution, and in such a manner that every fold of the conjunctiva is freed from the secretions. This should be done daily. Instruction should be given for the constant use of ice compresses. The nurse should be cautioned against removing the secretion, for, unless the greatest care is exercised, injury is done to the superficial layers of the cornea with subsequent ulceration. If the cornea is not already affected when this treatment is begun, a favorable termination can be absolutely guaranteed, which is by no means the case with other methods of treatment. Even when slight infiltrations of the cornea exist, by this means they can usually be made to subside, and it is only in extensive ulcerations and in prolapsus of the iris that this and other means of

treatment are of no avail. If the results of the ordinary method of treating this affection—namely, brushing with a 2 per cent. solution of nitrate of silver and neutralizing with a solution of sodium chlorid—be compared with those obtained by simply rinsing with the oxycyanid, the preference would be unhesitatingly given to the latter method. An efficient remedy for combating a disease which causes 41 per cent. of the cases of total blindness should be welcomed by all.

**Delayed Paralysis after the Use of the Antidiphtheritic Serum.**—Filiatre in the *Gazette Hebdomadaire de Med. et de Chir.*, June 4, has reported the case of a child 3 years old, presenting symptoms of laryngeal obstruction which proved on bacteriologic examination to be of diphtheritic origin. An injection of 15 c.c. of antitoxic serum was at once made into the right flank, and forty-eight hours later a second injection of 10 c.c. into the left flank. In the course of twelve hours the false membrane had completely disappeared, the child breathed easier, the pulse was normal, the fever had disappeared, and only the submaxillary adenopathy remained. The child continued well for more than a month, when it was observed to speak through the nose. A day later speech was almost unintelligible, and saliva dribbled from the mouth. In the course of several days more, the head could not be held up, the chin falling upon the chest. Deglutition also became difficult. The knee-jerks, as well as the pupillary reflexes, were preserved. Sensibility was intact. The muscles especially enfeebled were the extensors of the neck, the rotators of the head, excepting the sterno-mastoid, the supraspinous and the elevators and abductors of the scapulæ. The fascial muscles also were largely affected, as well as the recti abdominis. Under electric treatment, improvement rapidly set in, and soon proceeded to final recovery.

**Herpes Zoster.**—Dr. A. H. Ohmann-Dumesnil recommends the following in treatment:

R Acidi arseniosi . . . . .	.003
Pulv. piperis nigris. . . . .	.16
Extract gentian. . . . .	q. s.

Misce. Fiat pilula No. 1. Sig. To be taken thrice daily after meals.

Externally, campho-phenique powder liberally sprinkled upon absorbent cotton and applied to the eruption, or the following:

R Pulv. camphoræ. . . . .	8.0
Bismuthi subnitrat. . . . .	16.0
Crete preparat. . . . .	32.0

Misce. Sig. Apply twice a day.

—*St. Louis Med. and Surg. Journal*, August.

**Local Applications in Pharyngitis.**—The following combination is an antiseptic stimulant and protective:

R Oil Scotch pine . . . . .	2.0
Oil eucalyptus. . . . .	4.0
Oil cassia . . . . .	2.0
Menthol. . . . .	1.3
Ext. balm gilead, fld, q. s., ad. . . . .	128.0

Sig. Spray on pharynx.

One of the best combinations to be used as a spray in the simple acute form of the disease is the following:

R Cocain. . . . .	0.5
Oil cassia . . . . .	2.0
Menthol,	
Gum Camphor. . . . .	ãã 4.0
Albolene, q. s., ad. . . . .	128.0

—Dr. Lewis M. Somers, in the *Laryngoscope*, August.

**Chrobak's Use of Ovarian Extract.**—A post-operation treatment in ovarian cases has been adopted by Professor Chrobak in order to obviate, if possible, the symptoms that often annoy the surgeon; and also to mitigate the disturbances peculiar to the menopause, and is recorded by him in the *Centralblatt für Gynäkologie*. He was led to administer ovarian tissue and to practice ovarian grafting. He accordingly had prepared an extract of the ovaries of sexually active and healthy cows, and

had undertaken experiments to determine the practicability of ovarian grafting. The extract was employed in six cases in which the ovaries had been removed and in one of which, with perfectly normal genitalia, the climacteric molimina were severe. In three of the cases of the first group, in which the treatment had covered a period sufficiently long as well as in the remaining case, distinct improvement followed. The results of the transplantation experiments are detailed by Knauer. It was found that not only did ovaries grafted between folds of the peritoneum, or between fascia and muscle retain for a time at least, their integrity, but that they also continue to exercise their functional activity, as indicated by the maturation ovisacs.

**Palliative Treatment of Uterine Cancer with Chlorate of Sodium.**—This treatment, recommended by Brissaud for cancer of the stomach, has been found very effectual in arresting the pains, hemorrhages and discharges in cancer of the uterus, improving the appetite and digestion and the health of the patient in general and prolonging life, although it fails to stop the final progress of the disease. One patient treated by Boucher lived three years a "very supportable existence," although the inoperable cancer in the uterus and vagina was accompanied by a cancerous lesion of the stomach. He administers it internally in two to eight teaspoonfuls a day of the following mixture: Chlor. sod., 20 grams; orange flower syrup, 30 grams; acq. dest., 100 grams. It is also applied on a tampon to the neck of the uterus in a powder composed of equal parts of chlorate of sodium and subnitrate of bismuth with half the quantity of iodoform. If the latter produces symptoms of intoxication, viz., a coated tongue, bad taste in the mouth and the iodoform reaction in the saliva with calomel, it can be replaced by a tampon of salolized cotton dipped in a 20 per cent. solution of chlor. sod. In addition, a daily vaginal injection of 10 grams in a liter of boiled water is also given.—*Semaine Méd.*, July 15.

**Pruritus Ani.**—Dr. Charles G. Cumston says that patients suffering from pruritus ani are usually either arthritic or nervous. For local application the following are recommended:

R Menthol. . . . .	4.0
Alcoholis. . . . .	30.0
Aq. dest. . . . .	60.0
Acid acetic, dil. . . . .	150.0

Misce. S. For external use only.

R Acid, carbolic. . . . .	5.0
Kalii hydrat. . . . .	2.0
Ol. lini sem. . . . .	30.0
Ol. bergamot. . . . .	9.5

Misce. S. Apply at bedtime.

In very severe cases deep cauterization of the parts with nitrate of silver or the thermocautery had been employed. Section of the nerves gave good results in pruritus of the anus, vulva and scrotum when the affection was very intense.—*Am. Gyn. and Ped.*, August.

**Prolapsus Ani.**—Dr. Platt resorted to the following procedure in the case of a child operated on in vain by other methods: At the junction of the skin and mucous membrane, just beneath the latter, a curved needle is inserted in the median line below, and a silk thread is carried half way around the anus and out again, in the median line above, reinserted in the same opening and brought out at the first puncture, making a purse-string suture. The little finger is then put in the anus and the string tied snugly around it. Apparently this would cause suppuration, and possibly a fistula. It does nothing of the kind, nor does it cause any pain afterward. The child has his stools in the recumbent position. If the feces are at all hard, injections are given to soften them. After three weeks the suture is withdrawn when it heals immediately with no return of the prolapsus. By this method the bowel is kept in place long enough to contract adhesions.—*Johns Hopkins Hospital Bulletin*, July.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance . . . . . \$5.00  
Single Copies . . . . . 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the Association living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, AUGUST 22, 1896.

"MEDICAL DEFENSE."

It seems that of thirty-eight local branches of the British Medical Association, twenty-seven have written in favor of such alterations in law and practice as shall make the Association capable of acting in its corporate capacity for the defense of its members in case of lawsuits, etc. The meeting at Birmingham has adopted a resolution that may be considered as the preliminary step of the plan. This naturally brings into view certain criticisms—especially of those not unduly loving the Association or its managers—that the Association will find itself incapable of acting in this capacity, that it will prove expensive, that it is too huge and unweildy a body to act promptly and justly, etc., and lastly that it will lessen the respect of the general lay-world for the profession, and lead to a reversal of the esteem in which it has heretofore been held as a body of men not bent on self-aggrandizement or defense, but solely determined to alleviate the sufferings of humanity without thought of self.

To all of which criticism we would humbly answer, bosh! The esteem of the public for the profession may be most aptly synonymized by the word disesteem. And this disesteem is very largely due to the fact that the profession has heretofore shown little or no *esprit de corps*, and has been inexcusably weak in permitting the contempt of the world to stand as a confession of just judgment. By no means would we adopt the creed of ethics of the world, an eye for an eye, etc.,

but just as little should we longer hold our cheeks out for unjust and indiscriminate smiting. Self-defense is the first law of nature and when consciousness reaches anything like adult development it instinctively guards itself against injustice and unauthorized dictation. More than this the cause of the medical profession taken in its best sense is the cause of society and humanity. If they but knew it no one is more interested in encouraging the feeling of self-respect and honor among medical men than non-medical men. The evils of quackery exist because we are not united in crushing them out of existence, and in the estimation of the public our failure to do this is due to the fact that we are half-quacks ourselves, with but a faint-hearted belief in the therapeutic value or scientific quality of our own "science." It is one of the strangest facts of modern sociology that so large a body of men as we have no professional unity, that we present no united front to the enemies of our guild or to the public influences prejudicial to public health. Every other calling or occupation bands itself together and seeks to influence legislation or popular feeling by a hundred instrumentalities while we are content not only to do little or nothing and what little we do sporadically and by individual imitation and energy, but we allow our thousand enemies to deride us and "walk over us" by their unanimous and organized opposition. We trust the British Association may not listen to its critics so much as to prevent it from entering upon the proposed work, and that its success may inspire the American profession to undertake functions furthering our professional honor and importance, and the work we all have at heart.

MEDICAL CHARITY ABUSE IN ENGLAND—AND ELSEWHERE.

At last the British lay public is becoming aroused to the existence of what an editorial writer in *The Saturday Review* justly calls "an intolerable national scandal"—namely, the abuse of medical charities, and such being the case, we may hope for some abatement of the evil. From or through the medical profession we may apparently hope little or nothing at all. There are a hundred reasons for this, many of which have often enough been iterated and reiterated, and the fact is deplorable—but fact it is. It is true that there is a committee of the British Medical Association on medical charities, and the last report of its subcommittee through its chairman, Mr. THOMAS BRIDGWATER, concerning certain London hospitals (*Brit. Med. Jour.*, July 18, 1896, p. 139) is interesting reading—interesting from the positive proof it gives of the failure of "Reform within the Party," and also from the indirect evidence of the huge sin of omission left untouched by this or any other committee. The hospitals visited by the subcommittee were as follows: Charing Cross, Guy's, King's College,

London, Middlesex, Soho, Westminster, Westminster Ophthalmic, St. George's, St. Mary's, University, West London, Chelsea for Women. In six of these no attempt is evidently made to exclude those able to pay for medical attendance, and the notices to patients (that the institution is intended for those unable) recommended to be displayed in the waiting rooms, were not to be found. In only two or three was any thorough-going system of inquiry and exclusion in operation. The committee give examples of abuse they found, of people of property and even of wealth using the "charity" instituted for the poor. The report adds: "The painful fact is revealed that the wider the inquiry, the broader and deeper are the evidences of abuse of charity, not only in the metropolis, but through the country generally."

In his presidential address at the annual meeting of the Birmingham and Midland Counties Branch of the British Medical Association held last June, Mr. MESSITER devoted a portion of his time to this important question. The population of Birmingham is in round numbers 500,000. In 1885, in five hospitals there were treated 127,852 patients, and in 1895 the number had risen to 167,160.<sup>1</sup> "Can anybody pretend," said the lecturer, "that this system does not pauperize the public at the expense of the profession?" "How is to be remedied?" he asks. Acknowledging that the responsibility lies largely or entirely with medical men, he argues that the cure must come from them, but cites only two elements of relief—the return to "their own medical attendants" of first-aid cases after one treatment and the establishment of provident dispensaries, to relieve the hospitals, and where some small fee, tax or coöperative support shall be carried out. The cure is certainly homeopathic in "the thirtieth," or even a higher "potency"; Hahnemann might think it sufficiently high to suit him, and denominate it a cure by "olfaction."

The *Saturday Review* commends the recommendation of the 1890 Special Committee—a Central Hospital Board "empowered to receive and publish hospital accounts, to advise upon new schemes and to act generally as the authorized representatives of the public in the way of observing, appreciating and criticising hospital management and work," but also strikes at the heart of the matter in further urging outright governmental control. We suppose the writer to mean by this the local and not the supreme or central government. But whether local or general, we believe at least for England (if we as foreigners may hazard such an opinion) that there will be no adequate remedy found except in this way. The abuse has become so deep seated, the habit so inveterate that only by this means can thorough reform be brought about. As illustrating the extent to which

this "craze" has gone, it may be mentioned that in a number of cases some hospitals spend as much as 25 per cent., 50 per cent., and even more, of what they receive in contributions and subscriptions in advertising and appeals. Is it possible to have a more perfect and flagrant *reductio ad absurdum* than this? Let it increase only a little more and longer and the advertisements for patients and contributions will equal in cost the income, and then perhaps there will come some attempt at separation of the sheep and the goats, and exclusion of the unworthy. This is, perhaps, a method of "reform" not intended or expected. And if it should come about, can any one doubt that it will be precisely the very poorest, those most needing the charity, and those *ex hypothesi* for whom it exists, who will be the excluded? Because—and this is the essence of the whole trouble—every person now treated gratuitously who is at all able to pay some fee (insufficient or not, matters not) by the very fact itself, excludes the worthy poor from receiving the aid intended for them and not for the hypocrites. Many hospitals and dispensaries now are compelled to limit the number presenting to a certain maximum in order that the work may be got through with at all by the overworked staff. And when one thinks of one or two men attempting to scientifically diagnose and correctly treat in one hour or so the diseases of this maximum the absurdity grows to disgust. In such a mess has the profession got itself! Financially and therapeutically stultifying itself and committing the double suicide with its eyes wide open and supposedly in its right mind!

Are we in the United States any better off? By only so much as we are a younger people and that our institutions have not yet crystallized their abuses into such set systems and inveterate habits. Perhaps also there is not the same hypocritical desire to deceive on the part of the lay public. But we can teach them to be hypocrites fast enough, and beyond all doubt we are hard at the job. It would be interesting to know the proportion of subscriptions for treating the poor spent by American hospitals in riotously profuse illustrations and pictures of the hospitals thus advertising for money and patients. Every room is photographed, the water-closets, views, grounds, etc., and one wonders whence in all the world come the hothouse plants. The evidences of luxury everywhere displayed with confident and exulting pride. We have seen street-car and poster advertisements of hospitals, their advantages, number of beds—and, in big "caps," the names of all their visiting and consulting physicians. We strongly suspect that this latter display as much as the desire for patients (*to treat gratuitously*) was the hidden motive that begat the device.

One indirect result of all this unseemly rivalry, but one of the most important, one moreover confirmatory of our maxim, is the fact of the influence it has on the

<sup>1</sup> In 1890 in the London hospitals there were treated gratuitously 2,429,219 out-patients, while in 1894 the number had risen to 4,108,090.

character of the over-worked members of the staff, and on the kind of treatment the patients receive. When there is a lively competition for patients, then, like over-affable storekeepers, there is over-treatment of the few patients in order to attract more—"I was most beautifully treated there, the doctor was so agreeable and nice, etc.—go there!" But this soon becomes tiresome and useless, and at least at the engorged and popular places the very reverse plan becomes operative. Are hospital manners improving or not? Besides this, it is positively known to us that in those hospitals in which no inquiry into the patient's financial ability or social standing is permitted (and from one reason or another this is very frequently so, though usually adroitly hidden) certain of the assistants or of the staff, feeling the shame of treating gratis those with better incomes than themselves, deliberately *mistreat* such with the (laudable?) intention of driving them finally to the private office. We mean by the word, that in minor ailments a painstaking diagnosis is consciously shirked, and slipshod treatment and placebos or what-not instituted. Are we as a profession equally with our British confrères unable to cope with the disgrace? Surely we are fast going the same road to the same institutionalism and habitualization of abuse that they have reached. Shall we proceed recklessly without any attempt to haul up? It is not only a question of "where we are at," but where we shall be at in a few years if, at the present rate, we continue our *facilis decessus*.

#### A MALPRACTICE CASE OF EXTRAORDINARY AND UNUSUAL CHARACTER.

That is the way *RICHARDS v. WILLARD*, which was decided July 15, 1896, struck the supreme court of Pennsylvania, and it did not hesitate to say so. The plaintiff claimed damages against the defendant for negligent surgical treatment for an injury to his leg. He alleged that he had sustained a fracture of both bones of his leg at a short distance above the ankle joint, and was treated, not for a fracture but for a sprain, and was thereby greatly injured. If there were no fracture the plaintiff had no case, for he did not contend that the treatment he received was improper treatment for a sprain. The defendant denied most positively that there was a fracture.

The singularity of the case arose upon the character of the testimony, and the conflict developed as to the great leading fact. Two surgical witnesses testifying from actual examination, declared that there was an actual compound fracture, one of both bones of the leg, and the other of the tibia. Against this, three surgical witnesses for the defendant testifying also, from an earlier and more complete and thorough examination, several times repeated, declared most positively and emphatically that there was no fracture whatever of

either bone. Then, two experts, who examined the leg a year or more later, testified that, in their opinion, there had been a fracture. And again, on the other hand, nine experts who also made examinations at a later date, declared that, in their opinion, there was not and never had been a fracture.

A verdict for the plaintiff for \$12,000 was returned by the jury. After a painstaking, careful and minute study of the testimony the supreme court felt constrained to say that it regarded that verdict as an outrage upon the administration of justice. Coupled with this is the suggestion that it must not be overlooked that the medical and surgical service rendered by the defendant to the plaintiff was entirely gratuitous. For many years he had been rendering such service to the hospital to which the plaintiff was brought after receiving his injury. If such gentlemen are to be harassed with actions for damages when they do not happen to cure a patient, and are to incur the hazard of having their estates swept away from them by the verdicts of irresponsible juries, who, caring nothing for law, nothing for evidence, nothing for justice, nothing for the plain teachings of common sense, choose to gratify their prejudices or their passions by plundering their fellow citizens in the forms of law, the court rightly further states that it may well be doubted whether our hospitals and other charitable institutions will be able to obtain the gratuitous and valuable service of, as it calls them, these unselfish and charitable men.

The trial judge showed his appreciation of the verdict by promptly striking down two-thirds of its amount, but the supreme court says that he might with still greater propriety have set the verdict aside altogether, because of its being against the law and the evidence, and grossly excessive in amount.

The plain truth, adds the supreme court, is that the plaintiff was probably afflicted with a tendency to tuberculosis, and when he received his injury that tendency became developed in the bones of his leg, and the disease called "tuberculosis of the bone" fastened upon him at the seat of the injury.

For these reasons, and on account of certain other errors in the trial, the supreme court reversed the judgment for \$4,000 that was entered for the plaintiff.

Of the points of law of special interest established by this decision, it is to be noted that the supreme court holds that as the fate of the case in the hands of the jury depended upon the surgical testimony, there should have been, which there were not, instructions as to how the jury should reconcile the contradictions if they could, or, if they could not, then how they should regard it, or act in relation to it. They should also have been told just what the issue was, or the matter of fact upon which the case turned, as that it was whether there was a fracture or not, and whether the treatment administered was in

accordance with the usual and ordinary treatment practiced by competent surgeons in such cases.

As the actual fracture was not seen, it was only a matter of opinion whether it existed at all, and consequently the value of the particular testimony, the court holds, depended upon the competency of the witness to form a reliable opinion, upon the extent and character of the examination he made, upon the reasons given by him in support of his opinion, and upon the judgment of the jury as to the weight and character of the testimony submitted on both sides in support of the respective contentions, all of which should have been explained to the jury, with suitable comments.

Furthermore, it seemed probable that if the plaintiff had been content to remain at the hospital a week or two longer, he would have been cured of his hurt, and because he would not submit to such a reasonable detention, but chose to take the risk of leaving, which apparently brought upon him all his subsequent sufferings, the court says that he must take the consequences himself. And it being impossible to know what would have been the result of the treatment if the plaintiff had remained at the hospital, and this impossibility resulting from his own action, the court holds it would not be proper to attempt to separate the consequences of alleged negligent treatment prior to his leaving from the ulterior consequences resulting from his contributory negligence, after he left, in traveling and omitting to have medical treatment.

#### NO FULL DRESS UNIFORM.

It has been decided by the military authorities of the country, including Surgeon-General STERNBERG, at whose suggestion the action was taken, that there shall be no full dress uniform for the members of the hospital corps. The pomp and pride and panoply of war, the nodding plumes of grand parades and glittering military pageants are not for them. Although they may be *in* these parades and pageants hereafter, they will not be *of* them. When they are there they are there not for show but for business—in their fatigue suits, with their hand litters handy and their hospital corps pouches ready to furnish whatever is needful for the emergency. The process of trimming to fit their equipment to their duty has been going on gradually, and the present administration of the medical department is to be commended for the common sense which has dictated these changes. A cut was made in the right direction, when the useless sword was cut from the side of the hospital steward, and it was an equally good cut which relieved the men from the weight of the huge knife which they wore so long on their left side, and which was useful, so far as the ordinary observer could see, only in demonstrating how itself and its sheath could be utilized as extemporized

splints for a broken humerus during some fancy drill for the popularization of "first aid." The hospital corps man may be considered now to be in full dress when he has his sling on his shoulders, his pouch by his side and his litter at the "carry." This is a great improvement. He has one less suit of clothes to purchase out of his allowance for clothing and to keep from getting moth-eaten during his enlistment; and as his clothing allowance has not been cut down correspondingly, he can now provide himself with white suits for hospital wear without having to invest some part of his small monthly stipend on this account.

And this leads us to consider what is and what ought to be the full dress uniform of the soldier. The medical department has solved this question for itself as regards the sanitary soldier. May we be permitted, from our professional standpoint, to suggest that the military authorities might profit by the example. Is the full dress uniform of the soldier that in which he is ready for any duty that may be required of him, or that which his care keeps from getting moth-eaten so that it may be on hand for special occasions of ceremony? Is it the uniform best suited to show off the mobility, gracefulness and power of the human figure? The officer who can not bring his hand to the salute without risk of dislodging his shoulder knot, can hardly say so, nor can the soldier who, from heat exhaustion or sunstroke, sinks, before the parade is half over, into the hands of the hospital corps to have his full dress coat unbuttoned as the first step of the first aid they have been taught in such cases. Military officers recognize the rigidity of the helmet, the stiffness of the padded coat and the general unsuitability of the full dress uniform to the active duties of the soldier; but they fear that in abandoning it there would be a risk of developing in the carriage of the men, we will not say a tendency to slouchiness, but some loss of that dignity or stateliness which is usually considered to be a visible manifestation of the reserve power of the individual. But this is a poor argument against a desirable reform. Troops that require to be splinted into a military set-up are not those that will win the battles of the future. The erect figure and martial bearing of the soldier should be the development of graded gymnastics and athletic games, and should ask nothing from the uniform except freedom of movement for every muscle in the well-developed physique.

The soldier's leathern stock died hard more than a generation ago. Is it not time to consider and reject what remains of the stiffness of antiquity about the full dress uniform? This may not be a consideration of national importance as concerns the uniform of our small regular army, but it becomes so when we consider the larger number of our State troops and the tendencies manifested in uniforming the various schools, public and private, of the country.

## CORRESPONDENCE.

## The Michigan Legislation League.

OPEN LETTER NO. 3, TO THE MEMBERS OF THE MEDICAL PROFESSION (REGULAR) IN MICHIGAN.

DETROIT, MICH., Aug. 10, 1896.

*To the Profession in Michigan:*

The letter of Dr. Shurly in the JOURNAL of last week is surely a most astonishing document. He begins by saying that "of course there is no use of continuing a controversy" and then he proceeds to "continue." In so doing the writer plunges head foremost into ancient history and appears to revel in confessing the iniquities and follies committed by himself and friends in former times. In that respect we are perfectly in accord with every word. The confessions have our sincere and cordial endorsement. But when Dr. Shurly presumes to accuse me and my friends of the crime of emulating the horrible example set by him and his friends twenty years ago, I have no choice but to charge Dr. Shurly with a degree of inaccuracy utterly unworthy of the man who occupies the exalted position of President of the Michigan Medical Legislation League!

Twenty years ago the medical faculty of the Michigan University found themselves face to face with a most trying dilemma. We had to choose whether we would stand by regular medicine and defend its good name against all comers and protect the university from the evils of sectarianism in medical teaching, or whether we would accept peace and popularity for ourselves by handing over the whole institution to the enemies of science and honest medicine. Dr. Shurly and his friends, by his own confession, cruelly and bitterly urged the latter alternative, but we preferred the former, and the time soon came when the profession and the public, with wonderful unanimity, applauded our course. The eloquence sneered at by Dr. Shurly certainly proved effective with the profession and the public although he admits that so far as he and his friends were concerned it was "*pearls before swine.*" In other and perhaps plainer terms I hereby solemnly declare that Dr. Shurly and his friends, in the emergency to which he refers to proclaimed with intense bitterness their ambition to secure the engrafting of homeopathy on to the great State institution of Michigan in the hope that thereby the University Medical School, with all its honorable record, might be crushed and disgraced and the embryo weaking, the Detroit College of Medicine built up on its ruins. At that time the scheme was to deliver the university into the power of irregulars. The scheme now is to hand over the whole profession of the State into the same hands!

Through all that painful and discreditable controversy, Dr. Shurly and everyone else knows full well that I and my associates in the faculty and in the profession never for a moment entered into any association or compromise with the homeopathic sect. On the contrary, in the medical societies and in the medical journals, in season and out of season, we consistently and persistently denounced them and all their pretentious claims to respect and public recognition as unfounded and fraudulent. We never justified or approved the graduation of a single homeopathic doctor. We never signed a single homeopathic diploma. Our utmost efforts were used at all times to convince everyone of the folly and iniquity of that peculiar form of mental and moral aberration called "*homeopathy.*" We opposed by all the means in our power, the crime of introducing sectarianism into the medical department. With calm, cool dignity we stood entirely aloof from the homeopathic department in the university, never condescending to contend with or notice them in any way, except when grossly attacked to defend ourselves. Consequently we enjoyed the privilege of seeing their institution pass through one long interrupted series

of internal squabbles and scandals and failures until now it has got to be a by-word and a reproach among the educational institutions of the State and the nation, repudiated even by its own followers.

When Dr. Shurly ventures to draw a parallel between the admittedly shameful conduct and policy of himself and friends in that old controversy and our attitude toward his Michigan Medical Legislation League, he is as illogical and ridiculous as he would be if he propounded the following problem: "If a barrel of pork cost \$10, how much would a gold mine in Nevada cost?"

Even Dr. Shurly justifies now our course in the old homeopathic controversy, but I defy him and all his league to justify or defend their associations with the whole army of quacks and imposters for the purpose of obtaining legislative action, the aim and object of which, by their own published avowal, is to "protect the new beginner by limiting competition."

From the best information which we have been able to obtain, there would seem to be well-founded expectations that the "Michigan Medical Legislation League" is causing painful apprehensions as to its "viability." Its nearest and dearest friends, as we are informed, are seriously alarmed for it, and the hopeless term "stillborn" seems quite likely to sum up its whole unfortunate and discreditable career, suggesting the oft-quoted and pathetic couplet: "If I am so soon done for, I wonder what I was begun for." It seems pretty certain that the "League" is, to say the least, a "dead issue." In these circumstances it seems to be incumbent upon all right thinking members of the profession to bestir themselves and in the true spirit of professional honor and wisdom endeavor to evolve some plan by which the best interests of humanity and of science may be sufficiently provided for in the matter of medical legislation in the State of Michigan. It is inconceivable that this must of necessity prove to be a hopeless task. If approached in a proper spirit it ought to be, if not an easy, still a practicable, undertaking, to construct a policy and perfect a program by which, while granting reasonable and just recognition to all parties and paths outside the pale of regular medicine, the honor and the good name of the latter shall still be preserved safe from charges or insinuations of weakness, evil association and cowardice. If it should ultimately appear that the time is not yet ripe for the accomplishment of such a program surely the regular profession is the one party which is strong enough to maintain itself unaided in the future, as it has in the past, and while regretting for the sake of the sick and the suffering the unfortunate condition of affairs in Michigan, we as a school, or party, can best afford to go steadily forward in our honest endeavors to promote the interests of science and humanity. We of all others can afford to wait and hope for the time to come when the clouds of ignorance and quackery shall pass away and justice be done to science and humanity so far as the practice of medicine in our State is concerned. We take this opportunity to suggest to those who may feel an interest in the subject a careful study of the medical law of the State of Pennsylvania.

Without being in any degree prejudiced in favor of any individual law at present in operation, and while we stand ready now and always to do all in our power to secure a sound and satisfactory solution of this problem, no matter what source or quarter the idea may spring from, we feel free to say the Pennsylvania law would seem to contain many valuable and practical features. But in any event we are more than willing to cooperate with any man or set of men (so long as they are fit for gentlemen to recognize and associate with) for the purpose of accomplishing or in any way advancing the matter of medical legislation for the suppression of quackery with all its distressing accompaniments of cruelty and robbery, and at the same time conferring increased honor and power upon all those who are honestly and sincerely devoting their lives and labors to the

relief of suffering and the extension of science and art in medical practice.

We will be glad to communicate with all persons whose views are in accord with those set forth in these "open letters," or to listen respectfully to those who differ with them, if any such there be.

In conclusion, I am perfectly willing to accept and endorse the suggestion of Dr. H. B. Young of Burlington, Iowa, in his letter to our JOURNAL this week. There seems to me to be something of a professional wisdom and dignity in his plan which is a great deal more than anyone can claim on behalf of the avowed policy of the Michigan Medical Legislation League.

Here must end this correspondence so far as I am concerned.

DONALD MACLEAN, M.D.

### Professor Klebs Repudiates an Attempt to Place Him in a False Light.

CHICAGO, ILL., Aug. 14, 1896.

*To the Editor:*—The enclosed is a copy of a letter which I have this day sent to the President and Secretary of the Harvard Evening Medical College and Hospital of Chicago.

I never authorized the use of my name in any capacity, in connection with said institution, and their using it in an Announcement, is entirely without a shadow of right.

Respectfully yours, EDWIN KLEBS, M.D.

"CHICAGO, ILL., Aug. 14, 1896.

"A. H. Tagert, M.D., President, and Walter M. Fitch, M.D., Secretary, Harvard Evening Medical College and Hospital, Chicago, Ill.:

"Gentlemen:—I have received a copy of your Announcement for the session of 1896 and 1897, and have to express my astonishment that you put me down as 'Professor of Morbid Anatomy, Bacteriology and Original Research' in your institution.

"I never consented to accept any such position in your school, and you are hereby notified that, unless you immediately suppress these Announcements, I will be compelled to take legal measures to compel you to do so. I have also made public announcement of the fact that I have no connection whatever with your school.

"Respectfully yours, EDWIN KLEBS, M.D."

### It was Pernicious Fever.

NEW HAVEN, CONN., Aug. 13, 1896.

*To the Editor:*—Replying to yours of the 11th inst., would say, the case you allude to was probably one of malarial poisoning in a severe form, but the symptoms taken in connection with a recent visit to New York, Brooklyn and Newark, fully justified the suspicion of yellow fever. Her first symptoms were great lassitude and supra-orbital pain. She had a very severe chill lasting several hours, which was followed by high fever and nausea and vomiting. Temperature 106 degrees, followed by collapse. At one time the vomit was blackish. She had only one paroxysm terminating in collapse and death. An intense and rapidly developed jaundice, shortly before death. Some uterine hemorrhage.

The New York health authorities say however, that no source of infection is known to exist in that vicinity, either now or recently. No autopsy was made. The present opinion is that the case was one of pernicious or congestive fever.

Respectfully yours, C. A. LINDSLEY,  
Secretary, Connecticut State Board of Health.

### Another Diploma Mill in Wisconsin.

MADISON, WIS., August, 17, 1896.

The Attorney-General of the State of Wisconsin, Hon. W. H. Mylrea, has filed the following petition. Any of our readers

having circulars or letters relating to this institution will confer a favor by sending them to this office.

In the matter of the application of the Attorney General for leave to bring suit to dissolve the corporation known under the name of the Milwaukee University (Medical and Dental College), to the Supreme Court of the State of Wisconsin.

The Attorney General of the State of Wisconsin respectfully shows: That on or about the 24th day of February, 1896, there was formally organized under the laws of this State, by Dr. Samuel Shorer, Dr. Theodore Walther and Dr. Oscar Abert, a corporation to be known under the style and name of the Milwaukee University. That said corporation was formed without capital stock "for the purpose of teaching students the science of medicine and dental surgery, and preparing and educating them to practice as physicians and dentists, and conferring upon them, upon examination, and they having succeeded in passing such examination as to their knowledge of such sciences, the Degree of Doctor of Medicine or Doctor of Dental Surgery, or such other degree which may be proper, according to their knowledge exhibited on such examination.

Your petitioner further shows that heretofore he has been credibly informed that said corporation in breach of its trust has knowingly and wilfully abused the powers conferred upon it by its articles of association and certificate of incorporation, and also has knowingly failed to exercise its powers so conferred, and still wilfully neglects to exercise its powers and trusts as provided by law.

That after receiving said information and within a few days last past, your petitioner visited the city of Milwaukee, being the city in which said corporation is located, and visited its alleged college, located at the corner of Eighth and Chestnut streets, in said city and state. That your petitioner there met and interviewed said Dr. Oscar Abert, who claimed to be the secretary and treasurer of said corporation, as well as the dean of the dental faculty thereof. That at said time and place said Dr. Oscar Abert admitted that as far as he knew no records had been kept of the meetings of the board of directors, and that no by-laws had been adopted, or any means whatever taken to preserve the records of any of the acts or doings of said corporation, contrary to the statutes in such case made and provided. That Dr. Abert stated to your petitioner that possibly such records had been made by the president thereof or by the dean of the medical faculty, Dr. Theodore Walther, but that no such records were kept in the University. That your petitioner visited the alleged office of said Dr. Theodore Walther and found that he was absent from the city of Milwaukee, and State of Wisconsin, and that no definite information as to his return could be obtained. That the office of said Dr. Theodore Walther was in a small building, the lower part of which was occupied as a saloon. That the keeper thereof informed your petitioner that said Dr. Theodore Walther might return to the city of Milwaukee on the following day and might not for some time. That the building of said college was formerly a residence, and later a small private hospital, and as your petitioner is informed, is not owned by said corporation. That the said Dr. Oscar Abert further admitted to your petitioner that all the college library in use in said building was two small bound volumes, printed in the German language, and a few pamphlets. That the said Milwaukee University does not own or possess the necessary appliances for the successful teaching of medicine, surgery and dentistry. That the University owns and possesses only one skull and a few bones of the human skeleton, and is not supplied with any of the ordinary paraphernalia used in teaching the sciences before mentioned.

Your petitioner further alleges upon information and belief that said college was formed without capital stock and that it does not even possess sufficient medical and surgical instruments as would be used by an ordinary member of the profession in every day practice. That no salaries have ever been paid to any teachers. That the only resident of the college building or person in charge thereof is said Dr. Oscar Abert.

That said Milwaukee University publishes a prospectus from which it appears that one Dr. Shorer is president thereof. That said Dr. Shorer is a resident at No. 571 Mitchell Street, Milwaukee, Wisconsin, and is engaged in the private practice of medicine. That one Dr. Carl Wagner is also a director of said corporation and resides at the city of Chicago, and that he has never visited or given any instruction in said college. That the vice-president of said college is one Dr. E. Schoene, a resident of Fredonia Station, Washington County, Wisconsin.

That your petitioner has been informed and verily believes it to be true that said Milwaukee University has issued a large number of diplomas conferring the degree of Doctor of Medicine or Doctor of Dental Surgery upon persons who have never even visited the city of Milwaukee. That said Dr. Oscar Abert admitted to your petitioner that quite a large number of such diplomas had been issued to parties residing in Germany, and that the sum received for each diploma issued was two hundred dollars (\$200.00), and in addition the notary fees necessary to furnish the party with a certified copy of the articles of association and certificate of incorporation. That said diplomas, as your petitioner is informed and verily believe, were fraudulently issued to persons utterly unqualified to practice medicine, and who had never pursued a proper course of study, and who fraudulently intended to procure these diplomas for the purpose of enabling them to practice medicine and surgery, the same as the graduates of the best medical schools of the land. That said Dr. Oscar Abert further admitted to your petitioner that he was not a graduate of any medical college and had never received any authority to practice medicine, and that the only diploma he had ever received was that of Doctor of Dental Surgery. That he was unable to exhibit to your petitioner said diploma, but in lieu thereof exhibited to your petitioner what purported to be a license issued by the Board of Dental Examiners of the State of Illinois.

Your petitioner further alleges upon information and belief that the said Milwaukee University was never organized or formed for the purpose of teaching students the science of medicine and dental surgery, and that said Milwaukee University has never prepared or educated, or intended to prepare or educate any person or persons for the purpose of enabling them to practice as reputable physicians or dentists, or for the purpose of conferring upon them, after due study and examination, the degree of Doctor of Medicine or any other degree, according to their knowledge as exhibited on such examinations. Your petitioner further shows upon information and belief that said corporation was not organized in good faith, but was knowingly and wilfully organized for the purpose of issuing diplomas in order to enable unfit and unskilled persons to secure authority to practice medicine and to enable the organizers and promoters of said Milwaukee University to secure large sums of money for false and fraudulent diplomas, not only from the innocent and unsuspecting, but from ignorant and corrupt persons who desired the pretended authority to practice medicine for their own selfish purposes.

That your petitioner is informed and verily believes that said Milwaukee University has caused large numbers of advertisements to be

inserted in newspapers throughout the different States of the Union soliciting such persons as are above described to apply to it for diplomas and licenses such as would permit them to practice medicine in this and other States without being qualified or prepared for such profession.

That said corporation has issued a great many diplomas to persons who have made no preparation or study of the science of medicine or dentistry. That said Milwaukee University sends out a large number of prospectus to different persons throughout the United States and foreign countries for the purpose of soliciting applications to purchase the fraudulent and bogus diplomas, heretofore mentioned. That said corporation is in no wise a *bona fide* corporation, or organized for the purpose of advancing science, or for the maintenance and use of a college for the study of medicine and dentistry, or for any other lawful purpose whatever, but for the purpose of falsely and fraudulently obtaining money from the innocent and vicious.

Your petitioner further alleges on information and belief that to permit this corporation to carry on its alleged business is detrimental to public policy and good morals and contrary to the interests of the State of Wisconsin, as well as to the advancement of the science of medicine and dental surgery.

Wherefore, your petitioner asks leave to bring an action in the name of the people of the State of Wisconsin for the purpose of vacating the charter and annulling the existence of said corporation.

W. H. MYLREA, Attorney-General.

State of Wisconsin, } ss.  
Dane County.

W. H. Mylrea, being duly sworn on oath, says that he is the duly elected and qualified attorney-general of the State of Wisconsin, and acting as such. That he has read the foregoing petition and knows the contents thereof, and that the same is true of his own knowledge, except as to those matters therein stated on information and belief, and as to those matters he believes it to be true.

W. H. MYLREA.

Subscribed and sworn to before me this 11th day of August, 1896.  
JOHN PRICE, Jr., Notary Public, Dane County, Wisconsin.

## NEW INSTRUMENTS.

### A NEW MIDDLE EAR, MASTOID AND LACHRYMAL SYRINGE.

BY ALFRED HINDE, M.D.  
CHICAGO.

In suppurative inflammations of the middle ear, both acute and chronic, and of both atrium and attic and also in the

extensions of the same pathologic process into the mastoid antrum the difficulties of removal of exudate, drainage, irrigation and disinfection of the infected parts are almost insuperable. For some years past I have had made and used drawn out and bent glass syringes, not unlike medicine droppers with elongated bent points. These, though exceedingly valuable for the purposes required have now been relegated to the curiosity shelf and the following syringe, modeled on their plan but indestructible and of greater capacity and power has taken their place in my practice and has been found a most useful and satisfactory instrument for the purposes required.

The syringe has four hollow tips, each seven centimeters long; the diameter of the ear end of each tip is one millimeter and

that of the outer end three millimeters. One tip (B) is straight and the other three have a bend of four millimeters at right angles to the shaft. One of the bent tips (C) has an end opening at the ear end, one has an opening (E) on the right side at the tip, the other (D) has an opening on the left side at the tip; the two latter have closed ends. These tips fit on to a plain metal slip-joint on the other part of the syringe, which is as follows: From the extremity of the joint one centimeter, the shaft is bent at about an angle of 70 degrees and continues for a distance of four and a half centimeters, enlarging in caliber as it proceeds. At the widest end it fits upon a screw, the enlarged end of which is within a rubber ball. Between the screw and the rubber bulb is a metal cup into which the rubber ball fits. This cup covers one-third of the outer circumference of the rubber ball. The joint between the shaft and the ball being a screw requires a washer to render it water-tight. The syringe when filled with fluid has an emptying capacity of two drams as at present made, but larger rubber bulbs can be attached as desired, or a connection with an irrigating vessel be used. The metal parts are of German silver. The instrument can be readily taken apart and sterilized. The straight tip can be used and an excellent lachrymal syringe improvised. Also the bent tip with the opening at its end can be used for irrigating the antrum of Highmore. For ear purposes the straight tip is used for emptying, disinfecting and irrigating the atrium. The bent tips are used in the attic. The one with the end opening is merely for injecting the attic cavity after the latter has been emptied of its necrotic ossicles and suppurating contents. The two bent tips with the lateral openings placed posteriorly when in use are for injecting and disinfecting the mastoid antrum through its opening into the attic after the latter has been cleared, and in those cases where every means of cure is resorted to before chiseling the mastoid, and where the latter operation is positively refused by our patient. Messrs. Sharp & Smith have made the instrument for me and to Mr. Cotter of that firm I must extend my thanks for aid in getting it out.

## BOOK NOTICES.

**A System of Surgery.** By FREDERIC S. DENNIS, M.D., assisted by JOHN S. BILLINGS, M.D. Vol. IV. Tumors; Hernia; Surgery of the Alimentary Canal; Appendicitis; Surgery of the Liver and Biliary Passages; Of the Uterus; Of the Ovaries and Tubes; Gynecologic Surgery; Symphysiotomy; Surgery of the Thyroid; Surgical Peculiarities of the Negro; Surgery of the Female Breast; Use of the Roentgen Rays in Surgery. Profusely Illustrated. 80, cl., pp. 970. New York and Philadelphia: Lea Bros. & Co. 1896.

This volume completes the most extensive system of surgery exclusively American yet published in this country. We must accord it a very high rank among the surgical works of the period. Indeed, it is not too much to say that the work, as a whole, is a fair reflex of American surgery of to-day as practiced in New York city.

Liberal use without credit is made of Prof. Nicholas Senn's scholarly article on enterorrhaphy, first published in this JOURNAL Aug. 12, 1893, Vol. xxi, p. 215. Of the forty-four illustrations in the chapter illustrating the methods of intestinal suture, nearly one-half of them may be seen in the article on enterorrhaphy. Nor is this all. It is impossible to resist the conclusion, on a fair comparison of the two, that the Senn article furnished the basis for this portion of the chapter, as almost without exception every author quoted appears in the Senn article, in which, indeed, are many not quoted in the book. The language descriptive of these sutures bears

1 Since writing the above I have had a conical tip (A) one and a half centimeters long and with the small end of a diameter of one millimeter, and the latter diameter extending from the point for two millimeters distance. This conical tip fits on to the slip joint of the shaft as do the others, and is used for lachrymal syringing.

a very close resemblance to the Senn article, as may be seen on comparison.

In the article on hypertrophy of the breast two cases are mentioned, presumably on account of their exceptional size, neither of which approached in size the case reported by Professor Hamilton in this JOURNAL March 9, 1895, Vol. xxiv, p. 358, in which the glands after removal weighed respectively  $27\frac{1}{2}$  and  $24\frac{1}{2}$  pounds. Before removal, one of these breasts measured 42 inches in circumference at the nipple and the other 39 inches. The quotation from Williams also appears in Hamilton's article, but in the book there is a grammatical error in copying.

We notice in the excellent article on surgery of the thyroid gland, p. 830, that the old director of Kocher is figured. The one at present used by that distinguished operator has a fenestra near the end.

The chapter on the surgery of the alimentary canal from the ileo-cecal valve to the anus, by Dr. Lewis S. Pilcher, is one of the most satisfactory in the book.

The last chapter, by Prof. W. W. Keen of Philadelphia, "On the Use of the Roentgen X Rays in Surgery," presents in a condensed form the salient points of the subject, and gives this book the credit of being the first work on surgery in the English language to contain any reference to it. We can not close this notice without complimenting the editor on the happy conclusion of his arduous task, and the publishers on having produced a work with such uniformly excellent illustrations, and such splendid appearance. No general surgeon or general practitioner can consider his library complete without a copy of Dennis' System.

**Treatise on Appendicitis.** By JOHN B. DEEVER, M.D. Containing 32 full-page plates and other Illustrations. 80, cl. Philadelphia: P. Blakiston, Son & Co. 1896. Chicago: W. T. Keener & Co.

This monograph contains an account of the history, anatomy, etiology, pathology, symptoms, diagnosis, differential diagnosis, prognosis, treatment, complications and sequelæ and after-treatment of appendicitis.

Dr. Deever's work will be found in all respects satisfactory, the illustrations are accurate and clear and the author's advice is sound.

## SOCIETY NEWS.

**Alabama, Georgia and Tennessee Meeting.**—The Tri-State Medical Society of Alabama, Georgia and Tennessee will hold its eighth annual meeting at Chattanooga, Tenn., October 13-15. The prospects are favorable for a large attendance.

**Lehigh Valley Medical Association.**—The sixteenth annual meeting of this association took place in Wilkesbarre, Pa., August 6. Dr. George M. Gould, by request, read a paper on "Some Curiosities of Medical and Surgical Practice," in which he cited a number of instances of children having been born at railway stations, theaters and in street cars, and gave an explanation of the cause of the incidents that came under his practice within the past few years. The following officers were elected for the ensuing year: President, Dr. J. R. Bucher, Lebanon; vice-presidents, Dr. Mary Greenwalt, Stroudsburg; Dr. G. T. Fox, Allentown; Dr. O. F. Harvey, Wilkesbarre; Dr. C. J. Leaver, Reading; secretary, Dr. Charles McIntyre; assistant secretary, Dr. W. S. Stewart, Wilkesbarre; treasurer, Dr. A. Stout, Bethlehem.

**The American Electro-Therapeutic Association.**—The sixth annual meeting of the American Electro-Therapeutic Association will be held Sept. 29-30, and Oct. 1, 1896, in Boston, Mass. Prof. A. E. Dolbear, Tufts' College, Mass., is the Chairman of the Committee of Arrangements. Dr. W. H. White, 222 Marlborough Street, Boston, Mass., is the Vice-Chairman of the Com-

mittee of Arrangements. Dr. Frederick H. Morse, Melrose, Mass., is the Chairman of the Committee of Exhibition.

The next annual meeting promises to be a greater success than any former one. Great interest is shown in all quarters; a large attendance is promised. Many candidates of national reputation are proposed for membership, so that the amendment to increase the limit of members becomes a necessity. The best talent has already announced papers, a larger number than ever before, at this early date; material almost sufficient to make a program for the session of unusual interest. There will be two discussions of importance in electro-therapeutics, interesting reports of all standing committees, several scientific lectures on the first evening, with demonstrations and stereoscopic views (including Roentgen X Rays, and electric principles in the treatment of diseases), given by eminent talent. The Committee of Arrangements has surprises in store for the social element in receptions and excursions. The exhibition promises to be a good feature and of more than usual interest. The fifth annual volume of the Transactions of the American Electro-Therapeutic Association is now on press, and will be ready for delivery about the end of July, 1896; illustrated, cloth bound, gilt lettering, octavo, about three hundred pages. EMIL HEUEL, M.D., Secretary.

**The American Academy of Railway Surgeons.**—The third annual meeting of this Association will be held in Chicago, Sept. 23-25, 1896. The officers are: President, John E. Owens, M.D., Chicago; first vice-president, L. E. Lemen, M.D., Denver, Colo.; second vice-president, F. L. Peck, M.D., Clinton, N. Y.; secretary, Webb J. Kelly, M.D., Galion, Ohio; treasurer, C. B. Kibler, M.D., Corry, Pa.; editor, R. Harvey Reed, M.D., Columbus, Ohio.

The following papers will be presented and discussed:

- President's Address, J. E. Owens, M.D., Chicago.
- Use and Abuse of Expert Testimony, with some Recommendations for its Improvement. An Attorney.
- Diseases of Railway Men, caused by their Occupation. J. F. Pritchard, M.D., Manitowoc, Wis.
- The Personal Equation among Train-men; its Importance Equal or Greater than the Color Sense. Illustrated by an automatic machine which records both. Robert Tilley, M.D., Chicago.
- Penetrating Wounds of the Eye Ball. Archibald G. Thompson, M.D., Philadelphia, Pa.
- Penetrating Wounds of the Eye Ball. G. A. Wall, M.D. Topeka, Kan.
- Penetrating Wounds of the Eye Ball. T. J. Redelings, M.D., Marinette, Wis.
- Penetrating Wounds of the Eye Ball, with Special Reference to Differential Diagnosis. D. C. Bryant, M.D., Omaha, Neb.
- Remote Effects of Bone Trauma. D. S. Fairchild, M.D., Clinton, Iowa.
- Medico-Legal Aspects of Floating Kidney. R. Harvey Reed, M.D., Columbus, Ohio.
- Railway Surgery. Jessie Hawes, M.D., Greeley, Colo.
- Emergency Surgical Practice. C. K. Cole, M.D., Helena, Mont.
- First Aid in Railway Emergencies. James E. Pilcher, M.D., Columbus, Ohio.
- Experimental Research into Shock in Abdominal Operations and Injuries. Geo. W. Crile, M.D., Cleveland, Ohio.
- Shock and Collapse, with Special Reference to Amputations. Webb J. Kelly, M.D., Galion, Ohio.
- The Delirium of Shock. R. S. Harnden, M.D., Waverly, N. Y.
- Injuries of the Hands and Fingers. John McLean, M.D., Pullman, Ill.
- An Experimental Study of Colles' and Pott's Fractures on the Cadaver. A. D. Bevan, M.D., Chicago.
- The Cause and Mechanical Treatment of Subluxation of the Knee-Joint. S. L. McCurdy, M.D., Pittsburg, Pa.
- Compound Comminuted Fractures at the Knee, with Report of a Case. W. A. Ward, M.D., Conneaut, Ohio.
- Relation of Tuberculosis of the Knee to Injuries of said Joint. H. Reineking, M.D., Sheboygan, Wis.
- Fractures of the Femur. E. M. Dooley, M.D., Buffalo, N. Y.
- Past and Present Obstacles to the Radical Cure of Hernia. E. Wyllys Andrews, M.D., Chicago.
- Treatment of Tramps and Trespassers. H. J. Williams, M.D., Macon, Ga.
- Roentgen Ray Demonstration.

## PUBLIC HEALTH.

**Rochester Death Report.**—The Health Board of Rochester, N. Y., report the number of deaths for the month of July as 262: 108 were under 1 year of age, 23 over 60, and 22 over 80 years of age. Four of the decedents were 90 years old.

**Chicago Death Rate for July.**—During July the total number of deaths in the city was 2,457. One hundred and twenty-two were due to violence, 58 were from typhoid fever, 367 infantile diarrhoea, 385 acute intestinal trouble, and 107 heart disease. The death rate for the month was 1.52 per 1,000.

**Sanitary Rules for Mothers.**—The Board of Health of the city of Macon, Ga., has issued a little pamphlet for the benefit of mothers who have young children, and who need advice and warning in order to guard the health of their offspring from the diseases incident to hot weather.

**Necessary Precautions.**—Dr. Alvah H. Doty, Health Officer of the Port of New York, sailed August 8 for Cuba, where he will remain ten days collecting information for use in preventing the outbreak of yellow fever and smallpox among passengers en route to this port from Havana. The principal object of Dr. Doty's visit is to select and appoint a resident physician in Cuba upon whom he can call at any time for such work and information as might help him in the purposes of his own work here.

**New Orleans Free from Smallpox.**—New Orleans has practically stamped out the smallpox, which has been epidemic in that city for some time past. It made its appearance in 1895 and increased in the number of cases until in March of this year there were 334 cases and 83 deaths. Up to July 31 there had been 828 cases and 235 deaths this year. The methods adopted were general vaccination and strict quarantining. It is claimed that no such energetic campaign against the smallpox was ever conducted before. The climatic conditions and the nature of the population of New Orleans made this necessary.

**Health in Michigan, July, 1896.**—Reports to the State Board of Health, Lansing, by observers in different parts of the State, show that, compared with the preceding month, cholera infantum, dysentery, cholera morbus and diarrhoea increased in area of prevalence; compared with the average for July in the ten years, 1886-1895, consumption, intermittent fever, remittent fever and cholera infantum were less than usually prevalent. Consumption was reported present in Michigan in the month of July at 213 places; typhoid fever at 82; measles at 65; scarlet fever at 44; whooping-cough at 40 and diphtheria at 27 places.

**Inefficiency of Filters and Sterilizing Processes for Drinking Water.**—A couple of years ago the Paris authorities offered a prize for the best process of purifying and sterilizing large quantities of water. The committee in charge report now that no such process exists, that every attempt thus far has proved a failure, and that the only means to secure suitable drinking water is to procure it from unpolluted sources. The nearest approach to this is the sand filter, with or without chemicals, but enough filters must be provided so that they can be changed and used in turn, and they must be under the incessant and scrupulous care of experts. The only process for separate establishments, schools, barracks, etc., is to boil the water and keep it exposed to the air while protected from dust. No known filter, large or small, will supply permanently suitable drinking water, as they all require care and supervision beyond the possibility of realization.—*Semaine Méd.*, July 22.

**Formalin as an Official Disinfectant.**—According to *Hygienische Rundschau*, the above substance can be applied to the disinfection of rooms and goods such as is practiced by sanitary officials. An inquiry taken up at the Stockholm Hygienic Institute by Nils Englund into the best and most practical

method among the many proposed for the disinfection of rooms and buildings, has demonstrated that the original recommendations of spraying with a dilute formalin solution, or the suspension of clothes saturated with formalin solution in the space to be disinfected are after all the best. Both these methods proved most efficient in the destruction of bacteria in rooms: 1. The spray method. Walls, furniture, etc., were thoroughly sprayed with a 2 per cent. formaldehyde solution and the room closed for twenty-four hours; 60 to 70 c.c. of the above solution sufficed for each square meter of surface. 2. Evaporation of solutions. Clothes were saturated with one pint of formalin solution in which half a pound of calcium chloride was dissolved. The clothes were then hung in the room which was closed for twenty-four hours. For furs and books especially this method of disinfection with formalin proved specially useful. For dwelling-houses generally the spray method is exceedingly cheap. While working with it the eyes should be protected with spectacles and the mouth and nose with cotton-wool masks; the hands may be covered with vaselin or gloves.

**Violent Deaths in Great Britain.**—During 1895, 820 persons lost their lives in railway accidents, while 1,054 were killed in accidents to vehicles; 253 were run over by trains and 372 by vehicles. Other causes of accidental death were: Lightning, 15; cold, 91; football 16; cricket, 3, and cold baths, 2,172. Suicides, 2,052 men and 677 women.—*Prog. Méd.*, July 25.

**Improved New Sanitary Prisons for Paris.**—The new hygienic prisons at Fresnes, which are to take the place of the old ones inside the city limits are said to be models in every respect. The new Montesson school will receive the children until recently incarcerated in cells at the Petite Roquette, and teach them some useful trade amid beautiful, healthy surroundings. The men and the children are thus provided for, but the disgraceful old prison of St. Lazare for the women has not yet been superseded.

**Preliminary Medical Examinations in Pennsylvania.**—The State Medical Council having adopted a rule that all who expect to practice medicine in the State must submit to a preliminary examination. It will be conducted at the following places by the examiners named: Altoona, Prof. D. S. Keith; Easton, William W. Cottingham; Erie, H. C. Missimer; Harrisburg, L. O. Foote; Philadelphia, James F. C. Siekel; Pittsburg, George J. Luckey; Reading, E. Mackey; Scranton, George Howell; Williamsport, Charles Lose. The scope of the examination includes arithmetic, grammar, orthography, American history and English composition.

**Inspection of New York State Charities.**—We note with pleasure in the *Medical News*, August 1, an announcement that the veteran sanitarian and philanthropist, Dr. Stephen Smith of New York City, has been invited to assist in the reforming of certain of the charities of his State institutions that are said to receive more than \$20,000,000 annually. Dr. Stoddard, of Rochester, the associate of Dr. Smith, although ten years or more his junior, is not new in the sanitary field. Dr. Stephen Smith and Dr. E. V. Stoddard, are members of a newly appointed committee of inspection of charities, under the New York State Board of Charities. Their duties relate largely to the economic expenditure of moneys, bestowed by the State upon hospitals, dispensaries, and other charitable institutions. Under the new State constitution, supplemented by laws passed last winter, it is provided that the State board of charities "shall visit, inspect and maintain a general supervision of all institutions, societies, or associations which are of charitable, eleemosynary, correctional or reformatory character, whether State or municipal, incorporated or not incorporated, which are made subject to its supervision by the constitution or by law." The committee of inspection will investigate all charities in Brooklyn and New York, both public and private,

and will organize a system of direct supervision over all charitable work. The State has appropriated \$10,000 for this year's work. The charitable donations last year in New York State, public and private, amounted to the immense sum of \$23,000,000. No other State spends nearly as much. It is to provide for the wisest distribution of this money that the present supervision has been provided.

**Wide Dissemination of Typhoid Fever in North Carolina.**—According to the *Bulletin* of the Board of Health for July, not less than fifty-two counties in the "Old North State," out of ninety-six, reported from one to twelve cases of fever in the month of June. In Alamance County a physician lost his life by that disease. In some counties the health officers report rather vaguely, "typhoid fever in nearly all parts." The Secretary, Dr. R. H. Lewis, again demands that the water supply shall be watched in these fever stricken communities. The *Bulletin* gives the following explanation of the policy of the State Board: In order to assist in locating the origin of typhoid fever and checking its further spread when occurring in more or less epidemic form (the means at the disposal of the board would not permit it in sporadic cases), arrangements have been made with Drs. Albert Anderson of Wilson and W. T. Pate of Gibson Station for bacteriologic examination of suspected drinking water. On the back of the permit for this analysis the following appears: "Parties desiring a bacteriologic examination of drinking water must first apply to the Superintendent of Health of his county (or to the medical health officer of his city or town if it have one), who will, if in his opinion there be just cause to suspect said drinking water as the source of disease, write to the Secretary of the State Board of Health, giving his reason for such suspicion. Should they be satisfactory to the latter he will forward this permit either to said superintendent or such other physician as he may designate. The sample must be taken and packed by a physician, in strict accordance with the following directions: The fact that nearly twice as many counties reported typhoid fever this month as did last suggests the advisability of calling attention again to the importance on the part of both physicians and householders of carefully looking after the means of preventing its spread. When it is remembered that 50,000 people die annually in the United States from this disease, of which North Carolina's quota would be about 1,000, to say nothing of the constitutions shattered, of the suffering, anxiety, expense and loss of time, the gravity of the subject is apparent and no excuse for repeatedly directing the attention of both the profession and the people to their duty in relation thereto is necessary. Enteric fever is by long odds the most fatal of all the preventable diseases which occur within our borders. And it is undoubtedly preventable, in large measure certainly, and, too, by very simple and inexpensive methods. That the drinking water is the medium of transmission in an immense majority of the cases, and that the water is contaminated by the undisinfected bowel discharges of another case is practically demonstrated. So that the preventive measures necessary may be summed up in an immediate change to a water supply clearly beyond the risk of contamination, or boiling the home supply, and in promptly and thoroughly disinfecting the bowel discharges and the soiled linen."

**Health Report.**—The following reports of mortality from smallpox, yellow fever and cholera have been received in the office of the Supervising Surgeon-General U. S. Marine-Hospital Service:

**SMALLPOX—UNITED STATES.**

New Orleans, August 1 to 8, 1 death.

**SMALLPOX—FOREIGN.**

Birmingham, Eng., July 25 to August 1, 1 case.  
 Bombay, India, July 7 to 21, 12 deaths.  
 Calcutta, India, June 27 to July 11, 3 deaths.  
 Callao, Peru, July 5 to 19, 36 deaths.  
 Genoa, Italy, July 24 to August 1, 3 cases, 1 death.  
 Havana, Cuba, July 23 to August 7, 39 deaths.  
 Licata, Italy, July 18 to 25, 2 deaths.  
 Madrid, Spain, July 7 to 28, 58 deaths.  
 Naples, Italy, July 18 to August 1, 15 cases, 6 deaths.  
 Odessa, Russia, July 18 to 25, 5 cases, 4 deaths.  
 Prague, Bohemia, July 4 to 25, 6 cases.  
 Rio de Janeiro, Brazil, June 27 to July 18, 21 cases, 6 deaths.  
 St. Petersburg, Russia, July 18 to 25, 10 cases, 1 death.  
 Tuxpan, Mexico, July 18 to 25, 1 death.  
 Warsaw, Russia, July 18 to 25, 2 deaths.

**CHOLERA.**

India: Bombay, July 7 to 21, 29 deaths; Calcutta, June 27 to July 11, 54 deaths; Madras, July 4 to 17, 3 deaths.

Japan: July 13 to 21, Kisto Tu, 1 case, 1 death; Osaka Tu, 1 case; Tokio Tu, 10 cases, 4 deaths; Fuknoka Ken, 5 cases; Ibaraki Ken, 2 cases, 1 death; Kagawa Ken, 1 case; Kanagawa Ken, 2 cases; Okayama Ken, 1 case; Saitama Ken, 1 case; Sidzuoka Ken, 1 case; Wakayama Ken, 2 cases, 1 death; Yehime Ken, 2 cases.

Egypt, July 14 to 20: Cairo, 16 deaths; Alexandria, 20 deaths.

During this period, July 14 to 20, there were 1,540 deaths from cholera throughout Egypt, exclusive of those occurring in Cairo and Alexandria. Total since beginning of cholera epidemic 13,343 cases and 11,099 deaths.

**YELLOW FEVER.**

Havana, Cuba, July 23 to August 6, 210 cases, 95 deaths.

Rio de Janeiro, Brazil, June 27 to July 18, 20 cases, 13 deaths.

Sagua la Grande, Cuba, July 18 to August 1, 166 cases, 16 deaths. Vera Cruz, Mexico, July 30 to August 6, 3 cases.

According to reports of the Spanish Army Sanitary Corps in Cuba for the first twenty days of July, 1896, there were during that period 1,835 new cases of yellow fever admitted to the hospitals in Cuba. There were also during the same period 497 deaths among the yellow fever hospital patients.

**NECROLOGY.**

**JEROME COCHRAN, M.D.**, Montgomery, Ala., died after a lingering illness August 17. He was the descendant of a

**JEROME COCHRAN, M.D.**

PORTRAIT FROM WATSON'S PHYSICIANS AND SURGEONS OF AMERICA.

Scotch-Irish family, and was born at Moscow, Tenn., Dec. 4, 1831. Having received a common school education, afterward supplemented by a course of private study, embracing biology, theology, metaphysics, and the foreign languages, he entered the medical department of the University of Nashville, and was graduated from that institution in 1861. During the Civil War he served as surgeon in the Confederate Army. In June, 1865, he established himself in Mobile, where he resided for some years. For the past fifteen years he resided in Montgomery. Of his writings may be mentioned: "Administration of Chloroform by Deglutition," "History of the Yellow Fever Epidemic of 1873," "The White Blood Corpuscle; its Physiology and Pathology," "History of the Smallpox Epidemic of 1874-75 in the City of Mobile."

As a sanitarian he was one of the foremost and through his efforts many acts of the Alabama legislature relating to State medicine were passed by that body. He drafted the "Act to Establish Boards of Health in the State of Alabama" (passed by the legislature in 1875), constituting the State Medical Association, the State Board of Health, and the County Medical Societies; drew the "Health Ordinance of the City of Mobile," as adopted in 1872, and revised in 1875; and drew the "Act to Regulate the Practice of Medicine in the State of Alabama" (passed in 1877), requiring satisfactory examination of all persons desiring to practice medicine in the State. He had been an ardent advocate of this measure since 1871. Since 1873 he had been chairman of the committee on public health of the State Medical Association, a position equivalent to that of health officer of the State. From 1868 to 1873 he was Professor of Chemistry in the Medical College of Alabama, and since that time he has been Professor of Public Hygiene and Medical Jurisprudence in the same institution.

He was associated with the late Surgeon-General Woodworth of the Marine-Hospital Service, and the late Dr. S. M. Bemiss of New Orleans on the Yellow Fever Commission, which investigated the yellow fever epidemic of 1878, and collected the history of each single case that was obtainable. This report was remarkable for the vast amount of painstaking labor expended upon it. The traveling expenses of Drs. Cochran and Bemiss were defrayed by the late Elizabeth Thompson of New York and the MS. was turned over to the National Board of Health by Dr. Hamilton, who succeeded Dr. Woodworth. We believe that this report was never printed, although extracts were from time to time printed. Dr. Cochran was one of the most active health officers in the United States, and a man of phenomenal energy. His sanitary work at Decatur, Ala., in 1888 was intelligent and thorough. As a man his character was that of one devoted to sanitary science, of great learning and unwearied industry. His long and faithful service to his State is such that it can not be overrated or excluded from the history of its progress. He had his "quips and oddities," what genius has not? But take him all in all, we shall not see his like. His friends, his State, his country and our Association have suffered a great loss.

W. H. ROSS, M.D., at Pensacola, Fla., August 8. He graduated from the College of Physicians and Surgeons, New York, in 1868, and was a member of the Florida State Medical Association. He had formerly been house physician in the Charity Hospital, New York, professor of anatomy in the Medical College of Alabama at Mobile, assistant State health officer of Florida, etc.

JOHN H. NORRIS, M.D. (College of Physicians and Surgeons, Keokuk, Iowa, 1870), at Metropolis, Ill., August 13, aged 66 years. He was ex-mayor of the city and prominent among the medical fraternities of Southern Illinois and Southwestern Kentucky. He was captain of Company M, Thirteenth Illinois Cavalry, served with distinction throughout the late war, and was breveted major.

WM. H. MATLACK, M.D., of Downingtown, Pa., died there July 12, aged 59 years. He was of the class of 1859, Jefferson Medical College.

DAYTON E. DECKER, M.D., of Woodbridge, N. J., died at Princeton, N. J., July 20. He was the only son of the late Dr. Dayton Decker and a graduate of the Long Island College Hospital, class 1874.

JOHN H. MCGIVERN, M.D., died at Plympton, Nova Scotia, July 21. His remains were interred at St. John, N. B., the place of his birth. He was a graduate of the New York University Medical College in 1883, and soon after began practice in the Harlem portion of New York city, where he became somewhat prominent in the cause of municipal reform.

WM. A. ROTHACKER, M.D., Cincinnati, aged 42, died after a prolonged illness. Dr. Rothacker was compelled to retire from

active practice a number of years ago by reason of poor health, but up to that time he had occupied a prominent position in the local profession. He was at one time demonstrator of anatomy in the Medical College of Ohio, and edited a well-known work on anatomy. He graduated from the Cincinnati College of Medicine and Surgery in 1877.

SIMON M. CURTWEEL, M.D., of Maysville, Ky., aged 78 years, died August 4. He was surgeon of the Sixteenth Kentucky Regiment during the war and was the oldest practitioner in his county.

S. T. ANDERSON, M.D. (Rush Medical College, Chicago, Ill., 1881), at Bloomington, Ill., of apoplexy, August 10, aged 52 years. He was a prominent member of the State Medical Association.—Horatio H. Johnson, M.D. (Harvard University Medical School, Boston, Mass., 1869), at Belfast, Me., August 4, aged 51 years. He was a member of the Maine Medical Association and formerly secretary of the Board of Medical Examiners of Waldo County.—J. L. Henot, M.D. (University of Vermont Medical Department, 1888), at Winsted, Conn., July 26, aged 38 years.—James Dunlap, M.D. (College of Physician and Surgeons, New York, 1850), at Northampton, Mass., August 3, aged 77 years.—Fred C. A. Kellam, M.D. (University of Maryland School of Medicine, Baltimore, Md., 1866), at Pringoteague, Va., August 6, aged 83 years.—Edwin T. Morrison, M.D. (University of Maryland School of Medicine, Baltimore, Md., 1887), at Baltimore, Md., August 7, aged 47 years.—Charles H. Weinholtz, M.D. (University of the City of New York, Medical Department, 1883), at New York city, August 7, aged 45 years.—C. C. Chaffee, M.D. (Vermont Medical College, Woodstock, Vt., 1835), at Springfield, Mass., August 8, aged 85 years.—James Northrop, M.D. (Geneva Medical College, Geneva, N. Y., 1857), at Woodstock, Ill., August 9, aged 71 years.—Daniel H. Brennan, M.D. (University of Buffalo, Medical Department, Buffalo, N. Y. 1885), of Albion, N. Y., at Buffalo, N. Y., of appendicitis, August 11.—Clarence O. Arey, M.D. (Department of Medicine of the University of Pennsylvania, Philadelphia, Pa., 1894), at Cleveland, Ohio, August 11.—Curran C. Smith, M. D. (University of Louisville, Medical Department, Louisville, Ky., 1850), at Richmond, Ky., August 13.—William Joseph Morton, M.D. (Louisville Medical College, Louisville, Ky.), at Racine, Wis., August 14, aged 89 years.—Professor Kékulé, at the University of Bonn, noted for his important works on organic chemistry.

## MISCELLANY.

**Preliminary Question for the Court.**—The preliminary question whether a witness offered as an expert has the necessary qualifications, the supreme court of Minnesota says, in *Snedra v. Libera*, decided June 29, 1896, is for the court, and is largely within its discretion.

**A Good Showing for an American Medical College.**—We are informed that by some flaw or omission in the return of preliminary qualification of the Barnes Medical College of St. Louis to the Missouri State Board of Health, the unprecedented number of 101 matriculates were notified to appear before the said board to show cause why they should not be debarred from matriculation, all of whom responding to the summons, after a rigid personal examination and searching scrutiny of their credentials, were found by the board to be fully qualified by first grade teacher's certificate or academic or high school degree, many of them showing exceptionally high qualifications.

**Speculative Evidence.**—It is no more speculative to say that hernia causes pain, and might terminate fatally, so the appellate division of the supreme court of New York holds, in the case of *Stever v. N. Y. C. & H. R. R. Co.*, decided June 17, 1896, than it is to say the same of appendicitis or peritonitis.

Consequently, the court holds that it was not incompetent to ask a physician, who had testified to a party having what he termed "direct hernia," whether "a breach of that kind at any time becomes dangerous to life, or becomes dangerous or painful in any way." The answer here was: "I think it dangerous," and then the witness added, without any further question, "It may come out and become strangulated so it is impossible to return it without an operation." This reference to strangulation it is intimated was open to criticism as being speculative.

