IN'VERCAR'GILL. The capital of the County of Southland, South Island, New Zealand, on an estuary called the New River Harbour, 17 miles from its port at the Bluff (Map: New Zealand, South I., B 7). New River Harbour at the town takes vessels drawing 10 feet. The Bluff has a good harbor, with wharfage for vessels of any tonnage, and is a port of call for the Melbourne and New Zealand mail steamers. The Bluff is 150 miles southwest of Dunedin, with which it is connected by rail. Its industries include numerous woolen mills, saw mills, flour mills, breweries, and meat-refrigerating establishments. It is the centre of a large agricultural and cattle-raising country, and a large export trade has grown up in wool, timber, and grain. The town is well built on a rectangular plan, has government buildings and a hospital. It is lighted by gas and has street tramways. The first settlement of Invercargill was begun in 1857. Pop., 1901, 9950; 1911, 12,782, (with suburbs) 15,858.

INVERLOCHY, In'vēr-lōk'ē. A castle in Inverness-shire, near which, on Feb. 2, 1645, an army of about 2000 under Sir Duncan Campbell was routed and for the most part cut to pieces by an army numbering scarcely 1500 under the Marquis of Montrose (q.v.). The castle is now in ruins. Consult Gardiner, *History of the Great Civil War*, vol. ii (London, 1886-91). See GRAHAM, JAMES.

IN'VERNESS'. A town in Inverness Co., Cape Breton Island, Nova Scotia, Canada, situated on Big River and on the line of the Inverness Railway and Coal Company, about 150 miles by rail from Sydney and 61 miles by rail from Point Tupper. The colliery of the Inverness Railway and Coal Company is situated here. Copper, gypsum, and fire clay are found in the vicinity. Pop., 1911, 2719.

INVERNESS. A royal, parliamentary, and municipal burgh and seaport, the county town of Inverness-shire, Scotland, on both banks of the Ness, near its embouchure in the Moray Firth, 118 miles north of Perth. The Caledonian Canal empties into the Ness at Inverness (Map: Scotland, D 2). The town, picturesquely surrounded by wooded hills, has handsome wide streets and many beautiful residences. Its principal buildings are St. Andrews Episcopal Cathedral, the county hall, public library, observatory, infirmary, lunatic asylum, and Royal Academy. Other features are the fountain, containing the famous blach-na-cudain, long regarded as the town palladium; the suspension bridge, and the Islands promenade. It has a high school, a school of science and art, and an institute for the blind. There are iron foundries, shipbuilding yards, woolen manufactures, dis-

tilleries, tanneries, soap and candle factories, nurseries, saw mills, granite works, railway shops, breweries, and thread-making and bleaching works. The harbor, docks, and roads afford good accommodations, and a considerable trade is carried on. The town owns its own gas works. Inverness is of great antiquity, having been one of the Pictish capitals. William the Lion gave it four charters and made it a royal burgh. In 1411 it was burned by Donald of the Isles. The old castle where Macbeth murdered Duncan was razed by Malcolm Canmore, who replaced it by another which was destroyed by Prince Charles Stuart in 1746. The remains exist at the north of the town of the citadel which was built by Cromwell in 1652, and which was demolished at the Restoration. Pop., 1901, 23,075; 1911, 22,216. Consult: Mackintosh, *Invernessiana* (Inverness, 1875); Anderson, *Inverness before Railways* (ib., 1885); Grant, *The Commissariat Record of Inverness* (Edinburgh, 1897).

INVERNESS-SHIRE. The largest county of Scotland, in the northwest division (Map: Scotland, D 2). It includes several of the western islands, viz., Skye, Harris, North and South Uist, Barra, etc., and is bounded east by the counties of Aberdeen, Banff, Elgin, and Nairn; south by Perth and Argyllshire; west by the Atlantic Ocean; and north by Ross-shire and Cromarty. Area, 4211 square miles, most of which, except the valley of the Ness, is barren heath. The county consists chiefly of deer forests, which are rented as hunting ranges. It has valuable coast fisheries. Inverness, the county seat, is the only town. Pop., 1901, 90,104; 1911, 87,270. Consult J. C. Lees, *History of the County of Inverness* (Edinburgh, 1897), and *Records*, edited by Mackay and Boyd, vol. i (Aberdeen, 1911).

INVERSION (Lat. *inversio*, from *invertere*, to turn about, from *in*, in + *vertere*, to turn). In music this term is applied to intervals, chords, and phrases or passages. An interval is said to be inverted where the position of its two notes is reversed by transposing one of them an octave higher or lower. The inversion changes the name and to some extent the character of the interval. The name or number of an inverted interval will be found by subtracting its original number from nine. Thus, a unison inverted becomes an octave, a second becomes a seventh, a third becomes a sixth, and so on, as shown in the following table of inversions:

By inversion major intervals become minor, and minor become major; diminished intervals become augmented, and augmented become diminished. But the two perfect intervals of the fourth and the fifth remain perfect when inverted. In these examples the transposed note is placed an octave higher, but naturally the same result is arrived at by transposing it downward, as will be seen by reading the table backward. For inversion of chords, see **HARMONY, Chords**. For inversion of phrases or passages, see **COUNTERPOINT**.

INVERSION, IN MATHEMATICS. See **CIRCLE**.

INVERTASE (from *invert*). One of the enzymes (see **ENZYME**) which acts upon certain sugars, especially upon cane sugar (saccharose),

which it hydrolyzes, forming grape sugar (glucose) and fruit sugar (fructose). Invertase acts most rapidly at 50° to 60° C. in a slightly acid medium. It can break up practically unlimited quantities of the sugar without being itself materially diminished. Invertase occurs in many fungi and in some bacteria; more recently it has been found widely distributed in the seed plants, in whose nutritive work it plays an important part, because cane sugar is probably one of the most widely distributed foods in the higher plants. Invertase is secreted abundantly by yeast, and without it yeast is unable to ferment cane sugar. After inversion of cane sugar the products are broken up by the enzyme zymase (q.v.). See **ENZYME; FERMENTATION**.

INVER'TEBRA'TA (Neo-Lat. nom. pl., from Lat. *in-*, not + *vertebratus*, vertebrate, from *vertebra*, joint, from *vertere*, Skt. *vart*, OChurch Slav. *vrūtēti*, to turn, Goth. *wairþan*, AS. *weorþan*, OHG. *werdan*, Ger. *werden*, to become). Animals which do not have a vertebral column or spine. The term is used in contrast with *Vertebrata* (q.v.), or animals with a backbone. One group, then, is formed on positive and the other on negative characters. Before the anatomical structure and the embryological development of animals was very generally worked out, the barrier between invertebrates and vertebrates was supposed to be absolute; but with the refinement of anatomical and embryological methods of study, brought about in a great measure by the use of the microscope, the hiatus between them is nearly bridged over. Ascidians are now considered to be degenerate ancestors of vertebrates; some of the nemertean and chætopod worms approach vertebrates in certain characters, and *Balanoglossus* and *Cephalodiscus* (q.v.) are frequently called hemichordata (see **ADELOCHORDA**), because they are so near the boundary line between vertebrates and invertebrates that they can be said to be only half vertebrates. And not only has this barrier been broken down, but, with our increased knowledge, the absolute independence and isolation of many different groups of invertebrate animals which the earlier systematists believed to exist must be abandoned. The foundation of the zoölogy of these animals, as there defined, was laid by Lamarck (q.v.) in a monumental work, *Système des animaux sans vertèbres*, published in Paris in 1801; followed in 1815-22 by his *Histoire naturelle des animaux sans vertèbres*.

INVESTITURE (Lat. *investitura*, from *in-*

vestire, to invest, from *in*, in + *vestire*, to clothe, from *vestis*, garment; connected with Gk. *ἐνδύειν*, *hennynai*, Skt. *vas*, Goth. *wasjan*, OHG., AS. *werian*, Eng. *wear*). In feudal and ecclesiastical history, the act of giving corporal possession of a manor, office, or benefice, accompanied by a certain ceremonial, such as the delivery of a branch, a banner, or an instrument of office, more or less designed to signify the power or authority which it was supposed to convey. The chief interest is in ecclesiastical investitures, and the contest which arose concerning them is so interwoven with the whole course of mediæval history that a brief account of its nature and origin is indispensable to a right understanding of many of the most important events of that period. The system of feudal tenure had become so universal that it affected even the land held by ecclesiastics, and attached to most of the higher ecclesiastical dignities, monastic as well as secular. Accordingly ecclesiastics who, in virtue of the ecclesiastical office which they held, came into possession of the lands attached to such offices, were regarded as becoming by the very fact feudatory to the suzerain of these lands; and, as a not unnatural result, the suzerains thought themselves entitled to claim, in reference to these personages, the same rights which they enjoyed over the other feudatories of their domains. Among these rights was that of granting solemn investiture. In the case of bishops, abbots, and other Church dignitaries, the form of investiture consisted in the delivery of a pastoral staff or crosier, and the placing of a ring upon the finger; and as these badges of office were emblematic—the one of spiritual care of souls, the other of the espousals, as it were, between the pastor and his church or monastery—the possession of this right by the lay princes, which they had held since the time of Charles the Great, became in the latter part of the eleventh century a source of disquietude to the Church. On the part of the suzerains it was maintained that they did not claim to grant by this rite the spiritual powers of the office, their functions being solely to grant possession of its temporalities, and of the rank thereto annexed. But the Church party urged that the ceremonial involved the granting of spiritual powers; insomuch that, in order to prevent the clergy from electing to a see when vacant, it was the practice of the emperors to take possession of the crosier and ring until it should be their own pleasure to grant investiture to their favorites. The investiture strife was complicated by the rebellions of the nobles in Germany; by the strife between rival parties in the Lombard cities; by the conflict of parties in Rome; and specifically by the question of the property of Countess Matilda of Tuscany. (See MATILDA; GERMANY; HENRY IV.) The disfavor in which the practice of investiture was held by the clergy found its most energetic expression in the person of Pope Gregory VII, who, having in the year 1074 enacted most stringent measures for the repression of simony, proceeded in 1075 to condemn, under excommunication, the practice of lay investitures, as almost necessarily connected with simony or leading to it. This prohibition, however, only regarded investiture in the objectionable form in which it was then practiced, or investiture of whatever form, when the office had been obtained simoniacally. But other members of the clergy went much further, and a pope of the same century, Urban II

(1095), absolutely and entirely forbade, not alone lay investiture, but the taking of an oath of fealty to a lay suzerain by an ecclesiastic, even though holding lands of him by the ordinary feudal tenure. The contest lasted from 1075 to 1122. In the beginning of the twelfth century it assumed a new form, when Pope Paschal II actually agreed, in 1111, to surrender all the possessions with which the Church had been endowed, and which alone formed the pretext of the claim to investiture on the part of the Emperor, on condition that the Emperor Henry V give up that claim to investiture. This, however, never had any practical effect; but, the other subjects of contention being removed, the contest was finally adjusted by the celebrated Concordat of Worms in 1122, by the terms of which the Emperor agreed to give up the form of investiture with the ring and pastoral staff, to grant to the clergy the right of free elections, and to restore all the possessions of the Church of Rome which had been seized either by himself or by his father; while the Pope, on his part, consented that the election should be held in the presence of the Emperor or his representative; that investiture might be given by the Emperor, but only *by the touch of the sceptre*; and that the bishops and other Church dignitaries should faithfully discharge all the feudal duties which belonged to their fief.

For the investiture troubles in Germany, consult Mirbt, *Die Publizistik im Zeitalter Gregors VII.* (Leipzig, 1894); in England, Böhmer, *Kirche und Staat in England und in der Normandie im XI. und XII. Jahrhundert* (ib., 1899); for those in France, Ibach, *Der Kampf zwischen Papsttum und Königtum von Gregor VII. bis Calixtus II.* (Frankfort, 1884), and Imbart de la Tour, *Les élections épiscopales dans l'église de France du IXème au XIIème siècle* (Paris, 1891).

INVINCIBLE ARMA'DA. See ARMADA.

INVINCIBLE DOCTOR, THE (Lat. *Invincibilis Doctor*). A name given to the English theologian William of Occam, on account of his logical methods of argument.

INVINCIBLES (Lat. *invincibilis*, unconquerable, from *in-*, not + *vincibilis*, conquerable, from *vincere*, to conquer). Members of a secret Irish society composed of some of the most desperate spirits of the Fenian association. Each member was acquainted by name with but two others—the one who nominated him to membership and the one whom he in turn nominated. The chief was a mysterious person known simply as No. 1. The object of the society was the assassination of officials, and to its members was charged the murder of Lord Frederick Cavendish, the newly appointed Irish Secretary, and T. H. Burke, the Undersecretary, in Phoenix Park, Dublin, on May 6, 1882. Consult *Annual Register* (London, 1883, 1890). See FENIAN SOCIETY.

INVIOLABILITY (Lat. *inviolabilitas*, from *inviolabilis*, inviolable, from *in-*, not + *violabilis*, violable, from *violare*, to violate, from *vis*, Gk. *ἰς*, *is*, strength, violence). In international law, the freedom or immunity which attaches to a greater or less degree to the public vessels and their crews and to the diplomatic agents of one country when within the territory of another state, and also in a very limited degree to merchant vessels in foreign waters. This immunity is extended upon the fiction of exterritoriality (q.v.). With respect to public vessels it does not allow the granting of asylum (q.v.) to

criminals or fugitive slaves, but custom seems to have established the right of such vessels to grant hospitality to political refugees who without invitation come to them and ask for protection. This grant of asylum does not give the right to the foreign state to demand the surrender of the political refugee nor to expel the ship from its waters. When the commander of the vessel harbors a criminal, resort must be had to a diplomatic appeal; invasion of the ship is not allowed. Should the vessel, however, be made the headquarters of treason, or aid or assist in insurrection or disorders against the state, such measures as are necessary for self-protection may, of course, be taken. Merchant ships have but a slight degree of inviolability, such as that which permits them to regulate their internal discipline by their home laws, certain restrictions on the right of search, etc.

From the earliest times envoys or others sent on diplomatic errands from one state to another have been held sacred or inviolate in their persons during their stay. While this has been the general rule, the modern uniform observance of such immunity, as it now exists among civilized nations, is a late development. Formerly it was neither so extensive, nor was it free from frequent violation.

Inviolability attaches at once upon the entrance of the envoy or minister and extends during his entire residence. While it exists it protects him, his residence and movables, and his suite from the local jurisdiction, civil and criminal. His civil immunity may be waived only by his waiver at the time of his reception, or by his voluntary submission to the jurisdiction of the foreign courts with his sovereign's consent. The residence of the envoy or minister is entitled to absolute immunity from the execution of compulsory process and from all forcible intrusion. He cannot harbor criminals not of his suite, as was the common practice in the Middle Ages; but in barbarous countries and in the South American countries it is customary for asylum to be given to political refugees, although this custom depends rather upon the superior force of the nation represented by the minister than on any general policy of international law. The criminal immunity of a foreign diplomatic agent is suspended only in extreme cases, as when he is party to or aids in plotting or conspiracy against the government to which he is accredited, in which case he compels its authorities to arrest him in self-defense. In ordinary cases of violation of the criminal law his recall is demanded. Consult Hershey, *The Essentials of International Public Law* (New York, 1912), and the authorities noted under INTERNATIONAL LAW.

INVIS'IBLE EMPIRE. See KU-KLUX KLAN, THE.

IN'VOCA'TION OF SAINTS. See SAINTS.

IN'VOICE (probably from Fr. *envoi*, pl. *envoi*, OF. *envoy*, conveyance, a sending, from *envoyer*, OF. *envoyer*, *envoier*, to send, from Lat. *in*, *in* + *via*, way). A bill of parcels; a statement in detail of the nature, quantity, and price of certain articles. Although the term is used most frequently in connection with sales of goods, an invoice often accompanies a bailment, as when it is sent to a consignee by a shipper of goods, who has retained title in them by the bill of lading (q.v.). In such cases its function is

to inform the consignee that the goods invoiced have been shipped to him and may become his upon payment of the prices named in accordance with the conditions named in or accompanying the bill of lading. An invoice is not a document of title, and its possession does not indicate that the holder is the owner of the goods therein described. Nor is it a written contract of sale. It is a mere memorandum, always susceptible of explanation by parol evidence. It may, however, be a sufficient memorandum under the statute of frauds (see FRAUDS, STATUTE OF) if it contains all the material terms of the oral sale contract and is signed by the party to be charged. Invoices of imported goods are required by the tariff regulations of some countries to be verified before one of their consuls or to be vouched for by him. Consult the authorities referred to under SALE; BAILMENT.

IN'VOLU'CRE (Lat. *involutum*, wrapper, from *involvere*, to wrap, from *in*, *in* + *volvere*, to roll; connected with Goth. *walwjan*, AS. *wealwian*, Eng. *wallow*). As a rule, each flower in a cluster (inflorescence) is subtended by a bract. In case the flowers or their pedicels are close together, the bracts are thrown into a rosette, which is called an involucre. Such inflorescences as the umbel of Umbelliferae and the head of Compositae have very characteristic involucre. See INFLORESCENCE.

IN'VOLU'TION AND EV'OLU'TION. In mathematics, the raising to powers and the extraction of roots respectively. The result of taking a number twice as a factor is called the square of the number; the result of taking it three times as a factor, its cube; four times, its fourth power, and so on; e.g., $3 \cdot 3 = 3^2$, or 9 is the square of 3; $3 \cdot 3 \cdot 3 = 3^3$, or 27 is the cube of 3; $a \cdot a \cdot a \cdot a = a^4$ is the fourth power of a . This process is called involution. Evolution is the inverse of involution, or it is the process which undoes involution. The square root of a number is one of the two equal factors of the number, the cube root one of the three equal factors, and so on; e.g., the square root of 16 is either 4 or -4 , since $4 \cdot 4 = 16$ and $-4 \cdot -4 = 16$; the cube root of 27 is either 3 or -3 ($-\frac{1}{2} \pm \frac{1}{2} \sqrt{-3}$), since each of these cubed equals 27. The n th root of a perfect n th power is one of the n equal factors of that power. A number which is not a perfect n th power has not n equal factors. It is, however, said to have an n th root to any required degree of approximation. Thus the n th root of m to 0.1 is that number of tenths whose n th power differs from m by less than the n th power of any other number of tenths. The n th root of a is indicated by either $\sqrt[n]{a}$ or $a^{\frac{1}{n}}$. In the case of square root the index of the root is not written in connection with the radical sign; thus, we write $\sqrt{5}$ and not $\sqrt{2}5$.

When the number whose root is sought is a perfect power, the process of factoring is one of the most practical methods except the use of tables. In the case of numbers which are not perfect powers, and of certain algebraic expressions, the binomial formula is usually employed where tables are not available. Thus $a^2 + 2ab + b^2$, the square of $a + b$, may be applied to extracting the square root of a number or of an algebraic expression, since the root can always be expressed as a binomial whose square the power contains. The older methods of square

and cube root, depending upon the sections of a square and of a cube, were inferior, since they could not be extended to higher roots. The binomial formula is, however, of general application and may be extended so as to extract the n th root. The detail of these processes can best be obtained from textbooks. Practically to obtain the square or cube root of a number, reference is usually made to tables of roots or of logarithms, and therefore the subject is taught in the schools less frequently than it was at one time. See LOGARITHM.

In geometry two collinear ranges, three points each, are said to form an involution when the anharmonic ratios (q.v.) of any four, not two pairs of *conjugate* points, is equal to the anharmonic ratio of their four conjugates. Thus, in the figure

A, B, C, C', B', A' form an involution, A, B, C being conjugate to A', B', C' if $(A B C B') = (A' B' C' B)$. This form of involution is due to Desargues (1639). Involutions of higher degrees have been developed by Poncelet (1843) and Möbius (1855).

IO, ἰὼ (Lat., from Gk. Ἰώ). In Greek legend, the daughter of Inachus, King of Argos, and first priestess of Hera at Argos. She was loved by Zeus, who, on account of Hera's suspicions, changed her into a white cow. Hera, having obtained of him the cow as a present, set the hundred-eyed Argus to watch her (according to Æschylus, *Supplikes*, 299, it was Hera who transformed Io into a cow). Hermes, by command of Zeus, killed Argus and released her. Hera then sent a gadfly, which pursued Io far and wide, e.g., over the Bosphorus, "Oxford," and the Ionian Sea, both of which were said to have been named after her, until in her wanderings she reached Egypt, where she was restored to her original form and became the mother of Epaphus. A somewhat different account of this myth is found in the *Prometheus* of Æschylus. In the early Greek art Io is represented as a cow; about 500 B.C. it became customary to represent her as a maiden with horns on her forehead; later still there is a return to the earlier method. Various attempts have been made to explain the myth by natural phenomena, but none has obtained any general acceptance. Most authorities have regarded her as the moon and have found Argos in the stars. Consult: Engelman, *De Ione* (Halle, 1868); Plew, *Neue Jahrbücher für Philologie*, vol. cii (Leipzig, 1870); P. W. Forchhammer, *Die Wanderungen der Inachostochter Io* (Kiel, 1881); Engelman, in Roscher, *Lexikon der griechischen und römischen Mythologie*, vol. ii (Leipzig, 1890-97); Gustav Mellén, *De Ius Fabula* (Upsala, 1901); C. M. Gayley, *The Classic Myths in English Literature and Art* (2d ed., Boston, 1911).

I'ODATES. See IODIC ACID.

IOD'IC ACID, HIO_3 . A crystalline monobasic acid composed of hydrogen, oxygen, and iodine and prepared by boiling iodine with strong nitric acid. It is very soluble in water and acts chemically as a powerful oxidizing agent. The salts of iodic acid are called iodates. Neither iodic acid itself nor the iodates are used practically.

I'ODIDES (from *iodine*, from Gk. ἰώδης, *iōdēs*,

like a violet, from ἰὼν, *ion*, Lat. *viola*, violet). The salts of hydriodic acid (q.v.). The iodides of potassium, sodium, ammonium, strontium, and zinc are used in medicine. They are extensively employed in the tertiary stages of syphilis, causing the rapid absorption of syphilitic deposits. The iodide of potassium is further beneficial in gonorrhœal rheumatism, in certain joint diseases, in pleurisy, Bright's disease, asthma, and as an expectorant in bronchitis; it is also used in cases of chronic lead and mercury poisoning. The other iodides have much the same effect as that of potassium, and the iodides of sodium and strontium are even believed to be preferable. Overdoses of iodides, and even moderate doses in the case of some people, may give rise to certain symptoms that are collectively known as iodism: there is an eruption on the skin, running at the nose and mouth, sore throat, and even laryngitis and bronchitis. In such cases the dose should be diminished, and, if necessary, the administration of the salt entirely discontinued. Potassium iodide sometimes causes great general depression; if so, it may be replaced by the iodide of sodium or of strontium, or preferably by free hydriodic acid. The iodide of sodium forms an interesting series of crystalline compounds (crystallo-alcoholates) with the alcohols, including wood alcohol, ordinary ethyl alcohol, and propyl alcohol. Iodide of starch is a blue powder prepared by gradually adding starch powder to iodine triturated with some water, until the mass assumes a uniform blue color. It is used in medicine for administering iodine internally. See IODINE.

I'ODINE (from Gk. ἰώδης, *iōdēs*, like a violet, so called from the color of its vapor). One of the halogen elements, similar to chlorine and bromine. It was discovered by Courtois in 1812 in the ashes of seaweeds. Its character and properties were investigated by Gay-Lussac in 1814. It occurs chiefly in combination in the iodides and iodates of sodium and potassium, and is thus widely distributed both in the organic and inorganic kingdoms. It exists in sea water, in sea plants and animals, and in mineral springs. Along with lead, mercury, silver, and zinc it occurs in ores from Chile, Mexico, and Spain. It is obtained from seaweeds, especially those thrown up on the north coast of France, the coasts of Spain and Ireland, and the west coast of Scotland, but its principal source at present is the mother liquors of the nitre works in Chile. When the weeds just mentioned are burned (formerly in the open air, now in closed retorts to prevent loss by volatilization), they yield an ash called kelp, which contains from 0.1 to 0.3 per cent of iodine. The kelp is dissolved in hot water, and the solution is evaporated until the bulk of the sodium carbonate contained in it has crystallized out. An excess of sulphuric acid is then added to the mother liquor, and thus hydriodic acid is set free. Manganese dioxide (an oxidizing agent) is now added to the liquor in the distilling apparatus, and thus the iodine is liberated. The product can be readily purified by sublimation, the first and last portions only being very impure. The crude sodium nitrate (caliche) from Peru and Chile contains about 0.2 per cent of sodium iodate. The iodine is extracted from the mother liquors from which the sodium nitrate has been separated by crystallization. These are run into wooden vats lined with lead,

and the iodine is precipitated by a mixture of neutral and acid sodium sulphites. The resulting iodine is then washed with water and pressed into thick cakes, which are further purified by sublimation.

Iodine (symbol, I; atomic weight, 126.92) is a grayish-black soft solid, with a metal-like lustre. It has a specific gravity of 4.9 at 60° C., melts at 114.15° C. (237.47° F.), and boils at 184.35° C. (363.83° F.), giving rise to a very heavy violet vapor with a peculiar and penetrating odor. The presence of iodine is best detected by the addition of a little starch, with which it gives a blue coloration. Iodine finds extensive use in the arts, especially in the manufacture of coal-tar colors. Some iodine is used in photography. But the greater portion of the iodine of commerce is employed in medicine, partly in the free state, partly in combination as iodoform, and as the iodides of potassium, sodium, ammonium, strontium, and zinc, all of which are official in the Pharmacopœia. Iodine itself is but little used internally, although repeated small doses of it, in form of the tincture well diluted with water, are often successfully used to stop vomiting. (See IODIDES.) Externally, however, iodine is in constant use as a disinfectant, irritant, counterirritant, and parasiticide. The pharmacopœial preparations are: 1. *Compound solution of iodine*, or Lugol's solution; an aqueous solution, 100 parts of which contain 5 parts of iodine and 10 parts of potassium iodide. 2. *Tincture of iodine*, which is a 7 per cent solution of iodine in alcohol. 3. *Iodine ointment*, which contains 4 per cent of iodine, 1 per cent of potassium iodide, 93 per cent of benzoated lard, and 2 per cent of water. When applied to the skin, the preparations produce a stain, which disappears in time, largely owing to the volatility of iodine; the stain may, however, be readily washed off with potassium cyanide or sodium hyposulphite. As counterirritants the preparations mentioned are used for pleurisy, chilblains, chronic inflammation of the joints, etc. As an antiparasitic, iodine is often used for ringworm, in the form of *Coster's paste*, which is made from 1 part of iodine and 4 parts of wood tar. For the medicinal uses of iodides, see IODIDES.

Iodine is but sparingly soluble in water, 7000 parts of water dissolving only 1 part of the element. It is quite soluble in alcohol, and even more freely in ether. But it dissolves with great ease in hydrocarbons, in carbon disulphide, and in chloroform. It is also freely soluble in iodine derivatives of the hydrocarbons and in aqueous solutions of metallic iodides, but its solubility in all such substances is probably due to its supposed capacity for forming with them true chemical compounds. Among the compounds of iodine may be mentioned hydriodic acid and its salts (see IODIDES), iodic acid (HIO_3) and its salts, termed iodates, and periodic acid (HIO_4) and its salts, termed periodates. The anhydride or iodic acid is iodine pentoxide. The well-known compound of iodine with nitrogen is mentioned under the latter name. Very interesting are two compounds of iodine with chlorine—viz., the monochloride of iodine, ICl , and the trichloride of iodine, ICl_3 , both of which may be prepared by the direct action of chlorine on iodine. The trichloride has been recommended as an antiseptic.

It was mentioned above that iodine volatilizes

very readily. The density of its vapor has been studied by Dumas, Victor Meyer, Crafts, and Troost, of Paris. It will be remembered that, according to Avogadro's rule, the molecular weight of a substance equals twice its vapor density referred to hydrogen. Up to about 800° C. iodine vapor is found to be invariably about 127 times as heavy as hydrogen under the same conditions of pressure and temperature. Hence the molecular weight of iodine up to 800° C. is about 254, and as the atomic weight of the element is about 127, the molecule of iodine vapor is considered as made up of two atoms and is represented by the symbol I_2 . Above 800° C., however, iodine vapor grows lighter and lighter. At 1000° C. it is only 100 times as heavy as hydrogen; at 1400° C. only 75 times as heavy; and at 1500° C., and under reduced pressure, Crafts found it to be only 66 times as heavy as hydrogen under the same pressure and temperature. This indicates that the molecular weight of iodine vapor gradually diminishes above 800° C., seemingly approaching the limit 127 (i.e., 2×63.5), which is the relative weight of single atoms. In other words, the molecules of iodine seem to become gradually dissociated into single atoms, and at some limiting temperature and pressure which have not yet been found, the particles of the vapor would all be single atoms. The phenomenon, which has also been observed in the case of certain other elements, presents considerable interest from many points of view. Van't Hoff thinks that if the chemical elements can at all be decomposed, the method might be like that employed in bringing about the phenomenon just described.

Consult "Untersuchungen über das Jod von Gay-Lussac," in Ostwald, *Klassiker der exakten Wissenschaften* (Leipzig, 1889). See HYDRIODIC ACID; IODIDES; IODIC ACID.

I'ODISM. See IODIDES.

IOD'OFORM, or TRI-IODO-METHANE, CHI_3 . A chemical compound of carbon, hydrogen, and iodine, analogous to chloroform (q.v.). It is a yellow crystalline substance, having a penetrating sweetish odor and an unpleasant sweetish taste. It is very soluble in ether, moderately so in alcohol, and but very sparingly in water. It melts at 119° C. (246.2° F.) and can be readily distilled in a current of steam, although it undergoes decomposition if distilled alone. It also undergoes gradual decomposition under the action of light. It is produced when iodine comes in contact, in the presence of alkalis, with various organic compounds of the fatty series, such as ordinary alcohol, aldehyde, acetone, etc. Its preparation may be conveniently carried out as follows: Dissolve some caustic soda or caustic potash in alcohol diluted with water; warm this solution gradually, add iodine to it, and separate the precipitated iodoform by filtration. The filtrate contains considerable quantities of sodium or potassium iodide, and sodium or potassium iodate. These may either be recovered entirely, in the form of iodides, or else more alcohol and more caustic soda or potash may be added to the filtrate and a slow current of chlorine passed through it, the iodine of the salts being thus set free to form further quantities of iodoform. Another convenient method of preparing iodoform consists in gradually adding an aqueous solution of sodium hydrochlorite to an alkaline solution of potassium iodide in dilute aqueous acetone. Finally, iodo-

form may be manufactured by subjecting to electrolysis a solution of potassium iodide and acetone (or alcohol) in water with a current of carbonic-acid gas passing into the solution. The principal use of iodoform is for purposes of antiseptics, disinfection, and local stimulation. It has been demonstrated that iodoform itself really exerts no antiseptic action whatever and is incapable of preventing the development of microorganisms. When, however, it is brought in contact with a wound, the secretions of the latter speedily decompose it, and it is the decomposition products that possess the well-known antiseptic and disinfecting power. Iodoform, in the form of powder, of an ointment, or of its solution in collodion, has been extensively used as an application for syphilitic and tuberculous ulcerations, as well as for sores and wounds of any other kind, but it has been largely superseded by less disagreeable and less poisonous substitutes, such as aristol (q.v.) and xeroform. One of the disadvantages of iodoform is its disagreeable odor. But this may be masked by the addition of some musk, or by dissolving iodoform in volatile camphor oil or in balsam of Peru. Iodoform is rapidly absorbed from raw surfaces, and this sometimes gives rise to symptoms of poisoning, and has even caused death. The symptoms vary in different cases and may include any two or three of the following: quick pulse, fever, collapse, dilated pupils, erythema, hallucinations, and gastrointestinal irritation. The treatment consists in administering stimulants and diaphoretics and sponging the skin with warm water. A substance termed diiodoform has been introduced as a substitute for iodoform. See ACETYLENE.

IODYRITE. A silver iodide crystallizing in yellow to greenish hexagonal crystals. It is sometimes found with other silver ores, especially with cerargyrite (q.v.).

IOLA, i-ō'lä. A city and the county seat of Allen Co., Kans., on the Neosho River, 40 miles west of Fort Scott, on the Missouri, Kansas, and Texas, the Missouri Pacific, and the Atchison, Topeka, and Santa Fe railroads (Map: Kansas, G 7). Owing to vast wells of natural gas, the city has grown rapidly and is showing a substantial industrial development. It has immense zinc smelters, cement works, brick plants, foundry and machine shops, and a wholesale trade in groceries, flour, and confections. Noteworthy features are a Carnegie library, a hospital, and a United States Weather Bureau station. Settled in 1857, Iola received a charter as a city of the second class in 1898 and has adopted the commission form of government. It owns and operates its water works, gas, and electric-light plants. Pop., 1900, 5791; 1910, 9032; 1914 (U. S. est.), 10,412.

I'OLAN'THE. An operetta by Sir Arthur Sullivan with libretto by W. S. Gilbert (1882).

I'OLA'US (Lat., from Gk. 'Ιόλαος). In Greek mythology, the half brother and charioteer of Hercules (q.v.), whom he assisted in the destruction of the Lernæan hydra (q.v.) and in other contests. For his good offices Megara, the first wife of Hercules, was given to him. He also aided the children of Hercules against Eurystheus, and was worshiped with Hercules at Thebes.

I'OLITE (from Gk. ἰον, *ion*, violet + λίθος, *lithos*, stone), **CORDIERITE**, or **DICHRITE**. A magnesium-iron-aluminium silicate, containing

a small amount of water, that crystallizes in the orthorhombic system. It is found in various shades of blue, which is deeper in one direction and more grayish or yellowish in a direction at right angles to the first. (See **DICHRISM**.) It is transparent to translucent. It occurs in gneiss or granite, but rarely in volcanic rocks. Iolite is found in Bavaria, Hungary, Tuscany, Brazil, and in Ceylon, where crystals of an intense blue color, called saphir d'eau, are found. In the United States dark-blue specimens occur at Haddam and Norwich, Conn. Modern usage employs the name saphir d'eau to the light-blue varieties of this mineral in contradistinction to those showing the darker colors that are commonly known as lynx sapphire. The terms are not strictly exact because of the great variety of shades from pale to deep blue that are classed under one of the two names, iolite and cordierite.

ION, i'ōn (Lat., from Gk. Ἴων). A tragedy of Euripides, the chief interest of which consists in Creusa's attempt to poison Ion, who had been brought up in Apollo's temple at Delphi and is given to Creusa and her husband as a son. When detected, Creusa is threatened with death at the hands of Ion, who is finally revealed to her as her son by Apollo. The date of the play is uncertain.

ION. See **HELLEN**; **IONIA**.

ION. See **DISSOCIATION**; **IONIZATION**; **ELECTROCHEMISTRY, GENERAL**; **SOLUTION**; **ELECTRICITY**; **CATALYSIS**; **ESTERS**; **ACIDS**; **ETC.**

IONA, i-ō'nā (OI. *Hi, Hü, I*, island, whence the oldest Latin form, *Ioua*, corrupted in transcription to *Iona*). A celebrated island of the Hebrides; in Irish, Icolmkill. It is situated on the west coast of Scotland, a short distance from Mull and Staffa, and forms part of Argyllshire. It is over 3 miles long, varying in breadth from a mile to a mile and a half. Its area is estimated at somewhat over 2000 acres, of which rather more than a fourth part is under tillage. The soil in some parts is fertile and yields oats, barley, and potatoes in abundance. Dunii, the highest point of the island, is about 330 feet above the sea level. Pop., about 250.

The history of the island begins in the year 563, when St. Columba (q.v.) landed upon Iona with 12 disciples. Having obtained a grant of the island from his kinsman, Conall, King of the Scots, and later from Bruide, King of the Picts, he built upon it a monastery, which was long regarded as the mother church of the Picts and was venerated not only among the Scots of Britain and Ireland but among the Angles of the north of England, who owed their conversion to the missionaries of Iona. From the end of the sixth to the end of the eighth century the monastery of Iona was scarcely second to any monastery in the British Isles. In 838 it became the seat of the Bishop of the Western Isles. The island was several times invaded between the eighth and tenth centuries by the heathen Norsemen, and the buildings were burned and the monks slaughtered. Towards the close of the eleventh century the monastery was repaired by St. Margaret, the wife of King Malcolm Canmore, and was visited in 1097 by King Magnus the Barefooted, of Norway. It was now part of that kingdom and so fell under the ecclesiastical jurisdiction of the Bishop of Man and the Archbishop of Trondhjem. In 1203 the bishops of the north of Ireland disputed the authority of the Manx bishop, pulled down a

monastery which he had begun to build in the island, and placed the abbey under the rule of an Irish abbot of Derry. The Scottish church had long claimed jurisdiction in Iona, and before the end of the thirteenth century the island fell under the rule of the Scottish King. Its abbey was now peopled by monks of Cluny, and a nunnery of Austin canonesses was planted on its shores. At the beginning of the sixteenth century the island again became the seat of the bishopric of the isles. No remains of St. Columba's monastery now exist. The most ancient ruins are those of the Benedictine monastery of 1203. St. Oran's Chapel, now the oldest church in the island, may probably be of the latter part of the eleventh century. St. Mary's nunnery is, perhaps, a century later. The cathedral church of St. Mary seems to have been built chiefly in the early part of the thirteenth century. It has a choir with a sacristy on the north side and chapels on the south side; north and south transepts; a central tower, about 75 feet high; and a nave. An inscription on one of the columns appears to show that it was the work of an Irish ecclesiastic who died in 1202. On the north of the cathedral are the chapter house and other remains of the conventual or monastic buildings. The Reilig Oran, or ancient burial ground, is supposed to contain bodies of a number of Irish, Scottish, and Danish kings, but no monuments of these princes now remain. Consult: Reeves, *The Historians of Scotland*, vol. vi (Edinburgh, 1874); James Drummond, *Archæologia Scotica, Sculptured Monuments in Iona and the West Highlands* (ib., 1881); Fowler, *Adamnani Vita S. Columbæ* (Oxford, 1898); Robert Jaffray, *Iona, the Sacred Isle* (New York, 1907); G. C. Trenholme, *Story of Iona* (Edinburgh, 1909).

IONE, i'õn. A village in Amador Co., Cal., 40 miles east-southeast of Sacramento, on the Southern Pacific Railroad (Map: California, E 4). It is in an agricultural and coal-mining district and has deposits of clay. The Preston School of Industry is situated here. There are flour mills and a creamery. Pop., 1910, 1551.

IO'NIA, i-õ'nĩ-à (Lat., from Gk. Ἰωνία). The ancient name of the small but very fertile district comprising the centre of the western coast of Asia Minor from (approximately) the river Hermus in the north to Mount Latmus in the south, and the adjacent islands of the Ægean Sea (Map: Greece, Ancient, E 2, 3). It received its name from the Ionians, who, according to the mythological account, derived theirs from Ion (see HELLEN), the son of Apollo by Creusa, a daughter of a king of Athens. According to the usual tradition they were driven out of the Peloponnesus by the Dorians (q.v.), and removed to Attica, whence bands of them went forth to settle on the coast of Asia, led by Neleus and Androclus, sons of Codrus (q.v.). (See below in the account of the Ionians.) Here in historical times we find a sacred league of 12 cities, whose centre was the *Panionium*, a sanctuary of Poseidon Heliconius on the promontory of Mycale. The 12 cities, beginning at the north, were Phocæa, Clazomenæ, Erythræ, Chios (island), Teos, Lebedos, Colophon, Ephesus, Samos (island), Priene, Myus, Miletus. (See the articles on these cities and islands.) Each city was completely autonomous, though from time to time all united for some common purpose. The cities flourished and sent out many

colonies both to the north along the Propontis and the Black Sea, and to the west; thus, Smyrna was occupied by settlers from Colophon and became Ionian. During the seventh century B.C. they suffered from the Cimmerian invasion of Asia Minor and later were involved in wars with the Lydian kings, to whom in the sixth century they seem to have yielded a nominal submission and in turn to have exercised a powerful influence upon Lydian art and life. (See CIMMERIANS; CRÆSUS; GYGES; LYDIA.) The Persian conquest of Lydia, about 546 B.C., led to the reduction of the Ionian and other Greek cities. (See CYRUS THE GREAT; PERSIA.) They were left to the government of their own tyrants and merely paid a regular tribute, though nominally under the Satrap of Lydia and Ionia, whose residence was at Sardis. About 500 B.C. the Ionian cities revolted from Persia, at the instigation, said Herodotus, of Histæus (q.v.). At first successful with the aid of the Athenians, the Ionians burned Sardis (q.v.); but the insurrection collapsed with the naval victory of the Persians at Lade in 494 B.C. and the fall of Miletus in the same year. The aid lent to the Ionians by Eretria (q.v.) and by the Athenians gave Darius Hystaspis (q.v.) a pretext for his onslaught upon Greece. (See PERSIA; ATHENS, *History*.) On the defeat of the Persians at Mycale by the Athenians and the Spartans (479 B.C.), the cities of Asia Minor again revolted and joined the Delian League. They remained dependent on Athens until the close of the Peloponnesian War (404 B.C.), when they quickly fell under Persian rule again, especially by the Peace of Antalcidas (q.v.), where they remained till the conquests of Alexander the Great. From this period Ionia shared the fate of the neighboring countries and in 64 B.C. was added to the Roman Empire by Pompey, after the Third Mithridatic War. In later times it was so ravaged by the Turks that hardly any traces of its former greatness are left at present.

The name Ionian was not confined to the Greeks of Ionia. In Greek tradition the mythical ancestor of the Ionians was Ion, son of Xuthus and brother of Achæus. (See HELLEN.) In historic times it denoted one of the great divisions of the Greek race, occupying Attica and parts of Eubœa, and most of the islands of the Ægean, as well as the stretch of coast in Asia Minor described at the beginning of this article, and, of course, the colonies sent from these regions. It seems probable that these were the first Greeks known to the East, as their name was adopted by Eastern nations to denote the Greeks. They were distinguished by a dialect distinct from the Dorian and North Greek (see GREEK LANGUAGE), though containing several varieties, and seem also to have possessed greater artistic and literary ability, though also a greater tendency to luxury and ease, and a less vigorous and hardy character. (For the part played by the Ionians in art, see GREEK ART, *History*.) It is generally believed that they came from the mainland of Greece and gradually spread over their later territory. The movement may well have begun as early as the twelfth century B.C., but probably received its main impulse from the Dorian invasion and its attendant migrations. (See DORIANS.) This view was opposed by E. Curtius, who declared that the Ionians had originally come into Asia

Minor from the north of Asia and had crossed thence to the islands and Attica and Eubœa. More recently Bury, while admitting that the Ionians of history came from Greece, has maintained that the name is derived from the Asiatic tribe which they found in occupation of the coast. Curtius' view, though held by Holm in his *History of Greece*, is now generally discredited, nor is Bury's theory as yet more than an ingenious hypothesis. That the race was composed of many elements cannot be doubted, and indeed was recognized by the Greeks themselves. Herodotus, while defining Ionians as those who traced their origin to Attica and celebrated the festival of the Apaturia (see GREEK FESTIVALS), admits that neither Ephesus nor Colophon kept this feast, a fact which seems to indicate a considerable foreign element in these cities. In art, literature, and philosophy, Ionia enjoyed deserved distinction. Her great names are, among others, Minnermus, Anacreon of Teos, Thales, Apelles, Parrhasius, Zeuxis, and others mentioned under IONIAN SCHOOL. Consult the histories of Greece, especially Ernst Curtius, *Die Ionier vor der ionischen Wanderung* (Berlin, 1855); Eduard Meyer, *Forschungen zur alten Geschichte*, vol. i (Halle, 1892); Georg Busolt, *Griechische Geschichte bis Schlacht bei Chæroneia*, vols. i, iii (2d ed., Gotha, 1893); Ed. Meyer, *Geschichte des Altertums*, vol. ii (Halle, 1894); Bury, in *English Historical Review*, xv (London, 1890); Hogarth, *Ionia and the East* (Oxford, 1909); Lenschau, in *Klio*, xiii (Leipzig, 1913); Pöhlmann, *Grundriss der griechischen Geschichte nebst Quellenkunde* (5th ed., Munich, 1914). See also DIANA, TEMPLE OF.

IONIA. A city and the county seat of Ionia Co., Mich., on the Grand River, 34 miles east of Grand Rapids, on the Grand Trunk and the Pere Marquette railroads (Map: Michigan, E 5). It is surrounded by a farming region and has car shops of the Pere Marquette System, a pottery plant, gristmill, and reed-furniture, school-furniture, automobile-body, and petticoat factories. The Michigan Reformatory and the State Hospital for Criminal Insane are located here. Ionia was laid out in 1833 and incorporated in 1873. The city owns and operates its water works. Pop., 1900, 5209; 1910, 5030.

IONIAN (î-ō'nî-an) **ISLANDS.** A collective name given to the islands in the Ionian Sea (together with the island of Cerigo, farther south) belonging to Greece. They consist of six principal and a large number of smaller islands and fall mainly into three groups. The first and northernmost group lies off the west coast of Epirus and consists of Corfu and the little island of Paxos; the second group lies around the entrance to the Gulf of Corinth and consists of Santa Maura, Ithaca, Cephalonia, and Zante; the third group, consisting of Cerigo and its dependent islets, lies southeast of the Morea. The distance from the mainland to Santa Maura, the nearest of the larger islands, is scarcely more than a mile, while the distance to Cephalonia is 22 miles. There is little geographical unity between the islands; for geographical descriptions, see articles on the separate islands. Politically the western groups form the three nomarchies of Corfu, Cephalonia, and Zante, while Cerigo belongs to the nomarchy of Argolis. Their combined area is 1117 square

miles, and their population in 1896 was 266,223, and, in 1907, 226,590.

The collective term Ionian is of modern date. After the division of the Roman Empire these islands were included in the eastern half, the Byzantine Empire, and so continued till 1081, when they fell into the power of Robert Guiscard (q.v.). In the thirteenth and fourteenth centuries the possession of the islands was disputed by the Venetians, the rulers of Naples, and the Greek and Italian corsairs of the Mediterranean. In 1386 Venice obtained possession of Corfu, the most important of the islands. By conquest and purchase the other islands of the Ionian group were acquired by the Republic. Cerigo, the last, was taken from the Turks in 1717. The islands were taken by France when Bonaparte extinguished the Venetian Republic in 1797. They were seized by Russia and Turkey in 1798-99, but were returned to France under the arrangement made in the Peace of Tilsit in 1807. Zante, Cephalonia, and Cerigo were seized by Great Britain in 1809, though Corfu did not yield till 1815. The islands were reconstituted a republic under a British protectorate. Austria was allowed equal commercial privileges. The government was composed of the British High Commissioner and an assembly composed of two chambers—the Senate of six, the Legislative Assembly of 40 members. Up to 1848 the press was restricted, and the government was really a despotism, but in that and the following year widespread dislike of the British government became apparent. To remove what were supposed to be grievances, Lord Seaton, then High Commissioner, introduced sweeping changes in the constitution, including vote by ballot, lowering of the franchise, and freedom of the press. A demand was then made for annexation to the Kingdom of Greece, and an insurrection broke out in August, 1849, in Cephalonia. It was suppressed by Sir Henry Ward, who had succeeded Lord Seaton. Fresh concessions were granted, but without appeasing the malcontents. In 1859 Mr. Gladstone was sent as a special commissioner to the islands, and he reported against their cession to Greece. There was no great desire, however, on the part of the British government to continue its connection with the Ionian Islands. They had cost the United Kingdom £100,000 per annum and had been a continual source of annoyance. In 1863 the election of Prince George of Denmark as constitutional King of Greece gave England an opportunity of getting rid of this troublesome dependency. In that year the Parliament of the islands proclaimed their annexation to Greece. On March 29, 1864, a treaty was concluded at London between the five Great Powers, by which this annexation was consummated, and on May 30 formal possession was taken by the Greek authorities. The neutrality of all the islands was at first guaranteed, but later it was made to apply only to the islands of Corfu and Paxo. In February, 1867, the islands were visited by a series of earthquakes, most violent in Cephalonia, where they caused great destruction of life and property and almost destroyed the two chief towns. Since their annexation the islands have suffered a gradual decline.

IONIANS. See IONIA.

IONIAN SCHOOL. The earliest school of Greek philosophy, represented by Thales, Anaximander, and Anaximenes of Miletus, and Heraclitus of Ephesus. Its chief problem was the search for the first principle in nature, which different exponents of the school found in water, fire, air, or atoms. See GREEK PHILOSOPHY.

IONIAN SEA. The name of that part of the Mediterranean which separates south Italy and Sicily from Albania and Greece (Map: Greece, A 4). It is connected with the Adriatic by the Strait of Otranto. Its main arm is the Gulf of Taranto, between the Calabrian peninsula and that of Otranto, and it forms a number of deep inlets on the coast of Greece, the chief of which is the Gulf of Corinth. The Ionian Islands are located along the eastern margin.

IONIC DIALECT. See GREEK LANGUAGE, *Dialects*; IONIA.

IONIC MEDICATION. See CATAPHORESIS.

IONIC ORDER. One of the three orders of Greek architecture, so called because it was first used in the Greek (Ionian) cities of Asia Minor. It appears to have been developed during the sixth century B.C. from wooden prototypes no longer extant. Its use in Greece proper was almost wholly confined to Attica, where it appeared first as a distinct style, but was used in conjunction with the Doric as well as independently. (See GREEK ART.) It differs essentially from the Doric by its more slender proportions, carved ornamentation, banded architrave, plain frieze, molded base, and voluted capital. The column is from 7 to 10 diameters high in Greek examples, usually 9 in the Roman, and the shaft has 24 deep narrow flutes, separated by very narrow fillets. There are two types of cornice, one with and one without dentils (q.v.); the first was the universal Asiatic type. For illustration and details of the order, see ORDERS OF ARCHITECTURE. A very beautiful but unique example of the Attic-Ionic order is that of the Erechtheum (q.v.) at Athens. In this the upper part, or necking, of the shaft is enriched by an exquisite band of anthemion ornaments, and the channel of the spiral scrolls of the capital is double, while between the band connecting these and the ovolo there is a torus of braided pattern.

The Ionic order was generally used in the Greek cities of Asia Minor for peripteral temples (as at Ephesus, Priene, etc.), but in Greece proper its use was confined to small prostyle and amphiprostyle buildings (Temple of Wingless Victory, Athens), circular buildings (Philippeum at Olympia), and the interiors of some Doric buildings, as in the Propylæa at Athens and the temples at Bassæ and Tegea. There was, however, a general increasing tendency to

use it in Greek architecture. The principal change made by the Romans in its form was in the band which connects the volutes. In the best Greek examples this was curved, but it is straight in the Roman Ionic and in many modern examples.

IONIC SCHOOL. See IONIAN SCHOOL.

IONIZATION (from *ion*, from Gk. *ίών*, pres. p. of *ίέναι*, *ienai*, to go). The modern theory of electric conduction is that an electric current consists of the motion of minute particles of matter which are charged positively and negatively, the motion of the oppositely charged particles being in opposite directions. These charged particles are called ions, and they are in no case identical with molecules; in fact, it rarely happens that a molecule as such is charged. The formation of these ions is called ionization. In metals and all solid conductors there are ions probably always present, the negative ones being electrons. (See ELECTRON.) In a liquid which is not a fused metal, e.g., water, etc., ions are produced by dissolving in it some salt or acid, which dissociates in the act of solution (q.v.). (There are undoubtedly a small number of ions present in the pure liquid, these being fragments of its molecules.) In ordinary gases ions are probably always present to a limited extent, although in a pure dry gas there may be none; but in any case their number may be enormously increased in many ways. If the Röntgen, i.e., X rays (q.v.) are passed through a gas, it is ionized, as is shown by its becoming a good conductor; similarly, if rays from any radioactive substance (see RADIOACTIVITY), or ultra-violet light, or the cathode rays, pass through a gas, it is ionized. The gases from a flame are strongly ionized, so that they will rapidly discharge any electrified conductor near which they are allowed to flow. If a spark is passed between the two terminals of an electrical machine or induction coil, the gas on all sides is found to be ionized; if there is a brush discharge from points, the same is true. By subjecting gas, in which there are only a few ions present, to a very strong electrostatic field, these ions may be given velocities high enough to enable them to break up into ions neutral molecules which they strike in their path; these new ions in turn are set in motion and make more ions, until the number of ions may be enormously increased. This process is called ionization by impact, and has taken place whenever an electric spark occurs. In cases of ionization where no spark passes, the number of ionized atoms is negligibly small compared with the number of neutral atoms, for as soon as the number of ions becomes large, the number of positive and negative ions coming close enough to each other to recombine because of their mutual attraction becomes large, the rate of recombination increasing as the square of the number of positive and negative ions present.

When ions are formed in gases at low pressures they have definite masses, but in gases at atmospheric pressure they seem to collect neutral molecules about them, forming aggregations of varying mass. Negative ions formed in gases at low pressure are identical whatever the gas from which they are formed. The charge of such an ion is the same as the charge of a hydrogen ion in electrolysis, and its mass is about 1/1800 of the mass of a hydrogen atom. This negative ion is the natural unit of elec-

tricity, the electron. (See ELECTRON.) It is conceived that the process of ionization consists in tearing an electron away from a previously neutral atom, leaving the remainder of the atom positively charged and forming the positive ion. Positive ions thus vary in mass according to the mass of the atom of the gas in which they originate. A beautiful experimental method of demonstrating the presence of ions in a gas and their motions has been devised by C. T. R. Wilson (*Proceedings of the Royal Society of London*, vol. lxxxvii, p. 277, 1912). It depends upon the fact that drops of water may be condensed upon minute charged particles. Thus, if there are ions in a gas saturated with moisture, a sudden expansion of the gas will chill it and cause drops to form around the ions, and then these drops may be photographed. For a definite fall in temperature, drops will form only on the negative ions; a greater fall is required for the positive ones.

For further particulars, see also *Electrolysis* under the article ELECTRICITY.

ION (ī'ōn) **OF CHIOS**, kī'ōs (c.500-c.422 B.C.). A Greek author, who came to Athens when he was still young (478 B.C.). He was a member of the circle which included Cimon and Pericles, and was probably personally acquainted with Æschylus and Sophocles. His only work in prose, so far as we know, was the *Ἐπιδημῆαι*, 'Sojournings,' reminiscences of celebrated visitors at Chios, which was of great importance to the Greek historians who succeeded him, and has some value for literary history. The fragments of this work may be found in Müller, *Fragmenta Historicorum Græcorum* (1853). There is also a tradition that he wrote on the colonization of Chios. But his poetry was even more important; he wrote tragedies, lyrics, and elegiac and dithyrambic verse. Consult: Nauck, *Tragicorum Græcorum Fragmenta* (Leipzig, 1889); Allègre, *De Ione Chio* (Lyons, 1890); Theodor Bergk, *Poetæ Lyrici Græci* (Leipzig, 1900); Christ-Schmid, *Geschichte der griechischen Litteratur*, vol. i (5th ed., Munich, 1908).

I'OPHON (c.450-c.390 B.C.). A Greek tragedian, son of Sophocles. We know little of his life or of his plays. There is a statement in Valerius Maximus attributing the *Antigone* to him. The story told by Plutarch, and by Cicero, *De Senectute*, 22, that he accused his

aged father of insanity so that he might have control of his property, and that Sophocles proved his sanity by reading to the judges the famous chorus from the *Œdipus Coloneus*, 668 ff., is questioned in modern times, e.g., by Jebb, editor of the *Œdipus Coloneus*, pp. xl-xlii (3d ed., Cambridge, 1900). The few verses of Iophon which survive may be found in Nauck, *Tragicorum Græcorum Fragmenta* (1889). Consult Oswald Wolf, *De Iophonte Poeta* (Leipzig, 1884), and the editors on Aristophanes, *Frogs*, 73, 78.

IORGA, yōr'gā, NICOLÆ (1871-). A Rumanian historian and politician, born at Botoshani and educated at Iashi, Paris, Berlin, and Leipzig. In 1894 he was appointed professor of universal history at the University of Bucharest, and in 1910 was made a member of the Rumanian Academy. He became leader of the National-Democratic party. His works include, besides political writings, numerous and important publications of documents relating to Rumanian history, and historic monographs such as: *Philippe de Mezières et la croisade au XIVE siècle* (1896); *Notes et extraits pour servir à l'histoire des croisades* (1899-1902); *Geschichte der Rumänen* (1905); *History of the Byzantine Empire* (in English, 1907); *Geschichte des Osmanischen Reiches* (5 vols., 1907-13); *History of Rumanian Literature in the Eighteenth (1901) and Nineteenth Centuries* (1902-09), in Rumanian.

I'OS, or **NI'O**. One of the Cyclades, Greek Archipelago, situated about 13 miles south of Naxos (Map: Greece, G 7). Its area is over 45 square miles, and its surface very mountainous. The inhabitants cultivate cotton, olives, and the vine, and raise cattle. The only town, Ios, had a population, in 1907, of 2090. According to local tradition, Homer was buried on the island.

IO'TA (Lat., from Gk. *ἰῶτα*, from Phœnician *yōdh*, Heb. *yōd*, Ar. *yad*, hand). The ninth letter (ι) of the Greek alphabet, corresponding to the English *i*.

I. O. U. (I owe you). A memorandum of debt or due bill, named from its abbreviated form, viz.,

NEW YORK, January, 1915.

JOHN DOE, I. O. U. \$20.

RICHARD ROE.

In England and in most of the United States an I. O. U. is not treated as a *promissory note* (q.v.) for the reason that it does not contain an express promise to pay. However, by statute or by judicial decisions, it has been in some States declared to be a promissory note, and as such capable of transfer by indorsement. It can everywhere be sued upon as an account stated, without proof of the origin of the debt. See DUE BILL.

IOVILÆ, or **JOVILÆ**, yō'vī-lē or yō'vī-lī. Oscan monuments in Campania, dating from the fifth to the third century B.C., found at Capua and Cumæ. Some of them are dedicated to Jupiter; others were attached to graves. All show heraldic emblems peculiar to a family or a group of families; the inscriptions on them have to do with the performance annually, on fixed days, of certain ceremonies. Consult: R. S. Conway, *The Italic Dialects* (Cambridge, 1897); Von Planta, *Grammatik der oskisch-umbrischen Dialekte* (Strassburg, 1892-97); C. D. Buck, *A Grammar of Oscan and Umbrian* (Boston, 1904); id., *Ele-*

mentarbuch der oskisch-umbrischen Dialekte (Heidelberg, 1906). See the account of the Oscan dialect under ITALIC LANGUAGES.

IOWA, i'ô-wà (popularly known as the Hawkeye State). One of the North Central States of the United States. It lies between latitudes 40° 36' and 43° 30' N. and between longitudes 89° 5' and 96° 31' W. and is bounded on the north by Minnesota, on the east by Wisconsin and Illinois, from which it is separated by the Mississippi River, on the south by Missouri, and on the west by Nebraska, from which it is separated by the Missouri River, and by South Dakota. Its shape is nearly that of a rectangle, measuring 310 miles from east to west and 205 miles from north to south; its area is 56,147 square miles, and it ranks twenty-fourth in size among the States of the Union.

Topography. Iowa is a typical prairie plain with slight relief. The range in altitude is somewhat more than 1000 feet. The lowest point, 494 feet above sea level, is at Keokuk, in the southeast corner of the State; the highest point, the elevation of which is not definitely known, is on a great divide in Osceola County in northwest Iowa. The greater portion, though not perfectly level, is so free from natural obstructions that most of the country roads are laid out in squares, crossing at right angles with the absolute regularity of a checkerboard. The most rugged part is the Driftless Area in the northeast corner of the State. Iowa is divided into two hydrographic systems, the eastern two-thirds being drained by the direct affluents of the Mississippi, and the western third by those of the Missouri. The divide between the two systems runs obliquely across the State from northwest to southeast. From this the Mississippi affluents flow all in a southeast direction, and the Missouri affluents all to the southwest. The principal of the former are the upper Iowa, Turkey, Wapsipinicon, Cedar, Iowa, Skunk, and Des Moines rivers, the last being the largest river within the State. The principal Missouri affluents are the Big Sioux, forming most of the South Dakota boundary, the Little Sioux, the Nishnabotna, and the Nodaway. Many of these streams are navigable for very small craft, but, owing to the railroads, they are unnecessary as waterways and little used. Like all typical glaciated areas, Iowa is dotted, especially in the northern part, with numerous small but often beautiful lakes, several of which are favorite resorts, such as Spirit Lake in Dickinson County near the north boundary, a beautiful sheet of water, 2½ by 5 miles, with picturesque, wooded shores. Other beautiful lakes are East and West Okoboji, Clear Lake, and Storm Lake.

Geology. Owing to the heavy covering of drift, a thorough geological survey of Iowa is attended with difficulties. Nevertheless, our knowledge of the rock formations is fairly complete. In more than three-fourths of the State the surface consists of Paleozoic rocks appearing in parallel belts running northwest to southeast. Beginning at the northeast corner, there is a narrow belt of Cambrian rocks consisting of Potsdam sandstone; then follow the Ordovician, Silurian, Devonian, and Carboniferous systems, the last occupying the southwest corner. The northwestern part is covered by extensive Cretaceous beds deposited across and over the belts of the older strata. In Webster County is a small area of rocks probably of Permian age. Finally, in the extreme northwest corner

there are outcroppings of metamorphosed rock of the Algonkian system, known as Sioux quartzite, the oldest formation in the State. Over the entire surface, with the exception of a small driftless area in the northeast corner, is a deposit of glacial drift from a few inches to several hundred feet in thickness. It consists mainly of fine rock fragments with but few boulders and pebbles.

Mineral Resources. The most valuable of Iowa's mineral resources are the extensive bituminous coal beds found in the south-central quarter of the State. Lead and zinc ores have been mined in considerable quantities in the Galena limestone of the Ordovician system of the northeast. Extensive deposits of gypsum and cement materials are also found, and various other minerals occur in smaller quantities. The limestones of the Ordovician, Silurian, and Devonian systems furnish an inexhaustible supply of building stone.

Mining. The principal mining industries are coal mining and clay working, these two contributing about 77 per cent of the total mineral value. Over 60 per cent of the value is represented by the output of coal mines. The coal fields constitute the northern limits of the western interior region and occupy the central and southern portions. They have a total area of approximately 20,000 square miles, of which about 13,000 square miles are considered as workable under present conditions. The coal is of noncoking bituminous grade, somewhat high in sulphur, but is a fair steaming fuel. The market for Iowa coal is largely confined within the borders of the State. The production in 1913 was 7,525,936 short tons, valued at \$13,496,710. In that year Iowa ranked eleventh in the production of coal. The industry dates from 1840, but has not shown the same progress as in many Western States.

The value of clay products in 1913 was \$5,573,681. The chief products are draitile, in which Iowa holds first place among the States, and common brick. Cement ranks third in importance among mineral products; the output in 1913 was 3,623,674 barrels. In 1913 there were three modern cement plants of large capacity. Iowa ranked second in production of gypsum, the value of which in 1913 amounted to \$1,157,939. Large quantities of stone, sand, and gravel are produced. The other commercial products are lead, lime, mineral paints, mineral waters, sand-lime brick, and a small amount of natural gas. The total of the mineral production in 1913 was \$25,602,015.

Forest areas are small and are chiefly confined to the faces of the bluffs along the river courses. The most common trees are the oak, elm, cottonwood, hickory, and maple, while scanty forests of pine and cedar are found on some of the bluffs. Grasses are the predominant feature of the landscape as well of the flora of the State.

Climate. The climate in different parts of Iowa shows only slight variations, which are mostly due to differences in latitude and altitude. It is of the continental type, with great variations in temperature between summer and winter. The mean annual temperature is 47.5° F. The highest temperature recorded is 113° F. and the lowest is -43° F., giving the remarkable range of 156° F. The average winter temperature is 20.7° F., spring 47.5° F., summer 71.3° F., and autumn 50.5° F. The average an-

nual rainfall is 31.5 inches, more than two-thirds of which usually falls during the six crop months, April to October. These copious but not excessive rains, coinciding with continued high temperature during the summer months, are, next to the rich soil, the chief cause of Iowa's agricultural prosperity.

Soil. Practically the whole of the State is arable land. The soil may be divided into three distinct kinds: alluvial soil, glacial drift, and loess. The alluvial soil consists of recent deposits on the bottom lands of the principal rivers; the principal tract is the Missouri bottoms, 150 miles long and from 5 to 20 miles wide. This is, of course, the richest soil of the State, but is, nevertheless, rivaled by the drift soil. The latter consists of a fine loamy mixture of clay and sand, with a little gravel. It is of almost inexhaustible richness and scarcely needs fertilizing. It covers by far the greater part of the State. The loess is a fine yellowish silt highly charged with carbonate of lime.

It is found in various parts of the State, but is related chiefly to the valleys of the large streams. It is generally considered to be of Æolian origin.

Agriculture. Iowa has been from its earliest settlement one of the most important agricultural States in the Union. It has, however, passed out of the class of States which are adding to their total farm area. In 1910, of an approximate land area of 35,575,040 acres, 95.4 per cent (33,930,688 acres) was in farm land, and the improved land in farms was 29,491,199 acres. In that year the total number of farms was 217,044, and the average acreage per farm was 156.3. The average value of all property per farm was \$17,259 in 1910. The average value of land per acre was \$82.58 in 1910. Of the total number of farms (217,044), those operated by owners and managers in 1910 numbered 134,929, and those operated by tenants 82,115, i.e., slightly more than three out of eight were operated by tenants. In 1910 the percentage of farm land improved was highest for farms operated by tenants and lowest for farms operated by managers.

Of the total farm acreage in 1910, 50.7 per cent was in farms of from 175 to 499 acres and 33.1 per cent in farms of 100 to 174 acres; these two size groups comprising about five-sixths of the aggregate acreage. The native white farmers numbered 167,856 and the foreign-born white 48,987. The negro and other non-white farmers numbered only 187.

The acreage, value, and production of the principal crops in 1914, as estimated by the United States Department of Agriculture, are shown in the following table.

LEADING CROPS	Acreage	Prod. bu.	Value
Corn.....	10,248,000	389,424,000	\$144,712,000
Wheat.....	810,000	15,066,000	14,463,000
Oats.....	5,000,000	165,000,000	67,650,000
Barley.....	360,000	9,360,000	5,148,000
Potatoes.....	147,000	12,642,000	7,459,000
Hay.....	2,950,000	*4,071,000	41,117,000

* Tons.

The total value of the crops in 1909 was \$314,666,000, and the combined acreage of crops in that year was 20,374,925, representing 69.1 per cent of the total improved land in farms.

The general character of agriculture in Iowa is indicated by the fact that about three-fourths of the total value of crops in 1909 was contributed by the cereals and about one-fifth by hay and forage. The remainder, representing 7.9 per cent of the total, consisted mostly of vegetables, fruits and nuts, and forest products. Of the 15,041,039 acres reported for cereals in 1909, over three-fifths were in corn, which, together with the acreage of oats, formed over nine-tenths of the whole.

The total acreage of potatoes and other vegetables in 1909 was 252,243, and the value of the crops was \$12,021,408. Excluding potatoes, sweet potatoes, and yams, the acreage of vegetables was 80,402, and the value of the crops was \$5,266,000. In 1909, 3791 acres were devoted to the raising of plants and flowers and of nursery products, and the value was \$1,503,305. The total quantity of orchard fruits produced in 1909 was 7,234,000 bushels, valued at \$4,284,000. Of this quantity apples contributed more than nine-tenths and cherries, plums, and prunes most of the remainder. The production of grapes in 1909 amounted to 11,708,000 pounds, valued at \$330,000. The production of orchard fruits in 1909 was twice as great as in 1899. The small fruits produced are of considerable value, and these amounted in 1909 to 10,344,052 quarts, valued at \$966,894. Strawberries are by far the most important. A small amount of sugar beets is grown. The product in 1909 was 7,117 tons, valued at \$35,024. There was grown also 28,957 tons of sorghum cane, from which were made 250,205 gallons of sirup, valued at \$139,293.

Live Stock and Dairy Products. In 1910 the value of all live stock on the farms was \$393,003,000. The number and value of live stock on Jan. 1, 1915, is estimated by the United States Department of Agriculture as follows: cattle, 2,683,000, valued at \$100,612,000; horses, 1,600,000, valued at \$168,000,000; mules, 58,000, valued at \$6,438,000; swine, 8,720,000, valued at \$95,920,000; sheep, 1,249,000, valued at \$6,994,000. The fowls of all kinds in 1910 numbered 23,482,880, with a value of \$12,269,881. The milk produced in 1909 was 318,954,506 gallons, from which were made 38,679,568 pounds of butter and 78,538 pounds of cheese. The value of the milk sold was \$6,032,685, and the total value of milk, cream, butter, and cheese in 1909 was \$40,268,583.

Forest Products. The State contains very little timber land. For a number of years saw mills have been largely dependent upon the forests of Minnesota and Wisconsin for logs, and the depletion of these, with the establishment of many mills in these States, has caused a decline in the lumber industry of Iowa. In 1909 the value of products was \$12,659,000. There were produced on the farms in 1909 forest products valued at \$3,649,032. These included firewood, fencing material, logs, railroad ties, telegraph and telephone poles, materials for barrels, tanbark, etc.

Manufactures. Though preëminently an agricultural State, Iowa's manufactures are of increasing importance. In 1909, exclusive of the value of the products of the neighborhood and hand industries, the value of manufactures was \$259,238,000. The table on page 318 gives the most important figures relative to leading industries in 1909 compared with 1904. On account of the limitations of space only those in-

COMPARATIVE SUMMARY FOR 1909 AND 1904

dustries whose product had a value of 1,000,000 or over in 1909 are included in this table. Of the 61,635 wage earners, 51,770 were males and 9865 were females. The value, \$88,531,000, added to products by manufacture represents the net wealth created by manufacturing operations during the year. There were, in 1909, 59 industries which had a value of products in excess of \$500,000.

It will be noted from the table that the slaughtering and meat-packing industry is by far the most important when measured by value of products, although four other industries employed in 1909 a greater average number of wage earners. This industry is to a large extent confined to four cities: Cedar Rapids, Des Moines, Ottumwa, and Sioux City. The value of these products increased from \$25,763,000 in 1899 to \$59,045,000 in 1909. Industries connected with the making of butter, cheese, and condensed milk occupy second place when measured by value of products. Iowa has occupied a prominent place in the creamery industry ever since its establishment on a factory basis. From 1904 to 1908 the industry showed marked development, the value of products having increased 72 per cent. It ranked third in respect to its manufactured dairy products in 1909. Products of foundry and machine shops ranked third in value. This industry includes not only foundry and machine shops, but establishments engaged in the manufacture of gas machines and meters, hardware, plumbers' supplies, steam fittings and heating apparatus, and structural ironwork. Other important industries are those related to flour and grist mill products, lumber and timber products, printing and publishing, cars and general shop construction, and the manufacture of buttons. The lumber and timber industry includes logging operations as well as the mills. In 1909 the value of products was \$12,659,000. The output of buttons in Iowa consists of the fresh-water pearl variety, made from the shells of the Mississippi River mussel. Muscatine is the centre of the industry, and it had within its incorporated limits 43 of the 70 establishments in the entire State in 1909.

In 1909 the prevailing hours of labor for about three-fourths of the wage earners ranged from 54 to 60 a week. Sioux City had in 1909 the largest value of products of manufactures, \$37,424,450, with 3750 wage earners. Cedar Rapids ranked second in value of products, \$24,624,276, with 3565 wage earners; Des Moines had the largest number of wage earners, 5383, and ranked third in the value of products, \$23,584,667. Other cities having a value of product of more than \$10,000,000 in 1909 were Davenport, Dubuque, and Ottumwa. For additional details in regard to the manufactures of these and other cities of the State, see the articles under separate titles.

Transportation. The railway facilities, which consist of trunk lines and various branch lines serving as feeders, are excellent. In total length of track in 1909, Iowa ranked fourth among the States. Water transportation is afforded by the Mississippi River on the east boundary and the Missouri River on the west. Des Moines is the centre of a large number of railroad lines, and in general every section is amply provided with facilities. In the western part most of the railroads follow the course of some river, so that all of the larger tributaries to the Missouri River are paralleled by a rail-

road, thus giving them a northeast and southwest direction. The total railway mileage on July 30, 1914, was 9998. Railways having the largest mileage are the Chicago, Burlington, and Quincy (1365), Chicago Great Western (772), Chicago, Milwaukee, and St. Paul (1863), Chicago and Northwestern (1597), Chicago, Rock Island, and Pacific (2203), and the Iowa Central (798). The interurban lines in 1913 had a mileage of 413. The railroad rates are in the hands of the State Railway Commission. The interurban electric railways have been constructed mostly since 1906.

Banks. There were in Iowa on June 4, 1913, 340 national banks, with a total capital of \$23,085,000 and total deposits of \$234,583,000; 378 State banks with deposits subject to check amounting to \$37,065,756 and savings deposits amounting to \$24,180,259; 759 stock savings banks, with 354,742 depositors, deposits subject to check amounting to \$45,177,018, and savings deposits amounting to \$118,984,907; 16 loan and trust companies, with deposits subject to check amounting to \$100,404 and savings deposits amounting to \$1,134,622; and 84 private savings banks, with deposits subject to check amounting to \$1,787,012 and savings deposits amounting to \$189,276.

Government. Iowa has been governed under two constitutions. The first was adopted by the people in 1846, and the second, now in force, but amended in several important details, was sanctioned by the people at an election held in 1857. Amendments to the constitution may be proposed in either House of the General Assembly; if agreed to by a majority of the members of each House of two consecutive legislatures, such amendments are submitted to the people. In each tenth year dating from 1870, and also at such times as the General Assembly may provide, the question "Shall there be a convention to revise the constitution and amend the same?" shall be decided by the electors qualified to vote for members of the General Assembly; and in case a majority of the electors shall decide in favor of a convention, the General Assembly at its next session shall provide by law for the election of delegates to such convention.

Legislative.—The legislative authority is vested in a General Assembly, which consists of a Senate and a House of Representatives. The sessions of the General Assembly are biennial, beginning on the second Monday in January next following the election of its members, unless the Governor shall, in the meantime, convene it by a proclamation. Senators are chosen for a term of four years and Representatives for two years. The number of Senators shall be not less than one-third nor more than one-half the representative body. The Senate is composed of 50 members, and the House of Representatives consists of not more than 108 members. Members of the House of Representatives must be at least 21 years of age, and Senators must be at least 25 years of age.

Executive.—The supreme executive power is vested in the Governor, whose term of office is two years. He receives an annual salary of \$5000, an allowance of \$600 for house rent, and \$1200 for services as member of the Executive Council. The Governor must be at least 30 years of age. There is also a Lieutenant Governor, who holds office for two years and is elected at the same time as the Governor. The other executive officers are Secretary of State,

Auditor of State, and Treasurer of State. These continue in office for two years, or until their successors are elected and qualified.

Judiciary.—The supreme court consists of seven judges, four of whom constitute a quorum for the transaction of business. The State is divided into 21 judicial districts, and each district is entitled to from one to five judges. In 1914 there were 59 judges of the district court, elected for a term of four years. A superior court may be established in cities containing 4000 inhabitants. In 1914 there were seven such courts, in the cities of Council Bluffs, Cedar Rapids, Grinnell, Keokuk, Oelwein, Perry, and Shenandoah, elected for terms of four years. An attorney-general is elected for two years, and each county has a county attorney, elected also for two years.

Suffrage and Elections.—Every male citizen of the United States of the age of 21 years, who shall have been a resident of Iowa for six months next preceding the election, and of the county in which he claims his vote 60 days, is entitled to vote at all elections. The general election for State, district, county, and township officers is held on the Tuesday following the first Monday in November. There are statutory provisions for direct primaries and for the direct election of United States Senators. The Legislature of 1913 passed a measure providing for the nonpartisan nomination and election of all judges of courts of record. This includes judges of the supreme court, district court, and superior courts. This Legislature also adopted the amendment to the Federal Constitution providing for the direct election of United States Senators by the people. The Legislature of 1913 also passed a joint resolution providing for the initiative and referendum. This calls for an amendment to the State constitution.

Local and Municipal Government.—The unit of local government is the county. Counties must contain not less than 432 square miles. No county or other political or municipal corporation is allowed to become indebted in any manner or for any purpose to an amount in the aggregate exceeding 5 per cent on the value of taxable property within such county or corporation. The electors of each county elect every two years such officers as are necessary for its government. The cities may establish on the approval of 60 per cent of the voters a department of publicity, development, and general welfare. The Legislature of Iowa was one of the first to authorize the commission form of government for cities, and the system of city government adopted by Des Moines in June, 1907, came to be known as the Des Moines System. It aroused great interest among students of municipal government. (See MUNICIPAL GOVERNMENT.) Other cities which have adopted the commission form of government include Burlington, Cedar Rapids, Fort Dodge, Keokuk, Marshalltown, Mason City, Ottumwa, and Sioux City.

Other Constitutional and Statutory Provisions.—The property rights of husbands and wives are equal, each upon the death of the other inheriting one-third in value of his or her real estate, while neither is liable for the separate debts of the other. Women are eligible to all offices connected with public schools. There is a pure-food law, conforming in its essential provisions to the national law. The use of narcotics by minors is prohibited, as is the

sale of cocaine and certain other drugs. County attorneys in certain cases, with the approval of the court or a judge, are allowed to prosecute criminal cases to final judgment on information without the intervention of the grand jury. The Legislature of 1911 created the office of commerce counsel. It is the duty of this officer to investigate the reasonableness of rates charged for service rendered by railroads, express companies, parties, or corporations subject to the jurisdiction of the board of railroad commissioners. In general, he represents the people in matters pertaining to commerce. There is a workmen's compensation law and laws providing for safety in coal mines. The office of dairy and food commissioner was created in 1911. Thus Iowa is nominally under prohibition as the result of prohibitory laws passed in 1884 and in later years. However, the so-called Mule Law rendered the prohibitory provisions inoperative by permitting the sale of liquor in counties where petitions, requesting licenses, show the valid signatures of 65 per cent of the voters who voted at the last general election, and in cities of 5000 population or more where a special petition shows the valid signatures of a majority of such voters. In cities of 2500 population and under 5000, the law requires a petition with the signatures of 88 per cent of the voters in order to make liquor selling legal. There are laws preventing the sale of liquor on trains, and also a law prohibiting others than qualified electors engaging in the sale of intoxicating liquors. In 1913, 10 cities with a population of 5000 or more were under no-license. The largest of these were Waterloo, Ottumwa, Muscatine, and Mason City. On Jan. 1, 1914, there were 519 saloons in Iowa.

Finance. The report of the State Treasurer for the biennial period 1912-14 shows a balance on hand June 30, 1914, of \$737,860. The total debt on July 1, 1914, was \$142,313. This was entirely a floating debt. The State has no bonded debt. The chief sources of revenue are the general property tax, tax of insurance companies, the collateral inheritance tax and fees from corporations, tax on motor vehicles, etc. The chief expenditures are for education and for the support of State institutions and State officers.

Militia. The number of males available for military duty in 1910 was 306,669. The organized militia consists of one brigade of infantry and a sanitary troop, which includes a field hospital. The infantry brigade consists of four regiments of 12 companies each. The total number of enlisted men in 1913 was 2768, and the officers numbered 213.

Population. The population of Iowa by decades is as follows: 1840, 43,112; 1850, 19,214; 1860, 674,913; 1870, 1,194,020; 1880, 1,624,615; 1890, 1,912,297; 1900, 2,231,853; 1910, 2,224,771. The estimated population on July 1, 1914, was 2,221,755. In 1910 it ranked fifteenth in population among the States, and is the only State in the Union which showed a decrease in the population in the decade 1900-1910. This decrease of 0.3 per cent, while it affected most counties, was confined entirely to the rural population. The urban population (places of 2500 or more) increased from 567,267 in 1900 to 680,054 in 1910. The rural population decreased from 1,664,586 in 1900 to 1,544,717 in 1910; the decrease is attributed partly to the natural tendency which is evident in nearly all the States

for the population to centre in cities, and partly to the fact that, as the improved agricultural land has practically all been taken, many farmers moved to other States and to Canada, where new land could be obtained. The population per square mile in 1910 was 40. The native white population in 1910 numbered 1,935,707, the foreign-born white 273,484, and the negro 14,973. The population was divided by sex in 1910 into 1,148,171 males and 1,076,600 females. Males of voting age numbered 663,672.

There is no large centre of population, and the percentage of urban population is small compared with most of the North Central States. There were in 1910 eight cities with a population of 25,000 or over. These, with their populations in 1910, are as follows: Des Moines, 86,368; Sioux City, 47,828; Davenport, 43,028; Dubuque, 38,494; Cedar Rapids, 32,811; Council Bluffs, 29,292; Waterloo, 26,693; Clinton, 25,577.

Education. Educational standards in Iowa are exceptionally high. This is shown by the fact that the percentage (1.7) of illiteracy in 1910 was lower than any other State. Of a population of 1,760,286 of 10 years of age or over, the illiterates numbered 29,889. The total school population (ages 6 to 21 years), according to the thirteenth census, was 675,222. The total enrollment in the public schools in 1913 was 507,845. There were employed in that year 27,432 teachers, of whom 2544 were men and 24,888 women. The average monthly compensation of men teachers was \$83.22 and of women teachers \$49.91. The total expenditures for schools in 1913 was \$16,442,528. The total number of schoolhouses was 13,858.

Iowa has had administrative problems of unusual difficulty in the conduct of its schools. These include a too great multiplication of school districts, together with a decreasing rural population and the lack of gradation common in the country schools. These problems, however, have been studied carefully, and the difficulties have to a large extent been eliminated. Recent legislatures have passed a number of excellent measures which have contributed largely to the efficiency of the system. Each school district exists as a school corporation, and the consolidation of two or more districts as consolidated independent school districts is provided for. There were, in 1914, 802 high schools with an attendance of 48,770. In addition to these there were many private, normal, secondary, and parochial schools. The Legislature of 1913 enacted a large number of important measures affecting education. Among these was an act to establish a minimum wage for teachers in the public schools. The Department of Public Instruction was reestablished. The Superintendent of Public Instruction, appointed by the Governor for a term of four years, has supervision over all schools under the control of the State. The Legislature provided for normal training in high schools with State aid, and provision was made also for State aid to consolidated schools. Another measure provided for the teaching of elementary agriculture, domestic science, and manual training in the public schools after July 1, 1915. The compulsory attendance law was amended so that any person having control of any child at the age of 7 to 16 years inclusive is compelled, with exceptions, to cause such child to attend some public, private, or parochial school for at least 24 consecutive school weeks in each school year. Pro-

vision was made by this Legislature for the use of school buildings for public recreation grounds. Provision was also made for the education of deaf and dumb persons.

There are two private normal schools: the Normal and Scientific Institute at Bloomfield and the Western Normal College at Shenandoah. The institutions for higher education include Iowa State University at Iowa City, the Iowa State College of Agriculture and Mechanic Arts at Ames, Iowa State Teachers College at Cedar Falls, Coe College at Cedar Rapids, Charles City College at Charles City, Des Moines College at Des Moines, Drake University at Des Moines, St. Joseph's College at Dubuque, St. Ambrose College at Davenport, Parsons College at Fairfield, Upper Iowa University at Fayette, Grinnell College at Grinnell, Lenox College at Hopkinton, Simpson College at Indianola, Ellsworth College at Iowa Falls, Iowa Wesleyan College at Mount Pleasant, Cornell College at Mount Vernon, Penn College at Oskaloosa, Central University of Iowa at Pella, Morningside College at Sioux City, Buena Vista College at Storm Lake, Tabor College at Tabor, Leander Clark College at Toledo, Highland Park College at Des Moines, and Luther College at Decorah. All these, with the exception of St. Ambrose and St. Joseph's College, are coeducational.

Charities and Corrections. The charitable and correctional institutions include the Reformatory at Anamosa, the Cherokee State Hospital at Cherokee, the Clarinda State Hospital at Clarinda, the School for the Deaf at Council Bluffs, the Soldiers' Orphans Home at Davenport, the Industrial School for Boys at Eldora, the State Penitentiary at Fort Madison, the Institution for Feeble-Minded Children at Glenwood, Independence State Hospital at Independence, State Hospital for Inebriates at Knoxville, Soldiers' Home at Marshalltown, Industrial School for Girls at Mitchellville, Mount Pleasant State Hospital at Mount Pleasant, and State Sanatorium at Oakdale. These institutions are all under the supervision of the Board of Control of State Institutions. In addition there are a number of county and private institutions which are also subject to inspection and regulation by this board. The Legislature of 1911 passed a measure suspending the execution of sentence for the first offender except for murder, treason, robbery, or arson. In the same year surgeons in State institutions were authorized to sterilize criminals, idiots, feeble-minded, drug fiends, and epileptics. A commission appointed to investigate conditions in penal and correctional institutions reported in May, 1912, recommending many changes in penal administration, notably the abolition of the contract system and the purchase, for the use of first offenders and good-conduct and short-term convicts, of a farm of 2000 acres near Des Moines.

Religion. While the Roman Catholics have the largest number of members of all churches, the membership of the Methodist church, together with its adherents, is much stronger and is almost twice as great as that of any other Protestant denomination. Among a large number of other churches represented, the largest in their order are: Lutherans, Presbyterians, Baptists, Disciples of Christ, and Congregationalists.

History. The aboriginal inhabitants of the State were the Indian tribes of Iowa (q.v.) and Illinois (q.v.), who in the course of time

were driven from their homes by the Sacs and Foxes. Marquette and Joliet in 1673 and Hennepin in 1680 touched what are now the borders of the State. In 1788 Julien Dubuque, a Frenchman from Canada, obtained from the Indians the grant of a large tract of land, including the site of the city now bearing his name, and the rich mineral country surrounding it. He built a fort there, carried on the mining of lead, and traded with the Indians, but on his death in 1810 the settlement was abandoned. In 1803 the region passed to the United States as a part of the Louisiana cession, and Indian titles to the land were extinguished by treaties in the years 1804, 1832, and subsequently. It formed, in turn, a part of the Territories of Louisiana (organized in 1804), Missouri, Michigan, and Wisconsin. On June 12, 1838, it was organized as the Iowa Territory. In 1832 a number of emigrants settled on the site of Fort Madison, which had been erected by the United States government in 1808 and abandoned five years later. About the same time a settlement was made in the neighborhood of Burlington, and in 1833 Dubuque was founded. Six years later the government was removed to Iowa City, and in 1844 a State constitution was framed and admission to the Union sought for. After some delay, caused by the action of Congress in restricting greatly the boundaries of the new State, and after the rejection of two constitutions, the State was admitted on Dec. 28, 1846. Immigration was rapid and continued in spite of a bloody massacre of whites by Sioux Indians at Spirit Lake in March, 1857. In the same year the original constitution of 1846 was revised and Des Moines was made the capital. In the Civil War, Iowa, whose fundamental law prohibited slavery, took a zealous part. The two most important questions of public moment since 1870 have been railway legislation and prohibition. The development of the State was greatly accelerated by the building of railroads, of which there were, in 1900, nearly 10,000 miles; but with the rise of powerful railway corporations there ensued a continuous conflict between the Legislature and the companies in regard to the taxation of railway property and the regulation of rates. In 1872 an Act taxing railway property was passed, and in 1873 a powerful agitation stirred up by the Patrons of Husbandry (see GRANGE) against the extortionate rates imposed by the companies led to the creation of a board of railroad commissioners for the purpose of determining a maximum rate and preventing discrimination. Radical action on the part of the commissioners caused repeated appeals to the courts, and though many concessions were wrung from the companies, the advantage in general remained with them. A Prohibition amendment adopted in 1882 was promptly declared unconstitutional by the courts. A new law went into effect in 1884 and for some years proved fairly adequate. A very large part of the population, however, was opposed to sumptuary legislation, and in 1890, under the protection of the interstate commerce laws, a successful attempt was made to evade the antiliquor regulations by the importation of alcoholic products from other States. In 1894 the courts declared the prohibitory laws unconstitutional. From 1846 to 1854 the State was Democratic both in national and State politics. From 1854 to 1912 its vote in national elections was cast for the Republican candidate.

The State government, as a whole, has always been in the hands of the Republicans, and only in 1889 and 1891, years of stormy railway and liquor legislation, was a Democratic Governor elected. In the first decade of the twentieth century Iowa, under the leadership of Albert B. Cummins and others, became one of the more radical of the States in the adoption of new political policies. The "Iowa Idea" became the synonym for advanced steps in government. In 1908 Senator Allison, who early in the year had received the nomination to succeed himself to the United States Senate, died on August 4. At a special session held by the Legislature, Governor Cummins failed to be elected to the vacancy. However, at the senatorial primary held during the general election, he was nominated by a large majority and subsequently elected. In the election on November 3 the vote for President and Governor was as follows:

PRESIDENT		GOVERNOR	
Taft, Rep.....	275,210	Carroll, Rep.....	256,980
Bryan, Dem.....	200,771	White, Dem.....	194,129

The campaign and elections of 1910 were of especial interest, since the Progressives were stronger in Iowa than in any other State except Kansas. Governor Carroll received the Republican nomination for reelection by a small margin, and after a spirited campaign was elected. Two Democratic congressmen were elected. Senator Dolliver died on October 15 of that year, and after a 12-week deadlock the Legislature, in 1911, elected William S. Kenyon to complete the term expiring on March 4, 1913. On June 3, 1912, Senator Kenyon received the nomination for reelection over Lafayette Young, his principal opponent. He was reelected by the Legislature on Jan. 21, 1913. A Republican Legislature was elected, insuring the election of a Republican Senator. In November, 1914, Senator Cummins was reelected. The Progressive vote showed a great decline. The State has 11 members in the national House of Representatives. The vote for President and Governor in 1912 was as follows:

PRESIDENT		GOVERNOR	
Wilson, Dem.....	185,276	Clarke, Rep.....	184,148
Roosevelt, Prog....	161,783	Dunn, Dem.....	182,449
Taft, Rep.....	119,811	Stevens, Prog.....	71,877

The Governors of Iowa since its organization as a Territory have been as follows:

TERRITORIAL	
Robert Lucas.....	1838-41
John Chambers.....	1841-46
James Clark.....	1846
STATE	
Ansel Briggs.....	Democrat..... 1846-50
Stephen Hempstead....	"..... 1850-54
James Wilson Grimes, Whig and Free-Soil Democrat	1854-58
Ralph P. Lowe.....	Republican..... 1858-60
Samuel J. Kirkwood....	"..... 1860-64
William M. Stone.....	"..... 1864-68
Samuel Merrill.....	"..... 1868-72

IOWA. The name of a tribe of American Indians, belonging to one of the main divisions of the great Siouan linguistic family. At the beginning of the eighteenth century they dwelt in Minnesota and afterward farther south in the area which now bears their name. They were called Pahotcha or Pahucha (dusty noses) in their own tongue, Ayanway by Lewis and Clark, and Ajowes by French traders. In 1836 they were moved to the west bank of the Missouri above Wolf River, and in 1861 they ceded part of their lands to the United States, settling upon reservations in Kansas and Oklahoma. In culture they were similar to the Omaha, being an agricultural buffalo-hunting people. At present they number but 224. There is no good published account of this tribe, but for a brief sketch consult W. H. Miner, *Iowa Indians: A Sketch of their History* (Cedar Rapids, Iowa, 1912).

IOWA, STATE UNIVERSITY OF. A State institution for higher education, founded at Iowa City, Iowa, by Act of the Legislature passed in 1847. The capitol, together with the land upon which it stood, was given to the university in view of the contemplated removal of the seat of government from Iowa City. The delay in removing the capital prevented the opening of the institution until March, 1855. The organization of departments began in the same year. From 1858 until 1860, owing to the lack of funds, the normal department was the only one in operation, and the university was reorganized in 1860. The law department was established in 1868, the medical department in 1876, the dental department in 1882, the department of pharmacy in 1885, the Graduate College in 1900, the College of Applied Science in 1905, the College of Fine Arts, or Mark Ranney Memorial Institute of Fine Arts, in 1911, and the College of Education in 1913. In 1909, pursuant to an act of the General Assembly, the control of the university, together with that of the Iowa State Teachers College and the Iowa State College of Agriculture and Mechanic Arts, passed into the hands of the State Board of Education. The university is an integral part of the public-school system of the State. Its work is based upon the preparation afforded by the duly accredited high schools, whose students are admitted to the undergraduate and professional courses upon the presentation of the proper certificates—except in the colleges of medicine and law, which require two years of collegiate work in preparation. The State,

through the university, undertakes to furnish instruction in the various branches requisite for an education in the liberal arts, law, medicine, dentistry, pharmacy, fine arts, nursing, and engineering. It also aims to encourage research work in all departments. The income of the university is derived from the university funds and lands originally given by the United States and appropriations made by the State Legislature. The campus includes some 50 acres in the centre of Iowa City. On this are about 30 buildings, which are grouped around the historic old capitol grounds. The Iowa River has been dammed just below the university grounds, providing a water front for the enlarged campus and good facilities for aquatic sports. The majority of the buildings are new. The university is coeducational. In the collegiate year 1913-14 the total enrollment in all departments was 2669, and of these 1679 were men and 990 women. In the College of Liberal Arts were 1392, in the College of Law 203, in the College of Medicine 109, in the College of Homœopathic Medicine 5, in the College of Dentistry 246, in the College of Pharmacy 62, in the Graduate College 328. The faculty numbers about 275. The university library contains about 100,000 volumes and the university law library about 15,000 volumes. The publications of the university include a natural history bulletin, a law bulletin, university studies in psychology, and studies in sociology, economics, politics, languages, and history. The control of the university is vested in the State Board of Education, and the finances are administered by a finance committee, consisting of three members appointed by the board. The acting president in 1914 was T. H. Macbride, Ph.D.

IOWA CITY. A city and the county seat of Johnson Co., Iowa, on the Iowa River, 54 miles west by north of Davenport, on the Chicago, Rock Island, and Pacific and the Cedar Rapids and Iowa City railroads (Map: Iowa, F 3). The State University occupies the grounds and buildings of the former capitol, and also seven fine buildings erected by the Commonwealth. In Iowa City are the State Historical Society Library, Ranney Memorial Library, Iowa City Academy, Mercy Hospital, and the medical department and homœopathic hospitals connected with the university; and among other prominent structures are the county courthouse, a Carnegie library, Masonic Temple, post office, State tuberculosis sanitarium, and opera house. The industrial establishments comprise meat-packing plants, agricultural-implement works, a large jewelry factory, flour mills, knitting mills, glove and mitten factories, broom factories, soap and perfume factories, brick and tile works, a foundry, machine shops, etc. The government is administered by a mayor, elected every two years, and a unicameral council. Pop., 1900, 7987; 1910, 10,091; 1914 (U. S. est.), 10,412. Founded in 1839 and incorporated in 1853, Iowa City was from 1839 to 1857 the capital of Iowa Territory and State. It was connected with the East in 1855 by the completion of the Mississippi and Missouri Railroad. Consult "The Historic Capital of Iowa," in *Magazine of American History*, vol. xxi (New York, 1888), and B. F. Shambaugh, *Iowa City: A Contribution to the Early History of Iowa* (Iowa City, 1893).

IOWA COLLEGE, THE TRUSTEES OF. The legal name of the institution commonly known

as GRINNELL COLLEGE (q.v.). The name gave much trouble because of the confusion with the State University and the State College, and in 1909 the trustees authorized the name Grinnell College for use in all ordinary cases. This is the name used on all publications of the college.

IOWA FALLS. A city in Hardin Co., Iowa, on the Iowa River, 50 miles east of Fort Dodge, on the Chicago and Northwestern, the Illinois Central, and the Chicago, Rock Island, and Pacific railroads (Map: Iowa, D 2). It is the seat of Ellsworth College and contains a Carnegie library. A large shipping trade in grain, produce, and stone is carried on; and there are gasoline-engine works, tile and ditcher factories, etc. Iowa Falls adopted the city-manager plan of government in 1914. Pop., 1900, 2840; 1910, 2797.

IOWA RIVER. A river in the State of Iowa, rising in Hancock County, near the Minnesota line, and flowing southeast into the Mississippi, about 30 miles north of Burlington (Map: Iowa, F 3). It is 300 miles long and navigable to Iowa City, about 66 miles from its mouth. The river's drainage area is about 12,400 square miles, not including the basin of its chief tributary, the Cedar River (7600 square miles).

IOWA STATE COLLEGE OF AGRICULTURE AND MECHANIC ARTS. A coeducational State institution at Ames, Iowa, established by Act of Legislature in 1858. In 1862 the college came into possession of a grant of public lands bestowed by general act of Congress for the purpose of fostering agricultural and mechanic education. It was formally opened in 1869. It is a college of advanced technology, organized in divisions of agriculture, engineering, home economics, industrial science, and veterinary medicine. The department of agriculture is designed to give a general training for the career of a farmer and, in its longer course, to develop specialists in particular lines of work. A well-stocked farm provides practical work in all the agricultural processes, and the Iowa Experiment Station, in intimate relation to the college work of instruction, gives opportunity for original investigations of agricultural problems. In addition to courses in mechanical, civil, electrical, and mining engineering, the college gives instruction in clay working and ceramics and has a department of technology intended to equip students for the manufacturing industries. The division of industrial science supplies foundations in science, language and literature, and economic science. In the instruction of women emphasis is laid on the course in home economics. All male students are required to become members of the college battalion. The college domain includes about 1175 acres, of which about 120 acres form the campus. The buildings number 17 besides dwelling houses and buildings for farm stock, machinery, and work, all valued at \$2,000,000. The endowment in 1914 was \$683,709, the income \$349,407, and the value of all the college property \$3,000,000. The library contained 45,000 volumes. Tuition is free to residents of Iowa, students from other States paying an annual fee of \$50. Students are admitted on examination or on certificates from accredited schools. The college has of late developed rapidly and in 1914 had an attendance of 3458 students and a faculty of 217 members. The president in 1914 was Raymond A. Pearson.

IOWA WESLEYAN COLLEGE. A coeducational institution for higher learning founded at Mount Pleasant, Iowa, in 1842, under the control of the Methodist Episcopal church. In 1914 it had an attendance of 298, including 195 collegiate and 55 preparatory students. The faculty numbered 27. The endowment of the college is about \$300,000, and the annual income about \$40,000. The grounds and buildings are valued at about \$225,000. The library contains about 11,000 volumes, exclusive of government documents. The president in 1914 was Edwin A. Schell, Ph.D.

IPECACUANHA, ip'ê-kāk'û-ân'â (Portug., from Brazilian *ipcaaguen*, small wayside plant emetic, the native name). The name both of a very valuable medicine and of the plant producing it. According to the American and English pharmacopœias the source of this drug is *Cephaelis ipecacuanha* (referred by some botanists to *Psychotria ipecacuanha* and *Uragoga ipecacuanha*), which belongs to the family Rubiaceæ and grows in damp, shady woods in Brazil and some other parts of South America. It is somewhat shrubby, with a few oblong-lanceolate leaves near the ends of the branches, long-stalked heads of small white flowers, and soft, dark purple berries. The part of ipecacuanha used in medicine is the root, which is simple or divided into a few branches, flexuous, about as thick as a goose quill, and is composed of rings of various size, somewhat fleshy when fresh, and appearing as if closely strung on a central woody cord. The different kinds known in commerce (gray, red, brown) are all produced by the same plant, the differences arising from the age of the plant, the mode of drying, etc. Ipecacuanha root is prepared for the market by mere drying. It is collected at all seasons, although chiefly from January to March.

IPECACUANHA.

a, root.

The plant is seldom cultivated in South America, but is sought for in the forests chiefly by Indians. It has been successfully cultivated in India and elsewhere, but the slow growth and low price have kept it from being profitable. Various other plants are used as substitutes for it. The ipecacuanha of Venezuela is produced by *Sarcostemma glaucum*, of the family Asclepiadaceæ; and to this family belongs *Tylophora asthmatica*, the root of which is found a valuable substitute for ipecacuanha in India. Other un-

official plants which are said to resemble ipecac in their effect are *Richardsonia pilosa*, *Richardsonia rosea*, *Psychotria emetica*, and various species of *Ionidium*. *Gillenia stipulata* is called American ipecac.

It is in the bark of the root that the active principle, the emetine, almost wholly lies, the other ingredients, such as fatty matters, starch, pectine, saccharose, choline, lignine, etc., being almost entirely inert. Emetine is represented by the formula $C_{28}H_{40}N_2O_5$ according to Lefort and Wurtz, and by $C_{30}H_{44}N_2O_4$ according to Glenard. It is a white, inodorous, almost insipid powder, moderately soluble in alcohol, and having all the characters of the vegetable alkaloids. It acts as a violent emetic in doses of one-sixteenth of a grain or even less, and is a powerful poison. In small and repeated doses ipecacuanha increases the activity of the secreting organs, especially of the bronchial mucous membrane, and of the skin. In larger doses it excites nausea and depression, while in still larger doses it acts as an emetic, without producing such violent action, or so much nausea or depression, as tartar emetic. Ipecacuanha is useful as an emetic when it is necessary to unload the stomach in cases where there is great debility or in childhood. As a nauseant, expectorant, and diaphoretic, it is prescribed in bronchitis, etc., and in disorders in which it is desired to increase the action of the skin. Besides the powder, the most useful preparations are the wine of ipecacuanha and Dover's powder, in which ipecacuanha is a constituent. To produce the full effect as a sudorific, a dose of Dover's powder should be followed by copious drafts of some warm and harmless drink.

IPEK, ê-pâk' (i.e., silk), Serb **PEČ**, pëch. A pleasant town of Montenegro, on the Bistrica (Bitritsa), or White Drin, close to the Servian frontier (Map: Balkan Peninsula, C 3). The houses are large and handsome, and as a rule have gardens in which fruit and mulberry trees are cultivated. Silk is extensively spun, and arms are manufactured. Ipek has a celebrated monastery, the former residence of the Servian patriarchs. Pop., about 10,500, mostly Serbs and Albanians. Ipek belonged for centuries to the Ottoman Empire, constituting an important town in the Sanjak of Novibazar, but in accordance with the territorial settlements of 1913, which followed the Balkan War (q.v.), it came into the possession of Montenegro.

IPHIC'RATES (Lat., from Gk. Ἰφικράτης, *Iphikratēs*). An Athenian general of the first half of the fourth century B.C. He was of humble parentage. At an early age he began his military career in the so-called Corinthian War. He was in command of the Athenian troops at Lechæum, near Corinth, in 393 B.C., where the Spartans were victorious over the allies. Immediately afterward he proceeded to introduce important changes in the armor and discipline of his troops. Thus, he made their swords and javelins longer, and, by substituting linen corselets for coats of mail, and light leggings or greaves for heavier greaves of metal, he made them capable of much greater rapidity of movement. With a band of the light-armed troops, called *peltasts*, he unexpectedly fell upon and destroyed or put to rout a Lacedæmonian *mora* of hoplites, or heavy-armed infantry, 600 strong, near Corinth. In 389 B.C. he was sent to Thrace to combat the Spartans under Anaxibius, and by a well-planned attack he inflicted

a crushing defeat upon the Lacedæmonians. After the Peace of Antalcidas (387 B.C.) Iphicrates remained in Thrace, employing his peltasts in the service first of King Seuthes and then of King Cotys. In 378 B.C. he was sent, at the request of Pharnabazus, to assist Artaxerxes II in reconquering Egypt, but the undertaking was a failure. In 373 B.C. he was appointed joint admiral with two others to go to the relief of Corcyra, then besieged by the Spartans; in this command he was successful. In 369 B.C. he was sent to the neighborhood of Corinth to assist the Spartans against the Thebans, and later in the same year he commanded a small squadron on the coast of Macedonia. He remained in this neighborhood three years and was instrumental in retaining the family of Amyntas on the throne of Macedonia. He later held a command in the Social War (see GREECE, *Ancient History*), but was arraigned, on a charge preferred by Chares, his colleague, for neglect of duty and traitorous conduct in the battle at the Hellespont. He was acquitted, though his colleague Timotheus, who was arraigned at the same time and on the same charge, was fined 100 talents. Iphicrates died in Thrace (or, as some say, in Athens) in 353 B.C. Consult the Latin Life of Iphicrates by Cornelius Nepos, and, for his changes in the equipment of his troops, etc., Bauer, *Die griechischen Privat- und Kriegsaltertümer* (2d ed., Munich, 1893).

IPH'IGENI'A (Lat., from Gk. Ἰφιγένεια, *Iphigeneia*), or **IPH'IANAS'SA** (Lat., from Gk. Ἰφιάνασσα: see Leaf on *Iliad*, ix, 145, and Merrill on Lucretius, i, 85). According to the usual Grecian legend, a daughter of Agamemnon and Clytemnestra. Her father having offended Artemis, the Greek fleet, when on its way to Troy, was detained at Aulis by calms and a plague. Calchas, the seer, declared that only the sacrifice of Iphigenia could appease the goddess. At the altar the goddess took pity on the victim, substituted a hind, and carried Iphigenia in a cloud to Tauris (see CHERSONESUS, 2), where she became priestess of the Tauric Artemis, to whom strangers were offered in sacrifice. Thither came her brother Orestes (q.v.), and he was on the point of being sacrificed when he was recognized by his sister. Together they fled with the sacred wooden image of Artemis to Sparta, Argos, or, according to the Attic version, to Brauron in Attica, where Iphigenia remained as priestess of Artemis Brauronia, or Artemis Tauropolos, and where her grave was shown. (See BRAURONIA.) Hesiod declared that Iphigenia did not die, but was by Artemis made the goddess Hecate. The Spartans declared that the image of the Tauric Artemis was brought to Laconia, and that there the goddess was worshiped as Artemis Orthia. The legend is unknown to the Homeric poems, but was told in the *Cypria* (q.v.) and later became very popular, especially through the influence of the Athenian dramatists. The story is also represented on late vases, sarcophagi, and Pompeian wall paintings. Iphigenia is originally a goddess akin to Artemis and worshiped in early times with bloody rites, or else her whole story was developed out of an epithet of Artemis. Consult: M. C. H. E. Jacobson, *De Fabulis ad Iphigeniam Pertinentibus* (Königsberg, 1888); R. Förster, *Iphigenie* (1898); C. M. Gayley, *The Classic Myths in English Literature and Art* (2d ed., Boston, 1911);

F. A. Hall, *Iphigenia in Literature* (St. Louis, 1911). The story figures largely in plays, Greek and Latin, and in modern literatures. See IPHIGENIA AMONG THE TAURI; IPHIGENIA AT AULIS; IPHIGÉNIE; IPHIGENIE AUF TAURIS; IPHIGÉNIE EN AULIDE; IPHIGÉNIE EN TAURIDE; IPHIGENIE IN DELPHI.

IPHIGENIA AMONG THE TAURI (Gk. Ἰφιγένεια ἡ ἐν Ταύροις, *Iphigeneia hē en Taurois*). A play of Euripides, produced about 412 B.C., continuing the story of Iphigenia after her rescue from the sacrifice, and her transportation to Tauris, where she is made the priestess of Artemis. Orestes, pursued by Furies, comes with his friend Pylades to Tauris, and is to be sacrificed to the goddess, when he is made known to his sister in a touching scene, and carries her back to their land. The play is original and careful in plot, and is the best known of the works of Euripides.

IPHIGENIA AT AU'LIS (Gk. Ἰφιγένεια ἡ ἐν Αὐλίδι, *Iphigeneia hē en Aulidi*). A play by Euripides, produced after his death by his son in 405 B.C. Its subject is the intended sacrifice of Iphigenia, who is saved by Artemis by the substitution of another victim. The play, which is probably the last written by Euripides, seems to have been left unfinished. Of his tragedies, it alone has no prologue.

IPHIGÉNIE, é'fě'zhā'ně'. A tragedy by Racine, dealing with the Greek story of Iphigenia, first produced at Versailles in 1674.

IPHIGENIE AUF TAURIS, if'ě-gā'nīe ouf tou'ris (Ger., Iphigenia in Tauris). A metrical drama by Goethe produced in 1789.

IPHIGÉNIE EN AULIDE, é'fě'zhā'ně' äN' nō'léd' (Fr., Iphigenia in Aulis). An opera by Gluck (q.v.), first produced in Paris, April 19, 1774.

IPHIGÉNIE EN TAURIDE, äN tō'réd' (Fr., Iphigenia in Tauris). An opera by Gluck (q.v.), first produced in Paris, May 18, 1779.

IPHIGENIE IN DELPHI, if'ě-gā'nīe in dēlfě. A dramatic poem by Friedrich Halm (1856), a continuation of Goethe's *Iphigenie*.

I'PHIS (Lat., from Gk. Ἴφισ). A Cretan girl, brought up as a boy, betrothed to Ianthe, and at her mother's entreaty changed into a man by Isis on the wedding day.

IPIALES, é-pyā'lās. A town of Colombia, situated in the western part of the Department of Cauca, on the frontier of Ecuador (Map: Colombia, B 3). It lies at an altitude of over 10,000 feet and has a customhouse. The population is estimated at over 10,000.

IP'OMŒ'A (Neo-Lat., from Gk. ἵψ, *ips*, worm + ὁμοῖος, *homoios*, like). A genus of the family Convolvulaceæ, differing very little from the genus *Convolvulus*, embracing about 400 species of tropical and warm-temperate plants. The species are mostly twining or trailing herbs and shrubs, although in the tropics a few become arborescent. Many are cultivated for their beautiful flowers, as the morning-glory and moonflower; others for their thick fleshy roots, as the sweet potato (*Ipomœa batatas*) and jalap (q.v.) (*Ipomœa purga*). The large fleshy roots of *Ipomœa batatilla*, *Ipomœa fastigiata*, and *Ipomœa digitata* are sometimes employed in the same way as sweet potatoes, and *Ipomœa megapotamica*, *Ipomœa cathartica*, and *Ipomœa jalapa* have properties similar to jalap, though less active. The ornamental species are very numerous and are easily cultivated. *Ipomœa quamo-*

clit, the cypress vine, beautiful in both flower and foliage, is a native of tropical America, but now well established in the warmer portions of the United States. *Ipomœa versicolor* and *Ipomœa purpurea*, natives of Mexico and tropical America, are among our most common morning-glories, the latter having escaped from gardens and become naturalized throughout nearly the whole country. The famous Japanese morning-glories are referred to *Ipomœa hederacea* by some authorities. There are many strains that have been developed by selection, some of them of very great beauty. The moonflowers are derived from *Ipomœa bona-nox* and *Ipomœa grandiflora*. The flowers open in the evening and close before noon of the next day. They are pure white or striped with green and very fragrant. *Ipomœa fastigiata* and *Ipomœa leptophylla*, both indigenous to the United States, are noted for their large fleshy roots, specimens weighing 20 pounds of the former and 100 pounds of the latter being not uncommon. They grow in dry soils, their thickened roots protecting them from injury by drought. *Ipomœa fastigiata*, known as man-of-the-earth and wild potato vine, in some regions is a troublesome weed, difficult of extermination on account of its huge roots. *Ipomœa arborescens*, a Mexican species, is a tree 20 to 30 feet high and a foot in diameter. See Plate of DICOTYLEDONS.

IPPOLITOV-IVANOV, ép-pōl'ě-tōf-ě-vā'nōf, MICHAÏL MICHAÏLOVITCH (1859-). A Russian composer, born in Gatchina, Nov. 19, 1859. From 1875 to 1882 he was a pupil of the St. Petersburg Conservatory, where he studied composition under Rimsky-Korsakov. For the next 10 years he lived in Tiflis, in the Caucasus, as director of the conservatory and conductor of the symphony concerts and the opera, both affiliated with the Imperial Russian Music Society. During this stay he became deeply interested in the folk songs of the Caucasian district, especially those of Georgia. The results of these studies he published later in a book, *The Georgian Folk-Song* (in Russian), which has become the standard authority. Through the influence of Tschaikowsky he became in 1893 professor of composition at the conservatory in Moscow, and in 1906 succeeded Safonoff as director of that institution. After 1899 he was also conductor of the Moscow Private Opera, through which he greatly encouraged the efforts of the younger nationalist composers, although his personal sympathies inclined more towards the style of Tschaikowsky. His chief works are: the operas *Ruth* (1887), *Assya* (1900), *Yabava Putyatishna* (1901), *Treachery* (1911); a concert overture *Yar Khmel*; a symphonic scherzo; an orchestral suite, *Caucasian Sketches*; a sinfonietta; several cantatas and choral works, a *cappella* and with orchestra; chamber music of a very high order; songs; compositions for piano.

IPSAMBUL, ip'säm-bōōl'. See ABU-SIMBEL.

IPSARA, ip-sä'ra. See PSARA.

IP'SUS (Lat., from Gk. Ἴψος). A town of Phrygia, Asia Minor, near the modern village of *Eski-kara-hissar*. It is noted for the battle (301 B.C., or, as Grote attempts to show, 300 B.C.) in which Antigonos and his son, Demetrius Poliorcetes, were overthrown by Seleucus and Lysimachus. Ipsus was the seat of a Christian bishop in the seventh and eighth centuries.

IPSWICH, ips'wich or ips'ich. A town of Stanley Co., Queensland, Australia, on the

Bremer, at the head of navigation, 23 miles west of Brisbane (Map: Queensland, H 9). It has manufactures of woollens, lumber, and iron-work, and, as the centre of a rich agricultural and coal-mining district, is a place of increasing business importance. In North Ipswich are large railway shops. Pop., 1901 (with suburbs), 15,246; 1911, 14,028, (with suburbs) 25,000.

IPSWICH. A municipal, county, and parliamentary borough, the county town of Suffolk, England, on the Gipping River, 11 miles northwest of Harwich (Map: England, H 4). The older portion of the town consists of narrow and irregular streets and contains many quaint old houses. Its notable public buildings include a modern town hall, corn exchange, an art museum, and the Tudor mansion in Christchurch Park. Among its educational institutions are the grammar school founded in 1477, an endowed girls' school, and a workingmen's college. It manufactures iron goods, railway supplies, fertilizer, bricks, sacking, agricultural implements, tobacco, clothing, shoes, and soap, and has shipbuilding establishments. Its docks and lock are commodious and admit vessels of 19-foot draft. The town owns profitable real estate, wharves, and markets, and maintains baths, free library with museum and school of science, and an arboretum with two well-laid-out pleasure grounds. Ipswich has sent two representatives to Parliament since 1447. It has Roman remains, but is first mentioned in 991 and 1000, when sacked by Northmen. Numerous charters date from the first granted by King John in 1199. Pop., 1901, 66,630; 1911, 73,932. In 1909 important anthropological discoveries were made. Consult John Wodderspoon, *History of Ipswich* (Ipswich, 1850), and "Manuscripts of the Corporation of Ipswich," in Great Britain Historical Manuscripts Commission, *Reports*, vol. ix (London, 1883).

IPSWICH. A town in Essex Co., Mass., on the Ipswich River, 28 miles northeast of Boston, on the Boston and Maine Railroad (Map: Massachusetts, F 2). It possesses the Heard Library, the Coburn Home for Aged Women, a House of Correction, and the Manning High School. The Ipswich Historical Society, founded in 1890, possesses a collection of old furniture, documents, etc., and its contributions to historical literature also are of value. There are planing and grist mills, some clam interests, and manufactures of hosiery, isinglass, heels, boats, and canocs. The government is administered by town meetings. Ipswich owns its water works and electric-light plant. Pop., 1900, 4658; 1910, 5777. Ipswich was settled as Agawam in 1633 by John Winthrop and 12 associates, and in the following year the Massachusetts General Court passed a resolution that "Agawam shall be called Ipswich" (from Ipswich, England). When in 1687 Governor Andros levied an arbitrary tax, the town formally protested, on the ground that this tax "infringed their liberty as free English subjects of his Majesty, and the statute law that no taxes should be levied upon his subjects without the consent of an assembly chosen by the freeholders for assessing the same." Several of its citizens were thereupon arrested and punished, one of the judges asserting that English laws did not extend to America, and that colonists had no more privileges left them "than not to be sold as slaves." This was one of the earliest instances of Colo-

nial resistance to arbitrary taxation. Ipswich was the home for a time of Nathaniel Ward, Anne Bradstreet, Nicholas Easton, William Hubbard, and John Norton.

Townsend, *Sand Dunes and Salt Marshes* (Boston, 1913); publications of the Ipswich Historical Society.

IPSWICH MAN. See MAN, SCIENCE OF, *Ancient Types*.

IQUIQUE, ê-kê'kâ. A seaport and the capital of the Department of Tarapacá, in northern Chile, on the coast (Map: Chile, E 2). It is regularly built, but lies in such an arid district that its water supply is secured by an aqueduct from Pica, a distance of 88 miles. Inland are the famous saltpetre mines for which the town is the port, and with which it is connected by a railroad, and a few miles to the north are the famous silver mines of Huantajaya. The harbor is very well sheltered, but its rocky shore and the strong surf make it necessary for vessels to anchor a considerable distance from the shore. Besides saltpetre, the town exports borax, iodine, and copper ores. The imports are chiefly machinery and fuel for the mines. In 1911 the imports amounted to \$27,975,005, and the exports to \$64,849,196 (bulk saltpetre). It is the seat of a United States consul. Pop., 1914, estimated at 45,000. Iquique suffered from earthquakes in 1868 and 1877. It formerly belonged to Peru and in 1879 was the scene of a naval battle between Peru and Chile, being occupied by the latter in 1880. In 1891 it was bombarded and captured by insurgents against the Chilean government.

IQUITO, ê-kê'tô. An important tribe, living about the junction of the Napo River with the Marañon (Amazon), eastern Ecuador. They are expert spearmen and are noted for their making of *chicha* liquor, which they flavor with the twigs of a plant having the effect of an opiate. In religion they are still devoted to fetichism.

IQUITOS, ê-kê'tôs. A city of Peru, the capital of the Department of Loreto (Map: Colombia, C 4). It is situated on the Amazon River, 2500 miles from Pará, Brazil, at the head of navigation for ocean steamers, and has extensive docks for handling its trade. It is connected with Europe by three steamship lines with regular sailings. Above Iquitos the Amazon is navigable to river steamers for 425 miles. It is 1268 miles from Lima, the journey thence, by rail, mule back, and river steamer, occupying 17 days, which time will be reduced when the railway connecting the Amazon with the port of Paita, on the Pacific, is completed. It is the centre of a very extensive rubber trade, this product from the districts along the Huallaga, upper Amazon, and Madre de Dios rivers forming the chief export. It is the second port of Peru, having in 1910 imports to the amount of \$4,373,946 and exports, \$5,428,064. It is the seat of a United States consul. Iquitos was founded in 1863 for the purpose of having a

port in direct connection with the Atlantic Ocean. It has a mean annual temperature of 75° F. Pop., 14,000.

IRADE, ê-rä'dâ (Turk. *irâdah*, will, desire). An Imperial decree promulgated by the Sultan of Turkey and corresponding to the European order in council.

IRAK, ê-räk'. The name of an indefinitely bounded region extending on both sides of the confluence of the Euphrates and the Tigris, from the Syrian desert northeastward to the Elburz Mountains, on the south shore of the Caspian Sea (Map: Turkey in Asia, E 4). The region consists chiefly of sandy desert lowlands in the west, called Irak-Arabi, and in the east a region of parallel ridges and furrows, mostly barren, with fertile river valleys, called Irak-Ajemi. Irak-Arabi is nearly coterminous with ancient Babylonia and includes parts of the modern Turkish vilayets of Bagdad and Basra. It includes the ruins of the ancient cities of Babylon, Seleucia, and Ctesiphon, and the modern cities of Bagdad, Basra, and Kerbela (Meshed Hussein). Irak-Ajemi coincides nearly with the ancient Media and includes a large part of western and central Persia, containing its largest and most flourishing cities, Ispahan, Teheran, and Hamadan. The population of the whole of Irak is estimated at about 3,000,000. The inhabitants of the western part are largely nomadic.

IRAK-AJEMI, -äj'e-mē'. See IRAK.

IRAK-ARABI, -ä'rá-bē'. See IRAK.

IRAN, ê-rän'. The native name of Persia, in its broadest sense. (See PERSIA.) The word *Irân* itself, in its modern form, is earlier found as *Erân* (whence often Eranian as an adjective), and it is ultimately connected with *Aryan* (q.v.) as a racial designation. In the *Avesta* (q.v.) the people speak of themselves as *Airyā dāinhavō* (Aryan nations), and *Ariya* in the Old Persian cuneiform inscriptions is employed in the sense of what we should to-day call Persian in the larger application of the term. As a more or less defined unit in ancient and modern times, the land of Iran is important geographically, ethnologically, historically, and linguistically.