**Thyroids in Catalepsy.**—After giving detailed histories of cases treated by thyroid medication, Dr. Joseph G. Rogers makes the following deductions: 1. That in conditions marked by inhibition of sensory, motor, and mental activity, without gross organic lesion, such as obtain in katatonia and in certain types of stuporous insanity and melancholia, we may expect benefit from thyroid medication, judiciously used. 2. That the effects of thyroids in full dose bear a striking resemblance to many of the symptoms of Graves' disease, namely, orbicular weakness, consecutive conjunctivitis, skin eruptions, and temporary bronzing, without icterus of eyes, profuse local fetid sweats, subjective sense of heat and thirst, excessive metabolism, decided tachycardia, and the absence of any fixed relation between pulse rate, respiration, and temperature. 3. That, in so far, the theory of Möbius, that Graves' disease is due to hyperactivity of the thyroid gland, is strongly supported.—*Am. Jour. of Insanity*, July.

**Foreign Graduates in French Medical Schools.**—Important modifications have been made in the regulations for the admission of foreign students to the medical schools of France, and for granting them permission to practice their profession in that country. Heretofore, American medical students who went to Paris with the view of graduating from one of the medical schools were allowed certain facilities. When they were graduates of well-known American colleges, or held a diploma of doctor of medicine issued by a reputable foreign scientific institution, they were permitted, upon application being made through the American embassy, to follow the regular courses of the French medical schools, the same as French students who had graduated from the French faculties, and if successful in the final examination, were awarded the same diploma as those to Frenchmen, which carried with it the privilege of practicing in France. The number of foreign students having considerably increased in numbers and the proportion of those who remain in Paris to practice their profession having also become much larger, the French government has adopted a stricter rule for the admission of foreigners to the French medical schools. In the future foreigners desirous of obtaining the same diploma of doctor of medicine as that awarded to Frenchmen will have to submit to the same conditions imposed upon French students, that is, the diploma they may have obtained abroad or in any private institution will not be considered, and before being allowed to register at any of the French medical schools they will have to produce a French state diploma of *Bachelier de l'enseignement classique*, and the *Certificat de sciences physiques, chimiques et naturelles*. To foreign students who do not intend to practice medicine in France the facilities usually extended to them will be continued and even enlarged. But they will only be entitled to a special diploma granting no rights to practice in France. These regulations were issued on the 21st ultimo, and are not applicable to foreign students already registered.

**Cure of Sarcoma in Algeria by Native Doctors.**—Legrain describes several cases of sarcoma which he had removed and examined histologically. These had been treated by native doctors, who applied a tar obtained from certain bushes in the Sahara district, among them juniper. In each case the sarcoma was entirely and permanently cured. The question arises whether

the supposed sarcoma may not have been a tuberculous affection, as tar is especially efficacious in them, while it has no effect on sarcoma, and it is not always easy to distinguish a sarcomatous from a tuberculous tumor. Legrain adds that epitheliomata are unknown in Algeria except as they appear on a European. This may possibly be due to the vegetarian diet without meat, and absolutely without pork. Verneuil and Reclus asserted long ago that the herbivorous animals were much less liable to cancer than the carnivora, and they ascribe the six-fold increase in the number of cancers at their hospital during the last forty years, to the increased consumption of meat by the laboring classes.—*Bulletin de l'Académie de Méd.*, July 21.

**New Method of Anastomosis Without Opening Organs.**—Souligoux unites the stomach to the intestines, or one part of the intestines to another, or the gall bladder to the intestines, without opening into the organs, by creating artificially a process similar to the pathologic process in tuberculosis or cancer when a communication is established between organs. This is accomplished by seizing and squeezing a piece of the intestine in a clamp forceps; when released, this piece is reduced to a thin transparent membrane no thicker than a piece of cigarette paper, about 4 cm. long by 2 to 3 wide. A similar piece of the other organ is crushed to correspond, and the two bruised portions are then united and one long edge sutured. The crushed surfaces are then lightly cauterized with potassa, the assistant instantly sponging off any liquid that exudes. The rest of the suture is then completed, and if any of the black produced by the caustic shows, a separate suture is made to enclose it. The bruised walls give way very soon, in forty-eight hours at farthest, and communication is established, with the formation of adhesions that strengthen the suture. Some of the Paris surgeons are enthusiastic in their praise of this new "easy, certain and elegant" method of anastomosis, by which all the dangers of opening into vital organs are obviated. One necropsy showed perfect union with only a small fragment of the bruised tissue still adhering. Reclus advises cocain instead of ether in these operations. Chaput has been experimenting with the thermo-cautery which he prefers to the cold forceps for this purpose, and makes a row of separate sutures around the eschar. He also proposes a circular union on this principle, by thermo-cauterizing the bunch formed by ligating the intestine, and then making a circular suture enclosing it. He has had perfect success on dogs. Raynier very sensibly doubts whether this will prove practicable, as it totally closes the intestines until the bruised portion breaks away.—*Bulletin Méd.*, July 19, and *Sem. Méd.*, July 22.

**Gleanings.**—Vaccination made compulsory in Peru and vaccine institute established at Lima. (*Cronica Méd.*, May 31.)—Diphtheritic toxins exposed to a weak electric current for three or four days become transformed into effective antitoxins. (*Gaz. d. Osp. e d. Clin.*, July 19.)—The International Institute of Bibliography founded last September (Brussels) to collect in one catalogue all the scientific, artistic, literary and intellectual publications of the world, advocates the general adoption of the American Dewey decimal system. (*Progrès Méd.*, July 18.)—Bequest of \$20,000 to the Paris Académie de Médecine from Mme. D'Ernesti, and twice this sum bequeathed by M. Marelleau to the society that aids tuberculous children. (*Union Méd.*, July 18.)—International Congress of Applied Chemistry met at Paris, July 27, with more than fourteen hundred members. Monument erected at Dijon to Woicikowsky, who performed the first successful ovariectomy in France. Red Cross corps of Scotch colliers trained to carry all that is needed for first aid to the wounded and seek them out as they fall. In readiness for the autumn maneuvers of the German army. (*Progrès Méd.*, July 18.)—Menstruation of healthy child at 46 months. (*Marseille Méd.*, No. 9.)—

Case of akinesia algera, nineteen years in reclining posture, lower extremities spastic, atrophic and powerless: cured by suggestion. (*Wien. Klin. Rundsch.*, July 16.)—Epidemic of ieterus in children, eighteen cases. (*Deutsche Med. Woch.* July 16.)—Honorary title of M.D. conferred upon Bismarck by the University of Jena. Dermatitis and alopecia caused by exposure to the Roentgen ray during a month of experimentation with the fluorescent screen. (*Deut. Med. Woch.*, July 23.)—Apparently healthy child of healthy mother gives syphilis to wet nurse and her family, who sue for damages. Court of appeals (Poitiers, France) decides for the defendants, as no fault could be proved. (*Journ. de Méd. de Paris*, July 19.)—Twenty-nine cases of abdominal typhus treated with guaiacol salicylate with negative results. (*Polnit. Gas. Botk.*, No. 2.)—Successful extirpation of wandering spleen and left ovary, both much degenerated, without interference with pregnancy. Average annual consumption of alcohol in Russia from 1827 to 1863  $4\frac{1}{2}$  liters per capita; since been decreasing, until in 1893, it was only half this amount, which is less than in any other country, Norway excepted. (*St. Peters. Med. Woch.*, July 18.)—Recent case of infection emphasizes importance of sound teeth in a wet nurse. Gelatin found efficacious in arresting hemorrhages, 5 to 10 per cent. solution, at 95 degrees. Death follows enema containing 40 grams of boric acid. One-fifth to one gram boric acid fatal to guinea pigs. Barth reports two severe cases of pneumonia cured by digitalis, daily doses, 2 gr. pulv. digitalis leaves in an alcoholic infusion with syrup of orange peel. (*Semaine Méd.*, July 15.)—Seasickness prevented by suggestion. (*Semaine Méd.*, July 22.)

**Pasteur Monument Committee of the United States.**—The following circular has been issued:

It has been decided to erect in one of the squares of Paris a monument to the memory of M. Pasteur. Statues or bust will also no doubt be located at his birthplace and in other cities. The Paris committee has, however, wisely determined that the statue obtained through international effort shall be located at Paris, where it will be seen by the greatest number of his countrymen and also by the greatest number of his admirers from other lands. The Paris committee has for honorary members the President of the Republic and his cabinet, together with about one hundred and sixty of the most prominent officials, scientists and other distinguished citizens of France. The active members of the committee are J. Bertrand, President, member of the French Academy, Perpetual Secretary of the Academy of Sciences. J. Simon, Vice-president, member of the French Academy, Perpetual Secretary of the Academy of Moral and Political Science. Grancher, Secretary, member of the Academy of Medicine, Professor in the Faculty of Medicine. Bruardel, member of the Academy and of the Academy of Medicine, Dean of the Faculty of Medicine. A. Christophle, Honorary Governor of the Credit Foncier, Deputy from l'Orne. Count Delaborde, Perpetual Secretary of the Academy of Fine Arts. Duclaux, member of the Academy of Science and of the Academy of Medicine. Magnin, Governor of the Bank of France, Vice-President of the Senate. Baron A. de Rothschild, banker. Roux, Assistant Director of the Pasteur Institute. Wallon, Perpetual Secretary of the Academy of Inscriptions and Belles-Lettres. The Paris committee has kindly extended the opportunity to the people of the United States to assist in this tribute of appreciation and love and have authorized the organization of the Pasteur Monument Committee of the United States. The members of this committee gladly accept the privilege of organizing the subscription, and of receiving and transmitting the funds which are raised. We believe it is unnecessary to urge any one to subscribe. The contributions of Pasteur to science and to the cause of humanity were so extraordinary, and are so well-known and so thoroughly appreciated in America that our people only need the opportunity in order to demonstrate their deep interest. All can unite in honoring Pasteur. He was such an enthusiastic investigator, so simple, so modest, so lovable, and yet so earnest, so great, so successful—his ideals were so high and his efforts to ameliorate the condition of humanity were so untiring that we anticipate an enthusiastic response from the whole civilized world. The United States will vie with the foremost of nations in this tribute. Chemists, zoologists, physicians and all others interested in science will wish to be represented. No one is expected

to subscribe an amount so large that it will detract in the least from the pleasure of giving. A large number of small subscriptions freely contributed and showing the popular appreciation of this eminent Frenchman is what we most desire. This committee supplies subscription blanks, which should be returned in the accompanying envelope, together with a money order, check or draft covering the amount subscribed. All checks, etc., should be made payable to "Treasurer Pasteur Monument Committee," and when received by the secretary a numbered receipt will be forwarded to the sender. The original subscription papers will be forwarded to the Paris committee for preservation. It is our purpose to do our work as largely as possible through societies or other organizations. We prefer to have each organization appoint one of its members as an associate member of this committee with authorization to collect and forward the subscriptions. The amounts thus far subscribed by individuals vary from fifty (50) cents to ten (10) dollars. It is hoped that no one who is interested will hesitate to place his name upon the list because he can not give the maximum amount. Please let this receive your early attention and in that way assist our committee which must conduct correspondence with the societies of the entire country. The committee consists of Dr. D. E. Salmon, Chairman, Chief of the Bureau of Animal Industry; Dr. E. A. de Schweinitz, Secretary, President of and representing the Chemical Society of Washington, Chief Chemist Biochemic Laboratory; Dr. Geo. M. Sternberg, Surgeon-General U. S. Army; Dr. J. Rufus Tryon, Surgeon-General U. S. Navy; Dr. Walter Wyman, Surgeon-General U. S. M. H. S.; Prof. S. F. Emmons, U. S. Geological Survey, representing the Geological Society; Prof. Lester F. Ward, President of and representing the Anthropological Society of Washington; Dr. G. Brown Goode, Treasurer, Assistant Secretary of the Smithsonian Institution; Dr. Wm. B. French, Representing the Medical Society of the District of Columbia; Hon. Gardiner G. Hubbard, President of and representing the National Geographical Society; Mr. C. L. Marlatt, Assistant Entomologist U. S. Department of Agriculture, representing the Entomological Society; Dr. Ch. Wardell Stiles, Zoologist U. S. Bureau of Animal Industry, representing the Biological Society of Washington.

The JOURNAL will be pleased to forward any subscriptions received for this purpose.

#### Cincinnati.

THE MORTALITY REPORT for the week gives: Zymotic diseases 20; constitutional, 30; local, 50; developmental, 6; violence, 6; under 5 years, 32; total, 112. Annual rate per 1000, 16.49; corresponding week, 1895, 104; 1894, 115; 1893, 95.

AT THE MEETING of the State Board of Charities held at Longview Asylum the reports from the different institutions show them to be all full and in many instances it has been necessary to refuse admittance on account of the over-crowded condition. Superintendent Ratliff of the Dayton Hospital said that he thought insanity was increasing but that the old prejudice against institutions for its treatment was dying out. The new hospital at Massillon which is being built at a cost of over \$700,000, will accommodate 2,000 patients and is expected to give relief to the other institutions. Much of the session was spent in discussing the cost of supplies at the various hospitals, and suggesting methods to equalize prices. At Cleveland cereal foods for each inmate for the past six months cost \$2.09, while at Longview they cost \$3.23.

DR. VAN DER VEER TAYLOR, a recent graduate of this city, has been appointed Medical Director of the Cincinnati Young Men's Christian Association. Dr. Taylor will act in conjunction with Physical Director Fisher and will also deliver a course of lectures during the winter on anatomy and physiology before the class in preparatory medicine.

A CINCINNATI PHYSICIAN has been arrested upon the charge of violating the U. S. Postal laws in sending through the mails a threatening postal card. The card was sent to a man whom the doctor claims owed him \$106, and whom he threatened to put to trouble if the account was not paid by a certain time.

OWENSBORO, KY., and vicinity is suffering from an invasion of typhoid. There is hardly a farm house along the banks of Mud River, for twenty miles, in which there is not at least one case. Berea, Ky., is also suffering from a typhoid epidemic.

THE CONTRACTS for the Massillon insane asylum have been

made to the extent of \$265,000, a portion of which it is claimed will have to be annulled by reason of the fact that the amount is in excess of the appropriations made by the last Legislature, although that body authorized the trustees to expend \$50,000 in excess of the appropriations. Attorney-General Monnett and State Auditor Guilbert have decided that this is unconstitutional.

THE MIAMI MEDICAL COLLEGE have completed the organization of their new dispensary and announce the following staff: Chas. H. Castle, clinical director; G. L. Bailey, assistant clinical director; Robt. Suttler, ophthalmology; Chas. E. Caldwell, surgery and andrology; C. R. Holmes, ophthalmology; J. A. Thompson, laryngology; E. W. Mitchell, medicine; R. B. Hall, gynecology; W. McMillan, surgery; Julius H. Eichberg, medicine; E. H. Shields, surgery and andrology; George Sudhoff, medicine; F. W. Langdon, neurology; H. W. Bettman, medicine; R. H. Ingram and H. K. Dunham, medical assistants; W. E. Schenck, neurological assistant; Ernest Jacob, pharmacist.

JAMES T. SCOTT, M.D., of Greentown, committed suicide August 10. Dr. Scott was mentally deranged as the result of a kick from a horse received forty years ago.

THOMAS FREELAND, M.D., of Boston, Ind., was shot by a patient named Philip Cochran on the 11th of this month.

#### Louisville.

KENTUCKY INSTITUTE FOR THE EDUCATION OF THE BLIND.—An address has just been issued by the trustees of this institution, which contains much of interest to the profession as well as to those who have under their care children who are so afflicted. Kentucky established her school for the blind in 1842, the eighth school of its kind in the country, last year there being 132 inmates of the Kentucky school out of a total of 3,757 blind children educated in thirty-five such schools. The purpose of the State in founding such a school was to give to the child with defective sight as good an education as is offered to the seeing child and, in addition, to give it instruction in manual training. In 1884 the general assembly passed an act providing for the addition of a department in a separate building for the care of the colored blind children of the State. The board has provided that the children under their control have the best teachers, faithful and devoted servants, improved educational appliances, and have also provided that the children shall be properly and kindly cared for as regards their clothing, food, shelter and health, all free of cost to blind children of the State. Notwithstanding this, about 70 per cent. of all the blind children of the State between the teachable age of 6 to 16 years are allowed to grow up in ignorance, without any share in the advantages so freely offered by the State. The American idea of a school for the blind is as far removed from its being an asylum on the one hand, as it is from its being a hospital for treatment of diseases of the eye on the other. Its work is strictly educational. A blind child should be sent to school as soon as it can get along without a nurse, say at 6 or 7 years of age. Every year's delay after that renders the task of its education difficult and incomplete. From the moment it reaches the school the sense of touch has to be persistently trained. The kindergarten is of inestimable value for this purpose, and the work done in this department excites the admiration of every visitor. After the kindergarten the child studies things and models of things, and in its study of geography, models in sand and clay the surface of the State and country and the grand divisions of the globe. He is taught to read and write and cipher, studies grammar, history, natural philosophy and all the branches of a good education. If he has any musical ability it is scientifically and sedulously cultivated, for it is in the practice of the art of music that he can compete with his seeing comrades on more equal terms than in any other occupation. He is also given a course in the workshop, where he learns to cane chairs, make brooms and practice simple upholstery, such as the repair of lounges and mattresses. Piano-tuning is also taught to those who are capable of learning it. The girls are taught the use of the needle, and learn as they progress how to patch and darn and mend, how to knit and use the sewing machine, how to cut

out, fit and make their own garments. In this course of study and development, extending over eight or ten years, the blind child gains a confidence in his own powers that enables him to overcome, to a great extent, the natural awkwardness of his blindness. He is to a considerable extent enabled to earn a livelihood for himself. The school term is from September to June, and at its close the children are returned to their homes, as it is the desire of the trustees to maintain as far as possible the home ties of the child.

## THE PUBLIC SERVICES.

### General Order No. 37.

The following is a copy of the order discontinuing full dress uniform for the Hospital Corps of the U. S. Army:

HDQRS. OF THE ARMY, ADJUTANT GENERAL'S OFFICE,  
WASHINGTON, AUG. 13, 1896.

11. By direction of the Secretary of War, from and after this date, the issue of the full dress uniform to hospital stewards, acting hospital stewards and privates of the Hospital Corps, U. S. Army, will be discontinued, and an equivalent allowance in money value of white cotton duck clothing will be made instead.

By command of General Miles.  
SAMUEL BRECK, Acting Adjutant General.

**Army Changes.** Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from Aug. 8 to Aug. 14, 1896.

First Lieut. Henry A. Shaw, Asst. Surgeon, will proceed to Ft. Brady, Mich., without delay, and report for temporary duty at that post.

Lieut.-Col. Alfred A. Woodhull, Deputy Surgeon-General, and Major Charles Smart, Surgeon, are detailed to represent the Medical Department of the Army at the twenty-fourth annual meeting of the American Public Health Association, to be held at Buffalo, N. Y., Sept. 15, 1896.

Major Clarence Ewen, Surgeon, extension of leave of absence granted on account of disability is further extended one month on account of disability.

First Lieut. Benjamin Brooke, Asst. Surgeon, so much of S. O. 69, A. G. O., March 23, 1896, as directs him to report to the president of the examining board appointed to meet at San Francisco, Cal. April 14, 1896, for examination by the board, is revoked.

**Navy Changes.** Changes in the Medical Corps of the U. S. Navy for the week ending Aug. 15, 1896.

Asst. Surgeon M. K. Johnson, detached from the U. S. S. "New York," and to the coast survey steamer "Bache."

P. A. Surgeon G. A. Lung, ordered to the receiving ship "Vermont."  
P. A. Surgeon E. R. Stitt, detached from the receiving ship "Vermont" and ordered home on waiting orders.

### Change of Address.

Furay, Chas. E., from Omaha to Chadron, Dawes Co., Neb.  
Galbraith, T. S., from Norman, O. T., to Seymour, Ind.  
Gedge, D. M., from Honolulu, H. I., to 168 Stockton St., San Francisco, Cal.

Houston, Jas., from Ingersoll, Ont. to Swartz Creek, Mich.  
Kuhlman, F. E., from 2245 Mulphany St. to 2323 Cass Ave., St. Louis, Mo.

Kneedler, W. L., from Barracks to 2003 D St., San Diego, Cal.  
Paine, H. M., from Atlanta, Ga. to West Newton, Mass.

## ORIGINAL ARTICLES.

### THE PREVENTION OF WAR AND THE PROMOTION OF PEACE, IN RELATION TO STATE MEDICINE.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY E. D. McDANIEL, A.M., M.D., LL.D.

MOBILE, ALA.

The common saying that every question has two sides is generally true. But it is also true that the reasons in favor of one side are more numerous and stronger than those in favor of the other. It is fortunate that this is so. Persons of a fair degree of intelligence, by laying aside selfishness, passion and prejudices and by honestly using proper available helps, can reach such proofs as render truth plain and duty clear. One of the greatest questions that can arise in the course of human affairs happens to be before the nations as *the question of the hour*. It is the question of "war or peace." Two strongly antagonistic tendencies are in energetic action over nearly all the civilized world. The tendency toward war is manifested by the popular masses and their legislative representatives in our own and many foreign countries by an unusual restlessness, a want of forbearance, a spirit of aggressiveness, of pugnacity and a loud clamor for hasty and extreme action. On the other hand, the tendency toward peace is equally pronounced. It is heard in a strong, clear, solemn, impressive voice that comes in great earnestness, spontaneity and harmony from the consciences and convictions of the foremost, the best and the most intellectual men of the times—the great leaders in education, science, statesmanship, economics, ethics, beneficence and industry. Especially comes this voice from the two great English speaking centers of christendom—Great Britain and the United States. It demands that a system of international arbitration be adopted for the impartial and authoritative settlement of international disputes and wrongs, without resort to war. The question is open and urgent. Prompt decision must be had. Even if complete unanimity of *opinion* be unattainable, no neutrality in *action* is practicable. All influential persons and all potent agencies must act with one of the parties or with the other. The present occasion furnishes a fit time and place for discussing and deciding what part State medicine, as the proper representative of all the coördinate departments of medicine and of all the men who make up the medical profession, is to act in the great cosmopolitan drama that is being planned. To invite this discussion and to have the opinions and actions that may be elicited properly set forth is the motive of this paper.

In a subject so momentous in magnitude and scope as the one before us, many things that are more or

less important must be passed without mention. The limited time allotted imposes this necessity. Moreover, the thorough knowledge and agreement known to exist in many pertinent matters would make it equally a waste of time and an abuse of patience to attempt to prove what is already believed and to gain assent to what is already granted. Let us not be understood as ignoring the matters that are omitted or as underrating or disparaging such as may seem to be too little elaborated, or insufficiently emphasized. Let us try to get a correct conception of State medicine, of war and of peace, respectively, then let us view the three in close juxtaposition, that we may better see their just relationship.

State medicine has for its function to formulate, apply and enforce rules for the protection and improvement of health and for the prevention and management of disease in organized communities. Its great and final aim is, therefore, the preservation, protection and improvement of human life. Its *importance* must be estimated by the value of human life. But how may this value be ascertained and if possible standardized? Only by one, or two, or all of three methods: 1. Sacred and human tradition confirmed by the common agreement of mankind. 2. By consciousness and ratiocination. 3. By observation of the work that can be done by man.

Let us look, as in a dictionary, for the value of human life—meaning by life, the *living human being*—as indicated by tradition and fixed by the common estimate of our race, and we find it among the foremost, if not the very foremost of all precious and sacred earthly things. The first uttered injunction to the primal human pair was this: "Be fruitful, and multiply and replenish the earth and subdue it." The first penal verdict was a sentence pronounced upon a shedder of human blood. Subsequently the command was given: "Thou shalt commit no murder." Old Testament writings abound in evidences that the care of life is the first duty of law. In the enumerations of rights and in the preambles and drafts of forms for organic laws submitted to men of various countries, races and times, preparatory to the formation of governments, constitutions and laws, the provision for the protection of life has been a leading requirement and by being ratified has become a solemn pledge of the race. That life is a foremost, if not the foremost and greatest of values, is plainly implied by the fact that prophecy, history, poetry, philosophy and philanthropy voicing the concurrent sense of our race, deplore wars, famines, pestilences, earthquakes, floods, poverty and oppression as among the greatest of human evils, because of their destructiveness to human life and, on the other hand, extol peace, plenty, security, wealth, domestic repose and abounding health as among the greatest of public blessings because of their benign influences upon the life-interests of the world. That the greatest of these

evils is war, and the greatest of these blessings is peace, are conclusions based upon the clearly implied predicate that life is the greatest and most sacred of human interests and values.

Let us next appeal to the tribunal of consciousness and ratiocination. In doing so let us clothe ourselves in devout humility. Let us remember that we are nearing the dark border of the spirit land, and let us take heed that we put not unholy footprints beyond the proper boundary of human territory. Let us exclude all physical, metaphysical and theologic methods, doctrines and dogmas—efforts to understand or demonstrate the essence, origin or eternity of life, as not at all pertinent to our present purpose. Let us also leave out all evolutionary questions as to what may have been the forms and capacities of man in periods of duration that have long vanished into the remote past, or what may be his possibilities in a future period that lies beyond the reach of all reasonable and practical speculation. Thus we will find ourselves at home, as it were, among beings of like size and born with ourselves—face to face with incarnate life—life with bodily limitations and instrumentalities, with consciousness, sensation, power of motion, reason, conscience, speech, knowledge of good and evil and tendencies to both. This is plain, practical, undeniable, tangible, personated life—rather it is living man, the man of our past, present and future—the typical man of our planet and our era. What value do his conscious superiority, and his capacious attributes and his regular courses of action, assent and maintain, as due to his life? Obviously the highest that can attach to any earthly interest, and beyond all fixable estimate. All else that man has, will he give for his life; and, as a rule, all else that he has, he does give for his life when its redemption is required.

In the Declaration of American Independence life is held to be an "inalienable right." In accurate definition life is not an inalienable right, nor, indeed, a right at all. The life of a living being is an attribute, an endowment, a possession of that being, and like other endowments, possessions or trusts, it is conditioned, forfeitable and alienable in case of both individuals and communities. It can not be maintained that human life is an absolute, persistent, fundamental good; it is only a fundamental *possibility* for good, and this even alone makes it a thing of priceless value.

The third and only remaining method of ascertaining the value of human life is the plain and easy one of judging a tree by its fruit. What work, then, and how much of it, both on the side of good and of evil, is man able to do, so far as we can judge from what he has already done, what he is now doing, and what he is evidently proceeding to do?

Thousands of times he has desolated the earth by his resistless blows in war, and thousands of times he has restored it to prosperity, by his all-conquering perseverance in peace. In schemes for wreaking his vengeance on the one hand and of extending the field of his blissful beneficence on the other, he defies all dangers and disregards all costs. He compasses both sea and land, sending his ships and his cables through the one and his telegraphs and cars over the other. He scales the loftiest mountains and fathoms the deepest oceans. He marches through clouds of dust and seas of blood. He enters as a missionary the far off abodes of horrid cruelty in the face of all privations and perils. He treads under foot the slow mov-

ing glacier and the never melting snow. He traverses Alaska by voyage and Sahara by caravan, and explores and develops the resources of both. He tames the massive elephant into a kneeling beast of burden. He drags from the rivers, the shores and the seas their monster crocodiles, alligators, sturgeons, sharks and whales, and converts them into food and merchandise. He plays with the manes of the strongest lions of Africa and with the teeth of the fiercest tigers of Bengal. He sinks quarries and mines for sandstone, freestone, limestone, granite and coal, the useful and precious metals, thus furnishing employment to the idle, indispensable necessities to the poor, comforts to such as can afford them, desirable luxuries to the affluent and rich. Many valuable commodities to commerce; many appropriate materials to manufacturers, artists and artisans; many avenues to varied employment; to trade a widened domain and to finance an available standard of value. In pasture, forest, farms, fields and fishery, he provides the great ruling contributions to clothing and food for the human family. He opens wide and deep channels through everglades, pocosons and lakes at once making waterways for trade and reclaiming for cultivation millions of acres of valuable land. He sinks artesian tubes through the thick, dense strata of many vast unwatered areas and brings up copious unfailling streams to fructify the soil and soften the air, and thus causes the desert to blossom as the rose and waste places to teem with population and wealth. He bores deep into the earth's crust and taps great long-sealed reservoirs of gas and oil and brings up the contents to furnish mechanical illuminating and various other materials that give diffusion to human progress and well-being. He spans great rivers and straits with bridges and ferries. He has already or will shortly have, his sleepless sentinels on watch, in hailing distance of each other, all over the continents and islands to give timely notice of storm centers that may form or threaten to form, and to warn all men to provide against blighting blizzards, desolating tornadoes, wrecking ocean forces, or inundating cloud bursts. In Byron's day, it was only in the transporting frenzy of poesy and when live lightning leaped from cliff to cliff and the loud thunder shook the far off air that "Jura answered back to Alps;" now in words of soberness and in stormless calm, the Himalayas can talk with the Rockies and the Urals with the Andes. Orders of the President, issued with gentle but considerate firmness in Washington, are instantly heard throughout most of the States and territories of the Union. Victoria speaks in London and her words of love and authority are promptly heard by dwellers in Great Britain and Ireland, in India, Australia and New Guinea, in the East and West Indies, in the Dominion of the Canadas, in provinces in South America, and in various other far off possessions. Nearly two thousand years ago the Great Galilean told his Apostles that they should do greater works than even he was then doing, and, by the instrumentality of railroads, telegraphs, telephones and phonographs. Talmage and other evangelists are now enjoying the promise and fulfilling the prediction by preaching in New York or Washington and being heard the same day, to the ends of the earth.

Cleveland touched a button, and instantly the machinery from all the world went into motion in far distant Chicago. He touched a button and every spindle, lever and engine in Atlanta responded to the touch.

In travel, the day's journey of antiquity is now accomplished in less than an hour. We lie down to sleep when we start for a distant destination and when we awaken we are there. The hours of darkest night are now as valuable for travel and many other purposes as those of brightest day, and rest is as effective as the most energetic toil. In midst of densest darkness men can cause radiant light to shine—not by the slow word of command, but with the quickness of thought. In all the departments of applied mathematics man displays his wonderful works of perseverance and capacity. He gives to navigation all her maps of the stars and constellations, her charts of the oceans and seas, her compasses, barometers, chronometers and quadrant. He marks the boundaries and calculates the areas of states, nations and continents, and the altitudes of their various parts; locates routes and estimates costs for railroads and inland water ways for travel and transportation and adjusts the gradings of railroads for thousands of miles. In the department of bookkeeping he is the accountant without whom no census could be taken, no tax levied, assessed or collected, no financial suits settled in law, and by whom it could, without egotism or boasting be said: "By me kings reign and princes decree justice." In statuary, painting, poetry and oratory man has opened in the hearts of his fellows new fountains of justice, pity, tenderness, sympathy, compassion, forgiveness and of love. But it is in astronomy, geology, cosmology, physics, chemistry, biology and medicine that in the more recent times man's achievements have become the most transcendently glorious, marvelous, beneficent and financially important. He has analyzed the earth, separated, differentiated and classified its elements and their combinations; has measured and weighed the earth and the moon and ascertained their orbits, distances and revolutions; has done the like for the other planets and satellites of our system; has discovered and explained the causes and laws of the tides and predicted the times of their coming for all the points of the coasts of the world. Away back in the millenniums of time much was undoubtedly known about the conditions of health. Thirty-five hundred years ago the great Hebrew lawgiver wisely recognized cleanliness as essential to health, and enjoined morality, isolation and purification as safeguards of the life of individuals and communities. But disregard of this wise enactment was followed by outrage and war and these by famine, poverty, filth and discouragements. These conditions brought on many horrid and loathsome pestilential epidemics that ravaged and sometimes almost depopulated medieval nations and cities. One hundred years ago, there lived in Gloucester, England (the place just now under an epidemic of smallpox) a humane physician of very studious turn and great aptitude for scientific research. His name was Edward Jenner. His acumen, patience and perseverance were all taxed to the utmost for a time longer than the average man lives, but finally accomplished the wonderful and beneficent discovery of a preventive of smallpox. The discovery was so valuable in itself, so hard to account for, and so suggestive of some great underlying principle that it excited the curiosity of scientists all over the world. These scientists by careful, persevering and protracted study, observation and experiment, have discovered many disease germs and germicides, and much about the sources and laws of action of these, and have

already obtained such control over some of the dreaded epidemic diseases of animals, plants and man as to effect an annual saving of thousands of human lives and of countless millions of property values in animals and crops.

In the above feeble attempt to place in view man's working power, not as much as a tithe of all that invites consideration has been said or even alluded to. But surely enough has been said to show that man is, in reality, the lord of earth's present era, that he is discharging the commission of subduing the earth, with a prospect and promise of final success, that his life is, therefore, the leading object of human care, and that everything that either directly or remotely affects it, for better or for worse, lies within the domain of state medicine.

We come next to consider how war and peace stand related to human life.

It is admitted that war deserves the credit of having done much good, of having sometimes carried the blessings of civilization to benighted barbarians, of having aroused activity where energy was dormant, of having forced hostile and disunited tribes to dwell together and form states and nations, of having improved its votaries in enterprise, courage, patriotism, magnanimity, gallantry and chivalry. It may also be admitted that peace has its proneness to certain evils, such as supineness, slothfulness, effeminacy, enervation, gluttony. It is believed to be fair to let these opposite influences offset each other and that our purpose will be most quickly and fairly subserved by placing the conceded effects of war and those of peace side by side and letting the spectator impartially judge for himself.

It has been shown already that by the traditions and common consent of the human race, the fact is admitted that war is the arch enemy of human life and peace its best friend. To some it may seem that our whole case might rest here. But others may think that proofs are so numerous, obvious and available and the cause so momentous that something more should be added.

Especially formidable would be an array of the statistics of war and of peace. But for this there is no time available here. We must refer to histories, official reports, and compilations of census returns for figures to show how vastly and palpably peace protects life and war destroys, how peace increases population and war diminishes it, how peace establishes law and order and war brings anarchy and chaos. Peace clears land, fences it, plants seeds, raises crops, builds homes and farm houses, rears domestic animals for food, clothing and profit, drains and reclaims swamps, fens and bogs, thus converting sources of pestilence into fountains of health, wealth and life. War burns or razes these homes, kills or otherwise destroys the inmates, consumes the flocks and herds, leaves fields that were ripe for harvest a naked surface on which victims of famine must drop down and die. How peace by long periods of patient toil, steady perseverance and unselfish economy, builds highways and factories, villages, towns and cities; and how war rapidly reduces all these to ashes and ruins. How peace covers continents and islands with happy travelers and merchants, with depots and stores of food and clothing and other human comforts and luxuries; war with armories and magazines for destruction and death. How peace checks the oceans and rivers with merchantmen, happy voyagers and hopeful trad-

ers, that as they pass each other exchange smiles and wave friendly greetings; war with privateers and battleships commissioned to rob, kill and destroy. How peace, by encouraging thought, industry, invention, discovery, enterprise, science and art among the millions of earth's inhabitants, stores up billions upon billions of accumulated value—crystallized profit-coined capital—thus furnishing means for additional strides in the path of upward progress. How war, both by paralyzing the agencies of peace and by a wholesale process of consumption and waste, by enormous reduction of income and extravagant expenditures, exhausts the treasuries of states, of nations, and often of the entire civilized world; then resorts to promissory paper and accumulates public debts to amounts of billions upon billions, tempting following generations of children to repudiation, or subjecting them to endless oppressive, impoverishing, vexatious, demoralizing taxation for the payment of claims which they did not contract and did not approve. How peace, for all the countless and boundless benefits it creates and bequeaths, expects, and, as a rule, receives no state appropriations for its veterans and dependents, leaves no public debt and imposes no tax. Ben Franklin sent heavenward an ardent invocation. His prayer mounted up to a dark cloud that was flashing with lightning. From the midst of the cloud there descended a great angel agent and filled a vial with blessings to be poured out upon the inhabitants of the earth—blessings that now fill not only all lands but also all seas. They are blessings, the fruits of peace, priceless but costless. Franklin's compensation is the halo of glory that encircles his name. The like is true of Galvani, Faraday, Morse, Roentgen, and of the great host of scientists whose gratuitous but invaluable achievements can be accomplished only in the quiet retreats of peace. From the same beneficent retreats, in our own days, came the discovery of anesthesia, all without cost. A great phantom-like apparition that made its first earthly advent, that Eve might be born from Adam's painless side, and its second in the fullness of time for the fulfillment of the prediction: "There shall be no more pain." Long, Wells, Jackson and Morton received no compensation or pension. Military and naval academies, navy yards, veterans and their families cost the world billions upon billions of dollars annually, necessitating oppressive taxation, this taxation causing poverty, and poverty bringing exposure, disease and death.

But the industrious work of many lives and the vast volumes of many libraries would not suffice for the endless detail of the stunning contrasts between war and peace, and the opposite tendencies of their respective works as shown in the gross and obvious facts that are presented in ordinary statistics. Even if this overwhelming task were accomplished only a few pages of the momentous history would be written. Nature has vast regions that lie beyond the domain of statistics. The greatest and dearest of human interests are of things for which there is no commercial unit and no possible place in mathematics. During one of the fierce battles of our recent war it is estimated that ten thousand men were killed in not more than ten minutes, but the value of these men in all directions and the cost to the aggregate interest of the world of their horrible slaughter can never be estimated until death sighs can be painted and family agonies analyzed, family bereavement measured and the suppressed possibilities of themselves and of their

prevented offspring can be understood. It is a saying that more men are lost in war by disease than by the enemy. It is probable, on due reflection, that the damage caused by the remote, long-lasting, unrecorded and ramifying influences of war far transcend its direct, obvious and loud-crying evils. These remote and recondite influences contribute in numberless ways, in various degrees and for indefinite periods, to reduce human vitality and to increase the mortality of disease. They are solid realities in casting shadows on the face of the world and in darkening the homes and the highways of men. They are not visible to man's eye, nor audible to man's ear, nor enumerable in man's figures, but, nevertheless, they are potent agencies in drying up fountains of life that otherwise would have fed perennial streams of hope, faith, love and happiness.

Here this humble thesis must end. The conclusion reached is: That human life is man's paramount earthly interest and the foundation of his temporal happiness; that war and its effects are great destroyers of life; that peace and its fruits are great conservators of life; and, therefore, that the prevention of war and the promotion of peace are not only legitimate but imperative works of State medicine.

Hoping that the medical brotherhood of this country may desire to place itself properly on record on the question above presented, and that some practical action may be inaugurated and expedited, I beg to submit to the Section on State Medicine, and through it to the AMERICAN MEDICAL ASSOCIATION, the following resolutions:

*Resolved*, That the AMERICAN MEDICAL ASSOCIATION is in favor of the movement now in agitation for the establishment of an international system of arbitration for the settlement of international disputes and wrongs without resort to war.

*Resolved*, That the said ASSOCIATION constitute the Surgeon Generals of the U. S. Army, U. S. Navy and U. S. Marine Hospital Service its representatives to act with the great organization already at work in favor of said arbitration.

## HEALTH BOARDS AS DISTURBERS OF THE PEACE.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1895.

BY CHARLES MCINTIRE, A. M., M. D.

EASTON, PA.

LECTURER ON SANITARY SCIENCE, LAFAYETTE COLLEGE, ETC.

With a title as sensational as the one that I have ventured to announce for this paper, it may not be amiss to hasten the statement that no violent attack upon boards of health is contemplated. The great good accomplished through the official supervision of these boards, whether municipal or State, is so patent that he would be foolish, who, at this late day, would asseverate the contrary. It is not necessary to attempt to enumerate the good accomplished nor to chronicle the unselfish labors of the men to whom all honor should be given, and by whom these things have been brought about. But, acknowledging the good, and wishing them greater usefulness and power, it may not be amiss to have some of their acts pass in review for kindly inspection, and to criticize, in a friendly manner, should errors or failings appear.

You are all familiar with the Oriental fable, where the Cholera on his way to Bagdad, informs a dervish in the desert, of his intention of killing 10,000 people with his plague. And on returning from his mission, is met by the same dervish who accuses him of a much

higher death rate. The Cholera replied that he had kept himself well within his bounds, the excess was due to fear. Doubtless, if you have not read, you have all looked at that volume of goodly size by Daniel Hack Tuke, entitled "Illustrations of the Influence of the Mind upon the Body in Health and Disease." With the thought suggested by these illustrations in mind, may not a doubt arise that sometimes our health authorities in their efforts to warn, really alarm; wishing to awaken, they really affright; desiring to preserve peace, they really disturb it.

I have known in a case of diphtheria, where neither an appeal to gratitude for past favors bestowed, nor to greed for a present reward offered, was able to secure any one to perform the household duties for the well, in a house where the proper isolation could be maintained in the apartments assigned to the ill. Of a husband who was not able to be with his wife at the deathbed of their son; she must bear the strain alone, or he would be so quarantined that, not being subjects for public support, the proper supplies could not be brought to the imprisoned household. Of an arrangement by which the death of a child would be announced to a neighbor after the manner of the telegraphy devised by the political prisoners in Russian fortresses, as described by Mr. George Kennan, because no one ventured beyond the door, on which the dread placard was placed, to do a neighborly deed. Making an inspection for our state board of health in an outbreak of diphtheria, I inquired as to possible carelessness in isolation, and was told that the simple announcement of the presence of the disease was enough to keep every one away, regardless of what might be the ability of the family to properly care for the suffering.

I might multiply examples, but these are enough for my purpose. And I ask you that if this is the outcome of the teachings of our health boards, is it not a fair inference that one result of these teachings is to disturb the public peace?

You all remember the scare attendant upon the last visit of cholera in New York Harbor. Of the meetings of the health boards, their preparations and pronouncements, for inspection of trains, detention of the suspected, etc. One effect of that effort on the part of the state boards was to unceremoniously, let us hope not uncharitably, take a man from his comfortable bed-room in a certain Pennsylvania hostelry, to a covered porch, because he was attacked with vomiting and purging. The fear that the man might be attacked with the dread disease, and the business of his house ruined because of its contagious nature conquered every other feeling in the heart of the landlord. Fortunately the night was a warm one, and no serious result followed.

These are trivial incidents, no doubt, and some of you may be inclined to quote:

"Diseases, desperate grown,  
By desperate appliance are relieved  
Or not at all."

And some to point to the fact, of which we are all proud, of the restricting the disease to the harbor whence it came and to the communities bordering on it; or to the wonderfully encouraging statistics that demonstrate the decrease of communicable diseases through the employment of such agencies as are here criticized. Still others may deny the conclusion and assert that these incidents are not an outcome of any action of the health authorities.

To the former objections, permit me to make clear that the contention is not for a disregard of precautions, but the unnecessary alarm to defend against a danger that does not exist; the exciting a dread of a hygienic bugaboo. The latter objection is a fair one. If such incidents as I have described are not fairly the results of the teachings of the boards of health, it is not only unfair, but unkind as well to even associate the two in the same paragraph.

As I examine some of the pamphlets prepared by our State boards for popular reading, I am reminded of a habit in dress of the worthy burghers of New Amsterdam as chronicled by that most careful historian, Diedrich Knickerbocker. These worthy heroes, you will remember, were wont to wear a half score pair of breeches at one time. Whether these indispensable nether garments were placed one over the other at one time, or whether a period of time elapsed for one pair to become somewhat threadbare before another pair covered the sturdy limbs, the historian is not careful to state. If the latter supposition be the correct one, the resemblance suggested by the pamphlets is closer. At some time in the past the medical world was using an hypothesis as to the method of communication of a disease, and the sanitarian arranged his precautions accordingly. The world wears out the hypothesis and there is need for a change of procedure. There remains, however, the doubt of conservatism. May it not be possible, under some circumstances, no matter how remote, that the older attempts to express the methods of communication may still be true? What a risk may be run if every possible precaution be not taken. The old garment is not discarded although the new one is added, and some of the circulars are almost worthy the name of "Tenbroek." Does this seem to be an exaggeration? I quote a few paragraphs, first from some of these circulars prepared by our boards of health for the instruction of the citizen; secondly, from certain named physicians who have written for the profession. I use but a very few of the possible citations from the former, and only enough from the latter to demonstrate that I have not restricted myself to the opinions of the few. I will then leave it to you to determine if my illustration is an apt one.

"Most of the so-called 'contagious' diseases are usually spread by means of atmospheric dust of which the germs of these diseases sometimes constitute a part. Consumption, diphtheria, pneumonia, influenza, scarlet fever, measles, whooping cough and smallpox are usually spread in this manner."

"Diphtheria is spread by the sputa, saliva and whatever comes from the throat and mouth of the patient, and by the dust which results from the drying of such saliva."

"Diphtheria poison has great vitality and may lie dormant in clothing, blankets, paper and houses for weeks and even months. It seems to be able to travel in the air of sewers, and thus to pass from house to house; also to rise from the emanation of putrid privies and cess-pools."

"Close attention should be paid to the sources of water and food supplies. If possible, only the purest water should be used. If there is any doubt about the purity of the water, boil it thoroughly before using it." (From a pamphlet on diphtheria.)

"A general rule applicable to all persons sick or well, is that the handkerchief should be looked upon

with suspicion. They should not be used after any secretion from the nose has been permitted to dry upon them. After being used they should be put into a paper bag which may then have its top twisted shut, there to remain until put into boiling water."

These are enough for our purpose, and it is not necessary to give the source of the quotations; they were selected hap-hazard from various pamphlets; had the circulars of other boards been used, essentially the same language would have been found. Nor is it asserted that everything quoted is open to adverse criticism; the general excellence of the suggestions makes the harmful portions all the more dangerous. The only arrangement attempted was to group several statements regarding diphtheria for the convenience of brevity in the discussion.

Permit me now to bring several quotations to your notice *à propos* to the extracts already read.

"The relation between imperfect drainage and the diphtheria poison has not yet been satisfactorily determined. Perhaps as Thorne suggests, the faulty conditions produce sore throat of a benign character, which, as in scarlet fever, affords a soil suitable for inoculation of the diphtheria germ, when present in the air. Drains, too, he thinks may retain the virus received through the sputa and dejecta of the sick. This author states that no prevalence of diphtheria has ever been definitely traced to polluted water."<sup>1</sup>

"Diphtheria is a highly contagious disease, readily communicated from person to person. The poison is given off in the pharyngeal secretion and in the saliva, but not in the breath. . . . The virus attaches itself to the clothing, the bedding and the room in which the patient has lived and has, in many cases, displayed great vitality. The disease may be transmitted by inoculation. The contagion does not seem to be widely diffused in the neighborhood of the patient. At the Montreal General Hospital we rarely had cases develop in the wards adjacent to those in which there were diphtheria patients, in bed."<sup>2</sup>

"There is no evidence that the disease (diphtheria) can be disseminated by the air for more than a few feet; it is usually necessary to come in actual contact with the bacillus at its lodging place in order to become infected, and unless it is propelled from the patient for some little distance by the patient in coughing, it is rarely taken through the medium of the atmosphere."<sup>3</sup>

The *New York Medical Journal* quotes Flugge in *Ztschr. f. Hyg. u. Infectiouskrankh.*, for July 1894, as saying that the bacilli causative of diphtheria perish when dried and converted into fine air-borne dust. Accordingly the danger of the infection being carried through the air is minimal. It is by direct contact that most harm results. Inanimate objects keep the contagion alive. In moist climates it survives better than in dry regions. If soiled clothes are kept in closed containers or in cellars, the germs there have a good chance to live and do harm.

Overcrowding and lack of personal cleanliness assist in spreading the disease. Common use of the same unclean spoons, dishes, etc., Decomposing filth piles (as such) and sewer gas are not causes. Houses where it has occurred are not so much to be feared as are the people who are unclean and careless.

"Wright and Emerson examined the dust upon the floor of the diphtheria pavilion of the Boston City

Hospital and upon the clothing and persons of the attendants, to determine if the bacilli were present. Four cultures were made from the floor sweepings, and in only one did the examination reveal the presence of the Löffler bacillus, although other bacteria were present. In four examinations of the dust adherent to the shoes of the attendants, three showed the presence of the Löffler bacillus with other bacteria. Cultures were made from the hair of the attendants in four cases, with positive results in one. Examination of the margins of the dresses of the attendants, of the bed-clothes, shirts and finger nails of the patients were negative as regards bacilli, as was also the examination of the air of the pavilion. In two of the five examinations in which bacilli were found their virulence was slight."<sup>4</sup>

"The inhalation of sewer-gas wherever diphtheria prevails has been regarded as a common cause of this disease. For this reason the following investigations relating to the nature of sewer gas are instructive and important. J. Parry Laws presented to the main drainage committee of the London County Council the results of his investigations on the composition of sewer gas. His examination as well as those previously made by Carnelly and Haldane, showed that the air of sewers was much better than might have been expected. . . . The number of microorganisms was less in the sewer air than in the outside air at the same time. . . . Moreover, the sewer air contained a much smaller number of microorganisms than the air examined in domiciles. Laws found that the microorganisms of sewer air are related to the microorganisms of the air outside, and not to those in the sewage. . . . He also found that a considerable increase in the velocity of the air currents did not increase the number of microorganisms found in the sewer air, and that the results of experiments were the same in small as in large sewers, and led to the belief that all microorganisms in sewage air are non-pathogenic."<sup>5</sup>

It is not necessary to unduly lengthen this paper with additional quotations. Admit that they are selected with the purpose of an advocate to further his plea and that other opinions are suppressed; enough is given to show some physicians of good repute, when addressing the profession, do not positively state that diphtheria is usually spread by means of atmospheric dust and should be classed in this respect, as an air-borne disease, with smallpox; that it seems to arise from emanations in putrid privies and cess-pools; or that it is a water-borne disease. And to the degree that such things are asserted beyond the proven knowledge and in an opposite direction to the trend of investigation, by so much is a needless dread aroused and the public peace disturbed.

One can easily see why this is done and suggest excuses for it. The burden of responsibility placed upon the health officer who has any fellow feeling for mankind is so great that he naturally prefers to take ten needless precautions than to run the risk of omitting to take one that is necessary. He fears that the teaching of the biologist and clinician may not include the whole truth and, while he makes use of their teachings, he does not, on that account, entirely neglect other sources of information and adds, it may be, that other knowledge whose fountain is said to lie with elderly ladies; for fear he may make a mistake. In much of this, I fear, he brings sanitation into disrepute and prevents the public support that it would

<sup>4</sup> Sajous Annual, 1895, vol. 1, p. 4. <sup>5</sup> Ibid, p. 6.

otherwise receive, and fails to produce in the public mind that confidence which should always manifest itself.

Sanitarians are not alone among physicians in their methods of mingling science and sentiment. The history of medicine displays a grand march of hobbies and hobby riders. Just now our steeds are agriculturally inclined; we are in the midst of a time of weed-killing. The farmers in the region about my home have their fields at times invaded by sorrel (*oxalis stricta*), but they never think of entering upon a campaign of pulling them out root and branch. No! they sprinkle the ground thoroughly with air slaked lime and change the character of the soil; then the weed can not grow. In our anxiety to kill the weeds we suggest, in effect, that every one of us who may suffer from a slight coryza should carry a a bale of pocket-handkerchiefs and a package of paper bags (preferably of waxed-paper) and, presumably, a grip-sack; for even the capacity of a small boy's pockets would not be equal to the emergency were the cold a brisk one. If you have ever had any experience with "hay-fever" you will be able to testify of the added burden that this would be to those already heavily laden. At the same time, so little attention is paid to the soil factor, with suggestions along the line of hope and not despair. I am glad to note that a paper on this side of the subject was presented at the last meeting of the American Public Health Association; may it be the harbinger of a renaissance.

But, shall we cry "peace, peace, when there is no peace?" Assuredly not! Let our efforts not be for calming into false security but rather into that state of mind that prevents a panic. Let us be scientific in all our processes, and it is scientific to admit a lack of knowledge when such lack exists. If we have become convinced of the truth of any supposed fact in medicine, let us act honestly by its teachings, laying aside all that is contrary. If we are convinced that typhoid fever is a water borne disease, and rarely, if at all communicated by contact, why insist that the dead be wrapped in a bichlorid sheet or object to the transportation by rail for burial? Our train robbers and train wreckers, however vicious and debased, are not cannibals; and the risk of an accident whereby the body will be precipitated into a source of water supply of any community is so remote that the most painstaking need not consider it. Let us be honest in our presentation of sanitary statements. President Lincoln's suggestion about the ability and inability of fooling the people is so trite that it need not be quoted; but it is true.

Let us be more vigilant than ever; pressing reform, acknowledging error, seeking to educate, striving to prevent. But science, not dogma; deductions not presumptions nor assumptions, only should pass current. Not only safety but peace of mind should be our aim. Let us strive rather to increase our efficiency, and in striving remember that efficiency is never measured by the manifest exertion or parade in its execution.

#### DISCUSSION.

DR. COCHRAN—I think the health authorities in various cities have put themselves to much useless trouble to instruct the people by the leaflets and circulars they send around. In Alabama we do not try to teach our people hygiene. We do not send them leaflets about how to avoid diseases. We would send them pamphlets about treatment of disease. We tell

them to send for a doctor, and when they want sanitary work done to send for a sanitarian. We do not try to make every man his own health officer. I have been struck with the extremes to which these health officers go.

The Doctor related an instance of three cases appearing at Stone's Bank, Ala. The physicians vaccinated the people, and there was never another case, but the people at a town fifty miles below went to the unnecessary trouble of quarantining against them, and invoking the aid of the service, after the danger is over.

## DUTY OF THE PHYSICIAN TO THE PUBLIC.

Read by Title in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY JAMES W. COKENOWER, M.D.

SECRETARY IOWA STATE MEDICAL SOCIETY, AND PROFESSOR ORTHOPEDIC SURGERY, COLLEGE PHYSICIANS AND SURGEONS, DES MOINES, IOWA.

The tendency among modern medical writers has been to present a subject pertaining to some special branch of medical and surgical science and, especially, to ride some "hobby" or pet theme, wholly ignoring the more practical thoughts which come before us in everyday life.

It is the purpose of this paper to point out briefly some of these errors, and it will make no pretense to science, but endeavor to present such thoughts as come under the writer's observation almost daily, while engaged in a general practice. And, it seems to me, they are of sufficient importance to invite the attention of the entire medical fraternity. It is true that science, and advanced theories of medicine and surgery have done much, and no doubt will do more, and are not to be disparaged, but they have in the past, it seems to me, been prosecuted to the detriment of the more common and practical things. I have observed, daily, in the families, where I am called to practice, the amount of good which the physician might accomplish in teaching them how to live; how to ventilate their homes, and such other hygienic measures as would advance their physical, as well as mental and moral interests. And, not only this, but the ravages of hereditary diseases, which are annually apparently increasing in our land, seem to imperatively call for legislation with regard to the intermarriage of such people as are known to have such hereditary taints. However, since there are none, and since it does not appear to be practical, that a law can be made prohibiting the intermarriage of such persons, it occurs to me to be the duty of the physician to counsel and advise those who are under his observation of the dangers that lurk unseen within them, and, thereby if possible, cut short and limit the number of such cases.

Again, while there are laws prohibiting the physician from producing abortion, and which, I regret, is not as fully carried out as it should be, yet, perhaps, as nearly so as most of the laws not wholly a dead letter on our statute books, the writer's observation has been directed to another class of people aside from the physicians, and that is the women themselves. These counsel with no physician, or any one else, but do the work themselves and, if everything passes off smoothly, the physician is never consulted, but, in case they fear trouble, the physician is invited in to assist and, thus, bear the blame for whatever injury may have resulted.

And, so I might go on enumerating things wherein the physician, in his greed for science, wholly ignores the more practical things, thereby causing grief

throughout our land. It seems to me if the physicians would unite upon some means of extending their influence in the proper directions with regard to these facts, they could wield a great force, mold public opinion, and so instruct their patrons, which means the entire public, as to bring about a change that would be effective in the end and would be, in fact, more practical than any legislation upon the subject.

I have been endeavoring, in a quiet way, to manifest my influence in this direction with those whom I come in contact, and it is my opinion that a vast amount of good can be done in this way. And, whenever physicians unite in this one cause, and cease to ignore simple things, things apparently of not sufficient value to give heed to; whenever they cease to ride their hobbies, and look at such a thing as the writer has endeavored to point out, then, and not till then, will the time come when there will be that change wrought upon the public that will improve and advance the physical condition of the community in which this influence may have been exerted, and prove to the unsuspecting public that there is no class of men who have more to do with the confidence, and are better able to mold public opinion than the physicians, when they work in harmony and manifest their influence.

## ON HEALTH DEPARTMENTS OF LARGE CITIES AND THEIR ORGANIZATION.

Read by title in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY JOHN B. HAMILTON, M.D., LL.D.  
CHICAGO.

SURGEON, FORMERLY SUPERVISOR SURGEON-GENERAL U. S. MARINE-HOSPITAL SERVICE; MEMBRE HONORAIRE SOCIÉTÉ D'HYGIÈNE, PARIS, FRANCE; MEMBER AMERICAN PUBLIC HEALTH ASSOCIATION; CONSULTING HYGIENIST CITY OF CHICAGO.

The progress of sanitary science, and the increase of knowledge among sanitarians, is one thing; the putting in practice of that information, is another. All science is concerned with the former; the State, the Government and the people, with the latter.

Our cities have grown so fast that the problems which confront them of civic administration, have not been dealt with as if they had come gradually on a community prepared by long years of dwelling together, to meet them; and so in our great cities we find great advances in certain directions, and we find ourselves very far behind the age in others.

Among the unsettled problems in large cities is that of the best means of securing a perfect sanitary organization, and in the securing of that result, we are more or less hampered by the laws which have been enacted in the village before it became a town, and the ordinances of the town before it became a city, all of them more or less changed by acts of the State Legislature in which the city is situated. It therefore follows that in most cases, it is better to create these sanitary organizations of our large cities by legislative enactments rather than by municipal ordinances, because in many cases the city charter will be infringed upon or violated in some of its provisions by the adoption of certain salutary regulations, or prevent their adoption.

I recently had occasion to make a report to the Mayor of the City of Chicago, providing for a sanitary organization which would meet the exigencies of the existing law of that place, and at the same time create a new department on a basis that would

provide for proper scientific work, in the interest as well of promoting sanitary science generally as in that of the health of the people of that city alone; in other words, to draft a plan for the organization of a model Health Department.

In drafting this organization, I was struck by the fact that in this country there can be only two systems of sanitary administration, and these systems are radically different; the one is an enlargement of the old town meeting plan, whereby the select men of a town meet at stated intervals and adopt regulations in which there is no individual responsibility either on the part of the select men themselves, or the person who has to execute them. The other system is the military one, in which every person is held responsible, from the commanding officer down to the private; each for the division of labor assigned to him. When responsibility is thus fixed, we insure better administration, because the results are always apparent. A person responsible for a bad result can be properly dealt with and removed from his position, to enable his place to be supplied by some one judged more competent.

In the city mentioned, the occupancy of a position of health officer by a layman, without knowledge of chemistry, engineering, sanitary science, or any part of medical education, made it necessary to provide for his retention in the act; although in my judgment such positions can not be filled with credit to the incumbent, or with safety to the public, by any person, however able he may be, until after some training in the fundamental branches of the education of a health officer, and I feel obliged to say to the Section that, in my opinion, whatever measure of success has since been achieved by the health department named, it has been done by reason of the advice of the Board of Health, and the advice and experience of the trained Assistant Commissioner of Health, our colleague, Dr. Frank W. Reilly, who, during the present administration has guided the sanitary affairs of the department, practically unhampered by his titular lay chief. I do not doubt that any layman by close application to study and honest attention to his duties, may in time become thoroughly informed in hygienic matters, but in such case the education is acquired at the expense of the city, and without adequate compensation to the public.

I herewith present to the Section a revised draft of an ordinance, which in my judgment, is best adapted to meet the requirements of a health department of a large city:

AN ORDINANCE TO REORGANIZE THE DEPARTMENT OF HEALTH.

Be it ordained by the City Council of the City of \_\_\_\_\_: There is hereby established in the municipal government of the city of \_\_\_\_\_ an executive department to be known as the Department of Health.

### Appointments—General Provision.

SECTION 1. No person shall be appointed to any office or position in the said Department, until proper inquiry shall be made by examination, or otherwise, into the ability and fitness of such person to perform the duty that may be required of him, should he be appointed.

### Removals—General Provision.

SEC. 2. No officer or employe of this Department shall be removed except for cause and no person shall be appointed, promoted or removed for any political reason. Any officer or employe may be removed for crime, malfeasance, habitual neglect of duty, willful misconduct, insubordination, disobedience of orders, incompetence or insanity, and for no other cause.

Officers and Employes shall not accept Gifts or Bribes.

SEC. 3. Any officer, inspector or member of the Sanitary or

Ambulance Corps who shall accept any gift of money or other valuable thing for reporting or not reporting the existence of any nuisance or case of contagious or infectious disease, shall upon proof thereof be dismissed by the Sanitary Director, and shall in addition be subject to such other penalty as the ordinance may prescribe.

*Enumeration of Officers and Employes.*

SEC. 4. The Department of Health shall hereafter consist of the following officers and employes to-wit: a Sanitary Director; an Assistant Sanitary Director; a City Physician; Chief Clerk; a Sanitary Captain; a City Chemist; Medical Inspectors; a Sanitary Corps; Clerks and Interpreter.

*Sanitary Director—General Qualifications.*

SEC. 5. The Sanitary Director shall be a physician of not less than ten years' practice and shall be skilled in sanitary science. He shall be appointed by the Mayor, by and with the advice and consent of the Council. He shall hold his office until his successor shall have been appointed and qualified.

*Duties of Sanitary Director.*

SEC. 6. The Sanitary Director shall supervise all matters connected with the sanitary interests of the city, and shall perform such specific duties as may be defined in this ordinance, and he shall have authority over all officers and employes in said Department. And when at any time it shall become necessary to establish sea, lake or land quarantine, he shall have command of such quarantine. He shall according to circumstances and season, issue such circulars of popular instruction as shall lead to the preservation of the public health.

*Assistant Sanitary Director—Qualifications.*

SEC. 7. The Assistant Sanitary Director shall be a physician of not less than ten years' practice, and shall be skilled in sanitary science. He shall upon recommendation of the Sanitary Director, be appointed by the Mayor, by and with the advice and consent of the Council, and shall hold the office until his successor shall have been qualified and confirmed.

*Duties.*

He shall perform such duties as may be assigned him by the Sanitary Director. In case of the sickness, disability or prolonged absence of the Sanitary Director, he shall by direction of the Mayor, act in the stead and perform the duties of the Sanitary Director.

*City Physician—Qualifications.*

SEC. 8. The City Physician shall be a physician of not less than ten years' practice in the State of —, of which not less than five shall have been in the City of —. He shall be appointed by the Mayor, by and with the advice and consent of the Council. He shall appoint a physician as City Pathologist, who shall, under his direction, make such post-mortem examinations of animals or men as may be required by the Sanitary Director, to whom his report must be sent by the said City Physician.

*Duties.*

He shall supervise the administration of the hospitals established by the city, including hospitals for contagious diseases, excepting quarantine hospitals. He shall prepare regulations for the government of police surgeons, ambulance physicians, resident physicians and superintendents of the city hospitals and the pathologist in the performance of their duties and shall have immediate supervision of the city ambulance service, when established. He shall attend or cause an assistant to attend the sick in the city workhouse, calaboose, watchhouse, police stations or houses of correction, and shall attend such meetings as may be held by the Department of Health, and in case of epidemic, he shall render such assistance and coöperation, and perform such duties in connection therewith as the Sanitary Director may require.

*Chief Clerk.*

SEC. 9. The Chief Clerk of the Health Department shall be skilled in business affairs and statistics and shall be appointed by the Mayor, by and with the advice and consent of the Council.

*Duties.*

He shall have supervision over all clerks of the Department except as hereinafter provided; and shall have charge of all accounts. He shall keep an accurate record of all receipts and expenditures and shall be responsible for all fees received. He shall keep the records of births, marriages and deaths, and issue burial permits under regulations to be made by the Sanitary Director. He shall disburse all monies, pay all officers and employes, make all purchases of supplies, and execute all contracts and bonds, but he shall make no purchase of sanitary

or special appliances without the approval of the Sanitary Director.

*Sanitary Captain.*

SEC. 10. The Sanitary Captain shall be a person accustomed to superintendence of workmen, and qualified to keep records. He shall be appointed by the Mayor on the recommendation of the Sanitary Director, and shall have the rank and pay of a Captain of Police.

*Duties.*

He shall be the custodian, and have charge of the storehouse of the Department with all property belonging thereto, including horses, wagons, carts, ambulances, fumigating apparatus and sanitary appliances of every kind belonging to the Department, and shall make a semi-annual return thereof to the Chief Clerk. The return shall show from whom the property was purchased or received, to whom issued, and the present condition thereof. No property of any kind shall be issued to any person except upon requisition duly approved by the Sanitary Director, Assistant Sanitary Director, City Physician or Chemist as may be required. He shall have charge of the Sanitary Corps, and under the department regulations, supervise the work.

*Chemist—Qualifications.*

SEC. 11. The Chemist shall be a graduate in medicine, skilled in chemistry, pharmacy and bacteriology. He shall be appointed by the Mayor on the recommendation of the Sanitary Director. He shall have an assistant, who shall be City Bacteriologist, and who shall be nominated by the Sanitary Director and appointed by the Mayor.

*Duties.*

His duties shall be to have charge of the laboratory, and to direct the conduct of such chemical and bacteriologic investigations as he may from time to time be instructed to make by the Sanitary Director, to make test investigations of food products, milk, water, ice, beverages and drugs, and to make report thereof to the Sanitary Director.

*Medical Inspectors.*

SEC. 12. The Medical Inspectors shall be appointed by the Mayor on the recommendation of the Sanitary Director, but no person will be appointed Medical Inspector until after such examination as shall satisfy the Sanitary Director that the applicant is fully informed in the principles of sanitary science.

*Qualifications.*

Physicians holding the collegiate degree of Doctor in State Medicine, or its equivalent, will not be required to pass such examination.

*Chief Inspector.*

One of the said Medical Inspectors shall be specially skilled in the diagnosis of the exanthematous and contagious diseases, and shall be designated as Chief Medical Inspector.

SEC. 13. Medical inspectors, except the Chief Medical Inspector, will perform such service as may be required of them from time to time, and they shall be paid according to the service actually performed, on a schedule of pay to be prepared by the Sanitary Director and approved by the Mayor.

*Sanitary Corps.*

SEC. 14. The Sanitary Corps will consist of three divisions, viz., first, those employed in the division of the City Physician as litter bearers, ambulance drivers and hospital attendants; second, milk, meat, food and other inspectors employed in the chemist's division; third, plumbing inspectors, fumigators, and persons employed in the work of placarding infected premises, and disinfection of the same, acting under the Sanitary Captain.

*Uniform to be Worn.*

SEC. 15. All members of the Sanitary Corps shall wear the uniform of their grade, and shall receive such monthly compensation as the Mayor may by order promulgate, as equitable for the services respectively performed by each class.

*Clerks and Interpreter.*

SEC. 16. There shall be employed in the Department of Health — clerks, who shall be appointed after due examination into their fitness for such position, and they shall be assigned to such duty as the Sanitary Director may designate, and the Sanitary Director is hereby authorized to employ one person as stenographer and clerk to serve under his immediate direction, and one person as interpreter and translator. No person shall be employed as translator who can not read correctly and converse in five modern languages to be designated by the Sanitary Director.

*Repeat Provisions.*

SEC. 17. So much of any and all previous ordinances as conflict

with or in any way impair the operation of this ordinance are hereby repealed, and all provisions of law and ordinances relating to the Department of Health, the Commissioner of Health, the City Physician, the inspection of food, milk, ice and drugs, and miscellaneous ordinances relating to health, shall, so far as they may be applicable, remain of full force and effect.

I will now take the bill up by sections for the purpose of explanation. Sections 1, 2 and 3 are, in my opinion, necessary to secure the perfect working of the officers and employes of the department. Indeed it will be found impossible to secure the appointment of proper persons unless the tenure of office be made more secure than has been the case under previous ordinances. Moreover, it is such as to bring the department in line with the civil service laws of the State and of the United States. I had charge of a Bureau of the Treasury Department when the present civil service law was enacted, and I am entirely familiar with its operations. Some passages in this ordinance will be recognized as quoted directly from that law.

Sections 4, 5, 6 and 7 are self-explanatory, and relate to the different classes of officers, and especially to the qualifications and appointments of the Sanitary Director and Assistant Sanitary Director.

Section 8, relating to the City Physician, after giving the qualifications, makes specific mention of his duties.

Section 10, providing for a Sanitary Captain, is self-explanatory. It must be obvious that some one must be had to account for the property owned by the Department, to have charge of the same, and to superintend and to direct the outdoor work. This section is not only calculated to protect the interests of the city, but to prevent misuse or misapplication of any property or appliance belonging to the Department.

Sections 11 and 12 relate to the appointment of a City Chemist and a Medical Inspector, which are self-explanatory, except that definite qualifications are provided for. The system of examination of medical inspectors, as preliminary to appointment, as proposed in this ordinance, should by all means be adopted at the earliest possible moment, as the appointment of persons through motives of friendship or political association fails to secure that standard of professional qualification that a great city should always be able to command.

The adoption of an ordinance or law like this provides the skeleton organization; as will be seen, it provides for indefinite expansion by increasing the number of persons employed, when the necessity for so doing may arise; it provides for extraordinary powers in case of epidemic; and more than all, a unity of system is provided and responsibility fixed.

As all cities have an Engineer Department, City Engineer or Department of Public Works, it is not deemed necessary to provide specifically for that coöperation which may be always secured by the comity necessarily existing between different departments of the same administration. Should that fail the Mayor as chief executive can always settle the matter by special order.

The details of executive work, the regulations governing the special office and the Department, are by this organic act left to be framed by the Sanitary Director to suit the particular city. But in no case need they conflict with the organic law, which, as will be seen, is sufficiently broad to allow the framing of all necessary regulations.

NOTE.—The essential features of this draft were commented upon with approval by the distinguished editor of the *Journal d'Hygiène* of Paris, and a translation formally presented to the Société d'Hygiène.

## THE METHODS OF DRAINAGE NOW PREVAILING IN SOME OF OUR EASTERN SEABOARD MUNICIPALITIES, TENDING TO THE PRODUCTION AND DISSEMINATION OF DISEASE.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY AUGUSTUS P. CLARKE, A.M., M.D.

CAMBRIDGE, MASS.

Crudely constructed latrines and cesspools, without connections with regularly laid drains, were the devices which often obtained among the early inhabitants of the country; they were places for receiving the waste water and the dejecta of occupants of houses and other buildings, and were for the most part recommended merely for the convenience they afforded. The method which these contrivances furnished for disposing of refuse liquids and excrementitious elements worked no serious manifest injury unless some of the more deleterious products had gained, by percolating through the surrounding soil, admission into a well or other source of water to be used for domestic purposes. Among the more dangerous products of this class have been those derived from the albuminoids and the nitrates, and from carriers of some of the forms of bacteria that were capable of giving rise to diseases that have been regarded as of a zymotic character. The development of morbid conditions from such sources in sparsely inhabited districts has not been of common occurrence, from the fact that the free ventilation which takes place through the open vaults, and also the diluting action of water from the frequent storms, have had a counteracting effect upon the potency of the bacterial agents, and have thus rendered immunity to persons not particularly susceptible to influences of such disease factors.