Geography and Ethnology of Iran. As far as modern times are concerned, the more important geographical and ethnological points connected with Iran will be found treated under PERSIA. In remote times, as later, the Iranian boundaries comprehended the entire region from the Caucasus, the Caspian Sea, and Russian Turkestan on the north, to the Tigris, the Persian Gulf, and the Arabian Sea on the west and south, and extended to the Indus on the east, likewise comprising the modern Afghanistan and the territory to the north of it as far as the Jaxartes River (Sir Darya). The wide extent of this area showed as great a variety of climate, extremes of heat and cold, in antiquity as at present, and presented considerable diversity of features and characteristics. While the larger part of the country has ever been marked as highland or mountainous, there are extensive low or depressed tracts, with salt deserts and arid wastes alternating with swampy districts and plains. What we know of the country in antiquity shows that it was generally fertile and well wooded in parts; but irrigation is not infrequently referred to. With regard to territorial distribution in ancient times, it may be added that in the *Avesta* the lands on the west which came more prominently into notice were

the country known in history as Media (q.v.), including Azerbaijan or Atropatene (q.v.), and the districts about the Caspian Sea, and on the east, Bactria (q.v.), including the modern territories of Khorassan and Seistan, together with parts of the present Afghanistan. Persis (ancient *Pārsa*), or Persia proper, is first mentioned at the time of the founding of the Achæmenian kingdom. (See ACHÆMENES.) From that time the real history of the Iranian Empire as a whole begins. Ethnologically the Iranian people are members of the Aryan or Indo-Germanic family. The general Iranian type may be deduced by a comparison of the racial features of the Persians, Kurds, Ossetes, Baluchis, Afghans, and inhabitants of the Pamir districts. The Iranian type, however, has been somewhat affected, even from the earliest times, by admixture with the adjoining Semitic, Turanian, and Indian tribes that border on the land itself. On the other hand, the spread of Iranian blood beyond its own country may be recognized, e.g., among the people of north-western India. Similarly, Iranian lineaments, like linguistic traits, may be found penetrating into Armenia and Asia Minor, even from a remote period in the past. When the gradual dispersion of the Aryan or Indo-Germanic tribes took place in prehistoric times, it is presumed that the Iranians may have entered the great plateau from the north, on the west of the Oxus and Jaxartes, and have thus begun their advance into the country that later became their habitat. Linguistic, mythological, and religious evidences prove that they must long have remained in union with their Indian cousins.

History of Iran. The beginnings of Iranian history are shrouded in darkness, although the existence of an ancient kingdom in Bactria is inferred from early Oriental and classical references. (See BACTRIA.) With the Median kingdom, however, we are on historic ground, even though the early tradition of a Median conquest of Babylonia (2400 B.C.) as recorded by Berosus (q.v.) may not be authentic. Nevertheless, with the presumed advance of the Iranian peoples westward in their land, the Medes came earliest into real prominence, and though subject to Assyria for centuries, they were able to throw off the Assyrian yoke about the ninth century B.C., and real unity was given to the Median kingdom in the eighth century by Deioces, an able Iranian monarch. (For the subsequent history of the kingdom, see MEDIA.) The account of the overthrow of the Median dynasty by Cyrus (about 550 B.C.), and the events which led to the founding of the great Persian Empire of the Achæmenian kings, and to its fall through Alexander the Great, will be found in the several articles devoted to those topics. The Seleucid dynasty (see SELEUCIDÆ) swayed the fortunes of Iran for about 70 years and gave place to the Parthian dynasty of the Arsacidæ (q.v.), which reigned for nearly five centuries (250 B.C.–226 A.D.). This rule yielded in turn to the Iranian monarchy of the Sassanidæ (q.v.). The overthrow of this house by the Arab Mohammedan invasion in the seventh century changed the history of Iran, nationally, religiously, and linguistically. For details of these events, consult the article PERSIA.

Bibliography. The standard work relating to all Iranian subjects is Geiger and Kuhn, *Grundriss der iranischen Philologie* (Strass-

burg, 1895-1904), where the fullest bibliographical references will be found. Besides this work, for the history and antiquities of Iran, consult: Rawlinson, *Seven Great Monarchies of the Ancient Eastern World* (London, 1865); Spiegel, *Eranische Altertumskunde* (3 vols., Leipzig, 1871-78); Geiger, *Civilization of the Eastern Iranians* (trans., London, 1885); Gutschmid, *Geschichte Irans von Alexander der Grosse bis zum Untergang der Arsaciden* (Tübingen, 1888); Curzon, *Persia and the Persian Question* (London, 1892); Justi, *Iranisches Namenbuch* (Marburg, 1895); J. J. Modi, ed., *The K. R. Cama Memorial Volume: Essays on Iranian Subjects Written by Various Scholars in Honor of Kharshedji Rustamji Cama* (Bombay, 1900); Marquart, *Eranšahr nach der Geographie des Pseudo-Moses Xorcna'i* (Berlin, 1901); Eduard Meyer, "Zur ältesten Geschichte der Iranier," in *Zeitschrift für vergleichende Sprachforschung* (ib., 1907); J. Modi, ed., *Spiegel Memorial Volume: Papers on Iranian Subjects Written by Various Scholars in Honor of the Late Dr. Federic Spiegel* (Bombay, 1908); Prašek, *Geschichte der Meder und Perser bis zur makedonischen Eroberung* (Gotha, 1906-10); Eduard Meyer, *Geschichte des Altertums*, vols. iii-v (3d ed., Stuttgart, 1910-); Y. B. Mirza, *Iran and the Iranians: Being an Account of the History, Religion, Constitution, and Arts of the Persian People* (Baltimore, 1913).

IRA'NIAN, or **ERANIAN**. The term applied to peoples, some of which are now almost or altogether extinct, speaking languages belonging to the Aryan stock and inhabiting the plateau lying between Asia Minor and the Caspian on the west and the Hindu Kush Mountains on the east (of which modern Persia forms the chief part). The chief Iranian peoples, which number some 15,000,000 members, are the Persians (Tajiks of the East; Hajemis of the Caspian littoral, and the Teheran-Ispahan country; Parsis, now principally resident in western India, but also in the region between Ispahan and the Persian Gulf), ancient and modern, and the old Bactrians, whose descendants are said to speak still a purer Persian than that in vogue in Persia itself, together with the partly civilized Kurds; while the Tats and Azerbaijanis, the Sarts of Russian Turkestan, and certain portions of the population of Afghanistan, Baluchistan, etc., are physically Persians who speak, more or less, Turkic dialects. Earlier authorities classed the Armenians with the Iranians, but it is better to regard them as independent members of the Aryan stock. The Ossetes are generally regarded as Iranians. The mass of the Aryan tribes of Afghanistan and Baluchistan, by some considered Iranian, show, on the whole, greater affinities with the Aryans of Hindustan. The Golchas of Pamir are rather an independent Aryan branch than a subdivision of the Iranians. Müllenhoff and V. Miller have shown that many place names in southern Russia are of Iranian, and especially Ossetian, origin, and this agrees with the theory which considers the bulk of the Scythian peoples to have been Iranian. From the dawn of history the land from the borders of Asia Minor to the mountains of Pamir has been inhabited, generally speaking, by tribes and nations of Aryan stock, and chiefly of the variety called Iranian. Even beyond the Oxus, the traditional frontier between Iran and Turan, Iranian culture, old and new, can be traced beyond the borders of

China, and no doubt some of the nomad hordes who hovered about western Europe were not all Turanian in their make-up. Within the Iranian area many blends exist. Besides the descendants of the Aryan Medes and Persians of a fairly pure strain, and the purer Eastern Iranians, almost every people of Asia Minor and of Central Asia has added its quota to the hybrid populations. Mongolian, Arabian, Turkish conquests, and the commercial and colonizing instincts of Jews, Armenians, natives of the Caucasus, etc., have also contributed their share to the mixture. War, slavery, and peaceful nomadism have likewise helped, both in ancient and in modern times. The range of culture of the Iranians is very extensive, reaching from the civilizations of ancient Bactrians, Medes, and Persians (and their modern representatives) to the half-savage seclusion and isolation of some of the small hill communities. Most authorities do not assign to the Iranians as high a rank intellectually as is possessed by the Aryans of India or by the Semites, to say nothing of the Aryans of Europe. The situation of the plateau of Iran between India and China on the one hand and Asia Minor and Arabia on the other has made it inevitably an absorber and a transmitter of culture, a highway of commerce, and a theatre of religious disputes. The great mass of the Iranians are now professors of Islam, but of the Shiite or "unorthodox" sort—a protest, as it were, of the Aryan against the Semitic mind. The ancient Aryan religion, Zoroastrianism, indigenous to the Eastern Iran, with its dualism and reverence of fire as the sacred symbol, exercised considerable influence upon the Hebrews.

Some of the Iranians (Persians and Parsis in particular) have from time immemorial been devoted to commerce, and have spread Persian influence to the Red Sea on the west, and to the western shores of India in the other direction, while northward they have carried it into Siberia and China. The best side of the Iranians of the present time is seen in the educational and charitable activities of the great Parsi merchants of India, who in many respects are setting examples for the whole world. The worst is seen in some of the aspects of Persian tyranny. All grades between still exist here and there over the wide Iranian land. The Iranians in general are judged by Ripley to belong physically to the "Mediterranean" race, their ideal type represented to a certain extent by the Farsis about the ancient Persepolis and the Luris of the mountains of western Persia, having been modified in the southwest by the Semitic intruders, in the east and northeast (the mass of the people) by Mongolian admixture, and on the littoral of the Arabian Sea towards the southeast by Indian, or perhaps Negritic, additions. See **IRANIAN LANGUAGES**; **INDIAN PEOPLES**.

Bibliography. Besides the authorities mentioned under the subdivisions of the Iranians, the following works may be mentioned: Spiegel, *Eranische Altertumskunde* (Leipzig, 1871-78); Ayuso, *Los Pueblos Iranios y Zoroastro* (Madrid, 1874); De Harlez, *Etudes eraniennes* (Paris, 1880); Fontane, *Les Iranicns* (ib., 1881); Spiegel, *Eran* (Berlin, 1883); Darmsteter, *Etudes iraniennes* (Paris, 1883); De Morgan, *Mission scientifique en Perse* (ib., 1884-97); Geiger, *Civilization of Eastern Iran in Ancient Times* (Eng. trans., London, 1885);

Spiegel, *Die arische Periode und ihre Zustände* (Leipzig, 1887); Binder, *Au Kurdistan, en Mésopotamie et en Perse* (Paris, 1887); Hous-saye, *Les peuples actuels de la Perse* (Lyon, 1887); Dieulafoy, *La Perse, la Chaldée, et la Susiane* (Paris, 1887); Brunnhofer, *Iran und Turan* (Leipzig, 1899); id., *Vom Pontus bis zum Indus* (ib., 1890); Geiger and Kuhn, *Grundriss der iranischen Philologie* (Strassburg, 1895-1904); Minns, *Scythians and Greeks* (Cambridge, 1913), full bibliography; and the sections on the Persians and Iranians, in Friedrich Ratzel, *History of Mankind* (Eng. trans., 3 vols., London, 1898), and W. Z. Ripley's *Races of Europe* (New York, 1899).

IRANIAN LANGUAGES AND LITERATURES. Historically, the linguistic and literary monuments of Iran cover a period of more than 2500 years, dating from the early Zoroastrian scriptures and the Old Persian cuneiform inscriptions, through the Pahlavi, down to Modern Persian literature. From the standpoint of speech the Iranian tongues are most closely allied to the Indic languages, and together they make up the Indo-Iranian group. (See INDO-IRANIAN LANGUAGES.) Three great periods in the development of these tongues may be recognized—Old Iranian, Middle Iranian, and New or Modern Iranian. 1. The first of these, the Old Iranian period, includes the *Avesta* (q.v.) and the cuneiform inscriptions and antedates the Christian era by fully six centuries, although it probably extended into the fourth century A.D. There is practically a barren period of five centuries during the Parthian sway, from the third century B.C. to the early part of the third century A.D., during which time there are no real literary monuments, although possibly some later Avestan texts may have been composed, and certain inscriptions and devices in coins may be cited as helping to eke out our knowledge of the Old Iranian period till the rise of the Sassanian monarchy (226 A.D.). 2. The Middle Iranian period dates from the latter event and extends to about the ninth or tenth century of our era. It is represented by the language and literature known as Pahlavi (q.v.), including Huzvaresh, Pazand, and Parsi. 3. The New or Modern Iranian period begins practically in the tenth century A.D., with the rise of the Modern Persian language and literature (q.v.) under Firdausi (q.v.) and his immediate predecessors. Within this period, besides the New Persian, there come the various modern Iranian languages and tongues, Afghan, Baluchi, Kurdish, Ossetish, the dialects of the Pamir and Caspian districts, and the dialects of Central Iran. All the Iranian languages have certain phonetic characteristics which mark them and distinguish them from the kindred group of Indic tongues. Most conspicuous among these are: (1) the change of Indo-Germanic *s* into Iranian *h*; e.g., Skt. *samá*, 'same,' 'like,' 'all' = Av. *hama*, OPers. *hama*, Phl. *hamak*, Paz. *hamā*, NPers. *hamah*, Bal. *hama* (*k*), Kurd. *hamū*; (2) the presence of the voiced sibilants *z*, *ž*, e.g., Skt. *jānu*, 'knee' = Av. *zānu*, Phl. *zānūk*, NPers. *zānū*, Afgh. *zangūn*, Bal. *zān*, Kurd. *zān*; Skt. *bāhū*, 'arm' = Av. *bāzu*, Phl. *bāzih*, *bāzuk*, NPers. *bāzu*; Skt. *mṛḍiká* (Vedic *mṛḷiká*), 'mercy' = Av. *marəzdika*; (3) the use of spirants instead of aspirates, as well as a general tendency to spirantization (*th*, *θ*, *gh*, *γ*, etc.); (4) there are numerous minor phonetic, morphological, and syntactical features which

can be discussed only in a technical treatment of the individual languages concerned. The details regarding the various Iranian literatures, *Avesta*, Old Persian, Pahlavi, etc., will be found in the separate articles devoted to those subjects. The modern Iranian languages are written in the Arabic script, the ancient Persian inscriptions in wedge-shaped letters borrowed from the Babylonian characters, while the Pahlavi and *Avesta* are in a script based on the Semitic writing and read from right to left.

Consult linguistic monographs in Geiger and Kuhn, *Grundriss der iranischen Philologie* (Strassburg, 1895-1904), full bibliographies; Gray, *Indo-Iranian Phonology* (New York, 1902); Bartholomæ, *Altiranisches Wörterbuch* (Strassburg, 1904); *Avesta, Pahlavi and Ancient Persian Studies in Honor of P. Sanjana* (ib., 1904); *The Spiegel Memorial Volume*, edited by J. Modi (Bombay, 1908).

IRAPUATO, ē'ra-pwä'tō. A district town in the Mexican State of Guanajuato, situated on the National Railways of Mexico, 33 miles from Guanajuato, the capital of the state (Map: Mexico, H 7). Its climate is so equable that strawberries are marketed the year round. It has a number of old convents and churches. Pop., 1900, 19,640; 1910, 21,469.

IRAWADI, ir'a-wä'dī. A river of Farther India. See IRRAWADDY.

IRBIT, ér-bêt'. The capital of a district in the Russian Government of Perm, situated at the confluence of the Irbit with the Nitza, 110 miles northeast of Ekaterinburg (Map: Russia, K 3). It is famous chiefly for its annual fair, instituted in 1643 and second only to that of Nizhni Novgorod. It lasts the whole month of February and is visited by about 20,000 people. The chief articles of commerce are manufactures from Russia, silk, woolen, and cotton goods, trinkets, drugs, groceries, fruits, wine, and tea; hides and pelts from Siberia. The annual value of goods brought to the fair exceeds \$20,000,000. Irbit was founded by the Tatars in 1633. Pop., 1897, 20,064.

IREDELL, ir'del, JAMES (1750-99). An American jurist, born in Lewes, England. He was the son of a wealthy and influential English merchant largely engaged in the American trade, who secured for him a position in the customs service of North Carolina. He entered as a deputy collector in 1767, finally becoming in 1774 collector of royal customs for the entire Colony. Meanwhile he had studied law and had been admitted to the bar. In the pre-Revolutionary controversies between England and the colonists he openly showed his sympathy with the cause of his adopted country, resigned the collectorship, and entered enthusiastically into the work of organizing the Revolutionary government. The necessity for a reorganization of the law courts appealed to him particularly, and to this work he devoted his best efforts. In December, 1777, he was chosen a judge of the North Carolina Supreme Court, and in 1787 was commissioned by the Legislature to revise and codify the statutes of the State, which resulted in the important publication known as *Iredell's Revision of the Statutes of North Carolina* (1791). He was an ardent Federalist, but with his political associates could not overcome the opposition which prevented North Carolina from accepting the Constitution until several months after Washington's inauguration. In February, 1790, he was named by President Washington

as associate justice of the United States Supreme Court, in which capacity he served until his death. Consult McRee, *Life and Correspondence of James Iredell* (New York, 1857).

IREDELL, JAMES (1788–1853). An American jurist and legislator, son of James Iredell, associate justice of the United States Supreme Court. He was born at Edenton, Chowan Co., N. C.; graduated at Princeton in 1806; studied law; and was admitted to the bar in North Carolina. In the War of 1812 he raised and commanded a company of North Carolina volunteers. His political career began in 1816, with his election to the State Legislature. To this body he was repeatedly reelected, was Speaker of the Lower House in 1817–18, and, with the exception of a short term on the bench of the Superior Court in 1819, served until his election as Governor of the State in 1827. In the following year he succeeded Nathaniel Macon in the United States Senate, serving until 1831, when he retired permanently from public life and resumed the practice of law. He was a commissioner to revise the statutes of North Carolina, the result of his labors being the publication of the *Revised Statutes* (1836–37), and as the reporter for the Supreme Court of the State for many years he compiled 21 volumes of *Reports*. He also published a *Treatise on the Law of Executors and Administrators* (1837) and *Digest of Reported Cases in the Courts of North Carolina, 1776 to 1845* (1839–46).

IRELAND, ir'land. The smaller of the two great islands forming the United Kingdom of Great Britain and Ireland. It rises from the continental shelf amid shallow waters, the line marking a depth of 600 feet running from 25 to 100 miles west of the Irish coast. Beyond this line the bed of the Atlantic slopes rapidly to oceanic depths. Ireland is thus essentially a part of Europe and lies on the western rim of the mighty land mass of Eurasia. Its area is 32,586 square miles, including about 500,000 acres in water areas. Ireland extends through nearly four degrees of latitude, from the parallel of 51° 26' N. to that of 55° 21'.

Topography. On the east, along the waters of the Irish Sea and St. George's Channel, which separate Ireland from England and Wales, the coast, of softer rock than that of the west, is comparatively straight for long stretches and has few deep indentations. On the west, however, where the coast, of hard rock with drowned valleys, is exposed to the gales of the Atlantic, the sea penetrates far into the land through long, deep valleys. These valleys are true fiords like those of the west coasts of Scotland and Norway, and, as in those countries, at the entrance to the inlets and all along the coast there are steep cliffs and hundreds of little islands that were torn from the mainland mass by ocean storms and other destructive influences. The northwest edge of Europe, therefore, has the same general characteristics from Bantry Bay, at the southwest corner of Ireland, to the North Cape, far north of the Arctic circle in Scandinavia. The chief ports of Ireland are Belfast and Dublin on the east coast, Waterford and Cork on the south, and Londonderry on the north. The west-coast ports are of little importance except in the coasting trade.

In its general surface Ireland may be described as basin-shaped. A traveler sailing along the coast waters might get the idea that

Ireland is very mountainous. As he nears the coast from Holyhead—the common route from England to Dublin—he sees the blue line of the Wicklow Mountains rising 2000 feet above sea level. The details come into view as he approaches Dublin. He sees the rounded bosses of Killiney and the grim promontories of Howth and Bray, which are only the outliers of the high granite moorlands that stretch away for 70 miles to the south. Farther north, between Dundalk and Dundrum bays, he sees a still more rugged and picturesque coast, with the huge domes of the Mourne Mountains rising above it; and then at Belfast come into view the long, black scarps, terraced and uninviting, which form the edges of the high plateau behind them. Rounding the north coast, he sees along the Atlantic shores of Donegal and Mayo great walls of rock, 2000 feet high in places, the finest cliffs in the British Isles; and down the west coast are the rugged heights of Connaught, the high limestone terraces of northern Clare, and farther south range after range extends along the shores till they culminate in the gray masses that look down on Bantry Bay. The highest peak is Carrantuo Hill (Carran Tual), near the picturesque Lakes of Killarney, which has an elevation of 3414 feet above sea level. The interior of the northern portion of the country, from the latitude of Belfast, is partly broken and mountainous. The same is true of the southern part of the island a little south of the latitude of Dublin. The uplands are not comparable, however, to the Scottish and Welsh highlands, but resemble rather the hills of the Scottish lowland.

Broadly speaking, therefore, the highlands of Ireland are massed upon its margin. The central area, the largest single feature of the topography, is a plain with a breadth of 50 miles and an extent from east to west of 100 miles or more, in which numerous bogs and lakes have formed. When the traveler crosses Ireland, from Dublin to Galway (115 miles), e.g., he meets scarcely a hill on the way. He may travel over large parts of the central regions and feel himself on a great plain above which hills or ranges of elevated surface rise here and there, though they are quite insignificant in comparison with the wide expanse of brown bog or level meadowland.

Hydrography. So much of the high ground is for the most part insular masses with ill-determined divides that the river courses in most portions present no uniformity of system. The rivers, sometimes exhibiting sharp changes in trend, yet flow towards all the surrounding seas, even penetrating the coast highlands from the central plain, most of which is not over 500 feet above sea level. It is possible to go from the central plain to the sea by 12 lines through the hills without exceeding an elevation of 300 feet. The water parting between the eastern and western rivers may be traced from Lough Foyle to Mizen Head, but it is a winding line, marked by no definite and determining surface features.

The rainfall is abundant in the central plain, with the result that the slow-moving rivers widen into long lakes, or loughs. The Shannon and Erne rivers are chains of such lakes joined by stretches of river, the river sections being not very much longer than the lakes. The northern part of the central plain is drained by the Erne. The centre of the plain is drained

by the Shannon, which empties into the Atlantic through a wide estuary 70 miles in length. The Shannon, 250 miles long, is the longest river in the United Kingdom. Nearly half of it above the estuary is made up of the three lakes Allen, Ree, and Derg. All the most important rivers flow from the plain, the mountain streams on the coast sides being too limited in length and drainage area to have large volumes. Some of the plain streams, like the Boyne, have no lakes in their courses. A few of these sluggish rivers serve as means of communication with the interior, and their usefulness is augmented by the considerably developed canal system of the country. The Shannon River, navigable by large steamers for 129 miles, is connected with Dublin by the Grand and Royal canals, thus affording water communication across the island. Bogs covering a large part of the plain are the source of peat, so extensively used in Ireland for fuel. The Bog of Allen, to the east of the centre of the plain, is the most extensive of these wet, barren regions.

Climate. The most potent factor in determining the climate of Ireland is the Atlantic Ocean. The prevailing west winds blowing over the broad expanse of water are tempered by the influence of its comparatively warm surface, so that the mean winter temperature of Ireland, ranging from 40° F. to 45° F., is 20° F. to 30° F. higher than that of places on the same parallels of latitude in America and in west Russia. The influence of the equable sea climate is also very pronounced in summer, the mean summer temperature of Ireland, 59° F. to 62° F. being from 5° F. to 10° F. lower than that of east Prussia. Ireland has the greatest advantages, both as to temperature and rainfall, that an insular climate affords. It also has the disadvantages, as, e.g., the unpleasant damp winds that sweep in from the ocean and the fog and mist that hang around the flanks of the hills. In the south the average sunshine is 1400–1600 hours per year, while in the north this diminishes to 1200. The large average rainfall clothes Ireland with the vivid garb of green that has made it known as the Emerald Isle. The rainfall, averaging 40 inches per year, is quite uniformly distributed; the western hills, averaging a trifle higher than the central plains, do not stop the rain-bearing winds.

Soils. The fertility of Irish soils has long been recognized. About half of the island is formed of limestone, whose soils are proverbially rich. The red marls, calcareous grits, slate, and igneous rocks have also contributed fertilizing elements. The fact that the former glacial conditions transported the rocks of many localities and mixed them with those of others has, as in England, been very beneficial to the agricultural interests. Thus limestone detritus from the central plain was spread over hundreds of thousands of acres outside of it, contributing elements of fertility which the local rocks did not possess. In some regions the soil is naturally poor, and in many others bad tillage or overcropping has reduced fertility. Bog and barren mountain lands cover about one-fifth of the total area.

Flora. The Irish flora consists largely of English migrants, and England in turn derived most of her flora from the neighboring continent. The sedges, rushes, and ferns are most abundant in the wetter west. Grass is by far the largest product of the soil in every county of Ireland.

The pastoral lands (permanent grass) include about four-fifths, and the arable lands (cereal, root, and fibre crops, and hay under rotation) one-fifth, of all lands utilized for agricultural and stock-raising purposes. The forests (chiefly oak and beech in the lower grounds and birch and pines in the higher regions) cover only a very small part of the area.

Fauna. The fauna differs in no marked degree from that of England or France and is largely a thing of the past. The great Irish deer and the garefowl (q.v.) were exterminated in prehistoric times, and since civilization began Ireland has lost its bear, wolf, wild cat, beaver, native cattle, and other species of mammals and birds. Nothing remains except the small rodents of the woods and fields and such small birds as belong to the fields, gardens, and seashore. The popular saying that there are no snakes in Ireland is true, but there are none in Scotland and only two species in England. The only reptile is the lizard. British standard works on natural history cover Ireland, but it has had also a special treatise of high repute in Thompson, *Natural History of Ireland* (London, 1849–51). The fact that there are fewer species both of plants and animals common to the Continent and Ireland than to the Continent and Great Britain points to an earlier separation of Ireland from Great Britain than of Great Britain from continental Europe.

Geology. The central plain of Ireland is underlaid by limestone strata belonging to the basal portion of the Carboniferous system. Upper Carboniferous rocks, including the coal measures, were originally developed on an extensive scale, but they have been removed by erosion and are now found in only a few localities. The highlands bordering and partially inclosing the central plain have a more varied character. In the northwest—in Donegal, Derry, Mayo, and the District of Connemara—the mountain axis consists of crystalline rocks, which give way on the flanks to upturned Paleozoic sediments. This structural type is repeated in the southeast, in the highlands of Leinster. The northern counties are floored largely by Silurian rocks, although there are small areas where the Permian, Cretaceous, and Triassic formations outcrop. The Giant's Causeway (q.v.) and the bold cliffs of the north coast owe their character to basalt intrusions. In the southwest highlands the Old Red Sandstone appears along the central ridges, which are the axes of anticlinal folds, while the synclinal folds consist of Carboniferous limestone.

Mining. Irish coal resources are insignificant compared with those of Great Britain—a fact which has placed Ireland at a serious industrial disadvantage. During the last years of the nineteenth century about 24 mines were in operation, employing 1000 persons and yielding about 125,000 tons annually; in 1913 the output was 82,521 tons, of which County Kilkenny furnished 48,082 tons. The coal mines employed 576 persons underground and 194 above ground. The greater part of the output of coal is of the anthracite variety. The iron-ore resources are more considerable, but in the absence of coal have not been extensively exploited. The annual output during the last years of the nineteenth century was about 100,000 tons. In 1913 the output was 60,014 tons, almost the whole of which was mined in County Antrim. The mining of copper, which was of some im-

portance for many years, has almost ceased, only 778 tons of ore being mined in 1912. In 1913 the aggregate value of all minerals was £228,210.

Fisheries. The fishing industry, stimulated by a system of bounties and the necessity of drawing upon the resources of the country in consequence of the growth of population, was very active from about 1800 to 1829, when it employed 64,771 men, but the cessation of the bounties in that year caused a decline. Still more disastrous was the result of the famine period (1846), due to the blight and failure of the potato crop, and only in recent years has there been a revival in the industry. Deep-sea and coast fishing employed 4827 vessels and 19,523 men in 1912, as against 6458 vessels and 24,528 men in 1881. The total annual value of the catch, including shellfish, fluctuates about £400,000. It was £280,945, excluding shellfish, in 1913. Salmon fishing is pursued along the rivers and coasts, employing from 12,000 to 14,000 men and yielding an annual product of about £300,000. The haddock fisheries are carried on in the region to the east of the Leinster coast, hake fisheries on the south coast, and mackerel on the west coast. The revival of the fishing industry has been greatly encouraged by the government as one of the means of bettering the conditions of the poverty-stricken population. Piers and harbors have been built for the benefit of fishermen, money loaned them, and their interest protected by close inspection.

Agriculture. As a result of natural and historical conditions, the industrial activity of Ireland is largely confined to agriculture. Few countries have so large a percentage of area adaptable for cultivation. Most of the waste lands are in the mountains of west and south Ireland, though there is still much unreclaimed

from the English markets. Later these restrictions were removed, and the high prices of the Napoleonic war period gave a decided impetus to agriculture. During the first part of the nineteenth century there was a general movement towards the division of the farms into small holdings—the result largely of the landlords' desire to secure greater political strength through the increase in the number of ballots, and of the extensive practice of subletting indulged in by the middlemen.

The potato blight of 1845 precipitated a crisis, and important changes date from this event. In great measure it marked the beginning of the end of the small holding and the change from tillage to pasturage. The repeal of the Corn Laws aided in the relief of the Irish, but later so diminished the value of Irish cereals in the English markets that the landlords in the lowland regions evicted their tenants and turned the lands into pasture fields. The evicted tenants had to seek a location in the less desirable regions. In Ulster the tenant fared somewhat better; for there custom had long recognized a sort of tenant right, which operated to restrict the privileges of the landlord. The great diminution of the population through emigration had the effect of providing more labor for those who remained, though too often the location of the laborer was remote from the labor. On the whole the condition of the peasantry improved. But the fact that tenant and landlord were of different race and religion still prevented the development of sympathetic and harmonious relations between the two, and the prevalence of tenantry at will resulted in an aggravating uncertainty of tenure and prevented the discouraged tenant from making such effort to improve his holding as his

HOLDINGS (IN ACRES)

PROVINCES	Not exceeding 1 acre	From 1 to 5 acres	From 5 to 15 acres	From 15 to 30 acres	From 30 to 50 acres	From 50 to 100 acres	From 100 to 200 acres	From 200 to 500 acres	Above 500 acres	Total
Leinster	30,644	17,338	24,946	22,253	15,496	14,434	6,928	2,731	436	135,206

boggy area in the lowlands. The lowland region is naturally of a high degree of fertility. The climate is warm and humid, and consequently favorable to the growth of most plants, though the humidity is too great in some regions to allow wheat to ripen properly. While the country is favored by nature, the Irish system of agriculture does not result in the general welfare of the people, as may be understood in a study of Irish history. One of the features of the English subjugation of Ireland was the confiscation of the greater portion of the land and the granting of it in large dimensions to English citizens. These in many instances were nonresidents, and even when residents they did not always succeed in establishing cordial relations with the tenantry, who were not forgetful of the manner in which the landlord (as a class) came to his possession. During the eighteenth century Ireland was placed under the ban of the English commercial and colonial policy, and Irish agricultural products were excluded

interests demanded. Accordingly the land question persisted and became more serious. Relief was sought through the legislative Act of 1870, granting compensation for improvements and for the disturbance occasioned by removal, and through the Act of 1881, which provided for a fair rent, fixity of tenure, and free sale.

The period for which rent might be fixed according to the Law of 1881 was 15 years, at the conclusion of which time it might be fixed again for another 15 years. From 1881 to 1900 the number of holdings for which the rent was fixed for the first 15 years was 328,720, embracing 9,859,970 acres, the per cent of the reduction in rent being 20.8. Those upon which rent was fixed for the second 15-year period during that time was 52,396, embracing 1,432,615 acres, upon which there was an additional rent reduction of 22 per cent.

Still more radical was the policy of enabling the peasant to purchase land. The government advances money for the purchase, and the peas-

ant pays the government in annual installments for a term of years. In accordance with the Acts passed from 1870 to 1896, there had been advanced for land purchase, up to March 31, 1913, the sum of £24,779,176, and 2,508,937 acres of land purchased. Under the Laws of 1903 and 1909 the moneys advanced totaled £59,163,128, and the area purchased, 5,725,984 acres. For further particulars, see IRISH LAND ACTS.

The table on page 333 gives the number of holdings by provinces, grouped into nine different classes (1912).

Compared with 1904, there has been a decided increase in the holdings of less than one acre (11,750), and an increase in the groups of 50 to 100 acres, and above 500 acres. Farms in the group 30 to 50 acres increased in number 2366; 50 to 100 acres, 1575; 100 to 200 acres decreased 205 in number; and the number in the group above 500 increased 66. The 1 to 5 acre group increased 81 in number; the group 5 to 15 acres decreased 532, and the group 30 to 50 increased 2366.

With regard to the change from tillage to pasturage since the famine, the decrease was greatest for cereals. This acreage was 2,832,564 in 1855 and only 1,265,687 in 1912. The decrease in the green crops was also large, the total acreage being 1,444,390 in 1855 against 1,022,089 in 1912. The meadow crops increased during the same period from 1,314,807 to 2,487,349 acres. The following table shows in more detail the changes which took place in the period 1855 to 1912:

YEAR	Oats (acres)	Meadow (acres)	Wheat (acres)	Barley (acres)	Flax (acres)	Potatoes (acres)	Turnips (acres)	Mangold and beet-root (acres)	Total (acres)
1855.....	2,118,858	1,314,807	445,775	226,629	97,075	982,301	366,953	22,567	5,574,965
1890.....	1,221,013	2,093,634	92,341	182,058	96,896	780,801	295,386	46,457	4,808,586
1901.....	1,099,335	2,178,592	42,934	161,684	55,442	635,321	289,759	77,457	4,540,524
1905.....	1,066,806	2,294,506	37,860	154,645	46,158	616,755	282,105	72,570	4,571,405
1912.....	1,046,000	2,487,349	44,855	165,367	55,062	595,184	271,771	81,700	4,747,288
Per cent increase or decrease, 1855-1912	-50.6	+89.2	-89.9	-27.0	-43.3	-39.4	-25.9	+262.8	-14.8

It will be seen that the largest actual decrease was shown by oats, but the largest per cent decrease was in wheat, the growing of the latter crop having become altogether unimportant. The continued decrease in the cereal crops in the last third of the nineteenth century is attributed to the fall in price of those commodities

crops, 28,383. In 1913 the area under wheat decreased to 34,004 acres; that under potatoes to 582,303 acres; the differences shown by other crops are negligible.

In 1912 the area under crops, including clover, sainfoin, and grasses for hay amounted to 3,570,676 acres; under permanent pasture, 9,685,358 acres; under small fruit, 15,218 acres; under woods and plantations, 298,735 acres; under bog waste, barren mountain, water, and marsh, 5,761,611 acres.

Stock Raising. The increased importance of stock raising since the middle of the nineteenth century is shown from the fact that the number of cattle per 1000 acres of the total area increased from 143 in 1851 to 230 in 1901, while the number of sheep per 1000 acres increased from 102 to 215, and the number of hogs increased from 52 to 60 during the same period; while in 1913 the proportion per 1000 acres was cattle, 242; sheep, 178; hogs, 52. The large number of cattle is particularly noteworthy, there being in Ireland more head, area for area, than in any other European country. The short-horned variety predominate. The second table on this page shows the number of the different varieties of domestic animals for 1881 and 1913.

A peculiarity of stock raising in Ireland, especially cattle raising, is that a large proportion of the animals marketed each year are not prepared in Ireland, but are shipped to Great Britain for that purpose. Ireland is Great Britain's greatest single source of foodstuffs. Of meat alone, including animals for slaughter, the

exports from Ireland to England are valued at \$112,000,000 and form from one-third to one-half of England's total imports in this line. In August, 1914, the fancy prices paid for cattle induced many Irish farmers to sell live stock which should have been kept to replenish the supply next season. Ireland is not excelled in

YEAR	Horses	Mules	Asses	Cattle	Sheep	Pigs	Goats	Poultry
1881.....	534,873	26,392	187,143	3,956,595	3,256,185	1,095,830	266,078	13,972,426
1913.....	614,482	30,338	243,339	4,932,625	3,620,724	1,060,360	246,348	25,701,342

resulting from foreign competition, together with the superior adaptability of Irish soil for pasturage. Cereal production is carried on in all the provinces, but oats are most important in Ulster, and the raising of barley is largely centred in Leinster. Potatoes still constitute the most important food staple grown in Ireland; the average acreage, however, has fallen off nearly one-third since 1850. The area under crops not mentioned in the table, in 1912, was as follows: rye, 7765 acres; beans, 1421; peas, 279; carrots, 1332; parsnips, 651; cabbage, 37,950; vetches, 2008; rape, 3110; other green

the production of the hunter type of horses, this type being raised mainly in the country south of the Boyne River. Heavy cart horses are raised principally along the eastern seaboard from Wexford to Londonderry. On the western seaboard, especially in Galway and Mayo, ponies are the predominating breed. The raising of horses for general purposes is more widely distributed, with Ulster in the lead. It will be seen from the second table that the rapidly growing poultry industry has attained large proportions. A significant development latterly has been the growth in agricultural

coöperation. There was one coöperative society in 1890; in 1908 there were 292 dairy and agricultural societies, with 57 auxiliaries; 168 agricultural societies; 267 coöperative banks; 24 poultry societies; 59 miscellaneous societies; and 4 federations—making a total of 871 societies, having an aggregate membership of 81,710 and an annual trade turnover of £2,476,000. Ulster leads in the movement; Leinster falls furthest behind.

Manufactures. The manufacturing industries are of comparatively little importance. The adverse conditions imposed upon them in former centuries by the British government hampered their development, and the absence of local coal resources and the general non-prosperous condition of the social life of the country have limited its development in recent years. The history of the manufacturing industries, however, is a record of long and desperately continued struggle and is not without its periods of success. In scope the industries have been largely confined to the textiles—wool, linen, and silk. Prior to the time of Charles II manufactures of Irish woolens were well known in many colonial and foreign markets. But the navigation acts in the reigns of Charles I and II cut Ireland off from the British market, while those of William III severed Ireland from all foreign markets. The country could only export woolens to the English markets under heavy duty, thus limiting it practically to the local home market. When the American Colonies revolted, these restrictions were removed. But by this time the industry had secured so great a lead in England that, with the additional advantage given to the latter country through the abundance of coal which now began to supply power for the industry, Ireland was not able to regain its former prominence. The best known of the Irish woolens are the tweeds. They are noted for their durability. In 1907 there were 4461 persons employed in the manufacture of woolen, worsted, and shoddy goods. In 1907 the total production of this industry was valued at £769,000.

The manufacture of linen by the Irish was not at first so detrimental to English interests as was the manufacture of woolens, and it fared much better at the hands of the government. Indeed, for a period, the linen industry became prominent as the woolen industry decreased. The Lord Deputy Strafford and his successor, Ormond, did all within their power to encourage the industry, as did both the Irish and the English parliaments—the latter allowing the products to enter England free of duty. The superior methods of manufacture in vogue in France and the Netherlands were studied, and attempts were made to induce skilled workmen from these countries to migrate to Ireland. With these and other advantages the industry increased, but only at last to excite the ill will of England, which closed its markets to many varieties of the Irish products, and thus seriously hampered the industry, in spite of the generous aid it continued to receive from the Irish government. The wet-spinning process of linen manufacture was introduced between 1825 and 1830, and the factory system grew rapidly. The extreme moisture in the atmosphere gives to Irish linen that delicate whiteness which is unobtainable in any other country. The number of spindles used in its manufacture increased from 396,338 in 1850 to 826,743 in 1879, since which time they have

not greatly increased, having been 835,100 in 1900. The power looms, however, increased from 21,177 in 1880 to 32,245 in 1900. In 1907 the linen and hemp industry employed 1505 salaried persons and 70,944 wageworkers, of whom 68 per cent were women. Its products were valued at £13,354,000, distributed as follows: spinning, £5,779,000; weaving, £6,214,000; making-up, £1,361,000.

The manufacturing establishments are almost wholly centred in Ulster. The shirt-manufacturing industry has become very important in Londonderry County. Huguenots immigrating to Ireland after the revocation of the Edict of Nantes introduced the manufacture of silk, and for a time it enjoyed considerable prosperity, but it almost died out before the middle of the nineteenth century. In the early part of the nineteenth century a large number of factories changed from linen to cotton manufacture, and over 100,000 spindles were at one time used in the latter industry. But with the introduction of flax-spinning machinery the manufacture of cotton practically ceased. Owing to the small number of cotton factories, the British census of production does not give separate data on the cotton industry in Ireland.

Shipbuilding is a long-established industry and became especially prominent during the last three or four decades of the nineteenth century. Belfast is the centre of the industry; the principal yard at this place employed more than 10,000 men in 1913 and produced a larger annual tonnage than any other yard in the world. The whole fleet of the White Star Line, including the *Oceanic*, the *Celtic*, and the *Cedric*, were built at this yard. Shipbuilding on a small scale is carried on at Haulbowline and has been recently revived at Londonderry and Dublin. The milling industry is steadily declining. The number of mills decreased from 1482 in 1891 to 1351 in 1901, and their average output also diminished. Importations of flour increased in amount during this time, and importations of wheat decreased. Prior to 1870 there was a thriving leather industry, but machine methods were not adopted, and it has become insignificant.

According to the British census of production for 1907, the principal Irish industries, employing 291,304 persons (except outworkers), produced goods valued at £66,000,000 sterling. The production of the chief groups was as follows: food and drink trades, £27,335,000; textiles (except cotton), £15,836,000; brewing and malting trades, £5,906,000; iron and steel, engineering, and shipbuilding trades, £5,814,000; clothing trades, £5,190,000; public utility services, £2,904,000; spirit distilling, £1,416,000 (brewing and distilling are included in the food and drink trades).

The home industries are still widely spread through Ireland and, in the aggregate, contribute largely to the well-being of the people. Important among these home industries are hand knitting, hand embroidery, and lace making.

The brewing and distilling branches have become the most important of the Irish industries, whether estimated with respect to the number of persons employed or the value of the product. The output of the distilleries increased from 4,801,000 gallons in 1861 to 14,221,520 in 1901, but decreased to 9,723,815 gallons in 1911. It is somewhat less than the output of English distilleries and equals nearly one-half that of

Scotland. The production of beer increased from 1,437,703 barrels in 1861 to 3,762,629 in 1911, the latter figure being somewhat more than one-tenth the total output of the United Kingdom for the same year. Irish beer is remarkable for its purity, being made almost exclusively from malt. The largest part of it consists of porter, which first became the popular drink between 1850 and 1860.

Transportation. The railway system has been constructed, owned, and controlled by private capital. The system is peculiar on account of its large number of small lines, controlled by separate companies, though a tendency towards consolidation has been noticed in recent years. Since 1849 the main lines have had a uniform gauge. The total mileage increased from 1988 in 1871 to 3403 in 1912. The principal lines are the Great Southern and Western, the Midland Great Western, the Great Northern, and the Northern Counties. The number of passengers carried increased from 15,547,934 in 1871 to 22,202,258 in 1891 and 29,162,000 in 1912. The tourist traffic is comparatively large and receives special attention. Ireland has 173 miles of tramways and light railways and 848 miles of canals and canalized rivers, of which 95 miles belong to railways.

Commerce. Irish commerce is mainly with Great Britain and consists of the exportation of raw products and the importation of manufactured articles. The exportation of live stock leads and constantly increases as the pastoral industry grows in importance. Exports of fish are also important. The leading manufactured article exported is linen. Whiskies and beers are also shipped in considerable quantities. The exports to foreign countries and British possessions are quite small. The imports from foreign countries and British possessions, however, are considerable and are rapidly growing in importance. These consist largely of grains—corn and wheat—from the United States and flax and tow from Belgium and Russia. The value of the total imports in 1912 amounted to \$355,931,522, and of the exports, \$329,104,450. Of the total value of the imports, 36 per cent represented articles of food and drink, 49 per cent manufactured goods, and 15 per cent raw materials. About \$107,000,000 worth of farm products were imported. Of the exports, 52 per cent represented articles of food and drink, 41 per cent manufactured goods, and 7 per cent raw materials. The leading imports were: maize, \$20,655,455; wheat, \$16,060,044; wheat flour, \$12,588,637; coal, \$14,551,166; cotton goods, \$25,685,596; drapery, \$23,942,382; raw cotton, \$4,857,516; boots and shoes, \$8,342,651. The leading exports were: linen goods, \$68,158,428; linen yarn, \$7,910,793; live stock, \$59,987,478; butter, \$20,244,504; eggs, \$14,242,211; bacon and hams, \$20,538,421; ales and liquors, \$17,348,151; ships, \$16,358,739; cotton goods, \$12,969,145. The trade policy of Great Britain applies uniformly to Ireland. Only a few articles like tea, tobacco, sugar, and liquors are subject to import duties. For a discussion of the tariff duties, see *Finance*, under UNITED KINGDOM.

Shipping. The largest part of the trade of Ireland is through the ports of Belfast and Dublin. Belfast leads, both in the amount of foreign and of the total trade. The export trade of Ireland to foreign countries is mainly carried on through Liverpool and Glasgow. In

1912 Ireland owned 897 ocean-going vessels of 401,597 tons net. In the same year there arrived at the ports of Ireland 1716 foreign vessels, with a tonnage of 5,538,740 and 29,936 coasting vessels, with a tonnage of 7,410,829. In the trade between Great Britain and Ireland 26,993 vessels, of 6,964,235 tons, arrived at the ports of Ireland.

Banks. Ireland has nine banks, all of which are joint-stock and six of which are note-issuing. They have all adopted limited liability, except the Bank of Ireland. The authorized issue of notes may be exceeded if specie is held equal to the amount of the excess. The Bank of Ireland manages the public debt of Ireland free of charge. In 1865 the interest on advances to the government was reduced to 3 per cent. In January, 1913, there were also 683 branch banks. The total capital, reserve, and undivided profits of these institutions were £11,643,000, deposits and current accounts, £66,901,000, loans and discounts, £47,161,000. The cash money in hand and at call and short notice was £14,030,000, and the circulation, £7,228,000.

Savings Banks. Trustee savings banks were established early in the nineteenth century, and post-office savings banks in 1861. The greater security afforded by the latter has made them more popular, and deposits in them have become over three times as great as in the former. According to the Savings Bank Act of 1893, the maximum amount which each depositor might deposit in one year was raised from £30 to £50, and the annual maximum amount of stock which might be purchased, £100 to £200; the stock-holding limit was increased from £300 to £500. As a result, the total deposits increased. In 1893 the trustee savings banks contained £1,380,718 deposits; in 1900, £2,035,000; in 1913, £2,652,018. The deposits in the post-office savings banks increased from £663,000 in 1870 to £3,585,000 in 1890 and £13,161,895 in 1913. In 1913 the number of open accounts in the trustee savings banks was 56,867; in the post-office savings banks, 479,873 accounts were active and 199,350 "dormant," the latter being accounts with balances less than £1 and inactive for five years or more.

Coöperative Credit Associations. The want of capital sufficient to secure an improvement of conditions in the poorer rural sections of the west and south of Ireland led to the establishment (1895) of coöperative credit associations upon the Raiffeisen system, through which money is loaned. In 1912 the number of such "banks" was 308, but only 176 were really active; 110 of these held £32,350 of members' deposits. In a report issued on May 20, 1914, a select committee of the Department of Agriculture and Technical Instruction for Ireland recommended the promotion of limited liability societies to take the place of these credit unions.

Government. The chief executive officer for the government of Ireland is the Lord Lieutenant, who is assisted by a Privy Council. He is the personal representative of the crown, and as such occupies a viceregal position, the maintenance of which is his chief function. For this purpose he receives a yearly allowance of £20,000. The actual conduct of the government devolves upon the Chief Secretary for Ireland, who is President of the Irish Local Government Board, a member of the House of Commons, and, when Irish affairs are prominent in the debates, is a member of the cabinet, and as such

is chiefly responsible to Parliament for the manner in which the government of the island is administered.

Since the Act of Union (1800) Ireland has been without a parliament of its own, but is represented in the British House of Lords by 28 temporal peers chosen by the whole body of Irish peers, and in the House of Commons by 103 commoners chosen by an electorate substantially the same as that by which English commoners are elected, viz., a household and lodger franchise. (See UNITED KINGDOM.) The agitation for Irish Home Rule was finally brought to a successful issue in 1914. Owing to the European War, however, the carrying out of the measure was postponed until September, 1915.

The judicial system of Ireland is modeled upon that of England, and the Irish courts administer English municipal law. The chief judicial tribunal of the island is the Supreme Court of Judicature, which has two divisions—the High Court of Justice and the Court of Appeal. There are also a High Court of Admiralty, a Court of Bankruptcy, and a Land Commissioner's Court. The House of Lords is the final court of appeal from the decisions of the Irish courts. Minor offenses are tried by two justices of the peace.

Local government in Ireland has been revolutionized by the Irish Local Government Act of 1898, which undertook to collect, simplify, and adapt the mass of English and Irish legislation on the subject. Until then the chief county authority was the grand jury. By the Act of 1898 this was replaced by a popularly elected council, chosen for a term of three years. The lower administrative units, boroughs and urban and rural districts, were likewise given elective councils. Affairs formerly attended to by grand juries and presentment sessions, such as relate to poor relief, highways, public health, and local institutions, are now administered by the councils. The larger cities were erected into county boroughs, which are exempt from certain of the provisions of the Local Government Act.

Incorporated boroughs have a mayor, aldermen, and council, while those which are unincorporated are governed by commissioners. The borough councils have charge of such local matters as lighting, watching, sanitation, etc. The local councils are all subject to the supervisory authority of the Local Government Board, consisting of the Chief Secretary, the Undersecretary, and four commissioners. It advises, directs, and controls the action of the councils in many particulars. It approves or rejects the appointment of officials nominated by the councils, fixes salaries, and regulates their term of service. The four commissioners of the board are appointed by the Lord Lieutenant and receive large salaries for their services.

Finance. The Imperial British system of finance is applied to Ireland in practically the same way as it is to the other parts of the kingdom. In the union with Great Britain, Ireland became burdened with a share of the responsibility for a large national debt, which it had had no hand in making. The Irish generally maintain, and many financiers admit, that the burden which the Imperial revenue inflicts upon the country is out of proportion to its wealth, and this claim constitutes one of the most serious grievances of the Irish Nationalists. According to the royal commissioners' report (1896) on the financial relations of Ireland to Great Britain, the taxable capacity of Ireland

was only $\frac{1}{20}$ that of Great Britain or less, whereas the revenue collected was about $\frac{1}{11}$ of the amount raised in Great Britain. A comparison of Ireland with England and Wales shows that the per capita receipts from the income tax in the latter is almost four times that in Ireland. Assuming that the income tax returns are a fair test of the relative financial capacities of the two countries, the injustice wrought by the indirect taxes is striking, since the per capita amount of these is only a little less in Ireland than in England and Wales. The proportion of the direct to the indirect taxes in England and Wales is as 56 to 44, whereas in Ireland it is as 31 to 69. The figures given below indicate the great importance of the excise duties. It is this item particularly that seems to be overburdensome.

The following figures give the amount of the Imperial revenue collected in Ireland in the fiscal year ending March 31, 1913: customs, £3,166,000; excise, £3,259,000; estate, etc., duties, £987,000; stamps, £372,000; income tax, £1,484,000; land value duties, £5000; post office, £963,000; telegraphs, £190,000; crownlands, £21,000; miscellaneous, £120,500. The Imperial expenditures in Ireland for the same year were: civil government, £8,816,000; collection of taxes, £299,000; post office, £1,559,000; paid to local taxation accounts, £1,463,000. The taxes on real property are the principal source of local revenue. In the fiscal year 1910–11 the local receipts were as follows: rates, water, gas, and electric light, £4,217,555; tramways and light railways, £218,301; tolls, dues, etc., £422,386; rents, interest, etc., £289,302; government contributions, £1,364,328; loans, £1,788,354; miscellaneous, £476,028. The principal branches of local expenditures for the same year were: town and municipal authorities, for police, sanitary works, etc., £2,957,574; unions and parishes for poor relief, £1,365,383; county, rural, sanitary, and road authorities, £3,640,088; harbor authorities, £529,853; other authorities, £154,494.

Population. Owing to its insularity and its position on the extreme outskirts of Europe, Ireland received only the ebb flow of the great European migrations, and its population is therefore relatively simple in composition. Three major types are usually recognized. The most primitive is a short black-haired, brown-skinned, dolichocephalic race, sometimes called Firbolg in accordance with Irish tradition, which has been variously defined by anthropologists as Neolithic and non-Aryan, or again as Iberian or a branch of the Mediterranean race. The conquerors of this people were a tall and blond race known in Irish traditions as the Tuatha De Danann. It is not known whether the Tuatha De Danann (q.v.) were a Scandinavian or Celtic-speaking people. They were followed by the Gaelic invasion, probably within historic times—a Celtic-speaking race identified with the predominant Irish type of the present day. Stature and cephalic index in Ireland to-day vary little from the characteristic type of England and Scotland, and the Irish people is discriminated from the English and Scotch mainly on grounds of pigmentation (as among the so-called "black Irish"), language, and temperament. Not taking into consideration the different early immigrants, such as the Scandinavians and the Anglo-Normans, which were largely assimilated with the original stock, there are to-day three fairly distinct racial elements represented in

Ireland, a fact which is responsible in a measure for the social and political troubles which have long disturbed the country. By expulsion and by extermination the population had been considerably reduced by the end of Cromwell's reign, when the number was estimated at but a little over half a million. The depopulated districts of east and north Ireland were re-peopled by settlers from England and Scotland respectively, and the English became the land-owners throughout the other portions of the island. Until after the middle of the eighteenth century the population grew but slowly, being not infrequently checked by the ravages of famine. But towards the end of that century different causes conspired to bring about a rapid increase in the population. Chief of these was probably the universal adoption of the potato as the main staple of food, the plant giving more returns for the amount of area and labor devoted to it than other plants and being well suited to the needs of the people. Connected with this was the increased impetus given to industry in general during the wars with France, and also the decided tendency which developed at this time towards the division of the land into leaseholds, making the acquisition of a holding easy. Under these influences marriages were entered into early and families were large. Whereas, in 1785, estimates place the population at less than 3,000,000, in 1821 the first official census records the population at 6,800,000, and the census of 1841 showed a population of 8,196,000. Considering that the population was almost wholly rural in composition, it was much in excess of that which a healthy economic and social status would permit.

The sequel was precipitated by the potato blight in 1845. This resulted in a large number of deaths from starvation and disease, but its greatest significance was the starting of the tide of emigration which has continued to depopulate the island to the present time. Prior to the Revolution in the American Colonies the Scotch-Irish element of northern Ireland had found its way to the Colonies in large numbers, but not until the time of the famine did the movement affect the Celtic element. It is estimated that in round numbers there were 2,000,000 Irish emigrants between 1840 and 1860, and 1,000,000 in each of the following 20-year periods, most of whom went to the United States. In the aggregate the male emigrants exceed in number the female, though the contrary is true for the Province of Connaught. During the year 1911 the emigrants leaving Ireland numbered 49,280. The births usually exceed the deaths by 27,000 to 29,000 annually. The following table gives the population by provinces for each decade since 1851 and the per cent of increase or decrease of each for the last decade:

POPULATION FROM 1851 TO 1911

PROVINCES	1851	1861	1871	1881	1891	1901	1911	Per cent
Leinster	1,682,000	1,457,000	1,339,000	1,279,000	1,192,000	1,153,000	1,162,000	+0.80
Munster	1,860,000	1,513,000	1,393,000	1,331,000	1,174,000	1,076,000	1,035,000	-3.78
Ulster	2,014,000	1,914,000	1,833,000	1,743,000	1,620,000	1,583,000	1,582,000	-0.07
Connaught	1,012,000	913,000	846,000	822,000	719,000	647,000	611,000	-5.56

In 1911 there were 2,192,048 males and 2,198,171 females, a total of 4,390,219. It will be seen that Munster and Connaught have each declined much more than one-third during the

period, and the rate of decrease still continues high in those provinces, while Leinster for the first time shows a slight increase.

The average population per square mile is 135, or less than one-fourth that of England and slightly more than that of the State of Maryland. The loss of population has been in the rural districts, the urban population having held its own. The following table shows the population of cities above 25,000 for 1891, 1901, and 1911:

CITIES	1891	1901	1911
Belfast.....	255,950	349,180	386,947
Dublin.....	245,001	290,638	304,802
Cork.....	75,345	76,122	76,673
Londonderry.....	33,200	39,892	40,780
Limerick.....	37,155	38,151	38,578
Rathmines and Rathgar*.....	27,796	32,602	37,840
Pembroke*.....	23,992	25,799	29,294
Waterford.....	20,852	26,769	27,464

* Dublin suburbs.

While the density of population is no longer excessive, even for a country largely agricultural, a large number are scarcely able to secure a livelihood. Certain regions are known as congested districts, and a special board has been created to aid the people and improve conditions. The explanation lies in the fact that the tenants have been evicted from the more fertile regions (see *Agriculture*) and have segregated in the less fertile broken regions, especially in the western Province of Connaught, where the small holding of the peasant does not afford sufficient livelihood for the family, and large numbers are annually obliged to leave their homes during the harvest months and supplement their income by labor in the harvest fields of Scotland and England. The landowning class, or the old aristocracy throughout Ireland, as also the greater part of the well-to-do trading and professional classes, belong to the English element. In Ulster a part of this class belongs to the Scotch element, but a majority of the Scotch are artisans or cotters, whose economic standard of life is somewhat higher than that of the Celtic element, the latter belonging almost entirely to the peasant and the laboring classes. According to the census of 1911, there were 141,134 persons belonging to the professional class, 170,749 to the domestic class, 111,143 to the commercial class, 780,867 to the agricultural class, 613,397 to the industrial class, and 2,572,929, mainly children, to the indefinite and non-productive class.

The Irish language was almost universally used in the rural districts by the Celtic element until about 1835. Considering the resentment which the Celtic element has always held towards

the British, the general change from the Irish to the English language was remarkable for the little opposition that was made to it and the rapidity with which it was accomplished. In

1881, 18.2 per cent of the population could speak Irish; in 1911 only 13.3 per cent (582,446). The percentage is naturally greatest in Connaught and Munster, where the percentages in 1911 were 34.0 and 21.8 respectively (over half of the population of Galway and Mayo were able to speak Irish), while in Ulster the percentage was only 5.8, and in Leinster 3.5. In 1911 only 16,873 persons were reported who spoke Irish only. In very recent years a movement has been started to popularize the Irish language again. In the first decade of the twentieth century the number who were able to speak the Irish language decreased for the country as a whole, though the number increased more than 52 per cent in Leinster and about 4 per cent in Ulster.

Religion. That the religious denominations in Ireland correspond very closely to the different racial elements explains in part the social friction which exists in the country. The Celtic Catholic church resisted from the first the attempts of the English to break its connection with Rome and impose upon it the changes which had accompanied the religious revolt in England. The property of the church, of course, continued in the hands of the church that represented the government. Catholics were placed under serious disabilities, not being allowed to teach school or to act as guardians. Priests were obliged to remain in their own parishes and were excluded from public affairs. Tithes were exacted from Catholics for the support of the Established church. The disabilities were not removed until 1829. The tithes were commuted in 1838. When the political union with England was effected in 1800-01, there was also a union between the established churches of the two countries. The union was dissolved and the Irish church disestablished by an Act of Parliament which went into operation in 1871. The Act provided for the surrender of the property and revenue of the church, with the exception of private endowments. Since then the government of the church of Ireland is in the hands of a General Synod which meets annually. There are also 23 diocesan synods. There are 2 archbishops and 11 bishops.

It will be seen from the accompanying table that more than three-fifths of the Episcopalians are concentrated in the Province of Ulster, and the greater part of the remainder are in Leinster. The Scotch who settled in Ulster were mostly Presbyterians. More recently Methodism has secured a hold among them. Presbyterianism was proscribed during the reign of Queen Anne, but with this exception was generally tolerated by the government, and until the disestablishment of the Episcopal church received a small annual bounty. The largest Presbyterian body has 36 presbyteries and 562 congregations.

The table on this page shows the respective strength of the four leading denominations in the different provinces and the tendency of each for the 50 years from 1861 to 1911. It will be seen that even in Ulster the Catholic church outnumbers any of the others, and in the provinces of Munster and Connaught the non-Catholic elements constitute but a very small fraction of the population. The extreme north-east counties of Londonderry, Down, Armagh, and Antrim have a larger non-Catholic than Catholic population.

The Methodists are the only sect that did not show a decrease during the period, while the

percentage of loss was greatest for the Catholics. In the first decade of the century the Catholics lost 2.0 per cent of their membership, the Episcopalians 0.4 per cent, the Presbyterians

PROVINCES	Year	Catholic	Episcopalian	Presbyterian	Methodist
Leinster....	1861	1,252,500	180,500	12,300	6,290
	1911	990,045	140,182	12,866	8,068
Munster....	1861	1,420,000	80,800	4,000	4,430
	1911	973,805	50,646	4,180	4,175
Ulster.....	1861	966,600	391,300	503,800	32,000
	1911	690,816	366,773	421,410	48,816
Connaught..	1861	666,000	40,600	3,088	2,640
	1911	588,004	19,010	2,069	1,323
Total.....	1861	4,305,100	693,200	523,188	45,360
	1911	3,242,670	576,611	440,525	62,382

0.7 per cent, and the Methodists increased 2.0 per cent. The greater decrease of the Catholic population is due to the fact that the Catholics emigrate in larger numbers than the Protestants. See table under *Population*.

Education. In the establishment of an educational system in Ireland, as in many other countries, religion has been a seriously disturbing factor. Such educational advantages as were offered the Irish children by the government were thoroughly dominated by the idea of making them Protestants and essentially British, and consequently these advantages were shunned by all Catholics. At the same time laws passed in the reigns of William III and Queen Anne made it a penal offense for Catholics to teach or to send their children abroad to be educated. Catholic teaching, however, was carried on in violation of the law, such schools being known as hedge schools. A great deal of money from both private and government sources was expended on education during the eighteenth century and the early part of the nineteenth, most of it being expended through the proselyting societies. The Charter schools, founded in 1733, and the Association for the Prevention of Vice, founded in 1800, received government grants, while the London Hibernian Society, founded in 1805, and the Baptist Society, established in 1814, were supported mainly from subscriptions. The Erasmus Smith schools, dating from 1657, were endowed. A Catholic congregation—the Christian Brothers—was founded in 1802 for the purpose of teaching, and later attained considerable importance. In 1811 the Kildare Place Society was founded and after 1814 received government subsidies. This society introduced the policy of limiting religious instruction to Bible reading.

In 1819 the government began to make grants to schools established by voluntary subscriptions without regard to religion. In 1831-34 the so-called national system of education was established. Under this system secular instruction was given to children assembled together without distinction of creed, but it was provided that they should be separated for purposes of religious instruction, which should be given by the pastors of the respective local churches. At first the Catholics took kindly to the system, the Episcopalians and Presbyterians being opposed to it. However, concessions were made to the Protestants, and a proselyting spirit was allowed to creep into the secular teaching. The Catholics were unable to prevent this, owing to their small representation on the board of com-

missioners in charge; while the church condemned it, demanding (1850) separate education and forbidding Catholic children from attending Protestant instruction. In 1861 the Catholic membership upon the board was made equal to the Protestant. At present the system is divided for the most part along denominational lines. The children of the different religious faiths generally go to schools taught by teachers of their own faith. No child is allowed to attend a religious exercise of a denomination other than his own except upon the written request of the parent.

The Irish educational system differs radically from the English, in that the former is so completely under the control of the central administration. The regulating of teachers' salaries, determining the course of instructions, furnishing schools with supplies, including books, and even the erecting of a certain class of buildings, are all matters in the hands of the central board. The provision of textbooks by the state follows from its policy of not allowing religious questions to be raised in secular teaching and from the desire to prevent the fostering of sentiments out of harmony with Imperial unity. The omission of Irish patriotic songs and of Irish history naturally subjects the administration to much criticism. The supervision of the system is secured by dividing the country into districts and assigning an inspector and corps of subinspectors to each division.

Since 1892 there has been a compulsory school law, the compulsory period being from 6 to 14. The law is, however, not well enforced. Illiteracy is decreasing throughout the country, the percentage of persons five years and over who could neither read nor write having decreased from 25.2 in 1881 to 18.4 in 1891, to 13.7 in 1901, and to 9.2 in 1911. Illiteracy is much the most prevalent in Connaught, where in the last year it amounted to 15.2 per cent. The percentage among the Catholics was over twice as great as for any of the Protestant sects. In December, 1912, there was a total of 8255 elementary schools, of which 4397 were Roman Catholic, with 373,154 pupils; 1549 Protestant, with 117,985 pupils; and 2303 mixed, with 177,519 pupils. In that year 74.6 per cent of the enrollment was in average attendance. No special provision is made by the government for secondary schools other than certain grants in aid which are distributed without regard to the auspices under which they are conducted, according to the "payment in result" system. There are seven training schools for teachers, all of which are aided by the government; their attendance in 1912-13 was 1160.

About 94 per cent of the annual expenditure for schools is borne by the state. The system of apportioning the state grant to elementary instruction according to the results of an examination given the pupils was abandoned, and now the grant is based upon average attendance, with the teacher's salary additional, the salary being fixed according to the one of the three grades in which he teaches, though it may be raised within any given grade for "continued good service."

The principal higher institution of instruction is the University of Trinity College, Dublin, which had an enrollment in 1913-14 of 1285 students. The Catholic population have refused to patronize this institution and have sought in vain to secure state maintenance for a Catholic

university. The University College in St. Stephen's Green, Dublin, is under the direction of the Jesuits. There is a National University which only exercises, in the main, examining functions, and a large number of Catholics receive degrees from this institution. Of the three Queen's colleges, at Belfast, Cork, and Galway respectively, only the first is of true university rank. The Presbyterians maintain the McGee College at Londonderry. There are also a number of technical and theological institutions. Alexandra College is for the education of women, and members of that sex are admitted also to the Queen's colleges.

Charities. The poor-law system is similar to that described under UNITED KINGDOM for England and Wales. The adult able-bodied indoor paupers in 1913 numbered 4312, and all other indoor paupers numbered 32,705. The outdoor paupers for the same year numbered 40,129, and the number of inmates of asylums was 1653. Much was done during the last decade of the nineteenth century to improve the conditions of the districts which had long suffered from poverty. A Law of 1821 declared that, when the population of an electoral division exceeded a certain ratio to the ratable value of its property, it should be known as a congested districts county. These districts are wholly in west Ireland—principally in Connaught and in the counties of Donegal and Kerry. A Congested Districts Board was established, and means were made accessible for this board's use in the betterment of conditions in these districts. The system of cultivation practiced in them was found to be most deplorable, and it was generally necessary for the occupants of the holdings to have a secondary source of income, as, e.g., harvest migrations to Scotland and England, as already mentioned. Agricultural inspectors were employed by the board, and much has been done towards improving the soil and the methods of cultivation. Sometimes families are removed to more favorable localities, and not infrequently a number of small holdings are amalgamated into one sufficiently large to maintain a family. The board has done much also to aid in the development of the coast fisheries. The board has powers almost indefinitely wide to aid distressed regions in any manner, and the funds annually at its disposal are about £245,500.

History. According to native legends Ireland was inhabited first by various tribes, of which the most important were Nemedians, Fomorian, Firbolgs, and Tuatha De Danann, who were eventually subdued by Milesians or Scots. Although Ireland is mentioned under the name of Ierne in a Greek poem five centuries before Christ, and by the names of Hibernia and Juvenera in various Roman writers, little is known with certainty of its inhabitants before the fourth century after Christ, when, under the appellation of Scoti, they became formidable by their descents upon the Roman Province of Britain. These expeditions were continued, and extended to the coasts of Gaul, till the time of Lavgaire, or Loigaire, MacNeill (c.430), in whose reign St. Patrick (q.v.) attempted the conversion of the natives. Although Christianity had been previously introduced in some parts of Ireland, Patrick encountered great obstacles, and the new faith was not fully established in the island till about a century after his death.

From the earliest period each province of Ireland appears to have had its own king; accord-

ing to legend these kings were subject to the *ard-ri*, or monarch, to whom the central district, called Meath, was allotted, and who usually resided at Tara. Each clan was governed by a chief selected from its most important family. The laws were dispensed by professional jurists styled *brehons*, who received great consideration and were endowed with lands and important privileges.

In the sixth century extensive monasteries were founded in Ireland, in which religion and learning were zealously cultivated. From these establishments numerous missionaries went forth during the succeeding centuries, while many students of distinction from England and the Continent visited Ireland and received instruction at this period. The progress of Irish civilization was checked by the incursions of the Scandinavians, begun towards the close of the eighth century, and continued for upward of 200 years. Establishing themselves in towns on the east coast of Ireland, with the assistance of friendly native tribes, they continued to make expeditions into the interior until their signal overthrow at the battle of Clontarf, near Dublin, in 1014, by Brian, surnamed Boromhe.

The first step towards an Anglo-Norman conquest of Ireland was made by Henry II, who is said to have obtained in 1155 a bull from Pope Hadrian IV authorizing him to take possession of the island, on condition of paying to the papal treasury a stipulated annual revenue. This bull is probably a forgery. At all events, nothing was done until Dermot Macmurrough (q.v.), the deposed King of Leinster, sought refuge at his court and obtained permission to enlist the services of English subjects for the recovery of his kingdom. Dermot, returning to Ireland in 1169, with the aid of his foreign mercenaries and still more numerous Irish allies, succeeded in recovering part of his former territories and in capturing Dublin and other towns on the east coast. After his death the succession to the Kingdom of Leinster was claimed by his son-in-law, Richard, Earl of Pembroke, surnamed Strongbow. In 1172 King Henry, with a formidable armament, visited Ireland, received homage from several minor native chiefs and from the principal Norman leaders, and granted to the latter charters authorizing them, as his subjects, to take possession of portions of the island, in virtue of the grant made to him by the Pope. The chief Anglo-Norman adventurers, "Strongbow," De Cogan, De Lacy, Fitzgerald, Fitzstephen, Fitzmaurice, and De Courcy, encountered formidable opposition before they succeeded in establishing themselves on the lands which they thus claimed. The government was intrusted to a viceroy, and the Norman legal system was introduced into such parts of the island as were reduced to obedience to England. The youthful Prince John was sent by King Henry into Ireland in 1185, but the injudicious conduct of his council excited disturbances, and he was soon recalled to England. John made a second expedition into Ireland in 1210, to curb the refractory spirit of his barons, who had become formidable through their alliance with the natives. During the thirteenth century the principal Anglo-Norman adventurers succeeded in establishing themselves, with the feudal institutions of their nation, in some parts of Ireland, by the assistance or suppression of native clans. The Fitzgeralds, or Geraldines, acquired almost unbounded power in Kildare and East Munster,

or Desmond; the Le Botillers, or Butlers, in Ormond, or West Munster; and the De Burghs, or Burkes, in Connaught. After the battle of Bannockburn, in 1315, Edward Bruce invaded Ireland and attempted to overthrow the English power there. The Pope, at the instigation of England, excommunicated Bruce with his Irish allies; but although his enterprise failed of success, the general result was a decline of the English dominion in Ireland. The descendants of the most powerful settlers gradually became identified with the natives, whose language, habits, and laws they adopted to so great an extent that the Anglo-Irish Parliament passed, in 1366, the Statute of Kilkenny, decreeing excommunication and heavy penalties against all those who followed the customs of, or allied themselves with, the native Irish. This statute, however, remained inoperative; and although Richard II, later in the fourteenth century, made expeditions into Ireland with large forces, he failed to effect any practical result, and the power and influence of the natives increased so much at the time of the War of the Roses that the authority of the English crown became limited to a few towns on the coast and the district termed the Pale (see ENGLISH PALE), comprising a small circuit about Dublin and Drogheda. In the struggle between the houses of York and Lancaster, Ireland supported the house of York.

The participation of the Anglo-Norman nobility of the Pale in the War of the Roses greatly crippled the English interest. When he came to the throne, Henry VII left Gerald, Earl of Kildare, Viceroy of Ireland, although the Earl belonged to the Yorkist party. The assistance rendered by the Earl to the Yorkist pretenders finally compelled the King, in 1494, to remove him and to send over Edward Poynings to restore order to the Pale. Poynings represented the purely English interest, as distinct from the Anglo-Norman interest, which up to that time had prevailed in Ireland. He at once summoned the Parliament of Drogheda, which enacted most important legislation, providing for the defense of the Pale, reducing the power of the Anglo-Irish lords, and rendering the Parliament and judiciary of Ireland dependent on the English crown. The nobility was forbidden to oppress the inferior baronage, to make exactions upon the tenantry, or to assemble their armed retainers; their influence on the towns was diminished. The Statute of Kilkenny, which compelled the English and Irish to live apart and forbade Irish law and customs in the Pale, was confirmed. All state offices, including the judgeships, were filled by the King, instead of the viceroys, and the entire English law was to hold for the Pale. Most important of all was the so-called Poynings Law, which made the Irish Parliament dependent upon the King. It provided that all proposed legislation should first be announced to the King and meet with his approval, after which he should issue the license to hold Parliament.

Henry VII reestablished the Earl of Kildare, who was the most powerful of the Irish nobility, as Viceroy, and under his rule the Pale grew and prospered. His family, the famous Geraldines, rebelled and were overthrown during the reign of Henry VIII. Henry VIII, in 1537, attempted to introduce the Reformation into Ireland, and the dissolution of the monasteries was begun. Somewhat later, relics and images were destroyed and the dissolution was

completed. The native chieftains were conciliated by a share of the spoils and received English titles, their lands being regranted under English tenure. It was Henry's policy thus to conciliate them and to leave the Irish under their own laws. An English commission held courts all over the island, but Irish right was respected, and the country remained peaceful. This result came about under the wise rule of St. Leger, who was Viceroy during the latter part of the reign. In the Parliament of 1541, attended for the first time by native chieftains as well as the lords of the Pale, Henry's title of Lord of Ireland, which had been conferred by the Pope, was changed into that of King.

The religious changes under Edward VI and Mary had little effect upon Ireland. Although Mary was herself a Catholic, she was the first to begin the colonization of Ireland by English settlers. The Irish people of King's and Queen's County were driven out and their lands given to English colonists. Elizabeth at first followed her father's policy of conciliating the Irish chieftains, but the rebellion of Shayne O'Neill, an Ulster chief, caused a radical change in her policy. An act was passed making all Ireland shireland, and the commissioners of justice were invested with military powers. So far from respecting Irish right, they ignored it altogether. The religious wars of Elizabeth were attended by rebellions of the Irish Catholics. The Earl of Desmond, a representative of the great house of Geraldine, which ruled over the greater part of Munster, was defeated after a long struggle. Hugh O'Neill, called by the English the Earl of Tyrone, annihilated an English army on the Blackwater and baffled the Earl of Essex, whom Elizabeth had sent against him. A Spanish force coming to his assistance made the mistake of landing in the south, instead of in the north, as had been promised, which led O'Neill to make a march of 200 miles through desolate country in order to join them. His forces were too weak to withstand the English in the field, and about the beginning of 1603 he submitted to Lord Mountjoy, but was allowed to retain his earldom. During all these wars the greatest cruelty and treachery were practiced on both sides. In order to destroy Irish resistance, the English devastated the villages, crops, and cattle, putting to death all the inhabitants they could secure. The greater part of Munster and Ulster was laid desolate, and many more perished from hunger than by the sword.

Under Elizabeth and James I the Anglican state church was extended over Ireland, not only obtaining all that belonged to the church of the Pale, but being invested with the establishment belonging to the Celtic church as well. There was an ancient feud between these two Irish churches, and they were intensely hostile to each other. The church of the Pale was effected by the Reformation, but the Celtic church became increasingly Roman. The entire Celtic population of Ireland, and the majority of the inhabitants of the Pale, remained Catholic. The Anglican church thus became a mere instrument in the hands of the English rulers in Dublin Castle.

During the reign of James I the English system was introduced into Ireland on a grand scale. English law was pronounced the sole law of the land. The fight of Tyrone and Tyrconnell gave a pretext for the confiscation of the

land in six counties of Ulster. The independence of the Irish Parliament was destroyed by the creation of 40 boroughs out of small hamlets, which secured a permanent majority to the crown.

The despotism of the Earl of Strafford, the Viceroy of Charles I, produced order and prosperity in Ireland. By balancing the number of Catholics and Protestants in Parliament and holding out to the former the promise of toleration, he succeeded in obtaining liberal supplies for the King in his conflict with the English Parliament. The native Irish, who had been dispossessed by the plantations in Ulster and elsewhere, made use of the English situation to regain their possessions. Under the leadership of Rory O'More, a conspiracy was formed in 1641 to seize Dublin and expel the English. They succeeded in driving the English settlers out of Ulster and committed many outrages, not, however, so many as has been supposed. It has been estimated by English writers that at least 30,000 people were put to death, but this number is certainly exaggerated. The Scotch were, as a rule, spared. The insurgents were soon joined by the Catholic lords of the Pale, and together they chose a Supreme Council to govern Ireland. Charles I sent over the Earl of Glamorgan to treat with them, and the Earl went so far as to promise them the predominancy of the Catholic church in Ireland as the price of their assistance to the King. But the struggle in England was terminated in favor of the Parliament before the Irish Catholics could render effective assistance to the King. In 1647 the alliance between the lords of the Pale, who desired nothing beyond toleration for their religion, and the Celts, who hoped for the restoration of the ancient land system, came to an end. In 1648 the Earl of Ormond returned as the Viceroy of Charles I and made an alliance with the Catholic lords, thus securing Ireland to the Royalist party. In 1649 Cromwell landed at Dublin, which the Catholics had been unable to take. With his well-disciplined army, 10,000 men of the New Model, he stormed Drogheda and put its garrison of 2000 to the sword. At Wexford there was another slaughter. Cromwell's successors, Ireton and Ludlow, finished the war, and a great part of the best lands of Munster, Leinster, and Ulster was confiscated and divided among the soldiers of the Parliamentary army. The Catholics and Loyalist landowners were banished to Connaught. A portion of the land confiscated at this time was restored under Charles II, but at least two-thirds of the land in Ireland remained in the hands of the Protestants. The viceroyalty of Ormond did much to restore order and promote industry, but the Protestant ascendancy was maintained. James II, however, reversed this policy. Under his Viceroy, the Earl of Tyrconnell, Catholics were advanced to positions of state and placed in control of the militia, which Ormond had previously organized. Consequently the entire Catholic population took sides with James II in the English revolution of 1688, and when in 1689 James landed at Dublin with his French officers, Tyrconnell had an Irish army ready to assist him. The Protestant settlers were driven from their homes and found refuge in Enniskillen and Londonderry. James attempted to capture Londonderry, but he was hampered by the lack of artillery, and the city was relieved by way of the sea. His Parliament of 1689 restored all the lands

that had been confiscated since 1641 and passed an act of attainder against the partisans of William III. In the following year William landed in Ireland and in the battle of the Boyne (July, 1690) defeated the Irish forces. He failed, however, to capture Limerick, which was bravely defended. A brilliant sally of the Irish patriot Sarsfield destroyed William's heavy artillery, and he was forced to retire. The next year his generals defeated the Irish army at Aughrim, and Limerick was forced to capitulate. By the terms of the Treaty of Limerick, Catholics were permitted a certain amount of religious freedom, and the lands they had possessed under Charles II were to be restored.

The Parliament of England forced William to break the concession of the Treaty of Limerick regarding the restoration of the lands, and the Parliament of Ireland violated the terms granting religious toleration by enacting the penal laws, directed mainly against the Roman Catholics. The peasants were annoyed by cruel and vexatious restrictions alike on their religious worship and innocent amusements. Irish commerce and industries were deliberately crushed. In 1663, and again in 1696, all Irish trade with the English colonies was prohibited, and in 1665 and 1680 the Irish import trade to England in cattle, milk, butter, and cheese was forbidden. The trade in woolens, which had grown up among the Irish Protestants, was likewise crushed by an enactment of 1699, which prohibited the export of woolen goods from Ireland to any country whatever. Small amends for these injuries were made by leaving the linen trade undisturbed. The result of all these measures was the gradual decline of Ireland. A large percentage of the best elements of the population emigrated—the Catholics to serve in the armies of Spain and France, the Protestants to carry their industries to America.

The American Revolution awakened much sympathy in Ulster, especially among the Presbyterians, who, being disqualified from holding office, desired a general emancipation, including the Catholics. In 1778 the Irish Parliament passed the Relief Act, removing some of the most oppressive disabilities. Meanwhile the Irish Protestants, under pretext of defending the country from the French, who had formed an alliance with the Americans, had formed associations of volunteers, 80,000 strong. Backed by this military force they, under the lead of Grattan, demanded legislative independence for Ireland, and on motion of the younger Fox the British Parliament repealed both the Poynings Law and much of the anti-Catholic legislation. But the Irish Parliament was composed entirely of the Protestants of the Established church, who were unwilling to extend the suffrage, and it was even more corrupt and in need of reform than the British Parliament. The principles of the French Revolution found their most powerful expression in Ireland in the Society of United Irishmen, which organized the rebellion of 1798. The peasantry rose in Wexford and, although miserably armed, made a brave fight. At one time Dublin was in danger, but the insurgents were defeated by the regular forces at Vinegar Hill. A French force of 1100 landed in Killala Bay, but too late to render effective assistance. Pitt, the British Prime Minister, thought a legislative union of the two countries, together with Catholic emancipation, the only remedy for Catholic rebellion and Protestant

tyranny. By a lavish use of money and distribution of patronage, he accordingly induced the Irish Parliament to pass the Act of Union. On Jan. 1, 1801, the Union was formally proclaimed.

The history of Ireland since the Union is the story of a continuous struggle for civic and religious freedom and for separation from Great Britain. Hardly had the Union been carried out when the universal dissatisfaction gave rise to the outbreak of July 23, 1803, under Robert Emmet (q.v.). It was easily suppressed, and for some time there were no further armed revolts. Instead a conflict was carried on along parliamentary lines under the leadership of Daniel O'Connell (q.v.). In 1823 he founded the Catholic Association, which demanded first of all Catholic emancipation. This was finally obtained, for in 1828 Catholics were permitted to hold office, and in 1829 they were allowed to sit in Parliament. The struggle now turned upon the tithes, which all, Catholics included, were compelled to pay for the maintenance of the Anglican church in Ireland. Great cruelties were perpetrated on both sides during the so-called Tithe War, which was coupled with a renewed emphatic demand for the repeal of the Act of Union. O'Connell formed various societies to carry on the agitation, and there was considerable lawlessness, which was fostered by the so-called Ribbon Society. See RIBBONISM.

The reform of Parliament in 1832 aided the Irish leaders, for it increased the number of Irish members from 100 to 105 and, more important still, it gave the middle class more power, in place of the pro-English aristocracy. In 1838 a bill was passed converting the tithes into rent charge, to be paid by the landlords, and agitation in connection with the church ceased to be acute for a time. O'Connell had for a long period been supported by the more extreme of the Irish Nationalists, but in 1843 it became evident that he would never make an appeal to arms. The consequence was the formation of the Young Ireland party, whose leaders were all young men, the most notable being William Smith O'Brien, John Blake Dillon, Thomas Francis Meagher, and John Mitchel. The last named in turn seceded from the Young Ireland party and advocated an Irish republic. For a while Peel, the English Prime Minister, tried concessions, but in vain, the more so as from 1845 to 1847 rent-racked Ireland suffered from a terrible famine, due to the failure of the potato crop. Vast numbers emigrated, especially to America, whither they carried with them the hatred towards England and continued to give effective support to the Irish cause. Many also died, and it is said that in all one and a half million of people had disappeared by 1848. In the latter year the Young Ireland party sought to bring about a revolt, but the whole attempt proved a miserable failure; the leaders were captured and transported.

The work of the Young Ireland party was in time taken up by the Fenian Society (q.v.), which accomplished nothing, except arousing English feeling by various outrages, and thus giving rise to several coercive measures. Far-reaching reforms, however, came about through the efforts of Gladstone. On July 26, 1869, a measure was passed by Parliament which finally disestablished the Irish church, the Act taking effect on Jan. 1, 1871. (See IRELAND, CHURCH OF.) Many reforms in the land laws were also carried out, which are described in detail under

IRISH LAND LAWS; while the agrarian agitation is treated under LAND LEAGUE. Ireland, however, was not content with ecclesiastical and agrarian reforms, and Home Rule (q.v.) became the all-absorbing question, the cause finding a champion of great ability in Charles Stewart Parnell (q.v.). In 1880 the agrarian movement in Ireland developed into a system of organized terrorism. As a result of this lawlessness a bill became law on March 2, 1881, known as the Coercion Act, which gave the Lord Lieutenant of Ireland power, by warrant, to arrest any person, on mere suspicion, for treason, intimidation, and the like. Under this law Parnell and other Irish leaders were arrested, but, as usual, the Irish retaliated with outrages, which culminated in the murder of the Chief Secretary for Ireland, Lord Frederick Cavendish, and the permanent Undersecretary, Thomas H. Burke, in Phoenix Park, Dublin, on May 6, 1882. Thereupon the government passed an exceptionally stringent and severe Crimes Act, which, among other things, permitted the examination of witnesses without bringing any specific charges against individuals. By this means a body, known as the Invincibles (q.v.), was discovered, under whose auspices most of the outrages had been perpetrated.

The parliamentary election of 1886 gave Mr. Gladstone a very small majority in the House of Commons and made him dependent on the Irish Nationalists for their support. On April 8 he brought in his first Home Rule Bill, followed a few days later by a Land Purchase Bill—the latter a sop to the Irish landlord. Deserted by a large section of his following who did not believe in the policy of Home Rule, the bill was lost by about 30 votes, and Parliament was dissolved. In the July elections the Conservatives and Liberal-Unionists outnumbered the Gladstonians and Parnellites by 100, and Lord Salisbury was again Prime Minister. In the same year Mr. Parnell introduced a bill by which leaseholders might partake of the benefits of the Land Act of 1881 (see IRISH LAND LAWS); it also provided for a revision of the judicial rents necessitated by the fall in agricultural prices. The rejection of this bill was answered by the Plan of Campaign drawn up by Messrs. Dillon, O'Brien, and Healy. Briefly the plan was this: the tenant was to offer a fair rent, and if the landlord refused the offer, the money was paid to trustees for the purpose of resisting evictions. Mr. Parnell did not approve of the plan. Mr. Gladstone, however, would not condemn it, holding it to be the consequence of the ministerial policy. As a result of the Plan of Campaign, Mr. Arthur Balfour on his appointment as Chief Secretary in March, 1887, succeeded in placing on the statute book the Perpetual Crimes Act, which substituted trial by magistrates for trial by jury in cases of certain acts of violence. But the plan also forced the government to pass Mr. Parnell's Land Measure, which it had rejected in 1886.

Prominent Liberals visiting Ireland at this time were greeted with much popular enthusiasm. On the other hand Irish members were eagerly welcomed on Liberal platforms in Great Britain. Not relishing the turn things were taking, the London *Times*, the chief opponent of Home Rule in the English press, published a series of articles on "Parnellism and Crime," based on a series of documents received from the Secretary of the Irish Loyal and Patriotic

Union. These documents connected Parnell and many of his following with the agrarian crimes in Ireland and showed that Mr. Parnell himself condoned the Phoenix Park outrages. Parliament appointed a special commission of investigation, which continued in office for 13 months. This commission discovered that the chief documents were forgeries, executed by a disreputable and destitute Irishman named Richard Pigott, well known in Dublin. After confessing his crime, Pigott fled to Madrid and committed suicide. The special commission issued its report in 1890, and it seemed to be a turning point in the history of Ireland. Mr. Parnell became a hero with the English Liberals. The by-elections were beginning to go against the government, their majority was diminished, and hopes for Home Rule were very bright indeed when, on Nov. 17, 1890, Captain O'Shea filed a petition for divorce from his wife and named Mr. Parnell as correspondent. There was no defense and the decree was granted. The day after the judgment the members of the National League, with Mr. Redmond in the chair, passed a vote of confidence in Mr. Parnell. Mr. Gladstone expected that the Irish leader would retire for a time at least, but finding that he did not, sent a letter to Mr. Morley virtually demanding that he do so, and intimated that his continued leadership would mean the defeat of Home Rule. The Irish party was not prepared to make such a sacrifice for their leader, and Parnell was deposed by a vote of 45 to 26. The majority elected Mr. Justin McCarthy as their chairman. Mr. Parnell made a dogged resistance, attending meetings and making speeches week after week, but the strain upon his health was too great. He died at Brighton, Oct. 6, 1891. Party spirit among the Nationalists ran riot.

While the Irish members were disputing about the leadership, Mr. Balfour profited by the opportunity to silence his Liberal critics. In the autumn of 1890 he made a tour of Ireland. He found great destitution in many places, owing to the failure of the potato crop; this he remedied by a relief fund plus a small grant from the Exchequer. His Light Railways Act of 1890 opened up some of the poorest parts of the west and gave employment to some 14,000 men. The Ashbourne Acts were extended and modified by the Land Purchase Act of 1891, by which £30,000,000 were provided on security to convert the tenants of the Irish estates into proprietors. In the same year the Congested Districts Board was established. In February, 1893, the Liberals being in power, Mr. Gladstone introduced his second Home Rule Bill. It occupied the House of Commons 82 days; the third reading was carried on September 1 by a majority of 34. It was thrown out by the Lords by a vote of 419 to 41, and the public, rather tired of the Home Rule discussion, acquiesced in their decision. Early in the following year Mr. Gladstone retired. An Amending Land Act was added to the statute books in 1896. Two years later a Local Government Act, which the Unionists had made part of their programme, transferred the government of the counties and rural districts, except in some of the northern counties, from nonrepresentative grand juries to popularly elected county councils. This was not a substitute for Home Rule, nor was it intended to be. Most important was the passing in 1899 of an Act "for establishing a Department of Agriculture and other Indus-

tries and Technical Instruction in Ireland and for other purposes connected therewith."

In 1900 patriotism triumphed over party strife, the two factions in the Irish Nationalist party were reconciled, and Mr. Redmond, the leader of the Parnellites, was elected chairman of the United Irish party. In a speech at Liverpool in 1902 Lord Rosebery sounded what he thought was the death knell of Home Rule. A few days later Sir Henry Campbell-Bannerman, in a speech, took the supposedly buried issue under his protection, and Home Rule became one of the responsibilities of the Liberal party. Mr. Wyndham's Land Purchase Act of 1903 was founded on a report of a conference held between the representatives of the landlord and tenant, in Dublin, and £100,000,000 were provided for the buying out of the entire landlord class. Mr. Wyndham's policy of "devolution," i.e., the delegation to local bodies of larger powers, found little or no support among the Nationalists, and the Irish Unionists bitterly attacked it as a sop to Home Rule. In 1905 the Sinn Fein (Gaelic for "Ourselves Alone") was organized by the radicals in Ireland. Their aim was to regenerate the nation, not merely politically, but also linguistically, educationally, industrially, and socially. The General Elections of 1906 were disastrous to the Unionists. A Liberal government was in, with the largest majority ever attained since 1832. To the Nationalists, as the fruits of a generation of parliamentary agitation, Mr. Birrell in 1907 submitted the mild Irish Councils Bill. It was strongly opposed by the Sinn Fein and the Roman Catholic clergy. To the surprise of the Liberal party it was rejected with scorn at an Irish national convention at Dublin. Towards the end of the session an Evicted Tenants Bill was passed, by which the estates commissioners were empowered to force the sale of land by "compulsion." Owing to the inadequacy of the financial provisions of the Land Act of 1903, an Amended Land Purchase Act was passed in November, 1909, and £52,000,000 were granted for pending agreements and practically an unlimited amount for the future. (See IRISH LAND LAWS.) On Oct. 1, 1909, the two universities created by Mr. Birrell's Irish Universities Act of 1908 came into existence: the Queen's University with the Queen's College at Belfast, and the National University at Dublin with the Queen's colleges at Cork and Galway and a new college at Dublin. Each college in reality became an almost independent university. The governing bodies of these colleges are to a large extent Catholic and Irish. Religious services of any kind are prohibited within their precincts and there are no religious tests. Trinity College in Dublin remained untouched. This was the solution of the problem which Mr. Gladstone had vainly attempted to solve in 1873.

In 1911 the Nationalists, holding the balance of power in the House of Commons, insisted that Home Rule should have precedence over all other measures. In October Mr. Birrell, explaining the government's Home Rule Bill, declared that it involved a bicameral Irish Parliament, with an executive responsible to it, and with full representative powers and control over purely Irish concerns. The Ulster Unionists appointed a commission to draw up a plan of a provisional government for Ulster, which should come into operation if a Home Rule measure passed. On April 11, 1912, Mr. Asquith introduced the

Government of Ireland Bill, as it was officially called. It provided for an Irish Parliament consisting of a Senate and a House of Commons, which was empowered to make laws for Ireland, but certain classes of legislation were removed from its jurisdiction, including powers regarding peace, war, treaties, army, navy, trade, navigation, coast defenses, coinage, stamps, weights, measures, copyright, religion, and Freemasonry. Besides the veto prerogative of the Lord Lieutenant and the Imperial Executive, the British Parliament retains authority over all Irish legislation. The financial provisions were regarded as the chief difficulty. The first reading was carried in the House of Commons on April 16 and the second reading on May 9. While in the committee stage it was so amended as to allow, after the first five years, proportional representation, by provinces, in the Senate. On Jan. 1, 1913, Sir Edward Carson, leader of the Ulster Unionists, proposed an amendment to exclude Ulster from Home Rule, notwithstanding the fact that in the Province of Ulster Roman Catholics constitute about 40 per cent of the population. The amendment was rejected by a vote of 294 to 197, and on Jan. 16 the bill passed its third reading in the Commons. It was rejected by the House of Lords on January 30. The bill was reintroduced in the summer session, but on July 15 the Lords refused it a second reading and declined to proceed with a consideration of the bill until it had been submitted to the will of the country. It passed the third reading, for the second time, in the House of Commons on July 17. The Ulster Volunteers' preparation for armed resistance to any measure of Home Rule went on apace, and the English Conservatives, the avowed guardians of law and order, condoned and openly supported the revolutionary propaganda of the Ulster Unionists.

During the year the Cunard and White Star lines, claiming that Queenstown harbor was unsafe for their vessels, refused to allow them to call at that port, thereby delaying the American mail at least 24 hours. The government supported the companies in their breach of contract, and the Irish charged that the government was antagonistic to Ireland's commercial prosperity. The year 1913 was remarkable also for the great strike of the Dublin transport workers, fomented by James Larkin. The first strike was on the tramway system during Horse Show week; then it quickly spread to every class of transportation, crippling trade and closing the port of Dublin for a time. Twenty thousand men were out of work, and the suffering in the strikers' families was so intense that the English Socialists offered to take the children to England and care for them. This plan, which aroused much hostile feeling, was frustrated by the Roman Catholic clergy of Dublin. Sir George Asquith, chairman of a commission of inquiry, appointed by the British Board of Trade, declared the strike disastrous to all concerned and asked for a mutual agreement. The employers refused to recognize the Transport Union till that body repudiated the syndicalist principles with which Larkin had imbued it. Larkin was tried and sentenced to seven months' imprisonment for inciting to destruction of property, physical assaults, and seditious libel. The Labor element accused the government of injustice in imprisoning Larkin while they left Sir Edward Carson free to organize and utter treason. After the arrest of the leader the

strike was broken, and the men gradually returned to work. Larkin was released about the middle of November, owing possibly to the government's loss of the Labor vote in certain of the English constituencies.

Parliament reassembled on Feb. 10, 1914, with every prospect for a stormy session. Sir Edward Carson threatened civil war unless Ulster was excluded from control of the Home Rule Parliament. Mr. Asquith proposed to allow the various counties in Ulster to decide for themselves whether they wished to be under the jurisdiction of the Dublin Parliament or not. Those who decided in the negative were to be excluded for six years and then be automatically included, unless the Imperial Parliament decided otherwise. This was vigorously opposed by the Irish leaders and the Nationalist papers on the ground that it would partition Ireland. At the second reading in April the majority fell from 98 to 80, as the followers of Mr. O'Brien deemed it ridiculous to vote on a measure which was not intended to pass. Seeing that Mr. Asquith was willing to make further concessions to Ulster, the leaders of the Irish party answered by extending their patronage to the National Volunteer movement, which they had discountenanced up to this time. The as yet unamended bill passed the House of Commons for the third and last time on May 25, 1914, and became law under the Parliament Act of 1911. (See ENGLAND.) It was then sent to the Lords, and a month was given for its consideration. The Lords refused to act upon the Home Rule Bill until the amending measure was before them. The Upper House passed the amending bill on its second reading on July 6, and then proceeded to modify it radically. Ignoring the large numbers of Home Rulers in Ulster, the entire province was to be excluded from the jurisdiction of the Dublin Parliament. There were further amendments, and the bill passed its third reading on July 15. Five days later the Commons took up the measure as amended for extended consideration. The King, in an effort towards an amicable adjustment, called a conference of the leaders of all the parties. After prolonged meetings no agreement was reached, as Sir Edward Carson demanded the entire exclusion of Ulster, and Mr. Redmond felt he could not sacrifice the Ulster Nationalists, who had suffered most for the cause of Home Rule. Civil war in Ireland seemed imminent when a truce was declared by both parties as a result of the entrance of Great Britain in the Great European War of 1914. Mr. Asquith's Amendment Act allowing the counties of Ulster to decide for themselves was passed, but its operation was postponed for one year. See WAR IN EUROPE.

While the agitation for Home Rule has seemingly overshadowed everything else, those who know Ireland from within are aware that Irish thought upon Irish problems, during the last 20 years, has been undergoing a silent revolution. Among the new forces in Irish life are two, which stand apart from all political and religious struggles and deserve more than passing notice. One is the Irish Agricultural Organization Society, inaugurated in 1894 mainly through the efforts of Sir Horace Plunkett; the other is the Gaelic League, founded by Dr. Douglas Hyde in 1903. The former aims to do in the industrial what the latter attempts in the intellectual sphere, the rehabilitation of Ireland from within. At a meeting in Decem-

ber, 1913, Father Finlay, S.J., the chairman of the I. A. O. S., announced that their societies had increased to nearly 1000. These include industrial societies, creameries, agricultural societies for the purchase of seed, implements, etc., on coöperative lines, and credit societies, which loan money at low rates of interest, thereby freeing the small farmer from the thralldom of the gombeen man, or usurer. The membership in these societies is over 100,000, while their combined trade amounts to over £2,000,000 a year. This coöperative movement is spreading so rapidly, and in so many different directions, that in the near future it will give a distinct character to Irish industry, constituting the whole community a truly coöperative commonwealth. Equally hopeful is the outlook of the Gaelic League, which has over 964 branches. It is not only fulfilling its declared object—the popularizing of the national language and literature—but it is also developing the intellectual, moral, and social life of the Irish people and has done excellent work in the cause of temperance.

J. Smith, *Ireland's Renaissance* (ib., 1904); Goldwin Smith, *Irish History and the Irish Question* (London, 1906); Murray, *History of the Commercial and Financial Relations between England and Ireland* (ib., 1907); Paul-Dubois, *Contemporary Ireland*, translated from the French (Dublin, 1908); O'Donnell, *A History of the Irish Parliamentary Party* (London, 1910); O'Brien, *A Hundred Years of Irish History* (ib., 1911); McCarthy, *The Irish Revolution* (ib., 1912); Wilson, *The Beginnings of Modern Ireland* (ib., 1912).

HISTORY. For the early history of Ireland the most valuable sources have been published by the Irish Record Commission (London, 1802-69). Consult also: Joyce, *A Short History of Ireland to 1608* (5th ed., London, 1896); Bagwell, *Ireland under the Stewarts and during the Interregnum* (2 vols., New York, 1909); Smith, *Irish History and the Irish Question* (ib., 1905). Other material is in the *Calendar of State Papers for Ireland*, which at present extends to the end of the reign of Charles I. Consult also *Patent and Close Rolls of the Irish Chancery, Henry VIII to Charles I*, ed. by Morrin (Dublin, 1861-63). Only a few of the *Rolls of the Irish Parliament* have been published in various editions at Dublin. The *Irish Statutes at Large* appeared at Dublin, 1786-1804. Among the older *Histories of Ireland*, that of Leland (3 vols., London, 1773) is the best. Consult also: Plowden, *Historical Review of the State of Ireland* (Philadelphia, 1805); Richey, *Lectures on the History of Ireland* (London, 1869-70); Ball, *Historical Review of the Legislative Systems of Ireland, Henry II till 1801* (ib., 1889). Among

the many shorter histories perhaps the best is Morris, *Ireland*, in the "Cambridge Historical Series" (ib., 1896). Other short accounts are: Bryce (ed.), *Two Centuries of Irish History, 1691-1870* (ib., 1888); Hassencamp, *History of Ireland from the Reformation till the Union*, trans. (ib., 1888). The best account of Ireland from Elizabeth to the Union is in Lecky, *History of England in the Eighteenth Century* (ib., 1878). Froude, *The English in Ireland in the Eighteenth Century* (New York, 1875), is based on much documentary research, but is violently partisan. For the seventeenth century the chapters on Ireland in Gardiner, *History of the Great Civil War* (London, 1886-94), and id., *History of the Commonwealth and Protectorate* (ib., 1894-1901), are very valuable, as is also Carte's edition of the *Ormond Papers* (ib., 1739). For the more recent history, consult McCarthy, *Ireland since the Union* (ib., 1887). Other authorities are: Keating, *General History of Ireland* (ib., 1823); Gilbert, *Viceroy of Ireland* (Dublin, 1865); Lecky, *The Leaders of Public Opinion in Ireland, Swift, Hood, Grattan, and O'Connell* (London, 1871); Wills, *The Irish Nation: Its History and its Biography* (ib., 1875); Sir C. E. Trevelyan, *The Irish Crisis* (ib., 1880); Gilbert, *History of the Irish Confederation* (Dublin, 1882-91); Richey, *Short History of the Irish People* (ib., 1887); Zimmer, *The Irish Element in Mediæval Culture* (New York, 1891); La Faye, *L'Irlande au 19e siècle* (Paris, 1896); Duffy, *Young Ireland* (London, 1896); Justin McCarthy, *History of our own Times* (New York, 1897); Mitchel, *The History of Ireland* (Glasgow, 1898); Morris, *Ireland, 1798-1898* (London, 1898); R. B. O'Brien, *Life of Parnell* (ib., 1899); Ingram, *Critical Examination of Irish History* (ib., 1900); Haverty, *A Special Catalogue of Rare Books Relating to Ireland* (New York, 1902); Joyce, *Social History of Ancient Ireland* (2 vols., London, 1903); O'Dea, *Maynooth and the University Question* (Dublin, 1903); Justin McCarthy, *An Irishman's Story* (New York, 1904); Davitt, *Fall of Feudalism in Ireland* (London, 1904); Horace Plunkett, *Ireland in the New Century* (ib., 1904); Bury, *Life of St. Patrick* (ib., 1905); Herbert Paul, *History of Modern England* (New York, 1906); P. W. Joyce, *Outlines of the History of Ireland* (8th ed., ib., 1906); Stokes, *Ireland and the Catholic Church* (London, 1907); L. P. Dubois, *Contemporary Ireland* (Dublin, 1908); A. S. Green, *Making of Ireland and its Undoing* (London, 1908); Walpole, *Short History of the Kingdom of Ireland* (5th ed., ib., 1908); Orpen, *Ireland under the Normans* (2 vols., Oxford, 1911); John Morley, *Life of Gladstone* (2 vols., New York, 1911); Green, *The Old Irish World* (Dublin, 1912).

IRELAND, CHURCH OF. The name applied to the independent branch in Ireland of the Anglican communion. It was united with the Church of England by the Act of Union, which went into effect on Jan. 1, 1801. The Established church of Ireland, considering itself the rightful successor of the mediæval Roman Catholic church, took possession of the dioceses, parishes, and Church property, and for a long time retained the divisions then existing. The Roman Catholics, constituting a large majority (more than three-fourths) of the population, always regarded as unjust the existence, in their country, of an Established Protestant church in connection with that of England. Notwith-

standing its small membership, the church had, in 1833, 4 archbishoprics, 18 bishoprics, the income from which was estimated at from £130,000 to £185,000. In that year the first inroad was made upon the prerogatives of the Established church in the reduction of the archbishoprics to two and the bishoprics to 10. In 1868, on motion of Gladstone, the English House of Commons voted to disestablish the Church of Ireland. The House of Lords rejected the proposition. But so strong was the expression of public opinion against the continuance of the privileges of the Irish church that the royal commissioners on the revenues and conditions of the Church of Ireland recommended in their report, July 27, 1868, important reductions as to its benefices. They suggested, among other changes, the abolition of four bishoprics and one archbishopric, and that all benefices with less than 40 Protestants should be suppressed. Gladstone introduced, in March, 1869, a new bill for the disestablishment and disendowment of the Irish church, which, after a long and earnest debate, passed both Houses of Parliament and took effect Jan. 1, 1871. The disestablishment was to be total; ecclesiastical courts and laws were to cease; the bishops were to be no longer peers in Parliament; the ecclesiastical commission was to terminate, and a new commission of Church temporalities, composed of 10 men, was to be appointed, in which the whole property of the Irish church should be vested. Public endowments, including state grants or revenues (valued at £15,500,000), were to be retained by the state, and private endowments, such as money given from private sources since 1660 (estimated at £500,000), were to remain with the disestablished church. The vested interests connected with Maynooth College, with the Presbyterians who were receiving the *regium donum*, and the incumbents, were to be secured. The aggregate of the payments would amount to about £8,000,000, leaving £7,500,000 at the disposal of Parliament. A general convention held in Dublin, 1870, adopted a constitution for the disestablished church, according to which it was to be governed by a General Synod, composed of a House of Bishops and a House of Clerical and Lay Delegates, meeting annually in Dublin. The House of Bishops has the right to veto, but seven members must agree upon a veto to render it valid. The bishops are chosen by the diocesan convention, but if the convention fail to elect a candidate to a vacant see by a majority of two-thirds of each order, the election falls to the House of Bishops. The Primate, the Archbishop of Armagh, is elected by the House of Bishops from their own order. The property of the church is vested in a permanent Representative Body, composed of three classes—the ex-officio archbishops and bishops, one clerical, and two lay representatives for each diocese, and the coöpted members chosen by the ex-officio and representative members, and equal in number to the dioceses. One-third of the elected members retire by rotation. In 1912 the Church of Ireland had two archbishops (Armagh and Dublin), 11 bishops, a membership of about 524,000, and £9,403,956 in funds in custody of the Representative Body. The general feeling among the members of this church has been hostile to the introduction of High Church doctrines and practices, and the Prayer Book has, since the disestablishment, been modified in this sense. See ENGLAND, CHURCH OF.

Consult *Reports of the Representative Church Body* (Dublin, 1872—to date); J. T. Ball, *The Reformed Church of Ireland* (London, 1892); Olden, *The Church of Ireland* (ib., 1892).

IRELAND, JOHN (1838—). An American Roman Catholic prelate. He was born at Burnchurch, County Kilkenny, Ireland, Sept. 11, 1838, but was brought to the United States at the age of 11, his parents settling at St. Paul, Minn. In 1853 he was sent to France to be educated for the priesthood, to which he was ordained in 1861 on his return to St. Paul. Here he remained, except for a service of two years as chaplain of the Fifth Minnesota Regiment in the Civil War, becoming rector of the cathedral. In 1875 he was made Coadjutor Bishop of St. Paul, and on Bishop Grace's resignation, in 1884, succeeded him, the see being made metropolitan with the title of archbishop in 1888. The influence of his personality made Archbishop Ireland a commanding figure in many important movements, especially those for total abstinence, for colonization in the Northwest (he was a director of the National Colonization Association), and for the establishment of the Catholic University at Washington. He is the author of *The Church and Modern Society* (1897).

IRELAND, WILLIAM HENRY (1777–1835). A Shakespearean forger, son—probably, though his legitimacy is under suspicion—of Samuel Ireland, engraver and author, born in London in 1777. After attending various private schools he was sent to schools in France, where he remained four years. On returning to London he was apprenticed to a conveyancer. In 1794 he visited Stratford-on-Avon with his father, who was preparing a book descriptive of the town. Here he met John Jordan, a Stratford poet, who had published much gossipy information in regard to Shakespeare, even forging the will of the dramatist's father. After the return of the Irelands to London, William began on his own account a series of remarkable forgeries, which deceived first his credulous father and then many scholars. He produced legal documents, verses, and letters purporting to be Shakespeare's, a number of sixteenth-century volumes with Shakespeare's name on the title-pages, the manuscripts of *Lear* and of a fragment of *Hamlet*, and finally two plays, *Vortigern* and *Henry II*, which he tried to foist as Shakespeare's. On April 2, 1796, *Vortigern* was performed at Drury Lane amid peals of laughter. The same year young Ireland published a written confession, which he enlarged in 1805. Subsequently he wrote considerable verse in imitation of Chatterton, political squibs, and several Gothic romances. He died in London, April 17, 1835. His *Confessions* (1805) were reissued by R. G. White (New York, 1874). In December, 1795, the elder Ireland published facsimiles of the forged documents bearing the title *Miscellaneous Papers and Legal Instruments under the Hand and Seal of William Shakespeare*. These forgeries James Payn made the subject of an interesting novel, *The Talk of the Town* (1885). A collection of the Ireland forgeries in the Birmingham Library was destroyed by fire in 1879.

IRELAND ISLAND. One of the Bermudas. See BERMUDA ISLANDS.

IRENÆUS, ī-rē-nē'ūs (Lat., from Gk. *Εἰρηναῖος*, *Eirēnaios*), SAINT (c.130–c.202). Bishop of Lugdunum (Lyons) and one of the leading

Church Fathers of the West. He was born in Asia Minor, perhaps about 130, and died after the year 200. In his youth he had heard Polycarp, Bishop of Smyrna, who had been a disciple of the Apostle John. Thus Irenæus preserves a direct line of apostolic tradition. A fragment in the Moscow manuscript of the *Martyrdom of Polycarp* says that he was then teaching in Rome (155). Some time after this he removed to Gaul, where he became a presbyter in the church of Lugdunum. Pothinus, the aged Bishop of Lyons, suffered death in the persecution under Marcus Aurelius (177), and Irenæus was chosen to succeed him. Shortly before this time he visited Rome again, carrying letters with reference to the Montanists. (See MONTANUS.) The remainder of his life seems to have been passed in the successful administration of his see. When towards the end of the century the Easter controversy broke out afresh, and Victor, Bishop of Rome, threatened the Asiatic churches with excommunication unless they conformed to the Roman usage, Irenæus intervened with a fraternal letter to Victor, admonishing him to peace. Nothing is known about Irenæus' life after this time. A fifth-century tradition, which cannot be traced further back than Jerome, says that he met a martyr's death in the persecution under Septimius Severus (202). Gregory of Tours gives a full account of the alleged martyrdom in his *History of the Franks*.

Irenæus wrote in Greek. His work *Against Heresies* has survived only in a Latin translation. It was written in Gaul to combat the Gnostic teaching (see GNOSTICISM) and dates from 181 to 189. It is valuable for the history of doctrine. Fragments of some of his other works are preserved by the later writers. Harnack has recently shown that the so-called 'Pfaffian Fragments' were forged by Pfaff himself. The first edition of Irenæus' works was edited by Erasmus (Basel, 1526). Modern editions are by Migne, *Patrologia Græca*, vi, and (a better edition) Harvey (Cambridge, 1857). An English translation of the *Adversus Hæreses* may be found in the *Ante-Nicene Fathers*, edited by Coxe, vol. i (Buffalo, 1885). In general, consult Cruttwell, *Literary History of Early Christianity* (London, 1893), and Adolf Harnack, *Geschichte der altchristliche Literatur* (Leipzig, 1893).

IRENE, ī-rē'nē (Lat., from Gk. *Εἰρήνη*, *Eirēnē*) (c.752–c.803). Byzantine Empress from 780 to 802. She was a native of Athens and in 768 married Leo, who became Emperor as Leo IV in 775. Her husband died in 780, and Irene became Regent during the minority of her son, Constantine VI. A worshiper of images—in fact, this had during the lifetime of her husband almost caused her disgrace—she quickly began to plot for their restoration and with this purpose assembled a council of bishops at Constantinople (786 A.D.), which, however, was broken up by the opposition of the troops of the capital. A second council held at Nicæa in the following year was more successful, and image worship was reestablished in the Eastern church. (See IMAGE WORSHIP; ICONOCLASM.) In 790 the government was taken out of her hands by the partisans of her son; but in 792 she was again in power, and in 797 she caused Constantine to be blinded and excluded from all power. In 802 her treasurer Nicephorus rebelled, and

banished her to the Isle of Lesbos, where she remained until her death, the following year. It is stated by one authority that negotiations were begun for a marriage between Charles the Great and Irene, but these were frustrated by a favorite of the Empress.

Consult: Bury, *Later Roman Empire*, vol. ii (London, 1889); Diehl, *Figures byzantines*, vol. i (Paris, 1909); McCabe, *The Empresses of Constantinople* (Boston, 1913).

IRENE, SAINT (c.1084–1124). A Byzantine Empress, daughter of Ladislav I, King of Hungary. In 1104 she married Emperor John II, but she had lived for some time in a cloister before 1124, when she died. She was canonized by the Greek church for her piety and charity. The name St. Irene is often incorrectly applied to Irene, the wife of Leo IV and enemy of the Iconoclasts.

IRETON, ir'ton, HENRY (1611–51). An English general of the Commonwealth. He was the eldest son of German Ireton, of Attenborough, Nottinghamshire. He graduated B.A. at Trinity College, Oxford, in 1629, and studied law at the Middle Temple, London, but at the outbreak of the Civil War offered his services to the Parliament. He served under Manchester in 1644, with the rank of quartermaster-general. At Naseby, in 1645, as commissary general, he was in command of the left wing, and, his lines having been broken by the furious charge of Rupert, he was wounded and taken prisoner, but regained his liberty when Cromwell's Ironsides decided the fortunes of the day. Later in the same year he became a member of Parliament and took an active part in its disputes with the army. At first he favored a settlement between the King and Parliament and was the chief author of "the Heads of the Proposals," but upon being convinced of the impracticability of such an arrangement he became the King's implacable enemy and was one of those who signed his death warrant. His connection with Cromwell, whose daughter Bridget he married in 1646, greatly advanced his interests. When Cromwell went to Ireland to subdue that country, he was accompanied by his son-in-law, on whose vigor, judgment, and tact he placed much reliance. Cromwell's presence, however, was soon required in Scotland, and the complete subjugation of Ireland was intrusted to Ireton. His career was brief, severe, but successful. He compelled the surrender of Carlow, Waterford, Duncannon, and Limerick, and inaugurated a policy of civil government which was marked by fairness and religious sincerity. He died of an epidemic fever at Limerick. His remains were conveyed to England and interred in Westminster Abbey; but after the Restoration they were disinterred, hanged, and burned at Tyburn.

IRGENS, JOHANNES (1869–). A Norwegian statesman, born at Aas, where his father was professor of mineralogy in the Agricultural High School. He was educated at the University of Christiania, was in the consular service at Bordeaux and Antwerp in 1892–95, practiced law in Christiania for 10 years, was Secretary of the Norwegian Legation in London in 1906–08 and then Minister to the Court of St. James's in 1908–10. In 1910–13, in the Konow and Bratlie cabinets, he was Minister of Foreign Affairs.

IRI, ē'rē. A river of Greece. See EUROTAS.

IRIARTE, ē'rē-ār'tā, IGNACIO (1620–85). A Spanish landscape painter, born at Azcoitia in

Guipuzcoa. He studied under Herrera in Seville and was one of the original members and the first secretary of the Academy of Seville, founded by Murillo (1660). He painted the backgrounds in some of Murillo's pictures, and Murillo in turn furnished the figures for his friend's landscapes. There are four well-composed, conventional landscapes by him in the Prado Museum at Madrid which show his talent as colorist; others in the Louvre and the Hermitage. Murillo said of him that "he painted landscape so well, he must be inspired."

IRIARTE, or YRIARTE, Y OROPESA, ē'rē-ār'tā ē ō'rō-pā'sà, TOMÁS DE (1750–91). A Spanish poet, born at Orotava on the island of Teneriffe, Sept. 18, 1750; educated at Madrid under the care of his uncle, Juan de Iriarte, the head of the Royal Library. He began very early to translate French plays and to compose plays of his own. For his maintenance, however, he depended throughout his life upon the income derived from certain minor posts to which he was appointed in the Ministry of Foreign Affairs and of War and from other administrative appointments. The tranquillity of his career was somewhat disturbed by numerous literary quarrels with other writers of the time, notably with Juan Pablo Forner, and in 1786 he was summoned before the Inquisition to answer a charge of adherence to the doctrines which the French philosophers were then disseminating—a charge from which he seems, however, to have had little difficulty in clearing himself. He died at Madrid, Sept. 17, 1791. Much of his published verse consists of translations, most of which are not so good as his original poems. Among these are the *Epistles*, one of which forms the dedication of his translation of Horace's *Ars Poetica* to his friend Cadalso, and a didactic work, *La musica*, a discussion of the elements of music, which attracted attention abroad and won him praise from Metastasio. But his permanent fame is based upon his versified fables, the *Fábulas literarias*, still among the most popular in Spain. In their content these show considerable skill on Iriarte's part in adapting the peculiarities and habits of animals to doctrinal purposes; in their form they also display his ingenuity, being written in a great variety of metres with a due regard for harmony and symmetry. The fables were translated into many European languages. Belfour's *Literary Fables Imitated from the Spanish of Yriarte* appeared in London in 1806, and Rockliff's rendering of Iriarte reached a third edition in 1866. His name is given in the *Catálogo de autoridades de la lengua*, published by the Academia Española.

Bibliography. Iriarte, *Colección de obras* (Madrid, 1805); *Biblioteca de autores españoles*, vol. lxiii (ib., 1891), containing his poems; Iriarte, "Poesías inéditas," in *Revue hispanique*, vol. ii (Paris, 1895); Cotarelo y Mori, *Iriarte y su época* (Madrid, 1897); "Proceso inquisitorial contra Iriarte," in *Revista de Archivos*, etc., vol. iv (1900).

IRIARTEA, ir'i-ār'tē-ā (Neo-Lat., named in honor of Juan de Iriarte, a Spanish amateur botanist). A genus of South American palms which have lofty, smooth, faintly ringed stems, and pinnate leaves with somewhat triangular leaflets. The *pashiuba* or *paxiuba* palm (*Iriarteia exorrhiza*, by some botanists called *Socratea exorrhiza*), common in low, wet grounds in the forests of the Amazon district, is remarkable for its aerial roots, which extend from the stem

obliquely downward and often divide into many rootlets just before they reach the soil. As the tree grows, it produces new roots from higher points. Since the older and more central ones die, a man may walk erect under a palm of 70 feet high, supported as on legs rising straight above his head. The outer wood, which is very hard, is used for harpoons. It splits easily into straight laths, is excellent for floors, ceilings, shelves, etc., and is exported for umbrella sticks. The leaves are extensively used in Brazil as thatch.

IRIDACEÆ, ir'ī-dā'sê-ē (Neo-Lat. nom. pl., from Lat. *iris*, Gk. *ἴρις*, *iris*, rainbow, sort of lily), or **IRIS FAMILY**. A family of monocotyledonous plants, consisting mostly of herbaceous perennials, with tubers or rhizomes. The leaves are usually in two rows and equitant (i.e., so placed that one seems to fit over the back of the other). The perianth is six-parted, colored, and in some kinds very beautiful. The stamens are three with anthers turned outward. The ovary is inferior, with one style and three stigmas, which are often petal-like and add much to the beauty of the flower. The fruit is a three-celled capsule containing many seeds with small embryos in a hard endosperm. There are about 60 genera and 800 species known in temperate and tropical countries. South Africa and tropical America contain the greatest number. Some species, however, range to rather high latitudes. Familiar examples of the family are the garden irises, crocuses, gladioli, etc. Some species have acrid properties, while the corms of others are edible, and others have medicinal properties of considerable value. The representatives of the family indigenous in the United States are species of *Iris* (flag), *Nemastylis*, and *Sisyrinchium* (blue-eyed grass). Two additional genera, *Calydorea* and *Blerbertia*, grow in Texas, and there may be others farther west. See accompanying Colored Plates of IRIS FAMILY and FLEURS-DE-LIS.

IR'IDEC'TOMY. See CATARACT.

IRIDESCENT (ir'ī-dēs'ent) **GLASS** (from Lat. *iris*, Gk. *ἴρις*, *iris*, rainbow). Glass containing a display of changing colors on the surface somewhat similar to the delicate hues of soap bubbles. It is produced by rendering the surface of the glass imperceptibly uneven, either by artificial means or by the natural process of incrustation and decay. One form of treatment consists in applying to the surface of the glass to be treated a strong solution of hydrochloric acid under pressure in a closed vessel. Another method in use in many factories is to apply the fumes from chloride of tin or other chlorides volatilized in a reheating furnace. Glass which has for many years been submitted to the slowly disintegrating influences of natural causes, such as damp, successive heat and cold, light and darkness, will in many instances display an iridescent play of colors. The cause is due to a process of decomposition in the texture of the glass, resulting in the formation of minute scales. The action of water on glass has a tendency to extract the potash and soda which enter into its composition, together with a portion of the silica, the decomposition taking place with greater ease in proportion as the glass is richer in these alkalis, and more minutely divided, and the temperature of the water higher. The moisture in the atmosphere produces a similar alteration in the lapse of time. It separates the

potash and soda, leaving the greater part of the silica with the lime on the surface of the glass. It is this decomposition which causes the prismatic colors. If subjected to heat, numerous fine scales will peel off and leave the surface dull, opaque, and wrinkled. Many attempts have been made to imitate by artificial means the singular display of changing hues, and varied success has attended the efforts. In Venice the workers succeeded in giving the surface of their glassware a peculiar kind of metallic iridescence, and a similar result was reached by certain Hungarian glassworkers. The beautiful *Favrile Glass* made by Tiffany of New York in many styles and colors has a most striking iridescent play of color. See GLASS.

IRID'IUM (Neo-Lat., from Gk. *ἴρις*, *iris*, rainbow; so called on account of its iridescence). A metallic element discovered in 1802 by Smithson Tennant. It is found in platinum ores—as osmiridium, a native alloy of iridium and osmium in varying proportions—and in the form of native alloys with the other platinum metals. The principal sources of these ores are various districts in the Ural Mountains, and on the Pacific coast of the United States. The preparation of metallic iridium involves its separation from the accompanying metals by a long and complicated process.