As these places became more densely populated, there were also built, in connection with the receptacles, different forms of drains, into which the fluid and the less solid portions of the waste matter were discharged. Beyond this measure of dealing no very definite plan at first for the disposing of sewage was maintained, and so the contents of the drain were disembogued into a stream or water-course that perchance could be found in the vicinity. When the discharge was made into rivers whose courses had a steep and rapid descent, very little seemingly ill effects were experienced by those who dwelt above the point of the inlet. Those who dwelt along the river banks or in the valleys below were not always so fortunate, especially when they found it necessary to take from the river in that vicinity their water supply.

Water of large streams, if charged with deleterious products, will not after flowing several miles become wholly innocuous and be safe for drinking purposes. The tenacity of life possessed by certain bacterial elements will not be overcome by such an inadequate exposure. In this connection it is but just to remark that it is not so much the negative testimony of the chemist and the microscopist that insures safety in the choice of the drinking water, as it is that there exist no possible sources of contamination.

Many of our larger cities have already inaugurated measures for taking water where the unhealthful influences have been reduced to the minimum. Unfortunately, however, this freedom from contamination does not prevail in the majority of municipalities. Among the more prominent objectionable features of the present methods of drainage for municipalities is that of discharging large quantities of refuse matter into sewers which are connected, either directly or indirectly, with rivers that receive tide-water. The people dwelling in the less densely populated portions of a city or town where a good-sized sewer has its outlet into the river through a gate that opens and closes with the ebb and flow of the tide may not, perhaps, suffer to any great extent in availing themselves of the use of such a drain. A long open drain, however, connecting at one end with residences and at the other with tide gates to allow its vile contents to be discharged so as to be exposed to the rays of a summer's sun, and to have its evaporations wafted back through the long conduit by the counter-currents of air set up, and drawn back to the homes of the occupants, presents features that are far from being conducive to health.

A still more dangerous factor results even after the closure of the gates from the oncoming tide, by the rapid filling up of the sewer from the numberless drain pipes that are directly connected with the government drain; this arrangement tends to displace the air laden with poison or pathogenic organisms, and force it back toward the house connections with the sewer. When the pressure that produces this reflux is moderate, the effect may be overcome by the water in the closet traps, but during the time when there is much storm water to be carried off the pressure becomes inordinate, and thus forces not only the mephitic air, but causes a reflux of the filthy water; this may pass through the traps that are lower down, and in some instances also through those placed as high as the street level. This has been particularly noticed when great storms have been raging. The numerous conductors extending from the many high buildings in the neighborhood to these sewers tend to force, in accordance with a well-known law in physics, the water up through the house drains above the normal level, and thus to flood the basements and cellars with water and sewage that have been collecting in the drain during the storms and while the tide gates were closed.

This unhealthful condition of things has gradually increased since the custom of building large apartment houses and of other high structures has obtained. To show the inadequacy of the sewers or the drain traps employed for preventing the reflux when the sewer is being filled by the accumulation of storm water flowing from the conductors of high buildings and from the street catch basins during the closure of a tide gate, a drain pipe connected with a sewer leading to a house whose basement had been flooded by a regurgitation of storm water through the bowls, on being opened to determine its condition, a jet of water like a geyser spouted up several feet into the air, and continued thus to flow until the drains had been relieved of their excessive pressure.

The objectionable features arising from such a defective method of drainage have been sought to be overcome by the construction, at an enormous expense, of what has been designated as the "metropolitan sewer," for the accommodation of the inhab-

itants of Boston and of other municipalities within a certain radius. The benefits to be derived by the laying of this drain are not altogether what was generally anticipated, for the reason that the sewer is not of sufficient capacity for receiving and carrying off in a proper manner the storm water, in addition to the sewage it has to take in. The sewer has been built out some distance into Boston harbor, where the contents are discharged by means of large pumps into the deep water, that they may be borne out with the tide into the sea.

The object of the expedients adopted or suggested by the engineers of the cities that have been interested in the construction of the work, is that the storm water entering the great sewer may by an automatic device escape into the local sewers, and so pass into the Charles River or other water-courses with which they may be connected. It requires but little reflection for any one to comprehend the fact that more or less actual sewage will still be carried along with the storm waters into the river, and that the cessation of contamination of our natural water-courses by the carrying into them of drainage material will only be accomplished theoretically and not in real practice. Again, the storm water can be discharged by the devices above mentioned from the local sewers into the rivers only at ebb tide and while the gates are open. At other times the entering waters coming from the heavy rains will not all pass on, and when the sewers become overcharged will take a backward flow into the estates embraced within the lower sections of the district, as has so often occurred by the operation of the old system of drainage, with this difference, perhaps, that the new method, as the sections become more crowded, will nevertheless give rise to a greater reflux of the sewer contents.

It should be stated that some twenty years ago or more, statutes by the State government were passed, requiring certain lands below thirteen feet above mean low water mark to be raised to grade. The difficulties that are now being experienced are not, however, confined to such districts that have been filled, but are met with to some extent in places that are of a higher grade. It is too bad that after the enormous outlay of money that has been made by the inhabitants, and the annoyances and vexations experienced, beside the expenditure for the construction of sewers, so little of real permanent value has been achieved. This result is not dissimilar to the experiences of other State governments when they have attempted to accomplish any great, new and lasting benefit.

In order to overcome the unhealthful features incident to the working of the present system of drainage, special sewers for carrying off the storm water should be laid. Into these should pass all the water from roofs, gutters or conductors upon buildings, and the storm water of the streets after it has been well filtered through catch basins to deprive it of its more solid portions. These water conduits should be laid so deep that the water in the cellar and foundation wall trenches for some inches below the deepest portion of a cellar bottom may readily flow into them, to be carried off to the rivers or other depths of natural water channels.

In cases of tidal rivers there should be for the most part no tide gates; deep basins should be constructed for receiving such waters, that, after being filtered, could be discharged, by means of a pumping station, into the river. For times of great drought these

waters could be stored in receiving basins and could be used for the extinguishing of fires and for other purposes in cases of emergency.

The State Board of Health has already recommended that some independent system of sewerage should be employed for the disposition of storm waters. For one particular part of our city our mayor has given some encouragement that he would manifest his official influence for the construction of a sewer for the greater relief of water coming during the heavy storms. No definite experiments as yet have been instituted for determining the feasibility of carrying out the plan here proposed, but it is evident that something more radical than what has heretofore been attempted will have to be undertaken for the insuring of permanent relief and healthfulness in our municipalities.

Until there are adopted plans for drainage founded on more scientific principles than those still prevailing, we can not expect to achieve any great results in diminishing the occurrence of many forms of disease. We may raise the standard of our medical colleges and our universities, may improve our methods in pharmacy, extend the list of articles and remedial agents in our materia medica, and develop to the highest degree our surgical technique, but these promising helps will still be found capable of relieving only a mere moiety of the sum total of the suffering from disease, so long as occupants of dwellings continue to be exposed to the increasing dangers of overcrowding that is everywhere now taking place.

## A DEPARTMENT OF HEALTH, OR A BUREAU: WHICH?

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association at Atlanta, Georgia, May 5-8, 1896.

BY S. S. HERRICK, M.D.

SAN FRANCISCO.

It is assumed that the AMERICAN MEDICAL ASSOCIATION substantially agree that the time has come for some permanent branch of our national government to promote and administer the interests of public health. There is, however, a variety of plans of organization, each of which has its merits and defects, the most prominent of which may be designated a board of health, a department, a bureau, and the continuance of the present method as administered by the Marine-Hospital Service.

The plan of a board of health has been tried, with such want of success that, in my opinion, it would be unwise to experiment again. It is needless now to consider where the fault chiefly lay; and there are too many yet living and active, who participated in the controversy, safely to risk the danger of its revival. The plan most favored by the AMERICAN MEDICAL ASSOCIATION has been to create a department of public health, presided over by a secretary holding a seat in the President's Cabinet. Its conspicuous aim is to magnify the importance of public health and extract a large appropriation from the treasury. Without detracting from the value of health as one of the enjoyments of life, we must not overlook the fact that other great interests are clamoring for recognition and an appropriation. The agriculturists, who now number approximately 9,000,000 of our population, have recently secured a separate department. It may be expected that those engaged in manufacturing and mining (about 5,000,000) will

soon demand like consideration, and that they will be followed in due time by the trade and transportation interest (numbering about 2,500,000). The two latter are already anticipated by the sanitary interest, which may be represented by about 100,000. Roughly speaking, this number is now classed in the medical ranks (regular, irregular and defective), and I think it would be fair to deduct, as not being interested in sanitation, quite as many as should be added to those so interested from the laity. Teachers and scientists (representing the educational interest) now number approximately 300,000, or three times as many as the sanitarians. In 1867, the Bureau of Education was created by act of Congress, and it has done excellent work ever since. So far as I have learned, both the public and educators are satisfied with their modest organization, though, doubtless, they would like more money.

In 1885 the present writer, recognizing the excellent work done by the Bureau of Education, being deeply impressed with the need of a national sanitary service and at the same time warned by the troubles which had befallen the National Board of Health, formulated a plan for a bureau of health, which was approved by the American Public Health Association. Under its auspices a bill for this purpose was framed and introduced in Congress. It would serve no useful purpose here to dwell upon the reasons of its failure. In substance the proposed functions of the bureau were the following:

1. To gather information upon the state of the public health and the existence of contagious disease in foreign countries through the consulates of the United States government; to digest and communicate the same to all government posts and health authorities of our country; through medical officers attached to the consulates, when requested by the masters of vessels destined for ports of the United States, to inspect the vessels, cargoes, crews and passengers (including their personal effects), to use measures for cleansing and disinfection, and to vaccinate those requiring vaccination (all at the expense of the vessel), to furnish bills of health relative to the port of departure and full dealing with the vessel, or to notify the bureau by telegraph of neglect or refusal to accept such service.

2. To serve as a medium of intelligence in sanitary matters, including vital statistics, between health authorities throughout the United States, by means of a weekly publication, which would contain also foreign intelligence.

3. To inspect the various quarantine stations of the United States from time to time; to investigate outbreaks of pestilential disease in any part of the Union; to report such inspections and investigations; to recommend to local health authorities needed preventive and suppressive measures.

4. To conduct chemico, physiologic and pathologic investigations in the interest of sanitation.

5. To publish and distribute documents relative to public health.

It was contemplated to authorize the bureau to require the detail of suitable medical officers from the Army, Navy and Marine-Hospital Service for carrying out its functions at home and abroad. This would be a measure of economy and also a safeguard against political intermeddling. At that time it was not thought wise to give the bureau powers in quarantine matters, but it is now probable that there

would be little or no opposition to some exercise of authority, when needed, in international or inter-State quarantine. I am satisfied that a bureau organized on some such plan would fully meet all requirements of sanitation and could be enlarged so as to keep pace with the growth of the country quite as well as the Bureau of Education. Those who believe that the right way to gain the earth is to go for the whole solar system, may naturally suppose that the best way to obtain from Congress a bureau is to ask for a department. This is a matter of opinion, which I forbear to discuss. There is, however, a choice between a department and a bureau which, to my mind, vitally concerns the utility of the service. The secretary of public health would be a political officer, appointed for four years, and his subordinates would also belong to the same party. The one important qualification for office would be partisan services rendered during the preceding campaign. Those who are conversant with the customary methods of securing positions in State and municipal sanitary service in our country need no explanation of what might be expected. Now, the question is: Does the AMERICAN MEDICAL ASSOCIATION, claiming to represent the most numerous body of scientific men in our country, stand ready to commit the interests of preventive medicine to that class of adventurers who have control, for the time being, of the national political machine? If such be its deliberate choice, then I beg to recall Æsop's fable of the frogs who asked Jupiter for a king. At first he gave them a log (likened to a national board of health), which they sat upon in scorn, until it sunk out of sight; then they asked for another, and he sent them a stork (likened to a cabinet officer), which devoured them without mercy.

On the other hand, if the choice be some plan which will put our health interests out of politics, then I advise a bureau of health modeled after the Bureau of Education, in which a commissioner may hold office under successive administrations. Let his subordinates be drawn, as far as practicable, from the three national bodies of medical offices, detailed for the special qualifications which they have shown by their works. Already the Surgeon-General of the Army has organized a school, in which medical officers receive special instruction in hygiene, and the Navy and Marine-Hospital Services will not long delay in following the example. Perhaps in time State and municipal boards of health may be authorized and feel disposed to ask the detail of officers from these corps to serve as experts in sanitary work, and thus the whole country may see their health interests emancipated from politics.

The last proposition, that of leaving national sanitation with the Marine-Hospital Service, seems not to meet the wishes of the medical profession at large, though, to my knowledge, the reason has not been openly declared. The most obvious explanation is, that this plan does not satisfy the aspirations of an army of patriots anxious to serve their country. If we must choose between a department of health and the present system, in my judgment, the change would involve great additional expense with a strong probability of poorer service. On the whole, I find no valid reason to change the views held on this subject since 1885.

## ARGUMENTS FAVORING A DEPARTMENT OF PUBLIC HEALTH.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY LISTON H. MONTGOMERY, M.D.

CHICAGO, ILL.

Some of you perhaps may have views and ideas that are not entirely in accord with those of the writer. It is natural to suppose that some of us have hobbies or fads in medicine in general, the science of hygiene, or upon some branch of scientific study or research.

Emerson said, "Science surpasses the old miracles of mythology." It is with pardonable pride therefore that I offer this contribution and venture to briefly discuss this important subject, which as it appears to me, is one of the *most pressing needs of legislation that confronts us* and which our government can bestow and by so doing promote the welfare of the people of the United States.

It is a well known fact that by the acts of our National legislators during the past few years hundreds of thousands of dollars have been appropriated and expended for agricultural pursuits including that of saving the cattle and other stock products that belong especially and distinctively to the farming interests of our country, and which we as sanitarians most heartily commend. But have you considered the proposition that during the professional career of thousands of members in our profession, not one dime has been appropriated for public health matters, to save or prolong the lives of human beings, and while our Marine Hospital Service has its duties to perform, it is nevertheless very circumscribed in character, and can render very little public service to the people inland, when cholera for instance, or any other disease from a foreign country invades our shores, as was the case when this dreaded malady threatened New York city during the summer of 1892 and the year following. The disease was stamped out, or more properly speaking, what was supposed to be cholera was prevented from making inroads to the interior by the State's laws.

But we are reminded that New York State, and the City of New York has facilities for caring for an epidemic which very few other States possess.

That the United States is constantly exposed to the importation of disease from foreign countries, and subject because of the facility and rapidity of interstate transit to the rapid spread of infection and deadly germ infection of almost any city or town, is to the writer's mind something that ought not longer be tolerated by the patient people of this country.

While Philadelphia, Baltimore, Boston, New Orleans, Portland, San Francisco and our sister city Quebec, may be sufficiently provided for in this respect, there are numerous other cities on the Atlantic, Gulf, and Pacific sea boards that are not as fortunate nor properly protected and equipped to bar out disease that has been imported should it gain a foothold.

I think this is particularly the case with our Southern sea board cities. That they are not sufficiently prepared to combat the ravages of pestilential diseases that may invade them from some foreign country is a well-known fact to the practical sanitarian everywhere. This fact, lamentable as it is, has, to say the least, one specific cause, the absence of a department of public health. On the other hand we are well aware that the efficient health officer of the city of Charleston,

Let us have a Department of Public Health!

S. C., and of other cities along the southeast Atlantic and Gulf coasts are as alert and equally efficient as health officials can be, but oftentimes they are hampered in doing thorough painstaking work toward suppressing a threatened endemic or epidemic.

*What has our government done for the medical profession?* Congress should do all in its power to advance the scientific interests of the medical profession and promote the welfare of the people of this country. Has this been done? Governmental aid in this respect is not lacking in several other countries with which we are in daily commercial intercourse. I believe the time has fully matured, and the importance to the public welfare in the matter of sanitation and health laws has arrived for our people to require, yea demand, that we are entitled to another branch of the Federal Government and portfolio to be known as the Department of Public Health with a medical secretary at its head, to be on the same plane or parity or dignity as is accorded to the other departments in the general administration of public affairs.

The consensus of opinion in this respect is widespread as will be noted by the following illustrations. This subject, to quote as near as I can recall them the words of the late Prof. C. G. Comegys, "Is not for the promotion, welfare, or aggrandizement of the medical profession," but for *the welfare of the people* of a united country, the fairest the sun has ever shown upon, and to quote further from our late associate and worthy teacher, "Who is there that is more capable of judging of the welfare of our people, scientifically speaking, and I will add socially and morally than we who comprise the membership of this noble ASSOCIATION, representing as it does the hundred and twenty odd thousand physicians in the United States?"

Why need our government wait for a threatened invasion or approach from Europe or other foreign land of some specific form of deadly germ or disease infection?

Why wait for the advent of smallpox from Mexico, or yellow fever from the Spanish colony or States of South America, or the arrival on our border of some poor indigent immigrant sick nigh unto death with some form of pestilential disease, or until the germs of an infectious or contagious character have already made their appearance?

But some wiseacre (not a member of our profession) will say: Oh well, these cases will be quarantined or the maritime quarantine system will take care of them, etc. Scarcely two weeks ago the utter failure of this method was demonstrated at the city of Baltimore, Md., when there arrived several hundred immigrants at that port who had been exposed to smallpox or varioloid on board the steamship that brought them. The poor sick immigrant was detained, but the balance were allowed to pass through and take up their abode at their place of destination, many of them within three days arriving at Chicago, Ill.

While the maritime quarantine service does very well indeed and is a most useful system so far as it goes, yet it has no control in the inland and its power of authority is limited. Its system does not include all the ways and means of carrying into effect efficient prophylactic measures on a thoroughly scientific basis as should be done by scientific preventive medicine and thorough bacteriologic investigation beyond the few cities enumerated above. This system has no authority to carry out the enforcement where necessary of sanitary regulations tending to prevent or

abate the spread of epidemic or pestilential diseases beyond the seaport places it has found lodgment and where it may be equipped for this purpose.

At the Pan American Medical Congress, the first congress of this kind ever held in the United States, which convened in the city of Washington, D. C., in September 1893 under the auspices of our Government, this subject was critically and thoroughly discussed in all its phases, heartily concurred in, and reported in favor of such a Department, with a cabinet minister at its head.

The Chicago Medical Society having a membership now of upward of 750 members as early as the summer of 1884 at the instance of the writer had a committee appointed consisting of seven of the most able sanitarians of that city, including the Commissioner of Health to devise and formulate a plan to urge the importance of National legislation upon this subject.

The committee submitted its report in September following and it was unanimously adopted.

The American Public Health Association at several of its annual meetings has heartily and unanimously concurred in this measure, and has appointed its special committee to confer with a similar committee of this ASSOCIATION to devise the best ways and means toward establishing this *sine qua non*, and much is hoped for in this direction from this influential body at its coming meeting at Buffalo, N. Y., next September.

Various State, county, and municipal medical societies in a number of portions of the Union have within the past two or three years unanimously approved and adopted resolutions to this effect, and have heartily approved the bill now before Congress prepared by the special committee of this ASSOCIATION, to establish a department of public health.

#### STATE RIGHTS AND INTERFERENCE WITH STATE LAWS.

The possibility of interference with inter-state authority I think is a subject too mythical indeed to require discussion.

Section 2 of our bill provides for the cooperation of State and municipal health authorities, hence no obstacle can supervene in the matter of inter-state or municipal boards of health and all will be of the most harmonious advisory nature and unanimity in character, with the one main object in view, the advancement and improvement in the welfare of the American people, the prolongation of human life, the physical and mental development of our citizens, and I might go farther by saying, the evolution of the human race by the diffusion and promulgation of scientific facts and treatises compiled from the best literature prepared by the most thorough scientific painstaking sanitarians of our country, thus promoting the physical health of our people and a correspondingly cultured intellectuality.

*The following questions have doubtless been proposed to some of you already:* Is there a degenerative tendency in our advancing civilization, in these days of the new woman, hypnotism, bicycles, church affairs, etc., or is there a tendency for the rich of our Nation attaining a premature old age? Is insomnia, hypochondria, hysteria, dipsomania, suicide, insanity and cognate diseases including diseases of a tubercular nature on the increase?

I would answer in a general way. In certain geologic sections of our Union and among a certain class, most certainly this is true. We may ask our-

selves then, what is the cause of this vital or mental change?

The miscellaneous statistics on these and kindred subjects to which I have had access, imperfectly as they are collated, unmistakably prove this.

If the government could see its way to rise to the dignity of having a department of public health and a medical secretary a man of well known scientific attainments, as other nations have, statistics on this point could be made more reliable and valuable scientific accurate investigation could be carried on in a methodic manner from the center or fountain head.

In these days of specialism, the surgeon and the specialist receive for their professional services a fee which to my mind is greater and out of all proportion compared to that which the sanitarian or general practicing physician usually receives, or which he is justly entitled to.

While many of the ailments suffered by man are due to germs, morbid or toxic products or agents entering the system whether from food in any form, drinking water of polluted wells, rivers, lakes, etc., or germs of contagious nature, that enter the human economy through a wound, whether there be syphilitic, puerperal, tubercular, or sepsis due to other causes. The sanitarians of the medical profession in renewing their endeavors toward bringing about what this paper has for its object again manifest their unselfishness in exerting their influence in the matter of a department of public health.

What we do ask after this proposed branch of our government has been established, is that it shall have equal dignity and rank with other branches of the government, and the secretary be a member of the Cabinet. In order to carry out our undertaking to a successful conclusion we must do so intelligently. We must be public spirited and with earnest zeal enlist with renewed effort the united profession of our country.

The reports of the special committee appointed by the ASSOCIATION in 1891 has submitted its report annually since, viz., at Detroit in 1892, Milwaukee in 1893, San Francisco in 1894, one year ago at Baltimore. Each year its deliberations have been unanimously approved and adopted, all of which is very gratifying to the committee and tends to show that the committee is not, nor at any time has it been remiss in the performance of its duties.

But our ASSOCIATION and our profession must do something more than adopt resolutions, all of which are good enough in their way. We must encourage the profession everywhere, and by concerted action urge upon Congress the necessity of this measure. That the matter has been successfully carried on thus far I think no one will deny. But the profession must not become apathetic. If our Eastern confrères should hold different views, let us persuade them to unite with us, for, I am convinced after careful observation and study, that practically the entire western, middle and southern members of our profession are a unit and endorse the bill now before Congress which was prepared by the committee of the AMERICAN MEDICAL ASSOCIATION having this matter in charge.

With this strong force united, and our eastern professional friends with us, with renewed efforts on our part and the combined support of the medical journals and newspapers, shall we not be able to convince our friends in both branches of Congress of the neces-

sity of this urgent and needed legislation, for certainly our opinions on this topic are equally as valuable to public welfare, hygeia, and health as are those who have views upon finance, the tariff, the judiciary, theologic and ecclesiastic affairs, etc. The profession is too modest to claim more than this.

In reviewing the Constitution of our country, submitted Sept. 17, 1787, and which went into effect in 1788, I find in the first or opening sentence the following lines:

"We, the people of the United States, in order to form a more perfect Union, establish justice, insure domestic tranquillity, provide for the common defense, promote the general welfare and secure the blessings of liberty to ourselves and our posterity, do ordain and establish this constitution for the United States of America," etc.

Mark the words in the above clause—"establish justice," "promote the general welfare," "secure the blessings of liberty to ourselves and our posterity."

Is not this a sufficiently meritorious reason as provided in our Constitution to secure that which will prove to be a blessing to ourselves and posterity? And if so, are we not several years behind the times in the matter of this proposed department?

Is not the well known and oft-quoted maxim which I will paraphrase, "*Salus populi suprema est lex.*" a sufficient reason? Is it not sufficient to know that, for instance, where an epidemic of smallpox prevails, accurate information can not be obtained by neighboring States or municipal boards of health from the medical officer in charge, or commissioner of health regarding said epidemic by his refusal to promulgate information desired when requested to do so?

All the foregoing illustrations are facts and matters of history, and not hypothetical queries, specific instances of which can be furnished if needed. All of which prove that Congress is in duty bound to provide this additional department.

#### IT SHOULD BE AN IDEAL DEPARTMENT.

To have this proposed department an ideal and efficient one, it should be under the direct and personal supervision of the medical secretary, who should not only be a graduate of a medical school, and a man of letters, but a thorough sanitarian in all that this word implies, as well as possess an acquaintance with the requirements and needs of our own beloved country as well as those of foreign lands.

*Genuine civil service* reform should prevail in said department. The obliteration of the spoils system will mean a higher order of men. A spirit of *entente cordiale* will exist between all branches and schools of medicine and an *esprit du corps* will prevail also between the department, its secretary, and State and municipal boards of health everywhere.

This department should have control over the poor and unfortunate immigrants that land upon our shores. An instance which came under my observation recently may aptly serve as an illustration. During the first and second weeks in April about 17,000 Italian immigrants arrived in New York. On April 17 five of these unhappy and unfortunate people were arrested by the police of Chicago and placed in the police station, charged with vagrancy and begging on the streets. These poor unfortunate aliens had left their native country scarcely four weeks previously. This is but a single instance out of scores of analogous cases that came under my personal

observation during the past winter and spring months as an attaché of the Chicago Health Department. So that well may we ask what kind of citizens are we importing now? I am thoroughly convinced that a certain class of the illiterate and poorer classes of immigrants should be prohibited from landing on our shores—only to become a burden to us instead of a benefit to our nation.

NATIONAL VACCINE FARM, BACTERIOLOGIC  
LABORATORY, ETC.

Regarding this, and what might be regarded as kindred subdivisions of my topic, in the projection of sanitary improvements, etc., I will not attempt to discuss nor more than mention that they should be under the scientific observation of this department.

In concluding this imperfectly prepared paper, permit me to request of you to urge upon your representatives in Congress, your governors and others, in justice to the welfare of the people, in the name of science and humanity, the necessities and needs of our claim: That the medical profession and State medicine is broad and philanthropic and has made great strides and progress within recent years; that our medical representative or secretary will be a man of culture and intellect and *bon camaraderie*, thus assuring the profession and the world that our claim was not of the *ignis fatuus* kind; that at some future time the United States will have an ideal department of health with influence that shall be unsurpassed, will be our reward, for which posterity will bless us in my firm and sincere belief.

STATE MEDICINE IN PENNSYLVANIA AND  
HOW WE MAY INCREASE ITS  
EFFICIENCY.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association held at Atlanta, Ga., May 5-8, 1896.

BY EUGENE O. BARDWELL, A.M., M.D.

Health Officer of Emporium, Pa., County Medical Inspector to the State Board of Health of Pennsylvania, Fellow of the American Academy of Medicine, Vice-President of the West Branch Medical Association, etc.

EMPORIUM, PA.

The State Board of Health and Vital Statistics of Pennsylvania was organized in June, 1885, so that its existence covers a period of a little less than eleven years. The appropriation made for it on its natal day called for \$5,000 per year, and the appropriation made ten years later was for \$6,000 per year, so you may easily judge that there has been no great development of cerebral matter in the legislature of our good Keystone State during the past ten years. Out of this enormous sum \$2,000 is paid to the secretary and executive officer of the board. I understand that the clerk of the board receives \$1,500 per year, and this leaves the munificent sum of \$2,500, which according to the terms of the act is to be expended, or so much of it as may be necessary, for postage, telegrams, express charges, rent, incidental office expenses, traveling and other necessary expenses of the members and secretary of the board, and for sanitary inspections, analyses and protection of water supplies, and for scientific investigations. Think of it, \$2,500! Sanitary inspections, protection of water supplies, analyses, scientific investigations; and be sure to return an unexpended balance!

Pennsylvania in point of population is the second State in the Union. One of the oldest States. The

Keystone? Notwithstanding the parsimoniousness of our legislature in regard to appropriations for the protection of the public health, I am happy to be able to say that we have, as far as they go, as good legislative enactments for the control of contagious and infectious diseases and the regulation of health boards and all matters pertaining to the public health as could well be devised. In that respect nearly every session since 1885 has seen some improvement, chiefly through the efforts of one man, Benjamin Lee, M.D., to whose able and untiring work as secretary and executive officer of the State Board of Health, we primarily owe all our laws for the intelligent supervision and protection of the public health. To Dr. Benjamin Lee the State of Pennsylvania owes a debt she can never repay. But the people do not appear to appreciate the fact that to this one man all credit is due that the great State of Pennsylvania has, in sanitary matters, emerged from a condition akin to barbarism. Eternal vigilance, however, is necessary to prevent the repeal of our health laws. At every session of our legislature some learned member from Squeedunk, Daguscahonda or elsewhere will arise in his place with the air of a Solon, pull the fringe of whisker under his chin meditatively, and present a bill which, if passed, would destroy the result of the labor of years; labor, too, which has been done gratuitously without hope of reward, except such as comes through a man's inner consciousness of duty done. We have a large number of boards of health in small towns or boroughs, and the effectiveness of these boards is slowly increasing each year. The public is very slowly awakening to a knowledge of the utility of health boards and their work, but we are still woefully behind the times in many portions of the State. We have no boards of health in townships, although there is a total of 1,511 townships in the State. Now, such a state of affairs is a great drawback, and renders nugatory, to a certain extent, much of the effort put forth in towns and boroughs. In order to secure the best results every township should have its board of health and health officers; but our sapient legislature, having several times refused to legalize such boards, our State Board has, as a make-shift, appointed deputy inspectors who receive no pay, except when ordered by the State Board to investigate nuisances. One such inspector is appointed in each county, and when we consider the fact that many counties contain thirty, forty or more townships, it is easy to comprehend that such officer, serving without compensation, will not be able to exercise a very close or valuable supervision over sanitary affairs, the more so as the people are likely to look upon him as an outsider and give him no aid whatever. The cause of the apathy of the people in the matter is not general ignorance; it is ignorance on this one subject. The public control of matters pertaining to the health of communities is an idea comparatively new, and when it runs against that fetich of the American people, "personal liberty," it experiences a severe shock. Now how can we give an impetus to the dissemination of knowledge of this subject? To my mind the answer is easy and the result certain. Compel the State to pay for the service. It is entirely too much to ask men to serve on health boards for love of the people who abuse them. It has been my experience in the practice of medicine, that the people who pay promptly are my best friends in other ways. Nine times out of ten when a physician is stabbed in the

back it is done by some one to whom the physician has rendered services, either without fee or at a reduced rate.

Physicians who are supposed to act as health officers in most places, are surely the last people who should be expected to serve the State without fee. Physicians who give to individual members of the State from one-fourth to one-half of their total labor should not be expected to do more than that much for the public. In this State health officers receive all the way from nothing, in many cases, to \$100 per month, in very few instances, in towns of the same size; and where the salary is largest, there is the officer most appreciated and there is the intelligence of the people in sanitary matters the most marked. The increased knowledge of the people is partly the cause and partly the effect of the high salary of the health officer. Where a health officer receives no salary, the people very naturally think his services are worth just what he gets. Aside from the fact that the health officer gets no credit for philanthropy, which is a small thing, his work is thereby rendered of little value to the people and to the State, which is a very important thing. Even ministers of the gospel, followers of the meek and lowly Savior, do not labor for nothing, and I most earnestly protest against physicians serving the State free of charge. I have just noticed in a recent medical journal that a well-known surgeon of Philadelphia has declined to serve as consulting surgeon to a State hospital for the reason that he thinks physicians ought not to serve the State gratuitously. All honor to Dr. John B. Deavor, and may his example be widely followed. It is a small thing to ask doctors to make reports of contagious or infectious diseases for the benefit of a community, and very few physicians object to making such reports free of charge; at the same time it is rank imposition to frame laws making such services compulsory, and the supreme court of Illinois has recently decided that doctors can not be compelled to make such reports without compensation. In Pennsylvania the State prescribes the duties of health officers, and imposes the pains and penalties attaching to non-performance of those duties; such being the case, it is clearly the duty of the State to fix the salaries of these officers and see that they are paid; and this same plan should extend to townships. Every township in the State should have a board of health, or at least a health officer, and the State should fix the salary and in case of a board, of the secretary as well. The salaries should be small, but even in small townships, where a salary of not more than \$25 or \$50 a year would be paid, it would be easy to find good men willing to serve who would do their duty faithfully and well.

So long as the old plan is followed of no pay but curses, it will be found almost if not quite impossible to get men, especially in townships, to take any interest in public health problems, or to give such matters any efficient support. Large cities may be trusted to attend to the administration of health laws, but outside of cities the State should control and should fix the salary of every health officer and inspector and every secretary of a board of health, at a rate proportioned to the number of inhabitants in the territory covered by such official.

In the State of Pennsylvania a few years ago the State authorities printed, by order of the legislature, a bird book which was of no use to man, woman or

child, at an expense of about \$40,000. Every session the State votes hundreds of thousands of dollars to city hospitals, sufficient, one would think in some cases, to pay all legitimate expenses of the hospitals which pay, in most instances, nothing for medical services, yet a patient from outside the city can not be accommodated in any of them for a sum less than is amply sufficient to pay all expenses incident to the care of such patient while in the hospital. Why does money flow so easily for such purposes? The answer in each case is the same. The publisher or editor of the bird book and the managers of the hospitals each have a "pull."

Shall we not take a hint from this state of affairs? We have talked and reasoned with our legislators, we have explained the benefits to be derived by the people from a more liberal expenditure in the public health department, we have treated our lawmakers as gentlemen, and we get \$2,500 per year for expenses, scientific investigation, protection of water supplies, etc.

Now, in the writer's opinion, it is time to adopt a different plan. If we must adopt the methods of the politician in order to obtain anything from the State, then let us even do so and "fight the devil with fire." We all have friends who help make the laws; let us say nothing to them about benefits for the people, let us not appeal to reason or say anything concerning moral obligation. Let us say: "I am a friend of yours; I have voted the straight party ticket, lo, these many years; I supported you for school director and also for the Assembly. I carried a torch in the illustrated parade; I howled and hooted and yelled when the news came that you were elected, but now times have changed; I intend to fight your nomination in the caucus, or, if you should be nominated, to work against you at the polls, and get all the friends I can influence to do the same thing, unless you will promise to favor honestly and heartily an appropriation large enough to pay all health officers, inspectors and secretaries of health boards in the State, and also to pay for physicians' reports and to carry on scientific investigations as may be thought necessary or desirable by the State Board of Health, unless you show something like the liberality in providing means for preventing disease that you show in supporting hospitals and publishing bird books. If you promise to do this I will work for you in season and out of season; but it will not be enough for you to introduce a bill of this nature, or get some one else to introduce it, and then lay it under the table; you must work for the bill and work hard." Such a course is not a pleasant one to follow, but I confess I can see no other way that offers any reasonable hope of success. I am positive that we can never hope to have health boards in every township until we pay for the service rendered, and I am equally positive that were it possible to have a health officer in every township serving gratuitously, the benefits derived from such service would be infinitesimal as compared with that which would be received in case each health officer received a salary. Salaries should be made small enough to keep the office out of politics where it is possible to do so, but even a nominal salary tends to preserve the officer's self-respect and enhance his importance in the eyes of the public. That physicians will labor solely for love of humanity, work against their own interests to prevent sickness and do it without remuneration, the public will not believe, and such services are, in the end, of questionable utility.

It is the duty of every good citizen to preserve order and to suppress rioting or any public violation of the laws of the commonwealth, but such action is invariably left to the executive officers of the municipality or government, who are paid for performing those functions. I have looked the matter over carefully and I fail to find the slightest justification, the faintest shadow of a reason why the physician should serve the State gratuitously in any capacity. There is no class of men who give so much to the worthy poor ungrudgingly, there is no class who are so imposed upon and defrauded of their just dues as physicians, and it is time we refused to allow the State to add anything whatever to the sum total of the impositions we already suffer from individuals. In the way of public sanitation the Legislature of Pennsylvania has next to nothing to be proud of; but in coming generations, when our bones are dust, when the people understand fully the value, the immense benefits accruing to the State from public sanitary control and all that pertains to the functions of a State Board of Health; when our Christian civilization, so-called, shall present fewer elements of barbarism, when the true spirit of Christ is abroad in the land, and men who save lives are considered the heroes, then will the name of one physician stand high on the roll of honor as a public benefactor, as the founder and father of the State Board of Health of Pennsylvania, and the letters of that name, when written in order, will spell BENJAMIN LEE.

In preparing a paper on this subject to be read before this body, I have not thought it desirable to take up your time with an exposition of the reasons for advocating the establishment of health boards in townships, reasons which are patent to you all.

We ought to be and we are heartily ashamed of the position our State occupies on this question. Still, it is sometimes a good plan to air one's dirty linen in public, to the end that when the housewife learns that such a condition has become a matter of public notoriety, she may perchance reform.

### SHOULD THE STATE PROVIDE HOSPITALS FOR THE TUBERCULOUS POOR?

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY J. F. JENKINS, M.D.

TECUMSEH, MICH.

Tuberculosis prevails in almost every region of the habitable globe. It is the most destructive of all the contagious diseases, requiring no new proofs at the present to establish the fact of its contagious character. To control the spread of tuberculosis, which stealthily enters into so many households in every community, is a problem which our profession is called upon for solution.

Pulmonary tuberculosis is so insidious in its nature, so slow in its evolution, so chronic in its course, frequently requiring months for its development, while its duration may extend over many years. From its incipency to its termination the tuberculous patient is a menace to society, and although the subject of the disease neither excites public attention nor alarm, still he is more dangerous to the community than the leper, whom society abhors, or Asiatic cholera, which is feared by mankind everywhere.

We are well aware of the fact that many wealthy patients, or those of moderate means, may prolong

life and a certain percentage regain their former health by a residence in a suitable climate, or they may undergo treatment at their homes without endangering the public health; but there is a large class in every community without means, and with bad hygienic surroundings; this dependent class should be provided by the State with proper treatment, and the public protected by having the tuberculous poor conveyed to a hospital for consumptives, because it is this class of patients that spread the disease in all directions.

In the rural sections of the country these dependents frequently occupy hovels, while in cities they are the denizens of tenement houses, cellars and garrets, which are usually almost destitute of light and air, deluged in filth, and surrounded by abject poverty. In this position tuberculous patients are the disseminators of the bacilli, sowing the seed in the well prepared soil which has been so richly fertilized by their insanitary surroundings. In the condition above described it is impossible for them to secure the treatment that humanity dictates, for temporary aid is almost valueless, principally from the fact that the disease is essentially chronic. The alternating hopes and fears of a dependent family constantly come under our observation; frequently a father with a half dozen children depending upon him, a mother or son, the only support of a family, is stricken down with this inveterate disease, which is so graphically described in the following lines by the pen of Dickens in the death of Smike:

"There is a dread disease which so prepares its victims, as it were, for death; which so refines it of its grosser aspect, and throws around familiar looks unearthly indications of the coming change—a dread disease, in which the struggle between soul and body is so gradual, quiet and solemn, and the result so sure, that day by day and grain by grain the mortal part wastes and withers away so that the spirit grows light and sanguine with its lightling load, and feeling immortality at hand, deems it but a new term of mortal life; a disease in which death and life are so strangely blended that death takes the glow of life and life the gaunt and grizzly form of death."

From the shores of the Great Lakes to the Gulf of Mexico, and from the Atlantic to the Pacific Ocean, wherever towns and cities are built, there will be found special or general hospitals, and even the few lepers within this wide domain are either segregated, or are carefully provided with lazarettos, but for the "great white plague," consumption, which carries off one-seventh of the human race, scarcely a beginning has been made in the way of building and maintaining hospitals for their accommodation.

Our country is far behind England and Germany in providing hospitals for the treatment of consumptives, and it will be well for us to look over the field, in order to ascertain what has been done abroad and what may be done at home to stamp out a disease which is more destructive to the youth of our land than war itself; and when we place a commercial value on human life the aggregate annual loss would amount to many millions of dollars.

Over a century ago England began building hospitals for consumptives, and at present there are eighteen hospitals containing over seven thousand free beds for tuberculous patients, the result of which has been to materially lessen the death rate from pulmonary tuberculosis in that country.

The *Progrès Médical* in a recent issue makes a statement relative to tuberculosis in France and England which clearly demonstrates the results accomplished by special hospitals for consumptives. That journal states: "That there are three times as many deaths in Paris as in Great Britain, and that in 1870 the mortality in England and Wales was 2,410 for each 1,000,000 inhabitants, but since consumptives have been treated in special hospitals this number has fallen to 1,468, in 1893. In Paris there were 4,158 deaths from tuberculosis during 1894, or almost three times as many as across the Channel." If the foregoing statement is correct, England saves the lives of 20,000 of her inhabitants yearly by wise sanitary measures in maintaining special hospitals for her dependent class of consumptives; on the other hand, Paris loses several thousand of her citizens yearly from defective sanitary laws and deficient hospital accommodations for her indigent class of tuberculous patients. The city of Paris has recently built a hospital at Agincourt, some fifty miles from the city, with a capacity of one hundred beds, for her dependent class of tuberculous patients, and there are some half dozen more located in different parts of France. Many of the larger cities of Germany have recently built special hospitals for consumptives, as Berlin, Cologne, Hanover, Breslau, Dresden, Frankfort-on-Main, Worms, Würzburg and Bremen, besides there are two institutions located in the Hartz Mountains, and one in the Black Forest. German statistics have shown a marked decrease in the death rate from tuberculosis within the past few years. They are building an institution near Vienna for the tuberculous indigent, and even the "unspeakable Turk" has built a consumptive hospital for children on the banks of the Bosphorus.

The success attending the treatment of tuberculous patients in private hospitals is certainly an encouragement for States and municipalities to build and support hospitals for the dependent class. At Gorborsdorf in Silesia a private sanitarium was built in 1854 which in the course of eighteen years has had under treatment about 958 consumptive patients, of which 20 per cent were permanently cured; and in the private institutions located in the Alpine regions there have been reported cures in 40 per cent. of tuberculous cases. The city of Bale, Switzerland, has lately pledged herself to build and maintain a sanitarium for her tuberculous poor.

In our own country a number of private hospitals have been built by philanthropic persons and societies, and it becomes necessary to mention them, and the success attending them, in order to ascertain in a measure what may be accomplished by public institutions built for the treatment of the tuberculous poor. One of the most widely known is the Cottage Hospital, situated in the Adirondacks, which will accommodate eighty-four patients. This hospital during the past ten years of its existence reports a cure in from 20 to 25 per cent. of their cases. In the Adirondack Mountains, about 1800 feet above the sea, a hospital for consumptives is being built named the Sanitarium Gabriels.

The Sanitarium at Ashville, N. C., has an accommodation for 100 patients, and reports that of 600 patients treated in that institution 45 per cent. have recovered. The Home for Consumptives located near Philadelphia, it is stated, discharge each year about 30 per cent of their patients cured, and in that

city is the Rush hospital for consumptives; both of these are institutions of small capacity. In the vicinity of Boston is a small institution called the Sharan Sanitarium, and in Colorado there are three private sanitariums for tuberculous patients.

In all these institutions above named there are only about two hundred free beds, while England has over seven thousand free beds for her tuberculous poor.

Massachusetts probably has the largest death rate from tuberculosis of any State in the Union, but she has recently adopted measures which will doubtless lessen the death rate from this disease, her legislature having appropriated \$150,000 for building a hospital for her tuberculous poor. Dr. F. I. Knight, who was before the Finance Committee of the Massachusetts Legislature, states that the question was asked him: "Have the medical societies of the country made any formal declaration which has been put on record, in regard to the establishment of such hospitals?" Fortunately he could reply that "Some societies had made such a record." "I was astonished to see how readily these men—most of them politicians—favored the hospital idea, not only showing sympathy with the homeless patients, but with the idea of preventing the spread of a disease which is communicable. To our surprise on our first effort, both houses passed an appropriation of \$150,000, which was signed by the Governor, for the establishment of a hospital for the consumptive poor."

The above is a brief sketch of the first successful effort to build a State hospital for this purpose. A question was asked by the Massachusetts Legislature which would undoubtedly be the question propounded by State legislatures everywhere when requested to build hospitals for the consumptive: Have the medical societies of the country placed themselves on record relative to building these hospitals? Finally, has the AMERICAN MEDICAL ASSOCIATION made a formal declaration relative to States and municipalities building and maintaining hospitals for the consumptive poor?

#### REMARKS RELATIVE TO THE UNITED STATES MARINE-HOSPITAL SERVICE.

Delivered in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY WALTER WYMAN, M.D.

SUPERVISING SURGEON-GENERAL U. S. MARINE-HOSPITAL SERVICE.  
WASHINGTON, D. C.

I had hoped that I could prepare a paper in response to the invitation of the Chairman, but was uncertain whether I could attend this meeting, and was too hurried to prepare a formal essay. However, the day before I left Washington I received from the Public Printer the Annual Report of the Marine-Hospital Service, 1895, which had been in his hands four or five months, and as the material therein is new, I thought it might be of interest to bring it with me, and explain to this Section that portion of the report which relates to the public health service.

If you will turn to page 249 you will see a résumé of the operations of the service in the interest of public health during the last year. Referring to the preceding portion of the report I may say it deals directly with the operations of the Marine-Hospital Service in its care of the sick and disabled seamen of the merchant marine, about 53,000 being treated annually. It seems to me that any service in behalf

of the seamen of the merchant marine, is public health service in the broader sense. But returning to this section, you will find in this résumé an account of the danger of the introduction of yellow fever from Cuba, and operations to prevent the same.

You will find also an account of the threatened introduction of smallpox by the return to the United States of some four hundred negro colonists who had been to Mexico, where a colony had been attempted and failed, there being 178 cases of smallpox among them. The bureau took charge of these colonists, established a camp, fed and held them under observation until the last case disappeared, when their clothing was either disinfected or burned and replaced with fresh clothing and they were allowed to go on their way.

While these operations were in progress reports came from Japan, China and the Sandwich Islands with regard to cholera that created considerable alarm. The special measures adopted to meet the unusual danger are detailed in the following pages.

The national quarantine stations are described on pages 252-304 inclusive. I will not go into details as they are fully set forth in the reports of the medical officers.

An account of the division of sanitary reports and statistics is given on pages 305-310 inclusive. I will call your attention to a table prepared in this division, showing the yearly mortality of 199 cities in the United States.

The operations of the hygienic laboratory are found on pages 311-343 inclusive. In this report of the medical officer in charge of the laboratory will be found a complete discussion of the serum therapy of diphtheria. There will be found also an interesting account of some experiments which have been made in the serum therapy of variola. Also, an account of the examination of drinking water in the District of Columbia, and reference to experiments made with a view to practical disinfection of mails and school and library books.

The sanitary inspection service you will find described on page 344, showing results and giving a description of the inspections which were instituted by the bureau for the purpose of keeping out epidemic diseases.

I will not take your time by attempting to summarize the pages on cholera, smallpox and yellow fever, but I believe you will find them very interesting.

Since the date of this report I have prepared a circular letter addressed to the mayors of the cities and towns of the United States making inquiries relative to the water supply of the several cities, and the disposition also of the sewage. We have sent out these circulars to a few cities at first, but we propose to send them to all the cities in the United States, collect the information and publish it in a condensed form. The blank form which I have here has place for answers to the several questions relating to the source of water, its storage, purification, distribution, control and its disposition. The blank also relates to sewage and garbage disposition. In addition to the above the bureau has recently enlarged the scope of the health reports and improved the records pertaining to diseases of all classes throughout the United States.

#### DISCUSSION.

DR. VALENTINE—It seems to me one matter has been entirely overlooked. I refer to the disease which kills 80 per cent. of

the women, which destroys the health of 80 per cent. of the children who are born healthy. I will not speak of the particular cases directly due to gonorrhoea. I am not speaking of it as a disease, but as a sequel; but I desire to ask whether the disease is not one of importance, and whether it does not merit closer consideration and some active measures for the prevention of its spread. In many cities an effort is made requiring the prostitutes to be registered. In the city of Berlin there are more than twenty thousand registered. Without adequate methods of inspection the efforts are almost unavailing, and the disease is being propagated at from six cents up. This matter naturally belongs in this Section, but I think the Department which has rendered such signal service in the matter of public health should take it up also. It is my hope to show on Friday the manner in which 60 per cent. of the cases of gonorrhoea are curable in ten days, 30 per cent. within one or two weeks at the utmost, and 5 per cent. within two weeks, leaving 5 per cent. as yet without the reach of the new method. Why should not the Marine-Hospital Service adopt the method which requires no expense, obviates all danger of contagion and numerous other things which could be prevented.

DR. KELLOGG—I just want to enter a protest against this country adopting any such method for the supposed prevention of the disease named as that described in Europe. A recent investigation made in Berlin, even, shows that not one in ten of these diseases are discovered; and this method, while it gives a sense of security to every cautious man, at the same time really promotes the disease which it intends to prevent.

#### SERUM THERAPY IN DISEASE.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY GEORGE TULLY VAUGHAN, M.D.

PASSED ASSISTANT SURGEON IN COMMAND U. S. MARINE-HOSPITAL SERVICE. PHILADELPHIA, PA.

From the time of Jenner's discovery that the dried serum of cowpox prevented or modified smallpox when introduced into the human system, has existed the hope that remedies would be discovered somewhat of the same character which would cure or prevent all diseases.

But this bud of promise was slow in developing, and the bright expectations thus aroused were doomed to wait a century before they were even partially realized. As the ovum of the cicada septemdecem requires seventeen years to bring forth the mature insect, so the germ of Jenner's discovery after an incubation of one hundred years has blossomed into the science of bacteriology, which, through the labors of Pasteur, Koch, Behring and others, has already brought forth a wonderful harvest of relief from suffering and disease, and the day seems now at hand when, with a cure or preventive for every disease, cholera, yellow fever, diphtheria, leprosy, syphilis, and tuberculosis will be as rare as smallpox now is among those who are properly vaccinated. The ideal treatment of disease is to prevent it.

The fact that certain animals are immune from certain diseases, *e.g.*, that the lower animals do not have syphilis, has long since excited curiosity as to the reason, but nothing satisfactory was offered until the bacteriologists had established the existence of toxins and antitoxins, and that immunity can be induced or acquired by the proper use of the specific entity, its products, or effects, which causes the disease.

The theory of natural immunity now most in favor is that the blood serum contains in solution a germicidal proteid, alexin or nuclein, whose source is the

leucocytes, soluble only in an alkaline fluid, and that phagocytosis (the phenomenon discovered by Sternberg and developed by Metschnikoff) plays a subsidiary part. Nucleins are thus defined by Victor C. Vaughan: "Physiologically, nucleins may be said to form the chief chemie constituent of the living part of cells. Speaking broadly, we may say that nuclein is that constituent of the cell by virtue of which this histologic unit grows, develops and reproduces itself. It is the function of the nuclein of the cell to utilize the pabulum within its reach. It must be evident that those tissues most abounding in cellular elements contain relatively the largest amount of nuclein. It must also be seen that it is by virtue of their nuclein that the cells of various organs and organisms possess and manifest their individual peculiarities.

"We should therefore expect to find that the nuclein of the yeast cell is not identical with that of the bacillus tuberculosis, and that the nuclein of the spleen differs from that of the thyroid gland. The number of kinds of nuclein is limited only by the variety of cells. Nuclein is the chemie basis of that part of the cell designated by the histologist as the nucleus, sometimes called chromatin on account of the readiness with which it absorbs and holds coloring agents. It is the nuclein of the bacterium which takes up and retains the stains, and it is on account of the fact that the nuclein of the bacillus tuberculosis differs from that of other bacilli that we are able to distinguish the former from the latter by its tinctorial properties. Differences in reaction with staining reagents, so plainly seen under the microscope, are only outward manifestations of less apparent and more important differences in chemie composition. Chemically the nucleins are complex proteid bodies, characterized especially by the large amount of phosphorus which they contain. The phosphorus exists in the form of nucleinic acid, which is combined with a highly complex basic substance. So far as we know at present, the nucleinic acid of all nucleins is the same, yet the basic part differs in the various nucleins. This basic substance yields, as decomposition products, one or more of the so-called xanthin bodies, adenin, guanin, sarkin and xanthin. Some nucleins yield only adenin and these may be designated as adenyl nucleinic acids. Those which furnish xanthin most abundantly may be called xanthyl nucleinic acids. Generally speaking, the nucleins are insoluble in dilute acids and soluble in dilute alkalis. They resist peptic digestion and in this way may be separated from most other proteid bodies."

According to Buchner natural immunity can not, as a rule, be transmitted to the body of another animal by means of the blood.

Acquired or artificial immunity is of the greatest importance as it affords the physician the means of preventing disease. To Pasteur belongs the credit of having taken up the thread where Jenner left off and he was the second to show, by his experiments on chicken cholera in 1888, that infectious diseases may be prevented by inoculation with "attenuated virus." Immunity may be acquired: 1. By having the disease. One attack of certain diseases as yellow fever, smallpox, measles, scarlet fever, etc., usually assuring future immunity. Of course this may be induced by inoculation with the microorganism of any particular disease. 2. By inoculation with attenuated cultures. 3. By inoculation with filtered cultures which are free from bacteria, or with sterile cultures which contain dead bacilli.

Filtered cultures contain the toxins, while sterile cultures contain in addition some special property in the dead bacteria. The latter were used by Löffler and Abel in their experiments for immunizing against typhoid fever with the best results. This protective power afforded by one attack of a disease against other attacks of the same disease or by inoculation with bacterial cultures, is generally supposed to be due to the existence of antitoxins and something else (enzymes) in the blood serum. The antitoxins were discovered in 1890 by Ogata and Jasuhara of Tokio, when they found that the blood of an animal immune against anthrax contained something which neutralized the toxic products of the anthrax bacillus.

Experiments have shown that in some cases the blood serum of immune animals has no antitoxic power but acts as a germicide, and as a rule antitoxins have no such power. In such cases the immune animal may still be susceptible to the action of the toxins though unaffected by the bacillus. Brieger and Ehrlich had proved that antitoxin is contained in the milk of a goat which had been immunized against tetanus, by conferring immunity to the same disease on a mouse by injections of the milk. The *modus operandi* of the antitoxins is involved in considerable doubt.

According to Buchner, the action of the antitoxins does not depend on destruction of the bacterial poisons by contact with them but upon their action through the medium of the tissues of the body. The presence of the antitoxins produces a lower degree of susceptibility to the toxins of the bacteria, in the living cells of the body, thereby rendering it more resistant to the action of the specific toxin.

Sternberg says: "We must admit that the exact source and method of production of the antitoxins in the animal body, and their mode of action, are still undetermined; and for the present, we must be satisfied with the knowledge that, in some way, these so-called antitoxins, which have been proved to be present in the blood serum of immune animals, protect them from infection by pathogenic bacteria. And that when transferred to susceptible animals they confer upon them a temporary immunity; or if introduced after infection, may neutralize the pathogenic action of the toxins produced by specific disease germs." The following are the known differences between alexins and antitoxins. Alexins are germicidal and globulicidal, destroying both red and white corpuscles of animals belonging to different species from that whence they were obtained; they are coagulable and unstable, destroyed by sunlight and by a temperature of 50 to 55 degrees C. Antitoxins are not germicidal or globulicidal; they resist the action of sunlight and require a temperature of 70 or 80 degrees C. for destruction.

Failing to prevent disease the next best thing is to cure it, and the successful use of blood serum in accomplishing this result first seems to have first been made by the Japanese bacteriologists already mentioned, Ogata and Jasuhara, although their experiments failed of confirmation by others, when, in 1890, they announced that mice which had received a small amount of dog's, rat's or frog's blood (animals immune to anthrax) two or three days before, or a few hours (5) after, the injection of anthrax bacilli, all recovered from otherwise fatal doses of anthrax bacilli and proved afterward to be immune. No doubt the first step in this direction was made when in 1888, Nuttall demonstrated the power possessed by blood serum of

antagonizing the products of bacterial growth, while to Behring and Kitasato belong the credit of having, in 1891, established its use as a practical measure in the treatment of disease.

Blood serum has been used in the treatment of the following diseases with more or less success: Diphtheria, cholera, tuberculosis, leprosy, syphilis, tetanus, typhoid fever, pneumonia and others. Beyond question its greatest triumph and most convincing effect for good has been obtained in the treatment of diphtheria. I had the pleasure of seeing many cases treated by Dr. Kossel in Koch's Institute for Infectious Diseases in the winter of 1894-95. It is as unreasonable to doubt the efficacy of antitoxin in diphtheria as it is to doubt the power of vaccination to prevent smallpox or to modify its virulence.

Syphilis has been treated with the blood serum of one who has just passed through an attack of the disease by Dr. Edward Cotterell of England, in eighteen cases extending over a period of six months with the following results: 1. In the early stages with only a sore and glandular enlargement, injections of this serum caused the sore to heal rapidly. The adenitis in the groin became intensely marked, while the skin and throat symptoms were absent or slightly marked. 2. When the treatment was not begun before the rash and throat symptoms had developed, the skin eruption faded more rapidly than under mercurial treatment, but the throat symptoms disappeared rather slowly. 3. The general health improved. 4. Serum from a person with secondary symptoms appeared to be more active than that obtained from one with tertiary symptoms. 5. Dose of the serum from one-half to five cubic centimeters.

The importance of finding a remedy for the treatment of leprosy is evident when the rapid increase in the number of sufferers from this disease in certain countries is considered. The United States Minister to the United States of Colombia reports the number of lepers in that country to have increased in forty years from four hundred to twenty-seven thousand. Dr. Carrasquilla of Bogota reports fifteen cases of tuberculous leprosy treated with blood serum and four cured in less than a month, except for the scars caused by the ulceration. Dr. Putnam of the same place reports a case treated with serum with great improvement which promised ultimate recovery.

He prepares the serum by making a culture of the bacillus lepræ in the blood in the vessels of a living animal instead of in an artificial apparatus, thus: He takes blood from the leprosy patient, allows it to stand four hours in order to separate the serum which is then injected into asses or goats.

After the proper time the serum of the asses' or goats' blood is used as a remedy on the patient from whom the serum was originally obtained or on any case of leprosy. Dr. Putnam admits that he obtained ideas as to the treatment of leprosy from Dr. Carrasquilla. Dr. W. Impey, Medical Superintendent of the Leper Settlement at Robbens' Island, Table Bay, where 600 lepers live, says he has noticed that whenever a leprosy patient is attacked by any inflammatory skin disease as measles, smallpox, or erysipelas, the part affected is invariably cured of leprosy, and the patient either entirely recovers from leprosy or his life is prolonged beyond the normal period of eight years. Dr. Impey advocates the induction of erysipelas within three or four years after the disease begins and believes that by this means leprosy may be eventually stamped out.

Kinyoun (1895) reports two cases of smallpox treated by injection of serum from a vaccinated or immunized heifer, beginning with 15 c.c. with encouraging results. The treatment was commenced during the pustular stage.

More recently Beclere reports a case of smallpox treated by the injection, in the course of one hour, of 1500 c.c. of the same kind of serum on the third day of the disease, with rapid recovery.

Before ending this paper I will refer briefly to the use of serum in tuberculosis as recommended and practiced by Dr. Paul Paquin of St. Louis. He uses serum from the horse which has been rendered strongly antagonistic or antitoxic by the use of gradually increasing doses of tubercle bacilli toxins. It takes three months to prepare a horse and the method is similar to that used to prepare him for producing the antitoxin of diphtheria. Dr. Paquin reports the results of one hundred cases of pulmonary tuberculosis treated from three to eight months as follows:

In the first stage, recovered 14; in the second stage, improved, 26; disappeared from observation in all stages 35; died, treatment begun in second stage, 5; died, treatment begun in third and fourth stages, 20.

## THE ABUSE OF ALCOHOLIC DRINKS, ITS RELATION TO PUBLIC HEALTH AND ITS PREVENTION.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8.

BY W. BAYARD, M.D., EDIN.  
ST. JOHNS, NEW BRUNSWICK.

I have selected for discussion the abuse of alcoholic drinks, its relation to public health and its prevention. I emphasize the *abuse* as I am unwilling to believe that the moderate and proper use of them has relation to public health.

It will not be disputed that the abuse of them, with its attendant consequences, disease, insanity, crime, poverty and premature death, is the greatest evil of the age, and that it calls loudly for remedial measures. What those measures shall be has exercised the minds of many.

The subject has been discussed in the pulpit and on the platform, some claiming that nothing but coercive and restrictive measures will remedy the evil, while others declare that such measures will aggravate it, both wishing to arrive at the same goal, but differing as to the road; in their enthusiasm, too often ignoring all rights, appealing to passions and prejudices, claiming more than can be accomplished, and deliriously denouncing those who differ from them, thereby injuring a good cause. The subject is of such vast importance that it should be approached calmly and reasonably, appealing to the mind from a moral and sanitary standpoint.

Our professional education teaches us the physiologic action of alcohol, the base of all intoxicating drinks, upon the human system; when it shall be abstained from and when it can be taken with advantage. It teaches us that when taken into the stomach in a concentrated form a chemico action takes place in consequence of the strong affinity it possesses for

water, seizing that fluid contained in the tissue, producing a coagulation, rendering it hard and dense and destroying for a time the absorbing power of that organ, which will only be renewed when the alcohol becomes sufficiently diluted with the water in the tissue. It may be observed that pure brandy, which usually contains equal parts of alcohol and water, is sufficiently strong to produce this coagulation, and when diluted is absorbed into the circulation with marvelous rapidity, as proved by the experiments of Dr. Percy, who found that when death took place in two minutes after it was injected into the stomach of the animal, that organ was found almost void of it, while it was found in the blood and in considerable quantity in the substance of the brain. It appears to seek out and fasten itself upon the nervous matter, affecting in the first stage of intoxication the intellectual faculties through the cerebrum. In the second stage, a disturbed function of the sensory ganglia, as indicated by want of control over the muscular movements which are guided by sensation. And in the third stage, when the functions of the cerebrum and sensory ganglia are suspended and those of the medulla oblongata and spinal cord now begin to be affected, as shown by the difficulty of respiration, strabismus, dilated pupils and tetanic spasms.

According to Richardson the man who swallows eight ounces of alcohol in twenty-four hours increases the number of the beats of his heart from 100,000 to 124,046 during that period, at the same time altering the shape and quality of the red globules of the blood.

Observation teaches us that alcohol is partly eliminated from the system by the lungs, bowels, kidneys and skin. But the amount thus eliminated is so small that it does not account for all that disappears. Carpenter thinks that a combustive process takes place in the blood, at the expense of the oxygen it contains; while the experiments of E. Smith and others go to show there is no increase of carbonic acid produced. Anstie and Thudicum contend that it is consumed in some way in the economy, though how they do not say. It is urged by Beale and Bing that alcohol possesses the property of restraining the rapid growth of young cells and, like quinin, of checking the increase of the white corpuscles of the blood.

While alcohol is one of the means of keeping up animal heat through the increased action of the heart, it can not be classed as fuel-food. Animal heat is maintained by the combination of the carbon and hydrogen contained in the blood, with the oxygen taken in by the lungs. Fats and sugars in the blood yield the carbon and hydrogen, and while alcohol furnishes the same elements of combustion, it is not certain that it plays the same part in the body. Alcohol does not contain any of the constituents necessary for the growth and regeneration of the muscular system.

Our professional experience, too often, teaches us the baneful effects, morally and physically, upon the individual who indulges in the use of alcoholic drinks to excess. While the justice is daily and hourly brought face to face with the "moral evil," the physician is as often called upon to combat the inroads upon the constitution produced by the abuse of them.

Laudable efforts have been made to stay the progress of intemperance. Societies have been formed,

laws enacted and persuasive and coercive measures adopted. Yet according to investigations of the Harveian Society, it appears that in London one-seventh of all adult deaths (male and female) is directly or indirectly due to the consequences of alcoholic excess.

The statesman requires the aid of all enlightened minds to assist him in framing such laws as will meet the difficulty. And the people at large require to be taught that the abuse and oftentimes the continued use of alcoholic drinks leads to results dreadful to contemplate. They must be made to believe that they are swallowing a poison, which, if taken at improper times, in improper quantities, will sooner or later, inevitably create disease of the body and mind. Who can educate them so well on these points as the physician? It is our duty as custodians of the public health and as well-wishers of our race, by precept and by example, to exercise that influence which each and every one of us can command toward this end.

A certain amount of self-control is implanted in the mind of every individual; he knows that danger attends many of his acts; he commits the act and avoids the danger. So with the alcoholic drinks, the danger lies not in the use of them but in the improper use of them. His daily experience teaches that many, very many, become victims to the abuse. He thinks he possesses sufficient self-control to avoid the danger, and so he does, up to a certain period; but let him continue to indulge at improper times and in improper quantities, that self-control is lost and can only be regained by continued total abstinence; one glass will rekindle the appetite, when the fire will continue to burn until disease and death follow.

If an individual is so weak minded and so much the creature of impulse and selfish desire that having experienced the pleasurable effects of intoxicating drinks he will voluntarily surrender that power given him by Providence for his safety and throw aside the reins of self-government, he is to be pitied; can claim no respect and is a fit subject for restrictive laws and punishment. He should know that the highest attribute of a well-regulated mind is the power of self-control, that the act of self-government is noble, when exercised in the face of temptation, and nothing without it. He who will not restrain an injurious appetite degrades himself to the level of the brute creation.

The individual under the influence of alcoholic liquors feels an exhilaration of spirits, a sensation of gaiety, is pleased with himself and others, his ideas flow rapidly and he pours forth his thoughts with force of expression and richness of conception. But as the candle burning brilliantly in an atmosphere of oxygen soon burns itself out, so the over-stimulated brain becomes exhausted and demands rest, upon the well-known principle that undue mental excitement, from any cause, is invariably followed by depression and languor.

The fact that alcohol when taken into the circulation augments the force and rapidity of the heart's action, increases the excitability of the nervous system and supplies one of the means of keeping up animal heat commends it to the physician when other means of obtaining these effects are defective. Our practical experience teaches us that when administered with caution and discrimination it is a valuable remedy in various forms of disease and one for which no proper substitute has yet been found. As to its mode

of action in the cure of disease we can not speak with certainty. Dr. Berdon Sanderson's theory seems to be accepted, that in certain diseases the tissues waste, first the fat, then the muscles, and that the alcohol prevents their waste at a time when the patient's stomach is too weak to receive nutritious food. He says the cause of the waste of tissues is that they are used or burned in the process of respiration, alcohol takes their place and supports respiration when the stomach is too weak to prepare and assimilate any other food for the purpose. The practical application of them must be left to the judgment of the physician, no two cases being exactly alike, each differing in constitution, intensity and temperament. But he should be careful to avoid bringing the system into a habit of dependence upon the stimulus, for it can not be doubted that over-indulgence has commenced with the therapeutic use of it. Hence he should be ever on his guard.

Those who value good health and wish to enjoy the effects of alcoholic drinks socially will naturally ask at what time and in what quantity can they be used with impunity? We may answer that except in sickness alcohol in any of its forms should never be taken without food, and preferably at dinner. I wish to impress this precept as strongly as words can express it upon the minds of all who hear me, believing as I do, that food is the great antidote to its injurious effects, and that if this rule were adopted we should not see one inebriate for every hundred we see under the present pernicious custom of drinking at all hours of the day and upon an empty stomach.

A man meets a friend to whom he wishes to be "civil;" he asks him to have a drink; the friend is not thirsty, but he does not wish to be "uncivil," and they have their glass. They meet other friends in the shop, who also want to be "civil." The result is that many glasses are taken upon an empty stomach which can not at the time bear with impunity one glass. This is not the use; it is the abuse, and he who so indulges will sooner or later pay the penalty. Happily this "treating habit" is decreasing.

As to the quantity, it is difficult to lay down any rule; what would be enough for one would be too much for another. The quantity usually taken at a dinner party, if habitually taken, would prove injurious. From one to three glasses of port, sherry or claret should be the limit. Light wines are preferable, the stronger liquors should never be taken in larger quantities than from one to two ounces, and then largely diluted.

Before a remedy is applied to an evil its cause should be studied. The fondness for stimulants of some kind is almost universal, every nation exhibiting more or less of it since the time of Noah, who "drank wine and was drunken." And I may add that the most civilized, the most powerful nations are the most drunken. Does not this fondness for alcoholics originate in the "beneficent instinct" implanted in man, which prompts him to seek pleasure and avoid pain, bodily or mental? I think it does.

While the history of intemperance teaches us the evil is less than it has been at any time since the first century, still the existing evil is of such magnitude that it urgently demands remedial measures.

There are four that present themselves to a reflective mind, namely, sanitation, education, legislative regulation and prohibition.

Sanitation. There is abundant evidence to prove

that insanitary surroundings are the cause of more or less bodily and mental languor, often accompanied by lowness of spirits. The man returns from his daily work to a cheerless home, with few comforts, fatigued in body and worried in mind; he takes a glass; his cares assume a pleasanter aspect and, according to Solomon, "his heart grows lighter." Here lies the danger; continue the habit and this use is soon followed by the abuse. Give him a bright, cheerful, healthy and happy home and you remove a large cause of intemperance.

Education, I contend, is the most potent combatant against inebriety. Appeal to the man's fears and to his understanding. Teach him that alcoholic drinks do not assist his muscular power, that they do not enable him to withstand the effects of heat or cold, that they do not contain the necessary ingredients for his well being and that he is much better without them. Teach him that if he will take them, from one to two ounces of brandy or whisky should be the limit. Teach him that under no circumstances—in health—should they be taken on an empty stomach or without food. Forbid the use of any form except as medicine to the young. Teach him that the exhilarating effects of alcoholic drink is evanescent and that the effect is bound to be followed by a corresponding depression; that if he continues to take them in quantity or at improper times a dangerous craving and dependence upon them is produced which sooner or later will obtain control of him. No man intends or expects to arrive at this stage. He will say to you that this one or that one has taken them as he does, with impunity. True, but this is the exception to the rule and many are ruined by such exceptions. Teach him that they act injuriously upon every organ of the body and that the injury is not confined to himself, but extends to his offspring, entailing upon them insanity, idiocy and inebriety, a catalogue that should alarm any sane mind. Plutarch says that one "drunkard begets another," and Aristotle that "drunken women bring forth children like unto themselves." He may tell you that he will reduce his allowance. Impress upon him that he can not do this with safety; one glass will surely kindle the appetite. Total abstinence will alone protect him.

Temperance and total abstinence societies have done and are doing much good. While I do not altogether agree with their mode of education, inasmuch as they ignore the power of self-control in man and say to him: We will not trust you, we must have a pledge. Still, acknowledging the good they have done, I strongly advise all those who fear to trust themselves to take the pledge, but as men are more easily led than driven, I feel that temperance enthusiasts will accomplish more for their cause by claiming less and refraining from denouncing those who do not see eye to eye with them, as holding the cup to their neighbor's lip. Lectures should be given pointing out the evil, and it should be daily impressed upon the mind of every child in our public schools; through the child the erring parent may be educated.

Legislative regulation. From the year 1551 to the present date, laws have been enacted, canons, decrees, and anathemas made against the abuse of alcoholic drinking, and it may be asked, what have they accomplished? The Committee of the House of Lords in England declared in their report (1879) that "recent

legislation has had a beneficial effect throughout the country by producing good order in the streets, by abolishing the worst class of beer houses and by improving the character of licensed houses generally. It is not, however, proved that it has diminished the amount of drunkenness." "In certain localities drunkenness has increased among women, but as a rule the respectable class of artisans (both male and female) are becoming more sober and the apprehensions for drunkenness are becoming more and more confined to the poorer classes of the community."