Iridium (symbol Ir; atomic weight, 193.1) is a white steellike metal, brittle when cold, and somewhat malleable at a white heat. In its ordinary, compact form, iridium is insoluble not only in the several mineral acids, but also in aqua regia; the latter reagent, however, dissolves iridium powder, which may also be converted into the oxide Ir_2O_3 by heating in the air. Iridium has a specific gravity of 22.4, and it melts at about 2200°C . (about 4000°F). It combines with oxygen to form an iridium sesquioxide, Ir_2O_3 , and an iridium dioxide, IrO_2 , which in turn give rise to iridious and iridic salts. As Wöhler and Witzmann showed, in 1908, an oxide of the formula IrO does not exist, although iridium sulphide, IrS , may be readily enough obtained by heating metallic iridium in sulphur vapor. Similarly, iridious chloride, IrCl_2 (corresponding to the oxide IrO) is obtained by passing chlorine over spongy iridium. The metal itself alloys with copper, gold, and lead, as well as with other platinum metals, and the alloy consisting of nine parts of platinum with one part of iridium is extremely hard, as elastic as steel, perfectly unalterable in the air, and capable of taking a high polish. It is of this alloy that the international prototype standard meter kept in Paris was made. Iridium is also used for the manufacture of standard weights, knife edges of balances, and for other articles which it is desired to preserve from the influence of the atmosphere. It is also used to tip the edges of gold and other pens so as to produce a very hard surface. William L. Dudley invented a process for the electrolytic deposition of this material, and his process has been successfully used for coating surgical instruments and other articles requiring an exceedingly hard surface. Gutbier and Hoffmeier, in 1905, obtained a colloidal solution of iridium (see COLLOIDS) by reducing iridium chloride, in the presence of some gum arabic, with hydrazine hydrate. See HYDRAZINE.

IR'IDOS'MINE (from *irid-ium* + *osmium*). A native alloy of iridium and osmium that crys-

tallizes in the hexagonal system. It is tin white to light steel gray in color and has a metallic lustre. The proportions of iridium and osmium in it vary, and other platinum metals, such as platinum, rhodium, and ruthenium, are frequently present. The mineral occurs with platinum minerals in the Ural Mountains, in the auriferous drifts and sands in New South Wales, and in northern California.

IRIGA, ê-rê'gâ. A town of Luzon, Philippines, in the Province of Ambos Camarines. It lies on the right bank of the Buhi River, 23 miles southeast of Nueva Cáceres, and had a population (1903) of 19,297. Near by is an extinct volcano nearly 4000 feet high.

I'RIS. An opera by Mascagni (q.v.), first produced in Rome, Nov. 22, 1898; in the United States, Oct. 16, 1902 (New York).

IRIS (Lat., from Gk. ἶρις). In Hesiod, the daughter of Thaumás and Electra, and sister of the Harpies. (See HARPY.) In the Homeric poems she is the virgin messenger of the gods; but Alcæus and later writers state that she was the wife of Zephyrus and the mother of Eros. She is frequently represented on vases and in bas-reliefs as a youthful winged virgin, with a herald's staff. The name in Greek means 'rainbow,' and, though Vergil (*Æneid*, iv, 700-702) is the first writer to represent the bow as the path of the goddess, there can be no doubt of their original connection. It may be noted that to the Greeks the rainbow was a divine portent, pre-saging war or heavy rain. Consult Mayer, "Iris," in Roscher, *Lexikon der griechischen und römischen Mythologie*, vol. ii (Leipzig, 1890-94).—Iris is also the name of one of the planetoids (q.v.), discovered in 1847.

IRIS (Lat., from Gk. ἶρις, rainbow, sort of lily), or FLOWER-DE-LUCE, *Fleur de lis* in French. A genus of plants of the family Iridaceæ, having the three outer segments of the perianth reflexed, the three inner arched inward, and three petal-like stigmas covering the stamens. The species, about 875, are chiefly natives of temperate climates, especially of North America, Europe, and Asia. The yellow iris, or corn flag (*Iris pseudacorus*), is a well-known native of moist grounds in many parts of Europe, often spreading over a considerable extent of land, and conspicuous even at a distance by its tall leaves and large, deep-yellow flowers. It is also established in a few places in the eastern United States. The stinking iris (*Iris foetidissima*), a species with livid purple flowers and ill-smelling leaves, is very abundant in the south of England, but does not extend far north. The flowers of most of the species are beautiful. Some of them have received much attention from florists, particularly *Iris xiphium*, sometimes called Spanish iris; *Iris xiphoides*, or English iris; and *Iris germanica*, or common iris, all European corm-rooted species; and the Japanese irises, which probably are all referable to *Iris lævigata*. Many fine varieties have been produced. The Persian iris (*Iris persica*) is delightfully fragrant; the snake's-head iris (*Iris tuberosa*) and the Chalcedonian iris (*Iris susiana*) are also much esteemed. The roots of all these species are annually exported in considerable quantities from Holland. Many other species are of frequent occurrence in flower gardens, such as *Iris reticulata* and *Iris atrofusca*. The fresh rootstocks of *Iris pseudacorus* are very acid. Those of *Iris florentina*, *Iris pallida*, and *Iris germanica* are orris root (q.v.). Some species have

edible rootstocks. *Iris versicolor*, the large blue flag, is common in wet places through the United States as far west as Minnesota and Arkansas. *Iris cristata* is a dwarf species with fragrant flowers found in several localities, and *Iris verna* and *Iris lacustris* are other dwarf American species, all of which are cultivated as border plants to a considerable extent. See IRIDACEÆ and accompanying Colored Plates.

IRIS (Gk. ἶρις, iris). A term used in anatomy to denote the thin circular curtain, pierced by the pupil, which hangs in the anterior chamber of the eye in front of the crystalline lens. It is attached by its peripheral margin to the sclera, and its posterior surface is pigmented. See EYE; VISION; IRITIS.

IRIS FAMILY. A family of plants. See IRIDACEÆ.

IRISH. See CELTIC LANGUAGES; IRISH LITERATURE.

IRISH ACADEMY, ROYAL. A learned association in Dublin, Ireland, which developed from a society of gentlemen, chiefly of the university, which was established in Dublin in 1782. Its object was to promote the study of science, polite literature, and antiquities. It was incorporated in 1785. The first volume of its transactions appeared in 1788. It is governed by a council consisting of 21 members, divided into three committees, viz., the committee of science, the committee of polite literature, and the committee of antiquities. The meetings of the council are distinct from those of the academy at large and are held every month from November to June. The library contains a collection of Irish manuscripts, in themselves invaluable, besides papers of public interest, including those of the Ordnance Survey of Ireland. Since 1870 the academy has been publishing the more important of its Irish manuscripts. Its collection of Irish antiquities on exhibition in the National Museum, Dublin, under the science and art departments of the academy, is both interesting and important.

IRISH CATHOLIC BENEVOLENT UNION. A fraternal and benevolent organization, founded at Dayton, Ohio, in 1869. The membership in the union is confined to those who are members of the Roman Catholic church. There were in 1914 four national societies and 137 subordinate societies. The membership is about 15,000. Since its organization the union has disbursed about \$2,650,000. During the fiscal year 1913 there were disbursed for benefits about \$54,000.

IRISH DEER. See DEER; ELK.

IRISH GAELIC LITERATURE. See IRISH LITERATURE, I.

IRISH HARP. The oldest accounts describe this instrument, not as triangular, in which form it has served for centuries as the national emblem, but as quadrangular, thus resembling the crowd (q.v.). It seems that the triangular form came into Ireland from England towards the end of the tenth century, when it was a very rude instrument with strings made of untanned hide or twisted horsehair. Early in the eleventh century we have accounts of Irish bards possessing wonderful skill, playing on triangular harps having strings of gold and silver. At any rate, metal strings were used, and the front pillar was gracefully curved. The number of strings varied from 8 to 18, producing the diatonic scale of G. Only the right hand was used in playing, and the strings were

picked with the finger nails, which the harpers allowed to grow long. The ordinary harp was a little over 2 feet in height and was held on the lap, although illustrations from the fourteenth century represent also larger sizes resting on a stool. In this improved form the instrument passed again to England and to the Continent, where it underwent further development, culminating in the invention of the pedal harp and the double pedal Erard harp (see HARP); while in Ireland it maintained itself practically unchanged, except for a gradual increase in the number of strings to 30. An attempt made by John Egan about 1800 to introduce an improved Irish harp was unsuccessful. On the other hand, the new Irish harp, improved by the application of modern scientific principles by the American harp virtuoso Melville A. Clark, holds out every promise of success. Built after a model formerly owned by the poet Thomas Moore, it preserves all the characteristics of size, shape, and general construction, and has, besides, a vastly more powerful and beautiful tone. It is made in two sizes, 25 inches with 26 strings and 39 inches with 31 strings. The first of these instruments were placed on the market in 1913, and their quality demonstrated the same year on a concert tour of the United States by the Irish tenor John McCormack (q.v.) and the inventor. Consult R. B. Armstrong, *The Irish and the Highland Harps* (Edinburgh, 1904), and W. H. Grattan-Flood, *A History of Irish Music* (Dublin, 1906).

IRISH LAND LAWS. The land tenure of Ireland is the product of two distinct systems, the Irish tribal and the English feudal. In the former, as described in the Brehon laws, the land was ultimately the property of one of the four or five tribes into which the Irish population was divided. A portion of this land was set aside for the chief or king of the tribe, but by far the greater part of it belonged to the different clans of which the tribes were composed. The clan lands were subdivided among the septs, which were the lowest social units. Land was set aside both for the chiefs of the clans and the chiefs of the septs. The greater part of the sept land, however, was held by the free tribesmen, who owed both rents and military service to their immediate chiefs. These tribesmen held their lands by different kinds of free tenure. The Ceil had herds of cattle (the chief wealth of the country) of his own, while to the Saer and the Daer tenants cattle were lent by the chief. Besides these there were servile tenants (the Fuidhir), who were not original members of the tribal community. These were personally dependent on the chief, who had a right to quarter his retainers upon them or rackrent them at pleasure. It is impossible to determine the numerical proportion of the population represented by these servile tenants, but it is probable that at the time when the English system was superimposed upon Ireland the free element was predominant.

Under the Irish system land was conceived to be held on a communal basis. On the death of the chief his land was distributed among his descendants by the tribesmen, and on the death of a tribesman the chief redistributed the land of the sept. In contrast to this, under the English feudal system, the King was conceived to be the ultimate owner of the land, and the lords and other tenants derived their ownership

from him. The English law in Ireland, however, prevailed only within the Pale, while the Irish law prevailed in by far the greater part of the country. The evils of the Irish land system are to be ascribed to the dispossession of the native population and to the forced imposition of the English land law upon Ireland. The dispossession began under Queen Mary, when the Irish were driven out of King's and Queen's counties and the English settlers established there. Under pretext of the treason of two Ulster chiefs, James I in 1607 established the famous Ulster plantation. Later in his reign confiscations, though not such extensive ones, were made. All Ireland was divided into shires and declared subject to English laws. This policy was continued during the succeeding reigns, but no second great confiscation was attempted until the time of the Commonwealth. After his Irish victory Cromwell divided the best lands of Leinster and Munster and a part of the lands in Ulster among 40,000 of the English soldiery. A small portion of this land was restored under Charles II and James II, but more was confiscated by Parliament under William III.

The effect of these measures was to dispossess almost the entire Irish nobility and gentry. The penal laws enacted by the Irish Parliament after the defeat of James II carried this principle still further by making it impossible for a Catholic to acquire land. The confiscation acted with equal severity upon the lower classes. The English law confounded all Irish tenantry with the Fuidhir class, reducing them thus to a servile status. The lands were increasingly held by absentee landlords, who endeavored to obtain the highest possible rents. The large number of middlemen who held land under the lords and acted as their agents made the condition of the peasantry still worse. The need of reformation was seen by all classes, but was not fully realized by English statesmen until the report of Lord Devon's commission, which was appointed in 1843 and sat for two years. This report, backed by the famine of 1846, showed conclusively that the cause of the poverty and suffering in Ireland was not due, as was generally supposed in England, to the shiftlessness of the Irish people, nor yet to their religion, but to the disastrous relations that existed between landlord and tenant. It recommended that the tenant receive from the landlord compensation for the improvement of his holding. Accordingly in 1847 Lord Russell proposed a measure providing for such compensation in cases of eviction, but it was rejected by Parliament. His second measure, the Encumbered Estates Act, however, was accepted. This act compelled the sale of estates upon which the rents were mortgaged, the idea being that a new set of solvent landlords would not need to rackrent the tenants. This act, however, was a failure. Estates to the value of £25,000,000 were sold for £10,000,000 and the incoming landlords, regarding their possessions as purely financial investments, had less consideration for the customs which formerly safeguarded the tenantry than their predecessors.

In 1850 the Tenant Right League, composed alike of Presbyterians and Catholics, was founded at Dublin. It contended for fair rents by actual valuation, excluding the improvements made by the tenantry, for continued possession of the holding by the tenant as long as valuation rents were paid, and for relief from arrears

of rent due from the time of the famine. The League entered actively into political affairs, and in 1852 sent 50 members to Parliament pledged to adhere to no party that did not support the principles of the League. Three of its leaders were won over by the Liberal cabinet, and its strength was broken by the opposition of the Roman Catholic hierarchy and the holy see. In consequence of renewed agrarian disturbances, the Palmerston ministry brought forward the Land Acts of 1860.

The first really efficient land legislation enacted for Ireland was a consequence of the attempted Fenian rebellion and was the work of the Gladstone ministry in 1870. It established the Ulster custom throughout Ireland. This custom provided that tenants could not be evicted while their rents were paid, and that whenever a tenant gave up possession, either voluntarily or otherwise, he might sell his own improvements. Evictions for nonpayment of rent could only be made in case of three years' arrears, and could not be made at all in cases where the rent was under £15 if the court deemed the rental exorbitant. When a holding was relinquished, a tenant could legally claim compensation for his own improvements from the landlord. The Bright clause provided for the purchase of the holding by the tenant by enacting that the Board of Works should advance two-thirds of the purchase money.

The Act of 1870 failed, however, to remedy the existing evils.

The Land Act of the second Gladstone ministry, passed in 1881, was a result of the disturbances fostered by the Land League (q.v.). It was drawn up by Forster, the Irish Secretary. This act recognized that the tenant had a possessory right in the holding, by the provision that he might sell it for whatever it would bring, subject only to the landlord's right of pre-emption. Except for the nonpayment of rent, the tenant could not be evicted. In case of the increase of rent he could apply to the land commission, established by the act, and procure a rate which would hold for 15 years. This commission also provided for the easy payment of arrears. The clause providing for the purchase of the holdings by the tenants was strengthened in 1885 by the Ashbourne Act, which advanced £5,000,000 for this purpose. In 1887 an additional £5,000,000 was advanced. The Balfour Land Purchase Bill passed by the Conservatives in 1891 continued the same policy. It provided for purchase based on voluntary agreement between landlord and tenant, the government advancing the entire purchase money, such sum to be repaid by the tenants in 41 annual 4 per cent payments. The fund created for this purpose was £30,000,000, a sum deemed sufficient to establish peasant proprietorship in Ireland. John Morley's Land Law of 1896 improved the application of the law. Nevertheless, agitation did not cease, and in January, 1898, the United Irish League was founded, which aimed, among other things, to agitate for the abolition of the dual ownership of land, and the redistribution of the grazing ranches of Connaught among the small holders. In 1902 a conference between representatives of the landlords and tenants to settle the land question was urged, and a preliminary meeting was held at Dublin on Dec. 20, 1902. As a result of the agreements reached at that meeting, the Balfour

government introduced, on March 25, 1903, a comprehensive measure, known as the Wyndham Act, which went into effect on November 1. It provided for the creation of a land purchase fund not to exceed £100,000,000, by the sale of treasury stock, the proceeds to be loaned to tenants to enable them to acquire title to the lands they were occupying. Of the fund, £12,000,000 was to be distributed in the form of bonuses to the vendors of estates. The amount which each tenant might borrow was limited to £5000 or, in exceptional cases, £7000, and the loans were made repayable in 68½ annual installments that were on the average calculated to be 15 per cent less than the judicial rent for 1903 would have been.

IRISH LANGUAGE. See CELTIC LANGUAGES.

IRISH LANGUAGE, SOCIETY FOR THE PRESERVATION OF THE. A society with headquarters in Dublin founded in 1876 for the restoration of the ancient Gaelic tongue as a spoken language. The movement of which this organization is the result had its origin in Boston, Mass., in the Philo-Celtic Society, which was organized in 1873. From there it spread to other parts of the United States and finally attracted the attention of scholars in Ireland, where eventually the society became firmly established. Its publications are mainly textbooks of the Gaelic language designed for schools and colleges, and especially in demand after Gaelic became a subject taught in the government schools. See IRELAND.

IRISH LEAGUE OF AMERICA, THE UNITED. See UNITED IRISH LEAGUE OF AMERICA, THE.

IRISH LITERARY REVIVAL. See IRISH LITERATURE, II.

IRISH LITERARY SOCIETY. A society for the study of the Irish language, literature, history, music, and art, founded in London in 1892 by a small coterie of young Irishmen and Irishwomen, with the coöperation of leading Irish literary men in England and Ireland. The society has a large library of Irish books and during each season provides lectures on Irish subjects and social entertainments for its members and their friends. The membership is about 600 and includes the names of many prominent littérateurs, among whom may be mentioned Rev. Stopford Brooke, W. B. Yeats, Justin McCarthy, and Barry O'Brien. A sister institution is the National Literary Society of

Ireland, which has its headquarters in Dublin, holds weekly meetings, and has aims and functions similar to those of the former association. It is very active in publishing and in offering courses of lectures. It publishes books concerned with the interests it was founded to further.

IRISH LITERATURE. I. Gaelic. Irish literature shows an unbroken, if varying, continuity from the seventh or eighth century until the nineteenth. In its earlier periods it is of especial interest and in some kinds of production ranks with the richest literatures of mediæval Europe.

Three periods are regularly recognized by scholars in the history of the Irish language: Old Irish, from the time of the earliest monuments through the tenth century; Middle Irish, from the eleventh century to the seventeenth; and Modern Irish, from the seventeenth century to the present time. It is convenient to follow the same divisions in treating the history of Irish literature, though there is no such well-defined distinction between the literary productions of successive periods as between the corresponding stages of the language.

Old Irish.—There is an abundance of material for the study of the Old Irish language. The most archaic stage is represented by the Ogam inscriptions, some of which date from the fifth and sixth centuries and even earlier. They contain little besides proper names, but these are of great interest for the light they throw upon the beginnings of Celtic phonology and inflection. (See OGAM.) From the period between the seventh and the tenth century a score or more of manuscripts have been preserved containing thousands of Irish glosses, and on the basis of these a very complete grammar of the Old Irish language has been constructed. Unfortunately only a few continuous Irish texts exist in any of these early manuscripts. An ancient Latin-Irish sermon, a short sketch of St. Patrick's life, a few poems and incantations—this is about all that is preserved of the oldest Irish literature in contemporary copies. We have to wait for the Middle Irish manuscripts before we find much direct evidence of its character. However, many of the texts in these later manuscripts are composed in a language only half contemporary with the writers; they abound in archaic forms, which make it safe to set them down as being substantially Old Irish, in spite of the circumstances of their preservation. The reason for the scarcity of early literary monuments is to be found in the political conditions of Ireland from the eighth to the tenth century. This was the Viking age, and Ireland with the rest of western Europe suffered from the ravages of the Norsemen. Monasteries were repeatedly sacked and burned by the Scandinavian invaders, and few libraries survived the struggle. Nearly all the manuscripts of the Old Irish period have been preserved on the Continent.

Middle Irish.—In 1014 the Scandinavians were defeated in the battle of Clontarf, and from that time forth their power in Ireland declined. From the period between about 1100 and about 1500 there has come down to us a great body of manuscripts containing a vast variety of writings in both prose and verse. Among the most important of these Middle Irish manuscripts are the *Liber Hymnorum* (ed. by Bernard and Atkinson, London, 1895), and the

Book of the Dun Cow (facsimile reprint, ib., 1870), written about 1100; the *Book of Leinster* (facsimile reprint, ib., 1880), of the twelfth century; the *Yellow Book of Lecan*, the *Leabhar Breac* (Speckled Book), and the *Book of Ballymote*, all of the fourteenth century; and the *Book of Lecan*, from about the beginning of the fifteenth.

The religious element in Middle Irish literature, consisting of hymns and sermons, theological treatises, and lives of saints, bears a general resemblance to contemporary writings in other vernacular languages of Europe. The poetry is largely conventional and technical, but it often reveals a fine fancy and a strong love of nature.

In metrical form it is highly intricate and shows great artistic skill. Chief interest, however, attaches to the heroic sagas, which constitute the best contribution of the Irish to the world's literature. These hero tales fall into three main groups: (1) the so-called *mythological cycle*, which relates various traditions about the early settlement and conquest of Ireland and extends to near the beginning of the Christian era; (2) the *Ultonian*, or Red-Branch, cycle—the most complete, productive, and brilliant of the three traditional epochs—which tells of the wars between Ulster and Connaught in the time of King Conchobar and is identified with the period immediately before and after the commencement of the Christian era; and (3) the *Ossianic cycle*, which extends to the middle of the third century A.D. The tales of the first group are chiefly interesting for the light they seem to throw on the ancient Celtic pantheon. The characters are generally held to be derived by a process of euhemerism from the gods of the old mythology. The stories belonging to this period are fewer in number than those belonging to the later periods. Two of the *Three Sorrows of Story-Telling* are connected with this cycle, i.e., the *Aided or Tragedy of the Children of Tuireann* and *The Tragedy of the Children of Lir*, the latter dealing with the struggles between the Milesians and the Tuatha De Danann, races of demigods vying with each other for the supremacy of Ireland. The cycle of King Conchobar of Ulster represents ancient Irish literature at its best. Some 96 tales have been classified as belonging to this cycle, whose heroes are Conchobar, Cuchulinn, Fergus MacRoich, Conall, Celtchar, and Curigh. Among the most important of these sagas are the great prose epic *Táin Bó Chuaillgné, or The Raid of the Cattle of Cooley, Deirdre and the Sons of Uisneach, the Conception and Training of Cuchulinn, the Wooing of Eimer, the Battle of Rosnaree, Cuchulinn's Adventure at the Boyne, Eimer's Jealousy, Briciu's Banquet, the Death of Conlaoch, the Death of Cuchulinn, and the Recovery of the Táin*. While not uninfluenced by foreign thought, these old sagas are in the main a representative national product, and they furnish the best existing record of what the ancient Celtic people must have been. They were composed in a mixed prose and verse, which long remained the typical Irish epic form. Many of the sagas of this group seem to have taken practically their final shape before the end of the Old Irish period. The third cycle—that of Finn and Ossian—is found in later manuscripts than the second, and the tales are composed in a more modern language. The events with which they deal are supposed to have taken place two

or three centuries after those of the earlier group. The wealth of this cycle is so great that, according to O'Curry, its sagas will fill 3000 large quarto pages. Its leading heroes are Fionn, Gol MacMorna, Ossian the son of Fionn, Oscar the son of Ossian, Diarmad O'Duibhne, Caoilte MacRonan, Fergus Finne-bheoil, and Conan Maol. The literature of this cycle is divided into four classes, of which the first consists of poems ascribed to Fionn MacCumhail, to his sons Ossian and Fergus, and his nephew Caoilte, about 16 poems in all; the second class consists of stories in prose and verse attributed to one of the aforementioned bards, but related by some one else, such as *Agallamh na Seanórach*, or *Dialogue of the Ancients*; the third class consists of miscellaneous poems attributed mainly to Ossian and a large number which are ascribed to no particular author, such as the beautiful *Ossian and Eivir-Alin*; and the fourth class of prose tales, describing in romantic style the deeds of Fionn and of individuals of his band, such as the *Pursuit of Diarmad and Grainne*. The Ossianic cycle shows more traces of foreign influence, and in the opinion of some scholars owes its origin and character largely to the contact of the Irish with the Scandinavian people. But it is more likely that the stories of Finn were in the main a native product, and they have continued down to this day to be a favorite body of tradition with Irish and Scottish Gaels alike.

In addition to these three saga cycles there exist in Middle Irish manuscripts many separate tales, or groups of tales, of interest and importance. The *Immrama*, or stories of marvelous voyages, deserve special mention, both because they go back to very ancient Celtic tradition and because they appear to have had considerable influence on mediæval literature in other tongues. The *Voyage of Bran*, the oldest and in some respects the most interesting of this series, can safely be dated in the Old Irish period. An entirely different literary vein is represented by the *Vision of MacConglinne*, a satire of which the fun has seldom been surpassed. Far removed from either of these types is the story of the *Sons of Eochaid Muigmedoin*, who have an adventure similar to that related in Chaucer's tale of the Wife of Bath. Middle Irish translations (or adaptations) of foreign material are preserved in considerable number, and represent a wide variety of originals from the tale of Troy to the travels of Sir John Maundeville.

Modern Irish.—Throughout the older periods of Irish literature nearly all the greatest works are anonymous. In the Modern Irish period this is less the case. The later literature is on the whole less significant than the earlier, but the writers, as such, claim more attention. At the beginning of the period stand several prose writers of first importance: the Four Masters, who compiled the greatest collection of Irish annals (ed. by J. O'Donovan, 1857); Duaid MacFirbis, the genealogist; and Geoffrey Keating (also a poet), whose religious writings and *History of Ireland* are the standards of classic Irish prose. Treatises in prose, chiefly religious, continued to be written throughout the seventeenth century; but as education declined among the Irish-speaking population, literature of this sort found itself without a public and died out. Poetry, on the other hand, continued to be ex-

tensively cultivated; and the work of the modern poets, though it seldom rises high in thought or imagination, possesses great melody and charm. Much of it is distinctly popular in character and has long been common property of the Gaels in both Ireland and Scotland. The seventeenth century witnessed a great change in the form of Irish poetry. The metrical system of the old bardic schools, in which syllable counting and consonantal rhyme were the controlling principles, gave way to a new verse form, in which the accent was the unit of measure and the rhyme was primarily vocalic. The use of vowel rhymes was extended till it applied to all the accented syllables in the line, and a strangely melodious verse form resulted, in which whole poems are constructed with the same accented vowels recurring throughout in orderly sequence. The two systems existed side by side throughout the seventeenth century; but in the eighteenth, after the disappearance of the old bardic schools, the use of the newer metres became practically universal. The chief representatives of the classic style in its final stage were Teig mac Daire and Lughaidh O'Clery (the leaders in the great "Contention of the Bards"), Teig Dall O'Higinn, and Eochaidh O'Hussey. The later school of poets was very numerous, especially in the eighteenth century. Among the most representative of the number were David O'Bruadar, John O'Neaghtan, Torlough O'Carolan, Teig O'Naghten, Brian MacGiolla Meidhre (whose "Midnight Court" is one of the most remarkable pieces in Modern Irish), Timothy O'Sullivan (Tadhg Gaolach), Donough MacConmara, Egan O'Rahilly, Owen Roe O'Sullivan, and in the beginning of the nineteenth century Anthony Raftery, the blind poet of Killeadan.

In the nineteenth century even poetry ceased to be much written in Ireland, and the native language fell into disuse for literary purposes. Only in very recent years has a movement been set on foot to restore the language to general use and to revive Irish literature. An organized effort is being made to bring this about, and Irish books and periodicals are being published in large numbers every year.

Two societies have been especially active in the revival: the Society for the Preservation of the Irish Language, which has long labored to get more recognition for Irish in the schools; and the Gaelic League, a very large organization, which has lately waged a lively popular campaign all over the country. Dr. Douglas Hyde (q.v.), the president of the league, has been one of the leaders in the movement. Among others who have borne an important share in the work should be mentioned the late Father Eugene O'Growney and Fathers P. J. Dinneen and Peter O'Leary, who have contributed largely as authors and editors to the publications of the league.

Bibliography. GENERAL. O'Reilly, *Irish Writers* (Dublin, 1830); O'Curry, *Lectures on the Manuscript Materials of Ancient Irish History* (ib., 1861); id., *On the Manners and Customs of the Ancient Irish People* (4 vols., ib., 1873). Much of the contents of these older works is now superseded. Hyde, *A Literary History of Ireland* (4th ed., London, 1906), represents better the present state of information. McCarthy (and others), ed., *Irish Literature* (10 vols., Philadelphia, 1904), covers the entire field. MacLean, *Literature of the Celts* (London, 1906) is a useful general work, while Hull,

A Text Book of Irish Literature (2d ed., 2 vols., ib., 1910) is an excellent manual. Other works of importance are D'Arbois de Jubainville, *Essai d'un catalogue de la littérature épique de l'Irlande* (Paris, 1883); *Cours de littérature celtique* (12 vols., ib., 1883-1902); Nutt and Meyer, *The Voyage of Bran* (2 vols., London, 1895-97); Hull, *The Cuchullin Saga* (ib., 1898); Joyce, *Social History of Ancient Ireland* (2 vols., ib., 1903); Sigerson, *The Bards of the Gael and Gall* (Dublin, 1906); *The Cattle Raid of Cualnge (Tain bo Cuailnge), an Old Irish Prose Epic* (Eng. trans. by Faraday, London, 1904; Ger. trans. with text by Windisch, Leipzig, 1905; Fr. trans. by D'Arbois de Jubainville, Paris, 1907); Strachan, *Stories from the Táin* (Dublin, 1908); *Old Irish Paradigms and Glosses* (ib., 1909); Rolleston, *The High Deeds of Finn* (New York, 1911); *Myths and Legends of the Celtic Race* (ib., 1911); Hull, *The Poem-Book of the Gael* (Chicago, 1913). For other translations from the Gaelic of this and later periods, see bibliography below under *Irish Literature in English*.

OLD IRISH. Stokes and Strachan, *Thesaurus Palæohibernicus*, part i (Cambridge, 1902; vol. ii, 1904). The completed work will contain all the Old Irish monuments. Meyer, *Selections from Ancient Irish Poetry* (London, 1911) deserves to be mentioned.

MIDDLE IRISH. Stokes and Windisch, *Irische Texte* (4 vols., Leipzig, 1881-1909); O'Grady, *Silva Gadelica* (2 vols., London, 1892). Numerous texts have appeared in the *Revue Celtique* (Paris), the *Zeitschrift für Celtische Philologie* (Halle), the *Anecdota Oxoniensia*, Leahy, ed. (Oxford); *Heroic Romances of Ireland, translated into English Prose and Verse* (2 vols., London, 1905), and also in the publications of the Royal Irish Academy, the Irish Archæological Society, the Celtic Society, and the Irish Texts Society; Meyer, *Colmán mac Lúacháin*, in the "Todd Lecture Series," vol. xvii (Dublin, 1911); and Dottin, *Manuel d'irlandais moyen*, vol. ii (Paris, 1913), containing texts, glossary, and bibliography, are among the most important of recent works.

MODERN IRISH. Atkinson's edition of Keating, *Three Shafts of Death* (Dublin, 1890), is the best introduction to the modern language. Keating, *History of Ireland*, is being edited by D. Comyn for the Irish Texts Society (3 vols., London, 1901-08). Brooke, *Reliques of Irish Poetry* (Dublin, 1789), Hardiman, *Irish Minstrelsy* (London, 1831), O'Daly, *Poets and Poetry of Munster* (Dublin, 1850), and *The Irish Language Miscellany* (ib., 1876), represent the poetry of the last two or three centuries. Several poets of this period have been published very lately in the "Irish Texts Series" of the Gaelic League. Douglas Hyde's *Songs of Connacht* form also an important collection. In folklore the collections of T. Crofton Croker, Jeremiah Curtin, Patrick Kennedy, William Larminie, D. O'Foharta, and Douglas Hyde all deserve mention. For a good general bibliography, the *Esquisse d'une histoire des études celtiques* of Tourneur (Liège, 1905) is recommended. Monahan's *Nova Hibernia, Irish Poets and Dramatists of Today and Yesterday* (New York, 1914) contains studies of recent Irish poets who write in English.

II. *Irish Literature in English*. Side by side with the expiring Gaelic a new Irish liter-

ature in English began to make its appearance at the close of the eighteenth and the beginning of the nineteenth century—a literature distinctively national, though not in the native language, and standing quite apart from the imposing stream of English literature by which it flowed. This new Irish-English literature opened with songs and popular ballads, some of which sang of the sorrows of Ireland and breathed a passionate patriotism, while others were idylls of peasant love, or verses convivial or humorous. "The Boyne Water," "The Wearin' o' the 'Green"—a fine street ballad which is now the national anthem—"The Shan Van Vocht," "The Cruiskeen Lawn," and "Irish Molly O," are good examples of the early attempts at making the English language the vehicle of Irish feeling. Along with the popular literature of ballad and song which belonged to peasants and ragged street minstrels there went a more sophisticated sort of verse which belonged to the drawing room and found its most characteristic expression in the poetry—high and fine at moments, though in general facile and artificial—of Thomas Moore's *Irish Melodies* (1807), *National Airs* (1815), and other poems. In this period Gerald Griffin (1803-40), gratefully remembered for his "Eileen Aroon" and a little sheaf of lovely poems, was writing; and also "Father Prout" (Francis Sylvester Mahony, 1804-66), whose "The Bells of Shandon" still chime through uncounted anthologies. Dashing and racy verse was coming, too, from the pen of William Maginn; and Lever and Lover occasionally threw off such prime comic songs as the former's "The Widow Malone" or the latter's "The Widow Machree."

Contemporary with a part of the productions just mentioned were the beginnings of the literary movement of the Young Irelanders who were banded together under the banner of the *Nation*, the paper which, founded in 1842 by Charles Gavan Duffy, Dillon, and Thomas Davis, quickened the intellect and stirred the heart of Ireland and made the written word a power in the land. Around it sprang up a band of poets, conspicuous among them Thomas Davis (1814-45), Thomas D'Arcy McGee (1825-68), Denis Florence McCarthy (1817-82), Lady Wilde ("Speranza," c.1820-96), and Joseph Sheridan LeFanu (1814-73), who must always have a conspicuous place in Irish literary history. Their work was sincere, fiery, and strong in the rhetorical qualities of poetry—rhythm, phrase, and picturesque diction. But their importance is rather practical and political than strictly literary. Their art was subservient to ideals of nationality and patriotism, and the insatiable artist was often a stranger among them. The artist was, however, potent in James Clarence Mangan (1803-49), a fragile and tremulous spirit in the world of affairs, but, by virtue of some 20 or 30 splendid lyrics, unsurpassed among Irish poets of his own or a later day. In his poems of Gaelic theme and inspiration, and in the like poems of two of his contemporaries, J. J. Callanan (1795-1829) and Edward Walsh (1805-50), we have what is in a manner the prelude to a chorus of Irish poets who in the latter end of the nineteenth century were to constitute a part of a second literary movement. Sir Samuel Ferguson (1810-86) carried on the work of the three men last named and powerfully influenced the course of Irish poetry. His

Lays of the Western Gael (1867) may be regarded as the definite point of departure of the Celtic movement, and the poems of his which made free of the material of the old Irish sagas opened up a new poetic realm, abounding in fresh subjects and new impulses, of which later poets both Irish and English—and Tennyson among them—were to make good use. The Fenian and agrarian movements had their singers, but they were perhaps not of an importance that demands attention for them here. During the two movements just named, however, two other poets, who, like Ferguson, stood rather apart from politics, produced poetry of a rare and finished beauty. The reference is to Aubrey de Vere (1814–1902) and William Allingham (1824–89).

In fiction Irish genius was uninterruptedly at work, from end to end of the nineteenth century, on stories native both in style and in substance. The first of these was Maria Edgeworth's tale of the devil-may-care pre-Union gentry, *Castle Rackrent* (1800), the best thing that ever came from her pen, and a little masterpiece in its kind, which was followed by three other Irish novels, *Ennui* (1809), *The Absentee* (1812), and *Ormond* (1817). Miss Edgeworth wrote from the point of view of the Anglo-Irish Protestant gentry, and so did her fellow novelists W. H. Maxwell (1792–1850); the prolix Lady Morgan (?1777–1859); Samuel Lover (1797–1868); Charles Lever (1806–72); William Maginn (1793–1842), whose stories and sketches present the traits of the convivial Anglo-Irishman; T. C. Croker (1798–1854), the historian of the fairies; and the worthy Anna Maria Hall (1800–81), whose pictures of Irish life are thrown out of focus by her zeal for moral and social edification. Of this group Lever and Lover are the best—and the former is best represented by *Harry Lorrequer* (1839), *Charles O'Malley* (1840), and *Jack Hinton* (1843); the latter by *Rory O'Moore* (1837) and *Handy Andy* (1842), novels in which the Irish peasant is to the fore. Lever, in his comic extravaganzas of sparkling fun and irrepressible high spirits, is well-nigh incomparable among novelists, and Lover is a droll of no mean quality; but a taste for burlesque, caricature, and exaggeration has left their pictures of Irish life and character both misleading and distorted. Contemporary with these novelists who wrote in the spirit of the Anglo-Irish gentry worked a little company of novelists who wrote in the spirit of the peasantry and were themselves of Celtic stock and Catholic faith. This group includes John Banim (1798–1842) and Michael Banim (1796–1874), who collaborated in *Tales of the O'Hara Family* (1825–32); Gerald Griffin (1803–40), whose tale of middle-class, Catholic life, *The Collegians* (1829), is among the best of Irish novels; and William Carleton (1798–1869)—who turned Protestant, be it said by the way—the most gifted of them all, and now unduly neglected by a generation unaware how moving, graphic, and richly humorous are his *Traits and Stories of the Irish Peasantry* (1830), *Fardarougha, the Miser* (1839), etc. In his stories, beyond those of any other novelist, one comes to know the Irish peasant as he was in truth and reality. The years between the Irish story-tellers of the first half of the nineteenth century of whom we have just spoken and those of whom we are to

speak presently as a part of a new literary movement, were not inactive ones and witnessed the appearance, notably, of Joseph Sheridan Le Fanu's *Uncle Silas* (1864) and other sensational but fine novels; of Charles James Kickham's *Sally Cavanagh* (1869) and *Knocknagow* (1879); of Emily Lawless's *Hurricane* (1886); and of William O'Brien's *When we Were Boys* (1890).

During—and beyond—the period embraced in the foregoing brief survey of Irish poetry and fiction in the English language Ireland was by no means lacking in writers who distinguished themselves in other fields—in science, in history, in the essay, in the drama, in philosophy, and in scholarship—witness such names as Tyndall, Lecky, Dowden, Oscar Wilde, Bernard Shaw, and Professor Mahaffy; but their work, as well as that of other Irishmen in these fields, is so much a part of English literature, and has been so carefully treated in the article ENGLISH LITERATURE and under the names of the individual authors, that it is unnecessary to treat them here; nor, for a like reason, is it necessary to consider under this head such Irishmen as Congreve, Swift, Goldsmith, and Sheridan, who, discover in them as we may certain inalienable Celtic traits, have still fully identified themselves with the literature of the sister island.

With the passing of the writers of '48 literary activity in Ireland steadily declined, and was at the lowest ebb just before the fall of Parnell. After his fall part of the national energy which had been absorbed in politics turned once more to literature. In quick succession young writers began to make their appearance with plays and poems, novels and stories, essays and translations from the Gaelic. In 1899 the Irish Literary Theatre was founded in Dublin, and in 1892 the National Literary Society. By the last decade of the nineteenth century the activities of these young writers, known as the Irish Literary Revival, constituted the most interesting literary movement of its day, and one conspicuous in a time of confused ideals for the clarity and solidarity of its aims. While national in spirit and drawing inspiration from the past and present of Ireland, this movement took various forms and directions.

One band of young writers went for their material to the cycles of Gaelic romance and delighted to reveal to their own day, in the form of lyric, narrative poem, or drama, the beauty and glamour of the ancient creations of the Celtic imagination. In the forefront of these was William Butler Yeats (1866–), on the whole the representative man of the revival, who was a part of almost every phase of it, and its chief apologist as well. His best work is found in *Poetical Works* (1912), *Plays* (1912), and *Ideas of Good and Evil* (1903). Among lyric poets who wrote in English he was probably unsurpassed in his generation. Other poets who, like Yeats, used the materials and personages of the Irish sagas as vehicles for their own thought and feeling were Dr. John Todhunter (1839–), Nora Hopper (Mrs. W. H. Chesson, 1871–1906), and William Larmie (1850–1900). Work good in itself and a boon to original poets and dramatists was done by a number of translators who put into English the Gaelic romance and folklore that were the driving force of the literary awakening in Ireland. First among these was Lady Augusta Gregory, whose *Cuchulain* (1902) and

Gods and Fighting Men (1904), translations in the Irish idiom from the cycles of Irish romance, are likely to float Gaelic romance down the centuries as Malory did the romances of King Arthur. Among the translators may also be mentioned Dr. Douglas Hyde (1860-) and T. W. Rolleston (1857-). Religious poetry, as might be expected in the Isle of Saints, had its place in the revival, and is represented, notably and variously, by Lionel Johnson (1867-92), in point of strength and finished art hardly surpassed by any of his fellow singers; in G. W. Russell ("A. E.," 1867-), mystic and pantheist, also a finished artist, and in Katharine Tynan-Hinkson (186 -), like Lionel Johnson in being a Catholic poet, though in other ways unlike enough. Still another band of poets—and a very engaging choir they make—sings of the joys and sorrows of peasant life in verses of tender pathos or rich and mellow humor, and among them must be mentioned Alfred Percival Graves (1846-), "Moira O'Neill" (Mrs. Walter Skrine, ?-), and Jane Barlow (1857-).

No feature of the revival was more conspicuous than its dramatic activity, to which, notably, Yeats, Edward Martyn (?-), George Moore (1853-), Douglas Hyde, Lady Gregory, and, by no means least, John Millington Synge (1871-1909) contributed. Synge's *Playboy of the Western World* (1907) represents the climax of dramatic success reached by the dramatists of the revival. Like George Moore drawn into the movement by Yeats, Synge was an outstanding figure among the Irish writers, and his death was an irreparable loss. His plays, poems, and miscellanies are collected in his *Works* (4 vols., Dublin, 1910). The plays of the young Irish dramatists, and their philosophy of the drama, of acting, and stage effects were in practical protest against the shabby ideals of the commercialized theatre—a protest that had its effect, thanks to the talent of its dramatists and actors, to the critical resource of its apologists, and to the successful visits to England and America of the Irish Players.

The revival was fertile in novels and produced some books of excellent quality in this kind. Standish O'Grady (1846-) offered tales of the mythic Irish past of an epic sweep and with a kind of bardic afflatus. Jane Barlow, mentioned also above, could fill appealing stories with genre pictures of peasant life in the west. Life in the north was the field of Seumas Mac Manus (1868-) and of Shan Bullock (1865-). In *Luke Delmege* (latest ed., 1901) and *My New Curate* (1899), Canon P. A. Sheehan (1852-1913) presented pictures of the Catholic priesthood of Ireland and of Irish life at its points of contact therewith in novels that are a little provincial and prolix, but on the whole interesting and informing. Two collaborating ladies, Miss Somerville (?-) and Miss Violet Martin ("Martin Ross," ?-), have added to the gayety of English-speaking peoples in stories highly spiced with "divilment and divarshion," somewhat in the manner of Lover and Lever. Perhaps the best of their books is *The Experiences of an Irish R. M.* (latest ed., 1910). George Moore, whom Yeats and Edward Martyn lured back to Ireland to help with the Irish Theatre, stands high among the novelists. Though bred a Catholic,

Moore avows his strong anti-Catholic bias in the absorbing short stories of his *Untilled Field* (1903) and in his novel *The Lake* (1906), both of which were a result of his return to Ireland, as were also the three volumes *Ave, Salve, and Vale* which composed the trilogy entitled *Hail and Farewell* (1914). The last-named work is Moore's account, frank to the limits of indiscretion, of his decade's experience with the revival. It includes, in its wonderful portrait group, sketches from the life, not always flattering and sometimes far from good-natured, of most of the writers prominent in the literary activities of Dublin within the period covered. It should be read by all who would look behind the scenes of this literary movement, but somewhat discounted on the score of its whimsicality and unbridled satire. Finally we may mention the Rev. James Owen Hannay ("George A. Birmingham," 1865-), canon of St. Patrick's Cathedral, whose *The Seething Pot* (1905) and other novels concerned with the men and movements of his day invite the attention of every one who would know how faithfully and skillfully Irish life is reflected in Irish fiction, and we may name also James Stephens, whose *Crook of Gold* (1913), a prose fantasy, and *Demi-Gods* (1914) have found enthusiastic admirers.

Bibliography. Bibliographical and other information regarding most of the authors named above is given elsewhere in these pages under the name of each author. For criticisms and selections from Irish poetry in English, consult *A Book of Irish Verse* (London, 1895), edited, with an excellent introduction, by W. B. Yeats, and *The Treasury of Irish Poetry*, admirably edited by Stopford A. Brooke and T. W. Rolleston (ib., 1900). *Irish Literature* (10 vols., Philadelphia, n.d., but c.1904) is an anthology of prose and verse, editorially uneven and bibliographically unsatisfactory, but with some excellent critical articles, by Yeats, Hyde, Sigerson, and others. H. S. Krans, *Irish Life in Irish Fiction* (New York, 1903), is a careful study of Irish fiction from 1800 to 1850; id., *W. B. Yeats and the Irish Literary Revival* (New York, 1904), is a critical study of Yeats and a survey of the movement indicated in the title. Studies of the Irish Theatre and of the younger Irish dramatists are: Francis Bickman, *Synge and the Irish Dramatic Movement* (New York, 1912); C. Weygand, *Irish Plays and Playwrights* (ib., 1913); Maurice Bourgeois, *Synge and the Irish Theatre* (London, 1913); Lady Gregory, *Our Irish Theatre* (New York, 1913). Yeats's *Ideas of Good and Evil* (London, 1903), a volume of essays, and prefaces and introductions to various volumes of selections of Irish prose and verse of his editing, will be found informing. George Moore's *Hail and Farewell* (3 vols., New York, 1911-14), mentioned above, is of especial importance.

IRISH LORD. A yellowish, sculpin-like fish (*Hemilepidotus jordani*) of the waters about the Aleutian Islands, which is of great importance as food to the Aleut islanders. This is also known as yellow sculpin, and a more southerly species of the same genus is called red sculpin. Both are mottled or barred blackish and are from 1 to 2 feet in length.

IRISHMEN, SOCIETY OF UNITED. See UNITED IRISHMEN, SOCIETY OF.

IRISH MOSS. An edible seaweed. See CARRAGEEN.

IRISH MOSS GUM. See GUMS.

IRISH MUSIC. See CELTIC MUSIC.

IRISH PALE. See ENGLISH PALE; IRELAND, *History*.

IRISH POM'PANO. A West Indian food fish (*Gerres olisthostomus*), one of the mojaras (see MOJARRA), and also called mutton fish.

IRISH SEA. The almost circular middle expansion of the channel separating Ireland from Great Britain (Map: Europe, C 3). It connects with the Atlantic Ocean to the north by North Channel between southwest Scotland and northeast Ireland, and to the south by St. George's Channel between Wales and south Ireland. Its greatest width is 140 miles, and its length from north to south is nearly the same. It contains the Isle of Man in the north central part, and Anglesey in the southeast. The east half is shallow, and the Isle of Man belongs therefore to Great Britain rather than to Ireland, but the western half is a northward extension of the relatively deep St. George's Channel.

IRISH TERRIER. See TERRIER.

IRISH TEXTS SOCIETY. A society formed in London in 1898 to promote and foster the study of ancient Irish texts and to undertake their publication. In 1914 some dozen volumes had appeared under this society's imprint.

I'RIS ROOT. The fragrant root of various species of *Iris*. See ORRIS ROOT; IRIS.

IRISSON, é'rê'sôn', MAURICE HÉRISSON, COUNT OF. See HÉRISSON, MAURICE.

IRI'TIS (Neo-Lat., from *iris*, iris). Inflammation of the iris. The objective symptoms of iritis (those which can be observed by the physician) are: 1. Redness of the eye, arising from vascularity of the sclerotic around the cornea and general redness of the sclerotic from accompanying conjunctivitis. 2. Change in the color of the iris. When there is an exudation into the iris, a gray or blue eye is rendered greenish, while in a dark eye a muddy reddish tint is produced. The brilliancy of the color of the iris also disappears. When the inflammation is very violent, or has been unchecked by remedies, suppuration may take place, the pus settling at the lower part of the anterior chamber. 3. Irregularity, sluggishness, and sometimes immobility of the pupil, produced by the adhesion of the back of the iris to the crystalline lens. The subjective symptoms (those of which the patient is conscious) are intolerance of light, dimness of vision, pain in and around the eye, and lachrymation. The disease is often confused with acute catarrhal conjunctivitis. Many acute cases recover under treatment in a few weeks; others run a more mild but chronic course. Complicating inflammation of the deep portions of the eye increases the danger. Iritis may be followed by adhesions between the iris and lens, occlusion of the pupil, glaucoma, and sometimes blindness. Iritis may be primary, or secondary to inflammation of other portions of the eye. The primary cases are often caused by syphilis, rheumatism, injury, or, less frequently, by tuberculosis, gonorrhœa, acute infectious diseases, or diabetes. In the so-called idiopathic iritis no cause is found. The treatment consists in absolute rest of the eye, with protection from light, the application of moist, warm compresses, local bloodletting, and dilatation of the pupil by the instillation into the eye of a weak solution of sulphate of atropine, with the view of preventing adhesion of the iris, or of breaking, or, at all events, of stretching and elongating,

any adhesive bands that may be formed; and thus of preventing any impairment of the movements of the iris, and any irregularity of the pupil after the inflammation shall have abated. When this is done, the result must be carefully watched by the physician. Constitutional treatment must be directed to the cause of the inflammation, especially in cases of syphilitic origin. See EYE, DISEASES OF THE.

IRKUTSK, êr-kōōtsk'. A governor-generalship and a government of east Siberia. The former comprises the governments of Irkutsk and Yeniseisk (q.v.), and the Territory of Yakutsk (q.v.), with a total area of nearly 2,792,289 square miles, and a population in 1912 of 2,011,300 (Map: Asia, N 3). The Government of Irkutsk is bounded by the Territory of Yakutsk on the north, the territories of Yakutsk and Trans-Baikalia on the east, China on the south, and the Siberian Government of Yeniseisk on the west. Area, about 280,429 square miles. Its surface is generally mountainous. The Sayan Mountains run along the southern boundary; the Baikal Mountains along the west shore of Lake Baikal. The chief rivers are the Lena, which rises in the Baikal Mountains, and the Angara, with its numerous mountain tributaries. Irkutsk takes in a large portion of Lake Baikal. The mountains of Irkutsk are rich in minerals, containing deposits of iron, coal, graphite, salt, gold, and many varieties of precious and semi-precious stones, including great deposits of lapis lazuli and malachite. The climate is raw and severe, the annual average temperature at the capital being about 32° F. Only an insignificant portion of the cultivable land has been cleared, by far the larger part of the country being covered with forests, filled with fur-bearing animals. The land is fertile and yields ample crops of rye, wheat, oats, barley, buckwheat, and potatoes. The raising of domestic animals is confined mostly to the natives. The manufacturing as well as the mining industries are developing rapidly, and each year brings a remarkable increase in the wealth and population of the province. The manufactures, mainly centred at the city of Irkutsk, include flour milling, pottery, glass blowing, and iron smelting and working. The Baikal fisheries are important. The population (714,900 in 1912) consists mostly of Russians, Buriats, Tunguses, and Jews. Capital, Irkutsk (q.v.).

IRKUTSK. The capital of the Governor-Generalship and of the Government of Irkutsk, and the finest city of Siberia, situated at the confluence of the Irkut with the Angara, 40 miles north of the south extremity of Lake Baikal and 3385 miles by rail from Moscow (Map: Asia, M 3). It was almost entirely rebuilt after the destructive fire of 1879, and is now a handsome, well-laid-out city, with well-paved, wide streets, and all the essential features of a modern city. The climate is healthful, owing to the high altitude of the city; the winters, however, are severe. There are in Irkutsk a theatre, a library, a museum, a school of medicine, and numerous other primary and secondary schools, a meteorological station, and a branch of the Imperial Geographical Society. The cathedral, the seat of an Orthodox archbishop, dates from 1718, and is a fine stone building with five domes and a clock tower in the Russian style. The Roman Catholics and Lutherans have also fine places of worship. The manufactures are unimportant and go mostly

to satisfy domestic demands. The commerce is of great importance, Irkutsk being one of the chief centres of the Russian tea trade as well as one of the principal stations on the Trans-Siberian Railway. Each year an important fair is held in December which attracts merchants from all over Siberia and from Russia. On the left bank of the Angara lies the rapidly growing suburb of Glaskovsk, which contains the railroad depot and is connected with the city proper by a bridge of boats. Pop., 1911, 108,060, including over 5000 exiles. Some 45 miles to the northwest lies the village of Alexandrovskoi, which contains the great Central Prison of Siberia. Irkutsk was founded by Cossacks in 1653, created a town in 1686, and soon became the centre of the Russo-Chinese tea trade.

IRMINUS, ēr'mī-nūs (AS., exalted). The divine ancestor of the Germanic Hermiones, probably identical with Tiw or Tyr. The Saxons erected in his honor great tree trunks, the so-called Irminsūli, e.g., at Scheidungen, after the defeat of the Thuringians, and at Eresburg, Westphalia. The latter, which was looked upon as the national shrine, was destroyed by Charles the Great in 772. See HERMIONES.

IRNERIUS, ēr-nē'rī-ūs, or **GUARNE'RIUS** (c.1050-c.1130). An eminent Italian jurist, founder of the so-called School of Glossators. (See GLOSS.) He was born at Bologna. When quite young, he taught, in his native city, dialectics and rhetoric, but soon devoted himself entirely to the study of the Justinian Code, probably in Rome, where he also seems to have lectured on law. In or about 1084 he returned to Bologna and there established a new law school. He held an Imperial office under Henry V in the early part of the twelfth century. His most important work is the *Summa Codicis* (first ed. by Fitting, 1894), formerly attributed to Placentin. Consult Fitting, *Die Anfänge der Rechtsschule in Bologna* (Berlin, 1888).

IRON (AS. *īren*, *īsern*, Goth. *eisarn*, OHG. *īsarn*, *īsan*, Ger. *Eisen*, from OIr. *iarn*, Welsh *haiarn*, Corn. *hoern*, Bret. *hoiarn*, iron; possibly connected ultimately with Lat. *as*, Goth. *aiz*, OHG. *ēr*, Ger. *Erz*, bronze, AS. *ār*, Eng. *ore*, Skt. *ayas*, metal). The most abundant and useful of the metals. Unlike many of the common metals, iron is found only rarely in the native state. Nordenskjöld found it, embedded in basalt rocks, in masses of several tons each, in Greenland. Some native iron has also been found in Cañon Diablo in Arizona. Further, metallic iron has been found in meteorites, which proves the existence of the element in extraterrestrial regions. Spectroscopically iron has been found in many of the stars, and Angström has fully demonstrated its existence in the photosphere of the sun. Combined with oxygen and other elements, iron is widely distributed as a constituent of rocks and forms extensive deposits in many parts of the world.

Early History. Articles of stone, bronze, and iron have been found together on the site of the Swiss lake dwellings, but the most ancient specimens of iron at present known come from Egyptian and Assyrian ruins. There is in the British Museum a piece of iron taken from the Pyramid of Gizeh, which is believed to date from about 4000 B.C., and also an axe head of Egyptian manufacture dating from 1370 B.C. Though the earliest pieces of iron now known came from Egypt, it is thought that probably

the Assyrians were the first to use the metal freely in the manufacture of tools, weapons, and ornaments. Numerous samples of iron implements dating from 800 B.C., and including the fragment of a saw 44 inches long, were obtained from the ruins of Nimrud. In India the famous iron pillar at Kutub, near Delhi, standing 22 feet aboveground and weighing about 6 tons, dates from 400 B.C. It was made by welding disks of metal together, indicating a remarkable degree of skill on the part of those early iron-workers.

The Greeks were familiar with the uses of iron at least 600 years before the Christian era, although the metal was very scarce. It was not until the Roman Empire was fairly established that the use of iron became general over civilized Europe. The Romans made both wrought iron and steel, using the latter metal for swords and other edged implements. The ancient Britons at the time of the invasion of Britain by Julius Cæsar (55 B.C.) were found to use swords, spears, hooks, and scythes of iron, indicating a familiarity with the metal for a considerable period previous. During the Roman occupation iron manufacture was vigorously developed, and in the succeeding Saxon age it seems also to have flourished. After the Norman Conquest little attention was paid to iron manufacture in England. In Germany, however, the art flourished vigorously, iron implements being exported to other countries in considerable quantities. Until about the middle of the fourteenth century all iron was produced by the direct process, the product being wrought iron or steel, as the case might be, according to the details of the process. About 1350, however, cast iron began to be made in Germany, and the beginning of the modern process of iron and steel manufacture was inaugurated.

Iron (symbol, Fe; atomic weight, 55.84), in the chemically pure state, is a silver-white metal that crystallizes in the isometric system. Its specific gravity is from 7.85 to 7.88, and, according to Carpenter's determination of 1908, it melts at 1505° C. (2741° F.). It is the most tenacious of all the ductile metals, and it may be rolled into sheets so thin that the weight of a sheet of given size will be less than the weight of a sheet of paper of the same size. The magnetic properties are well known; it must, however, be observed that if iron is heated above 760° C. (1400° F.) its magnetic properties almost suddenly disappear. Pure iron may be prepared by the prolonged action of a weak current of electricity on a solution containing pure ferrous sulphate and sal ammoniac or sulphate of magnesium (a high temperature and the presence of ammonium citrate are favorable factors), and heating the precipitated metal with a view to freeing it from "occluded" hydrogen and diminishing its brittleness. Another method of obtaining chemically pure iron consists in preparing pure ferric hydroxide by adding ammonia to the solution of some pure iron salt and then heating the hydroxide in a stream of hydrogen gas. Iron and platinum are the only metals that may be welded together immediately, i.e., without the use of any soldering material. With mercury iron refuses to combine directly, the iron amalgam that has been used for electrical machines being made by a somewhat complicated process with the aid of the amalgam of sodium. After being immersed in fuming nitric acid, iron refuses to

dissolve in acids; it is said to be in the *passive* state, a condition that is not yet completely understood. Dry air or oxygen gas has no effect on iron. The "rusting" of iron in ordinary atmospheric air is due to the presence of moisture and of carbon dioxide; the fact that rust is invariably found to contain ammonia would seem to indicate that iron reacts chemically with the moisture of the air, combining with its oxygen and setting free its hydrogen, which in the nascent state forms ammonia with the nitrogen of the air. Rusting may accordingly be prevented by covering iron with a waterproof coating or some paint or varnish, or with a coating of some metal like lead, tin, copper, nickel, or preferably zinc.

In agreement with Osmond, it is now generally believed that pure iron can exist in three distinct allotropic modifications, which are referred to respectively as α -ferrite, β -ferrite, and γ -ferrite. Pure iron at ordinary temperatures is α -ferrite. At 760°C . (1400°F .) it quickly passes into the β -form—a change comparable to the transformation of ice into liquid water at 0°C . (32°F .), although of course β -ferrite is itself a solid. At 900°C . (1652°F .) a second rapid transformation takes place, β -ferrite changing into γ -ferrite; and finally, at 1505°C . (2741°F .), as we have seen, the solid, now γ -ferrite, melts. The changes from α to β and from β to γ ferrite are accompanied by considerable absorption of heat, just as the further change from γ to liquid and just as the melting of ice and all other solids. The specific volumes of α and β ferrite are nearly the same; on the other hand, the change of the β into the γ form is accompanied by a very considerable contraction of volume. That most important property of iron—its capacity for dissolving carbon, not only in the liquid, but also in the solid state—is possessed by only one of the three solid forms, viz., by γ -ferrite. If such a "solid solution" is allowed to cool slowly, its dissolved carbon is enabled to crystallize out in the form of graphite crystals of more or less appreciable size; the result is a soft iron (or rather steel), whose appearance, under the microscope, is quite heterogeneous and rough. If, on the contrary, the solid solution—which is now usually referred to as *martensite*—is cooled rapidly, then any carbon that separates out is in a state of very fine division indeed, the appearance of the metal under the microscope is comparatively smooth and homogeneous, and the metal is hard: we say, the steel has been *tempered*. This is the present-day view of the tempering of steel; in its details, however, the practice of tempering is awaiting much fuller explanation.