Laws upon the statute book are useless unless enforced. To accomplish this object the laws require to have the approval of a large majority of the community, who must feel that he who breaks or evades them degrades himself. This belief does not exist owing to the fact that a large majority of those who purchase and consume liquor, use it in moderation, are never intoxicated and do not feel that they are injured by it. They claim that a majority of ninety should not be coerced by a minority of ten, who are too selfish to obey the restraining power Providence has given them.

The object of all laws regarding alcoholics is to control and lessen the use of them. As you increase the cost and the difficulty of obtaining them so you lessen their consumption. To do this the price of the license to sell should range from \$500 to \$1,000 per year, and in number should not exceed one in every five hundred inhabitants. Happily individuals, as a rule, are ashamed to be seen in or going into a barroom, enter by a side door and drink behind a screen. I would foster this shame by making it imperative that the barroom shall face the street, have but one entrance, without blinds or shutters to the windows, enabling passers in the street to see those in the room. Barrooms should not be allowed in hotels, the boarder should be required to treat his friend in his room, and they should be prohibited in grocery shops.

The present licensing system is defective in every particular, inasmuch as the number exceeds the demand, creating such competition that the "publican" can not afford to refuse credit and must please his customer by giving him liquor at all hours. The hours of opening are too early. For I hold that under no possible circumstances is it necessary or beneficial for a healthy person to drink liquor before his dinner hour; on the contrary, when the appetite craves the stimulus in the morning the subject is on the road to ruin.

At the risk of being considered "Utopian" I do not hesitate to urge that no liquor should be sold for consumption on the premises at an earlier hour than 2 o'clock in the day, and then preferably with food. I might go further and urge that it be not sold for consumption on the premises at any time without food. It may be urged that the purchaser would pay for the food but not eat it. True, but the expense of the performance would have its influence upon the amount of liquor consumed by him. Legislation should encourage the use of light wines and beer as containing less alcohol.

The Gothenburg system commends itself to the rate payers, as all the profit accruing from the public-house sale of liquor is appropriated toward paying the debts of the municipality. It is recommended strongly by the committee before referred to, composed of seventeen of the leading men in England. It directs that no individual, either as proprietor or manager, shall

derive any private gain by the sale of spirits. That the whole public-house traffic be transferred to a limited liability company, who shall undertake by their charter to conduct the business solely in the interest of temperance and morality, and to pay to the town treasury the whole profit beyond the ordinary interest on the paid up capital. The capital annually expended was between \$30,000 and \$40,000, and the profits amounted to nearly \$120,000. The number of licenses issued by the new company was reduced from 119 to 56. The company had the power of fixing the hours of closing and prohibited all "bar" business from 6 P.M. on Saturday to 8 A.M. on Monday. The experiment appears to have worked well, for almost every town in Sweden has adopted it. The reduction in the taxation makes it to the interest of every man to see the law enforced.

Prohibition. As I have already said, temperance enthusiasts claim more than can be accomplished, indeed they are following a shadow. But legislators wishing to gain or retain power, may yield to combined pressure and place a prohibitory law upon the statute book. Prohibition failed in the Garden of Eden; it has failed in every instance when it has been placed upon the statute book; and it must continue to fail until the ninety out of the hundred adults who use alcoholic drinks without abusing them are educated to the belief that they are committing a sin. This belief does not exist and can not be enforced by prohibition, upon the principle: take from a man against his will his freedom of action, he chafes under it and considers it a hardship. It may be asked, will any reasoning mind believe that—with the existing appetite for stimulants—a prohibitory law would or could be forced, and would not the endeavor lead to disrespect for the law, smuggling, illicit distillation and the use of other stimulants and narcotics with all their injurious consequences?

Again, if such a law existed, would it not pave the way to others equally obnoxious? The sanitarian finds it difficult to administer laws where an injurious appetite is not involved, and where the benefit applies to all. It is claimed that a prohibitory law would lessen crime and consequent expense. This is more than doubtful, for the expense of enforcing prohibition would be necessarily large.

The next question for consideration is: What shall be done with the inebriate? Medical treatment has little influence upon him while he has the ability to indulge his appetite; entreaty is useless, the tears of a fond wife are of no avail, the finer qualities of his nature are destroyed, the terrible craving for stimulants has in a great measure taken possession of his will and he pursues his course to degradation and death regardless of consequences. How the law shall deal with him is a question of great difficulty. The liberty of the subject must be guarded and the community justly claim protection from the violence of his acts.

There are two classes of inebriates; those who voluntarily get drunk, possessing the power to resist, and those who are so far lost that their voluntary power is destroyed. The first should be treated as misdemeanants, the power of the elective franchise withdrawn from them, after the second conviction, and in other ways degraded.

The involuntary drunkard, if I may so term him, should be treated as a lunatic and kept in restraint for a period sufficiently long to cure his malady; how

long that should be must depend upon those in charge of him; and when that restraint is enforced for a suitable time it is often surprising to witness the recovery of mind and body under it. It is true that the inebriate is not in the strict sense of the term a lunatic. The church looks upon him as a sinner, the state as a criminal, while the observing physician knows that he has lost his power of self-control, is ruining his health, shortening his life, squandering his property, and oftentimes in his delirium commits acts of violence against those most dear to him. It may be said that the disease was caused by his own act. True, but that does not absolve the State from responsibility. Is he dangerous to himself and others? He certainly is, and therefore he deserves the same care as a lunatic.

While restraint is necessary I deem it highly improper that the inebriate should be associated with lunatics. The government receiving a very large income from the material causing the evil should be forced to supply and support hospitals for the cure of the disease—such hospitals stand upon a different footing from others, and it is obviously unfair for the private individual to be taxed for the support of them, beyond that which he willingly pays consequent upon the tax upon the material producing the disease.

Such hospitals should be established in a pleasant district in the country, built in cottage form, so as to receive the different classes and sexes, and so fenced as to prevent escape. Those who can not pay should be compelled to work at fixed wages, the proceeds of which—deducting the amount for their board—should be paid to those dependent upon them.

The present practice of imposing a heavy fine upon the inebriate is cruel in the extreme, inasmuch as it does not fall upon the offender but upon the unfortunate wife and family, already beggared by the selfish creature's act. Again, the imprisonment imposed has the effect of recouping him for another debauch.

Dr. Norman Kerr claims that 40,000 die yearly from inebriety in London and that one-third of those could be cured by proper isolation and treatment. I take it for granted that a like proportion die in the larger towns of America. If such is the case, the wonder is that legislators hesitate about applying the remedy. Recently those in authority are becoming better educated to the necessity for spending money for sanitary purposes; surely this sanitation should appeal to the sympathy and the judgment of all.

Voluntary isolation is valueless. The inebriate, as a rule, will not enter, and when he does it is for a short period and to exercise his own judgment about leaving. In a large majority of cases a year or more is required before the individual can be pronounced well.

I have been unable to learn the laws of your country regarding inebriety. But in the Provinces of the Dominion of Canada the friends of the inebriate are empowered by law to cite him before a judge of the supreme court who, upon sufficient evidence, may incarcerate him for a year in an inebriate asylum. The judge may also appoint a committee to take charge of his estate. This is as it should be. But each province is obliged to furnish and maintain its own asylum. While the large revenue received from the importation and manufacture of the material causing the evil is appropriated by the Federal Government, the law is only enforced in those provinces where asylums exist.

Believing as I do that education and hospital isolation are the most practical remedial measures for the gigantic evil of intemperance, I appeal to the members of our noble profession, who are ever foremost in philanthropic work, to exercise the power which each and every one of them may possess toward this end. If any thing that has fallen from me has the effect of enlisting their interest in this good cause I shall feel that I have not spoken in vain.

### NON-ALCOHOLIC TREATMENT OF CONSUMPTION.

Read in the Section on State Medicine at the Forty-seventh Annual Meeting of the American Medical Association at Atlanta, Georgia, May 5-8, 1896.

BY O. G. PLACE, M.D.

BOULDER, COLO.

That consumption is a disease of lowered vitality, I think, is not to-day questioned. While the tubercle bacilli is the active agent in this disease, yet observation shows us that while the body tissues are well nourished and the general vitality good, tissue cells have the power of repelling these germs, even though they may be quite plentiful in the body, but lowered vitality predisposes to tuberculosis.

Alcohol lowers the vitality of body tissue. On this point Dr. N. S. Davis says: "Alcohol is a poison and when taken into the system is not assimilated, and while passing through the body disturbs every physiologic process and is finally thrown off through the organs of excretion unchanged. Hence, if not assimilated it can not be a food, and as it disturbs every physiologic process it can not be a medicine. Therefore, if alcohol is not nutritious and serves no purpose as a therapeutic agent, then mankind should be so instructed and its promiscuous use abandoned. This work can alone be done by the medical profession."

Also the following from Dr. J. W. Squires is worthy of note: "Numerous scientific investigations by various distinguished authorities bear me out in the statement that alcohol is not a stimulant but a depressant; is not a tonic, but an anesthetic; is not a food, for it is not digestible nor assimilative; it impairs the senses, and that, too, in exact proportion to the quantity consumed."

A strong man in perfect health and strong mind will degenerate physically and mentally by a liberal use of alcohol in any form. It is true that in many cases alcohol increases the production of adipose tissue, but it is just as true that it decreases the amount of muscle. But in this case we are to choose between fat and muscle. What is the change in fatty degeneration of the heart? If adipose tissue is more valuable than muscle, why is our anxiety aroused and our advice so positive when we decide that the muscle fibers of the heart are gradually being degenerated and globules of oil are taking their place? Alcohol may and does, without question, often increase fat. Bodily inactivity will often do the same; but is a fat man stronger than a muscular man? Is a fat man more able to resist disease than a man who has less fat and more muscle? The cause of lowered vitality suggests the remedy.

That there is in all cases of consumption an unnatural and more or less rapid disintegration of bodily tissue is not questioned. Tuberculosis is a most treacherous disease and the germs are only waiting at the windows of our bodies to stealthily creep in and spoil the house as soon as by intemperance in any form, the body

has been rendered so dormant as not to repel the intrusion. In presenting the above, the point we wish to make before speaking of treatment, is that fat does not necessarily mean vitality; that adipose tissue is of a lower order than muscle; that weight and strength are not synonymous.

Hundreds of patients to-day are coming to Colorado with this advice: "Drink plenty of good whisky and keep in the sunshine and you will soon build up." The climate of Colorado does stand as the best refuge known to us for those infected with this disease. The sunshine helps to make this climate what it is, but the man who comes here with little vitality, low by disease and still lower by alcohol, and sits in the hot sun, will go down like an icicle in the streets of Calcutta in midsummer.

In the treatment of this disease better vitality is the one thing essential; oxidization brings better vitality; cold, not heat, promotes oxidization and gives tone to the body tissue. Patients must avoid the extreme heat of any country. The Rocky Mountain region is recognized as having a dry climate abounding in sunshine. It fully sustains this reputation; yet in some sections of this State, especially in the southern portion as well as other points along the foot hills south of latitude 40, there is not that cool, bracing air which is found extending farther north even into southern Wyoming.

Although there has not been discovered any specific preparation which taken internally or externally will destroy the germ, yet we believe that by proper care, combined with climatic advantages, a much larger percentage of complete recoveries may be obtained. We are convinced that tubercular patients need equally as regular management, advice and treatment as patients suffering from other protracted fevers. The following outline of treatment and general management during the past two years has seemed to bring gratifying results, and a few cases are cited below to illustrate conditions of patients and results obtained from the change of climate combined with careful treatment. The general treatment pursued has been substantially the following: All patients are kept in bed for a few days after arriving to prevent too much reaction. When there is much fever the patient is kept quiet until the temperature shows a decided drop, and remains down. The most nutritious foods are given which can be assimilated by the digestive system, paying attention to frequent change and good variety; but at the same time caution against "stuffing." When the temperature rises above 100.5 F. we have employed the moist compress, enveloping the whole chest and so adjusted as not to allow the air to pass under it. This is held firmly in place by another dry covering made of cheese cloth, which is wrapped about the chest and over the shoulders, completely covering the moist one and holding the same close about the chest. When this compress is removed in the morning, unless the patient is liable to chill, a cool, wet hand-rub is given by a skilled attendant, who follows it by a light, medium or thorough massage, according to the patient's condition and the prescription given in each case. In this way the circulation is well started just at the time when the temperature is generally the lowest.

The object of this treatment is two-fold, for its tonic effect on nutrition and its antiperiodic effect on the nervous system. For it is well known that in any fever if the periodicity can be broken or modified by

anticipating the chilly stage by a thorough warming of the body the chill is markedly decreased, and the fever is in like proportion lessened. The patient is especially protected and kept warm in the morning, but allowed to be out much in the cool air a little before time for the temperature to rise. When there is a tendency to night sweats a hot vinegar or salt sponge will usually control this and so quiet the patient as to induce sleep. From 5 to 30 drops of creosote by enema is also given in an emulsion of oil of sweet almonds and the yolk of eggs three times a week. General treatment by an attendant is given, such as light massage, electricity, dry or wet hand-rubs or sponges, according to the strength and reactive powers of the patient.

In cases where there is thickening or much accumulation of secretion in the smaller tubes or air cells, we have used quite liberal inhalations of ozonized oxygen, which serves to loosen up and clear out such exudate more satisfactorily than perhaps any other one measure. This gas acts upon the pus and exudate in a similar manner as dioxid of hydrogen would, but in a very mild manner; the results can be governed at will by regulating the quantity of gas inhaled. Ozone can be produced quite readily by whipping pure oxygen in the static flame generated from a large coil attached to a dynamo producing the direct current. Any coil which is strong enough to throw a ten-inch spark will produce a liberal amount of ozone by using the silent discharge, but not the spark.

In cases where the bowels are especially involved and there is much pain and looseness, we have been able to control both quite readily by the moist abdominal girdle, protected as for the chest, the use of hot applications over the bowels and hot starch enemas. In mild cases, usually the girdle will relieve in a few hours; in more severe cases, each or all of the above measures may be required. We find it necessary to keep patients quiet while the temperature is high.

The following cases taken from our book of records without selection, and including all tuberculous patients who entered during twelve weeks ending September 31, will give an average result from the employment of the above outlined treatment:

*Case 1.*—July 3, Miss F. B., aged 20; home, West Virginia; heredity, tuberculosis. Patient has been failing for a year, cough for past three months. When received had a very distressing cough, raising heavy yellow sputum; test showed tubercle bacilli; temperature 101.5 degrees. Quite extensive thickening in right lung and râles in both apices. Treatment as indicated above. Result: Patient began regular work as a nurse in one month, in three months all indications of thickening had disappeared and the temperature was normal. She had gained eighteen pounds in flesh and no return of any symptoms to date, and yet regular work has been continued since the first month.

*Case 2.*—F. T. J., aged 21, Iowa. Grandfather and grandmother died of consumption. Patient never very strong. Condition at examination: Left lung, lower lobe, solidified; upper lobe much thickened, with râles quite general; temperature 101 to 103 degrees, with chills. Patient gained during the first three months fifteen pounds. Temperature normal, but lower lobe did not entirely clear up. Was quite well until he took cold about three months ago, which again caused much thickening in the left lung. Patient at present has some fever, but is making a slow but steady gain. Temperature now about 100 degrees.

*Case 3.*—Mrs. J., aged 19, sister of above patient. Large cavity in upper lobe of right lung, lower lobe consolidated; left lung slightly thickened; not able to walk; temperature 102 to 103; chills, no appetite, bowels tender and loose, profuse night sweats. Patient made a steady gain for five months. Left lung gave no signs of further infection; right lung still slightly thickened but no râles; temperature normal; cavity contracted. March 1 patient was discharged from treatment,

but advised to remain in Colorado. Five days later took a severe cold from exposure, contracted pneumonia of the left lung and died the following week.

*Case 4.*—Capt. B., aged 60, Iowa. Grandfather died of consumption. Patient suffered since the war with stomach and bowel trouble. Pneumonia two years ago, involving the left lung; marked pleuritic effusion. Physical examination showed left lung to be practically consolidated, with breaking down near the apex, forming a small cavity. Examination of sputum showed tubercular bacilli in large numbers. Had three severe hemorrhages. Temperature on entering 100 to 101.5. Has had two quite severe hemorrhages while under treatment, but is now gaining in flesh and strength. Temperature now normal both morning and evening. Especial attention has been given in this case to the digestive system as well as to the lungs.

*Case 5.*—Aug. 20, 1895; Miss C., Michigan, aged 26. History, always delicate, troubled with enlargement of the glands of the neck for fourteen years; has been removed twice; was sent to Colorado by physician two years ago after having two hemorrhages. Made a very satisfactory gain for several months when she had what she termed "grippe." In my judgment, many of the so-called cases of "grippe" are simply an acute attack of tubercular invasion; that is, in these cases which later develop tuberculosis. Examination on entering our institution showed the left lung thickened, especially in the lower lobe, with only fine crepitant râles and little, if any, normal vesicular sounds. The upper lobe showed decided signs of softening near the apex, and either dilated tubes or a small cavity. The temperature varied from 101 to 103.6 during the first week. The ozonized gas was used carefully, and the exudates was quite readily cleared out of the lower lobe, but the indications of a cavity still remained near the apex. Patient has gained and lost at times, but on the whole is at present about as when we first examined her, except that the lung has cleared up almost entirely. Is still under observation but not treatment.

*Case 6.*—September 1, Miss E., aged 24, Michigan. Patient never strong; had two hemorrhages about eight years ago; began to decline about one year ago; sputum tested and the bacilli found; sent to Boulder by her physician. Physical examination showed marked thickening near apex of left lung with moist râles. Temperature varying from 100 to 101; no night sweats; annoying cough. Treatment pursued as given above and patient after two months showed no evidence of the thickening; temperature normal; no cough; had gained twelve pounds in flesh and has since worked continuously and no indications of return of the disease.

*Case 7.*—Mrs. W., aged 34, New York. Father died of consumption. Patient well up to about five years ago, then had pneumonia; has had seven hemorrhages; coughed most of the time for the past five years; has been failing for the past two years; shortness of breath, very nervous and appetites poor. Physical examination revealed general thickening and moist râles throughout both lungs with friction râles on right side. Temperature varied from 99 to 100 during the first week. Especial attention was given to diet and treatment. She was kept absolutely at rest for one month, after which she took some exercise, and for the past three months has been working from six to ten hours per day and her temperature has been normal for over two months. Much of the thickening has been cleared out and the râles have nearly disappeared. The patient was discharged about one month ago, but advised to stay in Colorado the remainder of her life.

*Case 8.*—September 10, Miss M., Indiana, aged 32. Heredity good; had what she called la grippe four years ago, since which time has had two hemorrhages with cough. For past year has had a persistent cough and throat remains irritable and husky. Physical examination showed general thickening of the right lung with mucous râles in upper lobe. The ozonized gas was used quite freely in her case with other treatment, and November 28 she was discharged with only slight indication of thickening in the back part of the middle lobe of right lung. Temperature had been normal for several weeks.

*Case 9.*—Sept. 12, 1895, Mr. T. M., aged 20, Iowa. One sister died of consumption. Patient in fairly good health up to about one year ago, when he "took a severe cold;" had pain in lungs and after the "cold" was relieved noticed a shortness of breath with cough. Sputum was examined and tubercular bacilli found. His physician advised him to go to Colorado by wagon; the trip was very tiresome and patient lost much strength and flesh while on the road. He was put under treatment at our institution September 12. Physical examination showed the upper lobe of the left lung softened and the whole lung thickened, with crepitant râles in lower lobe. Temperature first week varied from 101 to 103.6, with chill daily.

Patient was kept absolutely quiet, the cool compress kept constantly about the chest. The ozonized oxygen was freely used, about ten gallons twice daily. Later took careful exercise and spent much time on the verandas and in the sun when not too warm. The appetite was very poor, bowels tender and the patient much emaciated. Patient was discharged from treatment Dec. 10, 1895, after having gained twenty-two pounds. Appetite good, and but slight thickening in upper portion of left lung.

*Case 10.*—Mr. W., aged 23, New York. One sister died of consumption. Had been running down for about a year; slight, dry cough at first, gradually grew more troublesome. Physical examination revealed marked thickening of upper lobe in right lung and some considerable infiltration into the small tubes of the lower lobe. Chills daily in the morning, with a rise of four degrees of temperature by 2:30 p.m. Tubercle bacilli found on examination; considerable expectoration. Temperature gradually lessened under treatment and patient was discharged December 1, to all appearances well, but advised to remain in Colorado for one year at least. Two months later he passed an examination for life insurance, and has, to the present time, shown no indications of any return of the trouble.

The above ten cases are taken without selection, in the order in which they entered our institution. We are convinced, after watching a large number of patients in Colorado, that tuberculosis is curable in a large percentage of cases and without alcohol, provided the same study and care is employed with these cases as with other patients suffering with infectious fevers.

## REMARKS ON THE MANAGEMENT OF GLAUCOMA.

Read before the Michigan State Medical Society,

BY LEARTUS CONNOR, A.M., M.D.

DETROIT, MICH.

The literature of glaucoma is honeycombed with doubt and contradiction. If a writer advances a theory of its causation, others demonstrate its inadequacy; if one presents a pathology, another proves it incomplete; if one proposes a plan of treatment, others shortly affirm that they have tried the plan and found it wanting. One cures his cases by iridectomy; another by sclerotomy posterior; another by sclerotomy anterior; another by internal division of the sclerotic at the angle of the anterior chamber; another by division of the ciliary body; another by corneal punctures; another by myotics; others make a selection from these several modes of treatment according to the case in hand. This is a rational method, but as no two make the same selection the seeker for practical directions in treating a case of glaucoma must sift his own data and follow his individual judgment.

If the eye could be taken apart and studied during the very early manifestations of the disease, we should more directly attain that knowledge which shall unite all discords into one consistent tune. As a fact, we are compelled to wait till the eye is blind or the patient dies from some intercurrent disease, for a chance to study the actual changes in the eye made by glaucoma. Experiments upon the eyes of lower animals are utilized to fill this gap in our knowledge, but these are always discounted by the doubt as to the extent to which they represent the reactions occurring in the human eye during the progress of a case of glaucoma. Then cases of glaucoma are rare, so that an individual observer has relatively few with which to pursue his practical studies. Worse still, of the cases he does see, few are within his observation during the entire course of the disease. In spite

of these and many other obstacles, the management of glaucoma is progressively more satisfactory; what can be, is more definitely separated from what can not be done and a clearer light illumines the entire subject.

On one point all agree—normal ocular tension should be restored at the earliest possible moment, because an increase of intra-ocular tension is to the contents of the eyeball what a strangulation is to the intestine in a case of hernia. Von Graefe first proved that iridectomy would cure some attacks of glaucoma, a discovery of inestimable value. Added experience has shown that an iridectomy will not cure all attacks of glaucoma, or all stages of any one attack; that it is useless to stay the progress of some, and absolutely hastens the destruction of the eye in other cases. Yet with all its limitations it remains *the* remedy for attacks of glaucoma with increased tension. The cause of this increased tension has been the occasion of a vast amount of research. Present facts seem to support the following as the chain of events leading to an attack of glaucoma:

Normally the fluids secreted in the posterior chamber of the eyeball escape through the cribriform disc of the optic nerve and the suspensory ligament. From the anterior chamber the outflow is by the anterior angle through Fontana's spaces and the canal of Schlemm, thence through the sclerotic to Tenon's capsule. The spaces through which this outflow occurs are in connective tissue and devoid of epithelium. Hence the fluid has a constant contact with the connective tissue fibers of the suspensory ligament, optic nerve and angle of the anterior chamber. If this fluid becomes abnormal and remains so during long periods, the connective tissues through which it flows must undergo changes. If the fluid be defective in nutritive materials and loaded with irritative elements it is clear that ultimately the connective tissues through which it passes must undergo degeneration. Such changes in the secreted fluid of the posterior chamber may be expected when the blood constantly supplied to the chamber be what is known as "dirty" blood. Such blood is found in numerous diseases, as gout, rheumatic gout, syphilis, imperfect digestion from either bad food, or good food taken in excessive amounts. After a time the degenerative process in the connective tissue outflow spaces of the posterior chamber becomes so advanced, as to no longer suffice for the free transmission of the fluid secreted in the posterior chamber. If now this fluid be changed by a disturbance of the secreting vessels, through the nervous, muscular or digestive systems, we may have the outflow spaces absolutely closed, and an acute attack of glaucoma. Dr. Richey has especially emphasized the origin of glaucoma through the operation of "dirty" blood.

Knies has experimentally shown that the composition of the fluid in the posterior chamber may be so altered as to effectually clog the outflow spaces, both anterior and posterior, when the connective tissues are perfectly normal. Much more will such changed secretion clog the spaces when they are diminished in size and altered in character by degenerative processes. Thus glaucoma is a chronic constitutional disease, with occasional local outbursts in the eye due to obstruction of the outflow spaces. Generally ophthalmologists have called the local outburst glaucoma, and devoted their exclusive attention to its management. Evidence is accumulating to indicate that it

is a part of wisdom to treat the general constitutional dyscrasia that produced the local outburst, in the expectation that the local treatment will prove more satisfactory and future outbursts prevented.

Simple glaucoma has little to distinguish its presence in many cases, other than diminished visual field and excavation of the optic nerve. Under the operation of the constitutional dyscrasia the connective tissue of the optic nerve loses its power to hold these fibers in place, so that with the central retinal vessels they drop into the hole. The peculiar appearance of the blood vessels at the sides of this hole make it quite easy to recognize with the ophthalmoscope this excavation. If the anterior connective tissue spaces have escaped the ravages of the dyscrasia no other symptom may attend the case from beginning to end. But if the anterior spaces become involved, other symptoms of more or less gravity will appear. Without these latter the management of such a case is wholly constitutional, as there is no reason to suppose that either operation or medical treatment, locally applied, will avail. To secure such habits of life as will insure an abundant supply of pure blood to every portion of the body, including the eyeballs, will afford the patient the best chance of retaining vision for the longest period. It is surmised that some of the cases in which iridectomy was followed by an immediate reduction of vision belonged to this class. But most cases of simple glaucoma, at some time in their course, present other symptoms, as increased tension, diminished field of vision, dilated pupil, pain, etc. These call for local treatment, surgical or medical, or both. Typical of the first is iridectomy; of the second eserin.

As to the value of iridectomy in chronic simple glaucoma, the studies of Dr. C. S. Bull (Trans. Amer. Oph. Society, 1889) are very conclusive. He gives the history of ninety cases treated during a period of seventeen years, all of which he was able to study for a considerable period after operation.

Vision was temporarily improved in two cases in both eyes, in six cases in one eye; but in all the eight cases a steady loss of vision and a narrowing of the visual field set in and continued progressively so long as the patients remained under observation. The vision remained unchanged in eight cases in both eyes; and in twenty cases in one eye. Vision grew steadily worse in forty cases in both eyes, and in forty cases in one eye. Vision grew rapidly worse after operation in two cases in both eyes, and in one eye in eight cases. Of the one hundred and eighty eyes, only ten eyes were at all improved by the iridectomy, and these steadily grew worse. In thirty-six eyes the vision was unchanged for a year after the iridectomy. In one hundred and twenty eyes, vision grew steadily worse after iridectomy, while in twelve eyes vision grew rapidly worse after iridectomy. It is thus clear that in chronic simple glaucoma iridectomy is far from a brilliant success.

Of the comparative value of eserin and iridectomy in simple glaucoma, an excellent study is given by Drs. Zentmayer and Posey (Will's Eye Hospital Reports, Vol. 1). One hundred and sixty-seven cases are reported from the service of Drs. Norris and Oliver.

Sulphate of eserin was used in all cases when well borne and was continued for years. At first the doses were small, being increased or diminished according to results. The cases irritated by its use were treated

by iridectomy. When well borne it improved central visual acuity in 62.16 per cent. of cases, while it retained vision unaltered in 21.62 per cent.; in 16.21 per cent. it was powerless to prevent decrease of vision. In 85 per cent. of the cases it diminished intra-ocular tension. The visual field improved in 50 per cent. of the cases; remained stationary in 18.75 per cent., and steadily diminished in 31.25 per cent.

When well borne, eserin kept the fields improved ten months, and vision fifteen months. In cases not improved fields remained stationary for three months; vision for thirteen months.

Iridectomy improved 60 per cent. of cases; did not change 20 per cent.; failed to prevent loss of visual acuity in 20 per cent.; diminished it in 10 per cent.

Tension improved in 90 per cent. of cases. The improved visual field lasted on an average eighteen months; the degree of visual acuity twenty months after iridectomy.

The facts show that it is advisable to employ eserin, when well borne, for a month; if the field of vision has diminished nothing further can be hoped for from eserin, and an iridectomy must be done. If there be an improvement of the visual field, eserin should be continued, as there is reason to expect a beneficial action for ten months upon the extent of the visual field, and fifteen months upon the visual acuity. In half the cases we may expect iridectomy will check the course of the disease for eighteen months. Ten per cent. of the cases will not be benefited by either eserin or iridectomy, or both. Both successfully reduce intraocular tension. Thus in simple glaucoma we have the following elements of management:

1. In every case make the nutrition of the entire body as perfect as possible, by removing defects of excretion or secretion; disturbances of digestion; constitutional dyscrasias, as gout, rheumatic gout, syphilis, etc. Medicines avail much, but wise regulation of diet, exercise, sleep, bathing, etc., will generally be most efficient.

2. Place the affected eye under the influence of eserin, if well borne, and keep it there so long as it controls the tension and prevents a diminution of the field of vision. This failing,

3. Do a large upward iridectomy, and follow with eserin, if well borne, while any manifestations of the attack continue. This failing; a sclerotomy anterior may be done.

4. Correct and keep correct all defects of refraction and muscular balance.

Acute inflammatory glaucoma presents a remarkable likeness to acute inflammatory gout, just as simple chronic glaucoma resembles rheumatic gout. The following is given because the attack could be studied from inception to close.

On March 29, 1880, Dr. Fletcher placed in my care a boy, aged 15, suffering from an injury to his left eye by an exploded gun-cap. The eye was operated upon and the wound treated at a hotel under the care of his father, a man 45 years old, of unusual intelligence. Aside from a history of sub-acute rheumatism, this man's general health had always been good. His eyes were astigmatic, hyperopic and presbyopic, though he wore a simple spherical glass to correct the same, selected by a jeweler. While watching his suffering child, he read much in a poor light. On the morning of April 3, five days after coming to Detroit, he complained of slight discomfort in his left eye, and thought that at times his vision was dulled. A

careful study of the eye revealed a slight intra- and extra-ocular congestion, with a trifling increase of tension. A saline cathartic was administered; a soothing lotion applied hot to the eye at short intervals; the eye protected from bright light and small doses of quinin administered internally. On the following day the eye was worse in all respects; the pain in and about it had become intense; the pupil dilated and very sluggish; the tension plus 2; the field of vision contracted; the cornea insensitive; the anterior chamber very shallow; the iris crowded into the anterior angle which was filled from behind with the ciliary body; the anterior ciliary vessels much dilated and the entire circumcorneal margin of the sclerotic covered with engorged blood vessels; the fundus oculi was engorged, the optic papillæ being considerably swollen; the retinal arteries pulsated on the slightest pressure of the eyeball. Patient could not count fingers and complained of flashes of light, when the lid was closed, and rings about the light when the lid was open. Thus we had a case of typical acute glaucoma. To reduce the intense congestion, several ounces of blood were at once abstracted by an artificial leech from the temple, relieving the pain and reducing the tension. A drop of a two grain solution of eserin was placed in the eye every hour while the pupil remained dilated. Previous to each dose the eye was soaked in hot water for five minutes. These measures so modified the attack that the patient was more comfortable on the following day, but the tension was still above normal; the fundus could not be seen with the ophthalmoscope, and the eserin had failed to keep the pupil contracted. Iridectomy was now urged, but rejected. Local abstraction of blood was repeated, a saline cathartic given, and the other treatment continued, but with less effect than on the previous day. Iridectomy was urged at each visit, but rejected till the sixth day. Then vision was reduced to a mere perception of light; the media cloudy; pupil widely dilated; iris immovable; anterior chamber very shallow; cornea steamy and insensitive; great circumcorneal injection and very severe pain. Because of the shallow anterior chamber a Von Graefe's cataract knife was used to make the corneal incision, which was done upwards so as to admit the removal of a full third of the iris. This was drawn out of the wound by the iris forceps, till it was placed upon the stretch and then divided by Wecker's scissors, close to the sclerotic. The angles of the wound being freed from the remaining iris the lid was closed and protected from injury by a light bandage. The little aqueous which escaped had a straw-like color. The pain immediately disappeared never to return; the wound healed kindly, the vision gradually improved until it equals that in the other eye, and the entire eye resumed its former condition, aside from the mutilated iris. The cure of the attack was complete.

To prevent future attacks the following measures were adopted: His defects of refraction were fully corrected and the correction glasses ordered worn constantly. He was placed upon a diet and habit of life, such as would tend to eliminate the arthritic taint, and appropriate remedial agents were ordered. There was no recurrence of the attack in the left eye, nor did one develop in the right eye. The case remained cured during many years till his death.

In this case we have an arthritic disorder existing long anterior to the acute attack of glaucoma, in a

man who had reached middle life, suddenly subjected to intense mental worry and marked eye strain. Without the last two factors he might have escaped the attack, but with them the secretion of the vitreous was so modified as to clog the connective tissues of the suspensory ligament and optic disc. This was followed by an accumulation of secretion and enlarged blood vessels in the posterior chamber which pushed forward the ciliary body, the lens and iris, and forced the aqueous out of the anterior chamber. An iridectomy removed this obstruction to such a degree as to admit of the normal circulation of the intra-ocular fluids. No doubt the sudden change in the tone of the intra-ocular blood vessels modified the changes described.

The management of acute inflammatory glaucoma by constitutional remedies, eserin and iridectomy, is satisfactory to patient and surgeon if it can be applied promptly at the onset of the attack. Sub-acute glaucoma differs mainly in degree from the acute. We find moderate degrees of vascular obstruction and some sharp pain: an enlarged and sluggish pupil; increased tension; shallow anterior chamber; hazy vitreous; pitted optic disc, in varying degree. The following abstract of a case places it fairly before us.

Mrs. F., age 70, seen first Oct. 22, 1885, a large fleshy person of Hebrew extraction, and for many years a more or less constant sufferer from rheumatic gout, but otherwise perfectly healthy. At a period prior to her visit to me she had noticed occasional obscuration of vision, a little redness of the eyes; rings about lights: and some pain. At first the attacks were infrequent, but of late they occurred almost daily, and vision of right eye was 10-200, of the left 6-200; pupils widely dilated and almost immovable; aqueous cloudy; tension of right eye 2 and left eye 1; fields of vision greatly contracted; much circumcorneal injection and enlargement of the anterior ciliary vessels.

She was given a mercurial cathartic followed by full doses of salicylate of soda; her diet regulated so as to secure the best possible digestion; her skin and bowels were also so stimulated as to enable them to perform their normal functions. Locally, eserin, one grain to the ounce, was dropped into each eye every hour till the pupil contracted, and then as frequently as was needed to keep it moderately contracted. Before using the eserin the eyes were bathed in hot water for five minutes each. On the following day all symptoms were improved and in two weeks the eyes had become nearly normal in appearance, aside from the cupping of the optic discs. On correcting the hyperopic astigmatism and presbyopia her vision was right eye 20-40, left eye 20-50 and she could read Jaeger number 2 with each eye.

On recovering from the attack she was directed to wear the correction glasses for her ametropia constantly; to continue her anti-gouty diet and mode of life, and to use a weak solution of eserin once daily, if the eye seemed at all uncomfortable. She has been faithful in following directions, and ten years later reported no return of the disease, and fairly good sight.

I have met many cases from syphilis, that were successfully managed by the use, in a vigorous manner of antisiphilitic in addition to the local treatment. But in other cases such treatment fails and resort must be had to iridectomy. If the cases can be kept under close observation, and the fields of vision do not

diminish, and other symptoms improve it is safe to wait till eserin and constitutional agents are clearly futile, ere doing an iridectomy. But if the case can not be carefully watched the iridectomy should be done without delay—except in case of a degenerated iris, when the operation is disastrous.

Absolute glaucoma presents a notable picture: eyeball of stony hardness; devoid of all expression; blindness complete; pupils widely dilated and immovable; pupillary space filled with the glistening opaque lens; sclerotic of marble whiteness streaked with the tortuous and enlarged ciliary vessels; the glaucomatous process has done its worst. No treatment remains except such as will render the patient more comfortable, which may necessitate a sclerotomy or an iridectomy or enucleation.

We can not speak of glaucoma which is secondary to other local diseases or injuries in the eye; each of which must be managed according to its specific indication, the object in each case being the restoration of a normal circulation through the chambers of the eyeball. Pertinent to the management of glaucoma, is a brief note on the technique of the operations for its relief. In glaucoma the iridectomy differs materially from that done for optical purposes in that it needs to be as large as possible, and the iris removed close to its scleral attachment. Owing to the shallowness of the anterior chamber, great care is needed in making the corneal section, to avoid wounding the lens; otherwise grave consequences follow. I have found the use of Von Graefe's cataract knife most suitable for this purpose, as by it one can skirt the angle of the anterior chamber, keeping in the sclerotic, and make a section as large as desired. The incision should always be made in the sclera.

When the anterior chamber is nearly normal, the lance shaped knife may be employed, or the Graefe knife, used as in making the incision for cataract extraction. It is desirable to make the withdrawal of the knife so slow as to avoid the sudden freeing of the tension of the posterior chamber. On completion of the section, the iris is seized by the forceps and drawn till it is fully without the eyeball, then divided close to the sclera. Especial attention is given to the edges of the wound that they do not retain any of the remaining iris. Formerly a general anesthetic was required but now cocain suffices if the patient be controllable.

Anterior sclerotomy is possible only when the pupil is contracted and the anterior chamber of nearly normal depth. A Von Graefe's cataract knife is introduced about two millimeters above the horizontal margin of the eye and a counter puncture made directly opposite. By gentle movement the blade of the knife is made to cut its way, till it has nearly reached the surface, when its withdrawal completes the operation. This operation is called for in cases threatening hemorrhage, or after iridectomy has failed. Posterior sclerotomy is done by opening the sclerotic between the lower and external recti muscles, and posterior to the ciliary processes. The blade of a Von Graefe's cataract knife having been entered horizontally through the sclerotic, is turned at right angles and slowly withdrawn. Some fluid or vitreous may follow this operation, and the tension of the eyeball reduced so as to admit of an iridectomy which otherwise could not be correctly done. Numerous other operations have been done for the relief of glaucoma; thus a large portion of the sclerotic at the anterior angle has been

divided from within and good results reported; the ciliary body has been divided; the cornea has been punctured at each end of the vertical and horizontal meridians; the supratrochlear nerve has been stretched. But after all iridectomy furnishes in the ordinary case the largest hope of relief.

Lately Dr. Gould has proposed the use of massage of the eyeball for the purpose of freeing the outflow spaces of the debris clogging their meshes. He reports one case in which the results at date of writing were satisfactory. To a certain extent all the operations mentioned, exert a massage at the point of greatest obstruction, and doubtless, in this way produce their effects.

Dr. Pilgrim lately advocated with much show of reason the local use of the galvanic current placing the negative pole over the affected eye and the positive at the nape of the neck. In three cases of acute inflammatory glaucoma he reports the happiest results. He thinks that the current modifies favorably the obstructing fluid, and the obstructive connective tissue at the outflow spaces.

My own experience supports the claim of Dr. Sutphen, that salicylate of soda often relieves the severer pain of glaucoma, and accords with the fundamental idea of this paper, that the foundation of glaucoma is a constitutional dyscrasia, which should be sought out in every case and removed so far as possible.

#### CONCLUSIONS.

In the management of glaucoma, such attention should be given the bowels, skin and kidneys as to secure the most prompt and complete elimination of the effete tissue metamorphosis. The diet should be so regulated as to admit only such articles and in such quantities, as can be perfectly digested. The liberal use of water internally and externally greatly assist in restoring the fluids of the body to a state of reasonable purity. The continuance of such diet and mode of life affords the largest hope of preventing future glaucomatous attacks.

Such medicines should be employed as are called for to remove the constitutional dyscrasia found in each case, as arthritic, gouty, syphilitic, etc.

In simple glaucoma with no increase of tension such treatment may suffice; but should there develop increased tension, diminished visual field, pain, shallowed anterior chamber, myotics should be first employed (if they can be constantly watched) and if they keep the symptoms under control, nothing farther is called for. But if they are not well borne, or if at the end of a month, the visual field has diminished, then an iridectomy should be done. If the tension still persists, a sclerotomy should be performed and myotics again employed.

In acute inflammatory glaucoma, the tension must be promptly reduced by general treatment and myotics if possible, but if these do not act immediately in reducing the ocular tension and in keeping it reduced, an iridectomy must be promptly done.

Sub-acute glaucoma is managed along the same lines as the acute except that operative action may be delayed a longer time, though the rule should not be deviated from which demands an iridectomy in all cases that grow worse under general management and myotics.

Chronic glaucoma is managed in the same manner as the sub-acute except that iridectomy is contraindicated

in cases of degeneration of the iris, the results of the operation in such cases being unfavorable.

Absolute glaucoma is treated only to relieve pain, if salicylate of soda fails, the treatment is exclusively surgical, sclerotomy, iridectomy and enucleation.

Hemorrhagic glaucoma is rarely benefited by any operation, owing to the weakened condition of the blood vessels within the eyeball. Hence if general and local medication fail, and pain persists, enucleation is the only resource.

Secondary glaucoma calls for specific treatment according to the condition inducing it. If it be an intraocular tumor, enucleate the eye; if it be lens swollen from dissection, extract the same and so through the list.

Finally, he who would do the most for a case of glaucoma, must not only be able to quickly detect the disease in the form of its acute exacerbation; to apply the local remedies or do the operation which will quickest and surest restore the normal intraocular currents; but he must be able to recognize the constitutional dyscrasia, underlying such acute attack and put in operation the wisest measures for its mitigation or removal.

#### HYGIENE OF THE EYE.

Read before the Medical Society of the District of Columbia.

BY CLARENCE R. DUFOUR, PHAR.D. M.D.

Physician in Charge of Eye Department, Eastern Dispensary; Ophthalmologist and Otologist to Sibley Memorial Hospital; Assistant in Eye and Ear Department of Central Dispensary and Emergency Hospital, and Instructor in Ophthalmology and Otology, Georgetown Medical College.

WASHINGTON, D. C.

The many cases seen in private and hospital work, which earlier could have been more effectively treated, if not entirely cured or corrected, and the earnest desire to obtain the coöperation of the general physician is my only excuse for bringing this subject before this society. As a rule, healthy parents beget healthy offspring; therefore, that the eyes may be free from disease and have perfect vision, the parents should live such lives as will conduce to health, that their children may be perfect physically and mentally; there should be legislation preventing marriage and intermarriage between those suffering from disease that may be transmitted to their children. The disastrous effect upon the eyes by syphilitic heredity is well known, also that of consanguinous marriages; in the first class we find various inflammatory conditions of retina, choroid and cornea; in the latter class we frequently find retinitis pigmentosa and sequelæ. One disease that is responsible for a large percentage of blindness and which costs the government millions of dollars annually for support of the blind, is ophthalmia neonatrum, but owing to the unceasing efforts of physicians this disease is becoming rare. Several States have laws making it a penal offense for nurses or midwives to neglect reporting a case of sore eyes in infants which they alone have attended at birth. I have seen the gradual decrease of this disease in the clinics with which I am connected. It is the class of persons who, from their mode of living and lack of hygienic surroundings, and often want of medical attendance, whose infants are more liable to this and other ocular diseases. These people still need educating as to the necessity of applying early relief in all eye inflammations and affections. As a rule, when they seek advice much damage has been done, which is almost, if not entirely, irreparable; as a result of

this we find many cases with all sizes and shapes of opacities of the cornea, disfiguring it and interfering more or less with vision; there is not a day that we do not meet men and women with eye affections which could have been remedied by early treatment. Children have been allowed to grow up with affections of the eye which handicap them in their studies. The failure of those having the children in charge to have all ocular troubles treated in their incipiency is due either to ignorance or indifference.

By the adoption of the Credé method of dropping a 2 per cent. solution of nitrate of silver into each eye of the newly born infant and by the adoption of scrupulous cleanliness to avoid reinfection, ophthalmia neonatorum can be prevented. So it is possible to prevent the disastrous effects of purulent ophthalmia, of iritis, keratitis and other ocular diseases by early and prompt treatment.

It is no uncommon experience of the ophthalmologist to have patients brought to him who are past the period when treatment will be of benefit. Recently I have had two such cases brought to my service at the Eastern Dispensary, one a colored youth who had cyclitis of both eyes, which developed into a panophthalmitis, with total destruction of both of them. This case was seen by one of our general practitioners during the period of intense inflammation, and who instructed him to apply at the dispensary, but he refused to go. He will always be a charge upon his friends or the community, perhaps both. I shall not be surprised at any time to see him among the many who are daily soliciting alms on our thoroughfares. The other case was one of purulent ophthalmia, which was treated at home by his people; the result was total destruction of the affected eye. Neglect of the eyes in infancy or at an early age is often the cause of poor eyesight; they are more sensitive to light than at mature age; children are often taken out of doors with their faces unprotected from the bright sunlight, or are allowed at night to stare at the gas or lamp-light for hours; this is all wrong; the child's eyes should be protected from the glare of light of any kind; also from dust and other irritating substances and from atmospheric changes. Should this be neglected an impairment of vision may result. As they arrive at the age of 6 years, the age at which they begin school, their eye work should be regulated by their physical development; it would be better to educate them by the kindergarten method and by object teaching until they are about 10 years of age; their eyes would be in better condition to stand the work to be put upon them in the future. In a report of the public schools of one of our cities I found for the year 1893 that of the total attendance, 69.63 per cent. were in the primary grade; the ages of this grade ranged from 5 to 10 years; 26.06 per cent. were in the grammar grades, and only 4.31 per cent. were in the high school. By these figures it was seen that a little over 50 per cent. failed to enter the grammar grades; the average age at that time was 10 years; at the termination of the grammar grades 71.68 per cent., more than three-fourths, failed to enter the high school; the total loss between primary and high school was about 96 per cent.

The question naturally arises as to what is the cause of this loss and why so few enter the high grade. Removals, sickness and death are factors in causing these results, but are they the sole causes? Many may be taken from school because their parents

think that it is necessary that they receive only sufficient education to enable them to read and write and perhaps have a slight knowledge of arithmetic. Still, if this be so, there are others who fail to enter the higher grades because of their inability to keep up their studies. Many of them are not in full vigor of health, are weak and poorly nourished, have bad hygienic surroundings, and their whole aspect is one of lack of nutrition. These children, as a rule, also suffer from defective vision. Not only from this class are those who drop out of school or keep up in their studies with difficulty, but we find them among the healthy and well nourished; the reason of this is that having some visual defect they can not do their work without such physical discomfort that they finally yield and leave school. The children at our public schools are kept too continuously at work, long lessons are assigned them for memorizing, and the general curriculum, especially of the grammar grades, is one liable to produce eye strain and mental fatigue. I think we should have some legislation compelling an examination of the eyes of all children at the time of their entrance to school, and as they progress and reach the higher grades there should be some method whereby a supervision of their eyes could be maintained. Their studies should be regulated so that the hours for home study would not be too long. The lessons given in the eighth grade and high school in this city are, in my opinion, too long; the brightest and best scholars are compelled to begin their studies in the early evening and continue them until 10 and 11 o'clock in order to complete and memorize them; the effect upon their eyes is bad, and not only upon them, but upon their general health. It is no uncommon experience to be told by parents that their children's eyes and health began to fail after their entrance into the grammar grades of our schools. We need more physicians on our school boards who will take an active interest in all matters pertaining to the education of our children, such as the amount of work to be done daily, the arrangement of desks, light, ventilation, etc. They are better qualified to regulate such matters than any other class of persons, and I think that the country at large would be better served had we more physicians to represent us in the different legislative bodies of the United States. The city of Washington is fortunate in having so many of its prominent physicians actively engaged in endeavoring to secure such legislation as will be of great benefit to the city and its entire population. Poor light is a factor in producing eye strain, therefore, particular attention should be paid to the manner of allowing the light to enter the school room, it should not be allowed to shine directly in the faces of the scholars, but, if possible, from behind them. The walls of the school room should be painted some neutral tint, thus doing away with the white walls, the glare from which further contracts the pupil, already contracted by the effort of accommodation. When we remember that the contents of the eye is really a liquid, and that we have six muscles attached to it externally, we can readily see that a strain of this character together with the effect of poor light and the dependent position of the head usually assumed in studying, will tend to produce myopia, which will, as a rule, increase as the child advances in its studies and keeps pace with the higher education of universities and colleges. The effects of a high degree of myopia are sometimes very grave, complete blindness of one or both eyes

ensuing from detached retina, stretching of the pericipient elements of the eye, etc. Divergent strabismus is mostly associated with myopia, and if not early corrected by glasses and an operation, if necessary, the sight of the diverging eye may become permanently impaired. Parents and others having children under their care have a great responsibility upon them; these children are to be the bread winners of the coming generation and everything should be done that they may enter their respective vocations of life in as perfect physical and mental condition as possible. We need the coöperation of the family physician in this, as he is usually the one from whom advice is first sought, and it is he also who is to advise the parents to have all abnormal conditions of the eyes promptly treated.

Another condition from which children and adults suffer is hyperopia, so-called far-sightedness. This I believe to be the normal condition of the human eye. Prof. Jaeger of Vienna examined the eyes of a large number of new-born children and found nearly all of them hyperopic. This condition is due to the shape of the globe, it being too short antero-posteriorly, the rays of light that enter the eyes do not focus upon the retina, but behind it, so that in order to sharpen the vision the ciliary muscle is called into action, to make the lens more convex, thus practically elongating the globe, that the rays may focus upon the proper place, the macula. This constant effort of the ciliary muscle, which should only be brought into action for near vision, will cause headaches, pain in the eyes and other distressing symptoms, and often affects the entire nervous system and general health; the nervous system is kept under constant strain by the effort of the eye muscle endeavoring to secure perfect vision; general character and disposition are frequently affected by imperfect sight. Children often appear dull and stupid from this cause, if they are compelled to use their eyes for long and close work, in the glare of too much light or insufficient illumination. As long as they have out-door work and their physical condition is good, they suffer little if at all. Children with hyperopia will find that by squinting they can see more distinctly; they will not squint constantly at first, but only when looking at near objects, and sometimes when looking at a distance; this is periodic squint and manifests itself about the fourth or fifth year, when they are learning to spell. Convergent strabismus is mostly associated with hyperopia, and unless promptly corrected the vision of that eye may become permanently impaired. Both of these conditions may be corrected by properly adjusted glasses, an operation, or both; as a rule the glasses are always needed by the patient. It is the hyperope as a rule who suffers most from his eyes, is prone to headache both temporal and occipital, and nervous symptoms; these latter are more aggravated when associated with muscular imbalance. Cases are on record where chorea and epilepsy have been cured by the correction of the refraction error and the heterophoria. The usual train of objective symptoms due to the eye strain are impaired vision to a greater or less degree, winking the eyelids, constantly inflamed conjunctiva, scales and crust in and among the cilia, crops of styes, strabismus divergent and convergent, etc. The subjective symptoms are inability to use the eye for any length of time on account of pain and blurring of the image; the running together of the type, or lines or both; sensation

as of grit between the lids, etc. The ophthalmologists have of recent years devoted considerable attention to the prevention of disease and have achieved considerable success. I believe with earnest efforts in this direction that further good can be accomplished. It is a well-known fact that the older text books on ophthalmology contain much in regard to pathology and treatment, but very little in regard to refraction; true we have works which treat theoretically of refraction, such as Donders and Landolt, which can not be improved upon, but they do not treat of heterophoria or state that errors of refraction are a causative factor in certain diseases and that their correction cures them. We now know that many of our ocular diseases, such as conjunctivitis, chalazions, styes, blepharitis, etc., which were once believed to be local in their origin, are largely due to eye strain, that when they are corrected by a properly adjusted glass, the cause being removed a cure is effected. It is the belief of the writer that refraction errors can produce not only the above-mentioned diseases, but that it is capable of producing more serious eye troubles as well as constitutional ones. Lately I read a paper before this society on "The Relation of General Disease to the Formation of Cataract." I would state that I believe also, that there is a relation of eye strain to the formation of cataract and to the causation of glaucoma; the etiology of the latter disease is yet open to doubt; it is generally conceded that its secondary cause is the closure of the filtration angles; the canal of Schlemm and the spaces of Fontana. These spaces become closed from increased ocular pressure, the reason for the increased ocular pressure can not be so easily explained. In this connection a paper written by Dr. Swindell may be quoted.

In twenty-five cases of glaucoma seen by him nineteen had errors of refraction, the other six he could not test satisfactorily; all of those tested had hyperopic astigmatism. The ill effects of hyperopia and hyperopic astigmatism have already been mentioned, therefore, who can deny that these nineteen cases of glaucoma were not due to eye strain? We have now in a general way mentioned the ill effects of errors of refraction. We know also that they as a rule are corrected by properly adjusted glasses; the question naturally arises as to who should make these examinations and prescribe. I unhesitatingly say that no one but a graduate of medicine and one who has had several years' practical experience in that line should do so. Theory without practical experience is of little avail; all of the leading medical colleges of this country recognize this fact and give their students the practical as well as theoretic instruction. The great physicians and surgeons of our age became such through practical experience gained in the hospitals and clinics. It is there they put their theory into practice, there the surgeon gained his operative skill and physician's eye, ear and touch become educated. The pharmacist who has only theory at his command would not be a desirable one to compound a complex prescription; the chemist, the bacteriologist and others could never become expert and accurate in their work without practical experience; so it is impossible for one to examine the eyes (one of the most delicate organs of the human economy), measure the refraction error and correct it, without having had practical experience in doing so. It is the prevailing opinion of the public that fitting glasses is an

easy matter, that anyone who chooses may do so for their financial benefit, notwithstanding the fact that they have never received a medical education nor any special preparation or experience in this line. This is a grave error, the correction of which will be of great benefit to the welfare of the public and ophthalmology in general. We have in this city a class of men who have none of the above requirements, but who advertise to fit all eyes with glasses. They are to be found in many of the jewelry stores; there is not a day the oculists of this city do not correct some of the errors of these men. The glasses they furnish are injurious to the eyes of those wearing them; they think that all eyes having defective vision need glasses, therefore, prescribe them when the visual defect is due to choroidal or retinal inflammation, beginning cataract, optic neuritis, etc. One of the first and most important methods of examining an eye to determine whether an error of refraction or disease exists is by means of the ophthalmoscope; in many instances photographs, as it were, of many diseases which have their origin in remote parts of the body can be seen: patients who have applied to the oculist for glasses have learned for the first time that they are the victims of some incurable disease; we see such photographs in albuminuria diabetes, cerebral tumors, locomotor ataxia, etc. In such cases the oculist instead of trying to remedy the lack of visual acuity by glasses refers the patient to the family physician for general treatment. Have we not here an object lesson? Who can say how many diseases have gained headway and progressed beyond being remedied, among those in whom the first symptoms became manifest by the lack of visual acuity and who applied to the optician for aid and were furnished with glasses, the true condition not having been discovered until in despair they consulted an oculist.

The assurance of these men is appalling and they are a menace to the welfare of the public, against the perpetuation of such iniquitous optical practices as described; in this city we are powerless at present to do more than protest. Ohio has taken the initiative step to correct this evil. "The regulation about to become operative under the 'medical regulation law,' recently passed by the Legislature, will materially reduce the evils of refracting opticians by making a large portion of the work done by them a penal offense. Other States must follow suit; the future is encouraging; all that is needed is determination and action!" We have now, through the united and untiring efforts of our physicians, a medical bill, which a few amendments will make an ideal one, and we hope that in the near future, the same champions of our cause will secure such changes as will make it perfect in all its requirements, and we sincerely hope that a clause will be inserted making it a penal offense for any but a graduate of medicine and one who can pass a satisfactory examination in practical refraction to examine, prescribe or fit glasses to the eyes of the public; for it is the belief of the writer that, with better correction of refraction errors by skilful ophthalmologists who have kept abreast of the times and who are thoroughly equipped with the best of modern paraphernalia, great and lasting benefit will result to the eyes of the present and coming generations, preventing and curing many serious ocular diseases, as better methods of sanitation and hygiene have been effective in preventing the ravages of such diseases as cholera, typhoid fever, yellow fever, etc.

1016 I Street.

## MEDICAL PARIS.

NOTES FROM MY SKETCH-BOOK

BY L. HARRISON METTLER, A.M., M.D.

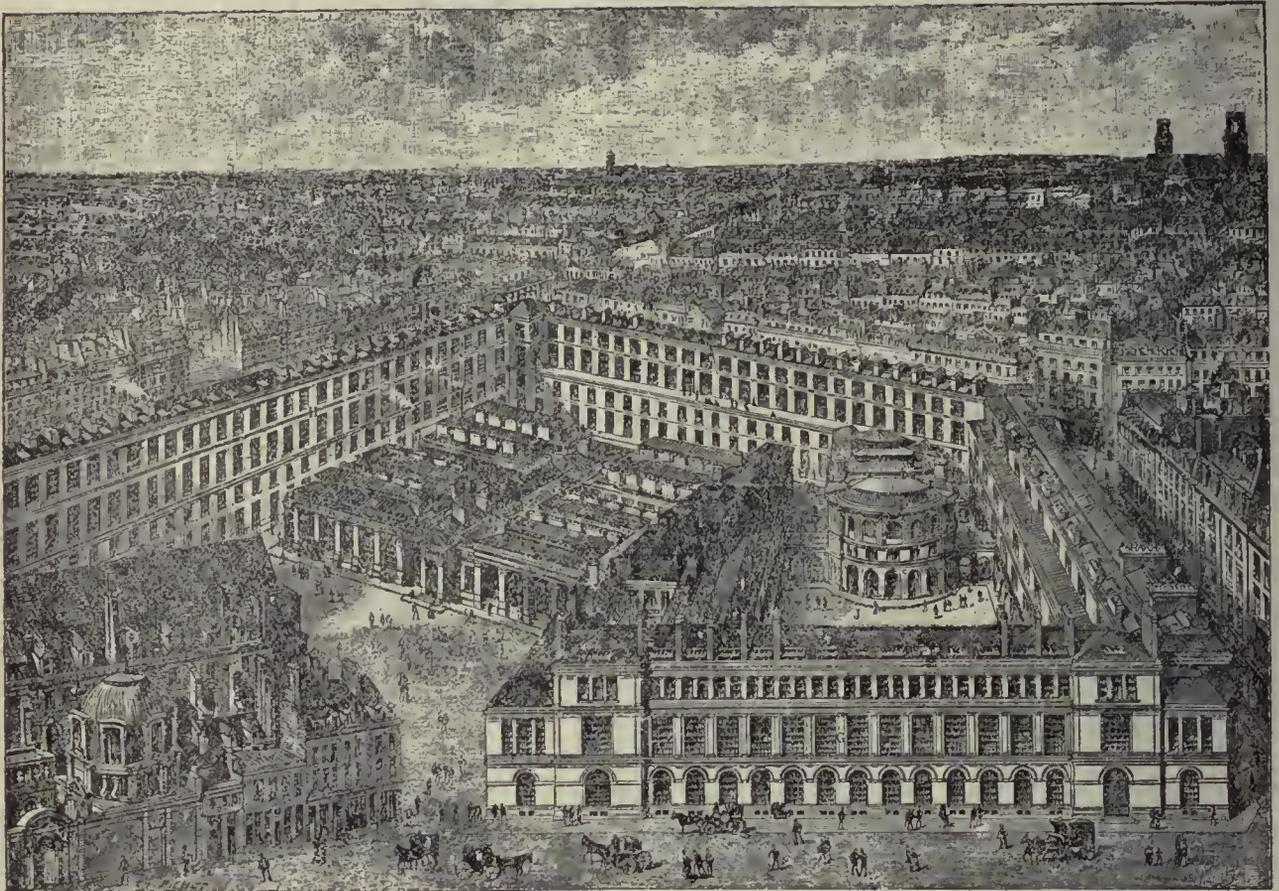

CHICAGO, ILL.

To have seen Paris is to have seen the world; few are the tourists, however, that ever see Paris. A room in a hotel near the Opera and a few buildings viewed from an open barouche is not Paris. Once I met a traveler who had sauntered about the "city of delights" some three long months, and yet had not observed that the Notre Dame cathedral was upon an island. Except Rome, probably no city in the world has been so much written about or has played so picturesque a rôle in history as Paris. It is so full of novel attractions, historical relics and romantic reminiscences, so adorned with all the beauties of art and architecture, so enriched with the most modern scientific and sanitary improvements, so systematized in government and municipal management, that an American physician might well be excused for forgetting that medical Paris is equally as full of historic anecdote and modern achievement. Ah! no, be not deceived; medical Paris can not be seen in a three-days' sojourn, with an occasional call at the Pasteur Institute or the Hotel Dieu Hospital. When Vienna was little else than a Roman fortress, when Berlin was still a little group of huts and drying fish-nets, when Munich was only a monastery and when even London was little more than a Saxon hamlet, Paris was a royal city, the seat of government and the site of a university. In the sixth century Clovis chose it as his residence, and in the tenth century Hugh Capet encouraged its learning so as to lay at that early day the foundation of the future reputation of its great schools.

The actual beginning of the University of Paris was in 1253 under Robert Sorbonne. One of its earliest and most flourishing departments was that of medicine. To-day there are six medical schools in France, namely, Paris, Montpellier, Nancy, Lille, Lyons and Bordeaux. The great reputation of Paris as a medical center began about the middle of the fifteenth century. In 1618 the first amphitheater for anatomic demonstrations was erected. This was rebuilt in 1744 and was soon discovered to be inadequate. Lamartinière, Surgeon to Louis XV, obtained the ground of the College of Bourgogne in the Rue des Cordeliers and began the construction of the present vast assemblage of buildings known as the *École de Médecine*. They were not completed until 1785 and on account of their architectural beauty they made the reputation of their designer, Gondouin. They were opened for use Aug. 31, 1776. There is a main building, flanked by two wings, joined by an open gallery. In a word, there are four buildings surrounding a court-yard, sixty-six feet in depth and ninety-six in breadth. The main frontage upon the street extends a distance of 198 feet. The open gallery, consisting of a double row of Ionic columns, is surmounted by a second story. The anatomic museum and library are found on the first floor. The amphitheater at the bottom of the court is capable of holding 1,200 persons. In the wings are spacious halls for various demonstrations. Over the main portal is a bas-relief of Louis XV, between the allegoric figures of *Wisdom*, little of which he seems to have possessed, and *Benevolence*, too much of which he exhibited for his own good. In front of the entrance stands the bronze

statue of Bichat, the anatomist. In fact, all about the buildings are memorials of various eminent medical men, such as Broca, Petit, Marechal, Paré, Pitard and Peyronnie. During the latter years many additions have been made to the old *École de Médecine*, especially the magnificent façade upon the boulevard St. Germain. To the casual tourist of a medical turn of mind, however, the most interesting of all this assemblage of bâtimens is the ancient structure, which looks from the outside like a church. It is the ancient refectory of a Franciscan monastery, but is now used as a pathologic museum and known as the Musée Dupuytren. How many names, now famous in the history of medicine, did I see on the specimens in this quaint old museum! As I saw upon this bottle or that skull, the names of Paré, Velpeau,

Quarter is and why it is so called, the tourist can not do better than read Victor Hugo's "Notre Dame," wherein a certain chapter is set apart for a brilliant description of the origin and development of Paris. Originally Paris was confined to an island in the middle of the Seine River. To-day this part of the capital is known as La Cité, and contains among many notable buildings the Notre Dame Cathedral, in the shadow of which nestles the historic old Hotel Dieu Hospital, of which I will have something to say later on. As the city grew, its extension beyond the limits of the island away to the north, or right bank of the river became known as La Ville, and contains the palaces, municipal buildings, art galleries and residences of the aristocracy. On the south, or left bank of the river stood the University in all its pride, independence

ÉCOLE DE MÉDECINE, PARIS.

Larrey, Nélaton, Broussais, Dupuytren and others, it seemed to me as though I were reading a history, not only of medicine but of Paris as well; and memories of the early kings of France and their wars, of Napoleon and of the French revolution poured in upon me.

The applicants for admission to any of the medical schools of France must possess the "diplôme de bachelier ès lettres," or the "diplôme de bachelier ès sciences restreint," equivalent to the B. A. of London University, with considerable knowledge of chemistry, zoölogy, botany, geology and astronomy.

The *École de Médecine* is in the heart of the Latin Quarter of Paris, whither one must go, if, as Thackeray says, "he is to study the humanities or the pleasant art of amputation." Now to learn where the Latin

and scholarship, and its immediate vicinity, so dear to the heart of the student, ere long became known as Le Quartier Latin. I am unable to say why this particular part of Paris should be called the Latin Quarter, unless because here are most of the great schools and here the scholars congregate in their crowded lodgings, conferring upon the neighborhood the general air of Latinity that usually surrounds student life. As it is also one of the oldest sections of the city, that, too, may have a little to do with its pagan appellation. To know the Latin Quarter is to know Paris, and to dwell therein awhile is to observe student life such as it will be seen in no other city in the world. Space forbids my description of it here, but the reader who wishes to revive memories of his days in the good old

Latin Quarter, will do well to read a few chapters of Ohnet's story of "Dr. Rameau."

One day shortly after my arrival in Paris I found myself in the great courtyard of the Ecole de Médecine. Groups of students standing about or seated upon the doorsteps of the main entrance were vehemently discussing the "examens." It was a rare sight, these fiery, excitable, gesticulating French lads—or rather men I might say—chattering and bobbing to one another in a most tremendous fashion, about the soul-harrowing examinations which they were to undergo or had just escaped. They could not talk fast enough (a Frenchman never can) and each individual that emerged from the doorway was pounced upon as wolves pounce upon a helpless lamb and was all but annihilated with questions and gesticulations. There were others who stood silently apart and in rather a comical manner kept their lips moving while their eyes were riveted upon mysterious looking little bits of paper which they kept stored away somewhere in the depths of their capacious pockets. All at once there was a profound stir among the various groups. The mysterious papers disappeared, the mutterings changed to mute reverence, ears were less strained, the noisy chatter and wild gesticulations ceased, some of the fellows moved off in a kind of nonchalant manner, others seated on the doorsteps leaped up and started off or stood near where they had been sitting in an attitude of almost oriental obeisance, while all acted as if royalty itself were approaching. Their majesties consisted, however, of only a few members of the faculty including the late Professor Charcot. When this section of the faculty had vanished beneath the shadow of the doorway, the chatter and gesticulations, as only Frenchmen are capable of, began again with tenfold energy. I saw many of the students following the professors and did likewise. In one of the upper corridors the professors scattered and disappeared in various small apartments. In and out of these rooms strolled the students as though they were merely visiting some anteroom of the Louvre or Luxembourg. I did the same and this is what I saw: At one end of the room, behind a railing was placed a green-covered table, behind which sat the examiner, the referee and perhaps an additional member or two of the faculty or subfaculty. Outside of the railing, huddled as closely to one another as possible, were fifteen or twenty students, one of whom at the time was undergoing an oral examination, causing him untold miseries. He would blush like the setting sun, his knees and hands would tremble like the sunbeams on a ruffled lake, and his tongue would scarcely realize whether it were talking sense or nonsense. He felt ill at ease, to be sure, but he was not in the least ashamed, for he knew he had the hearty sympathy of the fellows about him. Their turn was yet to come. Thus are the examinations conducted at the great medical school of Paris; open to all and before several witnesses and referees. It is a severe test, but one has the consciousness of knowing that it is fair and equal to all alike. The questions were plain, direct, and practical. They were not in the least framed merely to trip the student on some rare and abstruse item. Scholars whose homes were in most distant parts of the world were undergoing the ordeal.

In the vicinity of the medical school are many book stores, some of them devoted exclusively to medical literature. They are patronized freely by the pupils and in some respects resemble small public

libraries, in that every one is welcome to enter and thumb over the books. Paris publishes quite a number of excellent medical journals, notably *La Semaine Médicale*, *La France Médicale*, a small but sprightly sheet which appears three times a week, *Le Journal de Médecine*, which is Dr. Luteaud's organ, and a vigorous one it is, too, and many others of lesser importance. There are quarterly publications with the clinics of the Salpêtrière and special reports of the French Academy of Medicine. I can not say, however, that the French journals compare favorably with the great English weeklies; in style and general typographic appearance, however, they maintain the proverbial French reputation for this particular kind of work.

The history of the management of the public charities, and especially of the hospitals of Paris, forms an interesting chapter in itself. In the earliest times the convents and monasteries, both of the city and its suburbs, offered a retreat not only to pilgrims, but also to the sick and insane. Gradually these establishments erected special buildings for the sick within their domains, and while the monks administered the treatment, the sisters attended to the nursing. In 816 Charlemagne decreed that at each See one of the canons should always govern the hospital or hospice; and that these institutions should always be in close proximity to the cathedral. This explains the near association of hospitals and great churches in many parts of Europe to-day, as, for instance, Notre Dame and the Hotel Dieu of Paris. The control of the hospitals by the clergy continued until the beginning of the sixteenth century. After that date governors were selected partly from the laity, though the religious orders continued to bear an important share in their management. As the charitable institutions developed, as they were more and more assisted by the state and private benefactions, the transfer of their government from the church to the state became more and more complete.

The Assistance Publique forms one of the administrative departments to-day of the Prefecture of the Seine. Its revenues exceed forty million francs, obtained by a tax on the receipts of theaters and other places of amusement, on burials and on the Monts de Piété or government pawning offices, of which there are twenty-five. Among other charities it has under its supervision some twenty-two civil, general and special hospitals, nineteen public hospices, twenty-seven asylums and almshouses and three military hospitals.

The largest as well as the most famous of the Paris hospitals are the Hotel Dieu and the Salpêtrière. As a student for a number of weeks at the Salpêtrière, I enjoyed the opportunity of watching some of the work at both institutions and in another paper will have something to relate of their history and clinics. I would that space allowed me to do more than merely refer to some of the others, for a visit to the Charité with its 504 beds, its history running back to Marie de Medicis in 1602, its founder, and its interesting chapel constructed at the end of the last century and now used for the meetings of the Academy of Medicine, or a morning call at the modern and elegant Lariboisière, with its 636 beds and the magnificent tomb of Madame Lariboisière, its benefactress, in the chapel, is something to carry long in one's memory. The Hôpital du Midi was in 1613 an old convent, but is now a hospital with 336 beds. Was it not here

that Ricord, the famous Frenchified American doctor came and first established his own school after his rupture with the great Dupuytren! And was it not here that he made those marvelous pathologic studies in regard to certain unmentionable diseases, which ran counter to and overthrew all previously conceived notions! Certainly, and the American physician who is interested in les hommes atteints de maladies vénériennes, will be sure to visit Le Midi. As that same American physician is singularly interested in les maladies de la peau, he will go direct from the Midi to the Saint Louis, which was founded in 1607 by Henry IV. and contains 823 beds. I would like to be able to sketch this quaint old hospital for skin diseases as I saw it, its low creaking doors, its musty, close little rooms, its pleasant, quiet little courtyard with gravel walks and ancient trees, its energetic, loquacious old porter, and its remarkably rich clinic, presided over by the distinguished Fournier, but I must hasten on.