The dissolution of carbon in molten iron lowers, as usual, the freezing point (q.v.), and when the molten mass contains as much as 4.3 per cent of carbon, its freezing point is no longer 1505°C ., as when it was pure iron, but only 1130°C . (2066°F .). This is the lowest temperature ("eutectic point") to which the freezing point of molten iron can be depressed by the addition of carbon. And if heat were abstracted from the liquid, which contains, as stated, 4.3 per cent of carbon, it would begin depositing a mechanical conglomerate of graphite and a solid solution of carbon in γ -ferrite containing 2 per cent of carbon. On cooling, this solid solution would become supersaturated and would deposit some of its dissolved carbon. At 1000°C . (1832°F .) the solid solution would

contain only 1.8 per cent of carbon, but, if further cooled from now on, it would deposit, not graphite, as heretofore, but an important carbide of iron having the formula Fe_3C and known as *cementite* (a sort of white cast iron). The separation of cementite, on account of the considerable proportion of carbon in it, would still further impoverish the solid solution, and finally, if cooling were continued, a temperature would be reached (viz., 670°C . or 1238°F .) where metallic iron also would begin separating out, and the solid solution would be gradually decomposed into a conglomerate of cementite and metallic iron. This conglomerate (a sort of gray cast iron) is known as *perlite*. It is designated by this special name because it is always found to contain the same percentage of carbon, viz., 0.8 per cent; it is, however, certain that perlite is not a definite compound but a mechanical mixture.

The Oxides of Iron. With oxygen, iron forms three distinct compounds: ferrous oxide, FeO ; ferric oxide, Fe_2O_3 ; and ferroso-ferric, or magnetic, oxide, Fe_3O_4 . *Ferrous oxide*, or rather ferrous hydroxide, $\text{Fe}(\text{OH})_2$, may be obtained by adding caustic soda to a solution of ferrous sulphate. It is a white compound readily absorbing oxygen from the air, even if kept under water, and thus changing into ferric oxide; the oxidation causes its color to change gradually from white to green, gray, and brown. It is but sparingly soluble in water, the solution having an alkaline reaction. If boiled with a solution of caustic potash, ferrous hydroxide attacks the water of the solution, setting free its hydrogen and combining with its oxygen to form ferric hydroxide. *Ferric oxide*, in its anhydrous form, is found extensively as hematite. It is prepared artificially, by heating green vitriol, for use as an oil paint for wood, being known as *colcothar*. Ordinary *rouge*, which is used for polishing glass and metals, is artificial ferric oxide reduced to a fine powder. Ferric oxide may be obtained in the form of crystals having a dark-violet color, by heating green vitriol with common salt. If strongly heated, ferric oxide loses its property of readily dissolving in acids and can then be dissolved only in strong acids and only at a high temperature. If heated to a white heat, it loses part of its oxygen and becomes converted into Fe_3O_4 , which exhibits marked magnetic properties. The hydrate of ferric oxide, as ordinarily obtained by adding alkalis to solutions of ferric salts, has the composition $2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$, and is readily soluble in acids. Another hydrate of ferric oxide has the composition $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ and, like the anhydrous oxide, does not, if heated, readily dissolve in acids. By exactly neutralizing a solution of ferric chloride with alkali, and subjecting the resulting liquid to a process of hydrolysis, ferric oxide may be obtained in aqueous solutions. According to Tribot and Chrétien, a better way to obtain a solution of pure ferric oxide is to subject a solution of ferric chloride to electrolysis in a porous vessel. But, like other colloidal solutions (see COLLOIDS), that of ferric oxide is unstable, and the oxide readily passes from the soluble to the insoluble form. The hydrated forms of the oxide may be converted into the ordinary anhydrous form by the application of a moderate heat; at a certain point of this process the substance suddenly becomes incandescent—showing that a peculiar molecular change is taking

place in it—and after that it is found to have lost its property of readily dissolving in acids. The exact nature of the change is still unknown. *Ferric anhydride*, sometimes referred to, is unknown in the free state. It is the hypothetical anhydride of ferric acid, H_2FeO_4 , which is likewise unknown in the free state, but certain of whose salts may be readily prepared. Thus, potassium ferrate, K_2FeO_4 , may be obtained by heating small pieces of iron with the chlorate of potassium. From the existence of such salts it is evident that, much unlike ferrous oxide, which is distinctly alkaline in reaction, the peroxide of iron acts as a feeble acid. The tendency of peroxidized iron to pass into the stable ferric state is even greater than the tendency of ferrous iron to pass into that state, and hence the ferrates act as powerful oxidizers, readily burning such substances as oxalic acid, readily changing manganous oxide into manganese dioxide, etc.

The Salts of Iron. Corresponding to ferrous oxide and ferric oxide, respectively, are two series of iron salts, ferrous salts and ferric salts.

The action of acids on metallic iron, in the absence of oxidizing agents, causes the formation of ferrous salts, among which deserve mention the sulphate, the sulphide, the chloride, and the oxalate. *Ferrous sulphate*, known as green vitriol, or iron vitriol, is the substance from which the compounds of iron are generally prepared. The sulphate itself is obtained as a by-product in certain industrial processes and may be prepared by the action of sulphuric acid on metallic iron. In its ordinary, hydrated form its composition corresponds to the formula $FeSO_4 \cdot 7H_2O$. It has a greenish color that is scarcely perceptible when the salt is dissolved in water; the solution readily takes up oxygen, which causes the formation of ferric sulphate, and hence must be kept in sealed vessels out of contact with air, if it is to be preserved unchanged. Two other hydrates of ferrous sulphate are known—a pentahydrate, $FeSO_4 \cdot 5H_2O$, and a tetrahydrate, $FeSO_4 \cdot 4H_2O$. Ferrous sulphate is used for a variety of purposes in the arts; it is employed in making fuming sulphuric acid, in dyeing, as a disinfectant, in making colcothar and rouge, etc. With the sulphate of ammonium it forms a stable double sulphate, whose crystals have the composition $Fe(NH_4)_2(SO_4)_3 \cdot 6H_2O$. *Ferrous sulphide*, FeS , which has been found in many meteoric stones, may be made by heating iron filings with flowers of sulphur. It is largely used in chemical laboratories for the preparation of sulphureted hydrogen, which it yields on coming into contact with dilute sulphuric or hydrochloric acid. *Ferrous chloride*, or rather its hydrated form, $FeCl_2 \cdot 4H_2O$, may be prepared by the action of hydrochloric acid on metallic iron. The crystalline anhydrous chloride, $FeCl_2$, may be prepared by the action of gaseous hydrochloric acid on red-hot iron. *Ferrous oxalate*, which is a powerful reducing agent, is used as a developer in photography, potassium-ferrous oxalate being used for the same purpose. Another important compound containing iron in the ferrous state is the well-known potassium ferrocyanide, or yellow prussiate of potash, which may be found described under HYDROFERROCYANIC ACID.

Among the ferric salts deserve mention the chloride, the sulphide, the nitrate, and the phosphate. *Ferric chloride*, Fe_2Cl_6 , is a volatile

and extremely hygroscopic salt prepared by passing a rapid stream of chlorine over red-hot metallic iron. Its solutions in water have a brown color which is due, not to the ferric chloride itself, but to the formation of basic chlorides of iron and of colloidal ferric hydroxide, which are eventually precipitated out of solutions of ferric salts. Commercial ferric chloride contains a considerable percentage of water and hence contains basic chlorides, probably some free ferric hydroxide, etc. It is prepared by dissolving ordinary ferric hydroxide in hydrochloric acid. Ferric chloride forms four distinct hydrates: a dodecahydrate, $Fe_2Cl_6 \cdot 12H_2O$; a heptahydrate, $Fe_2Cl_6 \cdot 7H_2O$; a pentahydrate, $Fe_2Cl_6 \cdot 5H_2O$; and a tetrahydrate, $Fe_2Cl_6 \cdot 4H_2O$. Each of these melts completely at a certain temperature: the dodecahydrate at $37^\circ C.$ ($98.6^\circ F.$); the heptahydrate at $32.5^\circ C.$ ($90.5^\circ F.$); the pentahydrate at $56^\circ C.$ ($132.8^\circ F.$); the tetrahydrate at $73.5^\circ C.$ ($164.3^\circ F.$). The solubility of these hydrates exhibits an interesting phenomenon: that the solubility of a salt depends upon the form and composition of the crystals used in saturating the solution is now generally understood, so that it is not surprising that at some given temperature two different solutions may be obtained—both saturated—if two different hydrates are used in making up the solution. But with the hydrates of ferric chloride, at certain temperatures, it is possible to obtain two very unequally concentrated solutions—both saturated—by using *one and the same hydrate*. However, this interesting phenomenon is not confined to ferric chlorides, and many other substances are now known to exhibit it. *Ferric sulphide*, FeS_2 , occurs in nature abundantly as iron pyrite; it is used for the preparation of sulphurous anhydride in manufacturing sulphuric acid and in bleaching. *Ferric nitrate*, $Fe_2(NO_3)_6$, is obtained by dissolving metallic iron in an excess of cold nitric acid and allowing the solution to evaporate in a vacuum; the crystals thus obtained correspond to the formula $Fe_2(NO_3)_6 \cdot 9H_2O$, and melt at $35^\circ C.$ ($95^\circ F.$). In aqueous solution the nitrate gradually decomposes unless an excess of free nitric acid is present. *Ferric phosphate*, $FePO_4$, is an insoluble white substance formed when acid sodium phosphate is added to solutions of ferric acetate. Another compound containing iron in the ferric state, viz., potassium ferricyanide, may be found described under HYDROFERRICYANIC ACID.

Medicinal Uses of Iron Compounds. Iron itself and a number of its compounds are used in medicine in the form of various preparations; in the stomach all such compounds are converted mostly into ferric chloride and to a small extent into ferrous chloride. One of the best medicinal compounds of iron is ferric chloride, the evil effects of whose strongly acid properties may be avoided by free dilution or by the addition of bicarbonate of sodium. Another way to avoid the undesirable effects of acid compounds of iron is to administer them in the form of coated pills which may pass through the stomach unchanged, the acidity being then neutralized in the alkaline juices of the intestine. The constipating effect of iron compounds is well known, but is generally somewhat exaggerated; this effect may be readily avoided by the use of suitable purgatives. To avoid indigestion, iron compounds should not be taken

shortly before or after meals. In the mouth iron salts may (if acid) attack the enamel of the teeth, and by combining with sulphur (from food or the tartar of the teeth) form a black deposit of ferrous sulphide on the teeth and the tongue. For these reasons iron preparations are usually administered through a glass tube, and the mouth is to be carefully rinsed immediately after taking the dose.

Besides constituting the best-known local astringents for external application, iron salts are extensively used as a remedy for many forms of anæmia and the conditions caused by them, the best results being obtained by the use of ferrous sulphate and ferric chloride (the latter together with some glycerin). Iron salts have also been given with success in diphtheria, tonsillitis, and other forms of sore throat, as well as in erysipelas. In anæmia they have the effect of restoring the number of corpuscles and the normal amount of hæmoglobin in the blood. The fact that this takes place was long considered remarkable, since it was believed that no iron is actually absorbed into the system. Late investigations show, however, that both the organic and inorganic forms of iron are so absorbed. The substance has been demonstrated in the thoracic lymph soon after the ingestion of ferric chloride. We have seen above that in the stomach iron salts are transformed into ferric chloride. On reaching the intestine the chloride is transformed into ferric hydroxide, and subsequently the latter is in turn transformed into the black sulphide and tannate of iron, which are voided with the fæces. Most of the iron taken is thus voided, and none passes into the urine. On the other hand, when injected into the blood, even in very moderate quantities, iron salts produce symptoms of poisoning. The question therefore arises: In what manner do iron salts act in relieving anæmia? Definitely this question has not yet been answered. According to a theory advanced by Bunge, the iron normally present in the blood enters it in the form of complex organic iron compounds that are contained in food. That iron in some form or other necessarily enters the blood is evident, if we remember that the amount of iron in the body of a child increases with age. Now, according to Bunge, the alkaline sulphides that may be present in the intestines are capable of depriving the iron compounds of food of their iron, the resulting sulphide being of course incapable of absorption. But if sufficient quantities of iron are taken internally, the alkaline sulphides are decomposed, and the organic iron of the food becomes available. The amounts of iron required depend of course upon the amount of alkaline sulphides in the intestines, and this is why it may be found necessary to administer as much as 18 grains a day to an anæmic woman whose body in a normal state contains altogether about 30 grains. A strong argument in favor of Bunge's theory of the indirect action of iron is found in the fact that manganese, copper, and certain other substances not at all present in the blood are almost as efficient as iron in curing anæmia. An excellent discussion of this long-debated question is to be found in H. C. Sherman's *Chemistry of Food and Nutrition* (New York, 1911).

Ferrie chloride, the most important medicinal salt of iron, is usually administered in the form of its tincture, which contains about 3.25 per

cent of iron, corresponding to about 9.5 per cent of anhydrous ferric chloride. The tincture is prepared by making up 250 parts of the official aqueous solution of ferric chloride to 1000 parts with alcohol. *Ferrie hydroxide with magnesia* is known as "arsenic antidote," being an effective remedy for poisoning with arsenic. The antidote may be best prepared by gradually adding 10 parts of magnesia in water to 50 parts of ferric hydroxide in water and shaking the mixture vigorously. It should be prepared immediately before using and should be given repeatedly in large doses. Iron salts should never be given together with any preparation containing tannic or gallic acid. Besides the preparations mentioned above, several other iron salts and compounds are extensively employed. Among these may be mentioned reduced iron (iron by hydrogen) and the carbonate, iodide, lactate, nitrate, citrate, acetate, phosphate, valerianate, and oxide of iron. A useful preparation for strumous conditions in children is the sirup of the iodide of iron, which combines the tonic effect of iron with the specific action of iodine. Many preparations of organic iron are also used, most of them proprietary medicines, and many of weak or doubtful therapeutic value. See BLAUD'S PILLS.

IRON ORE

The ore minerals of iron, together with their composition and theoretic percentage of metallic iron, are: 1. *Magnetite*, or *magnetic oxide* (Fe_3O_4), with 72.4 per cent iron. 2. *Hematite* (Fe_2O_3), known also as *specular iron ore*, *red hematite*, *fossil ore*, and *Clinton ore*, according to its character, and containing 70 per cent iron. 3. *Brown ore*, consisting usually of limonite ($2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$), but containing also other hydrous iron oxides, such as turgite, goethite. Other names are *brown hematite*, *bog iron ore*, and *oehre*. The limonite has 59.89 per cent iron. 4. *Siderite* (FeCO_3), with 48.27 per cent iron, also known as *elay iron stone*, *kidney ore*, *black-band ore*, *carbonate ore*, and *spathic ore*.

Pyrite (FeS_2) is occasionally used as iron ore after it has been roasted for the recovery of sulphur in sulphuric-acid manufacture. *Franklinite* [$(\text{FeZnMn})\text{O}$, $(\text{FeMn})_2\text{O}_3$] is employed in the production of spiegeleisen, after extracting the zinc by roasting.

Composition. The ores of iron rarely approach the theoretic percentage, owing to the presence of common rock minerals in the gangue. The impurities which they supply are alumina, lime, magnesia, silica, titanium, arsenic, copper, phosphorus, and sulphur.

Some of these, like phosphorus, sulphur, and titanium, are especially objectionable. Phosphorus cannot be eliminated in the blast furnace or acid converter used in making Bessemer steel, and for this purpose very low phosphorus ores must be employed, the high phosphorus ones requiring special treatment. Sulphur is undesirable, as it makes the iron brittle.

Titanium, found in many magnetites, renders them difficult to smelt and causes a loss of iron. The carbonate ores are first roasted to free them of carbon dioxide and thus raise the iron contents. Brown ores are similarly improved by washing, and magnetite, if of low grade, by crushing and magnetic separation.

The table on page 364 gives the composition of a number of iron ores.

Classification. The chief types of iron-ore deposits found in the United States are: 1. Magmatic segregation deposits. 2. Contact metamorphic deposits. 3. Sedimentary ores. 4. Ores concentrated by surface waters percolating through the rocks, the ore being deposited as replacements, or in residual materials. 5. Lenticular masses in metamorphic rocks, of variable origin. 6. Gossan ores. For description of these types, see ORE DEPOSITS.

I, magnetite, Mineville, N. Y.; II, titaniferous magnetite, North Carolina; III, high-grade hematite, Mesabi Range, Minnesota; IV, Clinton hematite, New York; V, Alabama brown ore.

Resources of the United States. Iron ores are widely distributed in the United States, and in geologic age they range from Pre-Cambrian to Recent. The relative importance of the different iron ores mined in the United States is shown by the following percentages of the total output for 1913: hematite, about 93 per cent; brown ore, under 3 per cent; magnetite, about 4 per cent; siderite, 0.045 per cent.

A large part of the *hematite* production comes from the Lake Superior region, where vast deposits have been found in metamorphosed Pre-Cambrian rocks. Six important productive belts—or “ranges,” as they are commonly called—as well as several smaller districts, are known. The first six are: 1. The *Marquette*, opened in 1856 and situated in Michigan, east of the Keweenaw Peninsula. 2. The *Menominee*, first developed in 1877 and lying on the border of Wisconsin and the upper peninsula of Michigan. 3. West of the Menominee is the *Gogebic*, opened in 1884. 4 and 5. *Vermilion* and *Mesabi* ranges, situated northwest of Lake Superior, in Minnesota. 6. *Cuyuna*, lying southwest of the Mesabi, in Minnesota, and of recent development. The deposits are mostly near the surface, and in the Mesabi, after removing the overburden, the soft granular ore is excavated by steam shovels, which deposit it directly on the cars. A single mine in Minnesota produced, in 1913, 3,457,608 long tons of ore. The total production of the Lake Superior mines up to and including 1913 was 632,728,394 long tons. Most of the ore is forwarded by rail to ports on Lakes Superior and Michigan and thence shipped by boat to Chicago and Lake Erie ports, a large proportion being destined for the manufacturing centres of western Pennsylvania. A great shipping industry is engaged in the transport of Lake Superior ores.

Hematite ore is also mined in many of the Appalachian States, the most important being that found in the Clinton formation of the

Silurian, which outcrops along the western slopes of the Appalachians from New York to Alabama. The ore is a true bedded deposit, but owing to its comparatively low grade is not extensively developed anywhere, except in the Birmingham district of Alabama. There it is far removed from other sources of richer ore that might compete with it. In the Western States, notably in the Cordilleran region, there are scattered deposits of hematite and magnetite of the contact-metamorphic type, but they form a reserve source of supply.

Brown ores, chiefly of the residual type, are of importance in the southern Appalachians from Virginia to Alabama.

The *magnetite* ores found in the United States are of three types: 1: *Nontitaniferous magnetites*, found chiefly in a belt of gneissic rocks extending from the Adirondacks to North Carolina and most extensively worked in the former region. 2. *Titaniferous magnetites*, usually associated with igneous rocks of the gabbro type and found at a number of localities in the United States. They are of little or no commercial value at the present time. 3. *Magnetite sands*, of no commercial importance.

The quantity of iron ore shipped from the mines in the United States in 1913 amounted to 59,643,098 long tons, valued at \$130,905,558. This, as compared with 1912, represents an increase in quantity of 4.6 per cent and in value of 22.28 per cent. The average price per ton in 1913 at the mines was \$2.19. Of the quantity marketed in 1913, Minnesota supplied 60.07 per cent; Michigan, 22.44 per cent; Alabama, 8.38 per cent; and New York, 2.05 per cent. The imports of iron ore in 1913 amounted to 2,594,770 long tons; the exports, 1,042,151 long tons; and the pig iron production, 30,966,152 long tons.

The latest available figures of the production of the important countries are as follows:

COUNTRY	Year	Long tons
United States.....	1913	61,980,437
Germany and Luxemburg..	1911	29,408,812
France.....	1911	16,376,967
United Kingdom.....	1911	15,519,424
Spain.....	1911	8,635,523
Sweden.....	1911	6,056,868

China.....	1911	109,542

Foreign Countries. *Oölitic limonites*, which form well-defined and extensive beds in sandstones, shales, and marls of Jurassic age, in Germany, France, and Luxemburg, are of great importance as present and future sources of supply, even though the iron content ranges only from 31 to 40 per cent. In England the *oölitic siderite* of Jurassic age is also very extensively mined, the largest supply coming from Cleveland Hills in the Yorkshire district. Of great importance are the *magnetite* deposits of northern Sweden, probably the largest in the world. At Kiruna the ore body forms an enormous, steeply dipping mass, lying between porphyries. The product of these mines goes chiefly to Germany, and borings have shown a re-

serve of 480,000,000 tons. In recent years considerable development has demonstrated the existence, in eastern Cuba, of millions of tons of *residual ores*, whose iron content ranges between 40 and 50 per cent. The ore has been derived from the weathering of serpentine, and in the Mayarí district extends, with a thickness of 15 feet, over an area of 10 by 4 miles. Brazil contains large reserves of iron ore in the district of Minas Geraes, some 300 miles from the coast. The ore is chiefly hematite and in its mode of occurrence closely resembles the Lake Superior ores. In British North America *bedded hematites* have been extensively worked in Newfoundland, and *magnetites* and *hematites* in Ontario.

IRON AND STEEL, METALLURGY OF. Native iron in the free or metallic condition is almost unknown, and it is therefore necessary to resort to special processes to extract it from the mineral compounds (see IRON) in which it occurs. These minerals, mixed with varying amounts of foreign or earthy matter, principally sand or clay, and technically known as the *gangue*, constitute the huge ore deposits which are widely distributed over the globe. To be of commercial value the character of the ore, its location with respect to sources of fuel and flux, and its ultimate point of consumption or market must be taken into consideration as well as its content of iron calculated on a metallic basis, i.e., as the element Fe. The most important deposits of the United States are those of the Lake Superior region, which contain from about 49 to 61 per cent of iron, with an average of, say, 55 per cent; the Southern ores (Alabama) are not so rich, their content being about 40 to 50 per cent.

Ores with less than about 30 or 35 per cent can be employed only in special cases, and if below about 40 per cent must generally be concentrated by some operation which will remove as much as possible of the foreign material. The operation may consist in *calcination*, the simple application of heat to drive off (a) moisture, (b) water of combination if the ores or minerals are hydrated, and (c) carbon dioxide in the case of carbonates. *Roasting*, consisting in heating with free access of air (oxygen), is employed to burn off organic matter or sulphur if the ores contain too high a proportion. *Weathering* is for the same purpose and consists in exposing the ore to atmospheric conditions for a long period. *Washing* is an

operation to separate substances of different specific gravities which are only mechanically mixed, by forming different layers or strata in a pulsating current of water, the layers being drawn off separately.

Ores in too fine a condition, or which readily crumble, give trouble on account of their tendency to choke up a furnace and so prevent the necessary freedom of passage for the gases through the charge. Much attention has recently been given to methods designed to correct this condition. *Nodulizing* consists in sintering or partially fusing the small particles into large coherent lumps; *briquetting* aims to attain the same end by mixing the ore with some binding substance, such as lime water or molasses, and molding it into bricks which are subsequently burnt hard. The fine material carried out of the furnaces by the blast, known as *flue dust*, has also been similarly treated.

GENERAL PRINCIPLES

Even where concentration is applied, only a partial removal of foreign matter and impurities can be effected. The problem presented to the metallurgist can be broadly divided into:

1. Removal of mechanically intermixed matter and preliminary purification.
2. Reduction to the metallic state.
3. Final purification.
4. Adjusting the composition to secure the desired physical properties.

The first and second processes are generally effected in the blast furnace, while the third and fourth are performed in some purification or steel-making process. In commercial practice all the various processes depend upon reactions taking place at high temperatures, which are nearly always obtained by the combustion of fuel, usually carbon in the form of coal, coke, or charcoal. For certain purposes gaseous fuel or its equivalent is necessary. During the last few years electricity has been adopted to a very limited extent. See *Electrothermic Processes*, below.

In the case of ores part of the carbon in the fuel unites with and removes the oxygen combined with the iron, the latter being thereby reduced to the metallic state, the attraction or affinity of oxygen for carbon at high temperatures being greater than for iron. The gangue is separated by melting, usually assisted by the special addition of material known as *flux*, with which it combines to form a more fusible compound termed *slag* or *einder*. This is either allowed to run off, or else collects on top of the iron by reason of its lower specific gravity, and an almost perfect separation can be attained in this way. As will be explained more fully later, the slag performs two functions: (1) mechanical—the removal of material chemically inert towards the iron; (2) chemical—a purifying action, more or less perfect, of removing and retaining impurities which would otherwise contaminate the iron.

Five elements are always found in the iron and steel of commerce—carbon, manganese, phosphorus, sulphur, and silicon. The first is derived from the fuel or special additions; the others from the raw materials or special additions. Many others may be present in special cases.

The reduction of iron to the metallic condition can take place at relatively low tempera-

tures—considerably below its melting point—and under such conditions it is in a pasty or spongy condition. Probably the oldest method of procedure was to dig a hole at the top of a hillside, forming a crude fireplace or hearth, which was filled with selected ore and charcoal. It was then covered over, a hole left in the top for the escape of the hot gases, and another at the bottom so that the air could enter and burn the fuel, the prevailing winds being depended upon for the draft. A portion of the iron oxide of the ore combined with the siliceous gangue to form a slag sufficiently fusible to melt and run down to the bottom of the hearth, where it collected and enveloped the mass of pasty iron which had been reduced. A large portion of the slag was subsequently expelled from the interstices of the iron ball or *bloom* by hammering it while hot.

Early improvements consisted in forcing the air in under a slight pressure by means of a crude form of bellows, later replaced by some form of blowing engine, usually operated by water power. This removed the dependency on prevailing winds; hence the furnace could be located wherever most convenient to the supply of raw material. With air under pressure it became possible to increase the height of the charge, and the furnaces were accordingly constructed of stones or bricks, the output being correspondingly increased. The increase in height brought about still another advantage, not at first anticipated. This was an increase in temperature and reduced fuel consumption per unit of iron produced. It was therefore only natural that when these facts were realized the tendency was towards increased size and height of furnace. Finally a point was reached where a sufficiently high temperature was attained to melt the iron, which collected at the bottom, with the much lighter slag floating on top.

The molten iron so obtained differed, however, materially from that produced at lower temperatures in a solid pasty condition, as it could not be worked under a hammer, even when hot, and could be shaped only by pouring it while molten into the desired form. It was therefore called *cast iron* to distinguish it from the variety which could be so worked, hence called *wrought iron*. The reason for this difference was later found to be due, in the case of the cast iron, to the absorption of a considerable amount of carbon from the fuel with which it was in contact, this absorption being directly due to the high temperature and to the strongly reducing conditions. Under such conditions the amount of carbon absorbed cannot be controlled, and the excess responsible for its brittleness must be removed subsequently by some oxidation process if it is desired to restore its malleability. This double treatment for producing wrought iron or steel is called the *indirect method*, to differentiate it from the *direct method* by which only one operation is necessary. The direct method has practically been abandoned except in primitive regions where there is a very limited demand and no real competition. The indirect method, even with its double treatment, is very much less expensive on account of the economy in fuel and particularly in labor and also because cheaper raw materials can be used. Since cast iron is produced in a molten condition, it can be handled largely by gravity and in enormous units by the aid of mechanical equipment. For

the latter reasons steel is generally less costly than wrought iron produced from cast iron. By the direct method the material must be worked by hand to be effective, hence in small units, which results in heavy labor charges. The quality of the raw materials must also be better (e.g., charcoal instead of coke), and the loss is much greater.

DIRECT PROCESS

By this method wrought iron or steel (when the percentage of carbon is higher) is produced from the ore in one operation. This process has not been used in the United States since 1901, in which year only slightly over 2000 gross tons were produced. Two classes of product may be obtained according to its intended use: (a) wrought iron or steel blooms, to be subsequently forged or rolled into the desired shape; (b) spongy iron very low in carbon and, as the name indicates, not welded up into a solid mass, to be used as part of the charge in some steel-making process.

Typical of the first class is the **Catalan Process**, a brief description of which will be given. The furnace proper (see Fig. 1)—or “forge,” as it is called—is square or rectangular in cross section and somewhat resembles a large packing box in appearance. It is from 20 to 40 inches wide and from 20 to 32 inches deep, with a height of about 1 to 2 feet. It is usually formed of heavy cast-iron plates which are double and water-cooled to prevent their being overheated and burnt through. The interior of this box or chamber is called the hearth, and being open in front, to permit of charging the raw material and withdrawing metallic iron and slag, is termed an *open hearth*. At the back, about halfway up from the bottom, is the single *tuyère* or pipe, inclining slightly downward, through which the air necessary for the combustion of the fuel is introduced under a moderate pressure. Above this chamber is a stack or chimney for carrying off the waste gases. In the stack is set a pipe in which the air is preheated before entering the hearth,

FIG. 1. CATALAN FORGE.

thereby increasing the temperature and correspondingly reducing the fuel consumption. The hearth, initially heated by burning fuel in it or hot from the previous charge, is filled to about the tuyère level with charcoal, upon which

(FOREGROUND, LEFT) SLAG RUNNING INTO LADLE. BETHLEHEM STEEL COMPANY

are piled small lumps of ore in a separate column, with additional charcoal separating it from the tuyère so that the oxygen of the blast must first pass through the charcoal. The reduction is completed by contact with the solid carbon in conjunction with the high temperature in the neighborhood of the tuyère. As the charcoal burns away and the charge sinks, more ore and charcoal are shoveled on top, until it is judged that a sufficient amount of iron has been produced. A part of the ore is not reduced, but melts and, combining with the siliceous gangue, forms a liquid slag which collects in and around the spongy mass or ball of metallic iron at the bottom of the hearth. This slag, being highly oxidizing and basic, serves to restrain most of the phosphorus from entering or remaining in the iron and also prevents the iron from taking up any considerable amount of carbon from the fuel, the only moderately reducing conditions in the hearth being highly favorable to both of these conditions. Owing to the character of the fuel and ore employed, there is very little sulphur present. The blast is now stopped, and the ball or bloom removed from the hearth and hammered to remove most of the intermingled slag and compact the particles; the latter operation was formerly termed *shingling*. Reheating and hammering may be repeated one or more times, both to remove additional slag and to secure the desired form. With the average size of furnace about 300 to 400 pounds of iron were produced in from four to six hours. The loss of ore was considerable, and the fuel consumption was relatively high.

The **American Bloomary Process** resembles the Catalan in general details, both as regards the process itself and the type of furnace employed. The charge consisted of fine ore and charcoal mixed together (instead of piled separately), and a bloom weighing approximately 300 pounds was obtained in about three hours.

The *stückofen* or *old high bloomary* was a shaft furnace about 10 to 16 feet high, and even more nearly approaching the present blast furnace in its dimensions and operation was *Husgafvel's high bloomary* or *continuous stückofen*, which was about 26 feet high. In the latter furnace the raw materials were charged at regular intervals. While both forms were intended for the production of wrought iron, cast iron was occasionally made owing to the much more pronounced reducing action.

Sponge-Making Processes. The principle of nearly all these processes is to reduce the iron at a comparatively low temperature by means of solid carbonaceous matter mixed with the ore, or else by passing reducing gases through it, sometimes by a combination of both methods. The product was obtained as a spongy mass. The necessary heat was supplied either externally or by the combustion of a portion of the solid carbonaceous matter mixed with the ore, and in some cases in both ways. These processes have also been abandoned, as they were found unable to compete with other modern methods. The best-known processes of this type were Chenot's, Blair's, and the Eames or Carbon Iron Company's process.

BLAST FURNACE

Historical. In speaking of the high bloomary it was stated that, if the reducing action were too strong, cast iron, instead of wrought iron,

was unintentionally produced. From this to the modern form of shaft furnace—or *blast furnace*, as it is always called—is a simple and natural transition. The old name *high furnace* is still used in France and Germany (*haut fourneau*, *Hochofen*). The first blast furnace was operated about the thirteenth century. Until the beginning of the last century they were about 20 to 30 feet high, rectangular or circular in cross section, shaped outside like the frustum of a pyramid or cone with the smaller end on top, and were constructed of blocks of stone. They were situated close to a steep hillside, so that a level trestle could be placed from the hillside to the top of the furnace to avoid the expense of a hoist for charging the raw materials. Frequently there was only one tuyère, of a peculiar construction, quite unlike the water-cooled tuyères now employed. Cold air, under only moderate pressure, was furnished by blowing engines of the simplest possible type, generally driven by water power, with wooden connecting rods and wooden blowing "tubs" or cylinders provided with leather valves. As the furnaces were open at the top, the combustible gases produced escaped into the air and frequently ignited. Charcoal was the principal fuel used. Dudley in 1619 demonstrated that coke could be successfully substituted, but no advantage was taken of this discovery until considerably later.

Unquestionably the greatest improvement was the introduction of hot blast by J. B. Neilson, of Glasgow, Scotland. He was granted a patent in 1828 for preheating the blast for smiths' fires, and the next year this was adopted for a blast furnace at the Clyde Iron Works. In a few years it was almost universally employed. Like most other great discoveries, the principle upon which it is based is comparatively simple, being briefly as follows: A pound of carbon, whether burned in a minute or in a year, generates the same amount of heat. In the former case, however, the degree of heat, or the temperature, will be very much greater. Also the temperature generated by a definite amount of fuel, burned in a given time, will depend upon its initial temperature and the nature of the surrounding materials (including the products of combustion) which absorb the heat, other conditions being the same. In a blast furnace a certain temperature is requisite to effect the proper reduction and fusion. Therefore, if part or all of the materials is introduced in a heated condition, a smaller amount of fuel will develop the necessary temperature. A fuel ratio of about eight to one in 1820, with cold air, has been reduced to one to one and even less at the present time; but it should be stated that a considerable part of this is due to other improvements, mentioned below.

Blast-Furnace Equipment. Before taking up the process, as at present conducted, a clear idea should be formed of the apparatus used. A modern plant, comprising one or more furnaces with an individual capacity of 300 to 600 tons of pig iron per day, is constituted as follows: In the first place there is the furnace proper or *stack*, in which the actual smelting of the ore takes place. The raw materials are hoisted to the top in a large box or bucket, called a *skip*, and there mechanically dumped. When the ore comes from the Great Lakes, a large supply or *stock pile* must be provided for use during the winter months, as navigation is open only from

about May to November. The ore is taken from the stock pile by means of gantry cranes equipped with buckets and is placed in separate bins, according to the grade, which is carefully determined by chemical analysis. From these it is transferred to the skips by scale cars in which the predetermined mixture of the various ores is carefully weighed.

The engines for compressing the blast are driven either by steam or, more recently, by gas. The engines must be powerful enough to deliver the air at a normal pressure of 12 to 16, and in an emergency up to 25, pounds per square inch. When steam is used, a battery of boilers must be provided, usually fired with the gas given off from the furnace. The advantage of gas engines is their greater efficiency, and the excess power is then available for generating electricity or for some other purpose. The air, after being compressed, is passed through regenerative fire-brick stoves, of which there are usually four to each furnace. These stoves, although of smaller diameter, are frequently taller than the furnace. The gas given off from the blast furnace is first led into a large chamber or *dust catcher*, where most of the suspended particles of dust are deposited. From this it may be led directly to the stoves and boilers, where it is burnt. If used for gas engines, however, the remaining dust must be further removed as completely as possible, and it is therefore *cleaned* and *scrubbed* with water in special apparatus. In front of the furnace is the *cast house*, which is a roofed structure with a sand floor if the iron is to be cast directly into pigs, or else of smaller size and provided with runners and spouts for delivering the molten metal into ladles in which it is transferred to the steel plant or to the pig-casting machine. In some cases the metal is run into iron or *chill* molds set in the cast-house floor so that the surface of the pigs will be free from sand. The molten slag is similarly removed in ladles and disposed of as waste material or in some cases used in the manufacture of cement.

We may now consider the more important parts of the equipment in somewhat greater detail.

Stack. The interior of the furnace was formerly of a cylindrical shape, i.e., the walls were perpendicular and the cross section circular. In modern furnaces, however, there are three well-defined divisions, as shown in Fig. 2: (a) at the bottom is the *hearth* (also called the *well* or *crucible*), which is cylindrical; (b) above this the walls slope outward, forming an inverted truncated cone known as the *bosh* (this term is also used to denote the point at which the internal diameter of the furnace is greatest); (c) above this again the walls converge to the top or *throat*, forming another longer truncated cone set upright, this portion being known as the *shaft* or *stack*. The reason for the gradual increase of the diameter from the top downward is to facilitate the descent of the charge, which would tend to stick and choke up the furnace if the walls were perpendicular. From the bosh line to the hearth the diameter is decreased, because it is principally here that the fuel is burned, and, unless due allowance were made for this reduction in bulk, the charge would descend too rapidly in this region, and the action on the ore or sponge would be uncompleted.

The furnace is built of fire bricks inclosed in

a jacket of riveted steel plates, which generally extends to the top. In the walls of the hearth and bosh are inserted *cooling plates*, through which water constantly circulates, to prevent excessive corrosion of the brickwork and thereby preserve the lines of the furnace as much as possible. The blast is introduced at a point near the top of the hearth through tuyères, of which there are usually from 8 to 16, depending upon the design and the size of the furnace. These are joined by pipes to the *bustle* pipe, which encircles the furnace and is connected with the hot-blast main. Surrounding the portion of the *blowpipes* which penetrates into the furnace are hollow water-cooled bronze or copper *blocks* to prevent them from being burned away at the very high temperature to which they are continuously exposed. The entire cooling system is of the greatest importance, and the discharge pipes are arranged in full view so that they may be under constant observation. A little below the tuyères is located the hole called

FIG. 2. SECTION OF ONE OF THE DUQUESNE BLAST FURNACES

the *cinder notch*, out of which most of the slag is tapped. Below this again, and at about 90° to one side, is the *iron* or *metal notch*, out of which the iron runs when the furnace casts.

Except during charging, the top of the furnace is closed, and the gases are led off through a large pipe, called the *downcomer*, into the *dust catcher*, and thence to the stoves and boilers or after cleaning to the gas engines. While the furnace is being charged, which happens at frequent intervals, the escape of the gases is prevented by an arrangement of two bells or cones, one somewhat smaller than the other and a short distance above it, one of the bells always

being closed, the space between forming a chamber. The charge is placed around the upper bell, which is then lowered, depositing it on the lower bell, when it is raised again and closes the top. The second bell is then in turn lowered and the charge dropped into the furnace.

Until nearly the beginning of the present century the charging was done entirely by hand. The stock was loaded on wheelbarrows, which were weighed and then hoisted to the top on an elevator. The contents were then dumped around the bell, of which there was usually only one. This method is inadequate to supply the necessary amount for the present large furnaces, and the material is therefore hoisted in skips running on an inclined track or *skip bridge*.

Stoves. The earliest type of stove consisted of a row of cast-iron pipes, generally U-shaped, inclosed in a brick combustion chamber and heated externally with fuel in much the same manner as in the case of a water-tube boiler. The blast from the blowing engines passed through these pipes uninterruptedly. Although this style of stove was employed for a long time, it was not satisfactory, as the temperature to which it could heat the blast was limited by reason of the danger of burning out or melting the cast iron. It has been superseded, commencing about 1860, by the regenerative fire-brick stove, the first of which was invented by Whitwell. The temperature which can be secured in this stove is limited practically only by the question of efficiency.

The general form is a very high cylindrical chamber with fire-brick walls inclosed in a steel casing. In this is a large flue or combustion chamber in which the gas from the blast furnace is burned. The hot gaseous products of combustion are then led through other smaller flues filled with bricks with small passages left around them, called *checkerwork*, the arrangement being such as to offer the maximum surface for heating purposes. Various designs and modifications are in use which differ slightly in the method of heating. The gases, after reaching the top of the combustion chamber, may be led through the checkerwork and thence to the stack, or they may then be deflected upward again, heating another part of the stove and escaping at the top. The former is called a *two-pass* and the latter a *three-pass* stove. When a stove has been sufficiently heated, the gas is shut off, and the blast is introduced, passing through in the reverse direction to that which was followed by the gas. Purification of the gas, in the same manner as when intended for gas engines, has shown a marked improvement. With four stoves to a furnace, each stove, in rotation, is "on gas" (i.e., is heated) for about three hours and "on wind" (is heating the blast) one hour.

Blowing in is the term applied to starting up a furnace when it is new or has just been relined. It is first necessary to dry it out thoroughly so that there will be no moisture present, and then to heat it up gradually to prevent cracking of the walls from the sudden expansion which would result if the full temperature were attained immediately. Principally fuel, with only small amounts of ore and flux, are charged at first, the proportions being gradually increased with succeeding charges of coke, the full *burden* (the proportion of ore to fuel) being reached only after a day or two.

Charging. The charge is made up of ore,

fuel (coke), and flux (limestone). The relative proportion of each is calculated from their respective compositions as determined by very accurate chemical analysis. The amounts of ore and limestone are based on a definite unit of coke. The ore and limestone are carefully weighed each time; the coke, however, is simply measured, as the weight of a definite volume practically does not vary. One complete charge of ore, coke, and limestone is termed a *round*. The coke is charged first, followed by the ore and limestone.

The rate of charging depends upon how fast the stock descends in the furnace. It is very important to keep the furnace constantly filled to a certain level, called the *stock line*, as otherwise irregular working would result. If, owing to part of the charge sticking to the walls, the material at the top is prevented from descending, the furnace is said to be *hanging*, and its subsequent sudden descent, after the obstruction has been removed, is termed a *slip*. When this occurs, there is an immediate increase in the internal pressure, which may result in a violent explosion, causing serious damage to the equipment as well as loss of life. To relieve this condition *explosion doors* are provided at the top of the furnace, which open automatically under any marked increase of pressure. A valve operated by hand, called a *bleeder*, may also be opened when a slip is anticipated. Julian Kennedy has attacked the problem in a satisfactory manner from the opposite standpoint by devising a *closed top* of sufficient strength to resist the force of the explosion, which thereby loses its suddenness and hence much of its violence.

The make-up of the charge requires good judgment and considerable experience, not only of the principles involved, but also of the individual behavior of different furnaces, the materials used, and the product desired. It is the function of the limestone to flux the siliceous gangue and also to render the slag sufficiently basic to prevent an undue amount of sulphur and silicon from entering the iron. There is a set of interdependent conditions involved: the larger the proportion of lime, the more basic the slag and the higher its melting point, which in turn determine the fuel requirements and the temperature of the furnace, which again largely controls the degree or intensity of reduction. By proper manipulation one condition may be made a greater factor than another, with corresponding success or failure in the object sought.

With ordinary ore, containing about 50 per cent of iron, the proportions of materials entering and leaving the furnace, per ton of pig iron produced, are approximately as follows, expressed in tons:

ENTERING THE FURNACE	LEAVING THE FURNACE
Ore.....2	Pig iron.....1
Coke.....1	Slag..... ½
Limestone..... ½	Gases.....6
Air.....4	
Total.....7½	Total.....7½

From this it will be seen that the air constitutes over one-half of all the materials going into the furnace, while the escaping gases represent over three-quarters of the material which comes out. The reason for this difference is that the oxygen, carbon, and other substances which enter the furnace as solids are converted into the gaseous state by certain chemical reactions.

Furnace Reactions. When the heated blast enters the furnace at the tuyères, it comes in contact with incandescent coke, and carbon dioxide (carbonic acid) is formed. This in turn reacts immediately with additional coke (carbon) and is reduced to carbon monoxide (carbonic oxide), both of which are gaseous. This carbon monoxide passes up through the charge and comes in contact with the descending ore. In this way the iron oxide loses nearly all of its oxygen, part of the carbon monoxide being changed to dioxide, so that by the time the ore has proceeded some distance down it is in a spongy, semimetallic condition. In the lower part of the furnace, in the region near the tuyères, the reduction of the iron is completed in contact with the solid incandescent coke, and about 4 per cent of the carbon is absorbed as the metal melts and trickles down into the hearth. The carbon dioxide in the limestone is driven off near the top of the furnace, and the calcium oxide (burnt lime) remaining gradually combines with the gangue, and the resulting slag finally melts somewhat lower in the furnace than the iron, as it requires a higher temperature for its fusion. It also collects in the hearth, floating on top of the iron on account of its lower specific gravity. The coke remains solid throughout its descent, gradually decreasing in amount as it is burned away. What remains is forced down through the slag and iron to the bottom of the hearth, where further opportunity is afforded for carburizing the iron.

Casting. The iron is allowed to remain in the hearth until a sufficient amount has collected. The usual practice for large furnaces is to tap out the iron about every four hours. Most of the slag is tapped out through the cinder notch at more frequent intervals, depending upon the volume formed, so that it will not rise above the tuyères and prevent the free entrance of the blast; this is termed *flushing*. It is allowed to run into a ladle which conveys it away. When the iron notch is first opened, nothing but iron runs out, but as the level in the hearth sinks it is accompanied by a certain amount of slag. This is separated from the iron by a *skimmer*, a depression or well in the main runner or trough, directly in front of the furnace, across which is set perpendicularly a cast-iron plate coated with loam and extending a little way below the regular bottom of the runner. The iron fills up the depression and continues to flow underneath; but the slag, being lighter, is backed up by the plate and overflows into a side runner leading to the slag ladle. The iron, by means of a main runner and a number of branch runners, is led into other ladles, being subsequently cast into pigs in a special machine, or else taken to the mixer or to some steel-making furnace for refining.

When the hearth is nearly empty, the hole is closed up by ramming in balls of clay, the blast being almost entirely shut off (by slowing down the blowing engine) while this is being done. This is the only time when the blast is not on full during normal working. The clay was formerly rammed in by hand, but this method has been practically abandoned in America in favor of a mechanical device known as a *gun*.

A few furnaces still employ charcoal instead of coke for fuel. They are necessarily smaller (about 30 to 40 feet high), as the charcoal will not sustain such a heavy weight (high column) without crushing as coke, one of the functions

of the fuel being to keep the charge sufficiently open for the passage of the gases. With charcoal the process is also run at a lower temperature, and occasionally the blast is not preheated. The product is accordingly known as *hot-blast* and *cold-blast charcoal iron* respectively. It is used almost exclusively for high-grade castings, as it possesses certain qualities which make it especially desirable for this purpose. Anthracite furnaces are usually operated with a mixture of coke and anthracite coal.

Product. As already stated, pig iron contains other elements besides iron, the range in composition in the United States being about as follows:

Iron.....	92.00 to 95.00	per cent
Carbon.....	3.00 " 5.00	"
Manganese.....	0.50 " 2.00	"
Phosphorus.....	0.05 " 1.00	"
Sulphur.....	0.02 " 0.10	"
Silicon.....	0.50 " 3.00	"

It frequently also contains other elements in varying amounts, such as copper, nickel, chromium, titanium, etc.

The carbon may exist either in combination with part of the iron as iron carbide, Fe_3C , or uncombined as graphite. In the former case the fracture of the pig is white, in the latter case black; and if part of the carbon is combined and part is free, the fracture will have an intermediate or mottled appearance. The condition of the carbon depends upon a number of factors. The tendency to be combined is increased by the presence of manganese or sulphur or by rapid cooling. It is decreased by the presence of silicon or by slow cooling.

Foundry irons—those used for making castings—must usually contain a considerable amount of silicon. This causes nearly all the carbon to be in the graphitic form so that the casting will be soft and readily machined. A certain amount of phosphorus may be desirable, as it makes the iron more fluid, so that the casting will be sharp, i.e., any intricate parts of the mold will be completely filled. Sulphur in any considerable amount tends to make the iron thick and sluggish.

For steel-making processes there is a general division based on the phosphorus contents. When it is below 0.1 per cent, it is suitable for the acid Bessemer and generally for the acid open-hearth processes in which there is no elimination of this element. For the basic Bessemer process, being depended upon as the source of heat, it must run over at least 2 per cent; for the basic open-hearth process, however, it is preferable to have it reasonably low. The former grade is termed *Bessemer pig*, and the latter *Thomas, basic, or non-Bessemer pig*. The sulphur in either grade is generally required to be low—for the acid processes not over 0.05, and for the basic processes not over about 0.05 to 0.10 per cent.

There are other special products similar to ordinary pig iron, but having a high percentage of some special element because of which they are principally valuable as additions to secure a given composition. These are termed *ferro-alloys* or *special pig irons*, and are made either in the blast furnace or, in some cases, in an electric furnace or by reduction by aluminium. A few of these are given below:

Ferrochrome: chromium about 60 to 68 per cent; produced in the blast furnace.

Ferromanganese: manganese about 80 per

IRON AND STEEL

cent. This term is also applied to any pig iron containing over 30, usually over 60, per cent. With manganese between 10 and 30 per cent it is called *spiegel* or *spiegeleisen*. *Silicon spiegel* contains about 17 to 22 per cent of manganese and also 6 to 12 per cent of silicon. These are all produced in the blast furnace.

Ferrosilicon: silicon about 10 to 20, usually about 12, per cent; produced in the blast furnace. A higher grade than this is also produced in the electric furnace and ordinarily contains over 40 per cent of silicon. It is known as *special ferrosilicon* or *special high-silicon iron*, and is commonly guaranteed to contain either 50 or 75 per cent.

Ferronickel: nickel 25 to 75 per cent, as specified.

Ferrotungsten: tungsten 60 to 85 per cent.

Ferrotitanium: titanium 10 to 12, and also about 50, per cent.

Ferrovandium: vanadium 20 to 35 per cent. The four last named, and in general those containing rare elements, are produced by special processes and are sold per pound of alloy or per pound of the element in question. The others are sold by the ton, except where some special process is employed to produce a given element as free as possible from impurities, in which case it is also sold on the pound basis.

Dry-Blast Process. This is a comparatively recent development in blast-furnace practice, although Mushet in 1879 took out a patent based on the use of calcium chloride, etc. The amount of water carried into a furnace due to the moisture in the blast is much greater than would at first glance seem possible. Thus, a furnace of the average size in the Pittsburgh district consumes about 40,000 cubic feet of air per minute and passes into the furnace approximately 40 gallons of water per hour for each grain of moisture contained in a cubic foot of air. This water, being introduced at the tuyères, is immediately decomposed by the incandescent coke by a reaction which absorbs a large amount of heat. This effect is not constant, for the percentage of moisture in the air varies according to the season of the year and even from hour to hour. The object of drying the blast is therefore twofold—to remove as much moisture as possible and to maintain the remainder constant.

This was first successfully carried out by James Gayley at Isabella Furnace No. 1 of the Carnegie Steel Company in August, 1904. His method was to pass the air around pipes in which circulated iced brine cooled to a temperature below the freezing point of water, the moisture being deposited upon the pipes in the form of snow. The effect, resulting in reduced fuel consumption and more regular working, was even greater than expected, for a number of reasons which cannot now be considered. Since then a number of other methods have been devised in which calcium chloride is employed as the desiccating agent.

Disposal of Pig Iron. The molten pig iron from the blast furnace may be either used direct in its molten condition or cast into pigs for transportation cold. The latter method has the disadvantage that the heat lost must again be supplied when it is remelted, thereby adding to the cost of manufacture. The pigs may be cast in sand or iron (*chill*) molds in the floor of the casting house or by means of a *pig machine*. The type of pig machine most commonly

used in the United States consists of one or more endless strings or *strands* of metal molds mounted on vertically revolving drums. The metal is run from a ladle into the molds at one end and is rapidly cooled by being sprayed with water and later passing through a tank of water, as the molds advance, so that the pigs are cold enough to be dumped into a car or other receptacle when they reach the other end. If the metal is used direct in its molten state, it may be transported in ladles and poured into the furnace or converter in which it is to be further treated. A better practice is to pour it into a large vessel, termed a *mixer* (see Fig. 3),

FIG. 3. MIXER FOR MOLTEN PIG IRON.

which serves primarily as a reservoir from which it can be taken as needed, thus avoiding delays waiting for the blast furnace to cast, and also preventing chilling if the furnace is not ready to receive it. Generally a small amount of gas is burned in it to maintain the temperature of the metal. As its name implies, the mixer serves another useful purpose, which is to provide a more uniform and constant composition by permitting the metal from a number of different casts from the same or different blast furnaces to be poured into it. There may also be some removal of sulphur by a reaction with manganese, if a sufficient proportion of the latter is present, the manganese sulphide resulting passing out of the metal and into the slag; this requires a considerable time, at least an hour or more. The mixer is the invention of Capt. W. R. Jones, of the Edgar Thomson Works of the Carnegie Steel Company. Attempts have been made from time to time, generally with considerable success, to employ the mixer to obtain a partial or preliminary refining of the pig iron in order to reduce the amount necessary later.

Malleable Cast Iron. This is originally white cast iron, in which the combined carbon has been converted by special heat treatment into an uncombined amorphous condition, also usually more or less removed by oxidation. This carbon exists in small spots or patches which do not break up the continuity of the metal nearly so much or so detrimentally as do the large thin plates of graphite, in the case of ordinary gray cast iron, which promote or assist fracture by serving as cleavage planes. The usual method consists in heating the white cast iron (in which practically all the carbon is in the combined form) to a temperature between about 750° and 1100°C (1380° and 2010°F), when the conversion of the carbon to the amor-

phous, uncombined condition takes place. The essential conditions appear to be the proper temperature, a sufficient length of time, and the presence of a certain amount of silicon. The castings are generally less than an inch in thickness so that when cast the cooling will be sufficiently rapid to avoid the formation of graphite. After cleaning, the castings are packed in some material, such as ore or clay, in an iron box, called a *sagger* or *annealing pot*, to protect them from the air, which otherwise would cause excessive scaling. Depending upon the nature of the surrounding material, more or less oxidation of the carbon occurs. In the United States usually only the outer portion is affected, and the fracture shows a white border surrounding a black interior, from which comes the designation *black-heart malleable*. Abroad the oxidation is frequently carried further so that the entire fracture is white. The product is capable of some deformation (hence the name *malleable*) and also offers considerable resistance to shock. The process was discovered by Réaumur in 1725.

PURIFICATION PROCESSES

Practically any reduction process by which metallic iron is produced from ore or oxide has the disadvantage of introducing into the iron considerable amounts of foreign elements or substances which, for the majority of uses, are objectionable if not positively detrimental. We have already seen that, owing to its pasty condition, wrought iron produced by the direct process contains intermingled slag, and that, if the temperature is raised sufficiently to obtain it in a fluid state, it greedily takes up carbon, while phosphorus and silicon are also reduced and combined with it. The subsequent removal of impurities in excess of what is desirable constitutes a general treatment known as purification, which must, as a rule, be conducted under oxidizing conditions.

Purification, in general, is divided into: (a) *refining processes*, those principally concerned with the removal from pig iron of silicon, phosphorus, and sulphur, the action being stopped when the carbon is attacked—the product is further treated by some other process; (b) *purification processes*, those embracing certain details or modifications applied to ordinary processes for making iron and steel.

From a practical viewpoint purification processes are not considered to include the regular processes for the manufacture of steel and wrought iron, although, from strictly theoretical considerations, these should properly be included.

Fining, refining, and hearth refining are some of the terms given to this treatment, which is still employed to a limited extent to produce material principally for the charcoal hearth process (see below). The type of furnace is called a *finery, refinery*, etc. (see Fig. 4). It consists of a hearth, which is generally rectangular in cross section, formed of water-cooled iron plates, and of a capacity to treat a charge of about one-half to two tons of pig, which may be charged molten or more commonly solid. The fuel is either coke or charcoal which is burned by the blast, usually supplied by two tuyères opposite to each other, which also furnish the oxygen necessary for oxidizing the silicon, etc. If ore is added, part of the phosphorus is removed. Each change takes about two hours, but

less if the metal is initially molten. The product (*fine metal, refined metal, or refined cast iron*) is usually tapped out on the iron plates of the floor or into iron molds, which causes a white fracture due, however, even more to the almost complete absence of silicon.

Pig-Washing Processes are a modification of ordinary refining and are used to obtain a metal very low in phosphorus and silicon, for use principally in the manufacture of special steel. In *Bell's pig-washing process* the molten pig is agitated with molten oxides of iron only. At the low temperature employed and in the presence of the very basic slag most of the silicon and the phosphorus are removed up to 90 to 95 per cent of the original contents, the metal being tapped out, however, before the carbon has been materially attacked. Krupp's pig-washing process, patented a couple of months later, is essentially the same, except that a certain proportion of oxide of manganese was used. They are now commonly referred to as the Bell-Krupp process, and the special addition of oxide of manganese is dispensed with as unnecessary. Somewhat similar methods have been tried from time to time with more or less success. For example, *Talbot's slag process* consisted in removing some silicon and phosphorus by pouring molten pig iron through a layer of slag rich in lime and iron oxide contained in a vessel somewhat resembling a ladle.

FIG. 4. MELTING FINERY FOR TREATING PIG IRON.

In the *Ellershausen* process the metal from the blast furnace was run through troughs lined with iron oxide.

The processes mentioned above have only a slight effect on the sulphur. Among those designed specially for its elimination may be mentioned the following: The *Massenez* or *Hoerde process* is based upon the fact that sulphur combines with manganese (if in sufficient amount) in preference to iron, the resulting manganese sulphide being insoluble in the molten iron, and therefore passes off into the slag if the requisite time is allowed. In

Heaton's process nitrate of soda was placed in the bottom of a ladle or other suitable vessel, being kept in place by an iron grating, and molten pig iron was poured on top. It was claimed that the action of the nitrate was to remove some of the phosphorus, all of the silicon, and nearly all of the sulphur. The *Saniter process* depends upon the use of calcium chloride in a slag containing a high percentage of lime, the principal action of the chloride being, apparently, to render the slag very fluid, fluorspar also being added for this purpose. It should be observed that puddling and steel-making processes are merely special and highly developed applications of the foregoing methods and principles.

CHARCOAL HEARTH PROCESSES

These processes are designed for the production of wrought iron by the purification of pig iron. The metal is obtained in a pasty condition, as the temperature is not sufficient to melt it after its decarburization and purification, and hence contains a certain proportion of intermingled slag. The name is derived from the fuel and the type of furnace employed. The hearths are low rectangular chambers, with one or more tuyères, resembling those used for the bloomery or Catalan processes for the direct reduction of iron from the ore. They are usually built of unlined cast-iron plates, water-cooled in part at least. Brickwork is avoided, as it would contribute silica to the slag and decrease its basicity, thereby destroying its effectiveness.

The general practice is to fill the hearth to a point above the tuyères with charcoal, upon which the pig iron is placed and gradually melted down. The blast from the tuyères encounters the molten metal as it trickles to the bottom, oxidizing the carbon and impurities, which latter are largely retained by the highly basic slag which is present. The slag from a previous charge is usually allowed to remain in the hearth and is augmented by the simultaneous oxidation of part of the iron. It is usually stirred into the pasty iron to assist further in its decarburization and purification. The metal so obtained may be further purified and freed from slag by a second or even a third melting operation under the same conditions. Most of the remaining slag is then removed by hammering the bloom. If the decarburization is not carried so far, the metal can be obtained with sufficient carbon to enable it to be hardened by quenching, and on account of this property it is then termed *steel*. Quite a number of methods were designed with this object in view.

There are various modifications, known by special names, which differ principally in minor details which need not be considered here. The *Swedish Walloon process* is still used in Sweden for making bars to be converted into blister steel. The American Laneashire process, brought to America by Welsh workmen, is no longer employed; there is, however, a modification still used, but to a very limited extent, for furnishing material for special sheets and tubes, in which wrought-iron or soft-steel scrap is melted with charcoal. The *South Wales process*, employing refined cast iron from the finery, was also used in America under the name of the *knobbling process*. Charcoal hearth

iron is of better quality than puddled iron (see below), as it contains less intermingled slag, but principally because it is purer, being made from a better grade of material, preferably charcoal pig or refined cast iron, and charcoal which contains only traces of sulphur.

PUDDLING PROCESS

This process, like those just described, has for its object the production of wrought iron (rarely wrought steel) by oxidizing and removing most of the carbon, silicon, manganese, phosphorus, and usually some sulphur, contained in pig iron, the operation being conducted on the hearth of a reverberating furnace. The charge during the early stages is molten, but, owing to the temperature not being sufficiently high, the final product is in a pasty state and for this reason is mechanically mixed with a certain proportion of slag, most (but never all) of which is removed during subsequent steps in its manufacture.

Until 1784 all wrought iron had been made from ore by some direct process or from cast iron by a charcoal hearth process. In this year, however, Henry Court, in England, gave a new impetus to the iron industry by a patented process, termed *puddling*, which did not require an air blast and greatly reduced the cost of production.

The oxidation and removal of the carbon and impurities were effected by the oxygen in the air and in the gases passing over the charge, together with that furnished by the oxide of iron obtained by the oxidation of the iron itself. The loss of iron in this way was very heavy, as the hearth was originally lined with sand which, being acid in character, combined readily with the basic iron oxide formed. A sufficient amount of the latter had to be provided to render the slag sufficiently basic to complete the purification, particularly with regard to the phosphorus. An improvement introduced by Hall in 1830 consisted in lining the hearth with iron ore instead of sand and by adding a certain amount during the operation. By this means the heavy oxidation of the metallic iron was greatly reduced and there was greater control over the purification.

Puddling Furnace. The hearth (see Fig. 5)

FIG. 5. PUDDLING FURNACE.