A clinical lecture at the new and artistic Clinique d'Accouchement by the great Tarnier is a revelation to an American. The manner and method of it is something to be envied by all teachers of obstetrics. But I must forbear and close by simply mentioning the Hôpital Beaujon, with its 422 beds, the Cochin Hospital, with its 201 beds, the Hôpital Laennec, dating back to 1634 and containing 311 beds, the Necker Hospital, with 418 beds, the Hôpital Saint Antoine, with 594 beds, the Hôpital Tenon, with 635 beds, and such other special hospitals as the Lourcine, with its 276 beds, for women afflicted with venereal disease, the Maternité, with its 316 beds, the Hôpital des Enfants Malades, with its 518 beds for the little folks, and the Hôpital Broussais, with its 260 beds. These are not all by any means, and most of the hospices and asylums which are of particular interest I have not even attempted to mention.

4544 Lake Avenue.

## SELECTIONS.

**Abnormal Mobility of the Liver.**—Mr. John Morris, in the *Practitioner*, discusses some cases of this morbid condition that have lately been recorded, inclusive of one by Dr. J. E. Graham of Montreal. "Dr. Graham published his case with a facsimile of a woodcut showing a displaced liver, published by Heister in the year 1754. No fewer than seventy cases were tabulated, excluding all in which the displacement was due to causes above the diaphragm, and also those in which it was due to tumors or abscesses between the liver and the diaphragm. Of course the diagnosis was not certain in all the cases. A large majority occurred in women who had pendulous bellies after frequent child-bearing. In the only well-marked case that I have seen, the luxation followed the rapid disappearance of a large fibroid tumor at the menopause. The abdominal wall was thin, and the liver edge could be easily defined by palpation at the level of the anterior and superior iliac spines. The organ could be pushed into its proper position, and an abdominal belt gave considerable relief. Abdominal section has been performed (sometimes on a mistaken diagnosis), and the liver has been fixed to the abdominal wall; but I have not observed a record of any such case when sufficient time had elapsed to enable us to know whether real benefit resulted.

"Cases of undue mobility of a portion of the liver have been recorded. Bastianelli (*Il Policlinico*, 1895) has detailed a case in which he diagnosed a cancerous right kidney. An abdom-

inal section having been performed, the tumor was found to be a portion of liver attached to the main mass of the gland by a band of hepatic tissue. The pedunculate mass contained growths which were afterward found to be gummata. It was removed with the gall bladder, which lay on its under surface, and the patient was seen thirteen months later in good health, and seven months pregnant. I have seen a case in which a similar diagnosis of kidney tumor was made, and on operating, a portion of the right lobe of the liver was found to be bent on the main mass, the line of flexion being very thin, and permitting free movement. At a recent meeting of the Medico-Chirurgical Society, Mr. Mayo Robson related a case in which he cut down on a gall-bladder and found that it was the seat of malignant disease, there being also a nodule in the liver close to the growth in the gall bladder. The liver was somewhat displaced downward, and it was found possible to draw the affected portion of the gland and the gall-bladder out of the abdomen, and to make an artificial constriction of the liver substance behind the disease by means of an India-rubber tube. The constricted portion was transfixed by two knitting needles and secured outside the abdominal wound after the plan commonly adopted in performing hysterectomy, the distal part being cut away. A small growth, in which no malignant elements were found, was removed from the abdominal wall of this patient some three months later and ten days before the reporting of the case. Recovery followed, but sufficient time had not elapsed to allow of the permanent effect of the operation being recorded. Bastianelli (*loc. cit.*) attributed floating liver lobes to malformation, acquired deformity, as from pressure, and the traction of new growths."

**Acute Peritonitis Produced by the Pneumococcus.**—The three last numbers of the *Archives Clin. de Bordeaux* (3, 4 and 5) are almost entirely devoted to a critical study of this comparatively rare disease: Acute peritonitis caused by the presence of virulent pneumococci in the peritoneal cavity. As the disease usually terminates fatally, without prompt and sufficient surgical intervention, it is of the utmost importance to be able to diagnose it at once. The author, Professor Cassaet, first proves its existence as a pathologic entity, and its essential element, the virulent pneumococcus. It develops at all ages, without distinction as to sex or season, but preferably where there has been some former lesion in the abdomen or when the resisting powers of the organism are diminished from any cause. The infecting agent penetrates into the serous membrane without assistance from any other pathogenic or saprophytic agent, either through the skin or intestine after traumatism or from inflammations, tumors, etc., in the genital region or elsewhere, or conveyed by the blood or lymphatics. Colonizing there it produces its specific lesions, the same as in the lungs, with the same effusion and tendency to wall in the purulent collections. Cassaet suggests that one reason why the lungs are so much more frequently the seat of the disease than the abdomen may be that the microorganisms are so easily inhaled and remained unchanged in the lungs, while it is a much more difficult matter to reach the peritoneal cavity and run the gauntlet of the secretions of the alimentary canal. Primary pneumococcus peritonitis is distinguished by an absolute absence of prodromes, by its abrupt début, commencing suddenly, like a thunderclap, in the midst of apparent health or following some other disease. The principal manifestations are sudden, intense pain, vomiting of bile, profuse diarrhea, occasionally a few chills. In the secondary stage the fever rises, the pulse grows more rapid, respiration labored, the urine decreases and contains albumin, and the entire organism is gravely affected. There is no tympanitic resonance, although the abdomen is enormously distended; it offers a certain soft resistance to the finger, changing to an undulation, slight at first, becoming an actual fluctuation, amounting at last to the

sensation of a vast accumulation of fluid inside. The meteorism does not appear until a day or so after the pain period. As the meteorism gradually increases the fever declines and the pain subsides; an important indication differentiation. The terminal period is short if the infection is severe; death follows without much change from the preceding conditions. It lasts longer if the body has had strength enough to survive till the purulent period, when the symptoms are those of true septicæmia, subsiding to those of a circumscribed abscess, when the encysting process has been accomplished. Comparing it with the other forms of peritonitis, it is distinguished from puerperal peritonitis by its absolutely sudden beginning and the absence of repeated chills and fetid discharges. It resembles appendicular peritonitis, but as the treatment is the same for both, differentiation is not imperative. It can be distinguished from the peritonitis following perforation, as the fever in the latter is higher from the start, with subsequent hypothermia; the dysuria is more complete, the meteorism more sudden, the dulness more immediate and the evolution more rapid. The history of the case may also proclaim the probability of perforation. Careful study of all the cases on record and others proves that laparotomy is the only means of cure; and it must be prompt and effectual so as to open and clear every infected focus. It must be median laparotomy, extensive enough to insure a minute exploration of the flanks and hypochondriac region. Several cases reported, which were doing well after laparotomy, succumbed later and the necropsy disclosed unsuspected purulent collections behind the liver or elsewhere which had escaped notice. The percentage of recoveries in the cases on record which were treated in an effective manner amounts to 80 per cent., but the mortality is 75 per cent. in the general average of cases. We add the author's summary of the various pneumococcus infections which may follow or appear independently of pneumonia: Bronchitis, broncho-pneumonia, pleurisy, pericarditis, endocarditis, sporadic and epidemic meningitis, arthritis, amygdalitis, pseudo-membranous angina, enteritis, nephritis, metritis, inflammations of the nasal cavities and sinus, otitis of the middle ear, osteo-periostitis, abscesses and inflammations of the connective tissue.

**The "Curatel" Treatment of Inebriates in Austria.**—The treatment of habitual alcoholics in Austria is attended with difficulty, the laws having been so framed as to leave that class virtually without direct constraint. Drunkards, in that country, come under the same class as idiots or spendthrifts. A special report on this subject in the *London Lancet* for June 6 further states that the process of "curatel," whereby the court appoints a curator or administrator for persons who do not look after their own affairs and who are unable to defend their rights, is made applicable not only to children, lunatics and idiots, but also to those who having been declared "spendthrifts" by a magistrate, have been deprived of the administration of their property. A man may be judicially termed a spendthrift if it appears on examination of the charge that he is running through his property in a senseless way and that he is exposing his family to future destitution by contracting loans under reckless or ruinous conditions. In some kingdoms, as in Galicia and Lodomeria, there is a special law for the prevention of drunkenness, and one section provides that on being convicted of drunkenness three times in one year the district authorities may forbid the offender to visit public-houses or liquor shops in the neighborhood of his domicile for the period of one year, under pain of fine or imprisonment. "The inadvisability of mixing mere drunkards with the insane in asylums is fully recognized by the Austrian authorities. Last year a bill for the erection of public asylums or establishments for the cure and reform of drunkards was brought into the Reichsrath by the Minister of Justice. These

institutions are intended for the reception of 1, those who have been judicially punished for drunkenness three times in the course of one year; 2, those mentally affected owing to habitual or periodical abuse of alcohol who have been admitted into hospitals or lunatic asylums, and who, although they have recovered their sanity, have not sufficient self-command to resist the temptation to drink; and 3, those who, owing to habitual or periodical abuse of alcohol, endanger the moral, physical or financial security of themselves or their relations. Provision is also made for the compulsory retention of patients for a period which may not exceed two years, and placing the police and judicial authorities at the disposal of the administration of the asylum in order to recover fugitives from the same. Consideration is given to the proper safeguarding of the individual from the illegal and undue application of the various processes upon which detention in an asylum may be carried out."

**Dress Reform for Women Rendered Probable by the Bicycle Costume.**—A female medical practitioner who has ridden the wheel since 1888, has expressed herself as sanguine that a healthful and comfortable dress will be the outcome of the extension of the bicycle habit among females. She states that she has modeled one for her own use, which satisfies her as preferable, on a variety of occasions, to the dirt-collecting long skirt. "I frequently shop in my bicycle costume," she said, "and, while much staring and often audible comment greet me, yet I think if the costume were universally adopted it would soon cease to be noticeable. As to its merits there can be no doubt, and no woman who has experienced the freedom and comfort of the short, light skirt will willingly return to the long, heavily lined skirt which fashion now prescribes. Women are slaves of fashion, and it will be a difficult matter to bring the most approved style or short skirt in vogue, for it is detrimental to the interests of the mercantile trade. Many furbelows would follow the long skirt if it were discarded and in its stead a modification of the bicycle costume adopted, for the latter only lends itself to the severest adornment. I object to bloomers," she continued, "because they create unfavorable comment and are often immodest. I think it is a great mistake for women to walk around and sweep up the dirt with their skirts, and I am in hearty sympathy with any movement to get rid of them for a more sensible style of dress. I do not wear corsets, and I have used my pen and voice equally to persuade other women to discard them. In some cases I have been successful, but in nine cases out of ten a woman clings to her corset as the drowning man clings to a straw. The long skirt is equally reprehensible, and there is no garment so ungraceful, so suggestive of untidiness as a long, rain or dirt bedraggled skirt. Especially is this the case in stormy weather, when woman requires all her strength and the free use of both hands and limbs to battle with the elements, and is generally so encumbered with umbrella, bag and parcels, that her skirts are allowed to trail unnoticed through wet streets. Any dress which it will not be necessary to hold up and will be comfortable and useful, will be welcomed by all sensible women. The bicycle costume, when the skirts are a graceful length, and not too light about the hips, seems an ideal costume for a rainy day, and adaptable to walking and outing generally. I shall be most happy to advocate its use. A learned gentleman once told me that women would never attain the same power intellectually and physically as men until they freed themselves from hampering clothes. Men will not submit to uncomfortable fashions in clothing, and consequently do not suffer from the nervous disorders that are produced by the unhygienic and irritating clothes that are worn by women."

**A Mild Epidemic of Scarlet Fever at Louisville.**—In the *American Practitioner and News*, June 27, Dr. John Larrabee depicts the differences that present themselves in two epidem-

ics of fever, just twenty years apart, in the same town. The epidemic of 1876 was grave and distressful, while that of 1896 is designated as "benign"; and some of the physicians go so far as to disregard the isolation of the well. In the discussion of the subject before the Medico-Chirurgical Society of that city he went so far as to say that the type of the epidemic fever was so mild that he would not insist on quarantine because it was a good chance for the unprotected children to obtain immunization at a low risk. Other members expressed the like opinion. To those of us who have never yet encountered a benign epidemic of scarlet fever, an avowed neglect of isolation is "a hard saying," but these gentlemen of Louisville are open-eyed and humane practitioners, so that we know that the apparently "thin ice" they are testing will be abandoned so soon as they discover that their course is hazardous.

Dr. Larrabee opens his paper with a historic reference that illustrates in an admirable way the capricious behavior of scarlatina. He says: "It is well to remember that scarlet fever was differentiated from measles about two centuries ago. Its history for upward of two hundred years, the period in which it has been known, is peculiarly interesting. None of the exanthemata is subject to such variations. Thus the description given by Sydenham of the first great London epidemic, contrary to what should be expected, was that of a light and trivial disease, only dangerous by the officiousness of the doctors: 'Vix novem morbi merebantur.' And it was he who first differentiated scarlet fever from measles, an older and more prevalent disease. This is certainly a strange contrast with the observations of more recent periods both in Europe and America. Its prevalence in the eighteenth and nineteenth centuries warrants the conclusion that it has steadily increased in potency until it has come to be considered one of the most treacherous as well as fatal diseases of childhood. Löschner, fifty years ago, wrote that he had never seen a benign epidemic. Thirteen per cent. of all cases became dropsical, and 38 per cent of all dropsical cases died. Epidemics of scarlet fever vary not only in severity but also in complications. Some have been largely anginose, others noted for rheumatic complications. The mortality has ranged from 13 to 40 per cent. and then again as low as 3 to 4 per cent. Köstlen wrote that scarlet fever disappeared entirely from his practice for fifteen years, and that there was not a case in Stuttgart from 1830 to 1846, at which time an epidemic occurred in which there were no fatal cases. Those who have had experience with the present prevalence of scarlet fever will, I think, agree with me that in point of severity cases are in strange contrast with those which we have been accustomed to see in former epidemics. The word epidemic is not strictly proper to apply to the present prevalence as to the number of cases, and still the disease is so widespread as to be out of consideration as an endemic. If epidemic, it must certainly be considered benign.

Regarding first epidemics we are taught to believe in their severity, and such was the case with measles in the Phillipine Islands several years ago. In scarlet fever we have a disease in which the first epidemic known was as mild as at present. A point that has not been discussed sufficiently was the proportion of complications in different epidemics. It was my privilege to see the epidemic of 1876. I saw in my own practice thirteen deaths. In two cases the temperature ran up to 110 degrees F. before the eruption appeared, the other case being typical scarlet fever. In regard to middle ear troubles, the point I insist upon is that cleansing the throat should be made a routine practice whether the throat is sore or not, and in all cases of the disease however mild. In regard to the point of contagiousness the remarks have been surprising. Negatives never prove anything. The fact that a child does not contract the disease when exposed does not prove anything; but a child getting the disease when exposed proves the whole question. I have always looked upon scarlet fever as the high-

est and most persistent type of contagion with which we have to deal. In regard to the rheumatic complications of the disease and the discussion upon that point, I desire to be understood that this is a true rheumatism and that the conditions of metabolism are as perfect to produce it as could be. The rheumatism complicating scarlet fever yields at once to salicylates, which of course we all employ.

**A Bishop Upholds Vivisection.**—Bishop Lawrence, at the last annual meeting of the Massachusetts Medical Society, June, 1896, gave a pointed rebuke to the antivivisectionists of his State, which was wise and timely. The remarks given below contain the Bishop's reference to that subject and also a recognition of the debt the Commonwealth owes to the altruistic ranks of medicine:

"Speaking not only for myself, but also for the great religious sentiment of this Commonwealth, I can say that wherever one finds any representative member of this Society, one is impressed, he is humbled, by the devotion of the doctors to their work, by their instinctive love of their profession, by their interest in the scientific lines of their work, and by the service they devote unweariedly to their fellow men. The public spirit of the physicians throughout this State, in relation to their hospitals, to sanitary movements, and to all other civic movements which bear upon their profession, is recognized; but I can not quite believe that they are sufficiently recognized by the people. They are doing untold work in all those lines. The readiness with which the physicians of Massachusetts and of this Society respond to calls, without asking questions as to whether they are to receive money in return or not—and they are sometimes imposed upon—is remarkable. The work is done cheerfully and willingly, and is the best form of charity. I can not, therefore, understand how it can be that a great body of people in this Commonwealth can so far distrust the great body of these physicians—can so far distrust their tenderness, their humanity, their sensitiveness to pain—as to bring any unwise, unreasonable restrictions to bear upon scientific study as expressed in vivisection. The people of this Commonwealth have tender hearts, and though they may be New Englanders externally, they are desirous of seeing that no hurt shall come to the animals. At the same time, it seems to me that into no hands can the welfare of lower forms of creation and the question of vivisection be more confidently placed, than into the hands of the recognized medical fraternity of this Commonwealth. In reviewing in my mind the character of the good physician and his value to the community in which he lives, I can not help thinking of another medical man whom, like your president-elect, I have known as a friend and neighbor for many years, and to whose sympathy and help in time of need so many in Cambridge can testify; I mean Dr. Morrill Wyman. He comes of a family in which are united the love of pure science and the love of humanity. I need not remind you of the scientific work of his brother, Jeffries Wyman. Dr. Morrill Wyman unites the qualities of an enthusiastic, earnest, progressive student of the medical sciences, and a most skillful and devoted practitioner of his art. I remember his telling me of the remark of an old lady, a patient of his, upon whom he had just performed a very delicate operation, which illustrates the regard which is felt for such men by their patients. After the operation was over she said to him, rather to his chagrin, 'After all, physicians are but instruments in the hands of God.' But she soon set him at ease by adding, 'But there is a great deal of choice in the instrument.' If each physician learns, as I hope he does, to regard himself as an instrument in the hands of God, to be more fully developed for His honor and the welfare of humanity, he has within him untold possibilities of usefulness."

## PRACTICAL NOTES.

**Chronic Pharyngitis.**—Iodum .5 gm., potass. iodid 1.0 gm., menthol and glycerin aa q. s. ad 5.0 gms. Apply two or three times daily.—*Pac. Med. Jour.*, August.

**Loeffler's Solution.**—Alcohol 60 parts, toluol 37 parts, liq. ferri perchlorid 4 parts. Swab the affected parts with this every two or four hours.—*Pac. Med. Jour.*, August.

**Camphor Dressing for the Sores left after Furunculosis.**—Castellan states that the best dressing for this purpose for sailors and laborers is pulverized camphor sifted on the sore and covered

with an aseptic linen cloth, which is to be kept constantly wet with a boric solution or camphorated alcohol.—*Semaine Méd.*, July 29.

**As Anthelmintic.**—Tape worm is said to be best treated with ten drop doses in water, three times a day, of a mixture consisting of hydriodate of potash, 3 gms.; iodine, 1 gm., and water 40 c.c.—*Med. Sentinel*, August.

**Effects of Elevated Altitudes on the Constituents of the Blood.**—Recent experiments confirm the announcement that the number of red blood corpuscles increases in mountain air, and gradually returns to the usual number after return to a lower level. It is also established that the increase is an absolute formation of new corpuscles.—*Wien. Klin. Rund.*, July 19.

**A Point in Differentiating Obturator Herola.**—Landerer describes a rare case of acute osteomyelitis of the bony frame of the obturator canal, which had every indication of an obturator hernia, with pus formation, even after exploratory laparotomy and drainage. Two months elapsed before the discharge of a piece of the pubis with pus, followed by recovery.—*Cbl. f. Chir.* July 11.

**Treatment of Tetanus with Carbolic Injections; Baccelli's Method.**—A man of 68 arrested the flow of blood from a crushed finger with manure, and in six days tetanus followed. It was treated with seven to eight injections a day of 0.01 to 0.02 g. acidum carbolicum after the wound had been disinfected with sublimate and iodoform, and hourly tepid baths after the fourth day of treatment. The patient was dismissed in ten days entirely recovered.—*Gaz. degli Osp. e delle Clin.*, June 27.

**Early Diagnosis of Pregnancy; Hegar's Sign.**—Hegar's sign seldom fails to diagnose pregnancy as early as the sixth or tenth week. It consists in a change in the body of the uterus, which becomes spheroidal in shape and soft to the touch, while the neck retains its tenacity and shape until much later. The uterus is thus palpated as a round, yielding body mounted on the straight cylinder of the neck. In connection with the cessation of the menses, disturbances in the digestion, ptyalism, changes in the breasts, slaty appearance of the vagina and vulva in a primipara and varicose appearances around the external genital organs and on the lower limbs, the diagnosis of pregnancy is certain in the great majority of cases.—*Lyon Méd.*, No. 5.

**Treatment of Vitreous Hemorrhage by Sodium Iodid.**—Dr. De Schweinitz states that in vitreous hemorrhage, if not otherwise contraindicated, the internal administration of frequently repeated small doses of sodium iodid materially aids in the absorption of the effused blood. This is particularly true of myopic eyes which are predisposed to hemorrhages of this character by reason of changes in the choroidal and ciliary vessels. In place of the sodium iodid, or sometimes alternating with it, he is accustomed to give the fluid extract of jaborandi in doses just short of its diaphoretic action, or small doses, for example a tenth of a grain, of pilocarpin hydrochlorate.—*Weir's Index*, June 15.

**Catheterization of the Pylorus Through the Mouth.**—Kuhn of Giessen has invented a sound which can be passed through the mouth into the stomach and through the pylorus into the intestines, even as far as the iliac fossa. It consists of a long metal spiral spring enclosed in a rubber tube. It is so flexible that it makes its way through the most winding passages with a vermiform motion, when carefully twisted. A small rubber bag at the end can be blown up through the tube at any time. This can be palpated and the course of the sound followed. It promises to render great services in the treatment of strictures of the pylorus and intestines, in administering medicine directly into the intestines, sparing the stomach, and in radiography, etc.—*Semaine Méd.*, July 29.

**Action of Alkalies on Carbohydrates.**—If some alkali is added to the solutions of certain carbohydrates, the transforming

power is altered, and in such a way that one sugar is transformed into another. Glucose, fructose and mannose are thus transformed and it is immaterial which one is used to start with. There is also, at least for the substance thus formed, a certain equilibrium reaction, which is prevented from becoming absolute equilibrium by another reaction occurring at the same time, the formation of acid. In all probability the fructose is the immediate link in the transformation of glucose into mannose, and of the mannose into glucose. The process itself may be the work of some of the hydroxyl group. A similar process may occur in plants, which would explain the production of cane-sugar out of glucose.—*Cbl. f. Phys.*, July 11, from *Ber. d. d. ehem. Ges.* page 3078.

**Treatment of Pertussis.**—Dr. Charles Gilmore Kerley reports relative to treatment as follows: "Antipyrin, bromide and belladonna were each used in several groups of twenty. The ages of the cases treated varied from 6 weeks to 5 years. They were of every condition of bodily strength and weakness. The duration of an attack was not shortened in a single instance. Antipyrin gave the best results. Under its use the number and severity of the paroxysms subsided. A combination of the bromide of soda, potash and ammonia came next. The much vaunted belladonna appeared to exert little or no influence. It was given to the point of physiologic effect. Alum gave practically negative results. Dilute nitric acid and fluid extract of horse chestnut leaves were utter failures. The results in a few cases in which antipyrin was used were notably good. The number of paroxysms diminished one-half in some, one-third in others.—*N. Y. Polyclinie*, August.

**Hypertrophy of Prostate Treated by Castration.**—The *Medical News*, July 25, has an analysis of twelve cases of this nature, as reported by Dr. C. W. Mansell Moullin, the well-known author and surgeon to the London Hospital, before the Harveian Society, which were attended with gratifying results. "In two cases, both under his own care, death had taken place five and nine days respectively after operation; one death was due to cerebral hemorrhage, the other from fatty degeneration of the heart. In two cases, both of which ultimately recovered, traumatic delirium in severe form came on very soon after the operation. In all twelve cases, even inclusive of that which was fatal on the fifth day, there was reported a distinct improvement as to obstruction, and in those cases which remained under observation a sufficient long time to enable the surgeon to measure the size of the prostates, there was found an appreciable diminution in size, as measured both by urethral and rectal examinations. One case, less successful than others, was that of a patient, 80 years of age, the diminution in size when measured by the finger in the rectum was not very great, and voluntary control was not regained. But as a soft catheter passed easily, whereas before only a metal one or a bougie could be used, and that with difficulty, and as the stranguary, which had resisted all previous treatment, entirely disappeared, Dr. Mansell Moullin thought the case could not be considered a failure. It was never suggested that removing an obstruction at the neck of the bladder would be able to regenerate the muscular coat, if this had been destroyed by catheterism and previous cystitis. In another case the inflammation of the bladder persisted, but this again was not the fault of the operation, for the walls contained numerous sacculi, which could not be kept empty. Respecting the traumatic delirium in two cases, already referred to, Dr. Moullin avers that it is not due to the orchotomy, but to that tendency to delirium that obtains in elderly people after severe injuries, and may even follow the administration of an anesthetic."

**"Molding" Treatment of Club Foot.**—This method takes its name from the gentle, gradual way in which the soft parts of the foot are molded into the correct shape, stretching, pulling and

cutting where necessary, until a touch of the finger will turn the foot into the normal position. Not until this is attained is the cast applied, thus preventing gangrene from pressure. It is the exact opposite of Wolff's forcing method, which applies the cast and just as it hardens, the foot is forced into the correct position. Another advantage of Lorenz's method is that the various defects are corrected in turn, although at one sitting. Adduction and inversion are first altered into abduction and eversion; the tendon of Achilles is then cut, with care that the tuberosity of the calcaneum is brought down into place. Then supination is changed into pronation, and not until the foot is thus altered without force into a calcaneo-valgus, is the cast applied; split down the center to allow for slight swelling. It is left for six weeks, and the later bandage for two to three months. The treatment concludes with massage and active exercise of the muscles, especially the pronators. Lorenz has invented an instrument to assist in molding the feet of adults, as this requires more strength than a child's club foot. The method is described and illustrated in full in the *Wien. Klinik*, Nos. 11 and 122.—*Cbl. f. Chir.*, July 5.

**Pellotin, a New Hypnotic.**—According to the *London Lancet*, June 20, Dr. Jolly of Berlin, has made considerable progress in the study of a new hypnotic, called pellotin, which is not prepared by chemic synthesis, like the other sleep-producing medicaments of the present day, but is an alkaloid discovered in a species of Mexican cactus called anhalonium. The natives of Mexico are reported to swallow slices of this plant, to which they give the name of "pellote," and Dr. Hefter of Leipsig, has now succeeded in isolating its soporific alkaloid. Pellotin itself is not soluble in water, but its hydrochlorate is extremely soluble. Its physiologic action was first tried on frogs and then on mammals, which very soon became unable to stand or perform spontaneous movements, and shortly afterward an increase of the reflexes was observed, followed by tetanic convulsions. This action of the drug on animals was not identical with that which Dr. Heftner observed in himself, for after taking five centigrams (three-quarters of a grain), he became very drowsy and ultimately fell asleep. The drug was then given by Professor Jolly to a number of patients in the neurologic wards of the Charité Hospital in Berlin. The first case was that of a man suffering from alcoholic neuritis, who, after an injection of four centigrams, became very drowsy, and one hour afterward he fell into a sleep which lasted for four hours. Dr. Hefter had observed in himself a diminished pulse rate, and the same symptoms were perceptible in this patient, during the first hour of whose sleep the pulse fell to 56 per minute, rising again to 76 before the man awoke. Another patient with multiple sclerosis took five centigrams during the afternoon, and after half an hour he slept soundly for several hours. Similar results were obtained in a series of other cases. Some patients complained of giddiness and declined to take the medicine, but the greater number did not suffer in this respect. The cost, at present, of the article is about fifty cents per grain, but the chemists, Boehringer and Soehne predict that they will presently be able to bring down this high cost as the demand for the drug increases.

**Diagnosis of Calculus by the New Photography.**—The *Bulletin de l'Académie de Médecine*, June 2, records Dr. D'Aronval's opinion that a great diagnostic advantage will soon be reaped, in regard to renal and vesical calculi, by the Roentgen photography. The latest pictures obtained by Chappuis and Chanel, have an especial value, since they show that it will soon be possible to diagnose calculi in the urinary passages with absolute exactness. They not only show the existence of a calculus in the bladder, kidney or ureter, but it is possible to distinguish the substances of which it is composed, whether it is homogeneous or formed of different layers, whether the kernel is small or large and of what it is composed. The most inter-

esting photograph from this point of view showed: 1, the silhouette cast by a calculus of pure uric acid; 2, that of a calculus the same size as the first, but composed exclusively of phosphate of ammonia and magnesia; 3, that of a calculus much larger than the others, formed of several distinct layers of uric acid in the center, with an outer layer, 4 mm. thick, entirely different in color, and composed exclusively of the triple phosphate; 4, the silhouette of a bone 1 cm. thick, and another of the index finger of one of the experimenters. The differences in the depth of shadow in this photograph are so marked that it is impossible to mistake the characteristics and kinds of the calculi. The tiny kernel of uric acid is distinctly visible, while the outer layers of the large calculus are represented by clearly defined rings. A second photograph showed another calculus with a kernel formed of soda urate, inclosed in an outer layer of the triple phosphate, both very clearly defined in the photograph. A third represented a number of uric acid calculi lodged in the parenchyma of the kidney, one-half of which was 5 cm. thick. The rays passed through this thick layer of tough tissue and the calculi alone showed in the photograph. It will be a simple matter, therefore, preliminary to an operation, to take the photograph of similar calculi, and then compare them with the results of photographs taken through the patient.

**Cod Gall for Cod-liver Oil.**—Dr. Clarence Wright, in *London Lancet*, July 11, writes on the above subject. He says that while the claim of cod-liver oil as a powerful alterative in diseases of the respiratory tract has long been recognized, yet, owing to its unpalatability and the nausea oftentimes attendant on its administration, it is the common experience of all that the cases which on theoretic grounds are selected as most suitable often prove least amenable to such treatment. These are for the most part cases characterized by a general wasting of the body and failure of its nutritive functions. How insuperably difficult it is to overcome this inherent propensity of the oil may be remarked when we notice how the ingenuity and art of the pharmacist have been strained to the utmost in devising ways and methods whereby it may be disguised if not destroyed. Its combination with malt, the hypophosphites, etc., are so well known that allusion to them would be superfluous. It would likewise prove a useless reiteration to enumerate the many oils and fats that have been proposed as substitutes for it. However feasible such substitution as a theory may seem, yet in practice their use has not been attended by any marked success. Cod-liver oil has been proved by French investigators to owe its activity, not to any peculiarity in the nature and constitution of its oleaginous constituents, but to certain definite antemortem products of liver action, which not only promote the absorption of the oil, but also materially assist digestion and exert the well-known alterative action. It has likewise been proved by examination of frozen and prepared sections of a fresh liver that these physiologically active constituents of cod-liver oil are of biliary origin, for their distribution in sections so made bears a definite relation to the ramification of biliary radicles, and not to the fat cells of the liver. "I was induced thereby to utilize that biliary product of unchallengeable antemortem liver action cod gall as a substitute for cod-liver oil, and I can now after a trial of eighteen months, say that I have every reason to believe it an efficient, active and palatable substitute for cod-liver oil, and one that deserves a trial. My usual method of employing it is by making a wine of cod gall (*vinum gadeo-morrhuinum*) by adding one ounce of fresh gall, along with two and a half drams of extract of pancreas, to a pint of wine (sherry or port optionally), and after ten days filtering it through some cotton. I administer the wine so made in doses of one to four teaspoonfuls at or after meals four times a day."

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance . . . . . \$5.00  
Single Copies . . . . . 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, AUGUST 29, 1896.

A NEW MEDICO-LEGAL QUESTION.

The highest criminal court of the city and district of Magdeburg, Germany, in May last, decided a case that is entirely new in medical jurisprudence.

The defendant, Dr. HIRSCHFELD, treated a case of serous inflammation of the cellular tissue of the arm which resulted in septicemia and death, without any spirits or supporting wines. When the case became serious it was sent to the hospital and death followed. Dr. BOEHM, a member of the medical council and hospital, accused Dr. HIRSCHFELD of neglect of proper treatment in keeping the patient on what he called "a cold liquid diet," rather than the strongest wines, and most nourishing foods. The court charge was acceleration of death, or homicide by negligence, in not using spirits freely. Dr. HIRSCHFELD was permitted to present a scientific defense of his treatment of the case. He asserted that in his long experience he had never used any form of alcohol. He considered it very mischievous, and that it never added strength, but always detracted from the power and vigor of the case. A series of statements were offered by Prof. BINS of Bonn, Prof. STRUMPELL, of Erlangen, Prof. HARNACK, of Halle, Dr. SMITHE, president of the German Medical Society; also the medical council of Saxony, consisting of five physicians with the president, all confirming the following general facts: "The idea that alcohol gives strength is deception, while any form of alcohol may produce an

apparent form of stimulation, there is always a reaction in a profoundly marked diminution of energy. The special paralyzing action of alcohol on the brain and spinal cord is no longer a theory, but a fact that can be measured and proved. We are confident that experience will fully sustain our beliefs that no single human life, which would have fallen a prey to death without alcohol, has ever been saved by alcohol."

These general facts were supported by voluminous statements and clinical experience. The court adjourned twice in order to secure a great variety of authoritative opinions, and Dr. BOEHM, the prosecutor, seemed to rely on the statement of text-book authorities; finally the following discussion was presented by the court: After stating the legal aspect, the judge remarks: "It appears from the authorities offered, that in regard to the diet of fever patients strong soups and wines have in a comparatively recent period, been abandoned as increasing the fever. Prof. BINS has reported an instance where the medical man was arrested for treating a case of fever with alcohol alone. It is clear that opinions in regard to the value of alcohol have materially changed, inasmuch as its stimulating effect on the heart is regarded by many as valuable, and some maintain that it is always capable of lowering the temperature. Notwithstanding among the most eminent practitioners at the present day, there is a large number of opponents of this remedy. Some declare with emphasis that they have better success in their hospital and private practice without the use of a drop of alcohol than otherwise. It appears quite certain that alcohol in large doses exerts a paralyzing influence, increases the decomposition of albumin in the organism and is thus capable of influencing the course of the disease unfavorably. Therefore, without giving any definite judgment on this difficult question, we shall adhere to the principle that it is entirely inadmissible to lay down any limits to the exercise of the individual judgment of the physician in such matters." The defendant was accordingly acquitted. It would appear that considerable personal feelings were combined with this case, and a strong disposition exists to hold prominent medical men responsible for any new innovations of treatment where alcohol is supposed to be the remedy.

It is also noteworthy that the opponents to the use of alcohol as a remedy are very formidable in culture and scientific reputation, and defend their theories with great emphasis and spirit. This case is also of great interest, from the eminence of the parties in the contest, both of them being teachers of medicine and eminent practitioners. It would appear that no question of this nature could ever come into court in this country, because the use of alcohol therapeutically is becoming more and more unsettled every year, and while there is only an occasional paper in the medical journals, relating to this question, there is a wide-

spread distrust and skepticism of the value of alcohol as a medicine.

It is a curious fact that alcohol as a beverage is not much disputed, but when given as medicine its value is questioned at once, especially in continental Europe. Evidently a great revolution of theories concerning this drug has begun.

#### THE AUGUST HEAT.

The month of August was ushered in by a torrid temperature causing a reign of terror throughout the central and eastern sections of the country which equaled, if not surpassed, all previous records of lives destroyed by climatic causes. Day by day a stationary high thermometer swelled the long list of victims and the humid nights furnished no relief to the perspiring and exhausted multitudes. Even Chicago, "The Windy City," discarding her sobriquet, missed the invigorating breezes from Lake Michigan, and for a period of ten days the atmosphere was tainted by the odor of hundreds of putrefying animals lying in the streets, which the city authorities were powerless to expeditiously remove.

We are indebted to Acting Commissioner of Health, FRANK W. REILLY, M.D., of Chicago, for the mortality statistics of the various cities. The death rate in Chicago for the week ended was 697, making the annual death rate 22.38 per 1,000, as against 579 deaths during the preceding week with a rate of 18.62. There were 148 deaths from sunstroke during the week ended August 15. The following shows the mortality of four Eastern cities: New York, heated term began August 4; total deaths 2,429; maximum temperature August 9, 98; previous record July 24-30, 1892, total deaths 1,615, mean temperature 83, maximum temperature 97. Philadelphia, heated term began August 2; total deaths 1,328; mean temperature 82.7; maximum, August 11, 98; previous record June 30 to July 13, total deaths 1,649, mean temperature 86. Washington, heated term began August 1; total deaths 39; mean temperature 81; maximum temperature August 6, 98; previous record July 1 to August 3, total deaths 66, mean temperature 84.9, maximum 97. Baltimore, heated term began August 4; total deaths 344; mean temperature 84.2; maximum 98.

The deaths from sunstroke in Chicago amounted to 165. It is estimated that more than 800 horses fell victims to the heat. These statistics must cause some inquiry as to the diet and mode of life of the victims. As is well-known, alcohol continues to furnish a large proportion of the cases. But unfortunately the statistics are silent on that point.

Prof. STANFORD E. CHAILLÉ has well summarized the points to be remembered concerning hot-weather diet. In a recent letter to the Editor he says:

1. Nature's first lesson—a prolific production of edible and appetizing vegetables and fruits.

2. Nature's second lesson—a decrease of appetite, especially for fats and meats, and its greater gratification with vegetables and fruits.

3. The greater needs of the body for temperance in eating and in alcoholic indulgence.

4. The more abundant growth of microbes, and hence the greater need for cleanliness of food.

5. This greater need of microbic cleanliness most urgently requisite in the diet of infancy and childhood, and especially as to milk.

This last point is one to which too much attention is not likely to be given. For the benefit of those interested in these matters we reprint below an item which appeared in this JOURNAL December 29, 1894.<sup>1</sup>

It will be seen that while 1896 has contributed liberally to the heat statistics of the world, the season we have just passed through was by no means phenomenal. A London periodical in a recent article touching man's power to endure heat says:

To begin with, the difference between the highest and lowest limits is estimated at 250° Fahrenheit. French troops in Algiers must frequently march and manœuvre at a heat of 122° above zero. A French professor has, during a stay in the Sahara with a tribe of Tuaregs, observed a heat of 153°.

Attendants in Turkish bath establishments work ten hours a day in rooms where the air is artificially heated to 155, 175, and even to 195° Fahrenheit. A scientific gentleman in Paris not long ago spent fifteen minutes in a hot air room of the Paris Hammam, in which the dry air had been heated by his order until the thermometer registered 250° Fahrenheit. Issuing from this room, he plunged immediately into a bath filled with water of about 53°, a difference of 200° Fahrenheit which his body passed through in less than a minute.

On the other hand, man will stand greater cold than any of the other mammals. For instance, during the journey of Prince Henry of Orleans through the Central Asiatic highlands the party frequently had to withstand a temperature of 40 degrees below zero. The quicksilver in the thermometers had frozen solidly at this temperature, and even the alcohol in the alcohol thermometers became thick. Horses and camels died from exposure, while none of the men in the party suffered in the least.

In North America intense cold is frequent. A Captain Burn once measured at Fort Reliance a temperature of 70° below zero, while Captain Dowron, at Fort Rae, saw the thermometer down to 88° below zero in the month of April. The lowest temperatures known, however, have occurred in Siberia, where a temperature of 50° below zero is not uncommon, while at Werchojansk a temperature of 93° below zero has been observed. It appears, therefore, that men can stand a cold of 90° below zero, while a heat of 160° and even 180° Fahrenheit appears to be the extreme limit in the opposite direction. No animal is known which is able to resist such changes of temperature.

It must be remembered, however that power to resist extremes, to resist great changes in temperature, does not insure power of resistance for long

<sup>1</sup> PHENOMENALLY HOT YEARS.—The recent mild winter weather in this country somewhat harks the force for us of the contrast which the *Journal d'Hygiène* endeavors to make in furnishing a list of phenomenally hot years as "agreeable reading now that cold weather is at hand." Among the most remarkable of these torrid years, all of which had serious effects on the public health, may be mentioned A.D. 738 when the heat was so great throughout Europe and especially in France, that nearly all the springs dried up and thousands perished of thirst. In 879 reapers who staid in the fields after midday fell dead in great numbers. In 990 nearly all fruits dried up, occasioning a great famine and an enormous mortality. In the year 1000, amidst panic fears about the end of the world, the river sources dried up and vast numbers of fish putrefied, giving rise to a general epidemic; it was widely believed that the end of the world by fire was at hand. In 1132 rivers and springs again dried up and the bed of the Rhine became a dry sandy road. In 1182 the sand was so heated that eggs were cooked in it in a few minutes. The Seine, Loire, Rhine and Danube could be passed over dry-shod in 1308. All fruits withered and animals dropped dead from the excessive heat of 1393. Four years of great heat and continuous dryness, from 1538 to 1541, caused many rivers to disappear entirely, crops were failures and famine and sickness carried off large numbers. There were fifty-eight consecutive days of extraordinary heat in 1646. There was no rain from April to October in 1710; the Réaumur thermometer marked over 33 degrees; in gardens which could be irrigated fruit ripened twice. In 1818 the theatres of Paris were closed for a month on account of the heat; the thermometer marked over 88 degrees R. During June and July, 1830, the centigrade thermometers registered over 38 degree, in Paris in the afternoons.

continued heat. It is the long-drawn-out "hot spell" that tests the permanent resistant property of the human frame.

#### THE EXCELLENT WORK OF THE AMERICAN ACADEMY OF MEDICINE.

The new fields which the American Academy of Medicine have elected to till, and the noteworthy crops at present being gleaned deserve the most respectful consideration of the profession. More than this, its attempt and success in reclaiming waste and abandoned lands and making them yield rich harvests for professional and sociologic good demand the sympathetic interest of every physician who looks upon his work as something more than bread-winning.

For many years, about eighteen, the Academy labored with a singleness of purpose to raise the standards of medical education, and it should not be forgotten that the seed sown by it has been widely distributed by its members and their publications, and has been a highly important means of bringing about the remarkable changes in this respect by public legislation, and in spontaneously chosen standards by medical colleges, now proving and still more to prove of incalculable benefit to all concerned.

But the singleness of aim with which the Academy labored, became (sometimes and to not a few) somewhat monotonous; this fact coupled with the very patent associate factor that the work of the Academy was and remains genuine missionary work, offering no sort of reward, political or financial to its fellows, had served to make the function and even the existence of the organization altogether too little recognized and unsupported.

But all this is now, we are led to believe, a thing of the past, and with its new ground and methods of husbandry, the Academy is attracting the earnest attention not only of the medical world but of that greater world of which we form a part. Briefly stated, in the last two or three years the Academy has undertaken the tillage of the "Bad Lands" of Medical Sociology, not only as pertains to the profession considered in itself, but also as relates to the community at large. It might at first sight appear that this was only the old question of Public Health, but a glance at the last dozen numbers of the *Bulletin of the Academy* in which the papers and proceedings of its meetings have been published will show that without any desire or attempt to infringe upon the territorial rights of the organizations and agencies working these farms, the Academy has found vast domains wherein to exercise its energies. Two years ago the meeting of the Academy was largely given over to the subjects of the relations of the profession to the dependent classes, and the inter-relations of both to the community. Instead of exhausting even the most general of these subjects, it was evident that here was an extremely rich soil, well-repaying years

of study and tillage. The reports of this meeting, and the papers read there, as republished in the *Bulletin*, at once gained the attention of medical editors and of the lay-public, and were extensively quoted and bespoken both in this country and in Europe. The general subject then introduced has in subsequent meetings continued to arouse interest, and in future a not inconsiderable proportion of the time and attention of the Academy will doubtless be dedicated to it. At the meeting of last year besides due consideration of this aspect, the question of hospitals, their management and abuses was uppermost in the minds of the attendants. At Atlanta this year, one day's sessions were devoted to medical education again, and the number of the *Bulletin* just at hand (Vol. II No. 8) contains the able papers of many distinguished teachers upon its protean aspects. The "President of the Academy, Dr. HENRY M. HURD of Baltimore, presented a valuable contribution upon "Laboratories and Hospital Work."

DRS. OSLER, PARSONS, GERRISH, ROBERTS, SMITH, WRIGHT, EDGAR, WILSON, TAYLOR, HOLMES, PARK and others dwelt upon the best methods in education as regards the preliminary requirements, and each of the special branches of the medical curriculum. In reading these papers one finds himself in a new atmosphere, even a new world from that of but a very few years ago. Everyone who is interested in practical education and the new ideals and methods now ripening into certain near harvests will not neglect the reading of these articles.

The meeting of 1897 is to be held in Philadelphia and is noteworthy as being the 21st. The celebration of the attainment of its majority should be an exceptional and memorable gathering and the members are already at work to make it so, and to arouse a proper recognition on the part of the general profession to the vital issues of the time. The words of that ideal secretary, Dr. MCINTIRE, concerning the Philadelphia meeting are as follows:

"It has been suggested that next year another phase of the life of the physician and his environment be made the subject of investigation. Probably the theme can be expressed by the phrase, 'The Associated Duties of the Physician,' as by any other, although a more precise wording may be thought out later. There are certain duties to one's fellows that pertain to the profession; unless these are clearly understood and properly defined there is the danger of imposing on the benevolence of the physician on the one hand or an undue selfishness on the other. In either event harm is wrought. These associated duties may be crudely classified as his 1, with his fellow-physicians; 2, with his fellow citizens (as a physician of course); and 3, with the body-politic. The first of these divisions treats of medical societies, their history, use, proper method of conducting, etc.; the associations of physicians having insurance or financial relief in view; indeed of any question involving the united effort of several or many physicians to accomplish. The second division relates to

those problems involving medicine so frequently met with by us all in our private capacity, and in the solution of which we must be associated with our fellow citizens. Questions relating to the sanitary condition of the community, or the physical side of child-life in the public schools; the freely giving of our professional services to those who can not pay at the suggestion of others who, possibly, ought to be asked to share in the giving. While the third division includes the discussion of all questions involving the services of physicians as incumbents of public positions, whether merely of honor, or of honor and some profit. This outline serves to illustrate how extensive a field is included in the topic, and the purpose of this notice is to invite the promise of contributions from the Fellows of the Academy in order to ascertain if it will be practicable to arrange for a day's discussion along these lines. Those who may desire to contribute a paper are asked to write to the secretary stating their purpose and giving the title of the proposed paper. At the same time none of the themes of the previous years have been exhausted, so additional contributions along these lines are still acceptable."

#### THYROID THERAPEUTICS.

Thyroid therapeutics is an acquisition of the last six years, and one that better than perhaps any other illustrates the close relations between physiologic research and the rational treatment of disease. It is not very long since that the thyroid, like other ductless glands, was a physiologic puzzle, and the theories as to its utility in the organism varied from that of its being a merely esthetic appendage to round off the contour of the throat to the attributing to it an important action in mechanically regulating, as a diverticulum, the blood supply of the brain. The recognition of the connection of the cretinoid condition described by GULL with atrophy of this gland by ORD in 1877, and the subsequent experimental studies of SCHIFF and his assistants and of HORSLEY in England, and others, led directly to the theory of the chemico-vital function of the thyroid and to the suggestion of its utility in the therapeutics of myxedema.

While the suggestion and the demonstration by experiment on animals of the efficiency of the extract of the thyroid is due largely to VASSALE and GLEY, the first successful application in a human subject of this treatment was made in England by MURRAY in 1891, the method by hypodermic injections of a glycerin extract having been employed. A little later, in 1892, the more convenient plan of administration by the mouth was substituted for the hypodermic method and has become the general practice. The various preparations in the market seem all, or nearly all, more or less effective, and in some of them at least we seem to possess all the active principles of the gland itself so far as its specific action on the disorder is concerned. While myxedematous conditions are not extremely common, they are, like other newly described affections, becoming daily more and more

recognized, and the experience of the profession has already demonstrated sufficiently the practical value of the findings of physiologic experimentation. In any disorder which, like myxedema, seems to depend upon or be connected with deficient functioning of the thyroid gland, the use or, at least, the trial of thyroid extract is indicated and justifiable. Thus there appears to be a certain relation between the thyroid and the pituitary gland, and in acromegaly both are likely to be disordered. In those cases where the thyroid is atrophied, thyroid extract is probably indicated; where it is hypertrophied its utility is very questionable. The possibility of a vicarious functioning of the two organs, the thyroid and the hypophysis, suggested by ROGOWITSCH, seems to be disproven by the experiments of VASSALE and of OLIVER and SCHAFER, and the therapeutic experience is not especially in its favor. The results of the use of pituitary extract have not yet been so extensive as to enable us to affirm that its value is at all comparable to that of the thyroid, in the cases where it is theoretically indicated, and the treatment of acromegaly is therefore still a problem for the future.

In exophthalmic goitre the use of thyroid is generally condemned, and yet there have been cases in which it is reported to have been of benefit. While we may admit that as a general rule the theory of MOEBIUS, viz., of hyperthyroidization, best explains the pathology of the affection, there are possibilities of other conditions existing, and the cases where it tends to pass into myxedema (PUTNAM, JOFFROY) are very suggestive of a possible utility of thyroid extract in some stages of the disorder.

Aside from myxedema, the principal affection for which this medication seems likely to be of most value, is obesity. It is abundantly demonstrated by experience that it produces a most remarkable and rapid reduction of body weight, probably on account of its stimulating the fat consumption in the organism and increasing the urinary excretion. The fact that no change of diet is necessary and the comparative safety, so far as known, of the treatment, makes this property a very valuable acquisition to our medical resources, notwithstanding the often, or even generally, transitory duration of the effects after the discontinuance of the treatment.

The value of thyroid medication in true goitre must depend on the degree of functional inactivity of the organ. If the disease is, as is probably generally the case in its incipiency, a compensatory hypertrophy, the most we can reasonably expect of thyroid ingestion is that it may supplement an enlarged but perhaps still overtaken organ. It may indeed relieve the hypertrophy in some instances, but it is hardly in the order of things to consider it as yet a specific for this affection. In sclerodermy it has been reported as useful, and this is in accordance with some researches

that indicate a causal nexus between this condition and functional disturbances of the thyroid gland. In other skin affections and in syphilis it has also been tried, but no very positive evidences of its general value have as yet been given.

We are not yet able to say that the whole physiology of the thyroid is known, and therefore may in the future find other functions that will furnish indication for rational therapeutics. It is occasionally deranged we know in a large number of disorders, and whenever its secretory function is hindered or abolished it is reasonable to try thyroid medication. But beside this, this latter has in all cases a decided effect on the general nutrition, stimulating, it would appear, the metabolic changes, and in this way its effects may be valuable. Thus, in many cases of insanity where it has been tried empirically and because of the mental improvement it causes in myxedema, it has been found of benefit. Unless in these cases there was direct thyroid derangement, which it must be admitted may have sometimes existed unobserved, we can best attribute the beneficial effects, in the present state of our knowledge, to this general systemic action producing the change that was required in possibly a critical stage of the disorder, or perhaps we should better say that the stimulation of the systemic metabolism caused the carrying off of toxic substances poisoning and deranging the brain. As a general alterative of this kind thyroid medication may have a decided usefulness in certain cases, apart from its direct specific action in thyroid deficiency. There is possibly more than one active principle secreted by the gland; the thyroïdin of BAUMANN alone will suffice to account for the specific effects, as shown very recently by MAGNUS-LEVY, while he states that thyro-antitoxin presents a series of interesting peculiarities that will form the subject of a future publication.

The comparative innocuousness of the extract has been already noted. The inconvenient or excessive action of the remedy in a few cases is probably due to idiosyncrasy, though the possibility of imperfections in the manufacture and of impurities as suggested by LANZ, should not be neglected. In certain cardiac cases it ought certainly to be only employed with caution and the state of the urine and other secretions should always be watched during its administration. But, given with proper judgment and care, it is as safe as any remedy with equal physiologic effects and far safer than many of them. Within its range of usefulness, the limits of which are not yet fully determined, it seems to be one of the most important of recent medical acquisitions.

**Sunday Rest for Druggists.**—The drug stores of Soissons, France, close now at noon, Sundays, all except one, and the address of this one is placarded on the door of each. They take turns in remaining open this way on Sundays.

## CORRESPONDENCE.

### A Letter from Professor Edwin Klebs.

CHICAGO, Aug. 23, 1896.

*To the Editor:*—The paper of Dr. F. E. Stewart, "The Scientific Nature of our Patent and Copyright Laws," in the recent number of the JOURNAL, brings forward facts in the "Klebs Antiphthisin Case" which are entirely new to me, and which induce me to clear up my personal position in the matter.

Though the contents of the paper of Dr. C. P. Ambler, read before the AMERICAN MEDICAL ASSOCIATION, as well as the following discussion, are entirely unknown to me, as I was not present when the paper was read, I learn through the paper of Dr. Stewart some details in the matter which demand explanation of my standpoint on the question.

When I came the first time to this country in the fall of 1894, induced by Dr. Karl von Ruck of Asheville, N. C., to visit his institution, I was in every respect an entire stranger. Dr. v. Ruck made me the proposition to accept a position as director of a laboratory for experimental research and consulting physician to his institution. As the great advantage of an institution with the facilities for scientific research, and at the same time for the practical perfection of my more theoretically developed ideas, seemed evident to me, I accepted the offer, with the greatest expectations in a final solution of all these problems.

By the contract I entered with the Winyah Sanitarium and Hotel Company, whose medical director and president Dr. von Ruck was, I obliged myself to accept the mentioned position in the laboratory of the sanitarium at an annual salary and as well to interest myself financially in the institution, leaving to Dr. von Ruck entirely the management of the medical and business part of the institution, as well as the exploitation of substances prepared in the laboratory. I therefore did not see any harm in the application for a legal protection of Antiphthisin, as this lay entirely in the hands of Dr. von Ruck, whom I would expect to be familiar with the systems and ethics of the medical profession in this matter. In Germany nostrums are not patented at all, and scientific preparations only are patented. These scientific patents are frequently held by members of the medical profession, and I was not aware that there was a difference in the ethic practice of the two countries.

The application for the patent as not complying with the requirements of the office was refused, and Dr. von Ruck therefore tried to induce me to undertake certain experiments to fulfil these requirements. Declaring myself unable to do this and for other reasons, which I explained to the company, I left the institution early this year.

I was met in my efforts for a cancellation of the then existing contract by Dr. von Ruck at the end of May, by his proposition of a new contract. Both parties in this contract agree to cease the manufacture of Antiphthisin in this country. I agree to furnish the preparation from Germany, leaving to Dr. von Ruck the right to sell it here. One-third of my investment in the company was paid me, for the other two-thirds I had to accept notes. I have never received any payment of dividends from the company, only a small compensation for Antiphthisin furnished from my German laboratory, in whose management Dr. von Ruck and myself had equal shares at this time.

Being now more familiar with the customs of this country and better acquainted with the medical profession, I can only regret that ever an attempt was made to protect Antiphthisin by patent, and I am satisfied that this question will not need any further consideration. I consider the rule of the AMERICAN MEDICAL ASSOCIATION against proprietary medicines of

binding force, though its existence was not known to me at the time, and though I agree with Dr. Stewart, that a qualification of these medicines would be very desirable, which would not indorse the whole unscientific nostrum trade. The question has gained in importance since the introduction of bacteriologic products into therapeutics, as a protection by law of their methods of preparation, not in the interest of individuals, but as a guarantee for their purity and efficiency and as a protection against the production of such remedies by untrained hands.

Hoping that Dr. Stewart's paper will find the well merited consideration by the profession, to the benefit of science and further therapeutic efforts and to the strict exclusion of the entirely unscientific nostrums, I am yours very respectfully,

EDWIN KLEBS, M.D.

### Herman W. Mudgett alias H. H. Holmes.

MILWAUKEE, WIS., Aug. 20, 1896.

The article of Dr. Eugene S. Talbot in our JOURNAL for August 1, reminds me that I may say something about Holmes which may be of interest to members of the medical profession.

Holmes was a member of my class, which graduated in 1884, and he received his degree of Doctor of Medicine with the other successful members. A few failed in their examinations but Holmes was not among them. I was not intimately acquainted with him but knew him as well as I did any member of the class, excepting my immediate associates. What manner of man he was I remember distinctly and as distinctly recall several conversations I had with him.

Holmes was a mild-mannered young man, with a diffident air, possessing no characteristics in any direction which would attract attention. He evidently had not much in the way of pecuniary means, for he dressed plainly, almost shabbily, and he eked out his expenses by "doing chores" about the premises of Prof. Edward S. Dunster, who died several years ago. As a student he was below the average of the class, decidedly, both in ability to acquire knowledge and in readiness to express what he knew. I distinctly remember his halting, uncertain manner when called upon to answer a question at a "quiz," and I also remember a "scoring" which that earnest, conscientious old man, Professor Palmer, gave him on an occasion because he was remiss in answering a question in physical diagnosis. Indeed, a single circumstance indicating acuteness in any direction on the part of Holmes, can not now be recalled.

Holmes attended the meetings of the Y. M. C. A. Whether he was a member in good standing I do not know. He once told me that he intended to go to New Zealand as a medical missionary after graduation. At another time, when a clerical member of the class took exception to a eulogy of Thomas Paine, given incidentally by one of the professors, he had a supporter and sympathizer in the person of Holmes, when he (the clerical member) took the matter to the president of the University.

He seemed to take a good deal of pleasure in the uncanny things of the dissecting room. One afternoon's conversation with him I remember distinctly. He talked a great deal about what he had done in the dissecting room with what appeared to me at the time, unnecessary gusto, and told me that the professor of anatomy was to permit him to take the body of an infant home with him for dissection during the spring vacation, which was to begin on the following day. I asked where he would find a place in which to carry on his work without offending his neighbors, and he replied with something to the effect that he "would find a place."

There can not be much doubt that even at this time Holmes would lie when it was to his advantage to do so. On one occasion I was directly concerned in his lying, the circumstances of which may be of interest as throwing some light on his char-

acter. It occurred at a final oral examination. The members of the class were called in alphabetical order, one by one, and I was surprised to find Mudgett present himself in front of me. I called his attention to the fact that his name came after mine and asked for an explanation. He said that L., mentioning the name of a student, had gone out of town and that he (L.) had given him his place. I asked him when he saw L., and he said "this morning." Now, I knew as a matter of fact, that L. had left the city the night before, and, moreover, that he had been dismissed from the University in disgrace for attempted cheating in an examination. Feeling a little surprised at Mudgett's mendacity, I told him that I knew he was lying and I told him how I knew it, and that I would not permit him to go in for his examination ahead of me. He received my decision with very ill grace, but made no physical resistance. When I came out I found him in tears, relating the matter to a classmate, and he whined that it was "a damn mean trick" to deprive him of the place given him. This is the last conversation I remember having had with him.

While at the University I can not recall any direct evidence of his fondness for women. On one occasion, the latter part of his last year at the school, he spoke of his wife, and I was surprised to hear that he was married, as, up to that time, I supposed he was a single man. There must, however, have been some story current, connecting Holmes with women during his University life. I have a hazy remembrance of his being charged with some irregular conduct of the kind, and of his making a stout denial. Turning to the "Class Prophecy" which was written at the close of last year at school, I find that I wrote of Mudgett as follows:

"Herman W. Mudgett, unlike George Washington, no widow shall find favor in his eyes. After being charged with innumerable Don Juan escapades for which he is not responsible, he will retire to write a book on the 'Oppression of Man.' This book will make women very unpopular." This was, no doubt written apropos some affair with the other sex which was discussed by his fellows.

The stigmata of degeneration discussed by Dr. Talbot, no doubt existed at this time; but they did not attract enough attention to cause any remark that I ever heard, except on possibly one occasion. Following a custom which then existed, the members of the senior class ordered silk hats and a representative of a Detroit firm came to Ann Arbor to take the boys' measures. In doing this the usual periphery was sketched on paper. As is well known some startling irregularities are sometimes disclosed by this proceeding. A friend and myself took a good deal of interest in these outlines and Mudgett's was inspected among the rest; but I am unable to say what the irregularities were in his case, or how valuable they were if they existed. The outline may still be in the hands of Walter Buhl of Detroit.

It is not the purpose of this article to discuss Holmes as a probable degenerate. I simply write the facts concerning him, as far as I know them, while he was a student in the University of Michigan. On the whole the impression I had of him before he became notorious as a criminal, was that of a liar and sneak without ability or courage to do great deeds in any direction.

JOHN MADDEN, M.D.

### Concerning Dispensaries.

NEW YORK, Aug. 20, 1896.

To the Editor:—A circular of information wanted, is being sent to the various dispensaries of New York City by the State Board of Charities. I presume that it is sent to all dispensaries alike, both large and small. Among the questions to be answered are the following:

6. If connected with a medical college, hospital, or any other institution, state the name thereof.

7. The name of the governing board of the dispensary.
8. The stated times of meeting of said board.
9. The average attendance at meetings.
10. How often have the members examined the work of the dispensary?
13. What forms of records are kept?
14. What means are employed to determine that each patient is unable to pay for medical or for surgical treatment?
15. What charge, if any, is made to patients for treatment?
16. What charge, if any, is made to patients for medicine?
17. If any members of the medical staff are paid for their services, state for what service, and at what rate?
20. How are the medical men selected, and by whom?
21. Are any physicians or officers appointed after competitive examination?
22. Do the physicians ever treat the patients as their own private patients, and if so, give the particular rule under which the charge is made?
28. Is there a class of physicians assigned to the treatment of patients at their homes?
29. What pay do they receive, and from what source?
31. How many of the patients were non-residents of the county in which the dispensary is located?
38. Is a collector employed to solicit contributions?
39. If so, at what rate of compensation?

S. F. B.

*Audi alteram partem.*

### A Defense of the Bicycle.

BIRMINGHAM, ALA., Aug. 21, 1896.

To the Editor:—Will you kindly allow me space to comment briefly on an editorial in the *JOURNAL* of the 15th inst. entitled "Bicycling Pro and Con."

I would like to ask how many cases of deformity of the female pelvis from this cause have been noted? Also, how many patients have applied for treatment for vesical and prostatic irritation caused by the bicycle saddle?

To place the bicycle in its proper place as a machine for good or evil, it would seem to be necessary to compare all such damage done with the good it has accomplished. The great advantage which the wheel has over all other modes of exercise is the pleasure it affords. The therapeutic value of fun is, I think, undisputed. It combines fun with plenty of fresh air and exercise, and if there is any better combination from a health standpoint it is yet to be reported. The tired drudge of a clerk or book keeper, after being on his feet all day, does not relish such a prescription for his dyspepsia as a "long walk," but he can ride a wheel and enjoy it, and at the same time promptly cure his dyspepsia.

The reason for the wide extent of "the craze" is just this combination of exercise, pleasure and fresh air, which reaches all classes. And the good it accomplishes I think far outweighs the occasional harm it may do to a young girl or an old man.

Where little girls once spent all their idle time cramped up in a corner of a nursery, with their dolls or inane amusements, pale faced, dull eyed and constipated, or strolled languidly along the street in groups, anemic, round shouldered and spindle shanked, they now ride wheels and are animated, strong limbed and healthy. No doubt the morals of a few older girls suffer, but they are far fewer than was the case under the old style of buggy driving and entertaining their men friends in dark corners.

Idleness and erotic thoughts always go together. There are no such safeguards anywhere against bad habits as active mental and physical exercise. The reproductive instinct, the sexual appetite, is the result of a surplus of energy left after the body heat and growth, and the mental and physical expenditures, have been supplied.

There is no evidence, so far as I know, to substantiate the theory that the bicycle will deform the pelvis, and there is no more reason for it than to suppose that sitting on a chair will do it. On the other hand, it develops all the pelvic muscles, and must, by the general good health it induces, make the girl stronger in every way.

The bicycle costumes and contours are shocking to conservative eyes just as the modern bathing suits are shocking to the eyes of our Uncle Reubens and Aunt Marias, while others would feel it infinitely more shocking to see a bathing skirt which reached down to the heels. But the bicycle girl, like the summer girl, has cut her clothes for convenience, and will likewise probably leave the Uncle Reubens and Aunt Marias to get over it as best they may.

The bicycle has too many advantages pointing to its permanency to be called a fad. The people who first took advantage of comfortable railway coaches were, no doubt, called faddists by their philo-zoic contemporaries, and no doubt a great cry was raised about the harm to come to the morals and the hemorrhoidal veins of the nation from the slothful and luxurious habit of sitting all day on the soft and warm cushions. But the railway was more than a fad, and anything like a just recognition of its merits must show that the bicycle has also come to stay.

Book keepers, salesmen and others, whose lives were once one round of drudgery, bad air, no exercise and dyspepsia, now live two or three miles out in the country where their families can be healthy and they themselves can live on something more nourishing than tea, toast and pepsin.

Finally, the bicycle takes young men away from the saloons and those other places the natural allies of the saloons, the frequenting of which probably gives rise to a thousand cases of prostatic and vesical irritation where the bicycle saddle causes one.

The writer does not ride a wheel, consequently has no personal experience of vesical or prostatic irritation to report. He can readily see, however, that a busy practitioner forced to an explanation of a vesical irritation in his own person, by a recently developed monomania for urinals would be unfortunate indeed if he did not have a wheel to charge it to.

2220 1st Ave.

GEORGE S. BROWN, M.D.

### Practice in Africa.

MILWAUKEE, WIS., Aug. 20, 1896.

To the Editor:—Will you please inform me if our American diploma is accepted to practice medicine and surgery in any and all parts of Africa, and if not what procedure I will have to undergo to begin practice in that country. I was under the impression that anyone could practice in that country who was a regular graduate. Will you please be kind enough to give me the desired information I ask and oblige yours fraternally,

W. C. ARONS, M.D.

211 Grand Ave.

ANSWER:—Each country having provinces in Africa, has a different regulation. The independent states also have special regulations. A letter to the colonial governor in the case of the provinces would give you the desired information.

### Albinism.

NEW YORK, Aug. 22, 1896.

To the Editor:—As bearing on the subject of racial degeneracy, I report the following cases:

1. Mrs. B., an ultra-blonde, native of county Wexford, Ireland (limestone region), recently died of aortic stenosis and cerebral embolism, leaving as surviving family: a sister, congenitally hunchbacked, a deaf and dumb son, and two daughters, one unusually tall, who is goitrous, the other a *full albino*.
2. Miss C., aged 28, whose parents both were deaf mutes,

has a streak of *perfectly white hair* an inch in width, extending from occiput to forehead; this was congenital.

I ask the question therefore, is not albinism like deaf-mutism, goiter, dwarfing, etc., evidence of racial degeneracy? Certainly there exists some relation between vitiligo and leprosy, and the latter is found only in degenerate classes.

ALBERT S. ASHMEAD, M.D.

### Civil Service Commission.

CHICAGO, Aug. 24, 1896.

*To the Editor:* The Chicago Civil Service Commission will hold an examination for the position of medical inspector of the City Health Department (salary \$75), September 3, at 2 P.M., in the Council Chamber. Applications must be filed at the offices of the Civil Service Commission on or before September 1. Candidates must present evidence of recognition by the State Board of Health of Illinois to practice medicine in this State before application will be received.

Examining Board: Drs. Wm. Cuthbertson, Maurice L. Goodkind, S. C. Plummer, Arthur R. Edwards, Jos. R. Hawley. Respectfully, E. J. PHELPS, Secretary.

### BOOK NOTICE.

*The Journal of Experimental Medicine.* Edited by WILLIAM H. WELSH, M.D., Baltimore. Vol I, No. III. New York: D. Appleton & Co. 1896.

A stately volume of more than 200 pages, showing in its various contents how timely and successful appears the gathering of American experimental work in one organ. This will excite more and more the emulation of the investigators and of the institutions dedicated to this work.

If it is practical to bring about also pathologic and anatomic labors, I am not sure. But the division of the two lines of scientific investigation can be made later, if it seems to be needed.

We can give here but very short indications of the rich contents, hoping that they shall provoke the reading of the original.

1. On the pigment of the negro's skin and hair, by John T. Abel and Walter T. Davis, from the pharmaceutic laboratory of the Johns Hopkins University.

A fine chemic work, showing that the pigment of the negro's skin and hair forms, as is known, cylindrical or rod-like granules, contained in epithelial cells. The authors show that the pigment can be made soluble by treating the granular part by diluted hydrochloric acid, then by diluted alkalis. A very skillful use of acetic acid, ammonia and precipitation with alcohol ether (6 to 1) grants a high degree of purification. The brownish powder gives a markedly acid reaction. The first high percentage of salts can be reduced from 0.8 to 1.2 per cent. The quantity of pigment in the epidermis (3.08 to 3.78 per cent.), is greater than in the hair (1.9 per cent.).

The acid is probably identical with the hippomelaninic acid, prepared by Berdez and Nencki from melanotic tumors of the horse. The non-colored ground substance seems to be derived from keratin, giving pyrrol and hydrocyanic acid in dry distillation.

The substance has a very high percentage of sulphur (3.6 per cent.) and is nearly free from iron, a fact which correctly brings the authors to the conclusion that the hemoglobin, containing but a little more than .05 per cent. sulphur, can not be regarded as the mother substance of the melanin. That the melanin probably must be derived, as is suggested by the author, from proteids of the parenchymatous juices, coincides very well with the anatomic facts proved in melanotic tumors and the suprarenal melanosis (morbus Addisonii).

2. W. J. Bradley brings an anatomic description of hemorrhagic cysts of the thyroid gland, and thinks to have found a new form of goitre. So far as the writer can see, it is no other than a secondary degeneration in glandular and colloid struma.

3. A. C. Abbott has found in the Schuylkill River in Philadelphia a vibrio, very similar to *V. Metschnikovii*, and studies its cultural, biologic and morphologic properties in a very intensive and careful manner. The discovery of such a suspicious vibrio, of near relationship to the vibrio of cholera Asiatica, in a place that was free from cholera since 1873, is of a great practical and theoretic interest.

4. The same brings experimental investigations over the influence of alcoholism upon the susceptibility against certain pathogenic organisms. As control-animals supported infections that killed the alcoholized animals there can not be a doubt that the very high alcohol doses used in rabbits (10 to 15 c.c.) must heavily depress the normal faculty of resistance.

5. I. Adler and S. J. Meltzer (New York), have worked on the question of "the path by which fluids are carried from the peritoneal cavity into the circulation." By tying in rabbits the innominate veins, the authors searched to exclude the lymphatics; afterward they observed the quantities of fluid reabsorbed in a certain time (mostly forty minutes) from the peritoneum. Injecting small quantities of potassium ferrocyanid, they found only a retardation of the excretion in the urine, marked by the Prussian-blue reaction, showing that by excluding the lymphatic circulation thus indirect penetration of the peritoneal fluid into the blood vessels takes place, but after a longer time. After injecting larger quantities of fluids into the peritoneum, much more complicated processes must be expected, depending upon the quantity influencing the circulation, and upon the composition of the injected fluid, influencing the osmotic process.

The exclusion of the lymphatic ducts effects also in this order a retardation in the process of resorption, but the exceptions from the rule are greater and the differences not so striking as after injecting small quantities. Finally, they find the greatest resorption from the peritoneum in dead animals, demonstrating the swelling of tissues (Quellung) effected by the osmotic process. Also filtration was effected in these experiments by the gaseous distension of the intestines. The path in which, under these circumstances, the fluids are carried from the peritoneum, is shown by the edematous infiltration of the surrounding tissues.

In the explanation of these phenomena the authors find difficulties which they, as it seems to me, can not wholly resolve (pp. 518 and 519). They state a marked difference between lymph and tissue fluid, but they can not detect the forces that direct the movements of these fluids; forces that they do not like to name "vital forces." Certainly, if the entrance of fluids from the peritoneum into the tissues occurs also in life, as in death, there must be some forces that will cease with life. That is, what physicists may name "vital forces" so long as the physic of the living body is not more recognized as yet. The problem will absorb much labor before the truth is declared, but there is made by the authors a good step toward this end.

6. S. J. Meltzer reports very curious experiments on gastric resorption. Strychnia solutions are not reabsorbed and will not kill the animal, if the introduction into the intestine is hindered by ligature of the pylorus. Hydrocyanic acid, on the contrary, results fatally injected in the ligated stomach, as the author suggests, possibly by its volatility. It would have been interesting to see a statement of the action of the soluble salts of the same acid.

7, 8. B. Meade Bolton brings some studies over the modern theme of antitoxin, the first with Herbert D. Pease on the production of antitoxin by the passage of electricity through diphtheritic cultures, the other on antitoxin in normal horse blood.

The authors use in contrast to the last observers (D'Arsonval and Charrin, Bonomi u. Viola, *Centralbl. f. Bact.*, xix, 22, 23) constant currents of 110 volts (of the Edison light) working on diphtheria cultures in H-shaped tubes for dividing the products formed at the two poles. The products at the positive pole

had decided antitoxic effects, if mixed to efficient toxin in the proportion of 1 to 5 c.c. The product of the negative pole was inefficient.

Probably the toxins are destroyed by the current and the antitoxic effect depends upon the healing substance contained in every culture of diphtheria.

Bolton found antitoxic properties in the serum of some horses. The immunization of these animals is going on with very slight reaction. But reaching doses of more than 100 c.c. toxin, there is no more difference in reaction.

9. Henry G. Beyer gives the results of regular exercises on the growth and weight of naval cadets from 16 to 21 years of age. The increase in height reaches to nearly one inch, of weight to 25 kilos. over the increase in untrained young men of the same age. The lung capacity had gained in the five years 1,722 c.c. more in the trained than in the untrained.

10. Simon Flexner (Johns Hopkins University) reports in a highly interesting treatise the results of bacteriologic studies made regularly in the postmortems of the pathologic department (H. Welsh). We can not reproduce here the details, but it is clear that, if in 255 cases 213 or 83.5 per cent., give positive results, we have an important death-promoting factor not yet estimated. It is also shown by plate cultures that in cases of patients with bad prognosis, the bactericide power of serum is highly diminished, a fact in apparent connection with the origin of these "terminal infections."

## NECROLOGY.

WILLIAM C. BENEDICT, M.D., well known to the medical fraternity in Brooklyn, N. Y., for the last fifty-two years, died August 17. The cause of death was heart failure, brought on by the intense heat of the previous week. Dr. Benedict had been suffering from heart disease for a number of years. He became seriously ill on Thursday evening, but it was not expected that the attack would prove fatal. Dr. Benedict was born in Schenectady on April 19, 1820. He graduated from Union College in 1840 and from the Medical Department of the University of Pennsylvania in 1844. After his graduation he became connected with the Blockley Hospital for the Insane in Philadelphia, where he rose to the position of chief physician, and remained two years. He then became one of the managers of the Insane Asylum at Poughkeepsie, which place he filled for about a year. He moved to Brooklyn and became prominent during the cholera plague. He is said to have treated the first cholera victim and was successful in saving his patient's life. He served as physician at the Raymond Street Jail for a number of years. Altogether, Dr. Benedict practiced for forty-five years, retiring in 1877, after which he made a tour of Europe.

LEWIS MCKNIGHT, M.D., medical director, at Milwaukee, Wis., August 21, of neuralgia. He was 71 years of age and a native of New Jersey. He graduated from the Medical Department of the University of Pennsylvania, Philadelphia, Pa., in 1841.

WILLIAM C. PARKER, M.D., at Santa Cruz, Cal., August 11, after a lingering illness, aged 73 years. Dr. Parker was a native of New York and had just graduated with high honors in medicine and surgery when he received his appointment as surgeon in Colonel Stevenson's famous regiment, which was dispatched from his native State to California in 1846. At the close of his military service a few years later he settled in San Francisco, where he was prominent in professional and business circles for over thirty years.

ANDREW J. PIERCE, M.D. (Jefferson Medical College, Philadelphia, 1856), at Kansas City, Mo., August 13, aged 64 years.

JOHN H. CALLENDER, M.D., at Nashville, Tenn., August 7, aged 64 years. He graduated from the Department of Medicine of the University of Pennsylvania, Philadelphia, in 1855, since which time he has been in general practice in Nashville, except from October, 1861, to February, 1862, when he served as Surgeon in the Confederate Army. From 1855 to 1857 he was editor of the *Nashville Patriot*, and from 1866 to 1869 editor of the *Union and American*. In 1858 he was appointed profes-

sor of materia medica and therapeutics in the Shelby Medical College; in 1868 professor in the same chair in the Medical Department of the University of Nashville, and in 1870 professor of diseases of the brain and nervous system in the Vanderbilt University and the Medical Department of the University of Nashville. In 1869 he was appointed medical superintendent of the Tennessee Hospital for the Insane. He was a member of the AMERICAN MEDICAL ASSOCIATION, American Medico-Psychological Association and Tennessee State Medical Society.

J. A. S. GRANT BEY, M.D. Our readers will regret to learn of the death of Dr. J. A. S. Grant Bey of Cairo, Egypt, which occurred July 28. He was well known in this country, having attended the Ninth International Medical Congress at Washington in 1887, and the Columbian Exposition of 1893 in Chicago. No foreign visitor made more friends in the short trips made to America than the subject of this notice.

ROBERT FLEET SPEIR, M.D., of Brooklyn, and brother of the late Dr. S. Fleet Speir, died August 13, at his home, of valvular disease of the heart with dropsy and some intercurrent renal impairment. He had been ill about six months. His early training was obtained at the Polytechnic Institute of Brooklyn, and he was a graduate from the University of Vermont, just thirty years ago. He had not been in active practice for many years.

MARTIN C. MCCARTHY, M.D., of Brooklyn, died August 12, aged 30 years. He was a graduate of the New York University Medical School in 1891. Dr. McCarthy had a large practice in the eastern district of the city. The numerous cases of sudden illness caused by the heat overtaxed his strength. Dr. McCarthy came to Brooklyn from North Adams, Mass., five years ago, and obtained rapidly a profitable practice. He was married three years ago to Miss Rose McKeever, of Pittsfield, Mass. The cause of his death was certified as being acute renal disease, with a duration of less than three weeks.

NORMAND SMITH, M.D., of Yonkers, died at Keene Valley, N. Y., July 30, from apoplexy. He was a graduate of Yale, 1858; obtained the degree of M.D. from Columbia in 1861, and subsequently studied at Berlin and Vienna. He practiced medicine in New York for many years, and up to the time of his death was a member of the Century Club. Dr. Smith suffered from his first attack last January. The second was some time during last month, from which there was a temporary recovery. He leaves a widow with five children.

JOSEPH AUGUSTUS MONELL, M.D., a general practitioner in New York city for about forty-five years, died at his home August 12. He was born at Middletown, New York, on Sept. 25, 1826, and was an alumnus of the College of Physicians and Surgeons, New York, 1850; a fellow of the AMERICAN MEDICAL ASSOCIATION and of the New York Academy of Medicine, as well as of other leading local societies.

GEORGE R. HENDERSON, M.D., of Brooklyn, N. Y., who died July 28, was a colored practitioner of good position. He was 45 years of age and a graduate from Yale University in the class of 1876. He had been eight years a resident of Brooklyn. His death took place at St. Catharine's Hospital, whither he was taken for treatment on account of an overdose of morphin accidentally taken, for the relief of pain.

ALGERNON SIDNEY ROBERTS, JR., M.D., of Philadelphia, died August 17 at Halidon Hill, R. I., near Newport. He was a graduate of the University of Pennsylvania, 1877. He made a promising professional opening, but social and other opportunities led him to retire from active practice several years since.

WOODMAN W. ROYAL, M.D. (Medical School, Maine, 1863), died at his home in Portland, Ore., July 22, aged 61 years.—James W. Green, M.D. (Rush Medical College, Chicago, 1856), a member of the AMERICAN MEDICAL ASSOCIATION, and at one time president of the Shelby County Medical Society, died at Shelbyville, Ind., July 26, aged 72.—James Hanghey, M.D. (University of Louisville, Ky., 1846), died at Scooba, Kemper County, Miss., in his 79th year, July 26.—Richard G. Wharton, M.D. (University of Pennsylvania, 1837), died at Port Gibson, Miss., July 30, aged 82 years.—Elias S. Boatner, M.D. (Tulane University Medical Department, New Orleans, 1891), died at his home in Victoria, Texas, August 1.

## PUBLIC HEALTH.

**Mortality Report.**—There were sixty deaths in Louisville during the past week; none from typhoid fever though there is a great deal of it in the city. Seven cases of diphtheria were placarded and two cases of scarlet fever.

**Vital Statistics of Cape of Good Hope.**—A preliminary report issued by the registrar of births and deaths contains an account of the working of the new registration law of 1894. For the year 1895 there were registered 45,642 births, 31,467 deaths, and 7,358 marriages. Exclusive of the native territories, and taking the population in 1895 at 1,143,846, the birth rate amounted to 32.8 per 1,000 population and the death rate was 21.7 per 1,000. These figures will be somewhat increased in the final report owing to the addition of delayed returns.

**New Respirator for Factory-Workers.**—A valuable prize has recently been awarded by the French "Society for the Prevention of Accidents in Industrial Pursuits," for the best form of respirator produced, to Dr. Detourbe, whose design has now been adopted in quite a number of the most important workshops in northern France. The arrangement in question is described as a mask so shaped as to fit the lower half of the face closely, but not so as to interfere with the wearer's vision; a chamber in the middle, through which the air is filtered, which projects only a slight distance from the rest of the mask, contains a layer of asbestos and also one of cotton or wool, arranged between small plates of aluminum gauze. The mask is of copper, and a strip of elastic felt runs around the inner surface near the edge, thus insuring the necessary contact all around, and the device is held on with light elastic bands encircling the head, one being on a level with the forehead, and the other about opposite the lower lip. The orifice is of such a size, and the lining of the chamber so loosely packed, that the wearer of the appliance is enabled not only to breathe, but to talk without difficulty, these two points constituting the great advantages of the invention.

**Dangerous Water Tanks of City Buildings.**—Sundry are the improvements that the fertile minds of architects and builders have pressed upon the modern top-lofty city structures. Divers are the perils that attend these same devices in the case of accident or derangement. Fire Chief Bonner of New York City has said that in that city there are not less than 5,000 unsafe water tanks upon house tops. These are likely to destroy property by leakage at any time, and in case of fire they constitute a serious danger to the firemen of falling through the building when the lofts and roofs are burned away. But if there are 5,000 unsafe tanks, how many foul ones are there. Every such reservoir, furnishing as it does, water for drinking, washing, cooking, etc., should be cleansed every month or oftener, and it is not probable that one in a hundred receives this attention. Perhaps some of the most pretentious dwellings and the most famous hotels have the filthiest water. Too much care can not be addressed to this source of disease by those intrusted with the charge of public health; verily conveniences many and menaces many go hand in hand in our ways of civic life.

**Health Officer Doty's Return from Cuba.**—Dr. A. H. Doty, Health Officer of the port of New York, returned from Cuba August 17. The object of his adventurous midsummer visit was to arrange with the Spanish authorities for the lessening of the danger from yellow fever. His trip was partly successful. He appointed health officers at Havana, Cienfuegos and Santiago to represent the interests of New York harbor and the country at large. They will inspect all persons bound for New York and prevent those undesirable from a sanitary point of view from embarking. Dr. Doty is reported as saying that Havana is a most unhealthy place. There seem to be no methods of sanitation there at all. Many of the vessels in the harbor

are anchored near docks out of which the sewage flows, and thus bring infection away with them. He intended to visit the south side of the island, but he could not do so because the insurgents had practically blocked railroad traffic in that direction. He could not find the health officer or the health office in Havana. "Within the last two weeks preceding my departure," Dr. Doty said, "there were 300 cases of yellow fever there. No attempt has been made to sewer the city properly. By simply cutting through a narrow strip of land and dredging a channel the city's refuse might be carried into the gulf stream and far out to sea. With proper sanitary precautions Havana would be a remarkably fine city. The Spanish soldiers get sick on their way to Havana in the transports. When they land some of them are half dead from the effects of the fever."

**Culture Work in Diphtheria for the Buffalo Board of Health.**—Dr. W. G. Bissell, in the *Buffalo Medical Journal*, reports upon the bacteriologic work done at the laboratory of the Department of Health in 1895. He says that although a considerable amount of work relating to the diagnosis of diphtheria was carried on in the laboratory prior to January, 1895, it was at that time that the work was begun in a systematic manner. Out of 1,535 cultural inoculations made by the physicians in Buffalo since the inauguration of municipal bacteriologic examination, only eighty-three were found to be imperfect. Occasionally a culture was so neatly contaminated with various bacterial growths that it was impossible to recognize the Klebs-Loeffler bacillus, when the latter was present in small numbers. The smallest amount of certain germicidal fluids, especially the solutions of the bichlorid of mercury, in the throat of a patient at the time of the culture-taking will frequently prevent growth on the culture media. Of the 1,040 cultures which did not reveal the Klebs-Loeffler bacillus, the organisms found, named in order of the frequency of their occurrence, were as follows: Staphylococci, the most numerous being the aureus; cocci without any definite arrangement; streptococci; bacilli other than the Klebs-Loeffler and deserving of special mention, a very large strepto-bacillus was of frequent occurrence; the thrush fungus; diplococci. The greatest mortality in cases of diphtheria appears to be produced by a mixed infection; that is, the specific germ is usually associated with either the streptococcus or the staphylococcus. It seems also to be a fact that when both the staphylococcus and the streptococcus are associated in the same culture with the diphtheria bacillus, that the case is a mild one. From this latter point it would certainly appear as if there was a certain antagonism between the combined cocci and the diphtheria bacillus, and this latter point seems well worthy of consideration and experiment. Many experienced physicians still find difficulty in believing that cases in which the exudate or pseudo-membrane is entirely absent from the pharynx and tonsils are those of true diphtheria, and it is also difficult to impress upon parents that a case is diphtheria and capable of transmitting the infection, although the person infected is hardly in a condition to be called ill.

**Health Report.**—The following reports of mortality from smallpox, yellow fever and cholera have been received in the office of the Supervising Surgeon-General U. S. Marine-Hospital Service:

## SMALLPOX—UNITED STATES.

New Orleans, August 8 to 15, 1 case.

## SMALLPOX—FOREIGN.

Alexandria, Egypt, June 4 to 10, 1 death.

Buenos Ayres, May 1 to 31, 15 deaths.

Cairo, Egypt, June 4 to 10, 4 deaths.

Callao, Peru, July 19 to 26, 12 deaths.

Corunna, Spain, July 11 to August 1, 3 deaths.

Dublin, Ireland, July 1 to 31, 1 death.

Guayaquil, Ecuador, August 1 to 7, 1 death.

Hong Kong, July 11 to 18, 2 deaths.

Leith, Scotland, August 1 to 8, 1 case.  
 Licata, Italy, July 25 to August 1, 1 death.  
 London, England, August 1 to 8, 22 cases.  
 Madrid, Spain, July 28 to August 4, 26 deaths.  
 Montevideo, Uruguay, July 11 to 18, 3 cases, 1 death.  
 Moscow, Russia, July 25 to August 1, 1 case.  
 Odessa, Russia, July 25 to August 1, 5 cases, 3 deaths.  
 Osako and Hiogo, Japan, July 4 to 11, 47 cases, 21 deaths.  
 Prague, Bohemia, July 25 to August 1, 1 case.  
 St. Petersburg, Russia, July 25 to Aug. 1, 3 cases, 3 deaths.  
 Warsaw, Russia, July 25 to August 1, 2 deaths.

**CHOLERA.**

Egypt: Alexandria, June 4 to 10, 23 deaths; Egypt, June 4 to 10, 133 deaths.

**YELLOW FEVER.**

Matanzas, Cuba, August 5 to 12, 28 deaths.  
 Sagua la Grande, Cuba, August 1 to 8, 99 cases, 10 deaths.  
 Santiago, Cuba, August 8 to 15, 27 deaths.  
 Quantanamo, Cuba, July 1 to 31, 13 deaths.  
 Havana, Cuba, August 6 to 13, 160 cases, 52 deaths.  
 Vera Cruz, Mexico, August 6 to 13, 3 cases.

**SOCIETY NEWS.**

**Mississippi Valley Medical Association.**—The time of the twenty-second annual meeting of this Association at St. Paul, Minn., has been changed to Sept. 15-18, 1896.

**American Dermatological Association.**—This Association will hold its twentieth annual meeting at Hot Sulphur Springs, Va., Sept. 8-10, 1896. The following papers will be read: "A Pathologic and Clinical Classification of the Diseases of the Skin," L. A. Duhring; "Erythema Multiformis," with a report of two cases, W. T. Corlett; "A Peculiar Affection of the Mucous Membrane of the Lips and Mouth," with colored drawings and photographs, J. A. Fordyce; "A Favus-like Eruption of the Oral Mucous Membrane Caused by the *Aspegillus Niger*," J. MacF. Winfield; "What Effect do Diet and Alcohol have upon the Causation and Course of the Eczematous Affections and Psoriasis," discussion opened by J. C. White; "Cases of Mycosis Fungoides and Sarcomatosis," J. T. Bowen; "Xanthoma Diabeticorum," A. R. Robinson; "Some Glycosuric Dermatoses," C. W. Allen; "The Relation of Dermatitis Heptiformis to certain other Diseases," L. A. Duhring; "Bath Pruritus," H. W. Stelwagon; "Eruption from the Local Use of Iodoform (with colored drawings)," J. A. Fordyce; "Impetigo Contagiosa Universalis," C. W. Allen.

**Pan-American Medical Congress.**—Dr. C. H. Hughes, honorary president of the Section of Neurology, Psychiatry and Medical Jurisprudence of the Pan-American Medical Congress, is sending out the following invitation to the alienists, neurologists and medico-jurists of the United States:

*My Dear Doctor:*—Can the Section rely upon you for a paper or subject of discussion for the Pan-American Medical Congress to be held at the City of Mexico, November 16, 17, 18 and 19 proximo?

I have just been informed, rather tardily I think, of my selection as honorary president of the Section of Neurology, Psychiatry and Medical Jurisprudence for the United States.

The meeting promises to be an exceedingly profitable and agreeable one socially and scientifically. We should make the best showing we can for American psychiatry, neurology and forensic medicine. You can materially help in this laudable direction. Will you promise a paper and your presence on this interesting occasion? If so, please indicate on the enclosed your intention to be present. Address Dr. E. Licéaga, Secretary, Republic of Mexico, Calle de San Andres No 4, Mexico City.

Yours very truly, C. H. HUGHES, M.D.,

St. Louis, Mo., Aug. 14, 1896. Honorary President.

Accompanying each enclosure is the following announcement and request from Dr. Licéaga, Secretary-General of the Congress:

I have the honor to request your presence in the Second Pan-American Medical Congress, which will meet in the City of Mexico on November 16, 17, 18 and 19 of the present year, sending you separately the respective rules.

I beg of you to answer if you come, and how many persons

will accompany you. The invitation is also for ladies, and we hope to obtain a considerable reduction on the round trip rates, but for such reduction the railroad companies must know three months before the meeting the number of passengers and the places they come from.

Please send as soon as you can the answering card, filling the spaces marked for names and addresses.

DR. EDUARDO LICÉAGA, Sec'y 2d P.-A. M. C.

Mexico City, January, 1896.

Dr. Hughes requests his neurologic friends who contemplate attending the Congress and taking part in the work of this Section to accept in his name the foregoing request from President Licéaga and to answer direct to him the questions Dr. Licéaga propounds.

**MISCELLANY.**

**New Edition of Gray's Anatomy.**—Lea Brothers & Co., of Philadelphia and New York, announce a new edition of Gray's Anatomy. The few errors of previous editions have been corrected, and many additions made.

**Honorary Chairman.**—Dr. N. C. Morse, of Eldora, Iowa, has been elected, on behalf of the United States, honorary chairman of the Section on General Medicine of the second Pan-American Medical Congress.

**Professor Behring's Resignation.**—Professor Behring is about to resign his chair (hygiene) at the University of Marburg, in order to devote himself exclusively to scientific research. Wernicke will probably succeed him.

**The Vienna Medical Association.**—Dr. Adamkiewicz has been dropped from the list of members on account of his having advertised his cancer cure in the daily press. The inefficacy of the cure was fully established by Professor Albert and others after careful trial.

**Serum Treatment of Leprosy.**—Carrasquilla's success with fifteen cases of leprosy treated with serum from horses inoculated with the disease, has already been mentioned in this JOURNAL, page 943. A copy of his report to the Bogota Academia de Medicina (Republic of Colombia) has been received. His methods are similar to those generally practiced in sero-therapeutics, but until we read a detailed description like this few realize the infinite devotion and courage required in this branch of science.

**Evidence Required to Prove Intoxication.**—Evidence of intoxication which unfits one for his duties is competent in some cases in investigating whether his acts are negligent or not. But the supreme court of Missouri holds, in *Culbertson v. Metropolitan Street Railway Company*, decided June 30, 1896, that the mere habit of taking an occasional drink can not be regarded as any evidence of intoxication in the practical administration of justice, whatever abstract theories physiologists may advance on this subject. The evidence should and must go further, and show that the liquor affects the particular individual in such a way as to incapacitate him to some extent to attend to his duties.

**Too Speculative Opinion Evidence.**—The opinion of a medical witness as to the mental condition of a person at a certain time, based upon a physical examination made eighteen months afterward, where such witness is not informed as to the mental condition at the time when the mental capacity was in question, the supreme court of Kansas holds, in *Missouri Pacific Railway Company v. Lovelace*, decided July 11, 1896, is largely conjectural, and is too uncertain and speculative to be valuable or admissible. Opinion evidence, the court says, is only admitted from necessity, and then only when it is likely to be of some value.

**Does Not Believe in "Fortune Telling."**—The supreme court of Michigan affirmed, May 26, 1896, in the case of *People v. Elmer*, a conviction of "a modern day seer," "clairvoyant," "trance medium," and "healer" as a disorderly person. The court

quotes with approval the language used in the English case of *Penny v. Hanson*, which was, in effect, that no person who was not a lunatic could believe that the person referred to possessed such power as he advertised, his advertisement and circular amounting to pretending and profession to tell fortunes. And it is idle, says the court, to attempt to draw distinctions between professing to possess a power and pretending to exercise that power.

**Detection of Formol Added to Milk.**—Some of the milk sold as sterilized in the market has merely had formol added to preserve it, which is certainly not a benefit to infants. It can be detected promptly and rapidly by Denigés' method described in the *Bull. de la Soc. de Phar. de Bordeaux* for July. Boil two to three cubic centimeters of the suspected milk, add 10 to 15 drops of the following fuchsin reagent; then add one c.c. of pure hydrochloric acid. If the milk contains formol, the resulting mixture will be a violet blue, but if there is no formol it will be white like pure milk. The fuchsin reagent is prepared as follows: One-half per cent. solution of fuchsin, 40 c.c.; aq. dest., 250 c.c.; add 40 per cent. bisulphite of sodium, 10 c.c., and pure sulphuric acid, 10 c.c.

**The Bertillon Method in Brooklyn.**—At the Kings County Penitentiary, this system has been taken up with unusual thoroughness. A medical man, Dr. Stumpf, the assistant physician for the penitentiary, has been placed in charge of its early stages, and he is to have an exclusive cabinet or building wherein to conduct his examinations, and where the photographs and measurements can be made. This building, 20 by 18 feet, will have a north light, an abundant skylight roof and a photographic chamber.

**A Characteristic Anecdote of Pasteur.**—Once when Pasteur was dining with his daughter and her family at her home in Burgundy, he took care to dip in a glass of water the cherries that were served for dessert and then to wipe them carefully with his napkin before putting them in his mouth. His fastidiousness amused the people at the table, but the scientist rebuked them for their levity and discoursed at length on the dangers in microbes and animalcula. A few moments later, in a fit of abstraction, he suddenly seized the glass in which he had washed the cherries and drank the water, microbes and all, at a single draught.

**Atomizer Decision.**—May 21, 1896, the United States circuit court of appeals affirmed the decision of the circuit court in the case of *Codman v. Amia*, holding claims 1 and 2 of the Shurtleff patent, No. 447,064, for an improvement in atomizers, void for want of patentable novelty. This patent, the court says, simply describes a compact form of atomizer, which is better adapted than some others for nasal purposes. The specific improvement set out in the first claim consists in having the nozzle "secured directly to" the "cap or stopper, and adapted to be applied in the nostrils, and in open communication with the interior" of the vial; and in the second claim it consists of a cap or stopper having "its top formed with a seat for the nozzle." An examination of certain other patents mentioned, the court declares shows clearly that there was no invention in these improvements.

**Care Required of the Blind.**—The blind have as much right, says the supreme court of Florida in the case of the *Florida Central and P. R. Co. v. Williams*, decided April 14, 1896, to frequent railroad depots, public crossings and other places of danger, as any other of the general public. But, when they do so, due care dictates that they must provide themselves with such surroundings while there as are reasonably necessary to avoid upon their part all the known dangers that encompass the place. It is gross negligence in a blind man to expose himself alone and unattended in any situation where he knows that the faculty of sight is absolutely necessary to the safety of life and limb.

**Proper Testimony as to Probability.**—In an action for personal injuries the plaintiff's mother testified that since the wound in question had apparently healed it had broken out, and discharged blood and matter; that the wound was very tender; that she called no physician, but cared for it herself. A physician testified as to the cause of its breaking out, and that, from the fact that the wound had once broken out, it was liable to do so again. He was then asked: "What do you say as to whether that result is probable and likely to occur?" This question was objected to; but no objection was made as to want of knowledge by the witness of the facts, or that the form of the question should have been hypothetical, and the appellate division of the supreme court of New York holds, in *Penny v. Rochester Ry. Co.*, decided June 17, 1896, that the question was proper as calling for what was probable and likely to occur.

**Physiologic Action of Airoi.**—The *Gaz. degli Osp. e delle Clin.* of July 5 contains the results of a careful study of the effects of airoi made in Mosso's laboratory at Genoa. It was found that it slightly accelerates the coagulation of the albuminoids, and that in cold-blooded animals it retards the cardiac action. In warm-blooded animals the effect differed with the amount administered and the method of administration. There was no toxic action when injections were made hypodermically or into the ear, but symptoms of intoxication followed injections into the peritoneal cavity with renal inflammation. With these toxic doses there were noticeable alterations in the crasis of the blood, due to the special action of the iodine on the hemoglobin. Used externally airoi proved a good antiseptic, by no means inferior to iodoform.

**The New York Skin and Cancer Hospital.**—The old structures of this institution that have been in use for fifteen years are being torn down to give room to a more commodious hospital. The new building will be of four stories and basement, the material to be brick with white limestone dressing. The building will be substantial, pleasingly simple, with all modern sanitary features, with accommodations for forty-two patients and an outside department that can care for 100 patients on ordinary occasions. It will cost \$80,000. The basement will contain a complete system of Russian and medicated baths, so necessary in the treatment of skin diseases. The first floor will contain the dispensary, waiting rooms for eighty patients and the officers' rooms. On the second floor will be the ward for treating skin diseases, with the necessary operating rooms and nurses' quarters adjoining. On the third floor will be the wards for cancer patients. Then on the top floor will be private rooms for pay patients, operating room and quarters for attendants. Throughout, the building will be plainly and substantially furnished in brick and tile, that the utmost cleanliness may be observed.

**Enzymes.**—Fischer and Lindner have found that Froberg and Saaz's bottom yeast contains an enzyme that is capable of splitting melitose into hexose, a power entirely lacking in invertin. No substance containing an enzyme that had any power to split cane sugar or maltose, could be extracted from the *monilia candida*, and the yeast itself works in this way only in the presence of toluene. They therefore conclude that the enzyme of this yeast is an insoluble substance, which is gradually disintegrated by the toluene. No enzyme that would invert cane sugar could be derived from the *saccharomyces apiculatus*. (From the *Cbl. f. Phys.*, for July 11, which also reviews Arthus's study of the various theories in regard to the nature of enzymes.) According to one theory they are albumoses, as although they do not have the same proportions in their composition as the albumoses, they possess the same properties. Others take an exactly opposite view, and still others believe that the enzymes are carbohydrates or gummy substances. Arthus concludes by stating his own theory, which is that the enzymes are not material substances, but only properties of material substances, like the physical forces.

**Experimental Suture of Tendons.**—Baldassari has succeeded in securing complete regeneration of tendons in animals after cutting out a piece and making a tubular suture. In one or two months there was no apparent difference in shape, size or strength between the sutured tendons and the normal (rabbits).—*Gaz. d. Osp. e d. Clin.*, June 27.

**An Unfortunate Appointment.**—The appointment by Governor Altgeld of Mr. W. P. Boyd to the vacancy in the Illinois Board of Pharmacy, occasioned by the tragic death of President Coffee, while perhaps above criticism so far as concerns the qualifications and merits of Mr. Boyd, was nevertheless in deliberate defiance of wise precedents and of the manifest intent of the State pharmacy law, which contains a specific provision as to the manner of appointment, as sanctioned by the druggists of the State. The law provides that the State association shall annually recommend to the governor the names of persons deemed most worthy for appointment on the board. This provision applies in principle as forcibly to vacancies resulting from accidents or resignations as from term expirations. Governor Altgeld, in once before defying this wise provision, and now again exercising his prerogative in contemptuous disregard of the recommendations of the Illinois Pharmaceutical Association proves himself a lover of the very form of tyranny in himself which he affects to despise so heartily in others. The appointment of Mr. Boyd was clearly made for purposes of political profit for the governor in the pending campaign. Whether the outrage perpetrated upon the expressed sentiment of the druggists of the State will make the appointment one of net profit remains to be seen.—*Western Druggist*, August.

**Experimental Thyroidectomy.**—The *Cbl. f. Chir.* of July 25 contains a contribution to our knowledge of the effects of extirpation of the thyroid gland, with some curious facts collected by Lanz in his extensive investigations. He finds that removal of the thyroid gland and the absence of its secretions can be fully made up to the organism by transplanting other glands and even by subcutaneous injections or internal administration of the extracts, but it is necessary to commence the treatment the very day of the extirpation (dogs). A hen whose thyroid gland had been removed, only laid one egg, one-tenth of the usual weight during the four months after the operation, while, on the other hand, a normal hen fed with thyroid extracts, laid three times as many eggs during the month as any one of the eight control fowls. Lanz also extirpated the gland in fishes. Forty-four operations on the common shark prove that this gland performs a vital function in cold-blooded beings also. Death followed in from twelve to forty days, after a slow, gradual development of the chronic symptoms usually following thyroidectomy.

### Philadelphia.

**MIDSUMMER MORTALITY.**—During the week ending August 15, the number of deaths from sunstroke and heat exhaustion were 173. There were also 106 deaths from cholera infantum, the total mortality of the week among children under five years of age being 315. Probably a large proportion of these cases was caused indirectly by the exceptionally high temperature which prevailed from the 5th to the 14th inclusive. The total number of deaths was 838, which was 47 less than that of the memorable week ending July 13, 1872, during which the mortality from cholera infantum was frightful. Although recently the weather has been exceptionally severe and prolonged, yet the mortality has not been so much increased by the heat as might have been anticipated from the experience of former years. This may be attributable to several causes, among which may be prominently noted the improved paving of all the large streets and particularly of the alleys and small streets, which has been accomplished after several years work. The small streets are frequently flushed with water and great attention is given to the

daily collection of garbage and the abolishing of nuisances. Backyards and cellars are inspected and cleaned. Unwholesome and spoiled food is condemned and destroyed and street peddlers are fined for selling articles that are injurious or prejudicial to health. Special attention has been given to the inspection of milk, and vendors of adulterated or watered milk are prosecuted. In addition to these hygienic precautions, the city has six free bathing houses in different parts of the poorer districts, which are largely patronized. The city has recently established a number of small parks in the congested districts and the schoolyards have been thrown open, as well as some of the piers on the river front, for play grounds and breathing places, especially for the younger children. It is also believed that the open trolley cars have had a very decided influence in improving the public health by taking people out into the suburbs, where they can breathe purer air than in the heated streets. It has been stated that the business of the saloons has fallen off during the hot spell, which, if true, indicates that the public has learned the lesson of the special dangers from intemperance during such weather, and the close relation existing between alcoholism and sunstroke. It is also very probable that the decreased mortality may be attributed to modern therapeutic measures, especially in our large hospitals.

**TREATMENT OF INSOLATION AT THE PENNSYLVANIA HOSPITAL.**—The method of treating thermic fever by the external application of ice and ice water, combined with friction, originated at the Pennsylvania Hospital some thirty years ago, during the term of service of the late Dr. James Leveck, and its usefulness has been so fully demonstrated that now it may be regarded as the accepted treatment of hyperpyrexia following exposure to the sun. At this institution, temporary wards in tents have been established for the season on the lawn, under the shade of the trees, and the heat has recently been so great, that during the middle of the day the hose was played on the outside of the tents to reduce the temperature. The woman's insolation tent is smaller than the men's, and is in a remote portion of the enclosure. The management of a case is generally as follows: As soon as the patient is brought in by the ambulance, he is stripped and his temperature taken. If it is a case of high temperature, he is put into the bath to which pieces of ice are added and he is vigorously rubbed by the hands of attendants, or he is placed upon a couch and rubbed with pieces of ice, and an ice cap is applied to his head, until the temperature is reduced to the normal or under. If the pulse is weak, hypodermic injections of nitroglycerin (gr. 1-100) with whisky (m. xx) are repeated at intervals of an hour or two; hypodermics of atropin (gr. 1-60) or of strychnin (gr. 1-30) are substituted later, if the heart is weak. In one case hypodermic injections of tincture of digitalis (m. xv) given every hour for four hours, was apparently effective in saving life. Small doses of morphin (gr. 1-8 to 1-6) were also used, where great restlessness or muscular twitching was present. Where there was great fulness of the vessels of the head and neck with symptoms of central congestion, leeching at the occipital region, followed by the ice cap, gave good results. In one patient Dr. Starbuck, in order to relieve convulsive symptoms in an apparently moribund patient, took a pint of blood from the arm and a pint of normal salt solution with immediate good results. After the bodily temperature of the patient has been reduced to somewhere near the normal, he is removed to the medical wards, and there treated with cardiac tonics and a restricted diet, the amount of nourishment or stimulants being regulated by the condition of the patient. After a few days rest in bed, if the fever returns and the temperature of the ward is excessive, the patient is returned to the tent in the open air, and given cold baths, or the cold applications may be used in the ward. In cases attended by hyperthermia, the extraction of excess of bodily heat, and the sustaining of the heart's action are the prin-

cipal objects sought to be attained by the treatment. In heat exhaustion, where the temperature is not greatly increased or remains about normal, the patient is placed in a bed in the open tent, and nitroglycerin or atropin given in moderate doses, followed by strichnin or digitalis during convalescence. The success of this treatment is shown by the fact that out of a total of over sixty cases (of which only four were women) there were only two deaths during the ten days of hot weather. One case at the autopsy was found to have advanced degeneration of the kidneys, and the other had been taken ill on a train and it was several hours before he was brought into the hospital, when he was in a hopeless condition, dying shortly after admission.

**A CASE OF MIXED INTOXICATION.**—A man 43 years of age, after a prolonged indulgence in alcohol, being suicidally inclined, swallowed, it is said, ten ounces of laudanum and, in order to take the taste out of his mouth, immediately washed it down by a draught of two ounces of lead water. He was taken to the German Hospital, where the stomach pump was used with the result of bringing to light the lead water and laudanum mixture so familiar to a former generation of surgeons. The patient recovered promptly without any symptoms of narcotism, and may live to prove the truth of his assertion that his life was not worth saving.

**APPENDICITIS OPERATIONS.**—Operations for removal of the appendix vermiformis nowadays are of such common occurrence as scarcely to require comment. It is, however, noteworthy that the operation has been successfully performed upon a dozen or more of the physicians of this city, especially those who are rising into prominence in various specialties. Dr. Joseph Price, who has operated upon several physicians, is very positive that the tendency to suppurative inflammation of the appendix, which has recently occurred with so much frequency as almost to assume the proportions of an epidemic, is in reality one of the evil consequences of the grippe. He claims that physicians and surgeons of ten or twenty years ago were not so ignorant or unobservant as not to be able to recognize inflammation of the appendix, which every tyro can diagnose to-day, and the only explanation possible is that the cases did not occur, and in fact were extremely rare. The wide extension of the influenza epidemics and the well known tendency to mucous membrane inflammation, gastro-intestinal as well as pulmonary, affords, in Dr. Price's opinion, an efficient cause for the present prevalence of appendicitis. Certainly medical men are not fond of surgical operations upon their own bodies, and the fact that they have taken the risks and submitted to the surgeon's knife, demonstrates very clearly that the condition is a real one and not a figment of the imagination of the abdominal surgeon; nor does the frequency of operation argue the existence of an operative mania on his part.

**THE CITY BACTERIOLOGIC LABORATORY AND DISINFECTING PLANT.**—In the basement of city hall, Dr. J. M. Bolton and his assistant, Dr. Wm. G. Gillespie, have installed a plant for manufacturing a disinfectant solution out of sea water by means of electrolysis. The product is termed "electrozone" in the report just made by Dr. Gillespie of the result of his recent experiments, which proved the solution to be a powerful germicide. He stated that it kills anthrax spores in five minutes or less, and it is superior to corrosive sublimate, since it does not form an inert insoluble precipitate with all albuminous substances as the latter does, thereby diminishing its power and efficiency as a germicide. It is further commended for its cheapness and the facility of its manufacture in large quantity. It is considered an ideal agent for the purpose and as a municipal germicide and disinfectant; according to Dr. Gillespie, it can not be surpassed. As it is so easily manufactured it would seem obligatory upon health authorities to largely avail themselves of this cheap disinfectant.

**THE ROENTGEN RAYS IN SURGICAL DIAGNOSIS.**—In the recent case of a child, 4 years of age, who swallowed an iron toy "jackstone," which was lodged in the esophagus, it was found that the patient was too restless to permit the ordinary exposure to the X rays required to obtain a negative, and accordingly the fluorescent screen was substituted and the foreign body located between the clavicle and the second rib. Dr. A. C. Wood opened the child's stomach and succeeded in bringing down

the jackstone through the cardiac orifice by entangling it in the meshes of a skein of silk. This is the second case of this kind occurring recently at the Hospital of the University of Pennsylvania, the former operation having been performed by Prof. J. Wm. White. The condition of the bones of the foot in the condition known as metatarsalgia, or Morton's painful affection of the foot, was well shown in some radio-photographs exhibited by Dr. Thos. G. Morton, president of the Academy of Surgery, at the last meeting of this society.

## THE PUBLIC SERVICES.

**Army Changes.** Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from Aug. 14 to Aug. 21, 1896.

Major Henry McElderry, Surgeon (Ft. Robinson, Neb.), leave of absence granted is extended two months.

**Navy Changes.** Changes in the Medical Corps of the U. S. Navy for the week ending Aug. 22, 1896.

P. A. Surgeon A. M. D. McCormick, detached from the "Bancroft" and ordered to the naval academy.

P. A. Surgeon E. M. Shipp, detached from the "Monongahela" and ordered to the "Bancroft."

**Marine-Hospital Changes.** Official list of changes of station, and duties of Medical Officers of the U. S. Marine-Hospital Service, for the fifteen days ended Aug. 15, 1896.

Surgeon W. H. H. Hutton, granted leave of absence for thirty days from Aug. 25, 1896, Aug. 13, 1896.

Surgeon H. W. Sawtelle, granted leave of absence for twenty days from Aug. 25, 1896, Aug. 13, 1896.

Surgeon C. E. Banks, to assume temporary command of the Service at Vineyard Haven, Mass., for thirty days, Aug. 13, 1896.

P. A. Surgeon S. D. Brooke, to assume temporary command of the Service at Cleveland, Ohio, Aug. 8, 1896.

P. A. Surgeon R. M. Woodward, granted leave of absence for thirty days from Aug. 13, 1896, Aug. 11, 1896.

Asst. Surgeon Jos. B. Greene, granted leave of absence for twenty-three days from Sept. 14, 1896, Aug. 13, 1896.

### Change of Address.

Brassell, T. C., from Stroman to Leesville, Tex.  
Greene, H. S., from Masonic Temple to 70 State St., Chicago.  
Lacy, Hattie E., from 1461 Jackson Boul. to 820 N. Park Av., Chicago.  
Murrill, T. E., from Santa Fe N. M., to 2205 Colfax Av., Denver, Colo.  
Reun, T. H., from 1241 Milwaukee Av. to 227 Townsend St., Chicago, Ill.  
Smith, O. E., from Grand and Caroline Sts. to 3509 Lindell Av., St. Louis, Mo.

Seacat, G. M., from Kinsley to Cherry Vale, Kan.

Seagley, J. B., from Chicago, Ill., to Scott, Ind.

Tasche, J. C., from Sheboygan to Howard, Wis.

White, J. W., from 64th and Grace Av. to 754 69th Pl., Chicago, Ill.

Walker, Robt. S., from Beacon, Mich., to Toledo, Ohio.

## ADDRESS.

### THE MUTUAL RELATIONS OF THE MEDICAL PROFESSION AND THE PUBLIC.

President's Address Forty-sixth Annual Meeting of the Illinois State Medical Society, delivered before the Members of the Society and the Citizens of Ottawa, evening of May 19, 1896.

BY DAVID W. GRAHAM, A.M., M.D.

CHICAGO.

The Illinois State Medical Society requires of its presiding officer each year an address on some subject of his own choosing, the members of the Society for the most part constituting the audience. But to some extent the nature of the subject and the character of the audience for this evening have been determined by the circumstances under which this meeting is held, and the plans of the committee of arrangements.

The reciprocal relations and duties of the medical profession and the community is, as a theme, like an old jewel which requires an occasional resetting to bring it into harmony with the changes of time and circumstance.

While some of these relations and duties are always and everywhere the same, the subject still requires frequent restatement, both because of its perennial interest to the profession and the public at large, and also because in the progressive community the mutual relations of the various interests, occupations and component parts of that community are constantly undergoing change and requiring readjustment.

In a limited sense each individual member of the modern industrial community is pursuing that course and conduct of life which he chooses for himself so far as he is not prevented from doing so by the natural limitations of his own powers of mind and body, by his environment, and by the presence and plans of others. Every individual thus becomes a competitor or antagonist of every other within his own sphere of action in the struggle for existence and advantage. The rivalry of individuals is also a prominent characteristic in the uncivilized state of society. But division of labor with coöperation and mutual interchange of the benefits and products of effort is the law of civilized life. Without these no community can become civilized or maintain the civilized state. In such a community no one can be for himself alone. Every one must both give something to, and receive something from, others. Likewise a group of individuals which stands for a particular interest, or represents a given line of activities, is dependent upon, and accountable to, every other group of the same community.

There is a certain analogy between the human body as an organism and the civilized community, and the more highly developed the latter, the more perfect is the analogy.

The body is an aggregation of organs, as the hands, the feet, the eyes, the ears, the lungs, the nerve centers and so on. Each organ has a function to perform both with respect to itself, and also in its relations to the organism as a whole. The principles of division of labor and coöperation, with mutual interdependence, are perfectly exemplified. The civilized community is likewise an organism separable into, or composed of, individuals or groups of individuals, each unit or group corresponding in some sense to an organ of the human body. There is the hewer of wood and the drawer of water, the farmer, the merchant, the manufacturer, the teacher, the preacher, the lawyer, the physician and so on, the organs of the body politic; each having a place for itself and a duty to perform for all the others. No one interest can suffer without detriment to the whole. The more harmonious and symmetrical the development of the various component parts, the more perfect the development of the whole. The more perfectly and clearly the true relations and the relative duties and functions of the several factors to each other are recognized and kept in view, the greater will be progress in all that goes to make up the civilized life.

The medical profession as one of the constituent parts of the community has intimate relations to every other interest and to every other part of that community. Its work and the principles which it represents, are in their importance to organized society second to no other.

If, as a modern philosopher declares with respect to the moral quality of human actions, "the highest conduct is that which conduces to the greatest length, breadth and completeness of life," then the medical calling must take high rank if not the highest of all others; for the genius and the end of this calling are to secure that length, breadth and completeness of life for all mankind.

Not many centuries ago medical knowledge and medical practice were concerned with little more than the giving of crude drugs and caring for the more common accidents of life. Diagnosis was almost purely a mental process, with only a slender basis in the observation of the most superficial manifestations of disease. Causation was mythical speculation based on superstition. Prevention of disease was counted a sacrilege rather than as belonging to the science and art of medicine.

But medical science has outgrown the narrow limits of the past, and the history of its growth from the primitive state to its present position is a part of the history of civilization. It stands for the physical perfection of the individual not only, but also for the improvement and perfection of the human race. Though it deals first and chiefly with the diseases and imperfections of the individual, it extends its dominion over aggregate life in all its combinations and ramifications, and inasmuch as it discovers and

demonstrates the laws and influences of heredity, over transmitted life as well.

While its most evident functions are to treat disease and manage the sick, yet it is not less concerned with the prevention of disease and the discovery of its causes.

It is the source of modern psychology which dictates modern methods of education. It is the center of all that knowledge of the defective and dependent classes, as the insane, the idiotic, the deaf and dumb, the pauper, the inebriate and the criminal—which has led up to their humane management and rational treatment.

It puts every branch of science under tribute; as biology, of which it is now itself recognized as a part, which demonstrates that the diseases which afflict mankind are largely the result of conflict between the lower and the higher forms of life; and the whole range of the physical sciences whose wonderful development has been such a conspicuous feature of recent time, and whose contributions have added immeasurably to the powers and scope of medical knowledge in the way of diagnosis, treatment, prevention and the discovery of the causes of disease. Medical science thus includes all knowledge of whatsoever kind, or from whatsoever source that tends to prolong life and ameliorate its conditions. This is the high conception of the nature and the purpose of the science and the art of medicine for which we would plead.

Through medical science the medical profession has a twofold relation to the community at large. First, that in which the physician lives for himself, and second, that in which as a benefactor he contributes to the welfare of others, in which he is the exponent of all that medical science means to men.

By it and through it he earns his living as a citizen. He thus discharges his first duty to himself and others both in point of time and importance. It is the field in which he toils as a man, that sowing and tilling he may reap from it the rewards of the labor of his life.

The medical calling considered purely as a calling in which the physician manifests the selfish side of his life, selfish in the sense and to the extent that he lives for himself as distinguished from others, stands on the same footing and sustains the same relation to the community and the State as any other calling.

Physicians are not entitled to any special privileges and should receive none on their own account. If they sometimes ask for them on this ground, it is through ignorance and mistaken notions of their rights and privileges. There is a widely prevalent notion in the minds of the public that the laws and customs of society "hedge about" the medical calling in such a way as to favor the physician as compared with those of other occupations. A presumably learned judge of our own State, within the last year, has given public utterance in his official capacity to this erroneous interpretation of the laws and customs of society as they relate to the medical calling, in a case which has become somewhat celebrated on account of the ruling of the court and the arguments used to sustain his position. A physician was called as an expert witness by the city of Springfield, as defendant in a personal injury damage suit. The physician refused to testify unless a reasonable fee should be guaranteed him as an expert witness. The presiding judge in arguing against the position assumed by the witness, said among other things that, "so far as the witness is able to respond to proper questions propounded to him on

the trial of a cause, while he is upon the witness stand, without previously making special preparation or examination to enable him to answer that particular question, I think it is his duty to answer. Especially the court holds is that true of physicians. Physicians in this State are favored children of the State; a department of the State government is maintained very largely for their benefit; they hold a license to practice their profession and practice by grace as well as by right, and are so hedged about and protected by the laws of the State, and by public opinion and confidence, that in five minutes of a time a doctor may earn more than an ordinary laborer could earn in a day, and may continue to earn such fees all day long, even on a day he may be required to attend court, except the hour or so devoted to attending on the court. Very much of that is because of the laws of the State which nurse their profession, and by grace which the State and society extends to them in regard to their profession."

If the department of the State government here alluded to, viz., the State board of health, is maintained largely and principally for the benefit of physicians, then it ought to be wiped out of existence, and would be as soon as it were put to the test. If the State board of health has any reason for existence at all, it is because it is supposed to protect the lives and health of the people at large. And to the extent that these objects are secured, just to that extent is the physician in the pursuit of his calling, as it relates to himself, interfered with, rather than benefited. Perhaps the learned judge could tell us how the prevention of disease and the preservation of health by the State inures to the benefit of physicians, as a class, for it is not evident on the surface.

If the laws of the State "nurse the profession," and foster medical science, it is that the community as a whole may be benefited, and not the physicians as a class. If a law of the State exempts the physician from jury duty and other duties of the citizen, it is not because he himself has any claims to such exemption. If a city government gives the physician right of way in a crowded street, or allows him to break through a procession, it is not that he may thereby add to his comfort or his income, but because he is supposed to be on an errand of mercy and humanity for others.

"They hold a license to practice their profession, and practice by grace as well as by right," says our expounder of the law. If the practice of medicine is a legitimate calling, a useful calling, then the physician would seem to have the same right to pursue that calling as any other citizen has to pursue any legitimate calling. If so, then it is not in any degree by grace. The license of the physician like the license of the lawyer or that of the locomotive engineer is generally counted as an evidence of technical qualifications and a restriction or limitation. It has reference to the rights and safety of the community, rather than to the individual holding it. It tells the public that he is a physician in fact, not a pretender. It confers no benefit on the individual physician, but it does protect the interest of those with whom he deals, and is for their benefit, not his. Whatever benefits come to the physician by reason of the laws of the State, or customs of society bearing on the medical calling or the medical profession, are purely incidental to their primary object of conferring benefits on the community at large.

In this relation also the physician is entitled to the rewards of his labors. No less than others is he worthy of his hire. While he is treading out the corn like the ox, he should not be muzzled. If he tread the wine press he should share in the vintage. That every individual should receive all the rewards which his ability, his industry, and his opportunities can secure for him in a legitimate calling honestly pursued, is a self-evident proposition which admits of no exceptions. That community in which this fundamental principle is the most clearly recognized, and the most perfectly applied will be the best community, the most highly civilized, and the most perfectly adjusted in all its parts. If any one class or constituent part of a community is deprived of the legitimate reward of its labors, that class will lose something in its quality and in its power, and the society of which it is a part will suffer directly or remotely as a consequence. As when one member of the body deteriorates, the whole organism suffers loss.

Most physicians can be trusted as a rule to claim their own in the matter of pecuniary rewards for services rendered and they are not generally backward in asserting those claims. But as a class, physicians are inadequately paid if remuneration should bear direct relation to benefits conferred; and of all classes they are the most grudgingly paid.

The genius and the traditions of the medical profession require the physician to give his services whenever and wherever medical knowledge and medical skill are demanded for the relief of the sick and the afflicted, conscientiously to the rich and the poor alike, and with equal fidelity, and primarily without thought of reward. Thereby the medical calling becomes a profession as distinguished from a trade. By this token may we know the true, the ideal physician. But this conception of the professional aspects of the physician's life pertain to his obligation to his calling and his class, and does not carry with it the idea of unrequited toil. Neither does it absolve the individual or the community receiving those professional services from pecuniary obligations. While the physician is thus under obligations, by the very nature of his calling, to the poor around him, common equity would forbid that this obligation should be perverted by the community or any class of the community for its own benefit.

One of the most beneficent institutions of our day in theory and practice is the modern hospital, but there is a growing tendency to pervert and abuse it by certain classes of the community for the promotion of their own interest. The work of a large public hospital supported by general taxation, as for instance, the Cook County Hospital, is to a large and increasing degree taken up with the care of the sick and injured employes of the great corporations and the wealthy commercial establishments.

If such an employe can get free care and free medical attendance when sick or injured, he does not need and does not get as high wages as he otherwise would. There is, hence, more profit and larger dividends for the employer. If the multimillionaire corporation, half of whose capital is the value of the public franchise it possesses, and whose annual profits are so large that an occasional watering of its stock must be resorted to in order to keep the percentage rate of dividends within a reasonable limit in the eyes of the public, can require the medical profession and the public to treat and care for its sick and injured

employes free, in order that the profits of the concern may be larger on account of low wages of the employes; then why may not the public and other interests be compelled to furnish said employes with such other necessities as food, clothing and house rent? The sophistry and process of reasoning that would make one appear right and respectable can be used to justify the other also.

There are rewards other than pecuniary which are due the physician from the community, and of which he is sometimes deprived. It is due to the dignity of his calling, and in the interests of the highest usefulness of the profession to the public, that all positions of honor, profit, or trust, whose chief functions pertain to medical matters and require medical knowledge for their administration, should be held by physicians. The law expressly forbids that the president of the Board of Health of New York City shall be a physician, though a physician living in that city is eligible for the office of President of the United States, for that of Governor of his State or mayor of his city. Just why this prohibition exists is not explained, but it may be surmised that it is because it is the one position in the department which carries with it a high salary. In the chief city of our own State, the only medical office in the city government with a respectable salary is held by a layman, who never was suspected of having any knowledge of, or interest in, sanitary matters. The knowledge necessary for conducting the Department of Health is supplied by some ten or twelve physicians in subordinate positions, whose combined salaries amount to but little more than the salary of the layman who is at the head of the department. A company of West Point graduates going into battle commanded by a green recruit, would not be more anomalous. In our own State, as in most of the other States, the law provides for the office of coroner for each county. It is the chief duty of this officer to ascertain the cause of death in certain cases. The office is held in all the larger counties, that is, where there is any considerable remuneration attached to the office, by a man who possesses no medical knowledge whatever. He is ably assisted in his quest by six other laymen as jurors, who, in the large cities, are generally tramps. In our own State it is still allowable for six men, also mostly tramps in the large cities, to make a diagnosis of insanity in the name of the State.

There is another evil under the sun which pertains to the practitioner and the question of the rewards of his labors. A confusion of values in the minds of the public, and to some extent in the minds of the profession, has arisen in these latter days with respect to remuneration. This is partly due to the exuberant specialism which characterizes modern medicine. It is also partly due to the greater advance and wider scope of operative surgery, and in part to the relatively unimportant rôle which the internal treatment of disease by drugs has assumed in comparison with former times. There never was a time when the drug treatment of disease could accomplish more than to-day, when internal medication was more definite in its purpose, though its limitations are better recognized than before. While in former times it outranked in importance all other means and methods, to-day preventive medicine and operative surgery have outstripped it in the general advance in demonstrable results. But the physician who clearly saves a life by internal medication ought to have the same recognition from his fellow practitioners, and to

receive the same rewards from the public as he who does a life-saving surgical operation. If a practitioner prevents sickness which might or might not prove fatal, by timely advice to the family and neighbors who rely on him in times of thickness, as by preventing the spread of typhoid fever, diphtheria and other contagious diseases, he renders a service upon which an adequate money value can not be placed, and yet he rarely receives any pecuniary or other reward for such a service. Even the average educated, prosperous citizen would resent the effort to collect more than a nominal consideration.

The family physician who stands by his trust and faithfully guards and guides a whole generation from birth through childhood and adolescence to manhood and womanhood, directs their education, training and growth, and blazes the way against the pitfalls of hereditary tendency to disease of body and mind, and in all these periods and relations gives the best resources of the whole range of the science and art of medicine to his charge, outranks in point of service to the individual and humanity all other classes of practitioners. It is to the detriment of the medical profession and the community that he does not receive greater rewards, both honorary and substantial, for his work. As compared with the specialist and the surgeon he gets scant measure of either, and yet he outranks them all.

The medical profession has a standing grievance against the community in that the pretender, the unscrupulous and the ignorant so often receive the encouragement and the rewards which by right belong to the qualified, conscientious, educated physician. It is partly true, as the poet says, "'tis understood that the good are half bad and the bad are half good," and in the general mixture of motive and conduct who is competent to draw the line, and who shall furnish the standard of measurement? It ought not to be difficult, however, for those who desire to do so, to discriminate between the true physician who pursues his course animated always by the professional spirit which requires that his own interests be secondary and subordinate to those whom he serves, whose whole trend of life is right, whose attitude is in the right direction, and him on the other hand whose whole conduct and attitude are wrong. Two men may stand very close together and yet face in opposite directions. The charlatan is not only the *ignorant* pretender. He may be highly educated and skilful. He may have high social standing. He may not only be in evidence in the advertising columns of the newspaper, but be the special pet of the editorial chair. His chief and distinguishing characteristic everywhere and always is that he uses the public and his patients for his own aggrandizement. He considers always that his patient is made for him and not he for the patient. His attitude to the public is that of the tradesman, and he is animated by the spirit of the tradesman. He makes merchandise of his calling. He takes advantage of the foibles and weaknesses of humanity to add to his own fame, power and pelf. In his most perfect and typical form he is essentially a parasite on the profession. He assumes the color and the garb of his host, living on his vitality, receiving everything and giving nothing in return. He lives the life of the parasite and should receive the treatment of the parasite. Many of the best of men may be weak enough to yield to temptation of special influence or other causes to show some of these char-

acteristics in a greater or less degree some time or many times in their professional life, but wherever found, whether in the members or officers of our own medical societies, whether in the professors of colleges or in others, to the extent and in the degree that they are manifested, they become the acts and the methods of the charlatan and the unscrupulous. If the one attitude is right the other is wrong. Which course, followed to its logical conclusion, will prove beneficent and which destructive?

It ought to be better understood and more constantly kept in view that medical science is a field without metes and bounds, is one and indivisible, and all inclusive. There are no schools of medical science any more than there are schools of the science of chemistry or astronomy or law. Even the so-called "schools" or "systems" of medical practice are a mental abstraction, consisting more of traditional and rhetorical phrases expressive of a subjective mental state than an objective reality. Such a conception was more or less excusable and suitable, perhaps, in the pre-scientific era of the middle ages when metaphysical abstractions and dogma were the stock in trade of the schoolman, the transcendentalist and the doctrinaire, but it is a crime against the light of these latter days of the nineteenth century.

It is not the belief of the medical man or the doctrine which he holds; it is not what he does nor how he practices; it is not what society he is a member of, nor what written code of morals he professes to be guided by, that is the test of his right relation to medical science and the public. Here again it is his attitude by which he is to be judged.

No doubt there are many well informed people in this audience, well informed in other respects, as there are in every community, who persist in believing that this and similar societies require their members to subscribe to and be governed by a code of ethics which is more or less artificial in character and inapplicable in other walks of life. There is no such artificial code. What we have is but the amplification of the golden rule and the sermon on the mount, set to phrase suited to the medical relation. We teach through our code what is taught as good morals and good manners by every teacher of morals from the forum and the pulpit to mankind, from the cradle to the grave—this and nothing more. Whether it should be used for disciplinary purposes and to what extent, or whether it should remain as a formulary of precepts as its language would seem to imply was the original intention, are the only questions that can be or ever have been raised regarding the code of medical ethics.

No doubt also the belief is just as prevalent that we and all similar organizations require our members to subscribe to some set of doctrines, or a confession of faith, and to conform to certain modes of giving drugs. We know of no such doctrines or rules, except as they are sometimes put into our mouths through others. We hold that no truth is final, and that no man should limit his studies or his practice by any confession. We hold that every proposition of doctrine or of practice must stand or fall to the mind of every individual without let or hindrance, and that there are no limitations on what any man may do in the way of practice or hold in the way of belief except such as are due to himself—his own powers and disposition. More than this we could not do. Less than this would change our atti-

tude to medical science, to other medical men and to the public, and place us in the ranks of the sectarian physician. This attitude of mind in the physician in his relation to medical science and the public is in a limited way akin to that of the banker in relation to the coin of his customer. Every coin offered him he must accept or reject by his own mental process on the evidence obtainable. He scans it, handles it, turns it over, tests it ring, weighs it, and receives it for what it seems to him to be worth. If it is counterfeit, it is rejected at once and absolutely. If it is a debased or clipped coin, he ascertains its value and acts accordingly. If the man of science recognizes the falsity or counterfeit character of some supposed new science, new method or new proposition, and rejects it as peremptorily as the banker does the counterfeit coin, or after examining all its claims to being genuine, still rejects it or receives it only for what it is worth, he is likely to be called a bigot or to be charged with intellectual intolerance to a degree which only medical men are supposed to be guilty of.

Indeed intellectual intolerance is a charge which is too often laid at the door of the medical man when he turns away from the sciolist and declines to share with the pseudo-scientist.

An episode in the life of Israel's king, Solomon, affords a lesson and an answer. He proposed with his sword to divide the living child which was in dispute, in order to determine which was the real mother and which was the pretended mother. The latter counted it a liberal proposition, but the real mother surrendered rather than to submit to such a compromise. There are some things which can not be shared and are insusceptible of division.

Medical science appeals for help and wider recognition from the public and the State. It could easily be shown that the greatest discoveries in this field have through all the past and in recent times conferred much greater proportional benefits on every class of the community than on physicians as a class. It could equally be shown that almost all the valuable discoveries and resources for prolonging life, relieving suffering and preventing disease have been due to the individual efforts of those devoted to medical science with little or no aid from the State and the non-medical public. A few notable and honorable exceptions there may be.

Moreover it is not generally appreciated that almost every one of the epoch-making discoveries have contracted the field for the practitioner and curtailed his resources for earning a living. It ought not therefore to be expected that the medical profession be wholly responsible for the future progress of that science which adds so much to the public welfare and at the same time works to the detriment of the medical calling as a calling. It is unreasonable not to expect that some of the increasing wealth of private citizens and the fostering care of the State should share in the work of discovery and application and bear the burdens thereof.

One thing the situation demands: A better education of the citizen; not of the present generation already in the field of active pursuits, for that is practically hopeless; but better education of the present and future youth of the country—that all educational institutions from the lowest to the highest shall take cognizance of the new fields of knowledge and the new methods of thought and investigation

which have come into view in the last quarter of the century.

A recent writer on higher education says: "Men may be educated in literature and philosophy and yet only half educated or uneducated in science and thus liable to terrible mistakes because they are color blind as to the half of human knowledge. Some of our greatest orators and most popular writers are simpletons as to scientific methods and arguments." To which sentiment we all say, amen!

And another thing the situation demands, viz.: That the United States Government which professedly represents the most civilized, the most enlightened, the most progressive, the most peaceable and the wealthiest in resources of all the nations of the earth, shall nominally and actively recognize the claims of medical science as a science and in its beneficent relations to the people, and shall serve as a channel through which the energies and the wealth of the people shall be directed to these ends.

A peaceable government which spends eighty millions of money a year on its army and navy in times of peace, one hundred and fifty millions in pensions, sixty millions on its inland rivers and harbors, and many millions more to promote commerce and other material interests of its people, ought to spend more than one or two hundred thousand dollars a year in the interests and in the name of the health of all the people. This small pittance which is now expended in this direction is spent in the name and for the sake of trade and commerce by the Marine-Hospital Service for the purpose of quarantine, one of the subordinate functions of this department, which is itself a subordinate department of the executive branch of the government. We read of some of the minor employes of the government having charge of the inspection of meats and other food products; but we also learn that this is carried on wholly in the interests of our trade relations with other countries and not for the sake of the health of the consumer or producer. How many of even the best informed citizens of this country are aware of the fact that if smallpox existed as it did one hundred years ago, that if cholera and yellow fever could not be controlled better to-day than they were twenty-five years ago, to say nothing of other forms of contagion, pestilence and plague—with the increased means and rapidity of travel and with the hundredfold increase of running to and fro upon the earth, I say who and how many know that with these conditions, the towering industries would be brought low, the mighty channels of commerce would be closed, great cities wiped out, the whole population decimated every decade, and if we believe the testimony of the older days, those of the people who remain would nearly all be defaced with pock marks.

The militant type of government was proper enough in earlier history and is well enough now in some of the nations of the world, perhaps, but our government at least must be readjusted to the industrial peace type which our conditions require. The heads of the army and navy departments, now so prominent in the councils of the government, must give way to those who represent the arts of peace, industry and humanity. In this adjustment, we propose to take part and to be a part with the permission and co-operation of the intelligent people. Hygeia will rise step by step until she strikes hands with Ceres and have an equal voice in the councils of the nation.

Then we shall see tuberculosis, the remaining

greatest scourge of the race, which is now accredited with one quarter of the mortality of our time, shorn of its power and controlled.

To quote from a recent address of President Eliot:

"The public does not use its imagination sufficiently with regard to the future of preventive medicine. Leprosy and smallpox have been measurably conquered; it has proved possible to exclude cholera and yellow fever; and yet the public is not impatient for the conquest of every other infectious and contagious disease, and often not willing to provide the necessary means of deliverance from these evils. Some of the most intelligent communities refuse to establish public disinfecting stations. Bacteriological laboratories are few and far between, when they should be everywhere accessible. Pure water supplies have diminished typhoid fever in urban populations, but the rural populations, through ignorance, still suffer disproportionately from this preventable scourge. The faith and hope of the medical profession should arouse the public from this lethargy, and redeem it from this destructive ignorance and incredulity."

In our own State as well as in the general government, we are not living up to our requirements nor our opportunities. We are lagging behind less favored communities in the matter of legislation, looking to the best things in medical science relating to the control of disease and the promotion of health. We have many laws and fragments of laws which seem to have or to have had at some time, beneficent aims in this direction, but they were mostly enacted from and when enforced at all, are enforced from the standpoint of commerce and the good of some local material interest.

We have nominally a State Board of Health, but it has made little impression on the affairs of the State in the name of health, largely from lack of sufficient appropriations, and from lack of the moral support of the community and the medical profession. More of the intelligent and influential members of the profession should be willing to make some sacrifice of their own interest, and take part either directly or indirectly in legislative affairs.

An over-view in the presence of our legislature when in session, is both instructive and discouraging, but by this I mean no disrespect to the mass of well-meaning men who are there. A veteran in legislative halls summarized his experience epigrammatically by saying that the less one knows of how law is made, the more he will respect the product. Of the several hundred bills introduced into our last legislature, aside from general appropriation bills for current expenditures, nine-tenths of them were for the promotion of some local or special interest. A bill looking to the general welfare is generally crowded out or defeated. It has come to be more and more that a legislature is made up of representatives of interests rather than of representatives of a certain number of people. A sprinkling of intelligent medical men to represent the medical interests and to see that medical questions receive respectful and a due share of consideration, might improve a legislature and its work. It could not affect it seriously otherwise.

When medical men are willing to take part in public affairs instead of staying at home and grumbling, and writing jeremiads, medical questions may be better treated in legislative assemblies and by the public generally.

To quote again from President Eliot:

"The medical profession has before it an entrancing prospect of usefulness and honor. It offers to young men the largest opportunities for disinterested, devoted and heroic service. The times are passed when men had to go war to give evidence of endurance, or courage, or capacity to think quickly and

well under pressure of responsibility and danger. The fields open to the physician and surgeon now give ample scope for these lofty qualities.

"The times are past when the church alone asked men to devote themselves patiently, disinterestedly, and bravely to the service of their fellowmen. The medical profession now exhibits in highest degree these virtues. Our nation sometimes seems tempted to seek in war—that stupid and horrible savagery!—for other greatness than can come from vast natural resources, prosperous industries and expanding commerce. The pursuits of peace seem to pall for lack of risk and adventure. Would it might turn its energies and its longing for patriotic and heroic emotion into the immense fields of beneficent activity which sanitation, preventive medicine, and comparative medicine offer it! There are spiritual and physical triumphs to be won in these fields infinitely higher than any which war can offer; for they will be triumphs of construction and preservation, not of destruction and ruin. They will be triumphs of good over evil, and of happiness over misery."

## ORIGINAL ARTICLES.

### WHAT CONSTITUTES TRUE CLINICAL EXPERIENCE IN MEDICAL PRACTICE AND ITS RELATIONS TO THE PUBLIC HEALTH?

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY N. S. DAVIS, M.D.

CHICAGO, ILL.

Clinical experience is to be regarded as the knowledge gained by a direct study of diseases or morbid processes, including their causes, symptoms, progress, natural tendencies and results, and the actual influence of remedies in arresting, modifying them or shortening their duration. If this is correct, it must be obvious that the value or reliability of our clinical experience will depend directly upon the extent and accuracy of knowledge of the nature and modes of action of the causes of disease, the natural tendencies and results of each disease or group of morbid processes, and the actual mode of action of each remedy used in the treatment of such processes. In other words, the clinical experience of members of the profession will be reliable, just in proportion to their knowledge of etiology, pathology and therapeutics.

It was not until the last fifty or seventy-five years that organic and physiologic chemistry and microscopy had attained such a degree of development that many of the exciting or efficient causes of disease could be identified and their mode of action in the living body determined. Patient, persistent observation through the preceding centuries had led the profession to believe that all acute general diseases were caused by specific causes to which the names of malaria, miasms and contagiums were given. But their identification had, in far the greater number of instances, eluded the powers of simple observation; and consequently, neither their mode of development nor their mode of action on the functions or structures of the body could be traced with accuracy. The same remarks are applicable to our clinical knowledge of the action of remedies. Without the aid of the more recent improvements in chemic and microscopic methods of research it was not possible, in the first place, to separate the active agents from the crude materials of the drugs, and then so closely follow the active agents when administered as to see what changes, if any, they undergo, what changes they effect in any of

the functions or structures of the body, and through what channels they are finally eliminated.

So too, in the study of diseases by direct observations at the bedside. Only the knowledge of the manifest symptoms presented during the successive stages in the progress of disease, the greater or less amount of secretions, and the duration of each stage could be determined. And if postmortems were made, they revealed only the *results* of the morbid actions that had been taking place, and not the philosophy of the actions themselves.

It is true that our predecessors, while thus limited almost exclusively to observation, or the use of their own senses, in the study of disease, gave us more minute, painstaking and complete symptomatologic descriptions of the more acute diseases, than can be found in the medical literature of the present day. But as they could neither see nor determine the actual morbid processes or the *modus operandi* of their causes, they were compelled to define diseases by groups of associated symptoms, as fevers, inflammations, etc., and their causes by names that conveyed no real knowledge of their nature or origin, as miasms, septic poison, foul air, hereditary, meteorologic and epidemic influences. They logically assumed that every disease or group of associated symptoms must have a cause. If careful observation proved that a certain group of symptoms originated mostly near marshes or on rich alluvial districts of country, it was assumed that some causative agent was developed to which they gave the hypothetic name of malaria or marsh miasm. If another associated group was found prevailing principally in densely populated districts with crowded and ill-ventilated tenements, dirty streets and impure water, it was assumed that from these conditions another hypothetic poison was evolved, to which was given the name of idio-miasm.

With neither an exact knowledge of the nature and mode of action of the supposed causes of disease, nor of the morbid processes constituting disease, the selection and administration of remedies could not be otherwise than empiric or else aimed at the relief of particular symptoms. And this again necessitated the classification of drugs in the *materia medica* on a symptomatic basis, as emetics, cathartics, diuretics, diaphoretics, narcotics, stimulants, sedatives, tonics and alteratives, according as they increased evacuations from the stomach, intestines, kidneys or skin, allayed pain and induced sleep, increased the frequency of the heart's action with a sense of exhilaration or excitement, or the reverse; a feeling of increased strength or endurance; or such changes in metabolism as resulted in the removal of adventitious tissues and morbid growths.