Longitudinal section.

is built of cast-iron plates, water-cooled, and carried on brick walls or on short iron pillars. It is usually about 5 or 6 feet long, and 4 feet wide opposite the charging door. The fuel is generally bituminous coal, although gas is occasionally used. Between the grate and the hearth

is a fire-brick *bridge wall*, and at the other end of the hearth, and separating it from the chimney, is a second bridge or *altar*, both of these serving to prevent the overflow of metal during the working of the charge. On the side of the furnace opposite the middle of the hearth is the working door, closed by a slide lined with fire brick which can be raised or lowered. A small opening at the bottom of the door permits the introduction of a *rabble* (an iron instrument resembling an ordinary hoe), with which the workman can stir the charge. The roof of the furnace is in the form of an arch, about 2 feet at the fireplace, and sloping gradually until at the chimney it is less than a foot above the bottom of the flue. Such a furnace has a capacity of about 400 to 600 pounds per charge.

Lining and Fetting. The bottom and sides of the hearth are covered with ore or slag rich in iron oxide, which is set in place by heating to a high temperature. After a charge has been drawn, the hearth is repaired (*fettled* or *fixed*) by throwing in ore or similar material, slightly moistened. Since Hall's modification the process has been carried on without any material change except in relatively unimportant details. Efforts have been made to substitute mechanical devices for hand labor, but without much success.

Operation. After the furnace has been fettled, about 200 to 600 pounds of pigs are thrown in, and the door is closed. In about 20 minutes melting commences, and after the fusion is complete the bath is worked with a rabble to expose the iron to the action of the slag and the flame. The silicon is oxidized first, and when this has nearly all been eliminated the iron *clears*, i.e., the bath loses the mottled appearance it had up to that time. The phosphorus is removed during this and the subsequent period. The temperature is now slightly raised, and the carbon is attacked, the resulting evolution of carbon monoxide, a gas, constituting the period known as the *boil*, and puffing up the slag so that the level of the bath is raised. As the carbon is burned away, the charge becomes more and more pasty, owing to its increasing melting point, and finally the bath drops to its former level. About this time grains of nearly pure iron appear on the surface, and the iron is said to have "come to nature." At this point in the process the charge must be well worked to insure proper welding together of the particles. When the action is completed, the pasty mass is broken up with a bar into lumps called

FIG. 6. ROTARY SQUEEZER.

balls (the operation being termed *balling*) of about 100 to 200 pounds each. These are drawn successively from the furnace by means of tongs. The total time for a charge is about one to one and three-quarters hours.

The puddle balls are taken from the furnace directly to the *squeezer*, a machine in which the

greater part of the intermingled slag is expelled and the grains of iron thoroughly welded together. The present form (see Fig. 6), known as a rotary squeezer or Burden squeezer, consists of a cylinder with teeth, like a cogwheel, mounted on a vertical shaft and revolving inside a casing, set eccentrically, and also provided with teeth. The ball, A, is inserted where the distance between them is greatest, and is progressively crushed and reduced in size as it is carried around to the point where the distance is smallest. Hammers were formerly used for this operation, which was termed *shingling*.

Piling. After squeezing, the rough bloom is rolled out into a flat bar known as *muck bar* or *puddle bar*. This is then cut up into short pieces, and a number placed together to form a *pile*, which is heated and rolled again. The operation of piling and rerolling may be repeated with improvement in the quality of the product. Instead of piles, a rough box may be made, the sides, bottom, and top consisting of pieces of muck bar, the interior being filled with small pieces of scrap iron. This is termed a *fagot*. Small pieces of iron are also heated up in a furnace until they can be formed into a ball (*scrap ball*), which is handled in the same manner as already described. *Puddled steel* or *wrought steel*, now practically obsolete, is made in a similar way, and the same cinder may be used; but the process must be arrested before there is such a complete removal of carbon, and it is therefore carried on at a somewhat lower temperature. The product contains up to about 0.5 per cent carbon, while wrought iron has usually less than 0.1 per cent, but there is no sharp division between them. The term *steel* was applied only when the product could be hardened by quenching. Wrought iron is chiefly used for bars, principally where welding may be required, stay bolts for boilers and boiler fire boxes, tubes, and roofing sheets.

CEMENTATION PROCESS

This process, sometimes called in England the *converting process*, depends upon the fact that iron, when heated under the proper conditions in contact with carbonaceous matter for a long period of time at a temperature below its melting point, will absorb or become impregnated with a certain amount of carbon. It is used to a limited extent, chiefly in England, for the production of high-carbon bars to be employed in the manufacture of crucible steel and *shear steel*. The bars are usually of pure Swedish iron made by the Walloon process, already described. They are packed in layers, separated by and covered with powdered charcoal, in fire-brick chambers, called *converting pots*, contained in the *cementing furnace* (see Fig. 7). The top of each pot is closed with an arch of wheel swarf which frites when heated and forms an air-tight cover. The furnace attains its full temperature in about three to four days, at which it is maintained about seven to eight days for *mild heats*, about nine and one-half days for *medium heats*, and about 11 days for *high-carbon heats*. The cooling down requires about four to six days. If wrought iron has been employed, the finished bars will be covered with blisters formed by a reaction between the contained slag and the carbon, whereby carbon-dioxide gas is gen-

erated. From this characteristic appearance the name *blister bar* or *blister steel* is derived. These blisters are not produced when low-carbon steel bars are similarly treated, owing to the almost complete absence of slag. In the Sheffield district, where this material is principally made and consumed, practically nothing but wrought iron is used. If bars of very high carbon content are desired, a retreatment may

FIG. 7. TRANSVERSE SECTION OF CEMENTATION CONVERTING FURNACE.

A, short chimneys communicating with stack; B, holes for removal of trial bar; C, fire grate; D, holes for removal of trial bars.

be given, and the product is then termed *doubly converted bars*.

The penetration of carbon being from the outside, there is naturally a progressive decrease in percentage from the surface to the centre. As an example of this, a bar $\frac{1}{2}$ inch thick contained at the outside 1.50, at the centre 1.15, and an average for the entire cross-section of 1.33 per cent. In Sheffield six grades of cement steel are recognized under the following names, the percentages of carbon being approximately as given: (1) *spring heat*, 0.50; (2) *country heat*, 0.63; (3) *single-shear heat*, 0.75; (4) *double-shear heat*, 1.00; (5) *steel-through heat*, 1.25; (6) *melting heat*, 1.50.

Blister bars rolled or hammered down at a yellow heat are known as *plated bars* or *bar steel*. In the manufacture of shear steel a number of pieces, broken to a suitable length, are piled together, constituting a *fagot*, covered with fire clay and borax to avoid excessive oxidation, and drawn out under a hammer into a bar termed *single-shear steel*. If this bar is doubled back upon itself and welded together, it is then known as *double-shear steel*. Shear steel is used for various articles of cutlery, particularly to form the cutting edge, in which case it is welded to a softer grade to form a tough backing.

CRUCIBLE PROCESS

As shown by the analysis cited above, blister steel is not at all homogeneous, even with the most careful preparation, and consequently under the relatively crude conditions which formerly existed the irregularities in composition were much more pronounced. To overcome this objectionable feature, Huntsman carried out lengthy experiments with the idea of securing uniformity by fusion in small fire-clay pots or crucibles. He was finally successful in 1740, and his original process is still carried on at Sheffield and also serves as the basis of a number of modifications. The process is principally employed for the production of special steels for tools, machine parts, etc., where quality is of the first importance, its cost being prohibitive for ordinary grades, which are supplied by the Bessemer and open-hearth processes. It is also used to a limited extent for making small castings. The modifications have to do with the materials used rather than with the details of the process itself. Of these may be mentioned: (1) the *carburizing fusion method* of melting soft steel or wrought iron with charcoal; (2) the *pig and scrap method* of melting soft steel or wrought-iron scrap with a pure grade of cast iron; (3) the *Uchatius or pig and ore method*, in which ore is added to melted cast iron to reduce its carbon content as desired. The first of these is the one used in the United States.

The crucibles which hold the steel are made either of a high quality of fire clay mixed with a little powdered coke as a binder, known as *clay crucibles* or *white pots*, and used principally in England; or of a mixture of about half clay and half graphite, called *graphite crucibles*, which are practically the only kind used in the United States and on the Continent. After molding, the crucibles are fired or burnt at a high temperature. Their manufacture requires great care and skill in its details and is a considerable industry in itself.

The furnaces for heating the crucibles may be classed as vertical or horizontal, according to the method of charging. The horizontal type is a regenerative reverberatory furnace (Krupp furnace), resembling an open-hearth furnace, gaseous fuel being employed, and the crucibles standing on the hearth. With the vertical type the fuel may be either gas, coal, or coke. If gas is used, the furnace is regenerative, and consists of a number of rectangular chambers, or *melting holes*, in which the combustion of the gas takes place. There are about 6 to 15 of these chambers to a furnace, each capable of holding 6 crucibles. In coal or coke furnaces, also called *pot holes*, *coke holes*, etc., the crucibles are set directly in the fuel, which is supported by grate bars, a chamber being provided underneath for cleaning.

In the United States the charge is ordinarily 100 pounds, and the graphite crucible weighs about 50 pounds. The material employed is usually soft-steel or wrought-iron scrap, together with the necessary proportion of charcoal and a small amount of oxide of manganese and fluorspar or other flux; if blister steel is used, the charcoal is omitted. The larger pieces are put at the bottom, the charcoal and oxide of manganese poured on these, and the remaining space filled up with the smaller pieces. The cover is then put on, and the crucible set in the

furnace. Depending upon the nature of the charge (low-carbon heats, on account of the higher temperature necessary, require a longer time than those high in carbon), the melting, which is the first stage in the process, occupies about two to four hours. When this is complete, the charge is allowed to remain a certain length of time until the steel becomes quiet, i.e., does not evolve any more gas—a result probably due to silicon, reduced by the action of carbon on the wall of the crucible, combining with any oxygen present, either free or existing as oxide, and also conferring on the steel the property of absorbing and retaining a certain amount of gas. This operation is known as *killing* the steel, which, when perfectly quiet, is said to be *dead*, and requires about one-quarter to one and three-quarters hours, usually from one-half to one hour. The total time for a heat is about three to four hours, three heats being made during each *turn* of 12 hours. When ready for pouring, the crucibles are drawn from the melting holes and set on the floor. The covers are then taken off, and the slag floating on top of the steel is largely removed by means of a light iron rod with a ball of clay on one end, against which it chills and to which it adheres. The steel is now poured or “teemed” into the molds, the slag remaining on top of it being kept back by a bar (*flux stick* or *skimmer*) held against it. Each mold receives the contents of one crucible, or, if of larger size, several cruciblefuls are used. Several cruciblefuls may also be poured into a ladle, from which the molds are filled. Ingots, after cooling and before being worked down, may be *topped*, i.e., the tops broken off, to determine the grade from the appearance of the fracture, and also for the purpose of removing the piped portion. Chemical analysis has now almost entirely replaced this optical method for determining the composition. The average life of graphite crucibles is about six to nine heats. In English practice, where clay crucibles are used, the life of a crucible is about three heats, and the charges are reduced successively on account of the *slag* or *flux line* which is left after each melting. The first charge is generally 56 pounds, the second about 44 pounds, and the third 38 pounds. As the crucible is cold for the first heat, this takes about four and one-half to six hours, the succeeding heats taking considerably less time, as the crucible is then hot; three heats are made in 12 hours.

BESSEMER PROCESS

The present era of steel making commenced about 1855 with the advent of Sir Henry Bessemer's process, which he discovered while in search of a better material than cast iron, but not too costly, of which to manufacture ordnance. In the course of his investigation he experimented with a jet of air blown through molten cast iron. The use of air and steam had been tried before, but not exactly in the same manner. He introduced the air by means of a small clay tube passing through the lid of a crucible and reaching almost to the bottom. The crucible was placed in a furnace in order to melt the cast iron it contained and also to supply the heat necessary to keep it in this condition in view of the strongly cooling effect which it was supposed the air would have. When this experiment was actually performed, it was found that the air, instead of lowering the temperature,

greatly increased it, and that after the metal was once molten no external source of heat was necessary. This phenomenon is due to the large amount of heat generated by the *rapid* combustion of the silicon, carbon, and manganese which the cast iron contains. It is stated that William Kelly, in the United States, discovered and applied the fundamental principles at an earlier date, and this is apparently borne out by the fact that the Patent Office, some years afterward, allowed his claims for the extension of his patent.

In 1856 Bessemer read before the Royal Institution his now famous paper entitled “On the Manufacture of Steel without Fuel.” The method described appeared to be such a radical departure that it was not fully accepted until it had been actually demonstrated. When, however, the attempt was made at various works to put it into practice, it resulted in complete failure, the reasons for which now seem obvious. It required several years of laborious research to determine that with pig iron low in manganese the blown metal would be *red-short*, i.e., would crack and crumble when worked hot, owing to the presence of a large amount of oxide of iron; and that if the metal were high in phosphorus it would be *cold-short*, i.e., brittle when cold, owing to the presence of this element, none of which is removed by the original (acid) method. These facts had not been discovered in Bessemer's earlier experiments, as the cast iron used was low in phosphorus and contained a fairly high percentage of manganese. The final success of the process is due in great measure to Robert Mushet, who discovered that either a grade of pig iron rich in manganese or *spiegel* added to the blown metal would effect its deoxidation. Göransson, in Sweden, was also largely responsible for its ultimate adoption, being the first to operate it successfully on a commercial scale. It is also sometimes called the *converting*, *pneumatic*, or more rarely, *air-refining* process. It may be defined as a process for the production of steel, consisting in blowing cold air through molten pig iron contained in a suitable vessel, whereby certain impurities are oxidized and removed, and the product obtained in a fluid condition.

Depending upon the nature of the lining of the vessel, there are two modifications: (a) the *acid Bessemer process* (the original, and hence called simply the *Bessemer process*), by which nearly all of the silicon, carbon, and manganese are eliminated, the phosphorus and sulphur, however, remaining unaffected; and (b) the *basic Bessemer process* (due to S. G. Thomas, aided to some extent by P. C. Gilchrist, hence sometimes called the *Thomas-Gilchrist*, or, on the Continent, simply the *Thomas process*), in which there is elimination of nearly all of the silicon, carbon, and manganese, as in the acid process, and, in addition, most of the phosphorus and part of the sulphur.

The *vessel* or *converter* is shaped like an egg or a pear, the bottom or rarely (except for foundry work) one side of which is perforated with a number of small holes through which a powerful blast of air enters and passes through the bath of metal, thereby oxidizing the impurities, which go into the slag if solid, or out of the mouth of the converter if gaseous. After the oxidation of the impurities the bath contains a certain amount of oxide and free oxy-

gen, which are removed principally by manganese in some form, and the composition adjusted as desired.

The equipment of a modern plant, particularly as regards American practice, consists essentially of usually two to four converters, with the necessary appliances for handling the molten pig iron, the finished steel, etc.; large auxiliary vessels or *mixers*, in which molten metal from the blast furnaces is stored, or, if cold pig is used, cupolas for melting it as well as the *spiegel*, if rail steel or a similar grade is to be manufactured; and powerful blowing engines for supplying the blast. The operation of the vessels is controlled by a *blower* stationed on a platform or *pulpit* a short distance away, where he can see all that is going on. There are also pouring platforms, storage yards, etc.

FIG. 8. BESSEMER CONVERTER.
Vertical section.

The converter (see Fig. 8) is lined with either acid or basic material, according to the method that is to be employed, and is suspended, at a little above the centre of gravity, by trunnions so that it can be tilted through various angles. In the original form, now little used, it was set on a permanent foundation and could not tip. The lining is contained in a steel shell consisting of the following sections: the "bottom"; the middle portion, known as the "body" or "belly"; and the upper part or "nose," which is open at the top or "mouth." The blast, at a pressure of about 20 to 25 pounds per square inch, is admitted through the bottom by means of tuyère bricks in each of which are a number of small holes or tuyères; these bricks are set in refractory material or *bottom stuff*, and the whole is held in a suitable casting fastened to the body of the converter by cotter pins.

As the lining of the bottom wears away much more rapidly than that of the body portion, the advantage of the present form, which can be readily removed and replaced by a fresh one, is evident. This was designed by A. L. Holley, who was also responsible for many other important mechanical improvements. The bottom is closed by an iron plate, between which and the tuyères is an open space or *wind box* into which the blast is admitted from a pipe connected with one of the trunnions, which is hollow and is in turn connected with the blast main. In basic practice the refractory bottom portion is called the *plug*, and the tuyère holes are usually formed by ramming burnt lime, mixed with tar or pitch as a binder, around pins which are subsequently withdrawn. For acid vessels the body and nose sections are lined with blocks and pieces of ganister or firestone set in a mixture of moistened ground ganister or quartz together with a little clay to render the mass plastic. In basic practice crushed burnt dolomite, mixed

with tar or pitch as a binder, is rammed in between the shell and a temporary wooden form. The bottom and lining must be dried very carefully before use. When a vessel is tipped over on its side or *turned down*, there must be enough curve or belly to bring the level of the molten metal below the tuyères.

Acid Bessemer Process. The vessel, heated from a previous charge or from a fire built within it, is turned down, and the molten pig iron run in. The blast is then turned on, after which the vessel is *turned up*, i.e., rotated to the vertical position. The actual blowing takes about 8 to 12 minutes in the United States and usually over twice as long in England. The changes taking place in the charge are indicated by the character and appearance of the flame issuing out of the nose of the converter. At first practically only the silicon and part of the manganese are burned, and the flame is short and dull in color; after the silicon has been oxidized the carbon is attacked, and the flame becomes longer and of dazzling brilliance. This latter period is sometimes termed the *boil* on account of the copious evolution of carbonic oxide (carbon monoxide) gas which violently stirs up the metal and, after escaping, burns in the air to carbonic acid (carbon dioxide). As the flame is very trying to the eyes, special dark-colored blowers' glasses are worn in order to observe it. While the carbon is burning, it is long, clear, and brilliant. When the carbon is nearly gone, the flame *drops* or shortens and also becomes full of dark lines, showing that the blowing is finished. The vessel is then turned down, the blast shut off, and the metal *re carburized* (see below) preparatory to pouring it into molds.

The heat necessary for the process is derived principally from the combustion of the silicon and carbon. If the pig iron contains too high a percentage of silicon, too much heat will be generated, and the charge is said to *blow hot*. In this case it is necessary to cool the bath, and this is effected by blowing in steam with the blast or, better, by throwing in cold steel scrap, which is low in these elements. If, on the other hand, the iron contains too little silicon, the opposite condition results, and the charge is said to *blow cold*. The vessel must then be turned down so that the blast will strike the surface of the bath. This produces the required heat by the oxidation of some of the metallic iron. The metal is said to have been *blown full* when only traces of carbon remain (about 0.04 or 0.05 per cent); if the blowing is stopped shortly before this point is reached, the metal is said to have been *blown young*. In the United States the capacity of a vessel varies from about 8 to 25 tons per heat, the output of a pair of vessels being about 40,000 to 65,000 tons per month. The use of the converter in the *duplex* process is mentioned below.

Basic Bessemer Process. A certain amount of lime is charged with the molten pig iron, but otherwise the process is conducted in practically the same manner as the acid process until the drop of the flame. At this point, instead of turning the vessel down, the blowing is continued (sometimes after the removal of the old slag and the addition of a little more lime) for about four or five minutes as determined by experience, during which most of the phosphorus and some of the sulphur are removed. The end

of the operation is determined by taking a small test ingot, which is forged down while still hot, quenched in water, and broken. The appearance of the fracture and also the malleability of the metal indicate the state of the process. The first period, up to the drop of the flame, is known as the *foreblow*, and the second, the *afterblow*. When ready, the vessel is turned down and the blast stopped, as before. As much as possible of the slag is poured off before recarburizing to prevent an undue amount of phosphorus from being reduced and reëntering the metal. As this action always occurs to a certain extent, the charge must be *blown down*, i.e., the phosphorus reduced to a considerably lower percentage than that permitted in the finished steel. A heat requires about 20 to 30 minutes, and one vessel can produce about 1000 to 5000 tons per month, depending upon the size, which varies from about 15 to 25 tons per heat. As already stated, the basic process is not used in the United States, as the pig iron does not contain a sufficient percentage of phosphorus.

In steel foundries small converters, called "baby" Bessemer converters, with a capacity of about two to five tons, are frequently employed. Various types and modifications, principally as regards the apparatus, have been tried from time to time; but the process itself is essentially the same as described for the acid process, which is practically the only one used in connection with the manufacture of castings, at least those made outside of large steel works.

OPEN-HEARTH PROCESS

This is a process for the production of steel by the oxidation and removal of the excess of impurities contained in a bath of metallic iron lying on the hearth of a regenerative furnace, the product being tapped in a fluid condition. The metallic charge may consist of (a) pig iron (either solid or molten); (b) pig iron and steel or wrought-iron scrap; or (c) steel or wrought-iron scrap and carbon (coal or coke). As in the Bessemer process, there are two modifications, depending upon the nature of the lining of the

The process was invented by Sir C. W. Siemens in England and was first used commercially in 1865. The principle of keeping the charge molten throughout the entire operation of purification was not new as applied to reverberatory furnaces, but had previously failed owing to the insufficient temperature obtainable in this type of furnace as then known.

The original (acid) method of Siemens was to melt pig iron alone and oxidize the impurities by additions of ore (*Siemens or pig and ore process*), assisted by the oxygen in the furnace gases; it was therefore practically identical with puddling except for the higher temperature which maintained the charge in a molten condition. The brothers Martin, in Sireuil, France, added steel or wrought-iron scrap, without any ore, to molten pig iron until the desired composition was obtained, there being only slight oxidation (and purification) from the gases (*Siemens-Martin, Martin-Siemens, Martin or pig and scrap process*). The former was therefore strictly an oxidation process, while the latter was almost solely a dilution process. The various names mentioned have commonly lost their special significance and are used more or less interchangeably, the terms *pig and ore* or *pig and scrap* being employed when it is necessary to distinguish between them. Ordinarily a combination method, with varying proportions of pig, scrap, and ore, is practiced. The term *open hearth* as applied to the process is derived from the type of furnace; it is used universally in the United States and to a certain extent in England.

Open-Hearth Furnace. This is a regenerative reverberatory furnace, the name signifying that the hearth is open or exposed to the action of the flame. It should rather be called a *Siemens* or a *Siemens regenerative furnace*, as is done in England; the name *Martin furnace* (used on the Continent) is incorrect, as the Martins had nothing to do with the design of the furnace, only with the process.

The furnace (see Fig. 9) comprises the following essential features: (a) the hearth or *sole*, which contains the charge, covered (b) with an

FIG. 9. LONGITUDINAL AND TRANSVERSE SECTIONS OF STATIONARY OPEN-HEARTH STEEL FURNACE.

furnace: (1) the acid open-hearth process, in which nearly all the silicon and manganese, and the desired proportion of the carbon, are removed; (2) the basic open-hearth process, in which there is removal of silicon, manganese, and carbon, as in the acid process, and, in addition, most of the phosphorus and usually also some of the sulphur, but to an uncertain extent.

arched brick roof; (c) *ports* or passages at each end of the hearth, the air and gas for combustion entering through those at one end and the products of combustion leaving through those at the other end; (d) the *regenerators* or *regenerative chambers*, nearly filled with *checkerwork*, at each end of and below the hearth; the regenerators at one end are connected with

the ports by vertical flues or *uptakes*, and at the other with the chimney or stack by horizontal flues; at the bottom of the uptakes are (*f*) small chambers or receptacles called *cinder* or *slag pockets*, which can be easily cleaned, to catch any large particles of dirt and slag carried over from the hearth and thus prevent their entering and clogging up the checkerwork. The hearth of a modern furnace is constructed of steel plates, covered first with silica bricks, on top of which is the lining proper, consisting of (*a*) for acid practice, silica bricks with fine sand, burnt or sintered into place; (*b*) for basic practice, magnesite bricks covered with crushed dolomite, sometimes mixed with a little pitch or tar to serve as a binder. The roof and walls, above the level reached by the slag of the bath, are built of silica (rarely magnesite) bricks, and below this of silica (acid) or magnesite (basic) bricks, according to the nature of the process. Sometimes chrome (neutral) bricks are inserted between the silica and the magnesite bricks in the walls and lining. The hearth is provided with a tap hole through the back wall, which in the case of stationary furnaces must be closed up carefully with refractory material of the same kind as the lining; with a tilting furnace this hole, except when tapping, is above the level of the bath and so need not be closed up tightly. The hearth is usually rectangular in shape, rarely round or oval. The regenerators are the distinctive feature of the furnace and consist of fire-brick flues filled with bricks set on edge and arranged in such a way as to have a great number of small passages between them, called, on account of the fancied resemblance, *checkers* or *checkerwork*, which abstract most of the heat from the outgoing waste gases and return it later to the incoming cold gases for combustion, on the same principle as the stoves of a blast furnace. On account of the system of heating, only gaseous fuel, or fuels having the same general character, can be employed. In the case of producer gas, both the air and gas are preheated in separate regenerators, uniting and burning only after they have entered the furnace; with natural gas, petroleum, or powdered coal, only the air is preheated; they are introduced near the ports, the two latter being injected with air or steam.

The furnace may be built either on a permanent foundation, when it is termed a *stationary* or *fixed furnace*, or else arranged so that the portion comprising the hearth may be tipped, when it is known as a *tipping* or *tilting furnace*.

In the United States, steel-works furnaces, i.e., those of large size intended for the manufacture of ingots, generally have a capacity per charge of about 50 to 100 gross tons, the usual size of furnaces constructed recently being about 70 to 100 tons; for some special processes they may have a capacity up to 250 tons or over, and in this case are of the tilting variety. Smaller furnaces of about 10 to 20 tons' capacity are generally confined to use in steel foundries. In ordinary practice a heat requires about 6 to 12 hours, usually 7 to 10 hours, and a furnace will make about 12 to 22 heats per week of six days, depending somewhat upon the size, a large furnace, as a rule, requiring more time for a heat. The furnaces were originally charged by hand, the material being laid on a spadelike instrument, called a *peel*, which was rested on the sill of one of the doors and then pushed into the furnace. With large modern furnaces, how-

ever, charging is done by means of a machine. The stock for the charge is loaded into steel boxes, which are picked up by the *peel* of the machine, pushed into the furnace, revolved to deposit their contents, and then withdrawn.

Acid Open-Hearth Process. Ordinarily the charge is composed of pig and scrap, the latter, as a rule, forming the greater part, up to about 60 or 70 per cent. As in the acid Bessemer process, the materials must contain less phosphorus and sulphur than is permissible in the finished steel, as there is no elimination of these elements, and in the case of sulphur an additional amount may be taken up from the gases. In some cases the scrap is charged first, and the pig placed on top; in others this order is reversed. The first stage consists in melting the materials down, during which much of the silicon, manganese, and carbon are oxidized and eliminated. When completely melted, the bath should contain about 0.60 per cent carbon for low-carbon steel, and slightly over about 1 per cent for high-carbon steel when the carbon is secured principally from that in the bath without any considerable final addition. To determine the condition of the bath a sample is taken out in a long-handled spoon and poured into a small iron mold. The test ingot so obtained is removed immediately, quenched in water, and broken, the appearance of the fracture giving the desired information. In foreign practice the test ingot is usually forged down before quenching and breaking. Frequently when making high-carbon steel, say, over about 0.50 per cent, a rapid chemical determination for carbon is made.

If the heat *melts high*, i.e., if the percentage of carbon is still too high, ore in small amounts is fed in to hasten its oxidation, an operation termed *oreing*. Under these conditions there is little danger of corroding the lining owing to the protection afforded it by the metallic bath and the slag already formed. If, on the contrary, the heat *melts low*, with the consequent danger that the bath will not be hot enough by the time the carbon has been oxidized to the necessary extent, a certain amount of pig (which is high in carbon) is thrown in to supply the deficiency in this element, and this is known as *pigging* or *pigging back*. If the carbon has been eliminated too soon, and there is only slight agitation of the bath, owing to the small amount of carbon dioxide being evolved, there is danger of chilling, as sufficient heat cannot be absorbed by the metal through the relatively nonconducting blanket of slag. A certain amount of heat is furnished by the oxidation of the carbon and impurities, but the greater part necessary (owing to the slowness of the process, as referred to in connection with the Bessemer process) must be secured from the combustion of fuel. Contact of the metal with the hot gases, by which its heating is effected, is brought about indirectly by the oxidation of the carbon in the metallic bath itself, which causes it to bubble and seethe. Consequently, as mentioned above, it is essential at all times to have a certain proportion of carbon in the bath, as otherwise it would become too cold to tap. The temperature of the bath is usually determined partly by the eye (protected by blue glasses) and partly from the melting effect on a low-carbon steel bar submerged in the bath for about 10 seconds. If the bar is melted off almost squarely across, the bath is hot enough,

while if there remains a long tapering point it is still too cold. The direction of the air and the gas is reversed, by changing the valves, at regular intervals of about 20 minutes at the beginning, and 15 minutes or less towards the end of the heat. Just before tapping, a small amount of ferromanganese, containing about 80 per cent of manganese, is usually thrown into the bath to *hold the heat*, i.e., to prevent any further removal of carbon and also to effect a partial deoxidation by its own oxidation.

There are two methods for obtaining the desired carbon content in the finished steel: (a) by removing nearly all the carbon and adding the proper amount at the end; (b) by eliminating it only to the desired percentage ("catching the carbon on the way down") and then tapping immediately. In either case manganese, and usually a slight amount of silicon, must be added (generally in the ladle) to remove the remaining oxide from the metal. When the bath is in the right condition, both as to composition and temperature, it is *tapped* by knocking out the material in the tapping hole, if the furnace is stationary, or by tilting the furnace, if it is of that type, so that the metal can flow out.

Basic Open-Hearth Process. The charge is much the same as for the acid process, except that it is not limited in its phosphorus content; the sulphur, however, should be reasonably low, as its elimination is rather uncertain; the silicon should also be low to avoid the use of an excessive amount of lime, and also since its oxidation is not depended upon for the necessary heat. The limestone and ore to form the basic slag and to assist in the oxidation are charged before the metallic portion, as in this case there is no danger of excessive corrosion of the lining, since it is also basic in character; the actual elimination of the phosphorus and any sulphur is due to the lime. The limestone is generally employed in its natural condition, but is occasionally burnt beforehand. With these and certain other minor differences, the basic process closely resembles the acid in its operation. The proportion of pig is commonly larger and, whenever practicable, is charged in the molten condition direct from the blast furnace or mixer, as a considerable saving results.

Special Open-Hearth and Combination Processes. Certain special modifications have been adopted with a view to decreasing the cost, increasing the output, or making use of material otherwise difficult to treat, e.g., high-phosphorus pig.

Bertrand-Thiel Process.—This process was worked out about 1894 at the works of the Prager Eisenindustrie Gesellschaft at Kladno, Bohemia, by Ernst Bertrand and Otto Thiel, and was designed for use with pig iron too high in phosphorus (about 1 to 2 per cent or over) for convenient treatment according to ordinary practice, but which was still too low in this element for the basic Bessemer process. It consists in charging pig, either alone or mixed with scrap, in one basic furnace run at a relatively low temperature, in which nearly all the phosphorus and silicon, and only a small part of the carbon, are removed; this part of the process closely resembles *pig washing*. The resulting partly purified metal, without the slag, is then immediately transferred to another basic furnace in which scrap or ore, or both, together

with some lime (occasionally also a little additional pig), have previously been heated. A very rapid reaction at once takes place between the iron oxide and the carbon and remaining impurities in the metal, which are speedily reduced below the required limits. The further details are the same as in regular practice. The time for a charge is about two to four hours in each furnace, depending largely upon the size of a charge.

Monell Process.—This is a modification of the pig and ore process in which steel scrap may also be used, and was devised by Ambrose Monell at the Homestead Steel Works of the Carnegie Steel Company. It is usually carried out in a fixed basic furnace, but is equally applicable to a tilting furnace. It consists in heating lime and ore or some other form of iron oxide, the latter amounting to about 20 to 25 per cent of the pig, until they become pasty. When this has occurred, the pig in a molten condition is run in, and a violent reaction takes place. A large quantity of slag is formed, most of which runs out of a special notch in the back wall of the furnace, if stationary, into an auxiliary cinder pit, or by tilting the furnace, if of that variety, so that it can run out of the tapping hole. This first slag contains about 90 per cent of the phosphorus and most of the silicon originally in the pig, while at this point about 2 per cent of the carbon still remains in the bath owing to the initially relatively low temperature. The heat is then worked down and handled as in regular practice, requiring about the same time as an ordinary pig and scrap heat.

Talbot Process.—This is also a pig and ore process, although scrap is occasionally added, but principally as a means of disposing of it. It was originated by Benjamin Talbot about 1897 at the Pencoyd Iron Works, near Philadelphia. It depends upon the rapid oxidation of the impurities contained in molten pig iron by a liquid, highly ferruginous slag, and is carried out in a basic furnace, generally of the tilting type. The essential point is always to keep a certain amount of metal in the furnace for the purpose of (a) diluting the impurities contained in the subsequent additions of pig iron, and (b) furnishing a reservoir of heat to enable a very fluid slag to be maintained. A tilting furnace of about 250 tons' capacity or over is ordinarily employed, and about one-quarter to one-third of the finished steel is tapped out at one time. This having been done, additions of ore or other form of iron oxide and lime are made, and after they are thoroughly melted and incorporated with the former slag, the proper amount of molten pig iron is run in. This occasions a violent reaction, and most of the phosphorus and silicon is eliminated in a few minutes; while this reaction is in progress a large amount of the slag boils up and runs out of the furnace. The bath is then adjusted as in ordinary practice, a portion is tapped out, and the cycle of operations repeated. A furnace is emptied completely only at the end of the week or for a shutdown for repairs. A heat requires about two to four hours.

Duplex Process.—This consists in the combined treatment of pig iron, first in an acid Bessemer converter, and afterward in a basic open-hearth furnace, the object being to obtain the more rapid working of the former and the

greater purification characteristic of the latter. Osann in Germany patented the process, which is essentially the same as that used to-day. The blowing in the converter takes about 10 to 15 minutes, and the finishing in the open-hearth furnace about two to eight hours, depending upon the size of the heat and other conditions. As carried out at one works, part of the pig is blown until nearly all of the silicon and the carbon is oxidized, as in ordinary Bessemer practice. This serves as molten steel scrap, and, being highly oxidized, it produces a vigorous reaction with the remainder of the pig, which is blown only sufficiently to remove the silicon, the action being stopped before much of the carbon has been eliminated. The process is completed as usual. Blown metal is sometimes used in the Talbot process to replace part or all of the ordinary molten pig iron.

ELECTROTHERMIC PROCESSES

The term "electric processes," commonly used, is likely to prove misleading to the uninitiated as signifying that electricity per se exerts some peculiar action which confers a special quality on the product. As a matter of fact, in its present commercial application to the manufacture of steel or cast iron, it is chiefly a substitute for fuel as the source of heat. An alternating current is always used, as it can be transmitted at a high voltage, with lower cost of conversion to the required voltage than is possible with a direct current; in the case of induction furnaces a direct current is out of the question. Electrolytic methods, such as are employed for the refining of copper, by which the material is chemically decomposed or split up, require a direct current and have been applied to the production of iron only when it is desired to have the metal as pure as possible for experimental purposes and in very small quantities, the cost of these methods being prohibitive for general purposes. Electrothermic processes may be classified according to the type of furnace and the method of heating employed; another classification would depend upon the nature of the operation, such as smelting, refining, carburizing, etc.

1. Arc Furnace. The requisite temperature is obtained by radiation from an arc formed between two electrodes, or between one or more electrodes and the charge, either initially in solid lumps (between which small arcs may also be formed) or molten. When the charge is molten, the current may pass from one electrode into the bath, then out again to another electrode in series with the first, or else out through the bottom of the hearth which then contains one of the electrodes; a certain amount of heating by resistance also occurs, and to indicate this fact the term *arc-resistance heating* (or *furnace*) is sometimes employed.

2. Induction Furnace. This is based on the principle of an electrical transformer. It consists of an annular trough, or two or more such troughs connected together, which constitute the hearth, the contained metal acting as the secondary circuit of a transformer, the primary circuit of which is arranged as usual. The heat is obtained from the resistance offered by the metal itself to the transformed current of very high amperage and low voltage.

3. Resistance Furnace. The charge or bath of metal forms part of the circuit, and the re-

sistance it offers to the passage of the current yields the required temperature.

4. Surface-Resistance Furnace. Here the electrodes do not at first suffice for the passage of the current. To heat up the furnace it is necessary to connect them by means of some kind of conducting material, such as a bed or lining composed of or containing pieces of carbon. These conductors by their resistance to the passage of the current are highly heated and form a melting hearth upon which are placed the materials to be treated. The charge itself subsequently becomes a conductor between the electrodes.

The steel-making furnaces are practically always lined with basic material, so that purification with lime can be effected; however, for smelting ore they are frequently lined with fire bricks similarly to blast furnaces.

The first metallurgical use of electricity for heating purposes, of which we have definite record, was an experimental demonstration in 1810 by Sir Humphry Davy. Other investigators were Pepys (1815), welding; and Pichon (1853), electrothermic furnace. In 1878-79 Sir William Siemens, the inventor of the open-hearth furnace, took out patents for electric furnaces of the arc type which possessed most of the important details of the present arc furnaces. He employed an ordinary crucible to hold the charge, one electrode being introduced through the bottom and the other through the cover or at the top, this latter electrode being adjustable. In a later form the electrodes were introduced through the sides at points directly opposite each other. Other patents were taken out from time to time. The adoption of the more widely known furnaces at present in use has occurred chiefly since the beginning of this century.

The *Stassano furnace* is of the arc type (see Fig. 10) and is nearly cylindrical in cross section. It usually rotates about a vertical axis slightly inclined from the perpendicular; it may, however, be stationary. It is provided with three or more large cylindrical electrodes

FIG. 10. STASSANO ELECTRIC FURNACE.

Vertical section.

inserted through the sides, nearly meeting at the centre, and connected with a three-phase alternating current. The furnace is generally lined with magnesite, and the molten products are tapped out at the bottom. This type of furnace has been principally used to produce steel directly from the ore, but pig and scrap may also be employed as in ordinary steel-making processes. By the former method finely

ground ore, with the correct proportion of carbon and flux, is first molded into briquettes. The rotation of the furnace is to effect a thorough mixing of the charge.

The *Héroult* and *Girod* furnaces are both tilting and closely resemble this variety of furnace as used in the open-hearth process except that they are much smaller. Since no gas is to be preheated or burned, there are no ports, regenerative chambers, or stack. Working doors, which also serve for charging, are provided in the front of the furnace. While the method of heating for these two furnaces is the same, the manner of introducing the current differs. In the *Héroult* furnace (see Fig. 11) there are at

FIG. 11. HÉROULT ELECTRIC FURNACE.
Transverse section.

least two vertical carbon electrodes passing through the roof, their height being regulated by a suitable device. These are connected in series, the current flowing from one to the other after traversing the bath. The ends are lowered into the slag covering to form the circuit and are then usually raised a certain distance, whereby an arc is formed over the space separating each electrode from the bath, as this method of heating is much more effective than simply depending upon the resistance offered by the bath. In the *Girod* furnace (see Fig. 12) there are one or more vertical carbon electrodes, also passing through the roof, but in series with an electrode, consisting of soft steel pieces, embedded in the hearth, the upper ends being in contact with the molten metal. The current, entering by way of the upper electrode (or electrodes), passes by an arc into the bath and leaves through the bottom electrode.

The *Kjellin* furnace (see Fig. 13) is of the induction type. The hearth is of annular shape and is provided with covers. The metal in the hearth forms the secondary circuit of a transformer, the primary circuit of which consists of a coil of fine insulated copper wire wound around a laminated iron core. The winding is placed on one leg only. It is protected from the heat radiated by the furnace by air spaces and a water jacket. This furnace has generally been used for obtaining steel of any grade from low to high carbon by a suitable mixture of pure pig and steel scrap, with the proper additions of ferrosilicon, etc.; little purification of the charge has been attempted, hence pure materials are

used. In starting the furnace the hearth is warmed up by a ring of iron or steel which serves to carry the secondary current. If cold material is charged, only a portion of the bath

FIG. 12. GIROD ELECTRIC FURNACE.
Plan and sectional elevation.

is poured off at a time, but with the use of molten metal from an open-hearth furnace or a Bessemer converter the hearth can be entirely emptied, as it will be sufficiently hot to prevent chilling.

The *Röchling-Rodenhauser* furnace, also of the induction type, is a modification of the *Kjellin* furnace devised by Schoenawa and Rodenhauser. In addition to the induced method of heating

FIG. 13. KJELLIN ELECTRIC FURNACE.
Transverse section.

there are secondary coils of wire about the primary, connected by pole pieces buried in the hearth slightly below the surface. When the refractory lining has been sufficiently heated, it becomes a conductor of high resistance. After

the furnace is in regular operation, the heating is consequently a combination of induction and resistance. The hearth, which differs from those of other induction furnaces, varies in form, depending upon whether the furnace is operated with a single-phase or a three-phase current. In

FIG. 14. RÖCHLING-RODENHAUSER ELECTRIC FURNACE.
Horizontal section.

the former case it is like two Kjellin rings or hearths joined together to form a figure 8; in the latter case, like three joined together (see Fig. 14). In either case the grooves open into a distinct open hearth, where they intersect, constituting the working chamber or "laboratory," where all the metallurgical operations are effected. The grooves which have a relatively small cross section form the secondary circuits and serve only as heating channels, no purification being performed in them.

The furnaces at present used for steel-making purposes have a capacity varying from about 2 to 10 tons per heat. The length of time required depends principally upon the amount of refining and purification to be done. Materials may be treated in the same manner as by the open-hearth process, but it has been found more advantageous, owing to the high cost, to start with metal initially treated in a Bessemer converter or an ordinary open-hearth furnace, the electric furnace being then employed only for finishing purposes.

Of the furnaces for the production of pig iron it will be sufficient to mention the *Grönwall furnace*, which is in successful operation at Trollhattan, Norway (see Fig. 15). This is a shaft furnace and resembles most nearly an ordinary blast furnace in which the tuyères are replaced by carbon electrodes, three in number. The charge, consisting of ore, coke (or charcoal), and limestone, is introduced at the top by means of a bell and hopper, and the molten products are tapped out through a hole at the bottom of the hearth.

RECARBURIZATION

In all steel-making processes which depend upon oxidation for the necessary purification of the charge the action must usually be carried to such a point that not only is there an insufficient amount of carbon and manganese (and sometimes silicon) remaining, but also a certain proportion of the iron is oxidized and dissolved in the metal itself, which, if allowed to remain,

would render it unfit for use. Recarburization (sometimes "recarbonization") means, in its special sense, adding carbon in some form to metal too much decarburized in some steel-making process, to secure the proper percentage in the finished steel; in its more general application the term signifies the addition of all the material needed to give the steel the desired composition as well as to effect its deoxidation. The additions are commonly made cold, generally in the ladle; but if they are in such large amounts that there is danger of chilling the metal, they may be (a) preheated to about a cherry red, (b) melted, or (c) added in the furnace or converter, either wholly or in part. For high-carbon heats a fairly recent method is to add molten pig iron, usually in the furnace, just before or during the tapping of the heat, so that it is thoroughly mixed in while the steel is running into the ladle. The ladle additions are made while the heat is being tapped, and an important point is to get them all in before much slag has appeared on the surface of the metal. In the United States, for soft and medium-carbon heats, the carbon is generally added in the ladle in the form of crushed anthracite coal contained in paper sacks. This is a modification of Darby's method, according to which crushed coal or coke is introduced by means of a hopper and funnel which regulated the rate of flow. Nickel, as nickel steel scrap or ingot nickel, is usually charged at the commencement of the heat, as it is not materially oxidized during the process, at least no more than the iron.

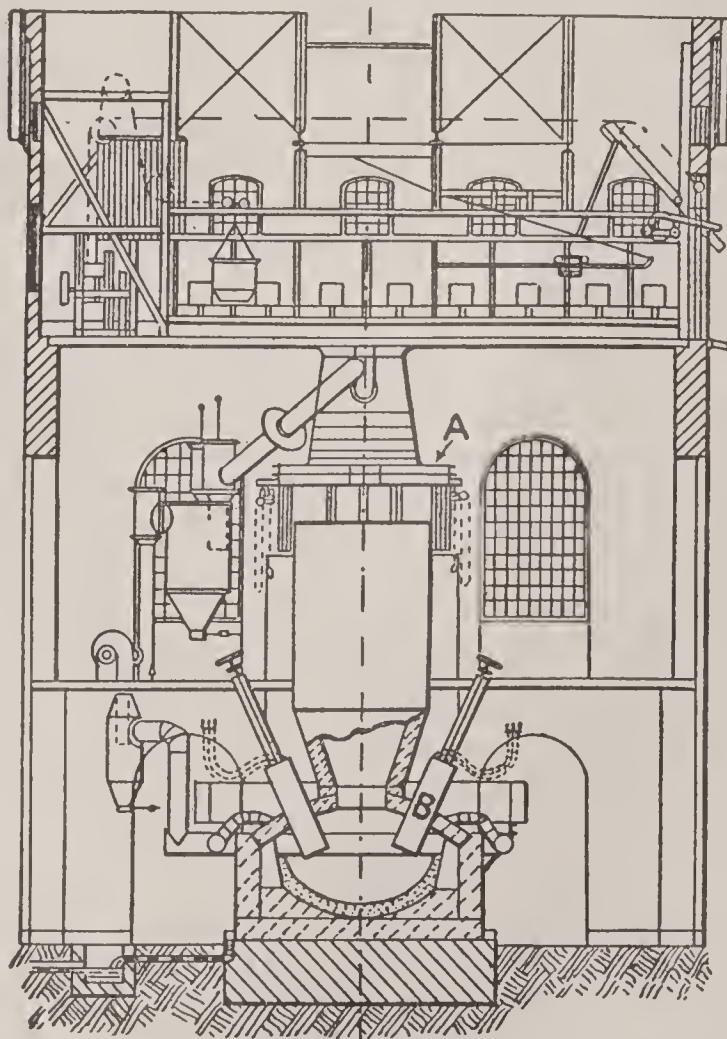

FIG. 15. GRÖNWALL ELECTRIC FURNACE.
Vertical section.

Other materials, as a rule, are added towards the end of the heat or else in the ladle, depending largely upon their amount (chilling effect) and any danger of their being excessively oxidized. For the latter reason ferrotitanium and ferrovanadium are put into the ladle after all the other additions.

INGOTS

The liquid steel, however made, is obtained in suitable shapes, called "ingots," for rolling or forging by casting it in special molds, usually made of cast iron, particularly for ordinary sizes, but sometimes of sand if of large size or for special purposes; recently steel molds have been tried, a longer life being claimed for them, but this has not yet been conclusively shown. The ingots are generally rectangular in cross section and slightly tapering to the top to permit of the removal of the molds. For crucible steel they usually do not exceed a few hundred pounds in weight, while for ordinary structural material they are generally of from 2 to 10 tons, and for special purposes, such as armor plate, they may weigh as much as 100 tons. In the case of crucible steel the pouring is commonly done directly from the crucible, but in the other steel processes the metal is tapped into a *ladle*, a large vessel or pot consisting of a steel shell lined with fire bricks or other refractory material. There is a hole in the bottom closed by a stopper which can be raised or lowered, thus controlling the flow of the steel. For the production of ingots, the steel is usually poured directly into the top of the mold; this method is sometimes objectionable on account of a certain amount of splashing against the sides. Where an ingot with better surface is desired, or in case a sand mold is used whose surface might be cut away by the falling stream, the metal is introduced at the bottom through a pipe or *runner* on the outside of the mold. The molds were formerly set on the floor of a pit, but this method has been largely abandoned, at least in the United States, in favor of car casting. This was devised by F. W. Wood, of the Maryland Steel Company, and consists in setting the molds on small cars or *buggies* on which they can be transported to their destination.

When the steel cools and solidifies, two conditions arise to a greater or less extent, depending upon the attendant circumstances, affecting (a) the chemical homogeneity and (b) the physical structure or soundness. As discussed under METALLOGRAPHY, steel when slowly cooled is made up of a number of distinct constituents, much as in the case of composite rocks. During cooling those constituents or elements whose combination with iron reduces its melting point segregate or separate out in the still liquid portion near the top of the ingot or casting, becoming more and more concentrated as the remainder freezes. Chemical analysis of such portions shows a higher percentage of carbon, phosphorus, and sulphur than is found in other portions. Somewhere near the bottom of the ingot a reverse condition exists, due to such elements or constituents leaving the steel to enrich the upper portions; this latter is termed *negative segregation*. Segregation may be reduced by different means, such as rapid cooling, the use of small sections, and the addition of certain deoxidizing substances, e.g., silicon or aluminium, but is never wholly prevented, although in many cases it is revealed only by the aid of the microscope. The evolution of gases during solidification may have a beneficial effect, by keeping the still molten metal stirred up.

Solidification naturally takes place first in

the portions in contact with the wall of the mold and gradually proceeds inward. As contraction also occurs, since the metal occupies a smaller volume the lower the temperature, there should result eventually a hollow space or cavity, termed a *pipe*, situated in the upper central portion of the ingot. Most of the gases dissolved by the metal when molten are evolved during freezing, and any which cannot escape freely, owing to the metal having become pasty, are mechanically held in little pockets or cavities, called *blowholes*. The space occupied jointly by the pipe and the blowholes may, in general, be taken as equal to the difference in volume of the steel when respectively molten and cold (solid). Hence, with a large number of blowholes, there may be no pipe, and the maximum amount of pipe can be present only in the entire absence of blowholes. The absence of both these defects is necessary to secure sound steel. The simplest and, as a rule, the most satisfactory method for arriving at this result is to eliminate the blowholes by proper manipulation and treatment and then remove (*crop*) and discard the portion containing the pipe. In the case of regular castings an extension is provided to contain the pipe, called the *sinkhead*, which is subsequently machined or broken off.

Special methods may be divided into chemical, mechanical, thermal, and a combination of two or all of these. Blowholes are prevented by the removal of gases either chemically, by the use of *dcoxidizers* or *dccgasifiers*, which may also have some effect in causing the steel to retain a certain amount of gases when cold; mechanically, by applying pressure during solidification which will also serve to eliminate the pipe, also by agitating the steel while molten, thereby assisting the gases to escape. So many different processes and methods have been suggested and tried that only a few can be mentioned here. *Brinell* regulated the number and position of the blowholes and the amount of pipe by means of the manganese and silicon contents. *Allen's agitator*, consisting of two arms fastened to a vertically revolving shaft, was intended to stir up the steel in the ladle to secure thorough incorporation of the additions, but it was also found to disengage a considerable amount of the dissolved gases. *Fluid compression*, also called *liquid* or *plastic compression*, as the name signifies, consists in applying pressure to the ingot during solidification which, to be effective, must be sufficient to expel the gases given off and to follow up the contraction of the metal in cooling so that no pipe or other cavities can form. *Whitworth* casts the steel in a cylindrical mold with vertical walls, a hydraulic plunger then being forced down on the top of the ingot. *Williams* and *Lilienberg* attack the ingot from the side in much the same manner. In *Harmet's process* a tapered ingot is driven upward in a tapered mold. *Centrifugal casting*, consisting in rotating or revolving the molds after pouring, has a somewhat similar effect, but to a less degree, as the pressure is not nearly so great. *Sebenius* pivoted the molds on swinging arms attached to and rotated by a vertical shaft. In *Stridberg's modification* the mold was rotated about its longitudinal axis. Pressure applied by steam or volatile substances within a closed mold have been suggested by *W. R. Jones* and *Bessemer* respectively. *Talbot's method* consists in rolling the ingot before

the centre has completely solidified. Retardation in the cooling of the upper portion of the ingot, as compared with the lower portion, is the principle upon which many processes have been based, with the idea that as soon as any pipe forms it will be filled up with liquid steel. Methods to retard cooling at the top consist in a refractory lining at the upper part of the mold; keeping the mold full by the overflow of steel from one mold to the next (*Sauveur method*); covering the top of the ingot with molten slag, covered in turn with fuel which is kept ignited by a blast of air (*Hadfield method*); having the ingot of greater cross section at the top; heating the top of the ingot by means of an electric arc or the effect of powerful induced currents on the principle of an electric induction furnace (see above); the use of *thermit* (a mixture of powdered aluminium and a metallic oxide whose reaction generates a very high temperature), formerly introduced near the top to keep the metal molten, but more recently near the bottom to secure reduction of any oxides in the steel and to assist the escape of gases by keeping the still molten metal stirred up; increasing the rate of cooling at the bottom by increasing the thickness of that portion of the mold wall, and reducing the thickness at the top, also increasing the cross section of the ingot at the top (*Gathman method*). There are, or may be, various combinations of the above.

COMPARISON OF STEEL

Difference in the quality of steel made by different processes may be due either to the process itself or to the raw materials used and the care with which the process in question is conducted: this latter cause is too frequently overlooked. Where the highest quality is necessary, e.g., for tool steel, the price is sufficient to permit of special selection of the raw materials and of attention to the smallest details. Where, however, as in the case of structural materials, moderate excellence is sufficient, a considerable variation in the choice of raw materials and the general practice is possible. But it should be noted that the proportionate degree of excellence of the respective materials for the purpose intended may be (and usually is) greater in the second case than in the first. As ordinarily conducted, the order of merit is usually considered to be: (1) crucible; (2) electric; (3) open hearth; (4) Bessemer. The two first are generally employed for the production of special material, and the two last chiefly for the great proportion of the tonnage consumed for general purposes.

PHYSICAL PROPERTIES AND THE EFFECT OF VARIOUS ELEMENTS

Iron, either pure or in combination with different elements, is capable of a wider range in physical properties than any other known substance, depending upon the composition and also to a large extent upon its physical condition. (See METALLOGRAPHY.) When chemically pure, in which form it is practically never used owing to the cost, it has a moderate tensile strength of about 40,000 pounds per square inch, with relatively high ductility and good conductivity for electricity and heat. With increas-

ing proportions of other elements, at least to a certain extent, particularly of carbon, its strength and hardness are progressively increased, and its ductility and conductivity decreased. Changes in its properties may also be effected by suitable treatment, either physical or thermal. For example, by drawing and treating, special piano wire has been obtained with a tensile strength of slightly over 460,000 pounds per square inch. The usual grades of structural steel have a tensile strength of between 50,000 and 70,000, with a carbon content of about 0.12 to 0.30 per cent; machinery steel and forgings, between 60,000 and 90,000, with about 0.25 to 0.55 per cent of carbon. Alloy steels, containing one or more of the elements nickel, chromium, vanadium, etc., usually also heat-treated, generally show from about 100,000 to 150,000 pounds' tensile strength or over. Further information will be found under STRENGTH OF MATERIALS.

Ordinary steels contain up to about 1 per cent of manganese, and in some cases even up to 1.5 per cent, without the resulting decrease in ductility destroying their commercial value.

Total.....	63,210,694	58,275,701

Above this, up to about 7 per cent, the material is rendered excessively brittle. When, however, the content is between about 7 and 15 per cent, a remarkable change occurs, for the metal, while increasing in hardness, may, by rapid cooling, be rendered tough and ductile. Its great hardness, in the sense of resistance to abrasion, is such that grinding must ordinarily be employed when any finishing is required. This material is known as "manganese steel" and is used for

* Includes small quantities of pig iron and ferro-alloys made with coke and electricity, etc.

A certain amount of phosphorus is desirable in steel for thin sheets to prevent them from sticking together when rolled in a *pack*; sulphur in combination with manganese, as manganese sulphide, enables steel to be more readily machined, particularly when low in carbon, without injury to its other properties. Silicon increases the strength, and to a certain degree the ductility, of

been for nickel steel containing from 3 to 4 per cent of nickel, particularly for important bridge work such as the St. Louis Municipal Bridge, the Quebec Bridge, and others. *High-speed* or *self-hardening steel* was discovered by Mushet and owes its peculiarities principally to tungsten, molybdenum, and chromium, usually now with a little vanadium, and very recently with

steel. The effect of these last three elements upon cast iron has been mentioned in connection with the product of the blast furnace. Oxygen, as oxide of iron dissolved in steel, is injurious except in very small proportions, rendering the metal both red short and cold short. Nitrogen and hydrogen may be absorbed or occluded to a considerable extent, particularly when the metal

cobalt (*cobalt steel*). Its importance is due to its use for machine tools which retain their cutting edge even when heated to a dull red by the friction of the chip which is removed. Other combinations with chromium—chrome-nickel, chrome-nickel-vanadium, etc.—are largely employed for parts of machines, engines, and automobiles which are subjected to severe stresses

(New York), especially its important annual numbers with their authoritative summaries; *Iron Trades Review* (Cleveland); *Stahl und Eisen* (Düsseldorf); *Bulletin American Institute of Mining Engineers*. See ANNEALING; IRON.

IRON AND STEEL INSTITUTE, THE. An English association, organized by the iron trade of the north of England, the first meeting taking place in London, Feb. 25, 1869. Its object is the discussion of practical and scientific questions connected with the manufacture of iron and steel. There are two general meetings each year, one in May, in London, and the autumn one in other cities, not always in Great Britain, for the institute has met in Paris, Vienna, Brussels, and New York. Since 1874 it has annually presented the Bessemer gold medal, for some invention or notable paper, and it awards annually research scholarships founded by Andrew Carnegie, who gave \$100,000 for this purpose. The Institute publishes the semiannual *Journal of Iron and Steel Industry*, containing original papers and abstracts and reviews from other publications.

IRONBARK TREE. A name given in Australia to certain species of *Eucalyptus* (q.v.), particularly *Eucalyptus siderophloia*, on account of the extreme hardness of the bark. These trees attain a height of 80 or 100 feet and a circumference near the base of 10 to 12 feet. The timber, which is very valuable for shipbuilding and other purposes in which hardness and durability are required, is rated as one of the strongest of Australian woods; its tensile strength exceeds that of hickory.

IRON CHANCELLOR, THE. A name given to Bismarck.

stituted in 1813 by Frederick William III as a reward for distinguished services in war. It consists of a Maltese cross, made of iron, edged with silver, and worn suspended from the neck or at the buttonhole. The superior decoration of the grand cross, a cross of double the size, is reserved for officers of high rank, who have successfully carried out a campaign, won a decisive battle, or conducted a brave defense of a fortress or position. The order was revived during the war with France in 1870-71, and in the Great European War of 1914- , when the Kaiser decorated great numbers of his soldiers. See Plate of ORDERS.

IRON CROWN. The name of the old crown of the Lombards, still preserved in the church of St. John the Baptist at Monza. It is made of six pieces and is adorned with 22 jewels, 26 golden roses, and 24 enamels. On the inside there is a circlet of iron, said to be formed from a nail used at the Crucifixion, brought from Palestine by the Empress Helena, given by Pope Gregory I to the Lombard Princess Theodelinda. Before the twelfth century it was called the golden crown. It was used at the coronation of the Lombard kings, and of the German emperors as kings of Italy. In 1805 Napoleon crowned himself at Milan with it. In 1838 it was worn by the Emperor Ferdinand I. In 1859 it was carried off by the Austrians, but after 1866 restored to Monza. Consult Bombelli, *Storia della corona ferrea* (Florence, 1870), and Thomas Hodgkin, *Italy and her Invaders*, vol. vi (Oxford, 1880).

IRON DUKE, THE. A popular sobriquet for the Duke of Wellington.

IRON GATES (Turk. *Demir-Kapu*). A celebrated pass on the lower Danube, near Gladova,

just below the point where the river leaves Hungary, where a spur of the Transylvanian Alps nearly barricades the river. It is the last great defile of the Danube and is about 2 miles in length. In 1890 the demolition of the obstructions to navigation was begun by a Hungarian company, and in the course of 10 years was practically completed. The work necessitated the excavation by blasting of nearly 1,200,000 cubic yards of rock, about half of which was in the river bed. The regulation work has afforded an artificial waterway for vessels, chiefly on the Servian side, through which there is an extremely rapid current.