It was during this long period of dependence upon simple observation, with very limited means for obtaining more complete and exact knowledge concerning the actual changes taking place in the living structures under either morbid or remedial influences, that all our literature relating to the departments of etiology, therapeutics and practical medicine was developed. And much the larger part of the hypothetic names and words, and phrases of ill-defined meaning, which they necessarily embodied, are retained not only in our text-books, but still more in all the secular literature of the present day, thereby causing an unlimited amount of confusion in both the public and professional mind.

Thus, while dependent on simple observation and our

sensations for judging of the action of remedies, we classed all agents that, when taken, induced increased frequency of the pulse, with sensations of warmth in the stomach and general feelings of excitement or exhilaration, as stimulants or restoratives. And as moderate doses of nearly all the narcotic and anesthetic drugs produced just these effects, they were made to constitute the greater part of the class of stimulants, with alcohol in the forms of fermented and distilled drinks at their head. Hence a resort to the latter for relief from weakness, weariness, coldness, faintness, depression, shock, or even apprehension of exhaustion, became almost universal both by the profession and the public. And it is still this underlying fundamental idea of their power to stimulate, restore and sustain, that leads to and perpetuates their use not only in the treatment of all diseases of supposed debility, but also in enormous quantities by nearly all classes of people, to relieve every depression of feeling or apprehended evil, mental or physical. And all this is easily traceable for its support to the simple alleged clinical experience of the profession as found in our standard works.

Thus, in one of the recognized standard works on the nature and action of remedies, we read that alcohol "taken internally, in small quantities appropriately diluted, excites a sense of warmth in the stomach and, if the person is very susceptible, an almost instantaneous glow throughout the body, with increased frequency and force of the heart and pulse, a livelier flow of ideas which are, according to the temperament of the individual, gay or gloomy, and actions which, in like manner, may be playful or malevolent." This, you will perceive, is a simple transcript of the sensations and actions of the individual under the influence of the drug. And the same high authority adds: "The use of alcohol in every age, and by every nation in the world, demonstrates that it satisfies a natural instinct, that it literally refreshes the system exhausted by physical or mental labor, and that it not only quickens the appetite for food and aids in its digestion, but that it spares the digestive organs by limiting the amount of solid food which would otherwise be required."<sup>1</sup> This, the author seems to say, is the actual clinical experience of the whole world in regard to the use of alcohol in appropriate doses, and yet it all rests on the sensations of the user, without any accurate knowledge of the actual changes produced by the alcohol on the constituents of the blood, the sensibility of the cerebral hemispheres, the cardiac and respiratory nerve centers, or on the metabolism of the tissues and organs of secretion.

The "natural instinct" spoken of by the author, and often repeated in popular literature, can be nothing more than the desire of a sentient or intelligent being to be relieved of any or all uncomfortable feelings, whether mental or physical. And as alcohol in moderate doses, like all other anesthetics, relieves, at least temporarily, *all* uncomfortable feelings, whether of grief, despondency, weariness, weakness, cold, heat or pain, it is *that* which constitutes the "literally refreshing" influence it is supposed to exert on the human race; and in *that way only* does it satisfy any "natural instinct" in the human family.

It is clearly apparent, therefore, that all the past and present uses of alcohol in the forms of fermented and distilled liquors, both as medicines and beverages, originated from, and still depends for support upon,

<sup>1</sup> See National Dispensatory, pp. 123-4.

the supposed *clinical demonstration* that in moderate doses it warms, stimulates, refreshes, strengthens and exhilarates all the functions of body and mind. Could there be a more striking illustration of the direct connection between the alleged clinical experience of the medical profession and the interests of public health and morals?

As has been already stated, however, all this clinical experience is based on the sensations, movements and opinions of the patient or person under the influence of the alcohol. He swallows a moderate dose, and its contact with the gastric mucous membrane produces a sensation of increased heat and he says it warms him. Being rapidly absorbed and carried to every tissue in his body, its contact with the nerve structures directly diminishes the sensibility of the sentient nerve cells, and therefore he feels less conscious of weariness, weakness, restlessness or pain, and consequently he thinks it refreshes, strengthens and comforts him. But the same lessening of nerve sensibility extends to the nerve cells connected with both mental and cardiac inhibition, and hence he believes he can think and talk faster, and do more, and the heart beats a little faster. Hence both he and his friends say it stimulates him.

Yet, when we apply the tests of philosophic instruments for accurate measurements, and thereby obtain results independent of the sensations of the individual, just when he thinks a moderate dose of alcohol is warming, strengthening and refreshing him, and enabling him to work and think or talk faster, we find his temperature diminishing, his nerve sensibility less [acute, its transmission of impression slower, his mental processes tardy and less accurate, his muscular strength and endurance less, less oxygen and more carbon dioxide in the blood, and diminished metabolic changes generally. And when his period of this kind of refreshment has passed, instead of being invigorated and ready for active work, either mental or physical, he is pervaded by a feeling of dullness and depression that makes him think another dose of the same refreshing liquid necessary.

In other words, we have the complete demonstration that the so-called refreshing and strengthening effect of alcohol depends entirely on its anesthetic properties, by which it diminishes the sensibility of the nerve cells of the brain, the material seat of consciousness, and thereby diminishes the consciousness of all impressions, whether of heat, cold, weariness, weakness or pain, and at the same time lessens every physiologic process taking place in the blood, tissues and organs of the body; thus showing the entire fallacy of all the clinical experience founded upon the patient's feelings or conscious impressions, and enabling us to see clearly how alcohol or any other cerebral anesthetic may cause patients to think they are stronger and better, when in truth all the vital or physiologic processes are diminished. And if the use of the agent is repeated from day to day, even in the most moderate doses, we see how the user is induced to think he is being refreshed or sustained, while all the metabolic processes are being retarded, his power to resist or eliminate toxic agents diminished and molecular degeneration of tissues encouraged.

Then why continue to call an agent a stimulant or tonic, that simply diminishes the patient's consciousness of weakness without adding anything whatever of strength or tissue repair, but really impairs both in direct proportion to the quantity used?

However, it is not solely in regard to the use of anesthetic and narcotic agents capable of diminishing the sensibility of our seat of conscious impression, that our clinical experience has proved fallacious. Only a few years since, the profession were taught to regard the degree of pyrexia or heat as the chief element of danger in all the acute general diseases. Consequently, to control the pyrexia became the leading object of treatment; and whatever would do this promptly, and at the same time allay pain and promote rest, found favor at the bedside of the patient.

It was soon ascertained that antipyrin, antifebrin, phenacetin and other analogous products, if given in sufficient doses, would reduce the pyrexia and allay the pains with great certainty and promptness, not only in continued fevers, but also in rheumatism, influenza or la grippe, etc., and their use soon became popular both with the profession and public. No one undertook to first ascertain by strictly scientific appliances the actual pathologic processes causing the pyrexia in each form of disease, or even to determine whether, in any given case, the increased heat was the result of increased heat production or diminished heat dissipation. Neither were any of the remedies subjected to such experimental investigation as to determine their influence on the elements of the blood, the internal distribution of oxygen, the metabolism of the tissues, or on the activity of the eliminations. Consequently, their exhibition was wholly empirical, and the one that subdued the pyrexia most promptly was given the preference.

Yet we all know that the pyrexia invariably returned as soon as the effects of each dose were exhausted, and in a few years the results showed that while the antipyretics served to keep down the pyrexia, and give each case the appearance of doing well, the average duration of the cases and their mortality were both increased. Step by step experimental therapeutic investigations have proved that the whole class of coal tar antipyretics reduce animal heat by impairing the capacity of the hemoglobin and corpuscular elements of the blood to receive and distribute free oxygen, and thereby reduce temperature by diminishing heat production, nerve sensibility and tissue metabolism. Therefore, while each dose temporarily reduced the pyrexia, it retarded the most important physiologic processes on which the living system depends for resisting the effects of toxic agents, namely, *oxidation* and *elimination*. This not only encouraged the retention of toxic agents and natural excretory materials by which specific fevers were protracted, but it greatly increased the number of cases of pneumonia complicating the epidemic influenza or la grippe as it has occurred since 1888-89. And it contributed still more to the production of that remarkable cardiac, vaso-motor and respiratory debility that has followed very many of the cases of the disease just mentioned.

I might cite other cases occurring both in the present and past history of the profession, showing the entirely fallacious character of the clinical experience founded on simple empirical observation, and the injurious effects of such alleged experience on the public health. But the illustrations already given are sufficient for my present purpose, namely, to urge the necessity of a much more thorough experimental study of the nature and action in the living body, of the toxic agents constituting etiologic factors; the nature, tendencies and results of morbid processes constituting

diseases, and the actual *modus operandi* of the medicines we use in their treatment. The facilities for such study afforded by our chemic, physiologic, pathologic and therapeutic laboratories and instruments of precision, should be so utilized as to speedily impart to the clinical experience of the profession a degree of reliability that, in its reflex upon the public, would greatly improve the public health, both mental and physical.

## STATE SUPPRESSION OF INEBRIETY AND CURE OF INEBRIATES.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 6-8, 1896.

BY O. EVERTS, M.D.  
COLLEGE HILL, OHIO.

Much attention has been given in this country and elsewhere, within the last fifty years, to the subjects of inebriety and the cure of inebriates. Many schemes for the suppression of inebriety and the cure, or reformation, of drunkards have been suggested, adopted and tested experimentally with—notwithstanding much good accomplished—unsatisfactory results. These schemes have consisted mostly of so-called temperance societies, on becoming members of which persons pledged themselves by signature, or oath, to totally abstain from intoxicating drinks; political party organizations, seeking by legislation to prohibit the manufacture or sale of intoxicants within the State; public and private asylums for inebriates; and last, if not least, innumerable gold-cures and other quack pretensions for the regeneration of drunkards.

Promising as some of these schemes were in their inception, that they have all failed to accomplish the desired end is not now a mystery to the more observing and thoughtful.

Such being the fact respecting schemes heretofore tested, it may be rationally affirmed that inebriety is not suppressible to any great degree by social influences, moral suasion, oath-bound obligations, or personal pledges; nor are inebriates, as a class, curable by medication, general or specific, secret or open, if not otherwise restrained; and that "prohibition does not prohibit." But as philanthropists, social scientists and physicians we can not accept this verdict as the end of contention and effort for a "consumation devoutly to be wished."

What further effort then shall be made for the suppression of inebriety and the cure of inebriates? After many years' observation and experience in the treatment of this class of persons, and careful study of the causes of failure already affirmed, it is evident to me that there are but two methods which give promise of much greater attainment than did those already tried and found wanting.

One of these methods contemplates absolute prohibition, or putting all intoxicants out of the reach of inebriates; and the other contemplates putting the drunkard under such (bearable) restraint that he can not reach intoxicants; methods, neither of which can be successfully administered by other than the authority of a State. The question then arises: Can or should the State interest itself in such matters?

It may be again rationally affirmed that the State, being simply the mechanism through which popular energy emanating from the people is transmuted into governmental energy, having in view "the greatest

good to the greatest number," should be interested and exercise authority for the suppression of inebriety, because inebriety is offensive to society and beneficial to nobody; and in the cure of inebriates, because inebriates are citizens of a defective class, disqualified for the functions of good citizenship and dangerous to themselves and others, by reason of disease that is not amenable to ordinary, or other, medical treatment.

The first of the foregoing propositions likely to be challenged is that which affirms the incurability of inebriates by moral or medical means. It is rational indeed for persons who see only the factor of vice in the problem of inebriety, to believe in the efficacy of moral suasion, or correction, for its suppression, or the cure of the inebriate. One may be rational, however, and yet very much mistaken. Reason finds in accordance with whatever testimony is before it, and is as facile in confirmation of error as of truth. The ignorant—at all times a comparative term including the greater portion of mankind—and some doctors of medicine—regard all phenomena as supernatural and occult. They ascribe the phenomena of evil to a supreme spiritual embodiment of evil immanent in the universe, between which and a supreme spiritual embodiment of good, also immanent, if less active, poor man is forever being attracted or repelled, as by the poles of a gigantic spiritual magnet, though boasting still of freedom. Inebriety being regarded as a vice, what could be more rational than the supposition that all that is required for its suppression is a renunciation of evil and submission to good? Regarding inebriety as a manifestation of disease, believing disease to be instigated by, or in some way related to supernatural influences, and ascribing the curative virtues of drugs to supernatural qualities, with the blind faith or fetishism of ignorance, what more rational than to suppose the inebriate can be cured by medicine? A wider range of testimony, however, discredits and renders irrational both theory and practice. If the testimony of a single century against these assumptions is not sufficient, the facts of human history stand arrayed in solid columns ready to confirm it. Nor should the more enlightened be impatient because of the credulity and delusions of the ignorant, as out of the same root-conditions they have grown into higher light and broader perceptions. Knowledge of the constitutional history of a man—biologic science, indeed—is a revelation of to-day. The physiologic effects of medicines, as related to constructive and destructive processes effected by them when ingested by living beings, are of too recent recognition to have become generally understood, or accepted as valuable knowledge. No physician of education and experience, however, will pretend that other than exceptional persons suffering genuine pathologic inebriety, have ever been cured by any social or moral influences that could be brought to bear upon them, or by the administration of drugs of any kind. By cure I mean restoration to primary conditions and normal appetites, the establishment of physiologic protection against almost immediate relapse.

Objection to State interference with inebriates, other than punitive, will be made by a class of pious or fanatic religionists, who fear that by consenting to any measures for the suppression of inebriety, or cure of inebriates, that do not express their ideas of sin and reclamation by fear of punishment, they will in some way commit themselves to toleration, if not

approval, of vice and thus become accessory to crime. A class conscientiously opposed to any legal enactments contemplating an amelioration of the conditions of the sinful, or the protection of the innocent, by "regulating" social vices that can not be eradicated under immediate circumstances, because of mistaken notions respecting the relation of vice to material conditions, and the relation of government to social circumstances. Persons incapable of reflection, because void of facts or inconsiderate of their significance, who feel that their whole duty has been done toward their fellow men when they have notified them of their sinfulness, warned them of consequences, and pointed out a narrow way of escape, saying to themselves: "Let them do as bidden, or be damned! If society suffers let society suffer! or join with us and make short work of this iniquity." In close practical alliance with these pious people are the makers and venders of intoxicants, and all of the vicious classes of society which blindly antagonize the authority of State on general principles. Still another class of citizens, pseudo-philosophic politicians, who maintain the rights of individuals as superior to the rights of society, and resent the interference of government in matters so personal as eating and drinking, or the observance of holy days, or any exercise of "paternalism" as a function of State; maintaining the right of a man to get drunk and suffer the consequences, if he so elects, oblivious to the fact seemingly that while the individual alone gets drunk, society is the principal sufferer of consequences. The affirmation that inebriates belong to a defective class of society, correlatable with the insane and criminal, may also be challenged. That they do constitute a defective class so correlatable may be inferred from the fact that, while the appetite for brain-stimulants, or sedatives, is common to mankind, and universally indulged by the use of some natural or artificial product, alcohol, opium, tea, coffee, cocoa, kola, tobacco, and others, but a small proportional number become inebriates, or pathological habitués of such intoxicants, showing that the potentiality of inebriety is as definitely referable to organic peculiarities as is the potentiality of insanity, about which there is no longer room for disputation. Were no distinction of this kind to be made, indeed, were the liability to become insane or inebriate the same for all persons under the same conditions of provocation, but few persons instead of the many, would escape lunacy or inebriety. A few drinks of whisky may determine the fate of a man of neurotic instability of nerve organization; while many others, not so constituted, may drink occasionally or frequently, for years, without danger of becoming inebriates. That inebriates are correlatable with the insane constitutionally may be inferred from the facts that an intemperate use of alcohol is regarded as an efficient exciting cause of insanity, and inebriety is recognized as the manifestation of cerebral disease by which mental capabilities are impaired and disordered temporarily or permanently. So parallel indeed are the psychic phenomena of insanity and inebriety even experts have sometimes to differentiate one from the other by physical signs and commemorative circumstances. What are the psychological characteristics of simple, typical lunacy?

1. Well marked departure from ordinary habits of thinking and acting on the part of the lunatic.
2. Loss of self-control, partial or entire.
3. Deterioration of moral perceptions, inveracity, immorality of conduct and depraved appetites.

4. Deterioration of general intellectual capabilities, disorderly imagination and defective reasoning, stupidity, insensibility, death.

Are these not also characteristics of inebriety? How close the resemblance of periodic mania and periodic inebriety, commonly called dipsomania? Are not the accessions of these two conditions as irresistible as the explosion of epilepsy, and indicative of correlatable neuroses? Was epilepsy ever cured by moral suasion? Did any other than a mercenary quack ever pretend to cure an epileptic by specific medication, who did not, sooner or later, discover the error of his pretension?

The affirmations that inebriety is a manifestation of morbid physical conditions effected by the interaction of intoxicants with the activities of defective structures, practicably irremediable by moral or medicinal treatment, and that the State is justifiable in administering all needful authority for its suppression, and the cure of its victims, because of its offensiveness and their helplessness, being admitted, the only question left for discussion is: By what method can the State accomplish the desired end most effectually and satisfactorily?

Of the two methods already alluded to, namely, putting intoxicants out of reach of inebriates, and its alternative, putting inebriates out of reach of intoxicants, the latter seems to me much more promising than the former.

Prohibitory liquor laws have failed of complete success because they can not be executed with the hearty good will of the people and are therefore imperfectly enforced. They are objectionable to many persons who have no need of protection from them, because of their own infirmities, for the reason that they require a large majority of citizens to forego certain privileges held in high esteem as pertaining to the rights and dignity of freemen, for the benefit of the few who have by viciousness or weakness forfeited such privileges. Furthermore, unless such laws could be made National, State lines are too thin to protect the citizens of one State from the liberality of the laws of adjoining States.

Inhibition of inebriates from intoxicants is less objectionable and more practicable, because laws providing for such restriction could be executed with the full approval of nearly all citizens, as they would deprive no one of liberty that had not forfeited some of the privileges of citizenship, or who would not be personally benefited thereby.

This method of suppressing inebriety, and curing inebriates, contemplates something more than the establishment of asylums, or recruiting stations, where inebriates can recuperate sufficiently to go out and enjoy another season of debauch; it contemplates a colonization, so to speak, by voluntary and involuntary settlement, or admission, of all inebriates within a given district of the State, where not only hospital accommodations and appliances for the treatment of the infirm will be provided, but such a variety of industries, under intelligent supervision, as will enable all persons so far restored as to be able to work to not only earn their own living, but accumulate something to the credit of themselves or dependent families. It contemplates a more or less protracted residence in such colonies of persons committed, and an unremitting supervision of colonists on parole, authorizing immediate return, for increasingly longer terms, on violation of conditions constituting the

basis of privileges granted, so long as the colonist remains within the jurisdiction of the State:

As neither time nor inclination permits a more elaborate presentation of such State provision for the suppression of inebriety, and cure of inebriates, as I have mentally evolved from materials of observation, memory and reflection, I will content myself with the suggestion that such provision should not be regarded as punitive in any sense, but benevolent and beneficent in every feature.

It will require, perhaps, more than one "campaign of education" to interest "statesmen" in such a scheme, but once tested I have no doubt of its success, and that the end will have compensated the labor.

### TWENTY-ONE YEARS' EXPERIENCE IN THE NON-ALCOHOLIC TREATMENT OF DISEASE.

Read in the Section on State Medicine, at the Forty-Seventh Annual Meeting of the American Medical Association at Atlanta, Ga., May 5-8, 1896.

BY J. H. KELLOGG, M.D.

BATTLE CREEK, MICH.

On becoming connected with the Battle Creek Sanitarium, an institution of which I have had charge for the last twenty years, and having been connected with the institution for a year or two previous, I established a rule that alcohol should not be relied upon as a therapeutic agent in the treatment of curable cases; that, if used at all, it should be only in those cases which were utterly hopeless, and in which it would consequently be useless to withhold any agent which would afford even temporary relief to the patient's sufferings. These cases have been so exceedingly rare that it may be said that alcohol has been absolutely discarded as a therapeutic agent under any and all circumstances, in this institution, although it had been previously used, sparingly.

The total number of patients treated during this time, of which careful records have been kept, is 16,869. In addition to this, a considerable number of cases who have not been inmates of the institution have been treated by myself and my colleagues in the city and surrounding country, and in dispensary practice in connection with our medical mission in Chicago, of which less complete records have been kept.

The majority of cases treated have been persons suffering from chronic diseases. As the larger proportion have been sent to the institution by their attending physicians, it is scarcely necessary to state that they have been cases of more than ordinary gravity, requiring advantages which they could not receive at home.

A city of nearly twenty thousand inhabitants, in which the sanitarium is located, affords opportunity for a limited observation of acute disease. In the twenty-one years I have been connected with the institution, however, myself and my colleagues have treated 333 cases of typhoid fever in persons of all ages, with nine deaths, or a mortality of 2.7 per cent. Within the same time we treated eighty-two cases of pneumonia, with four deaths, or a mortality of 4.9 per cent. When we recall the fact that under the alcohol treatment of pneumonia and typhoid fever, the mortality rate has been 30 and 20 per cent. respectively, I think it will be conceded that our patients have in no wise suffered in consequence of the disuse of this drug.

Alcohol is much less used in the treatment of

chronic maladies at the present time than formerly, but many physicians still cling to the idea that alcohol is a stimulant, a nutrient, or in some way a supporter of vitality, and hence prescribe it in a variety of morbid conditions which are more or less chronic in character. I have demonstrated to my satisfaction the absolute inutility of alcohol for the accomplishment of any useful purpose in the treatment of either chronic or acute maladies.

One purpose of this paper is to call attention to other measures which may be used in the place of alcohol as a means of meeting the therapeutic indications which alcohol has been supposed to meet, but which experiments made by Dr. N. S. Davis long ago, and in recent years confirmed by numerous investigators, have shown it to be entirely incapable of meeting.

#### ALCOHOL AS A CARDIAC STIMULANT.

I have never found alcohol necessary in any case as a

FIG. 1.—Sphygmographic tracing of a patient before taking a spray at a temperature of 80 degrees F.

FIG. 2.—Sphygmographic tracing of a patient (same as Fig. 1) after taking a spray for two minutes at 80 degrees F., with a pressure of twenty pounds.

cardiac stimulant, and all recent physiologic experiments respecting the effect of alcohol upon the heart go to show that it lessens its force rather than increases it; or, in other words, is a depressing agent rather than a tonic or stimulant. The cold shower bath is one of the most powerful of all means of stimulating cardiac activity. The application of cold water to the surface of the body produces an immediate increase in the strength of the pulse. This is very clearly shown by the sphygmograph, with which I have made a considerable number of tracings for the purpose of demonstrating the influence of peripheral applications of cold upon the heart and circulation. The cold shower bath, however, is by no means applicable in every case, neither is it always convenient. Cold may be applied to the skin in many other ways, as by the cool sponge bath or the short cold full bath; and the force of the application can be graduated to a nicety by varying the temperature of the water employed,

the length of the application, and the extent of surface to which the application is made.

The application of cold to the surface produces its effect upon the heart, both through its influence upon the peripheral blood vessels, and by means of a reflex action through the afferent vasomotor nerves and the sympathetic system. The effect of these peripheral applications upon the heart being almost instantaneous, it is very easy to graduate the dose to suit every possible case in which increased heart vigor is required.

The accompanying reproduction of sphygmographic tracings taken by my friend and colleague, Dr. W. H. Riley, very well show the influence of the peripheral application of cold as a cardiac tonic.

Alternate hot and cold sponging of the surface, or hot and cold sponging of the spine, short applications of dry heat over the heart, are also measures of value suited to particular cases. One would not apply cold to the general surface with the skin in a cyanotic condition or wet with perspiration. In such cases, vigorous hot and cold applications to the spine, hot fomentations over the heart, or general hot sponging immediately followed by a brief cold application, would be more appropriate. Drinking of hot water, the hot enema, and the alternate hot and cold foot bath, even the placing of the hands alternately in hot and cold water, are measures which operate powerfully in increasing the vigor of the heart. The value of applications of this sort in reviving the energies of the flagging heart are more clearly seen in cases of syncope, threatened death from chloroform, ether, cocain, opium, and other narcotic drugs, including alcohol.

I shall never forget the impression made upon my mind by a case of opium poisoning to which I was called some twenty years ago. Half a dozen physicians who were in the room had been applying various remedies, all without avail. I was sent for to bring galvanic and faradic batteries. I found the patient with respiration four a minute, pulse rate twenty, but very irregular. The breathing was labored. The patient had doubtless been unconscious for eight or ten hours. The electric applications slightly improved the pulse and respiration for a short time, but the patient quickly relapsed, and I then resorted to hot and cold applications, applying fomentations the whole length of the spine for one minute, then removing the hot cloths and rubbing the bare skin from occiput to sacrum with ice for ten or fifteen seconds, then reapplying the fomentations. In less than three minutes a change in the patient was noticeable. Perspiration appeared, respiration was increased to sixteen per minute, pulse rate to fifty, the patient moved about in bed, and even uttered a few words, to the astonishment of every person in the room. Although in this case the patient ultimately died, the wonderfully stimulating effect of the revulsive applications to the spine in arousing the activity of the cardiac and respiratory centers was apparent to all present.

I believe I have saved the lives of a number of persons under similar circumstances, by the use of this simple but wonderfully powerful measure.

The most powerful of all means of stimulating the heart is the alternate hot and cold spray or shower bath, applied to the whole surface of the body. In cases of chronic cardiac weakness, applications of this sort must be used with care. In some cases only the gentlest hydrotherapeutic measures should be em-

ployed; centripetal friction and carefully graduated joint movements should be depended upon as the most efficient means of gradually developing cardiac vigor.

I have, by the careful use of massage and the Swedish movements, frequently succeeded in bringing a patient suffering from cardiac insufficiency, from what seemed to be the very brink of the grave, to a condition of comparative health and vigor.

#### ALCOHOL AS A STOMACH TONIC.

In cases of chronic dyspepsia, the use of alcohol seems to be particularly deleterious, although not infrequently prescribed, if not in the form of alcohol or ordinary alcoholic liquors, in the form of some so-called "bitter," "elixir" or "cordial." Nothing could be farther removed from the truth than the popular notion that alcohol, at least in the form of certain wines, is helpful to digestion. Roberts showed, years ago, that alcohol, even in small doses, diminishes the activity of the stomach in the digestion of proteids. Gluzinski<sup>1</sup> showed, ten years ago, that alcohol causes an arrest in the secretion of pepsin, and also of its action upon food. Wolff<sup>2</sup> showed that the habitual use of alcohol produces disorder of the stomach to such a degree as to render it incapable of responding to the normal excitation of the food. Hugouencq<sup>3</sup> found that all wines, without exception, prevent the action of pepsin upon proteids. The most harmful are those which contain large quantities of alcohol, cream of tartar, or coloring matter. Wines often contain coloring matters which at once completely arrest digestion, such as methylin blue and fuchsin.

A few years ago I made a series of experiments in which I administered alcohol in various forms with a test meal, noting the effect upon the stomach fluid as determined by the accurate chemic examination of the method of Hayem and Winter. The result of these experiments I reported at the 1893 meeting of the American Medical Temperance Association. The subject of experiment was a healthy young man whose stomach was doing a slight excess of work, the amount of combined chlorin being nearly 50 per cent. above normal, although the amount of free hydrochloric acid was normal in quantity. Four ounces of claret with the ordinary test meal reduced the free hydrochloric acid from 28 milligrams per 100 c.c. of stomach fluid to zero, and the combined chlorin from .270 to .125. In the same case the administration of two ounces of brandy with the ordinary test meal reduced the combined chlorin to .035, scarcely more than one-eighth of the original amount, the free hydrochloric acid remaining at zero. Thus it appears that four ounces of claret produced marked hypopepsia in a case of moderate hyperpepsia, whereas two ounces of brandy produced practically apepsia.

There would seem to be no further proof needed that alcohol is of no use in the treatment of disorders of digestion. Indeed, Dr. Roberts asserts that alcohol is useful only as a means of hindering digestion, which he considers a very important function in it, owing to the tendency of excessive alimentation, especially in the excessive use of meats. Dr. Roberts' recommendation is perfectly consistent with the results of this investigation, so far as the effects of alcohol are concerned, although it would seem to be more sensible to suppress the excess of nitrogenous foods, or the total

<sup>1</sup> Arch. f. Klin. Med., 1886.

<sup>2</sup> Zeitschrift f. Clin. Med., 1889.

<sup>3</sup> Lyon Med., 1891.

amount of food taken, rather than to indulge in the use of a drug to act as a disturbance and hindrance to the digestive process. The disorders of digestion are easily managed by the rational employment of dietetics in connection with a careful investigation of the stomach fluid by the exact chemic and bacteriologic methods with which we are now acquainted.

Roberts has also shown, and the writer's experiments verify his conclusions, that wines, beers and similar liquors, in even comparatively small doses, prevent the salivary digestion of starch in the stomach. Thus it appears that stomach digestion is altogether interfered with, and inhibited by alcohol in any form.

#### ALCOHOL AS A TONIC OR STIMULANT.

Nothing could be more absurd than the use of alcohol or alcoholic preparations in the production of so-called tonic effects. Far from being a tonic, alcohol is not even a stimulant. Recent investigations show clearly that the drug is a narcotic and a sedative rather than a stimulant. In a paper presented before the American Medical Temperance Association three years ago, I gave the results of psychologic tests made upon a number of persons before and after taking alcohol, by which I showed that the reaction for the tactile and the temperature sense were both diminished more than 100 per cent., while the muscular strength was diminished more than 30 per cent. Alcohol benumbs nerve structures of every sort, and does not in the slightest degree increase either mental or nerve activity. Nothing could be more absurd than the common prescription of alcohol or of such mixtures as Vin Mariana, when tonic effects are desired. These drugs are simply nerve foolers. They lessen nerve sensibility and thereby diminish the sense of fatigue, exhaustion, weakness, or whatever discomfort may exist.

#### ALCOHOL AS A NUTRIENT.

It has long been known that the use of alcohol diminishes the elimination of proteid substances in the excretions. This was thought to be an evidence that, if it were not an actual food, it was at least a means whereby tissue degeneration might be lessened and thereby the bodily waste diminished. Careful investigation of this matter shows, however, that alcohol does not actually diminish the amount of the products of tissue activity, but that it prevents their elimination, so that they remain in the tissues.

It is only recently, since the subject of leucemias, ptomaines, and toxins has come to be appreciated from a practical standpoint, that the full significance of the diminution of tissue waste under the influence of alcohol could be understood. Instead of being an evidence of tissue preservation, this lessening of the elimination of tissue waste is simply an evidence of the accumulation of waste and poisonous substances within the body, through the lessened efficiency of the liver and the kidneys.

In an experiment made a year or two ago, I found the coefficient of urinary toxicity to be diminished 50 per cent. in the case of a vigorous young man, by the injection of two ounces of brandy. As I argued in a paper presented at the last meeting of the American Medical Temperance Association, this fact is one of profound significance in relation to the use of alcohol in such infectious maladies as typhoid fever, diphtheria, pneumonia, and similar disorders. In these diseases the system is struggling under the influence

of poisons, which the liver endeavors to destroy and the kidneys to eliminate. By lessening the efficiency of the kidneys as eliminating organs, and the liver as a disinfecting organ, it is evident that the risk of death must be considerably increased; hence the use of alcohol in cases of this sort must be condemned.

When we remember that in the majority of chronic cases, as well as most acute maladies, the system is suffering from more or less pronounced toxemia, through the failure of the liver, kidneys, lungs, skin, and other eliminative organs to do their full duty, it becomes apparent that the use of alcohol must be not only detrimental, but in many cases even absolutely dangerous.

The patient suffering from dilatation of the stomach is continually in a state of toxemia, through the development of ptomaines, as the result of too long retention of food substances in the stomach, and the consequent action of germs of various sorts upon the food elements. As a rule, a patient suffering from an acute disease requires simply good nursing and such treatment as will aid nature in the elimination of poisons to which the most active symptoms are due. In the treatment of chronic disease, the patient requires not only increased elimination of poisons, but the adoption of such measures as will suppress the development of these poisons, such as careful regulation of dietary, and maintenance of an aseptic or germ-free condition of the stomach. The system of the invalid needs to be generally reconstructed. This requires tissue renovation and regeneration. The use of alcohol in such cases, then, must be evil, and only evil.

I should not omit to mention the Turkish bath and similar therapeutic means, as one of the most effectual means of accomplishing the tissue reconstruction necessary for the cure of various chronic disorders, and particularly that class in which alcohol is so freely prescribed, and most of all in cases of alcohol addiction, in its various forms.

### SOME NOTES ON ALCOHOL IN THERAPEUTICS.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY T. D. CROTHERS, M.D.

SUPERINTENDENT WALNUT LODGE HOSPITAL, ETC., ETC.  
HARTFORD, CONN.

Some very strange conceptions of alcohol as a medicine exist, and are repeated in really excellent text-books of medicine. Evidently they are the repetitions of assertions of authors which have been accepted without question.

One of these precepts is to increase the amount of spirits if the smaller doses do not seem to have the effect desired.

In a given case one ounce of brandy every four hours is increased to the same amount every two hours. Spirits are said to be indicated and the dose and frequency is the measure of its power.

Recent text-books urge that spirits be given freely in certain cases and prescriptions containing large quantities of spirits are presented as guides. In some cases cautions concerning the dose and its frequency are given, but the fact is assumed that large doses have certain definite effects that can be studied and understood. These counsels are not in accord with the observed facts, and in some cases diametrically

opposite. Thus the effects of eight ounces of spirits a day is not double that of four ounces. Where spirits are taken as a beverage the man who drinks a pint of any kind of spirits does not manifest symptoms of double the intensity to one who uses half a pint. Observation seems to be conclusive that a point of toleration is reached beyond which there is no appreciable effects from spirits. In a case of diphtheria an ounce of spirits was given every two hours; this was increased to every hour without showing any alteration in the heart's action except a temporary fluttering. The skin seemed to be intensely stimulated and was bathed in perspiration and the kidneys were active, the exhalations from the lungs were increased, collapse and death followed, and the physician was sure that the poison of diphtheria had overwhelmed the nervous centers causing death. The spirits taken for two days before the end had not been absorbed but had gone on saturating the tissues and forming ptomains which were literally poison centers of greater magnitude than the diphtheria germs.

In a case of pneumonia the consulting physician urged spirits *ad libitum* as much as could be swallowed, for the reason that if the heart's action could be sustained he would recover. Of course the patient died. A quart of brandy was given daily. The skin, lungs and kidneys made a great effort to eliminate the poison of alcohol, but failed.

The real facts were, the process of inflammation which would have been self-limited, was supplanted by paralysis and the presence of a new source of poisoning of greater magnitude than the primary disease.

Beyond a certain point not clearly recognized alcoholic saturation begins and the effects of spirits after this time is not apparent except in general progressive depression and enfeeblement. At times this point of saturation is manifest in vomiting with excessive stomach and brain irritation. This may go on to what is termed delirium tremens and various manias, marked by cell and nerve exhaustion, with explosions of nerve force.

There can be no doubt of the cumulative action of alcohol in health, even when used in small doses and for long intervals. In disease of any form there are no reasons for believing that this effect is prevented or neutralized. The assumption that the anesthetic action of alcohol increases in proportion to the size and frequency of the dose or that any action it may have on the organism likewise increases, beyond a certain point, lacks clinical proof. In my opinion alcohol and its ptomains accumulate in the tissues, and are gradually eliminated beyond the danger point by purely natural processes. This process of elimination has a limit, which varies widely in different persons and is unknown. In disease it is feebler and is reached sooner than in health. The supposed tonic effect of alcohol is no doubt a poison of extreme fatality after a certain period. The point of saturation is reached in which the direct irritant and paralyzing action of alcohol, has reached an extreme limit. Beyond this spirits become a pure chemic poison. The center of new combinations of foreign products, that are not eliminated, but held in obedience, until some unknown condition expells them, or draws them into the circulation. The clinic experience of the sudden death of persons who are using as a beverage or taking as a medicine large quantities of spirits seem to confirm this view of the sudden absorption of alcoholic products beyond the power of resistance.

A strong man suffering from acute pneumonia had been taking over a pint of brandy daily for eight days. He was given a warm bath and an enema to clear out his bowels. An hour after he died suddenly. In my opinion the bath and enema had roused the absorbent to activity, and the accumulated alcoholic poisons had been absorbed to fatality. Before this the general palsy of the tissues had prevented the absorption of the poisons. Had all the alcohol been withdrawn and the process of eliminating been slowly stimulated this result would have been averted.

In the cases under my care alcoholic paralysis is treated with hot showers and hot air baths accompanied with saline drinks. In most cases this is followed by sharp reaction; a few hours after generally stupor and prolonged semi-partial coma. This I assume to be the absorption of the alcoholic products which have been accumulating in the past. The remedy for which is increased hot showers and hot air baths. This reaction is in some cases sudden delirium and hallucinations or strange morbid impulses. The alcoholic ether odors continue for days after the spirits are withdrawn, which seems additional evidence of this condition. I think the process of gradual reduction of alcohol either in medicine or the treatment of inebriates in direct opposition to experience and rational theory.

On whatever theory spirits may be given as a medicine, to gradually diminish the size of the dose and increase the interval of time of giving it, is without reason or judgment. Whatever special effect of alcohol may be desired, the attempt to reduce this down to a minimum in decreasing doses, is purely fictitious.

In a case of typhoid fever where large quantities of spirits had been given and recovery began, great stress was insisted to discontinue the spirits in decreasing doses. Death followed and no intestinal lesion could be found, hence the diagnosis heart failure. In my opinion it was alcoholic poison, with sudden absorption of accumulated products directly due to spirits. Some of the facts I wish to emphasize are first, anesthesia of spirits has a limit, beyond this there is saturation and accumulation of unknown chemic poisons, of great fatality. The toleration and fatality of excessive doses of alcohol in both health and disease, point to some unknown conserving force and capacity of elimination of great power. The sudden deaths which follow in these cases are additional evidence. The practical fact confirmed in many ways is that whatever the physiologic action of spirits may be, its action is limited, and does not increase beyond a certain point, that the effects on the body are cumulative, principally chemic products that are not readily eliminated.

These and other effects from alcohol seem to check elimination beyond a certain point, and become very dangerous. The exhaling of alcoholic ethers from the lungs is significant of saturation and crossing the danger line that should be heeded. In my opinion there is no remedy known of such uncertainty, and physiologic danger as alcohol. The need to-day is a new critical analytic study of the entire subject of alcohol in therapeutics.

**Enormous Sac of Pus in Abdomen.**—Eleven liters of thick, green, sterile pus were removed from an enclosed sac in the abdomen of a young female by Maydl of Prague, in which the uterus and annexes had been floating. Complete afebrile recovery.—*Wien. Klin. Rundsch.* August 2.

## TEACHING TEMPERANCE IN PUBLIC SCHOOLS.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY CHAS. H. SHEPARD, M.D.

BROOKLYN, N. Y.

That the temperance problem is fraught with imminent consequences both to the present and future generations, none can deny. The educational method of dealing with the subject commands itself to all, for if it is studied from a purely scientific standpoint, then whatever advance is made will be permanent, and leave no room for an emotional reaction.

The use of narcotics has become such an overshadowing calamity that it behooves all to make diligent inquiry if perchance there may be some way of escape for our people. Not those who give way to such indulgences are to become the permanent inhabitants of our land, for such conditions do but bring about an inferiority and degeneration that eventually and surely leads to extinction. We also well know that by studying and obeying the laws of life and health, the term is lengthened and its enjoyment enhanced.

This is a subject that comes home to every man of family. All right-minded parents desire to give their children the best opportunities for the struggle of life, and even the most besotted are frequently known to make a great effort to have their children shielded from the effects of their misdoing. It is rarely that a father who uses tobacco desires his son to do the same. The young man who is to join in the struggle of a boat race, or foot-ball game, knows that it is incumbent on him to conserve all his powers and not waste them on tobacco or alcohol, and he willingly denies himself to any extent for that purpose while in training, but when it concerns the race of his life, he too often becomes prodigal of his vital energies and makes fearful havoc of what he would give thousands to be possessed of in later years, simply because he is not conscious of the injury he is doing to himself.

For this reason it is that the school years are the most important season of the child's life, the formative period, and if at that time basic truths can be inculcated, he will be more likely to avoid many errors and grow up to a more vigorous and useful manhood.

We know that every great emergency brings a man to fill the gap. In this case it was a woman, Mrs. Mary B. Hunt, who has made it her life work to forward this object, traveling over a large part of the United States in its advocacy. Associated with her as an advisory board, are some of the noblest and ablest minds in the land. Through her persevering and unselfish efforts, all but five of the States in the Union have enacted laws requiring scientific temperance to be taught all the pupils in their public schools. Canada has also listened to her voice, and enacted similar laws, and her influence has extended to several of the European governments, notably France, England and Russia.

The saloon element in the cities of New York and Brooklyn is so dominating that it was not strange that a strong opposition was developed, and in some of the daily papers, ridicule was thrown upon the work. But no sane man will maintain that there is anything preposterous about the study of physiology. On the contrary, after mastering the "three Rs"

there is no more important study in the curriculum, and the reporters who attempted to ridicule this study were never more mistaken, for it is a well-meant and well-digested plan, and has the sanction and support of some of the best and most self-sacrificing people in the land. It is as surely bound to succeed as the right is to come uppermost in the not very remote future. It is undoubtedly true that the temperance movement is to be promoted more thoroughly and rapidly by an educational course than in a prohibitive way, and it will be like "kicking against the pricks" to oppose the instruction of our children in the action of alcohol and other narcotics.

If a child can be made to understand that the purpose of the stomach is the digestion of his food, and that by its thorough digestion, impeded by no irritating or debilitating element, the vigor of the system can only be maintained, and if it is shown that the use of alcohol impairs all the functions of the stomach and predisposes to disease, he will as much hesitate to use stimulants as he would to use arsenic or any other poison.

Let any unprejudiced man who loves his race observe what a vast amount of effort is given to the production and use of alcoholic drinks; how it permeates every class of society. So, also, the use of tobacco and other narcotics. Are we, as a people or nation, benefited by them, or are they a hindrance to our progress and development? The frequent death of a victim of the cigarette habit would argue that our children could easily find a more profitable field of effort. Many of the parents may be astonished when the children come home from school and tell what they have learned about the effects of the moderate use of alcohol and tobacco, but if it be true, we have not found it out any too soon. The books that have been compiled for use in the schools have had the revision of some of the ablest physicians in our land, and they will stand the test of scientific examination. Dr. Crothers, the eminent specialist in inebriety, says, "I have spent some time on the school books mentioned, and I have not found errors or extravagant statements."

If the facts contained in these books are not adapted to the comprehension of the children who are taught, it shows that the teacher has mistaken his calling. The question of the use of alcohol and other narcotics is one that is sure to come up for discussion more and more, and will never be quieted until it is settled rightly. If it is well for physicians to prescribe narcotics, then should the manufacture and sale be encouraged in every legitimate way. On the contrary, if their use is evil, and evil only, as some scientists claim, then all should know it, that they may avoid the pitfalls, and in no more holy ground can this knowledge be placed than in the minds of our children.

It would not be possible for the race to continue many generations longer in the free and increasing use of narcotics, for it would produce degeneration and wide-spread disaster. The light of science, which is simply increasing knowledge, will dissipate the clouds that now hang over us, and usher in the new era to a regenerated mankind. For these and many other reasons, we are satisfied that the law directing this study by the school children is a most laudable one, and should be encouraged by every right-minded person. It can be opposed only by the saloon element, and its strongest supporter, the moderate drinker, who can not too soon become aware of the

error of his ways. He needs education, not prohibition. If he is past learning anything new, his children are not.

The impressions made in our childhood being the more permanent, lead up to the fact that if our children can be taught the truths about alcohol and other narcotics, the time will eventually and surely come when their daily use will be abandoned.

DISCUSSION ON PAPERS OF DRs. EVERTS, KELLOGG, CROTHERS  
AND SHEPARD.

DR. GROSVENOR—If alcohol is not a stimulant, then why do we observe the flushed face, the increased intellectual activity, the elevation of temperature, the increased muscular power and the general feeling of well-being which persons, especially the weak and feeble, experience while under the influence of alcohol?

DR. KELLOGG—Alcohol may be very aptly termed a "nerve-fooler." Its effects are in a high degree deceptive. It makes a man who is cold feel warm, while the thermometer shows that his temperature is actually lower under the influence of the drug; it makes the weary man feel rested, and the weak man strong, whereas the muscular strength is actually less under the influence of the drug than before.

In experiments which I reported at a meeting of the American Medical Temperance Association held in Milwaukee two years ago, I showed that the man whose total strength as registered by the dynamometer while in his normal condition was 4,800 pounds, fell to 3,300 pounds under the influence of two ounces of whisky; the depreciation of nearly 30 per cent. makes a man imagine that he is stronger than ever before. Careful psychologic tests which I have made with various instruments of adaptability to the purpose, demonstrate how the tactile, the temperature sense, the sense of weight, etc., are all diminished from 30 to 50 per cent. under the influence of alcohol. A man is more talkative than when in his normal condition, but he uses less discretion in the selection of words. There is an evident lack of intellectual balance.

Under the influence of alcohol the face is flushed, because of the paralyzing and depressing influence upon the vasomotor sense, causing the laceration of the small blood vessels. Prof. Ayres' remarks, that if this were not proven, the surface should be red with blood after death instead of pale, is most absurd, for the reason that every physiologist knows that in death the heart ceases its action before that of the vessel, so that the blood is impelled on into the veins, and the arterial system is completely emptied. This surface cyanosis does not appear until the blood has passed on into the larger veins.

Professor Bunge and most of the authorities pronounce alcohol to be a depressor. Professor Reichert's experiments upon a frog's heart show alcohol to be a depressor. This question is scarcely at all discussed among physiologists, for the reason that recent experiments have been conclusive in establishing the fact that alcohol is a depressing agent, and in no sense a stimulant. It is true, that when first introduced into the body, whether by the stomach or hypodermically, alcohol seems to act as a stimulant. This is due to its irritant effect upon the nerves, whereby a reflex stimulating influence is produced, the same as would be produced by a plaster, a caustic, a hot iron, or any other irritating agent; but as soon as the drug enters the circulation and comes in contact with the nerve centers, its true physiologic effects appear, and there can be no question that these effects are those of a depressing agent, and not those of a stimulant.

DR. GROSVENOR—I have observed the different classes of drinkers, and I have noted the character of the drink which they take and I have never been able to tell by the coloring of the countenance of the drinking man whether he was a beer drinker or a strong drinker.

DR. KELLOGG—I think the temper has very much to do with this. Beer drinkers are thick skinned. So are certain classes of people that are pale while embarrassed, while there are classes who are flushed while embarrassed. There are some who turn pale while still flushing. I am told that is one reason why beer drinkers are more likely to be florid than pale, because the attack is upon the nerve centers, while in the strong drinker there is a reflex action so that the vessels are contracted.

THE CHAIRMAN—I merely wish to add the evidence of what little experiment I have made. I have found that the white corpuscles in some were vastly increased by the use of alcohol. If you put them under the microscope you will find that the red have been supplanted by the white, which was due to the toxin poison, which accounts for the difference in the pale and florid faces.

DR. KELLOGG—Speaking on this subject, I have been disappointed in the results of experiments, more than of the blood in strong drinkers. I have been connected with a missionary movement in Chicago, in which we had 450. We have a little church in the center of the city, and use it for a lodging house, and to catch drunkards in. Most of the men who come there are drinking men. We have a penny lunch counter, free baths and a laundry, and I made last year a careful study of 100 drunkards, 100 hard cases. I am very sorry to be obliged to report the fact that I found very little difference between their blood and the blood of normal character. There was some tendency, of course, to white blood corpuscles, but that was in cases of persons addicted to drinking beer, in which cases the blood is somewhat diluted. I think, too, there must be some other change in the blood than the change of corpuscles. We had no doubts, however, of the red corpuscles. But upon corpuscles of this kind we had small proofs, for the blood has peculiar resisting power against alcohol. Being sent directly into the blood, if not for the great resisting power we would be able to see an ill result at any time. And probably alcohol taken into the stomach is simply absorbed. The blood is itself stored up in the liver and passes out into the intestines and is absorbed and goes through the kidneys.

DR. GARBER—I object very much to the use, in Dr. Crothers' paper, of the word stimulant. The author states that in a case of diphtheria it was given freely, and as a result the child urinated more freely and averted trouble. I claim this action of the alcohol was not one of stimulation but one of paralysis. It so paralyzes the nerve centers that the vessels become dilated, if it is the increase of urination.

DR. CROTHERS (Hartford, Conn.)—In Prussia, Austria and in Germany, provisions have been made for drinking people the same as for the insane and the time is very near when we shall in this country be obliged in self defense to take care of those unfortunates and put them in asylums. This is a question we can discuss more thoroughly than the question of respiration, for on the question of respiration we shall differ and put into it our personal experiences; but when we come to great subjects like the care of these unfortunates we can but agree. This is a subject that will be pressed and carried home. What to do with these people who are near to each home circle is a subject upon which too much stress can not be laid. I think Dr. Everts will find long before his work is accomplished that he has undertaken a great work.

DR. QUIMBY—As long as the State institutions, the saloons are State institutions so to speak, if the State cultivates the people in habits of inebriety and establishes schools of drunkenness, which the saloons are, tempting the weak, the young and the foolish into habits of inebriety by her license system, just how long shall it continue to debauch a large percentage of them. If the State is particeps criminis through the laws established by it, she ought to take care of her feeble alcoholic patients. They are all feeble if they drink to excess, and if a man drinks at all he drinks to excess. He has defective qualities and should be taken care of. The law has made him drink or assisted in making him become an inebriate.

DR. KELLOGG—Regarding the paper on the non-alcoholic treatment of diseases, I want to say that the proposition of the paper was to show that there are sufficient means for accomplishing what alcohol is supposed to accomplish. In a great

many thousand cases it has been found entirely successful to treat them without using alcohol.

THE CHAIRMAN—I can add to Dr. Kellogg's statement, that for twenty-five years I have practiced on the non-alcoholic plan and I have been more than gratified with my success, even in the hospital.

DR. WORK—I have not used it for the last ten years except in the preparation of medicine, but not in the way of brandy or whisky or anything of the kind then. I have not prescribed whisky or beer or anything of the kind.

DR. GARNER—I once treated a case of rattlesnake bite without the use of whisky. I was called two miles in the country to see a lady who had been bitten by a rattlesnake. They had sent for whisky, but by the time the whisky came it was impossible for her to retain anything on the stomach, not even the whisky. It was about two hours after the bite, they told me, when I was called in. I used nux vomica and a ligation and cleansed the wound and extracted the blood. I injected a solution into the region of the wound and left the ligation on six hours. In ten days she was out of danger and is living to-day. Not one drop of alcohol was used in that case. I would treat a copperhead bite just as a rattlesnake bite. I learned at school that alcohol was good for most everything. We are taught that in the books, and one of our authors has made a great speech during this session in which he says that 70 per cent. of the cases of typhoid fever will get well without any medicine if treated with alcohol. I failed to see the use of alcohol in those cases. Until our professors teach differently in the class rooms and the authors teach differently in their works, it is going to be a hard matter to institute a reform.

THE CHAIRMAN—I had one case come under my observation in the New York hospital, of a man bitten by a species of snake, I think the cobra. He was treated in the most scientific manner and was kept constantly filled with alcohol. They continued that forty-eight hours, when the man died. It has always been a question in my mind as to whether the man died from the snake bite or from alcohol.

### AN APPEAL TO THE FELLOWS OF THE AMERICAN MEDICAL ASSOCIATION IN BEHALF OF DISABLED PHYSICIANS AND WIDOWS AND ORPHANS OF PHYSICIANS, MEMBERS OF THE ASSOCIATION.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY FREDERICK HORNER, M.D.

P. A. SURGEON (RETIRED), U. S. NAVY.

The total number of the fellows of the AMERICAN MEDICAL ASSOCIATION in 1884 according to the JOURNAL, was 4,108. In 1890 the number was 3,779, and in 1894 it was 4,095. From the three groups of figures given embracing a period of ten years, we learn that the growth of this representative body of the American medical profession has been almost at a standstill, though the number of physicians in the United States is about seventy thousand. According to the figures above presented there was a decrease of the ASSOCIATION'S membership of 329, due perhaps, in part, that during this period have been created the Gynecological and Surgical, the Military Surgeons, and the American Public Health Associations, all of which, like the British Medical Association, with its sixty-one branches in England, Scotland, Ireland and abroad are offshoots or branches of the parent association. And yet, such a statement does not allow us to reach the true explanation (as we believe) why the AMERICAN MEDICAL ASSOCIATION has not a larger membership, now that the organization is so complete with its eleven Sections of Practical Medicine, Obstetrics and Diseases of Women, Surgery and Anatomy, State Medicine, Ophthalmology, Diseases of Children, Dental and Oral Surgery, Medical Jurisprudence and Neurology, Dermatology and Syphilis,

Laryngology and Otology, and Materia Medica, Pharmacy and Chemistry, and a journal which is the organ now of the medical profession of the United States. If membership with the ASSOCIATION has attained only a minimum number and the majority of physicians have raised the question as to the "cui bono" to them individually and to their families, is not the conclusion logical that if membership only involves them in expense during their absence from their spheres of practice, and to some may be an occasion of temptation, a large number of this class decline to enter the ASSOCIATION. Now, our medical brethren in England have wisely incorporated in their organization a section of benevolence, as long ago as 1835-36, a period even prior to the birth of our ASSOCIATION, the members of which have raised thousands of pounds sterling, designated as the British Medical Benevolent Fund. The British Medical Association has since trebled its membership and now has sixteen thousand members; wherefore should not the AMERICAN MEDICAL ASSOCIATION have its "American Medical Benevolent Fund?" Clericals and laymen have theirs, the widows and orphans of deceased clergymen of the Protestant Episcopal Church have had in all a fund of \$81,000 for their relief. The operative classes, railroad men, commercial travelers, brewers and distillers, apart from the benefit some may derive from insurance companies, have their own mutual assessment fund; why may not the fellows of the AMERICAN MEDICAL ASSOCIATION? Bishop O. W. Whitaker, in his address at a late meeting of the Mutual Aid Society of Philadelphia said: "A professional man is taught to look after the interests of others before he looks to his own; that is the professional idea and the medical profession has lived up to that idea from the very beginning. As the captain of a ship looks to the safety of his passengers before his own, as the captain of a company of soldiers is willing to die for his country, as the engineer on the engine faces death to save those in his charge, so the true physician is at all times willing to sacrifice himself. A medical aid society has claims for support on the whole community and these claims should be recognized. Finally this recognition of the claims of the widowed and orphaned comes from the Son of God, who by a miracle raised from the dead the widow's son, and commended His own widowed mother to the care of the beloved disciple. Throughout heathendom there is no such sentiment. Jesus Christ taught the world the worth of a child as a child, of a man as a man, and of a woman as a woman. Outside of Christendom, there is no such recognition." In the scriptures as in the records of mankind, are mentioned the wrongs done to the widow and fatherless, evils that we by timely help may contribute to avert. If we fail in such duty, recognized now as a matter of privilege by all classes, the social, industrial and professional, there is One who will not. God, with the force of a commandment in His word says: Leave your fatherless children unto me, and let your widows put their trust in me and in the sweet strains of tenderest melody, comes the assurance "He relieveth the fatherless and widow," but, as Christian physicians let no one fail to remember vital union with the Bestower of life in time and eternity demands of us to recognize as the instruments to provide for the needy, viz., disabled physicians and the widows and the orphans of physicians. The writer could cite any number of examples of worthy physicians who stood bravely at the post

of duty and died, as some did, at Norfolk, Va., in 1855, when the plague of yellow fever decimated the population there, and at the Norfolk Navy Yard and Portsmouth. How common the record is for some faithful physician to be killed by accident—a fall from his buggy, run over by the cars, or as in country practice, drowned in the vain effort to cross a swollen stream and thus injured or perishing leaves a helpless family, if not otherwise destitute, with no accident or life insurance policy, and no stipend contributed by a medical aid society, save in one or two States as in Massachusetts, New York and Pennsylvania, though they may be Fellows of the State and AMERICAN MEDICAL ASSOCIATIONS, and physicians of high social and professional rank leaving behind the memories of spotless lives and

“Footprints, that perhaps another  
Sailing o’er life’s solemn main  
A forlorn and shipwrecked brother  
Seeing, shall take heart again.”

Dr. H. Tuck, Treasurer of the New York Society for the Relief of Widows and Orphans of Medical Men is correct in the opinion that every medical society in the union should have its medical benevolent fund, as well as our National Association, with a united purpose to carry on a systematic method of benevolence annually, however small the stock in hand may be at first. As an example of success may be cited the work of the Royal Infirmary of Edinburgh, Scotland, which shows from the last report that even shilling contributions were accepted among the larger benefactions of the rich, making a total of £4,228, to which were added other sums from public works and establishments, churches, donations, legacies from the counties and cities of Scotland, England, Wales, Ireland and abroad, summing up £9,388, details gleaned to prove how the laity and unprofessional do not fail to make annually a generous and munificent provision for the needy, it may be the insane, and the inebriate. The founders of the Massachusetts Medical Benevolent Society in 1857 can not be too much commended in the declaration that they endeavor to help worthy members of the profession, reduced in circumstances and also their families, should they need assistance and of such other medical members of the society and profession or their families as may be deemed by the society suitable objects of its beneficence, a broad platform on which to do good and worthy of adoption by the Fellows of the AMERICAN MEDICAL ASSOCIATION. But the absolute proof of the trial of an experiment to raise money as a fund for so good a cause, is furnished to the physicians of America by our medical brethren of England as presented by the late annual report of the British Medical Benevolent Fund for 1894–95. The most eminent, noble and titled physicians of Great Britain constitute the officers in charge of this fund: Sir James Paget, Bart., F.R.S., president; Sir William Jenner, Bart., F.R.C.P., Sir Richard Quain, Bart., vice-presidents; trustees, Sir H. Acland, Sir James Paget and Sir Edward Sieveking, Barts.; treasurer, Sir William Broadbent, Bart., M.D., 1884. Bankers, Bank of England.

Honorary local secretaries number seventy-nine, and are located in all the principal cities, towns and counties of England and Scotland and border counties.

This fund the report states is “for the relief of medical men in temporary difficulty or distress and for their widows and orphans, and also, for granting

annuities to those who are quite incapable of providing for themselves after sixty years of age. This fund has been in the form of annuities to the aged and of grants of money to urgent cases which required immediate help; such recipients must be members of the medical profession, or their widows and daughters and not less than 60 years of age. The annuities are £20 each, but may be increased to £26 a year, *i.e.*, ten shillings a week; the annuities are paid from the annual income of invested property. Of late years such have been greatly increased by legacies, so that in 1883 the annuities were 51; are now 104. There are special funds, one of £15 for two widows of medical men, and the other £36, to a physician’s widow having children to educate. The grants like the annuities are given in monthly installments. Subscriptions for 1894 amounted to £1,083, 14s., 5d., and the donations to £707, 8s., 4d. Grants in sums from £2 to £25, were distributed to 169 applicants. Donations were received from Bath, from the Southeast Branch, British Medical Association of Bristol, the Society of Apothecaries and the Salters’ Company; one of the legacies of £500, was from the late Mr. T. M. Stone, Librarian of the Royal College of Surgeons, and the wardrobe, besides £100, was left by will to the Fund. The committee consider the position of the annuity fund safe; a number of applicants could not be relieved because safe investments could not be found, and owing to the falling rate of interest of all trust securities and the low dividend on bank stock; it would lessen the difficulties of collecting the grant’s fund for regular subscribers to pay through the bank for which a banker’s form of order is given with the report. The collector may be the secretary of the association. The committee appoints medical local secretaries, *e. g.*, Bath, Brighton, Northampton, and in other cities to represent the fund, to collect the subscriptions and to distribute the grants in their respective localities, numbering in all forty-five and including the British Medical Association, Southwestern Branch and South Midland Branch, and great cities—Liverpool being the largest contributor; Edinburgh, Hull, Manchester, Plymouth, Perth, Cambridge and Oxford, Glasgow, Leamington and others. The committee urge that an appeal shall be earnestly made to all interested to make the existence of the fund more widely known and to urge its claims not only upon the members of the medical profession but also, upon others who have the cause of true charity at heart.”

In a brief conclusion of this appeal to the Fellows of the ASSOCIATION, we would respectfully claim that an experiment of the kind by the profession in America can not be esteemed an impracticable one in the presence of the facts above presented by the reports of the Massachusetts Medical Benevolent Society, the New York Society for the Relief of Widows and Orphans of Medical Men; the Mutual Aid Society of Philadelphia County Medical Society and of the British Medical Fund Society of England. On the contrary, we claim that now, after a half century’s existence of the AMERICAN MEDICAL ASSOCIATION, we firmly believe that to ensure a larger membership with the Divine blessing and to promote a common and widespread fraternity, and to perfect the glorious work of its founders, Drs. N. S. Davis, Chapman, Stevens, John C. Warren, Muesey, Moultrie, Wellford, Gross and others on the occasion of the birth of our glorious ASSOCIATION in 1846, that the capstone needed is the

creation of a section of Medical Benevolence—to be styled by Federal Statute law “The American Medical Benevolent Fund,” to be judiciously dispensed for the benefit of disabled physicians and of the widows and orphans of physicians in fellowship with the ASSOCIATION—as donors of the fund, annual contributors or by legacies.

## TUBERCULOSIS INFECTION FROM FOOD.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 6-8, 1896.

BY CHARLES E. WINSLOW, M.D.

LOS ANGELES, CAL.

Preventive medicine to-day, like a gigantic signal light, sends its piercing rays into all the world, guiding medical men upward to a plain above their forefathers which gives advantages unknown before. Old theories have developed into facts, prophecies of the past are now being fulfilled, and hygiene has been clothed in new garments of interest. There is more earnest thought along this line than ever before. We have the benefit of the most advanced laboratory investigations, giving us an understanding of the causes of disease hitherto unknown. With this growing enlightenment comes a greater responsibility and a more urgent need of earnest labor in preventive medicine. Science, as she turns the pages of this new book of knowledge, calls for pure food, pure drink, pure air and better protection from disease and death.

Man seems prone to disease, and of all the ills he is heir to, the most appalling in its dire results is tuberculosis. Like a great octopus it reaches out its tentacles after the human race, blighting all who come within its grasp, sapping the very life blood, making a wreck of noble manhood and bringing misery and despair to its victims. Having a death rate in the United States of over one hundred and seventy-five thousand a year, with one-seventh of all deaths in the world from this dread disease (Harsch), leaving in its wake seeds that will bring care, sorrow and death to thousands more, it becomes a hideous menace to humanity.

There is an increasing anxiety among the thinking medical profession due to the resistance of this disease to the advanced curative remedies, for at present all have come far short in checking the progress of this most formidable of all diseases. Although in respect to curative medicine we are still groping in darkness, the light of progress has illuminated the path of preventive medicine, showing that the enemy must be met and vanquished under its banner.

Comparatively a few years ago a majority of the medical men did not believe in the communicable nature of tuberculosis, but scientific research has proved it beyond a doubt, and the cloud of heredity that has hovered as a pronounced doom over hundreds of lives, shutting out every ray of hope, has been dispelled. Many with the predisposition to consumption have accepted this bow of promise, and by changing conditions have conquered the inherited tendency to the disease, becoming healthy and useful men and women.

That the colonization of Koch's bacilli in the animal tissue causes the disease is the belief of the most advanced investigators. If this be true, beside proving that the disease is infectious, it gives grounds upon which we can work out our own salvation by

controlling the spread of the disease. The two great mediums through which it reaches the human system are air and food. While the inhalation of bacilli-laden air affects the lungs more largely, tubercular food usually causes the infection through the bowels. The food of a people is its strength; a poorly fed will be a demoralized people. The more wholesome the diet the stronger is the nation. Among the food products none take the place of milk. There are produced in the United States nearly five and a half billion gallons of milk, more than one billion pounds of butter, and nearly nineteen millions pounds of cheese. How important that an article which forms such a large proportion of the food of the people of this country should be pure and wholesome. Tuberculosis is disseminated more largely through its agency than that of any other food.

The most common disease of the cow is tuberculosis. The close relation that exists between the cow and the human family render it possible for the spread of this frightful disease, and for man's best friend to become his worst enemy. Some writers have claimed that the only nations in the world free from tuberculosis are those that have not domesticated the cow, and that this disease is perpetuated by the domestic cattle. That this is no imaginary danger, but real and menacing has been repeatedly proved by experiment and research.

Human beings and the lower animals, living upon the milk from tuberculous cows, have contracted the disease. In one experiment seven out of twelve calves, and two out of five guinea pigs, fed with diseased cow's milk, developed tuberculosis, while the milk from seven cows infected seventeen animals out of eighty-seven inoculated. Obermuller found that out of forty guinea pigs, into which milk bought from dealers was injected, three became affected and died. In his experiments, using centrifugalized milk mixed with the cream of the same milk, ten out of sixty guinea pigs were infected. Roth and Broferro infected guinea pigs from butter made from the milk of tuberculous cows. In 55 per cent. of the experiments the milk from cows having tuberculosis has conveyed the disease to the lower animals. (Ballinger.)

Numerous cases have been reported before the societies where physicians have directly traced the disease from the cow to the human being. It exists to an alarming extent in our large dairies. Very little milk reaches our cities free from mixture with milk from tuberculous animals. (Bush.)

From 5 to 10 per cent. of the slaughtered animals have tuberculosis. The cooking of the meat used for food lessens the danger of infection from that source. The bacilli introduced into the system may migrate to different parts of the body, forming here and there little colonies, the lungs being most often the seat of attack, the digestive tract next. The infection of the intestinal tract by tuberculosis is more common among children than adults. The increasing cases of tuberculous joints, meningitis and infected bowels and glands in childhood can be largely accounted for by the use of diseased milk.

The majority of people are not predisposed to tuberculosis; the immature child and the invalid are most susceptible to the disease. The bacilli rarely find a home in a healthy human organism. Anything that depletes the system leaves it in a condition to become infected; therefore an impure diet of any kind tends toward tuberculosis, while good, wholesome food will

aid in throwing off the disease. The food of a human being may be full of the bacilli and still the system be so nourished that it will not retain the germs. While this may be true, still if the bacilli can not gain entrance into the organism there will be no danger of infection.

Tuberculosis is not so contagious as many diseases, but it holds its victims more firmly in its grasp than almost any other enemy of mankind. And yet this curse of the human race can be prevented. To accomplish this there must be strict sanitation. More and more attention is being given to the subject, not only by the physicians but by the people at large. To-day the hygiene of our cities is one of the great questions which municipalities have to deal. The sale of food that is infected with disease should be restricted and the punishment made so severe that the dealer will fear to sell such food. Each community should have an inspector, whose duty shall be to carefully examine all food sold. Some of our cities have greatly improved the quality of their milk supply by so doing. Sterilizing milk lessens the danger.

Milk containing tubercle bacilli is a diseased product. Wherever there is this microorganism there is tuberculosis. No tuberculous animal can give pure milk, the disease must affect all the organs of the body. Every cow, private or dairy, should be examined for tuberculosis and other diseases by an expert, and the milk of every new cow entering a herd tested before a drop of it is used. The inspection should be periodical, and carefully and systematically made. There should be a physical examination and the tuberculin test should be used, for it has been proved that milk from cows, which give no physical signs, is often infectious. Although Koch's tuberculin has not been a success as a therapeutic agent, it has proved a useful aid in the diagnosis of tuberculosis, and no herd can be thoroughly inspected without its use. The healthy cows should be marked, and all tuberculous animals, no matter how slightly affected, destroyed. It is a serious matter to go into a man's herd and kill his cattle, but it is pernicious to let such animals live, a menace to a community.

Not only should the cow be inspected but its treatment and surroundings. The animal from which milk is taken should have the best of care, be fed wholesome food and have stables and surroundings neat and comfortable. The utensils used for holding milk, making butter and cheese should be clean and free from dust. No person suffering with tuberculosis should be employed about a dairy, creamery or where food is prepared or sold.

Only milk and its products from inspected dairies should be placed on the market. There should be abattoirs where the slaughtered animals could be examined by competent experts, and no market should be allowed to sell meat which does not have the inspector's tag.

All articles of diet should be kept from contaminating dust. Even the wrapping paper may infect healthy food. Eating utensils used by consumptives should be disinfected.

Inspection is a necessity. To make it a success the inspectors should be educated men and their decisions enforced by law.

The cost of sickness is great, so immense that we fail to grasp its magnitude, nor can we form a proper conception of the annual financial loss to the nation from this king of terrors. Every life has a financial

value, every life saved is so much gained for the community. The child who dies before he is able to be a wage earner, is a loss of just so much as has been expended on him and what he could have earned had he lived. When a man dies of this disease it is not alone the expense of his sickness and the value of his wages that are lost to the world, but the time of those who cared for him, and the expense of the expanding influence of the disease he has left behind him.

With the wonderful development of our country comes increasing danger of infection from the foreign element which, absorbed by our people, by its lack of ordinary sanitary precautions aid in spreading disease. There is a demand for better means of protection.

Every charitable institution in this land is an unconscious recognition by the people of the importance of sanitation and teaches that man should not live for himself alone, but for humanity. It is our duty as physicians to devise means for the amelioration of the human race.

Progress in preventive medicine has given us facts that prove the danger and has shown us a logical means of prevention. With this light to aid us we must impress the truths upon our fellow men.

The people are thinking about these things and are increasing in knowledge; public opinion in all its unmeasured power is slowly progressing.

Education and a wise use of education will do much, but an educated people can not do all. There must be a willing government to enforce. The growth of sanitary science calls for advancement in controlling sanitation. State and local authorities can not shirk the responsibility; they are bound to protect life from the danger of death by disease, as from rapine and murder, no matter how great the expense. For a municipality to pay no attention to the sanitary condition of the community is to become the abetter of crime. Some of the States have taken up the subject and their health officers have done noble work in checking the advance of disease, but in order to do the greatest good to the greatest number there must be more legislation in favor of sanitation. There must be intelligent men at the outposts, guarding hamlet and city, a united action along the line, with a master mind at Washington advising and controlling the entire force.

When advancing civilization shall recognize justice to humanity and give place among our Presidential advisers to a man of science who will guard the common safety and welfare of our nation, lessening sickness and want, sorrow and suffering, wasting and death, then may we hope to see science triumph over disease.

## MODERN RESPIRATORY ADVANTAGES.

Read in the Section on State Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY W. T. ENGLISH, A.M., M.D.

PROFESSOR OF PHYSICAL DIAGNOSIS IN MEDICAL DEPARTMENT OF WESTERN UNIVERSITY OF PENNSYLVANIA, AND CONSULTANT IN CHEST DISEASES IN THE SOUTH SIDE HOSPITAL. PITTSBURG, PA.

The worker in the domain of preventive medicine often has occasion to feel that there are excuses for becoming pessimistic and for regarding his efforts as unprofitable. After some acute outbreak of disease, his heart is wrung with disappointment and his mind is distracted. A good remedy for such hypochondri-

asis is to rehearse for himself, or have another review for him, some of the modern respiratory advantages, and trace them to their source. All men are not alike possessed of the "vision and faculty divine," but that man must be indeed prosaic whose soul is not inspired with gratitude and whose heart is not uplifted with hopefulness as he beholds the human body rapidly and surely raised from the abnormalities of life, sublimated, refined and sacred through the avails of modern respiratory advantages. The individual who labors in the realm of preventive medicine is habituated to a life amid the vapors of melancholy and disease, and if no sudden or colossal change dispels those vapors, his mental visualizing is rarely illuminated. However, his efforts are continuously transforming the gruesome abiding places of disease into palaces of good cheer, and he is creating an improved state of existence for himself and his generation. The influence ceases not, but it steps in splendor the distant human prospect and reaches out its long arms like a benediction toward the ages that are yet to be.

The solicitude with which he guards the youth from the moment he leaves the nursery is like to the fabled spirit of good that keeps from all evil. So unremittingly has he demonstrated the ill influences of bad air and advocated the benefits of good respiration that the school curriculum has been extended to include a study of the laws which govern the respiratory organs, with those which govern other material things. By the intelligent application of the laws of respiration, which the schoolboy is thus taught to understand, there is not only a continuous development of the breathing apparatus, but an extension and versatility of its functions. The schoolboy of to-day knows better how to breathe than does his grandsire. In him is awakened an appreciation of the fact that the respiratory organs were never intended to act as involuntary parts of the body, and it becomes a portion of his daily care to observe that a fair proportion of the 25,000 respiratory cycles are voluntary and forcible acts. This age, so self-conscious in many things, is thus to be secured against lethargic, indifferent and unconscious respiration, which has been the cause of much of the pulmonary weakness of the past. The most casual observer will note that it is not our boys and girls who need reformation from respiratory delinquencies, but the fathers and mothers. It is only the children who have learned from their teachers how to use their respiratory organs who really know how to breathe. The large majority of those in adult life have never yet learned how to take a full inspiration or execute a forced expiration. They are totally ignorant of what is meant by a voluntary respiration. In consequence of this the average adult never employs the lungs beyond that which is essential to existence, and to those engaged in sedentary pursuits this need is exceedingly small. On the other hand, every child, disciplined to-day in the accepted respiratory school, is capable of taking in twice as many cubic inches of air as his parent, and habitually uses his breathing organs with proportionately greater freedom and scope. In comparison with the school children of to-day the parents are a race of pulmonary pigmies.

This constant oversight of the lungs brings with it respiratory fulness with perfect oxygenation that in turn develops material out of which energy proceeds. The augmented lungs and extended respiratory action begets an increased desire for air, and

these promote a condition of mind that is emulous of bright surroundings. There is nothing that secures appreciation of hygienic conditions like a personal experience of their benefits. To one thus endowed there is a delicious sense of pleasure in the pressure of the lungs against their confines, and it is not easy to deprive him of his powers to battle with bad air.

These methods of cultivation secure an esthetic and cultured respiratory demeanor and at the same time create a longing for complete and repeated changes of air, much as the cultivated taste of the epicure delights in changes of viands. How young, wholesome lungs do yearn for some new brand of alveolotitillating atmosphere! Moreover the highly educated breathing apparatus has analytical capabilities so that it may appreciate that a molecule of oxygen is an impact of two atoms of the element while it recognizes a molecule of ozone as a combination of three. Furthermore, the lungs feel the corroding energy of the triplet to be many times greater than that of the twin, and the influence it exerts upon the breathing apparatus exemplifies a higher intelligence than mere automatism. An educated pair of lungs observes that the air is not imponderable and notes the thermometric and the barometric rise and fall. The mind and the lungs together grow familiar with the physical character of the air, its invisible inhabitants, the microbes and their potencies for good or ill, as well as the general and specific qualities of the air dust.

If it is true, as is calculated, that in the air of the city a man breathes 37,000,000 spores every ten hours it is not from aerial purity that any of the city denizens continue to live and move and have their being. It is also well known that in the atmosphere everywhere there is an opulence of oxygen and the greatest need is a capacious and intelligently controlled breathing apparatus to utilize it, and at the same time to successfully conduct the hygienic chemistry of the perfect function. The educated and sensitive lungs will isolate the deleterious ingredients more rapidly than the microscopist or the chemist; and those objects entrapped upon the microscopic slide, which appear so interesting and beautiful to the visual sense are altogether unlovable to the breathing apparatus when they gain access within their sacred precincts. This ever-increasing discriminating capacity of the human lungs enables men to remain for a season amid deleterious influences with comparative safety.

It was assumed many years ago that the coefficient of oxygen needful and belonging to animals was fixed by the animal's intelligence. Thus, a dog required more oxygen than did a hare of equal weight; the chimpanzee, the nearest animal to man in point of anatomic resemblance, needed less than man. Whether these estimates were considered fanciful or not, it is certain that to breathe well to-day is the most modern method of demonstrating advancing intelligence.

Falling in line with this display of wisdom in the exercise and development of the lungs are the efforts that are everywhere made to reduce the aerial threatenings and improve the quality of the air we breathe. But for these efforts the vitiated city atmosphere would be most deplorable in its consequences to those compelled to remain within the urban limits. However, it is only amid such surroundings that we can discover how apparently insensible some persons are to the subtle influence of vicious atmosphere, and

observe the variety of means which contribute to counteract the bad air and unhygienic conditions.

The elaborate and perfect system of interchange that has been going on since the world began between the earth, the vegetable and the animal kingdom, with no waste of material, still continues to command the admiration and thanks of every grateful creature. This is also supplemented by a process of sanitary chemistry—more flexible and variable—by which the actions and reactions of materials and the affinities and aversions of the silent and unseen forces are made to conform in the main to the best interests of human kind through the provisions of the *vis medicatrix nature*.

To reinforce these natural efforts at sanitation, every city to-day has in its employ a capable corps of workers whose business it is to look after the various impurities. It is the custom in several municipalities to gather a measure of the atmosphere from different portions of the city and force it through materials in which are entrapped the impurities, and these are carefully isolated and estimated, and the result announced. To afford all who desire to acquaint themselves with the relative impurities existing in different localities a record is made at intervals not exceeding one week.

The use of the microscope and other instruments of investigation has become popular amusement, and there is an individual as well as public surveillance of the atmosphere. Through thousands of channels of observation the intelligent layman is accumulating experience that enables him to trace facts and inferences to their logical conclusions, and the good results are constantly multiplying. Knowing that evils exist he seeks to prevent their influences in himself and others, and though his supremest need demands his presence for a season amid the unwholesomeness, he provides himself with a home beyond its contaminations, where he can retire after his daily duties are over, and render his lungs clean again ere he starts them upon their fresh career of defilement. His household is continuously kept amid the respiratory advantages.

Toward the attainment of these possibilities every recent invention seems to felicitously trend. The proper thing is ever more and more becoming the popular thing. In modern street paving there are some remarkable advantages secured to the respiratory apparatus. The myriad crevices favoring the accumulation of dust and offal in the cobble-stone pavements are replaced by the smoother surfaces of the granite and asphalt. These pavements in the streets of the present city make the dust obvious to the street cleaner, and spontaneous removal by rainfalls is facilitated. The frequent use of the sprinkling cart has a salutary effect in lessening the contamination of the respirable air. We have recently bade adieu to the lumbering horse cars and the thousands of horses which contributed to the filth of every city. The dust, the offal, exhalations, effluvia, gas and odors innumerable incident upon the vast herd of horses upon the streets are no longer with us. By the electric and cable cars thousands of horses in addition to those formerly employed by the horse-car companies are rendered unnecessary. The commodious and wholesome rapid-transit cars are a desirable means of conveyance and the great celerity of travel yields additional advantages by expediting business, social and pleasure trips. By the reduction

of evil long prevalent, and the substitution of the most royal good, they contribute to modern respiratory advantages beyond computation.

The more recent methods of city illumination has done much that is favorable to wholesome activity in the breathing apparatus. The old-time fishtail gas jet, capable of consuming as much oxygen as several persons, is substituted by the electric light. This is especially noticeable in assembly rooms. By the use of electric light there is no oxygen waste and no products of imperfect combustion. Its universal employment would cause an oxygen saving to every city sufficient to supply twice the number of its inhabitants with good wholesome air.

In the matter of heating, the respiratory organs are considered. The air is not permitted to become gloomy with smoke and other evidences of imperfect combustion, and the smoke-consumer is voluntarily or legally adopted. In the homes we can have our apartments warmed by the moist or dry methods and can so arrange that there will be an equable continuous dry atmosphere, free from dust. Again, we may imitate the barometric rise and fall to suit our fancy or gratify our wish. In the districts where natural gas abounds the air can be kept free from smoke by its employment as a fuel and without even the annoyance of dust from ashes. Some of the more recent methods of supplying air and heat to modern buildings embrace advantages that are destined to lift us out of the empire of death from aerial impurity. The air is drawn by fans through closely woven silk screens or forced through baths which wash and render it aseptic. The shafts into which the atmosphere is drawn are extended to a high altitude to avoid the dust and contamination. After gaining admittance to the basement it receives the desired barometric and thermometric qualities before it is delivered throughout the building. In each room is placed an indicator with a movable needle by the least motion of which the temperature of the apartment can be changed. This adjustment resembles that portion of our timepieces which enables us to regulate its speed. Hundreds of other aids and means of protection to the developing breathing apparatus can be observed in modern city building.

How eminently fitting that an age which protects and fosters its respiratory good should form a remarkably close alliance between its pastime and its business. Wherever we go on a Saturday afternoon we find the city denizens hastening, by every avenue, from the crowd and tumult into the more rural surroundings. The old dead roadways, that a few years ago were overgrown with weeds and grasses, teem with cyclists, and the little town along the way lifts up its head again as if possessed of a new life. The glorious half-holiday rescues many a failing respiration from the thralldom of disease. To take a stroll or join in some of these methods of oxygen hunting, or spend the Sabbath amid nature's wholesomeness, is to serve God. A half century ago this would have seemed sacrilege and the Saturday half holidays would have been regarded by our grandsires as sinful and profligate. But this is the end of the nineteenth century and the world is growing young again through its modern respiratory advantages.

Cricket, football, baseball, tennis, golf, fishing and athletics generally are familiar to every place and are regarded as suitable pastimes for all young Americans. How they have aided in the resuscitation of some of

the yielding respiratory organs! It is not the school-boy, neither the idle men of means who are interesting themselves in these sports and pastimes, but the masses. The countless excursions by rail or water are daily inviting a willing humanity to bathe their bodies in the sunlight and purify their lungs in the aerial change. Whatever morsel of air or quality of atmosphere one desires may be secured by application to the numerous competing land or waterways, and he will comfortably, cheaply and with great celerity be transported to the Eldorado of his desire. With these new experiences and ever-changing quality of the respired air the lungs not only develop their vital capacity but acquire a versatility in their methods of accommodating themselves to the aerial circumstances. There is undoubtedly a remarkable adaptability by which the lungs may adjust themselves to the conditions. And this serves their possessor in good stead when it is impossible to select the environments, because the respiratory versatility enables him to breathe the disease-laden air with comparative impunity. Man is to-day capable, for the most part, of educating and subjugating nature, and when the surroundings are at fault he makes or modifies them; failing in this, he can rely upon the discriminating care acquired by his lungs to render the atmospheric foes inert.

Through all the avenues of hygienic information the truth is being ever more and more impressed that pure air and exercise are equal forces acting in the same direction. The contaminations from disease germs and terrestrial impurities are to be met by an equable antagonism vouchsafed through the intelligent employment of the functions of respiration. Meanwhile most of us agree with Lord Beaconsfield that "the atmosphere has more to do with human happiness than all the accidents of fortune and all the acts of government."

The adjustment of the respiratory possibilities to the needs of each individual is largely a matter of his own choosing. There are some who have tarried too long under the lethal influences of indifferent respiration, and have in consequence bartered their birth-right. Some again there are whose lungs, like the Scotch farms of which we read, are "poor by nature and ruined by cultivation." There may be no regal duty for such to perform but even these can hold from future human struggle the burden of preventable suffering by negatively remaining away from the current of human life that is to-day flowing so directly toward the goal of physical completeness.

#### DISCUSSION.

DR. KELLOGG—In a certain school there was considerable difficulty in persuading the Indians to attend. I thought they would be glad to avail themselves of the opportunity. They were still in a primitive state and were running about in the forest absolutely nude. There was a lot of Indians who thought it unhealthy to be in the house, and took their children away on that account. It was instructive to me to see that they were so solicitous about their children's health.

He said we did not know how to breathe unless we learned it at school. It is not even known in school. I found the best teacher for breathing was a baby. The good Lord told them how to breathe and they breathe just right. I have told many ladies that the best of their breathing powers were tied up; and that if they wanted to learn how to breathe to take a baby and lay it on a bed, and notice how it breathes. I say breathe with the whole trunk. When he breathes the whole trunk will be inflated.

Women breathe with the upper and men with the lower part of the body. What all need is full respiration of the entire chest. I have two little boys and I frequently make them run up and down stairs once or twice to make them breathe properly.

I formerly practiced voluntary respiration, but I am convinced it is not a success. Simply breathing or exercising for the sake of it is tiresome. I have not been able to breathe voluntarily more than two or three minutes at a time. The muscles very soon get tired. But if you will compel yourself to breathe by bicycle riding, jumping up and down, room exercising, or anything else that will create a demand for pure air you will find that it is not so tiresome. The lungs will act in the most vigorous and voluntary manner. For the last seven years I have used gymnasiums for my patients with excellent results.

Dr. —, in some experiments made in the Dangerfield Academy, showed that after six months exercise in the gymnasium he found that the involuntary activity of the lungs was doubled. It became twice as great while the students slept, showing that the effects of gymnasium work are continuous during sleeping as well as waking hours.

There is another point: The position assumed in sitting. A lady said, "I want to talk to you about my lungs. My mother thinks I am to have consumption because I have no chest." I made her stand up and she stood with shoulders and chest contracted. A ruler laid on the chest would have touched the shoulders on either side. I made her bend and look upward, and found she had a well developed chest, but was carrying it all behind instead of in front. The lungs had not been properly expanded. In making her stand straight I entirely corrected the deformity. It is becoming a very common deformity. I think it is largely caused by sitting on the back instead of on the thighs, and it results in people becoming round-shouldered. The body is held in this mold for so long a time that it finally acquires a certain degree of permanency.

The doctors ought to be continuously calling attention to standing straight and raising the chest. While standing straight the lungs are expanded; and the abdominal viscera trained up. Walking, boxing, bicycling are agreeable and exhilarating, and accomplish these beneficial results. They render proper breathing more natural.

DR. GARBER—I have had considerable practice with men who were engaged in blowing window glass, and it has been my experience, that forced exercise will cause great development of the chest. In 500 glass blowers I can not remember a single case of lung trouble. I used a respirometer on some of these men, and found they can inhale 300 cubic inches of air, and I frequently found a difference of five and sometimes six inches between inspiration and expiration. Some people whom I regarded as consumptives have since become well, and lungs predisposed to disease of that kind became strong. I am very much in favor of gymnasium exercise of some kind for all.

DR. KELLOGG—The atmosphere is as important to us as the water that we drink, or the light that shines upon us. I want to ask a question in regard to the consumption of this oxygen; I want to ask the author if he thinks that it would materially affect the health of the city to change to electric lights on account of more consumption of oxygen by gas jets than by the electric lights.

DR. ENGLISH—I made, some time ago, an investigation as to the consumption of oxygen by the ordinary gaslight jet, and it showed that one gas jet consumed as much oxygen as would supply three ordinary persons. Assuming, then, that we have 100 lights in the assembly room, and 300 persons. We would have consumed by the lights as much oxygen as would have been consumed by the individuals in that room.

When we build a room the area is usually estimated to accommodate a certain number of people, and a building of

wholesale emporium is usually conducted upon the principle that so many cubic inches of air must be supplied to every individual. When we use the electric light, especially the incandescent, we consume no oxygen. The incandescence of the carbon must be considered the source of light. It burns in a vacuum, with no possible oxygen waste. In every city we have a certain proportion of people living in one room. Estimate the number of rooms in the city, and in that way we can estimate approximately the amount of oxygen we are consuming by the use of these burners. Then there is another point; just estimate the amount of contaminations, the smoke, gas, odors, and the various emanations which are contributed to the oxygen by these fish-tail gas jets, and the heat that the gas produces, whereas, with electric incandescent lights burning in a vacuum, we have a brilliant light that is satisfactory, comfortable to the eyes, do not have these contaminations, and we have a minimum amount of heat. The consequence is that we do not vitiate the atmosphere. With arc burners on the streets and in the rooms we would have a much larger result, for one arc burner was estimated to be equivalent to sixteen times the power of the ordinary burner, I believe. The comparison is between the two different kinds of light. The arc burner is exposed to the atmosphere, and consumes a large quantity of oxygen; but there is no comparison that would demonstrate the advantage that would be accorded the electric light. When we go back to oil lamps and candles and such devices for lighting purposes, they are often worse, because their contributions to the atmosphere are vastly in excess.

It is a fact that we do not in the schools to-day teach the children how to breathe. We should impress upon them that there are vital organs in the human body and that it is within the capacity of our volition to control these organs, these lungs. We may breathe fast or slow as we choose, and take in as much or as little air. We may suspend respiration, but we can not suspend the action of the mind enough to prevent the use of our lungs. I think Nature has demonstrated by placing these organs within our body it is our duty to use them, or they are indeed not vital organs. By that means Nature secures for us perfect respiration, good sound lungs and a wholesome body.

DR. KELLOGG—I just want to mention three disadvantages: gas stoves, kerosene stoves and gas grates as heaters. A doctor put a kerosene stove in a room and the next day the patient was dead. He told me he was satisfied the patient was suffocated by the odors arising from the stove. The gas stove produces ten times as much impurity as an ordinary gas burner, and a gas grate gives out at least twenty times as much impurity as a gas burner. It seems to me a very dangerous thing.

DR. ENGLISH—I would like to ask the gentleman what gas he has reference to—artificial, natural, illuminating or what?

DR. KELLOGG—It is coal gas. That is a hurtful gas. In natural gas heaters as well as in grates, the opening for the escape of the gases is in some scarcely  $\frac{1}{8}$  of an inch in width, so when the door was opened it was certain to drive all the foul gases out into the room, so that I think it applies to both natural and artificial gas.

THE CHAIRMAN—I think the general fashion of ladies' dresses is wrong, and that the weight instead of hanging from the hips, as is now the case, should hang from the shoulders. I think until that is done they will never have perfect respiration, and that if Dr. English will start a crusade on this line it will result in much better health in every respect, and especially there will be less falling of membranes which the women complain of so much and which gives the gynecologists so much work. They should also have their dresses made so that two or three inches additional would be allowed for expansion of the chest.

DR. ENGLISH—I think that the efforts of such reformers as

Jenness-Miller have influenced the women, and in my experience—and I have had rather large experience in respiratory difficulties because my special realm is the treatment of diseases of the chest—I find that women are disposed to lay aside their pains and corsets and take up more life and health. I really think if I incorporated that subject in my paper I should have illustrated the women of the future. They are growing sensible as well as the men.

DR. DRAYTON—This Jenness-Miller reform is simply a departure from the strict lines of fashion. It is simply an attempt to adapt certain principles of hygiene to fashionable dress. You may get some benefit from it, but it appears to me that the attempt will not be more beneficial than the attempts already made on that line. The new woman will make some difference in this matter of fashionable costume. The new woman likes the bicycle and the woman who rides finds it necessary to adopt a bicycle costume. She finds it is not only good to make muscles in the arms but also in the abdominal region, and after a little practice she would prefer to put her finger in the face of fashion than to give up the wheel. So I think we shall have a great improvement from this cause. I have advised the use of the wheel to a great many ladies. I have studied it and its advantages and I am satisfied its general use will be of great benefit.

DR. J. A. WORK, Indiana—The wheel is not available to all. We should give our women more employment that will have the effect of developing what is claimed for the wheel, which is for amusement, but as a vocation I believe general housework, such as our mothers and grandmothers used to do, would be better for them. I have found that the German servant girls who have not followed fashion have very good breathing apparatus and very good lungs. They stand erect and they have employment that compels them to do it. They have to breathe right and they have to clothe themselves right or not do the work required of them. Two young Swedish ladies came to my office for treatment. One wanted to know what was the matter with her side. I put my hand on the side of the chest and told her to take a long breath and her chest shoved up under her chin. She could not expand it around the base of the lungs one-half inch. Under the armpits above the breast she expanded three inches. I said: "That is the trouble with your side; take off your corset and you will breathe well." Let us give them employment that will make them breathe.

DR. H. E. GARRISON, Illinois—I believe I am the only woman doctor present. I have practiced for twenty years and I can ride and walk as readily with as without a corset. Mrs. J. S. Lane has a book upon the subject and if the gentlemen will read it they will know why we have worn corsets and will continue to wear them as long as we live.

## SURGERY OF THE KIDNEY.

BEING A STUDY OF A SERIES OF CASES IN WHICH METHODS OF DIAGNOSIS AND TREATMENT ARE ILLUSTRATED.

BY BAYARD HOLMES, B.S., M.D.

PROFESSOR OF PRINCIPLES OF SURGERY IN THE COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO.

### TUBERCULOSIS OF THE KIDNEY.

In this series of cases two appear to have been tubercular, although in neither case was an absolute diagnosis made before operation, and in the second case doubt still remains as to the real cause of the disease. In both cases, however, all the means of diagnosis known, except inoculation experiments, were made, and every step was guided by positive indications for treatment. In the first case, Mrs. S., nephrectomy was contraindicated by the desperate condition of the other kidney, determined by catheterizing the ureters. In the second case, Miss C., unusual

difficulties presented themselves and they were overcome, one by one. The treatment of this patient was most conservative and careful. The full report of these cases it is believed will be useful and suggestive.

*Case 1.—Synopsis: Sudden obstruction of right ureter three years ago; pyonephrosis; aspiration, drainage; occasional discharge of calculi through the wound; continued fever and chills with cystitis; catheterization of both ureters showing advanced disease of left kidney; removal of calculus and evidence; death in five months from uremia.*

Mrs. S., aged 34, mother of three children, consulted me in August, 1894, and gave the following history: Three years ago, and some years after the birth of her last child, she was taken with chills, fever and pain in the right side. The chills continued for three weeks, when a large tumor appeared in the right side. This tumor fluctuated and was aspirated repeatedly by the attending physician, and a large quantity of pus withdrawn. The puncture was at last enlarged and a tube inserted in the loin for permanent drainage. The temperature became normal and the patient gradually gained in health and strength, but she was continually troubled by the closing of the sinus and the recurrence of the chills. There was considerable irritation of the bladder and almost constant night sweats. Many small pieces of stone were discharged from the sinus, indicating the presence of other calculi. The patient was a thin, slight woman, of a nervous temperament and a quick, intelligent look, a bright, quick eye and expressive, nervous features. She had a well-formed thorax with no show of tubercular disease in either lung, no enlarged lymph glands in the neck or axillæ and no indication of general tuberculosis. The heart had a free, normal and regular pulsation which was rapid, 96, and violent. The apex was farther removed from the median line than is normal. The arteries were soft and flexible. The abdomen presented no abnormality except a tumor three inches in diameter in the right side, which was connected with a sinus opening through the skin halfway between the crest of the ilium and the border of the ribs. This tumor was painful on pressure and was evidently the enlarged displaced kidney. Examination of the urine showed a normal quantity containing from six to eight points of albumin measured by the Eshbach albuminometer, some casts and a large quantity of pus and mucus. Examination of the sediment for tubercle bacilli was made by me without result, though many other bacilli were found. In a vaginal and rectal examination the right ureter was found to be about 1 cm. in diameter, hard and painful to pressure. The left ureter was smaller and softer, but very easily recognized and somewhat sensitive. Still I hoped that the left kidney might be found sound and well. Although the patient's condition was not good, I determined to make an effort to remove the calculus from the right kidney and perhaps close the sinus, and at the same time make a positive diagnosis of the condition of the left kidney. With the assistance of Dr. George Nesbitt and Dr. Harry Wilder the patient was prepared and anesthetized with chloroform, the urethra was dilated and the ureteral sounds passed by touch into the two ureters. From the right ureter a thick pus a few drops at a time passed on pressure above the brim of the pelvis. From the left ureter an average quantity of turbid urine passed in intermittent jets of four or five drops, but the quantity was not measured. This urine contained considerable albumin and was very turbid. It

was immediately examined under the microscope. The quantity of pus and its character seemed to indicate an advanced condition of disease in the left kidney and contraindicated any extensive operation upon the remnant of the right kidney. The patient was again brought fully under the anesthetic and the sinus enlarged sufficiently to remove the calculus in the pelvis of the degenerated right kidney. This calculus was  $1\frac{1}{2}$  inches long and nearly 1 inch in diameter. The pelvis and ureter of the right kidney were carefully examined with the finger and no other stones were found. Nephrectomy seemed to be contraindicated by the condition of the remaining kidney; the granulation tissue, which was evidently tubercular, was therefore scraped away and the wound packed with iodoform gauze. The patient was put to bed in good condition and rallied promptly. The wound was dressed upon the fifth day and daily afterward by Dr. Nesbitt. The temperature, which had been about 100 degrees at night before the operation, gradually fell to normal, but the quantity of albumin in the urine increased for two weeks and then, with a milk and kumyss diet, it gradually fell to a mere trace. The wound healed slowly. The urine, however, began to be scanty three months after the operation, and the patient died in uremic convulsions two months later and five months after the operation. No postmortem was made.

In this case nephrectomy and ureterectomy would certainly have been made, in spite of the thickening of the left ureter, had not catheterization of the ureter demonstrated the advanced disease of the left kidney. Had this operation been done the danger to the patient's life would have been much greater, and the benefit to be expected no more than by the simpler procedure.

*Case 2.—Typhoid at 12 years followed by cystitis, bloody urine, pain in side, strangury; slow improvement; after ten years, drainage of the bladder for nine months with slight improvement; catheterization of the ureters demonstrates a healthy and competent right kidney and degenerated and suppurating left kidney; nephrectomy; partial ureterotomy; implantation of vesical end of ureter into the vagina; recovery.*

Miss C., aged 40, consulted me in December, 1895, for a pain which she constantly felt in her left side in the region of the left ovary, and for frequent painful urination and occasional attacks of chills and fever. She gave a family history of the best kind. Her ancestors were of healthy German stock and she was herself well until her eleventh or twelfth year, when she had a very severe attack of typhoid fever from which she made an imperfect recovery. Following typhoid fever there was painful and frequent micturition, which at last became so desperate that her clothes became offensive from ammoniacal urine, and it was impossible on this account for her to get any position to work. During this time there was great pain in the side which was relieved by lying down. Occasionally there would be a discharge of bloody urine and at all times, as appears from the history, a considerable quantity of pus at irregular intervals. The symptoms, however, somewhat subsided after two or three years, and the patient was able to go about in spite of frequent attacks of pain and painful urination. Many physicians were consulted without avail, and at last fourteen years ago the bladder was examined by Dr. E. C. Dudley, who made some operation upon it resulting in drainage of the bladder. This drainage was continued for nine months when

the opening was closed up and the patient had some relief. She frequently rose to urinate nevertheless as many as nineteen times in the night as she discovered by an ingenious method. Every time she rose she took a match from her match box, laid it on the table and counted the matches in the morning. About once in two or three months during the past ten years she had attacks of "pain in the side" of a very severe character. During these attacks there was a high temperature and rapid pulse. She used the thermometer and frequently found the temperature 105 degrees F. Vomiting often accompanied these attacks, and they usually passed off after two or three days with a discharge of urine containing half or two-thirds its bulk of pus. She could give accurate information upon this point from the fact that she collected the urine in a wide-mouthed bottle, and allowed it to stand long enough to see the amount of sediment. During the past five or six months the attacks have been more painful and more frequent than heretofore. They had appeared as often as once in three weeks.

When I first saw her she had just recovered from an attack of this kind. The specimen of urine which she gave me at the time had only a small sediment of pus, and contained only a small amount of albumin, there were no casts or other evidence of nephritis. The patient was large and covered with a thick layer of fat making examination difficult. The lungs were perfectly healthy, and the heart free from murmurs but enlarged considerably, so that the apex beat lay  $3\frac{1}{2}$  inches from the median line. The spleen and liver could not be palpated, and the area of hepatic dullness seemed to be less rather than more than normal. There was no tumor to be felt in the abdomen, but there was a region of very marked tenderness commencing at the edge of the left short ribs and extending downward into the left pelvis. The points of greatest tenderness seem to be at the upper and lower extremity of this line. The region of the bladder was also distinctly tender upon pressure. The vagina was found to be normal and very small, and the infantile uterus was found lying in its normal position and perfectly movable. In the pelvis there could be easily palpated a distinct tumor upon the left side which seemed to be quite hard, apparently cystic and excessively tender to pressure. The meatus urinarius was red and on pressure a small amount of pus could be forced out of the numerous folds of the mucous membrane. The patient's temperature at this time was normal and her pulse 72. There were 1200 c.c. of urine passed in 24 hours and this urine was alkaline and had a specific gravity of 1.011 and contained 28 grammes of urea; there was a considerable quantity of pus present but no casts. On February 15, the patient was put in the knee chest position, the urethra dilated, the bladder cocainized and inflated and the silver ureteral catheter successfully passed into the right ureter. She passed 6.5 c.c. of urine through this catheter in fifteen minutes. This urine contained absolutely no pus, no epithelium, no albumin and it registered 40 milligrams of urea to the c.c. It was of acid reaction but the quantity was not sufficient to allow me to take the specific gravity. It was not perfectly clear, but was slightly turbid with a sediment of amorphous urates and phosphates. At this time it was impossible to find the left ureter and the patient was so much exhausted that no farther examination was made. The bladder appeared perfectly normal except for a rather pale and anemic

patch where the left ureter would naturally be looked for. A day or two afterward a second attempt was made to find the left ureter but without avail. The right ureter was catheterized again with practically the same result. For nearly two weeks attempts were made on each succeeding day to find the left ureter, but no trace of it could be made out, although at each sitting the orifice of the right ureter was plainly visible. Search was made for an abnormally placed ureteral orifice in the urethra also. Various positions were tried and various methods of catheterization were equally unsuccessful.

Although a diagnosis of suppurative disease of the left ureter and kidney had been made it seemed necessary to make this diagnosis positive before so grave an operation as nephrotomy or nephrectomy should be undertaken. There was indubitable evidence of a painful tumor in the left side of the pelvis about where the ureter ought to be found, and this was also the location of occasional spasmodic pains accompanied by a desire to urinate. The possibility of a calculus in this portion of the ureter was kept in mind and on March 11 the patient was prepared for an anesthetic. On March 12 after a comfortable night, during which about three pints of distilled water had been taken by the mouth, and after the colon had been flushed with very hot water, the patient was anesthetized with chloroform and with the assistance of Dr. Fletcher, Dr. D. H. Galloway and Dr. Mary Bates the bladder opened along the line of the old sutures by an incision long enough to allow the finger to be passed into the bladder. The location of the right ureter could not be felt. The orifice of the left ureter was recognized by a hard mass in contact with the wall of the bladder and by the resistance of a line of scar tissue which extended about an inch upward from the normal location of the orifice of the left ureter to this hard mass. By means of a small probe passed into the bladder under the point of the finger the end of the scar was recognized as the contracted orifice of the ureter into which the probe passed with difficulty. The sound was withdrawn and a silver ureteral catheter passed in its place. Three ounces of a clear, watery fluid with a few shreds of pus then passed out the catheter with considerable force. Two ounces of this fluid were first secured for examination and then the region of the kidney and ureter was kneaded and one ounce of almost pure pus was forced out by manipulation. A long flexible ureteral catheter 2 mm. in diameter and fifty centimeters long was then passed in the place of the silver catheter and pressed forward until it was believed to be in the pelvis of the kidney and until it met a distinct resistance. Through this catheter three ounces of warm sterilized water was easily carried by gravity into the pelvis of the kidney and then allowed to run out. This was repeated several times. The catheter met with no obstruction in its course through the ureter. It was decided to leave this catheter in the ureter and wash out the kidney for a day or two, hoping in this way to save the kidney. This catheter and the irrigation produced no pain.

The patient was put to bed in good condition. The two ounces of fluid removed from the distended ureter at this operation contained a considerable amount of pus, a trace of albumin and some carbonates and less than one-seventh the amount of urea which normal urine contains. This pus was laboriously examined for tubercle bacilli by methods that

proved adequate with sputa, but none could be found. This examination seemed to me to indicate a nearly complete destruction of the left kidney. For the first time I had in my possession the information necessary to warrant the complete removal of this kidney and its ureter. During the succeeding week the patient's temperature never rose above 99.3 F. and her pulse varied between 82 and 96 as shown in the accompanying chart. (Fig. 1). She slept well. The kidney was washed three or four times a day with sterilized water or with a solution of permanganate of potash. During all this time a thick green pus poured out of the catheter at the rate of about one and one-half ounces per day but no urine escaped. After trying this irrigation for a week without any diminution in the amount of pus the catheter was carefully removed. The urine and the antiseptics which had been used had produced a hardening of the catheter so that it was no longer flexible but continued to keep the shape it had been in during the week. This made a very interesting cast of the ureter and showed that the kidney was displaced forward and that the ureter made quite a sharp turn about one and one-half inches from the end of the catheter

her respiration 24 per minute. Several small doses of calomel were given during the afternoon followed by castor oil and in the morning an enema. The patient was anesthetized with chloroform and an oblique incision was made below the margin of the last rib in the lumbar region and curved forward over the crest of the ilium and then downward. The muscles and fascia were divided down to the kidneys. The kidney was carefully separated from its surroundings by breaking up the adhesion and drawn up into the wound. During this manipulation the wall of the kidney was ruptured and a considerable amount of clear fluid apparently containing pus escaped into the wound. A clamp was placed upon the very small renal vessels and the kidney with the ureter attached was separated and drawn forward. The ureter was dissected out as low down into the pelvis as possible, where it was found about the size of the patient's middle finger, thin walled and at least 15 mm. in diameter. The ureter was grasped with forceps, cut off and its edges caught with catgut sutures and turned in and the raw edges brought together with sutures and tied. The end of the ureter was then dropt into the pelvis. The patient stood the operation very well but took the chloroform with some difficulty.

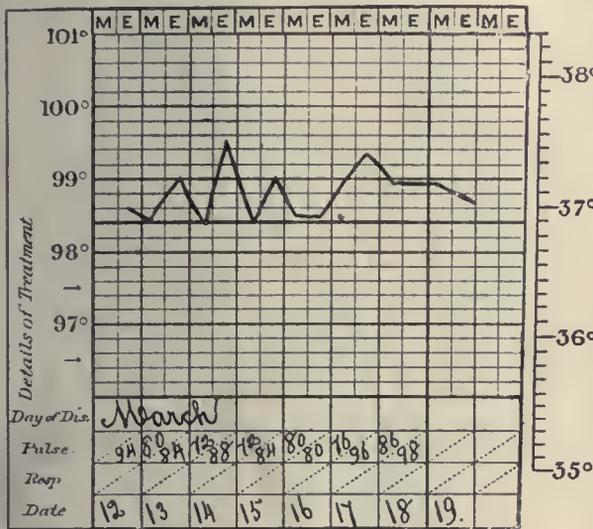

FIG. 1. Miss C.

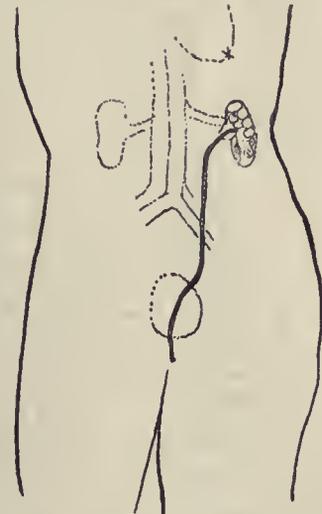

FIG. 2. Showing supposed position of catheter.

and that it maintained during the rest of its course to the bladder a rather broader excursion from the spine than is normal. A drawing of this catheter on a reduced scale with the supposed position of the kidney and bladder is given below. (Fig. 2). While in bed with the catheter in place an attempt was made to take a skyagraphic picture of the region of the kidney, hoping to demonstrate the presence or absence of a calculus, but this experiment was without result. The patient went home for a rest and was put on a full diet with one quart of milk and a quart or more of lithiated water each day.

On the first day of April the patient returned to my care in St. Luke's Hospital for the removal of the kidney. Examination at this time showed that 82 ounces, 2,624 cubic centimeters, of pale alkaline urine with a specific gravity of 1.004 and no albumin, no sugar and only a trace of pus and bladder epithelium, were passed in twenty-four hours. This urine contained 22.5 grams in twenty-four hours. The total solids for twenty-four hours was 44 grams.

Her temperature on the night before the operation was 98.8 degrees F. and her pulse 82 to 94 and

The temperature record during the succeeding four weeks is given in the accompanying chart. (Fig. 3). The wound healed up rapidly but there was a tender and painful spot in the pelvis which was supposed to be the end of the suppurating ureter and another operation was undertaken for the purpose of implanting it in the vagina if it was found impossible to remove it. This operation was done April 27. After the ordinary preparation the day before, the patient was anesthetized and an incision was made in the left cul-de-sac of the vagina and the finger pressed in. A catheter was again with great difficulty passed into the greatly contracted orifice of the left ureter and distinctly felt by the finger in the vault of the vagina. With the finger-nail and a dissecting forceps the ureter was loosened up as high as possible, but it was found to be impossible to remove the upper end of the ureter from its attachments. An artery forceps was passed into the opening in the vault of the vagina by the side of the finger until near the bladder it was felt to grasp the ureter with the ureteral sound in it. The sound was then removed, the artery forceps clamped and the ureter cut off on the bladder side of the

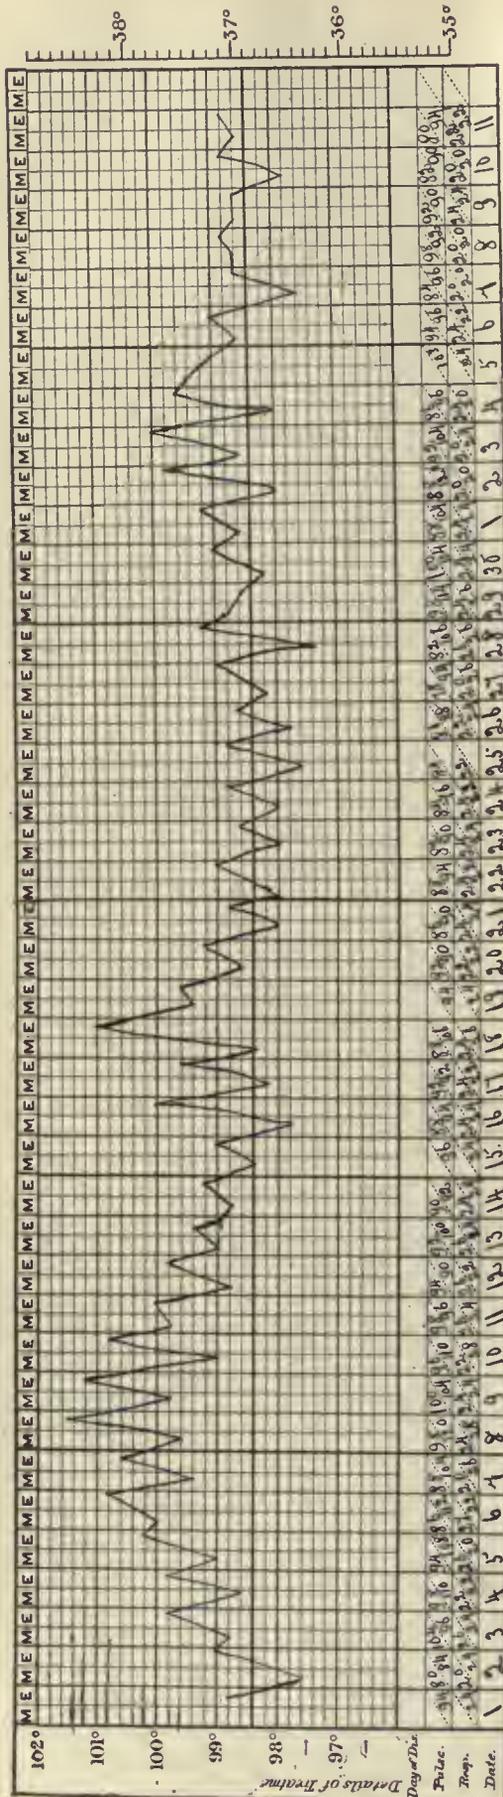

FIGURE 3.

forceps. By means of several sutures the end of the ureter was pulled down and fastened into the vagina. The contracted orifice of the left ureter in the bladder seemed to promise closure without any manipulation and it was let alone. The incision in the bladder through which the left ureter had been catheterized was then partially closed up and a catheter was left in the urethra for drainage.

The patient again suffered a great deal from the anesthetic, but otherwise did well. The temperature chart shows her condition after this operation as long as she remained in the hospital. The ureter remained firmly attached in the vagina and no urine passed from the bladder into the wound and there is every reason to believe that the left ureteral orifice in the bladder is closed up. The suture of the bladder, however, was not successful and it all opened in three or four days. After so many examinations and so much operative procedure the patient lost spirit and strength and she was sent home to recuperate. The urine has

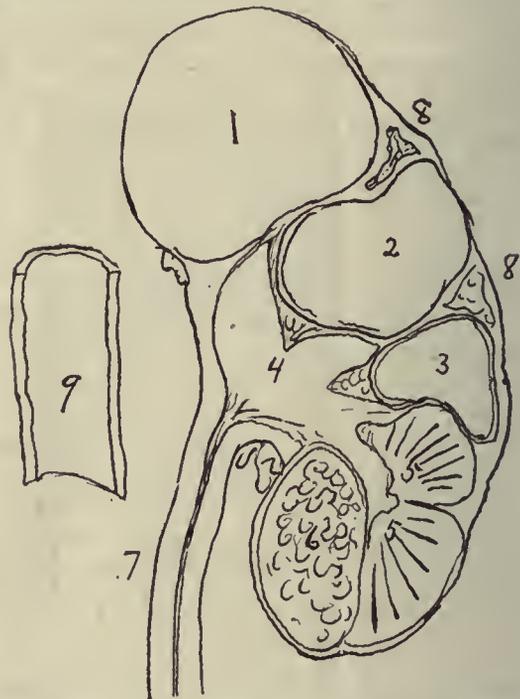

FIG. 4. Diagram of Kidney and Ureter. 1, 2, 3, Cysts not connected with ureter; 4, slightly dilated pelvis; 5, partially functioning remnant of kidney; 6, eucysted fatty degenerated material; 7, greatly thickened ureter; 8, massa of fat and connective tissue; 9, the relative size and thickness of dilated ureter.

been examined several times since the operation and it is entirely free from abnormal constituents.

The accompanying sketch (Fig. 4), gives a fair idea of the cystic condition of the kidney. The upper two-thirds of the kidney were entirely destroyed and the place of the normal elements of the kidney was filled with eight or ten cysts, some of them, at least, did not open into the pelvis of the kidney at all. One cyst contained a white cheesy substance which was insoluble in either cold or boiling hydrochloric acid or in dilute hydrochloric acid cold or boiling, or in cold or boiling nitro-hydrochloric acid, but turned yellow in the latter, or in cold or boiling water; or in cold or boiling alcohol; or in cold or boiling carbon disulphid. It was disintegrated and partly soluble in 5 per cent. solution of caustic potash. Its color was not changed by iodine. Under the microscope it was granular, but on pressure of the

cover glass it became homogenous like lard. Tubercle bacilli could not be found in the cyst contents. In the lower part of the kidney there was a mass of fatty degenerated substance and close to it, marked 5,5, two bits of functioning kidney substance. No valve formation could be demonstrated in the case of the single cyst which opened into the pelvis of the kidney and the other cysts were certainly entirely separated from the pelvis and from each other. The ureter as it left the pelvis of the kidney had a diameter of 1 centimeter and a caliber of less than 1 millimeter. Three inches lower down the walls of the ureter were 1 millimeter only in thickness and the diameter of the ureter was 13 millimeters. A segment of this ureter near the pelvis of the kidney is shown in (Fig. 5). In the section of the ureter, the plications of the mucosa occupy a little more than half the thickness of the tube. The mucous membrane is

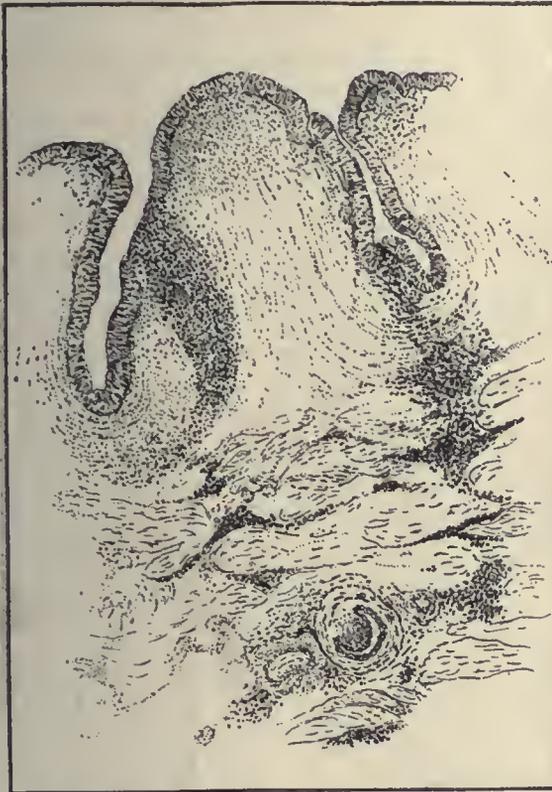

FIG. 5. Segment of the ureter an inch from the pelvis of the kidney drawn with the camera lucida and half-inch objective. This drawing shows two defects in the mucosa and adjacent inflammatory areas, reaching out beyond the muscular layer. Atheromatous arteries are also shown and lymph spaces filled with leucocytes.

intact for the most part and is covered by a regular layer of cylindrical epithelium overlaid by a fold of elastic connective tissue. This is surrounded by a double layer of muscular tissue in which are blood vessels and lymph channels. The pathology of this ureter seems to consist in increase in all the tissues beyond the cylindrical epithelium, in defects in the mucous membrane in places, and in masses of inflammatory tissue containing lymphoid cells which have infiltrated the muscular tissue outward from these defects in the mucosa. The active cells seem to penetrate between the bunches of muscle fibers and fill the intermuscular spaces. The blood vessels in places show advanced endarteritis and they are surrounded by inflammatory tissue, the cells of which take on a strong stain. Even outside of the outer layer of muscles are masses of leucocytes grouped about

defects or openings in the bundles of muscular tissue.

"Of the 63,000,000 persons living to-day in the United States 9,000,000 or more will die of tuberculosis. This would mean about 150,000 deaths from this disease each year." (Victor C. Vaughan). It is probable that one out of every sixty of the inhabitants of this country or of the world is in the process of dying of this disease. The number of persons actually infected is much greater. Probably one-half or three-fourths of the inhabitants of cities are tubercular. It is not a wonder therefore that renal tuberculosis is a common disease. Dickinson<sup>1</sup> gives the result of the examination of 600 consecutive post-mortems in two London hospitals, 300 were individuals over 12 years of age and 300 under 12 years of age; 180 of these individuals were tubercular, 126 under 12 and 54 over 12; 66 had renal tuberculosis, 49 under 12 and 17 over 12. In the young, males and females are attacked by renal tuberculosis with equal frequency. Among adults men are much more frequently attacked than women. Dickinson saw 44 cases in men and 23 women. Emil Palet<sup>2</sup> says that of 100 cases of renal tuberculosis studied by him only 16 proved to involve both kidneys, while in another series of 42 fatal cases operated upon, all were onesided except 12. Two thousand two hundred and thirty-one cases were treated in St. Thomas's Hospital<sup>3</sup> during the year ending Dec. 31, 1890, among which were the following:

Sarcoma of the kidney, 1; tubercular disease of the bladder, 2; hematuria, 4; pyuria, 2; renal calculus, 1; tubercular kidney, 1; pyonephrosis, 4; renal sinus (tubercular?) 1.

During the six months ending July 1, 1890, there were 3,860 patients treated in the Cook County Hospital,<sup>4</sup> among which were the following:

Perinephritic abscess, 1; movable kidney, nephrorrhaphy, 4; cirrhosis of kidney, 4; acute nephritis, 8; chronic nephritis, 34; pyelitis, 1.

During the six months ending December 31, 1890, 3,823 cases were treated, among which were the following:

Movable kidney, 3; perinephritic cellulitis, 3; rupture of the kidney, 4; cirrhosis of the kidney, 1; acute nephritis, 7; chronic nephritis, 56; pyonephrosis, 3; renal abscess, 1; renal colic, 1; tuberculosis of kidney, 1.

This disease begins as a metastatic focus in the kidney usually after an injury or at a time when the vital resistance is reduced by some intercurrent disease, or it arises from an extension upward of a tuberculosis from the epididymis or seminal vesicles through the prostate, bladder and ureter in the male, and from the urethra through bladder and ureter in the female. The greater number of cases are of renal origin. There may be some doubt of the secondary metastatic nature in some cases, but the frequency of a preceding injury, a preceding infectious disease and a latent tuberculosis elsewhere speaks strongly for the metastatic origin.

Much has been written of gonorrhoea and tuberculosis acquired at the same time. There is reason to look with some suspicion on these observations on account of the difficulty of distinguishing the tubercle bacillus from the smegma bacillus.

<sup>3</sup> Hadden and Anderson: St. Thomas Hospital Report, Vol. 20, 1892

The clinical history of these cases is illustrated in my cases and in those which every physician will revive from the memory of his own practice or from his reading. The beginning is insidious. There is usually a slight rise of temperature and some discomfort, sideache, backache, dragging or burning pains in the abdomen; but in other cases these symptoms are entirely wanting and the first symptoms are cystitis and pus in the urine. The diagnosis of renal tuberculosis presents the greatest difficulties and until very recently its absolute accomplishment has been declared by nearly all authors impossible in its early stages. Since the ureteral catheters of Pawlik and Casper have come into use an absolute diagnosis is certainly possible in many cases and in all cases the diseased condition of the tubercular organ can be detected and the healthy and competent condition of the opposite kidney can be established. This method is illustrated in my cases. On men it is necessary to use Casper's instrument.

The symptoms of renal tuberculosis are easily recognized, the fever, the pain, heaviness or tenderness, the cystitis, the pus in the urine and the granulating or inflamed condition of that portion of the bladder into which the ureter from the infected kidney opens.

FIG. 6. Renal vessels divided and ureter freed down to brim of the pelvis.

The urine should be allowed to settle and the sediment precipitated by the centrifugal machine. The precipitate should be examined for tubercle bacilli. They may be found and then may be overlooked. If they are found it must not be forgotten that some of the best observers have mistaken the smegma bacillus for the tubercle bacillus. Mendlesohn<sup>5</sup> lately demonstrated a kidney removed a few days previously from a patient with the following interesting history. She had noticed that there had been some pus in the urine for months. There was some pain but no tenderness. The urine was found full of pus, fatty acid crystals, red blood corpuscles and oxalate of lime crystals. The Casper cystoscope was used and the normal rhythmic flow of urine from the right ureter was observed, while from the left ureter there passed out a steady stream of thick greenish pus that settled down into the bottom of the bladder. The ureters were catheterized and the urine from the right ureter found to be normal, clear and abundant, while pus alone was secured from the left kidney. Tubercle bacilli could not be discovered in this pus though

they had been found in the urine before catheterization of the ureters. The diagnosis was, however, considered absolute, namely a tuberculosis of the left kidney with complete destruction of its function and a healthy and competent right kidney. The left kidney was extirpated and the kidney substance found almost completely destroyed. Two stones were found in the pelvis.

Professor Leyden in discussing this case called attention to the great difficulty of making a positive diagnosis of renal tuberculosis by examining the excretions from the kidney and finding the tubercle bacillus on account of the almost omnipresence of the smegma bacillus in pyelitis and the great similarity of this organism to that of tuberculosis. It is true there are differences; the smegma bacillus is more delicate and does not exhibit the granular divisions that the tubercle bacillus does, but the staining reactions are the same. Leyden thinks that the only reliable method of identifying the tubercle bacillus in such cases is by inoculation of animals. Senator and König agreed with Leyden.

Casper<sup>6</sup> gives an account of an interesting case illustrating the proper method of making an accurate and absolute diagnosis and as it brings out some new points it may be well to briefly abstract it here.

The patient was a woman 42 years old who had been well until six months before. At that time she took cold and had a catarrh of the bladder with painful urination and turbid urine. Then followed pain in the right side, with a sensation of tension. Irrigation of the bladder was tried without avail and at last through palpation some disease of the right kidney was diagnosed. When Casper first examined the patient he found her an undersized, delicate but apparently well-nourished and sound woman. She complained of pain in the abdomen, especially on the right side. The pain, she says, comes on with exercise and motion, and she is free from pain when resting in bed. Turning in bed, however, brings on the pain. Sometimes she is entirely free from pain whatever she does. She urinates oftener than formerly, during the day every three hours and two or three times at night.

The urine removed from the bladder with a catheter was slightly turbid, acid, specific gravity 1.018. It contained many pus corpuscles, some caudate epithelium, but neither red blood corpuscles nor casts. Albumin was present in considerable quantities. Tubercular bacilli were found in the sediment thrown down by the centrifugal machine. Palpation disclosed nothing abnormal. The kidneys could not be palpated. Neither the kidneys nor the region of the bladder were tender on pressure. The genital apparatus was apparently sound.

Casper's cystoscope was used to introduce 200 cubic centimeters of boracic acid solution into the bladder. This solution by irrigation quickly became clear and the surface of the bladder, except in the neighborhood of the right ureter, was seen to be perfectly smooth, whitish-yellow and glistening. Under the mucosa, the blood vessels could be seen as usual. In the locality where the right ureter ought to have been found, however, there was a granulating mass and the mouth of the ureter could not be seen. The mouth of the left ureter could be easily observed giving out every few seconds a spurt of clear urine. In the neighborhood of the granulation tumor around the

<sup>5</sup> Mendlesohn: Berlin klinische Wochenschrift, April 27, 1896.

<sup>6</sup> Casper, L.: Die frühe und exakte Diagnose der Tuberculose des Harntractus, Berlin, klinische Wochenschrift, April 27, 1896.

mouth of the right ureter occasional whirls of fluid could be seen as if the ureter was discharging there.

On the following day the left ureter was easily catheterized and a clear normal urine removed. The right ureter was also catheterized by manipulation, though the mouth of the ureter could not be seen. Turbid urine containing pus and albumin was withdrawn, but tubercle bacilli could not be found in this specimen. Three days later the right ureter was again catheterized and the urine found to contain tubercle bacilli and a larger proportion of urea than the bladder urine. A diagnosis of tuberculosis of the right kidney and circumscribed tuberculosis of the bladder was made. This patient was operated upon afterward and the right kidney removed. It was covered with tuber-

FIG. 7. Opening of vaginal vault to bring the extremity of ureter into vagina. The assistant's hand and scissors in vagina, operator's hand in lumbar wound after removal of kidney and abdominal portion of ureter.

cles and two cheesy foci were found in the parenchyma. The patient recovered and is well. The pain is gone and the urine clear.

When an absolute diagnosis of tuberculosis of one kidney has been made and when an equally positive demonstration of the healthy condition of the opposite kidney is at hand, then alone are the indications positive and absolute for the removal of the diseased kidney and ureter. This diagnosis may be tabulated as follows:

*a.* Tuberculosis of one kidney (absolute) secreting little or no urine.

*b.* Healthy condition of the other kidney secreting a normal amount of urine containing average amount of normal constituents.

*c.* Bladder only slightly involved near the ureter of sick kidney, patient otherwise in good condition.

Indications. Prompt removal of diseased kidney and ureter.

It may be asked on what data these indications depend; this study is of sufficient clinical interest to go into it more fully. The following questions will be asked and answered:

1. What is the course and duration of primary tuberculosis of one kidney if left to itself or treated medically?

Dickinson says all his cases terminated in death within four years after the onset of the disease. Belfield<sup>7</sup> says the disease always tends to a fatal termination; this end may, however, be delayed several years and cases are known in which the disease lasted ten, fifteen and seventeen years.

Tuberculosis elsewhere in the body is a progressive and destructive disease. It begins in the parenchyma of the kidney and advances through the ureter into

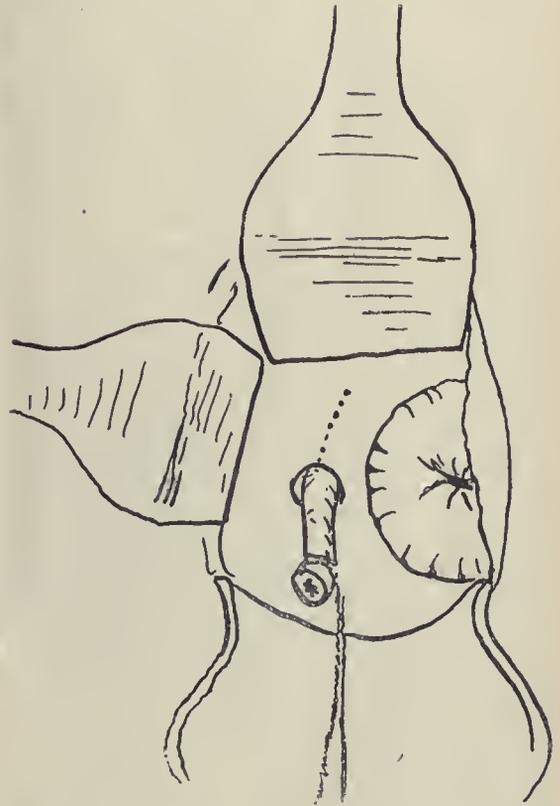

FIG. 8. Removal of the lower end of the ureter through the vagina distended with three retractors. The entire remnant of the ureter to be removed through incision in vault of vagina marked by dotted lines.

the bladder. Then it advances up the other side, but before this is accomplished the peri-renal tissues are invaded by the lymph channels, or the toxemia of secondary infection of the tubercular urinary tracts comes on together with temporary renal insufficiency and the exhaustion of cystitis.

2. What is the prognosis under nephrectomy? Very little statistic material is at hand. Palet (l. c.) records eight cases of death from general tuberculosis during the first six years after operation out of a total 136 cases operated upon, but the methods of diagnosis in those cases were imperfect as is shown by the fact that in seventeen cases nephrectomy was done with

<sup>7</sup> Belfield, W. T.: Diseases of the urinary and male sexual organs, N. Y., 1884, p. 254.

the other kidney so diseased that death from anuria followed immediately. In twelve of these seventeen cases the disease of the other kidney was tubercular.

There is an analogy which may be useful in this connection. The removal of local tubercular disease elsewhere in the body gives very good results. Tubercular foci in bones, tubercular lymph-glands and tubercular disease of the skin and mucous membranes can show a very large percentage of permanent recoveries after local mechanical removal.

Since there is only a small chance of life and that a very painful and miserable life, if the disease is let alone, and since the removal of the diseased kidney promises both theoretically and practically a great increase in the length of life and a greater improvement in its quality through relief from pain and the toxemia of secondary infection, *therefore in descending tuberculosis of one kidney with a competent kidney on the other side nephrectomy should be promptly performed.*

The 136 cases reported by Palet had so high a death rate that one would be slow to undertake the operation even on the above indications. When we come to analyze the deaths a different conclusion may be reached. Of the fifty-one deaths, seventeen died of anuria through disease and resulting incompetency of the other kidney. All of these cases could have been eliminated by the use of the ureteral catheters. Shock was the cause of death in eleven cases and usually in abdominal nephrectomy. The statistics are all against this method, which was used twenty-two times in Palet's series. In four cases death was due to unforeseen accidents, and in seven cases no postmortem was made.

In fifteen of Palet's cases fistula remained a long time, due, he thinks, to the tubercular stump of the ureter. On account of this unpleasant sequela and the danger which the tubercular stump might be, Howard Kelley's method of removing the ureter through the vagina should be used in all cases of nephrectomy for tuberculosis of the kidney in women.<sup>8</sup> This is done by following the ureter down with the fingers after tying of the renal vessels and bringing out the kidney. The stages of this operation are beautifully described and illustrated by Dr. Kelley. A reproduction of sketches of these pictures and a synopsis of one case will best give an idea of this exquisite procedure.

The patient was an unmarried woman, 23 years of age. As a child she began to complain of pain and weakness in the back, which compelled her at 9 years of age to remain in bed six weeks. She suffered from frequent urination, which was markedly worse after an attack of scarlet fever when she was six years old. For four years she has urinated so frequently that she could pass but a few drops at a time with great pain. A year ago she had an attack of spasmodic pain in the region of the left kidney, accompanied by vomiting and followed by pain in the bladder. These attacks have been frequent since, some time occurring as often as once a week. The attacks lasted from one to three hours.

Repeated examination of the urine showed it to be always acid, amber colored, containing albumin, pus, hyalin and granular casts, and had a specific gravity varying between 1.015 and 1.020. By vaginal palpation the left ureter was found transformed into a cord

three times the normal size. On the right side the ureter was not sensitive and not enlarged. The left kidney could not be palpated. The left ureteral orifice was found by cystoscopic examination deeply injected and surrounded by an area of granulation tissue two centimeters in diameter and extremely sensitive to touch and bleeding easily. The ureteral catheter was passed into the right ureter and normal urine obtained, but it was found impossible to catheterize the left ureter, either by sight or touch. No tubercle bacilli could be found.

In view of all these facts it was nevertheless decided to remove the kidney and ureter and that portion of the bladder that seemed to be infected with the tubercular disease. The operation was performed Dec. 18, 1895. The incision commenced just in front of the vertical muscles of the back at the costal margin and downward toward the middle of the ilium crest, and then in a gentle curve around the anterior spine and two centimeters from it and from this point in an oblique line downward to the lower terminus of the left semi-lunar line an inch above the symphysis pubis. The upper third of the wound was first made, the kidney detached, the renal vessels tied, the kidney removed and the ureter separated down to the pelvis. The lower portion of the incision was then made, the ureter freed with the fingers, the round ligament pushed aside, the uterine artery and veins ligated and divided, and the ureter clamped and tied two centimeters from the bladder. The kidney with ureter 23 centimeters long was then removed. The assistant then punctured the vault of the vagina and the lower end of the ureter was brought into the vagina as shown in Figs. 7 and 8. No ligatures were used except those on the renal vessels and the uterine artery and vein.

The pathologic examination demonstrated advanced tuberculosis of the kidney, but tubercle bacilli could not be demonstrated in the caseous material nor in the milky fluid in which it was suspended. The healthier portions were filled with many small white tubercles. The upper portion of the ureter showed a slight infiltration with leucocytes near slight defects in the mucous membrane.

There are reasons enough to make the following summary:

1. Tuberculosis of the kidney is a relatively common disease.
2. It usually begins in the kidney itself, descends through the ureter to the bladder and ascends to the opposite kidney.
3. It is, therefore, for a long time a unilateral disease.
4. It is a progressive and destructive disease not subject to improvement through medication, offering an unfavorable prognosis as to life and comfort and subject to extension downward by the urinary tract and outward through the peri-renal lymphatics.
5. Diagnosis can be made through the symptoms of cystitis, with a low temperature, rapid pulse, dilatation of the heart, the detection of tubercle bacilli in the urine, tuberculosis of the bladder about the orifice of the ureter of the diseased kidney, pus or blood with tubercle bacilli and diminished normal constituents in the urine from the diseased kidney; normal urine in increased quantity from opposite kidney; sometimes tenderness, pain and tumor *in situ* of diseased kidney and ureter.
6. The indications in case of an absolute diagnosis of tuberculosis of one kidney and healthy opposite

<sup>8</sup> Kelley, H. A.: Nephro-ureterectomy, extirpation of the kidney and ureter simultaneously. Johns Hopkins Hospital Bulletin, 1890, p. 31.

kidney are immediate removal of the diseased kidney and its ureter; in case of disease in both kidneys, no operation should be performed.

7. The competency of the healthy kidney should be proved by repeated catheterization of the ureters before nephrectomy and the removal of all toxic elements from the blood should be secured by a liquid diet, irrigation of the colon and hydration of the whole system for some days before the removal of the kidney.

8. Lumbar, extraperitoneal nephrectomy is the safer operation.

9. In women the removal of the ureter should be completed through the vagina.

10. Any remaining tuberculosis of the bladder should be treated locally by curetting or cauterization.

11. Catheterization of the ureter is not a dangerous procedure and it may easily be accomplished in women with the simple cystoscope of Simon, Pawlik or Kelley, and in men with the more complicated instrument of Casper.

### A FEW REMARKS ON THE PATHOLOGY OF SYNOVITIS HYPERPLASTICA GRANULOSA OF THE SHOULDER JOINT.

BY E. J. SENN, M.D.

Instructor in Surgery and Assistant to the chair of Practice of  
Surgery, Rush Medical College.  
CHICAGO.

Tuberculosis, which has such great predilection for bones and joints, appears to prove the rule by its exception as regards the shoulder joint. Its comparative infrequency is shown from the fact that in the surgical clinic of Göttingen from the years 1875 to 1891, there were only sixty instances of shoulder joint tuberculosis; while during the period from 1875 to 1882 there were 174 cases of tuberculosis of the knee. In the great majority of cases of tuberculosis of the shoulder joint, caries sicca, that peculiar manifestation of this disease which was first so accurately described by Volkmann, is almost invariably found. Caries sicca is a very mild form of tuberculosis, consisting of molecular decay with a consequent cicatrization, and very frequently terminating in a spontaneous recovery. Synovitis hyperplastica granulosa was called by Billroth fungous synovitis. The tuberculous nature of this affection was determined by Köster in 1869. While it is very frequently found in the knee joint, and is characterized externally by the white spindle-shaped swelling, the well-known tumor albus of the old authors; on the other hand, it is extremely rare in the shoulder joint. The shoulder joint is a peculiarly constructed joint. It differs from the other enarthrodial joints in that it has numerous bursæ, which may communicate with the joint proper, or if the communication is not complete, they form points of least resistance for the dissemination of disease, the three most important of which are the bursa synovialis subscapularis, bursa synovialis intertubercularis and the subacromial bursa. The capsular ligament is of considerable laxity and admits of great distension. It is composed of closely interwoven fibers, and is fixed to the scapula above by being attached to the margin of the glenoid cavity and the root of the coracoid process. Posteriorly it is attached to the rough surface of the glenoid process. Below the glenoid fossa, the capsule blends with the origin of the long head of the triceps. Below it is fixed to the anatomic neck of the humerus. The

capsule is strengthened materially by the tendons of the shoulder muscles which pass over the capsule from the dorsal and ventral surfaces of the scapula, and are inserted into the tuberosities of the humerus. With a brief review of the anatomy of the region, it is more comprehensible to understand the emigration of the tubercle bacillus into surrounding structures. Fungous synovitis of this joint is found in adult life, as a rule. The primary focus may be in the epiphyseal line of the head of the humerus, and secondarily cause a synovitis fungosa of the joint cavity and its adnexa. Osteal tuberculosis of this joint is almost without exception found in early life, when the embryonic tissues of the epiphyseal line are undergoing great transformation. The blood vessels are then immature and favor localization of the specific microbe; but even if the primary focus be of osteal origin, fun-

gous synovitis following is the exception, as osteal tuberculosis of this joint is very prone to be of the caries sicca type. On the other hand, synovial tuberculosis irrespective of location manifests itself during adult life, and synovitis hyperplastica granulosa of the shoulder joint is no exception. The primary focus is in the innermost layer of the capsular ligament or of one of the bursæ. The disease is inaugurated by a slight hydrops, due to a pathologic secretion by reason of microbial irritation. This catarrhal stage does not last long before here and there the continuity of the membrane becomes studded with minute tubercles, the catarrhal synovitis now having merged into a synovitis hyperplastica, s. pannosa. The membrane becomes very thick and hyperemic, and in due course of time the minute tubercles undergo casca-

tion. If this pathologic process is not interfered with, the endothelial cells assume great proliferative power, and as a result the capsule becomes filled with tubercular granulations; the evolution from a catarrhal synovitis into the pannus type, and lastly into the synovitis hyperplastica granulosa. The granulation masses do not only extend into the joint cavity itself, but also infiltrate into the subsynovial layer; especially is this the case where the subsynovial fat is abundant. The para-capsular tissues become edematous. If any of the bursæ have direct communication with the joint there is immediate extension of the disease, while if there are delicate septa intervening, they give away to the pathologic pressure. As a consequence, the whole shoulder region becomes immensely swollen, the normal contour being entirely lost. If the sub-acromial bursa is concerned, the prominences of the acromion and coracoid can be elicited only with great difficulty. The consistency of the swelling is variable. It may be quite tense, reminding one of the tumor albus of the knee joint; or it may be fluctuating, manual palpation giving the hand the sense of a cavity containing fluid. This is not true fluctuation, but pseudo fluctuation caused by intra- and extra-capsular granulation masses. Upon exploratory puncture with a trocar, there can be forced out of the canula a few granulations, fibrin and detritus intermingled with synovial fluid, if a portion of the synovial membrane remains intact. Akido-peirastic gives information as regards the density of the swelling. The supra-clavicular and axillary glands in the course of time become hyperplastic. There is often great pain in the region of the brachial plexus due either to a neuritis or pressure. The swelling in this region should not be confounded with sarcoma of the epiphysis of the humerus, a very rare disease indeed. Here the capsule is also filled with effusion. After the capsular ligament and the bursæ become destroyed, the cartilages and even the bone itself become implicated.

The case illustrated is a patient who was in my care a few months ago. It is typical of this disease and is especially interesting in that both shoulders were affected. The swelling and edema were enormous on the right side, the disease being in its incipency on the left. The principal bursæ were involved, also the para-articular structures, especially those posterior to the joint.

## ANTISTREPTOCOCCUS SERUM IN THE TREATMENT OF CONSUMPTION.

BY W. H. WEAVER, M.D.

CHICAGO.

For the past decade and more the tubercle bacillus has been studied and discussed to such an extent that the presence and activity of other germs as factors in the pathologic processes occurring in consumption were entirely disregarded. That the tubercle bacillus is present and determines the general character of the disease by initiating the inflammatory action is admitted. Tuberculosis of itself is not a suppurative process, hence the appearance of pus in the sputum must be considered as the beginning of a secondary infection which is more rapidly destructive. I believe that a simple tuberculosis of the lung is a mild disease and easily cured if proper antiseptic and hygienic measures are pursued. But it is seldom that a case of simple tubercular phthisis in the earlier stage comes

to the physician. It is only after the complications begin that the patient feels sick enough to consult his medical adviser. It is a question just when the streptococcus complication occurs in any particular case; but with the onset of fever and purulent expectoration may be found the streptococcus in the sputum. Dr. Prudden last year showed that the rapid inflammatory symptoms with cavity formation were due to the pyogenic action of the streptococcus. These destructive processes are slow or rapid according to the activity of these pyogenic germs. This germ activity must be checked and if possible abolished if the physician is of any assistance to his patient.

When the streptococcus infection accompanies the tubercular process from the beginning with high temperature and active germ life the invasion and destruction of lung tissue is rapid, and the case is one of rapid phthisis. Just why this germ activity is greater in one case than another, is a matter for future determination.