IRON MASK, THE MAN IN THE (Fr. *L'Homme au masque de fer*). The story of this mysterious prisoner confined at Pignerol, in the Bastille, and other French prisons in the reign of Louis XIV has long excited a romantic curiosity in the minds of students of history. The first notice of him in print was given in *Mémoires secrets pour servir à l'histoire de Perse* (Amsterdam, 1745-46), in which the prisoner was identified with the Duke of Vermandois, a natural son of Louis XIV and La Vallière, who had to expiate an offense against his half brother, the Dauphin Louis, with imprisonment for life. This absurd assertion was without foundation; for the Duke of Vermandois died in 1683, whereas the prisoner is known to have died in 1703; but the confidence with which it was made caused a deep sensation, and the romance of Mouhy, *L'Homme au masque de fer*, which immediately followed (Hague, 1746), was read with all the more avidity because it was prohibited by the court. Voltaire, in his *Siècle de Louis XIV* (1751), treated the anecdote historically, but without doing anything to unravel the mystery. The first authentic information with regard to the Man in the Iron Mask, therefore, was given by the Jesuit Griffet, who acted for nine years as confessor in the Bastille, in his *Traité des différentes sortes de preuves qui servent à établir la vérité dans l'histoire* (Liège, 1769). He quoted from the manuscript journal of Du Jonca, the royal lieutenant of the Bastille, according to which Saint-Mars, the Governor of the island of Sainte-Marguerite, in September, 1698, brought with him to the Bastille a prisoner whom he had already had in custody at Pignerol in Piedmont. The prisoner's face was always kept concealed by a mask of black velvet. The journal also mentions his death on Nov. 19, 1703, and that he was buried in the cemetery of Saint-Paul. This is confirmed by the register of burials for the parish of Saint-Paul, where the prisoner is mentioned under the name of Marchiel. These two entries are the bare facts of the case, and upon them have been erected theories and hypotheses without number. Besides the earliest story already mentioned, there have been at least four other explanations as to the identity of the prisoner. Among the minor conjectures are those which connect him with Fouquet, the financial minister of Louis XIV, and with the Duke of Monmouth, the illegitimate son of Charles II of England, to mention only a few of many. An addition to the article on the subject in the *Dictionnaire philosophique* freely states the opinion that the prisoner was a bastard brother of Louis XIV. The writer, who was probably the editor of the work, makes the prisoner an illegitimate son of Anne of Austria. Louis XIV first learned the existence of his brother when

he came of age, and put him in confinement to guard against any possible unpleasant consequences. Linguet, in the *Bastille dévoilée*, ascribes his paternity to the Duke of Buckingham. Saint-Michel, in 1790, attempts to connect the prisoner with a supposedly secret marriage between Queen Anne and Cardinal Mazarin. What is remarkable is that the court continued to manifest an interest in the matter and took every means to keep the identity of the prisoner in the dark. When the Bastille fell, the prisoner's room was eagerly searched and also the prison register, but all inquiry was vain. The Abbé Soulave, who published *Mémoires du maréchal Richelieu* (London and Paris, 1790), tried to establish from a document alleged to have been written by the tutor of that unfortunate Prince that the Man in the Iron Mask was a twin brother of Louis XIV, and that, to avoid the calamities of a disputed succession to the throne, Louis XIII had caused the later born of the twins to be brought up in secret. Louis XIV learned of his brother's existence only after the death of Mazarin, and the twin brother, having discovered his relation to the King by means of a portrait, was subjected to perpetual imprisonment. This view of the matter was at one time almost universally prevalent. The first conjecture of what is still held by many to be the truth is contained in a letter dated 1770, written by a Baron d'Heiss to the *Journal Encyclopédique*. The same is repeated by Louis Dutens, who declares in his *Interecepted Correspondence* (1789) that there is no point of history better established than the fact that the prisoner in the iron mask was a minister of the Duke of Mantua. This minister, Count Matthioli, had pledged himself to Louis XIV to urge his master, the Duke, to deliver up to the French the fortress of Casale, which gave access to the whole of Lombardy. Though largely bribed to maintain the French interests, he began to betray them to several countries vitally interested; and Louis XIV, having obtained conclusive proofs of his treachery, contrived to have Matthioli lured to the French frontier, where he was kidnaped April 23, 1679, and conveyed to the fortress of Pignerol, which was his first prison. The conclusions of D'Heiss and Dutens were followed up by Roux-Fazillac, who published a small work on the subject in 1801. This attempt to show that Matthioli was the Man in the Iron Mask, though clever, was not altogether successful; but the documents later discovered and published by M. Delort and M. Marius Topin seemed to leave little doubt on the subject, and the public had apparently made up its mind that the secret was at last discovered, until a still more recent work by a French officer, M. Jung, seemed to show conclusively that Matthioli could not have been the mysterious prisoner, and endeavored to prove that the Man in the Iron Mask was a soldier of fortune of Lorraine, Marechiel by name, who was the head of a widespread and formidable conspiracy, working in secret for the assassination of Louis XIV and some of his ablest ministers. In the course of his researches M. Jung examined some 1700 volumes of dispatches and reports in the bureau of the Ministry of War. According to his story, Marechiel was arrested by order of Louvois in 1673, and after being brought to Paris was sent to Pignerol to be under the care of Saint-Mars, who took him with him to Exilles (1689), Sainte-Marguerite,

and finally to the Bastille (1695), where the prisoner died in 1703. The so-called iron mask, really a velvet one, was burned with his clothes and effects. Lang in his work on the subject followed out this same idea, only his name for the prisoner was Dauger. Up to 1891 Jung's theory was considered satisfactory, but in that year Captain Bazières, of the garrison at Nantes, published a translation of some of Louis XIV's cipher dispatches to Louvois and the Minister's replies. From these it appeared that the mysterious prisoner was General de Bulonde, who was punished, for his mistake or cowardice in raising the siege of Cuneo, by lifelong imprisonment at Pignerol and later in the Bastille. During the last decade, however, there has been a reaction in favor of the Matthioli theory, due chiefly to the efforts of M. Funck-Brentano. Opinions still differ, and there is a tendency in many quarters towards regarding the Man in the Iron Mask as some obscure plotter, probably a valet possessed of a great secret, and therefore held in the strictest confinement. The whole question, however, is one of those mysteries of history that will probably never be satisfactorily solved, though it may be that the secret archives of the Vatican could throw light on the subject.

Bibliography. The literature concerning the Man in the Iron Mask is very large. Up to 1870, 52 works had been written to elucidate the mystery, and since then over 20 more have appeared. The following list, therefore, is merely a selection of the best and most noteworthy contributions to the subject: Roux-Fazillac, *Recherches historiques sur l'homme au masque de fer* (Paris, 1801); Delort, *Histoire du masque de fer* (ib., 1825); Topin, *L'Homme au masque de fer* (ib., 1870); Jung, *La vérité sur le masque de fer, 1664-1703* (ib., 1873); Loiseleur, *Trois énigmes historiques devant la critique moderne* (ib., 1882); Burgaud and Bazières, *Le masque de fer* (ib., 1883); Funck-Brentano, "L'Homme au masque de velours noir dit le masque de fer," in *Revue Historique*, vol. lvi (ib., 1894). The best work to consult in English is Hopkins, *The Man in the Iron Mask* (London, 1901); for the Dauger theory, consult Lang, *The Valet's Tragedy* (ib., 1903).

IRONMASTER, THE. A dramatization of Ohnet's *Maître des forges*, by Pinero (1884).

IRON MOUNTAIN. One of the isolated knobs of the St. François Mountains, in St. François Co., Mo. It is 81 miles south of St. Louis, on the Iron Mountain Railroad, and is 1078 feet in elevation above the sea and 200 feet above the adjoining valley. This mountain contains deposits of specular hematite iron ore.

IRON MOUNTAIN. A city and the county seat of Dickinson Co., Mich., 72 miles northwest of Menominee, on the Chicago, Milwaukee, and St. Paul, the Wisconsin and Michigan, and the Chicago and Northwestern railroads, and on the Menominee River (Map: Michigan, B 3). It is noted for large iron-mining interests and contains a Carnegie library. Settled in 1879, Iron Mountain was incorporated in 1888. The government is administered by a mayor, elected annually, and a unicameral council. Pop., 1900, 9242; 1910, 9216.

IRON ORES. See IRON, *Iron Ore*.

IRON PYRITES. See PYRITES.

IRONS. The fetters used for confining prisoners. They consist of handcuffs, or *hand irons*, and *leg irons*, a pair of the latter being

connected with light chains of sufficient length to permit the prisoner to walk, taking short steps. Irons are used to confine men for punishment, or for safekeeping when violent (as they frequently are when intoxicated), or when awaiting trial and it is feared they may attempt to escape. The Spanish used to confine their prisoners in *bilboes*, which consisted of shackles around the ankles joined by a bar of iron. In the seventeenth and eighteenth centuries bilboes were used to some extent in the British navy, and the name survived for a long time after the character of the irons had changed. The use of irons for confinement as a punishment has been abolished in the United States navy.

IRONSIDE, SIR. A knight of Arthur's Round Table.

IRONSIDES, OLD. A name popularly used of the United States frigate *Constitution*. See CONSTITUTION, THE.

IRONSMITH. A barbet. See COPPERSMITH.

IRONTON, i'ern-tün. A city and the county seat of Lawrence Co., Ohio, on the Ohio River, 134 miles southeast of Cincinnati, on the Norfolk and Western, the Cincinnati, Hamilton and Dayton, and the Detroit, Toledo, and Ironton railroads (Map: Ohio, E 8). The Chesapeake and Ohio Railroad, on the opposite side of the river, maintains a free passenger ferry and a large freight transfer. Ironton is the centre of a region rich in timber, iron ore, bituminous coal, and fire and pottery clay; carries on an important river commerce; and has extensive manufactories of iron (including foundries, machine shops, blast furnaces, rolling mills, wire-drawing and nail works, etc.), cement, lumber, machinery, boilers, stoves, furniture, doors and mantels, and fire brick. The city has a memorial hall, Masonic Temple, Odd Fellows' Hall, Briggs Public Library, fine Federal and Court-house buildings, and Kingsbury School. The parks are Beechwood, River View, and Lincoln. Settled in 1832, Ironton was incorporated in 1849. The government, under the municipal code of 1902, is vested in a mayor, elected biennially, a unicameral council, and boards of public service and public safety. The city owns and operates its waterworks. Pop., 1900, 11,868; 1910, 13,147; 1914 (U. S. est.), 13,690.

IRONWOOD. A city in Gogebic Co., Mich., about 135 miles (direct) west of Marquette, on the Chicago and Northwestern and the Minneapolis, St. Paul, and Sault Ste. Marie railroads, and on the Montreal River (Map: Michigan, F 2). Iron mining is the principal industry, though lumbering is of considerable importance. Among the more prominent buildings are a fine city hall, the Luther L. Wright High School, and the Carnegie Library. Settled in 1884 and incorporated in 1887, Ironwood is governed under the revised charter of 1893, which provides for a unicameral council and for a mayor, elected annually and controlling, subject to the consent of the council, the appointments of all subordinate officials excepting the school trustees, city clerk, and city treasurer. Pop., 1900, 9705; 1910, 12,821; 1914 (U. S. est.), 14,147.

IRONWOOD. A name given to various trees with hard, heavy wood. *Metrosideros vera*, a native of Java and other Eastern islands, is much valued by the Chinese and Japanese for making rudders, etc., and is exported in small quantities. The bark is used in Japan as a remedy for diarrhœa and mucous discharges. *Mesua ferrea*, a native of the East

Indies, is planted for its heavy hard wood and for its fragrance and roselike flowers. In Australia the name ironwood is given the timber of *Melaleuca genistifolia*, *Myrtus gonoclada*, *Notelæa ligustrina*, and *Olea paniculata*. In the United States it is applied to *Ostrya virginiana*, *Carpinus caroliniana* (see HORNBEAM), *Eugenia garberi*, and other trees which have tough wood. *Olea laurifolia* and *Sideroxylon inerme*, called ironwood in the south of Africa, are valuable timber trees. The name ironwood is given to *Casuarina equisetifolia* in Australia; to *Parrotia persica* in Persia; to *Mimusops djava* in tropical Africa; to *Ixora ferra* in the West Indies; and to various species of *Citharexylum* in tropical America. See CASUARINA.

IRONY, ἴρωνι (Lat. *ironia*, from Gk. εἰρωνεία, *eirōneia*, dissimulation, irony, from εἰρων, *eirōn*, dissembler, from εἰπεῖν, *eipein*, to talk). The name given to that peculiar style of thought and expression by which words are gravely made to convey literally a meaning quite other than that actually intended. When skillfully used, there is no more fatal literary weapon of destruction. Such an instrument it was in the hands of Swift, when, e.g., he proposed to the poor people of Ireland, apparently in all seriousness, that they should rid themselves of poverty by selling their children to the rich, who should eat them. Irony united with a kindlier feeling is one of the charms of Thackeray's style. There is also the irony of fate, or of events, where the issue is otherwise than might with reason or justice be expected. See RHETORIC, FIGURES OF.

IROQUOIAN (ir'ō-kwoi'an) **STOCK**. One of the most important linguistic stocks of the American Indians, formerly inhabiting a large part of the present Ontario, New York, Ohio, and Pennsylvania, with portions of eastern Virginia and North Carolina and the whole of the southern Alleghany region. The stock name is derived from that of the Iroquois (q.v.), or confederated Five Nations of New York—the Mohawk, Oneida, Onondaga, Cayuga, and Seneca. Other important tribes were the Wyandot (or Huron), Neutral Nation, Erie, Conestoga, Nottoway, Meherrin, Tuscarora, and Cherokee. See IROQUOIS; CHEROKEE; WYANDOT.

IROQUOIS, ir'ō-kwoi'. A confederacy of five tribes of Iroquoian stock—Mohawk, Oneida, Onondaga, Cayuga, and Seneca—to which the Tuscarora were afterward added. They called themselves by names signifying respectively "we of the long house" and "real people." The term *Iroquois* is of French origin, being possibly compounded from two ceremonial words of frequent occurrence in their councils, with the addition of the French suffix *ois*. Another theory makes it an Algonquian derivative. Their Algonquian neighbors knew them as *Mengwe* or *Nadowa*, about equivalent to "alien" or "enemy," while by the English they were designated as the Five, or Six, Nations.

The people found by Cartier in 1535 occupying the shores of the St. Lawrence River from the present Quebec to Montreal were of Iroquoian stock, as proved by linguistic evidence, and appear to have been, in part at least, the ancestors of the later Iroquois. These tribes were dispossessed shortly afterward by the more powerful Algonquian tribes, some, like the Hurons, taking refuge farther to the west, while others, including the Iroquois, retired to the south. Shortly after this withdrawal—probably

about the middle of the sixteenth century—the tribes known later as the Five Nations were persuaded by the counsel of their traditional legislator, Hiawatha, to form a league or confederacy upon such a well-ordered plan that it has endured for more than three centuries and exists to-day as their ruling government, in spite of all the changes brought about by the advent of the white man. The five tribes at this time occupied central and western New York, where they were found in 1609 by Champlain, who, by joining forces with their Algonquian enemies, brought down upon the French the lasting vengeance of the Iroquois League, which was one of the main factors in the ultimate loss of Canada.

By the formation of the league, in which each tribe represented a state government, with a central federal council of 50 chiefs sitting at Onondaga, the Iroquois were enabled to withstand the inroads of the hostile Algonquian tribes, and even to assume the offensive. On the establishment of the French missions among the Hurons (see WYANDOT), about the year 1630, the Iroquois, who in the meantime had been supplied with firearms by the Dutch on the Hudson, began war upon their kinsmen in Canada with such effect that in a few years those of the Hurons who had not been slaughtered or carried into captivity were forced to abandon their country and fly hundreds of miles to the west. The same fate soon after befell the cognate Neutral Nation and the Erie, as well as the Ottawa and others of Algonquian race, resulting in almost complete ruin to the French missions in Canada. The destroyers then turned upon the Conestoga and others in the south, the Mohican and others east of the Hudson, and the Miami and Illinois in the west, until by the year 1700 they claimed and were conceded a paramount influence and dictation from Hudson Bay to the Cherokee frontier of Carolina, and from the Connecticut almost or quite to the Mississippi, the only tribes able to make successful opposition being the Ojibwa in the northwest and the Cherokee in the south. From the beginning of the Colonial period they held the balance of power between France and England in the north, and were courted alike by both, but remained steadfast to the English interest. The few exceptions were chiefly in the case of the Mohawk and Cayuga, who yielded to the influence of the French Jesuit missionaries, by whom they were finally drawn off from the territory of the league and settled in the mission villages of Caughnawaga and St. Regis. About the year 1715 the cognate Tuscarora, who had been driven out from North Carolina in a war with the settlers, removed to New York, where they were assigned lands by the Iroquois and admitted as the sixth nation of the league.

At the outbreak of the Revolution in 1775 the league council declared for neutrality, while allowing each of the six component tribes to take sides as it thought fit. The great majority of the Iroquois sided against the Americans, only the Oneida and a part of the Tuscarora refusing. The Mohawk and Cayuga followed their great chief, Brant, in a body to Canada. At the close of the struggle these, with other Iroquois who had supported the English cause, were settled by the Canadian government on a reservation on Grand River, Ontario, where most of them still remain, others being at Quinte Bay, Thames River, and Gibson, in the same province.

The Catholic Iroquois are at Caughnawaga, St. Regis, and Lake of Two Mountains, in Quebec Province, but are no longer affiliated with the league. Those of Caughnawaga constitute the largest single Indian settlement north of Mexico. In addition to the Catholic St. Regis Iroquois in Canada, about as many more are on the New York side of the line, the reservation having been cut in two when the boundary was finally established by survey. The Iroquois in the United States are all on reservations in New York, excepting the Oneida, most of whom removed to Wisconsin about 1820, and a mixed band of so-called Seneca in Oklahoma.

The political importance of the Iroquois, although due in part to their geographic situation and early acquirement of firearms, was in great measure the result of their superior system of organization and of their individual force of character. The same traits have enabled them to hold their own in the midst of an alien surrounding. Prominent features of their system were the council of matrons, the elaborate clan structure, and the wholesale adoption of captives, who, if spared, were admitted to full tribal rights, instead of being reduced to semi-slavery, as among some other tribes. The best single source of information upon the confederacy is probably L. H. Morgan, *League of the Hodé-no-sau-nee or Iroquois* (Rochester, 1851; new ed., New York, 1904). Dialectically all the Iroquoian tribes closely resemble each other.

The Iroquois had a highly developed woodland culture (see INDIANS), being noted for their fields of corn, pumpkins, tobacco, to which they later added orchards of apple and peach. They built long bark-covered houses, the various families of a clan residing in compartments along the sides. This was the famous "long house," the symbol of the league, or government. They made fine black pottery, splint baskets, and fine mats of corn husk. The wampum belt was used by them for public records. They maintained many secret societies, known in literature as "false-face societies," because the members wore curious carved wooden masks representing various deities. Consult: C. Colden, *History of the Five Indian Nations of Canada which are Dependent on Province of New York* (2 vols., New York, 1904); W. M. Beauchamp, *Civil, Religious, and Mourning Councils and Ceremonies of Adoption of New York Indians* (Albany, 1907); H. C. Converse, *Myths and Legends of New York State Iroquois* (ib., 1908). The New York State Museum has large collections representing the aboriginal life of the Iroquois and has published many important monographs on them in which may be found detailed information.

The present number of the Iroquois, including those of the Catholic mission colonies which have cast off all allegiance to the ancient league, is considerably above 17,000, distributed as follows: Ontario, Canada, Iroquois and Algonquins of Gibson, 139 (perhaps one-half being Iroquois); Mohawks of the Bay of Quinte, 1271; Oneidas of the Thames, 770; Six Nations on the Grand River, 4195. Quebec, Canada, Iroquois of Caughnawaga, 2074; Iroquois of St. Regis, 1426; Iroquois and Algonquins of Lake of Two Mountains, 393 (perhaps one-half being Iroquois). In the United States—New York reservations, 4918; Wisconsin (Oneida), 2107; Oklahoma (Seneca), 215. See IROQUOIAN STOCK.

IROQUOIS, or MATILDA. A port of entry

of Dundas Co., Ontario, Canada, 43 miles southeast of Ottawa, on the left bank of the St. Lawrence and on the Grand Trunk Railway (Map: Ontario, J 4). It commands the entrance to the Iroquois Canal. Pop., 1901, 1097; 1911, 849.

IRRA'DIA'TION. In optics, the apparent enlargement of a white or strongly illuminated object when seen against a dark ground. Helmholtz attributes the phenomenon to want of perfect accommodation in the eye, whereby diffusion images are formed about the true image of the bright object and, encroaching upon the surrounding dark region, extend the borders of the image. See VISION.

IRRA'TIONAL NUMBER. Any number that cannot be expressed as the quotient of two integers. A fraction or quotient of two integers may be expressed in the form of either a terminating or a nonterminating decimal, the latter always containing a repetend. (See DECIMAL SYSTEM.) Thus, $\frac{8}{5}$ equals 1.6, a terminating decimal; $\frac{2}{3}$ equals 0.6666 . . . , a nonterminating decimal. In either case the decimal may be transformed again into the common fractional form by the formulas of series (q.v.). But when the process of evolution is applied to integers and the results are expressed decimally, there is often produced a decimal form that is nonterminating, contains no repetend, and cannot be expressed as the quotient of two integers. For example, the surd $\sqrt{2}$ equals a number (1.4142 . . .) containing a nonterminating and nonrepeating decimal, and cannot be expressed as the quotient of two integers. While, however, evolution thus often results in an irrational number, it is not every irrational number that can be expressed in the form of a surd. This may be plainly seen in the case of π , the ratio of the circumference to the diameter of a circle. The value of this irrational number to five decimal places is 3.14159 See CIRCLE.

Certain operations with irrational numbers were performed by the ancients. The Pythagoreans proved the irrationality of the square roots of 3, 5, 7, . . . 17. The arithmetic part of Euclid's *Elements* contains a geometric treatment of the subject. Archimedes approximated the value of a great number of surds, stating, e.g., that $1351/780 > \sqrt{3} > 265/153$; but the method by which he arrived at his results is unknown. In the Middle Ages Fibonacci, and still later Stifel and Rudolff, devoted much attention to irrationals. But not until very recent times has a purely arithmetic theory of surds been produced, through the researches of Weierstrass, Dedekind, G. Cantor, and Heine, whose efforts were inspired by a desire to fortify the bases of analytic mathematics. No adequate explanation of these methods can be given here. That of Weierstrass starts with a consideration of the formation of different kinds of number through arithmetical operations. Dedekind arranges positive and negative, integral and fractional numbers in order of magnitude, and observes that any rational number, as a , divides the system into two classes, C_1 and C_2 , such that every number in C_1 is less than every number in C_2 , and a is either the greatest number in C_1 or the least in C_2 . These rational numbers are then represented by points on a straight line. But there are still an infinite number of points on the line for which there are no corresponding rational numbers. He then shows that to every one of these points corresponds a unique irra-

tional number. Cantor and Heine introduce irrational number through the concept of a fundamental series. Following is an example of the series method. The surd $\sqrt{2}$ lying between 1.4142 and 1.4143 may be expressed thus:

$$\frac{14}{10} + \frac{1}{100} + \frac{4}{1000} + \frac{2}{10000} < \sqrt{2} < \frac{14}{10} + \frac{1}{100} + \frac{4}{1000} + \frac{3}{10000},$$

or, more generally,

$$\frac{N_1}{10} + \frac{N_2}{10^2} + \frac{N_3}{10^3} + \dots + \frac{N_p}{10^p} < \sqrt{2} < \frac{N_1}{10} + \frac{N_2}{10^2} + \frac{N_3}{10^3} + \dots + \frac{N_{p+1}}{10^p}.$$

Now, as p becomes indefinitely great, $\sqrt{2}$ evidently becomes the common limit of the two series, and may therefore be defined by them. Expressing the sum of the series on the left by P/Q , and that on the right by $(P+1)/Q$, the square root of 2 may be expressed by the relation $P/Q < \sqrt{2} < (P+1)/Q$. Similarly, any irrational number I may be expressed by the relation $P/Q < I < (P+1)/Q$, where P and Q are derived from the corresponding series.

Bibliography. Consult: Dedekind, *Essays on Number*, translated by Beman (Chicago, 1901); Dirichlet, *Vorlesungen über Zahlentheorie* (Brunswick, 1879); Stolz, *Vorlesungen über allgemeine Arithmetik* (2 vols., Leipzig, 1885-86).

IRRAWADDY, ir'â-wä'dī, or **IRAWADI**. The principal river of Burma (Map: Burma, C 3). It rises on the extreme northeast border, near Mount Daphabum, a peak of the Namkiu Mountains, and flows southward with a tortuous course over 1500 miles, till it enters the Bay of Bengal through a large delta between the cities of Rangoon and Bassein. The scenery along its banks is extremely varied; the lower valley, especially the delta, is occupied by wide and level rice fields; farther up there are undulating, fertile, and thickly populated agricultural districts, broken here and there by large forests, and in three places the river breaks through mountain ranges in narrow and rocky defiles. The third or uppermost of these, which is 140 miles above Bhamo and 1168 miles from the sea, is the head of navigation for boats and small steamers. Below this the river is wide and deep, and the current not too swift, even for sailboats. Steamers ply regularly to Bhamo, and the river is an important artery of commerce for the interior of Burma, though it has now been supplemented by a railroad running parallel with its valley from Rangoon to Bhamo, crossing the river at Mandalay. For 100 miles from the sea extensive embankments have been built to protect the low delta plain from inundations. The river rises in March and reaches its maximum height in September. During November and December it is at its lowest stage and considerably blocked by sand deposits. For a description of the river and the country on its banks, consult Mowbray, "A Sail Down on the Irrawaddy," in the *Scottish Geographical Magazine*, vol. xvii (Edinburgh, 1901).

IR'REDEN'TISM (from *irredentist*, It. *irredentista*, from *Italia irredenta* (unredeemed Italy), *irredenta* being from Lat. *in-*, not + *redemptus*, p.p. of *redimere*, to redeem, from *red-*, back again + *emere*, to buy, take). A popular movement which originated in Italy after 1878,

having for its object the recovery of what its adherents call "unredeemed Italy," *Italia irredenta*, meaning all that territory at present belonging to Austria, Switzerland, France, or England having an Italian-speaking population, but no longer forming part of Italy. Under this description would come southern Tirol, Triest, Görz, Istria, and Dalmatia, the Swiss Canton of Ticino, Corsica, Nice, and Malta. To all but the most exalted patriots the chimerical nature of the Irredentist programme is apparent, inasmuch as its execution would involve the surrender by Switzerland of territory it has held for more than 300 years, by Austria of its only seaport, Triest, and by England of its great base in the central Mediterranean, Malta. Besides, Italian is not the universal language in Tirol, Görz, or Istria. Malta has a dialect of its own, and Dalmatia is completely Slavic. Irredentism has ceased to be an influential factor save with the younger element in Italian politics. Whatever force Irredentism has is directed against Austria in order to recover Triest, but the movement received a severe setback in the formation of the Triple Alliance embracing Austria. Irredentism was revived by the Great European War which began in 1914. The failure of Italy to aid Germany and Austria was hailed with great jubilation, and the government was forced to call out the troops to quell anti-Austrian demonstrations. See **POLITICAL PARTIES, Italy**.

IR'REDU'CIBLE CASE. See **CUBIC EQUATION**.

IRREF'RAGABLE DOCTOR. See **ALEXANDER OF HALES**.

IRREG'ULARITY. In plants, a term used in connection with the descriptions of flowers. Flowers are regular in which all the members in each set are alike, and, conversely, irregularity means that all the members in a given set are not alike. In practice, regularity and irregularity have to do chiefly with the petals. There are many kinds of irregularity, but the three principal types are characteristic of the three great divisions of angiosperms. Among the Archichlamydeæ the Leguminosæ represent the most important region of irregularity, which is of the papilionaceous (butterfly) type, as in sweet pea. Among the Sympetalæ the characteristic irregularity is the bilabiate (two-lipped) type, as in the mints. Among the monocotyledons the chief region of irregularity is in the orchids, in which one of the petals usually develops a more or less elongated spur and a projecting lip.

IRREG'ULARS (ML. *irregularis*, not according to rule, from Lat. *in-*, not + *regularis*, relating to rule, from *regula*, rule, from *regere*, to rule). A military term generally applied to partisan and to guerrilla troops assisting the regular establishment. They are, as a rule, only partially trained and equipped, as, e.g., the Francs-tireurs (q.v.) in 1871; some of the Cossack (see **COSSACKS**) regiments of Russia; the Bashi-Bazouks (q.v.) of Turkey; and the armies of the feudatory chiefs and rulers of India. See **ARMIES; GUERRILLAS**.

IR'RIGA'TION (Lat. *irrigatio*, from *irrigare*, to irrigate, from *in*, in + *rigare*, to moisten; connected with Goth. *rign*, AS. *regn*, OHG. *regan*, Ger. *Regen*, Eng. *rain*, and probably with Gk. *βρέχειν*, *breehein*, to wet). In agriculture, the process of increasing the growth of crops by an artificial application of water.

The practice of irrigation is very ancient. There is evidence to show that works for the storage and distribution of irrigation water were constructed in Egypt as early as 2000 B.C. Extensive works, intended for irrigation on a large scale, existed in times of remote antiquity also in Assyria, Mesopotamia, Persia, India, Ceylon, China, and other parts of the East, as well as in Peru, Mexico, and the southwestern United States (New Mexico and Arizona) in the Western Hemisphere. In all these regions irrigation is necessary for successful agriculture, because the rainfall is insufficient for the needs of ordinary crops. Irrigation is also required even in humid regions for crops, such as rice and cranberries, which require a large amount of water, and is of advantage in growing truck and fruit crops, which are susceptible to injury by short droughts.

The area of the earth's surface over which the annual rainfall is deficient (less than 20 inches or 500 millimeters), and irrigation consequently generally practiced, is very extensive. In addition to this vast area in which irrigation is common, there are considerable areas in the so-called humid regions in which the irregularity of the rainfall makes irrigation profitable. The extent to which the arid lands can be reclaimed depends upon the water supply available for irrigation. It has been estimated that there is sufficient water to irrigate only about one-tenth of the arid region of the United States, or from 75,000,000 to 100,000,000 acres. Of this irrigable area probably not more than 15,000,000 acres have already been reclaimed. In Europe irrigation prevails chiefly in the south, where it was introduced by the Romans. It is most extensively and systematically practiced in Lombardy and Piedmont, in Italy, in Spain, and the south of France, but exists to some extent in other parts of Europe. Wilson estimates the irrigated area in Italy to be about 4,700,000 acres, in Spain 2,800,000 acres, in France 400,000 acres. Nowhere else is irrigation practiced on so large a scale as in India, and the irrigation systems of that country are being rapidly extended by the British government. According to a commission appointed by the British government, the irrigated area in India is about 40,000,000 acres. Considerable areas in Turkestan have been irrigated for many years, and the Russian government is now undertaking large extensions. The Turkish government is building works to irrigate the valleys of the Tigris and Euphrates and restore them to their ancient prosperity. China has large irrigated areas, and the Chinese government in 1914 appointed a commission of foreign engineers to study its irrigation conditions and recommend policies for the future. Egypt has an irrigated area of about 6,000,000 acres, although irrigation works now in process of construction will increase this area to some extent, and plans for further extension on the Blue Nile and the White Nile are being prepared. Only at a comparatively recent date has irrigation been introduced into Australia, but it is rapidly extending there. The same is true in a measure of South Africa and South America. The practice of irrigation has declined or entirely disappeared in many of those regions where it prevailed most extensively in remote antiquity, but the ancient works are being restored and new ones built in Mesopotamia. See INDIA.

Water Supply for Irrigation. Water for irrigation is derived from (1) natural streams, springs and lakes; (2) wells; (3) storage of storm waters. In some places, particularly in Europe, the sewage water of cities is used for irrigating purposes. The United States Census of 1910 showed that in that country 94 per cent of the land irrigated was supplied with water from streams. It is probable that fully as large a percentage of the land irrigated throughout the world is supplied from the same source.

In torrential streams with sandy bottoms, diversion dams are usually made of brush, rocks, and sand, and are expected to be washed out in almost every flood and to be replaced when the flood has passed. In streams where better foundations can be secured more permanent dams of wood, masonry, or concrete are built. (See DAMS AND RESERVOIRS.) These are for the purpose of holding back the water and directing it into the canals which are to convey it to the place of use.

At the heads of most canals there are more or less elaborate works for shutting out the water which is not needed or belongs to others. In new countries these sometimes consist of mere piles of rock which are increased or diminished as it is desired to get more or less water into the canals, but usually there are structures with openings for the passage of water, which are controlled by gates which can be opened to admit water to the canals and closed to shut it out. In the early days of irrigation in the United States most of these structures were of wood with vertical wooden gates which slid in grooves. As these decay or are destroyed they are being replaced by concrete and steel structures, and most of the newer works are of this type. In other countries masonry and concrete are more generally used than in the United States.

Most canals are excavated in the natural earth and are unlined, but in rough and rolling country water is carried through hills in tunnels, along steep hillsides and across valleys in timber, metal, and concrete flumes, and through deep valleys in pipes which go down one side and up the other, commonly called inverted siphons. Much water is lost from canals by seepage into the sides and bottoms, and many canals are lined with a thin coating of cement plaster to prevent losses by seepage.

Water is turned from the main canals to branch canals which carry it to the land to be irrigated, to which it is delivered by still smaller branches. The structures and gates for controlling the flow of water into the branch canals are much like those at the heads of the main canals, except that they are on a smaller scale.

With few exceptions streams which are used for irrigation are subject to annual floods which are followed by long periods of low water. It is therefore necessary, if all the water is to be utilized, to store the surplus water during flood periods for use during the low-water periods. This requires the building of reservoirs (see DAMS AND RESERVOIRS) in which to store the surplus waters. These are sometimes formed in the channels of streams by building dams in the places where large basins will be filled by the water held back, and are sometimes in natural depressions outside the stream channels filled through feed canals from the streams. The Census of 1910 showed nearly 7000 reservoirs in the United States with an aggregate

capacity of 12,600,000 acre feet. Among the famous reservoirs in the world are the one formed in the valley of the Nile by the building of the Assuan Dam, the Roosevelt Reservoir in the Salt River in Arizona, and the Pathfinder Reservoir in the North Platte River in Wyoming. Much water is stored by raising the outlets of lakes on the headwaters of rivers. This water is retained when not needed for irrigation and turned into streams when they are low.

In many countries small reservoirs, away from stream channels, are built to store storm waters. This practice is very common in India, where a considerable part of the land irrigated is supplied from such reservoirs, commonly called tanks. About 100,000 acres were watered from such reservoirs in the United States in 1910.

In the United States wells rank next to streams as a source of water supply for irrigation, serving about 350,000 acres in 1910. About one-third of the acreage was supplied by flowing wells and two-thirds by pumped wells. The larger part of this acreage lies in California and New Mexico. Since flowing wells occur only under peculiar geological conditions, it is not probable that they will ever be a very important source of water for irrigation. Ground water which can be pumped is, however, of very general occurrence and will be increasingly important as the supply which can be cheaply diverted from streams is exhausted. Springs are an unimportant source of supply, as they are not of very general occurrence and the flow is usually small.

In addition to the water pumped from wells, much is pumped from streams. This is particularly true of the rice-growing districts of Louisiana and Texas in the United States. Practically all of the water used for rice irrigation in the States named and in Arkansas is pumped, and along the Gulf coast most of it is pumped from the rivers and bayous which drain that section. In the rice districts most of the pumping is done with large steam plants burning crude oil, which operate large centrifugal and rotary pumps. In other sections, where individual farmers have their own pumping plants, gasoline engines are in very general use. In California electrical power, generated by water power, is much used for irrigation. Both centrifugal and deep-well pumps are used with the gasoline engines and electric motors. In Egypt many of the canals which carry water from the Nile are below the land to be irrigated, and the water is lifted from the canals to the lands by crude devices which have been in use for centuries, and also by the most modern motors and pumps.

Except where natural drainage is measurably good, long-continued irrigation has a tendency to raise the ground-water level to such an extent as to injure the land, and drainage becomes necessary. This is now being provided in many cases when the irrigation system is constructed. See DRAINAGE.

Types of Conduits. Main canals and conduits are often the most expensive part of irrigation works, owing to their length and the difficulties encountered in their construction. The cheapest and simplest conduit is a ditch, heading in the source of supply and departing just sufficiently from the natural contour of the country to insure a flow of water. In the early days of irrigation such ditches were little more

than single furrows, or channels no larger than might be formed by a plow, leading a short distance from the banks of a stream. To-day

FIG. 1. EARTH CANAL UNLINED.

there are thousands of miles of irrigation ditches or canals large enough for small boats, while in India and Italy it is quite common to build combined irrigation and navigation canals, thus

FIG. 2. CANAL IN EARTH LINED WITH MASONRY.

affording a ready outlet for the products of the irrigated area and inlets for supplies. In rolling or hilly country canals may have to follow circuitous routes to maintain their level, thus

FIG. 3. CANALS ON ROCK SLOPE WITH RETAINING WALLS.

adding greatly to their length. It may be cheaper or, when a stream or valley is encountered, even necessary to continue the line of the canal, changing the construction to an ele-

FIG. 4. SEMICYLINDRICAL WOOD-STAVE FLUME.

vated flume or else substituting a pipe or inverted siphon, laid on or in the ground.

Seepage should be guarded against. To this end lining with stone laid in mortar or with con-

crete or with cement mortar may be employed. A great advantage in linings, if reasonably smooth, is that they increase the carrying capacity of the canals by lessening the friction, and

FIG. 5. WOOD IRRIGATION FLUME ON TRESTLE.

aid in maintaining it by lessening the sedimentary deposits and plant growths on their sides and bottoms. Sometimes leakage may be diminished by throwing powdered clay into the water at the head of the canal. The sedimentary matter naturally carried by the water will often reduce the leakage in a few months or years.

Flumes are most commonly built of wood,

FIG. 6. STEEL IRRIGATION FLUME ON TRESTLE.

with a rectangular cross section, but in recent years steel has been employed, particularly in steep rocky locations or where the flume crosses streams or deep ravines. The ordinary flumes

of boards or plank are subject to leakage. To avoid this, and also to give a channel better adapted to the flow of water, wooden staves are sometimes being employed, formed into a semi-circular or other shape designed to give a curved bottom. The staves are held in place by steel rods or bands, so arranged that they can be tightened by turning nuts. The steel flumes are made of thin plates riveted together. Galvanized iron flumes are also quite common in the United States. Flumes may rest on mudsills or timbers placed on the ground, but, being generally designed to cross depressions, they are more frequently supported on trestles. The trestles, like the flumes, are generally of wood, but they are sometimes of steel, particularly where the flume proper is of that material or where the flume support must be in spans, as at a stream crossing. In the most recently built projects in the United States and in many older

FIG. 7. HEAD GATE FOR SMALL IRRIGATION CANAL.

projects in other countries masonry and concrete flumes are quite common.

When, instead of valleys or streams, hills are encountered, necessitating long detours for canals, tunnels are often employed. They do not differ materially from other tunnels. If lining is necessary, as in earth, or to reduce the friction when in rock, it may be of brick, concrete, or stone, and resembles that for masonry aqueducts in tunnels. See TUNNEL; AQUEDUCT.

Headworks of some kind are required for nearly all canals, flumes, or pipe lines. In America they are generally of timber or concrete, but in much of the foreign work they are more commonly permanent structures of stone. The essential features are a bulkhead, gates, and wasteway. Where there is a dam at the head of the canal, the headworks may be at one end of it or form a part of it.

Pipes may be substituted for canals or flumes, either to convey water across depressions or under streams, as already mentioned, or to prevent losses from both evaporation and seepage. Either riveted steel or wood staves are the materials most commonly used for such pipes, being preferable to cast iron on account of their relative lightness and consequent ease of transportation in rough country remote from

railways. Where the water is under little or no pressure, either vitrified clay or cement pipes are sometimes used, particularly in southern California, and reinforced concrete pipes are used where the pressure is greater.

Works for Final Distribution consist chiefly of open or closed channels, generally the former, leading from the main or branch canal or other conduit to the land to be irrigated. For the most part small ditches are employed, with permanent or movable gates, or temporary earth dams, to divert the water to or from the minor channels.

Except as modified by the topography, the application of water to land is chiefly a detail of agriculture rather than engineering, depending on the crop and the soil and also the ideas of the cultivator. Subsurface irrigation is gen-

FIG. 8. TAPPOONS (WOOD AND METAL) FOR USE IN IRRIGATION.

erally considered impracticable because of the difficulties experienced in securing a thorough spreading of the water, besides which the pipes may clog and the construction prove expensive. Surface application, therefore, is almost universally employed. Broadly speaking, the latter is effected either by flooding the whole surface or sending the water through furrows. Neither involves much engineering skill, but it is best to have the main channels located with the aid of a level, particularly where the areas are large or have an irregular surface. Where pipe systems are employed for final distribution, thin wrought iron or steel, vitrified pipe, or plain and reinforced concrete may be used, and hydrants must be provided for drawing out the water.

The distribution of water by means of underground pipes, standpipes, and hose is, however, too expensive for irrigation on a large scale.

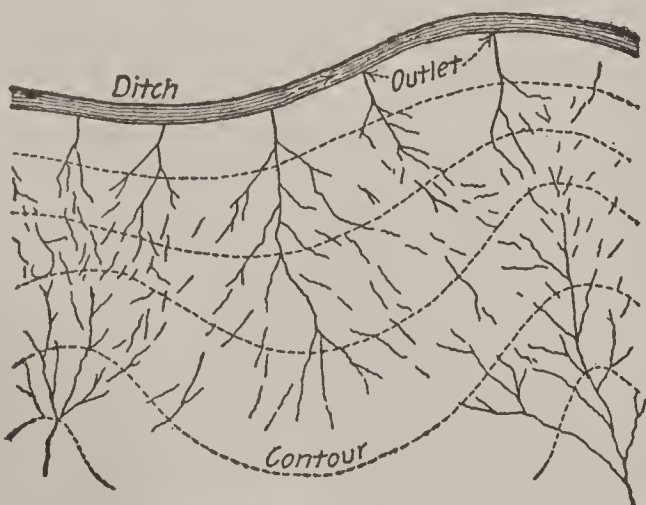

FIG. 9. IRRIGATION BY FLOODING.

The open ditch, which takes the water out of the larger canal or reservoir to the land to be irrigated, is made to follow the contour of the land, so that the flow is moderate and uniform and the water can be readily distributed to lateral ditches or flumes at any desired point. The simplest method of turning water from a

ditch is to cut a hole in the side and to use earth to make a dam in the ditch. An improvement on this method is the use of portable cloth, wood, or metal dams or tappoons. The water is spread over the land by a variety of methods, which belong, as a rule, in three main classes:

FIG. 10. CHECKWORK IRRIGATION.

(1) flooding, (2) furrow irrigation, and (3) subirrigation.

Wiekson describes the following methods practiced in the western United States: 1. Free flooding or running water on the land without restraint, except that of the banks of the lateral conveying it. In this method the ditches or laterals are carried along the higher parts of the field and the water is released by spade cuts at intervals in the banks, or it is made to overflow the banks by means of dams, as described above. This is the oldest and simplest method of irri-

FIG. 11. FURROW IRRIGATION.

gation. It is best suited to small grains and forage plants which are sown broadcast, and is most effective with nearly level ditches and on land of uniform grade. On account of the labor involved and the difficulty of securing uniform irrigation, this method has been superseded in many places by one of the check systems. 2. Flooding in contour checks or irregular areas of land inclosed by low embankments, the size and shape of these areas being determined by the

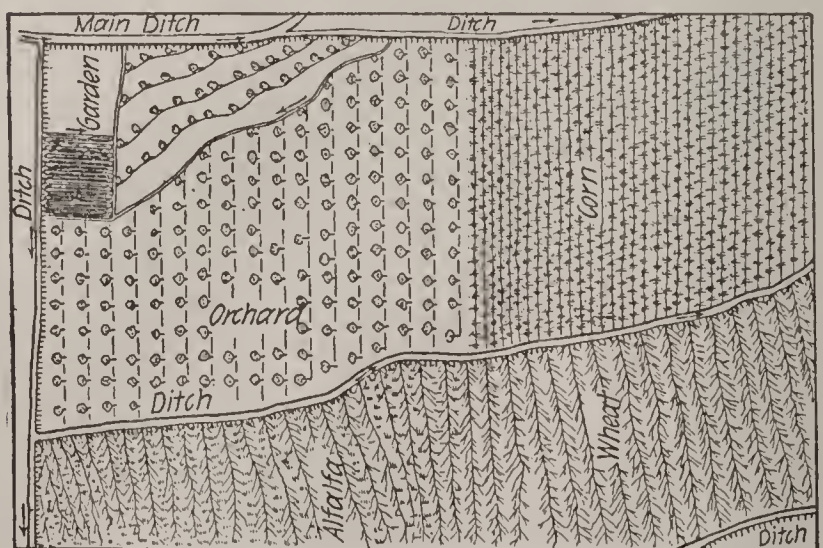

FIG. 12. PLAN OF IRRIGATED FARM.

inequalities of the surface. This method is best adapted to land of very gentle slope. Its first cost is considerable, but it permits more effective irrigation with less labor than free flooding. In

this method the highest check is filled from the ditch or lateral, and the water is either allowed to overflow into the next lower check or is drawn off into it by means of gates provided for the purpose. 3. Flooding in rectangular checks or level areas of approximately the same size inclosed by low embankments. This method is little used except for orchard, vineyard, garden, and rice irrigation, being largely superseded for other purposes by the contour check method. Unless the land is quite level, its preparation for the method involves the shifting of a large amount of earth, and the levees of irregular heights which are required interfere with the use of power machinery in cultivating. 4. Flooding by the border method, in which fields are divided into long strips by low parallel embankments between which water is made to flow over the fields. 5. Depressed bed method, in which the ditches are carried on the tops of the levees and the water is allowed to soak out into the checks inclosed by the levees. This is a garden modification of the rectangular check system and is used in the growing of vegetables and small fruits. It is best suited to porous soils, which require frequent irrigation. A primitive form of this method is ridge irrigation, in which plants are grown on the sides or at the base of raised ditches. 6. Furrow irrigation, or running water in furrows between the rows of crops, is the simplest, cheapest, and most widely used method of irrigating crops which can be grown to advantage in rows and is adapted to a wide range of slope and soil conditions. If the slope is not too great to carry a small stream without excessive washing, the rows are run straight down the grade from the supply ditch or flume, which occupies the crest of the highest ground; otherwise the rows are run diagonally at the angle giving the proper grade. The length of furrow that can be used depends upon the character of the soil and the head of the water. The more porous the soil, the larger should be the stream or the shorter the furrow. For most field and garden crops a larger stream and a shorter run are used than for fruit trees. Laterals or supply ditches are usually taken across the slopes of the land at intervals of about 25 rods. The laterals should be as nearly level as possible, so that they can be kept full and will discharge uniform amounts of water through the openings into the furrows. 7. The corrugation method lies midway between the furrow and flooding methods. After the land is seeded small and shallow furrows or corrugations are made with a marker. These serve as guides to the water, making it wet the field uniformly and preventing the wetting of the surface, which tends to make some soils puddle and bake. 8. Raised-bed irrigation, in which a raised bed is surrounded by a small ditch from which the water passes into the soil by seepage and capillary action, is a modification of the furrow system, especially suited to rather heavy, retentive soils in which water moves readily. 9. Subirrigation, or distribution by means of underground pipes with suitable outlets, or from tile drains or blind ditches, from which the water can rise to the roots of plants by capillarity. The method is expensive and of doubtful practicability, except on a limited scale in greenhouse and other horticultural work. A similar method, known as underflow irrigation, consists in opening furrows at considerable distances apart and keeping them filled with water

until the ground water rises so that it can reach the roots of plants by capillarity. The method is little used. 10. Distribution by means of underground pipes, standpipes, and connections for sprinkling is a method which is considered too expensive for use on a large scale.

The choice of a method must be determined by the amount of water available, the slope and nature of the land, the character of the crop, etc.

According to Wickson a method, to be of value, must secure the following results: "(1) distribution of moisture evenly throughout the soil mass to as great a depth as possible, providing it does not sink beyond the reach of the plant by root extension nor beyond recovery by capillary rise; (2) economy of labor both in aggregate time and in the feasibility of operating without employment of extra hands; (3) economy of water in the prevention of waste by overflow or evaporation or by rapid percolation and in placing the water where it will do the most good; (4) leaving the land in the best condition for attaining with least labor a state of tilth which conserves moisture and at the same time favors thrift in the plant." Crops sown broadcast can be irrigated only by flooding, corrugations, or sprinkling. The contour check, border, and furrow method require least labor. The furrow methods are best suited to subsequent cultivation by horse power, which is a matter of great importance, since thorough cultivation, to overcome the compacting tendency of irrigation and to secure a soil mulch, should in all cases follow as soon after irrigation as the condition of the soil will permit. Deep and thorough preparation of the soil increases its storage capacity for water, and frequent cultivation of the surface reduces loss from evaporation, thus reducing materially the amount of irrigation required and enabling the soil to utilize to the best advantage whatever rainfall may occur.

Duty of Water in Irrigation. The relation between the quantity of water used and the acreage irrigated, expressed either in acreage irrigated per unit of volume of water or in quantity of water per unit area of land, is commonly called the duty of water. When the rate of flow is given, the duty is usually expressed in acres irrigated per cubic foot per second, and when the quantity of water is given, the duty is usually expressed in acre feet used per acre irrigated, which represents the depth in feet to which the water used would cover the land if it were all held on the surface, since the acre foot is the quantity of water required to cover one acre to a depth of one foot.

The duty of water is sometimes confused with what is more properly called the water requirements of crops, i.e., the quantity of water actually consumed by plants in the processes of growth. It is not possible to grow crops under arid conditions without supplying water far in excess of the quantity actually consumed by the plants, and duty is an expression of the quantity which must be supplied and includes losses by evaporation from the soil, by percolation beyond the reach of plant roots, and by surface run-off, as well as moisture retained in the soil.

The water requirement of the crop grown is the minimum or ideal duty, towards which careful irrigators work by cutting down all losses so far as practicable. Many experiments have been made to determine the water requirements of various crops; but the more results become available, the more conclusively it is shown

that there is no fixed relation between quantity of water and quantity of crop, but that this relation varies with the fertility and moisture content of the soil, the character of the season, and many other conditions. It is evident that when to the variations in the actual moisture requirements of crops there are added the variations in the practically unavoidable losses by evaporation, seepage, and run-off, due to differing soils, subsoils, and climatic conditions, no definite quantitative statements can be made as to the duty of water.

Duty of water measurements have sometimes been divided into those showing gross duty, net duty, and duty for different crops. Gross duty has been applied to results showing the relation between the total amount of water entering a canal system and the acreage served by the system; net duty to the relation between the water delivered to a single farm and the acreage of that farm; while the duty for different crops represents the water applied to individual fields of those crops. The reports of the United States Census for 1910 give returns from something over 800 canal systems, supplying water to 2,500,000 acres of land, which show an average area of 62 acres served per cubic foot per second of average discharge for the season. This agrees almost exactly with general estimates for the arid region of the United States made by well-informed persons. The same report gives returns from nearly 1,000,000 acres for which the quantity of water diverted per acre irrigated was reported, which show an average of 4.8 acre feet per acre, or sufficient water to cover the land irrigated to a depth of 4.8 feet. The average length of the irrigating season for the United States is five months, and during a season of five months one cubic foot per second will supply almost exactly 4.8 acre feet per acre to an area of 62 acres. The United States Reclamation Service reports having delivered 3.5 acre feet per acre in 1910 and 3.7 acre feet per acre in 1911. The average for the two years, 3.6 acre feet, with an allowance of 25 per cent for losses by seepage, would indicate a diversion of 4.8 acre feet per acre. The exact agreement

crops in northern latitudes to 500 or 600 acres for citrus fruits in southern California.

As already stated, the United States Reclamation Service reports having delivered an average of 3.6 acre feet per acre during the season of 1910 and 1911. The United States Department of Agriculture reported in 1908 measurements from 24 farms scattered throughout the United States, showing an average net duty of 3.34 acre feet per acre. The average of these two quantities, or 3.5 acre feet per acre, is probably representative of common practice in the United States. Very few measurements from other countries are available, but these measurements are probably typical.

In sections where water is scarce and crops are of high enough value to justify large expenditures to prevent losses, many of the losses of water have been eliminated and the duty of water is high. In sections where water is plentiful, or where only crops of low value can be grown, the cost of preventing losses is too high to be met and the duty remains low.

The water necessary to be supplied to different crops has been the subject of much study and experiment in the United States. Experiments have shown that the quantity of water supplied affects not only the quantity of crop produced, but the chemical composition as well as the relative weights of stalks and seed.

There is a very general agreement in the results of experiments showing that, within reasonable limits, the larger the quantity of water supplied, the larger the yield of crop per acre. There is, however, as a rule, a very rapid decrease in the yield of crop per unit of water used as the quantity of water is increased. If, therefore, land is scarce and water is plentiful and inexpensive, it may pay to use much larger quantities than can be used profitably when water is scarce or expensive. On the other hand, where land is plentiful and cheap and water is scarce, it is more profitable to use smaller quantities of water per acre and spread the available water over larger areas. Woldtsoe gives the following figures to illustrate this point for Utah conditions:

CROP PRODUCED WITH 30 ACRE INCHES OF WATER USED ON DIFFERENT AREAS

CROP	30 ACRE INCHES SPREAD OVER								
	One acre 30 inches deep	Two acres 15 inches deep		Three acres 10 inches deep		Four acres 7.5 inches deep		Six acres 5 inches deep	
		Total yield	Yield per acre	Total yield	Yield per acre	Total yield	Yield per acre	Total yield	Yield per acre
Wheat, grain (bus.)...	47.51	91.42	45.71	130.59	43.53	166.16	41.54	226.86	37.81
Corn, grain (bus.)...	97.12	187.86	93.93	268.56	89.52	316.56	79.14
Timothy, hay (lbs.)...	6,054.00	7,688.00	3,844.00	11,739.00	3,913.00	11,928.00	2,982.00
Alfalfa, hay (lbs.)....	8,840.00	15,093.00	7,546.50	29,653.00	9,884.33
Sugar beets (tons)....	20.82	38.90	19.45	55.89	18.63	64.84	16.21	82.68	13.78
Potatoes (bus.).....	195.00	373.00	186.50	456.00	152.00	544.00	136.00	691.00	115.16

of these figures indicates that the figure given represents correctly the gross duty of water in the United States under present practice. This is a general average, the items varying from 1.5 acre feet per acre or less in places where the land is devoted principally to grain, to 8 or 10 acre feet per acre where the growing season is long and alfalfa is the principal crop. Expressed in acres irrigated per cubic foot per second, the items vary from 50 acres for general

Whether a given quantity of water will produce the largest net return when used on a greater or less acreage will depend in each case on the relative availability of land and water, the cost of land, the cost of water, and the cost of the growing crops aside from the cost of water.

The system of water rights, or of charging for water used, has a large influence on the quantity of water used per acre. The theory of American

water law is that the water user is entitled to as much water as he can use beneficially on his land, but that he may not dispose of any water which he cannot use on his own land. Under such a system the whole tendency is for a farmer to use as much water as he can, without injury to his land, since the more water used, the larger return. If he were allowed a fixed quantity of water which he might use on much or little land as he chose, the tendency would be towards the spreading of the water supply over the greatest possible area. Where water is disposed of under contracts, the usual practice is for the company supplying water to agree to furnish sufficient water for land for which rights are purchased for a given sum per acre. Within the limits of the quantity which the farmer can use beneficially, his water costs just the same whether he uses much or little or even if he uses none. From his standpoint it will pay him to put on water until the cost of applying it equals the increased return due to the increased quantity of water used. Here also a system under which the farmer would pay according to the quantity of water used would reverse the tendency and lead to the spreading of the water over the largest possible area. Existing laws and customs are all against an economical use of water. Since, the world over, the acreage which can be irrigated is limited by the water supply, this becomes a serious matter.

Amount and Frequency of Irrigation. The conditions that must be taken into consideration in determining the amount of water to be applied are: (1) the storage capacity of the soil, (2) the depth to which the roots of the particular crop penetrate, (3) the rate at which water will rise from the soil below the root zone, (4) the dryness of the soil and the subsoil, and (5) the water requirements of the crop grown. The frequency of irrigation will be determined by: (1) the amount of available moisture which the soil can store, (2) the rate at which moisture is lost by transpiration through the plant and by evaporation from the soil, (3) the degree of dryness of the soil which the plant will tolerate without injury, and (4) the stage of plant growth. Where the soil is deep and mellow, the roots of plants extend to a great depth and over a wide area. Thus, having a wider field from which to draw supplies of moisture and plant food, the actual percentage of moisture in the soil may be smaller without detriment to the plant than if the root feeding were more restricted. Again, compact, clayey soils hold moisture so tenaciously that plants growing on them begin to suffer for moisture, even when the soil contains a percentage of water which in case of less tenacious, sandy soil would be abundant for the plants' needs. The aim in irrigating should be to apply simply enough water to meet the needs of the plant without loss in the drainage. It is well to bear in mind, in attempting to accomplish this desired result, that plants vary in their water requirements at different stages of growth. Three to five irrigations seem to be about the average for wheat. With maize the number of irrigations needed varies from 3 in Italy to 15 in Egypt, but 5 to 7 irrigations appear to be about the average. It is usual to give only one irrigation for each crop of clovers and alfalfa. Water meadows are irrigated as often as the water supply will permit. The practice with potatoes is to give 2 to 4 irrigations, according to the slope and texture

of the soil, beginning when the plants have nearly or quite reached the blossoming stage. In actual practice the intervals between irrigations of fruit trees and vineyards vary from 7 to 40 days. According to Wiekson, fruits in California receive 2 inches of water per month during May to August, on retentive soils, and 3 inches during the same period on coarse soils. In rice culture the land is kept flooded the greater portion of the time during the growth of the crop. According to Maxwell, it is a common practice in Hawaii to apply 200 to 250 acre inches of water to sugar during a growing period of 18 to 20 months, although experiments have shown that 100 acre inches is ample.

Division and Measurement of Water. Successful irrigation is very largely dependent upon the judgment of the irrigator, and this in case

FIG. 13. MEASURING WEIR.

of an expert is probably as reliable as measurements, in our present knowledge of the duty of water. Measurements, however, are necessary when many irrigators draw their water supply from the same source. In this case various methods of division and measurements are used. When the supply is small and the whole of it

FIG. 14. FOOTE'S MEASURING WEIR AND SPILL BOX.

can be used by each irrigator to advantage, water is often distributed on the time basis, allowing each user to have the whole stream a length of time proportionate to the amount of water to which he is entitled. By this method there is a rotation in the use of water. When the supply is too large to be used by a single

FIG. 15. DIVISION BOX.

individual, various devices, called divisors, are used to apportion to each user the proportion of water to which he is entitled, or modules, measuring weirs, and spill boxes are employed to measure to each irrigator a definite quantity

of water. This division and measurement of water for irrigation is controlled by law. The right or privilege of using water from a canal, ditch, or stream in definite quantity or upon a prescribed area of land is termed a water right, and such right or privilege is usually acquired either by priority of use or by purchase. In an arid region, where so much depends upon the supply of water, a water right is a very valuable property. See HYDROGRAPHY; WATER SUPPLY.

Quality of Irrigation Water. The character of the water available for irrigation purposes is a matter of great importance. All natural waters carry more or less organic and mineral matter in suspension or solution and thus furnish, in addition to the water so necessary for the growth of plants, a certain amount of fertilizing matter. Waters carrying a large amount of soluble matter should, however, be used with caution, since they may cause the accumulation of alkali in the soil in injurious amounts. Of the waters available for irrigation, sewage is most valuable on account of the fertilizing matter carried to the land. Sewage irrigation is practiced with success in Great Britain and on the continent of Europe, notably on the Craigenlinny meadows, near Edinburgh; at Gennevilliers, near Paris; in the vicinity of Berlin; at Milan, Italy; and also at a number of places in the United States.

Laws and Institutions. As the water supply for irrigation comes largely from streams which serve also for domestic supply, power development, and navigation, the use of water for irrigation has always been subject to more or less public control and consequently the subject of legislation. The matter has been dealt with on three distinct legal theories. Under the Roman, or civil, law the water of streams is held to belong to the state or the crown, and rights to its use are required by grant; under the English, or common, law the right to use the water of streams attaches to the ownership of lands abutting on the stream; and under American legislation and judicial decisions in the arid States the water of streams belongs to the public, and its use is controlled by the States under their police power. In India, where more land is irrigated than in any other country, the use of water is controlled by the state.

Each of the arid States of the United States, except Arizona, California, Colorado, Montana, and Washington, has enacted laws under which a person wishing to acquire a right to water for irrigation must apply to the State for such right, and must submit to the State proof of having complied with the conditions prescribed by the State. In these States and in Colorado diversion from streams is controlled by State officials, the water being distributed in accordance with rights acquired under the State laws. In Arizona, California, Montana, and Washington rights are acquired by posting and filing notices of what is claimed, building works to convey the water to the place of use, and actually putting the water to use. Rights so acquired are protected by the courts.

In the United States about two-fifths of the land irrigated is supplied by works built and controlled by individual farmers or a few neighbors without formal organization. The most common form of organization for controlling the larger enterprises is the stock company, the stock of which is owned by the water users.

In 1910 such companies supplied water to about one-third of the acreage irrigated. A small part of the land is watered by works controlled by irrigation districts, which are public corporations having power to issue bonds to obtain funds for construction or purchase of works and to levy and collect taxes to pay off their bonds and cover interest and operation and maintenance charges. In 1894 the Federal Congress passed what is known as the Carey Act, under which the Federal government granted to each of the States containing arid land 1,000,000 acres of such land on condition that the State provide for its irrigation. A small area of land has been reclaimed under this law. In 1902 Congress passed the Reclamation Act, under which works are built directly by the Federal government with the proceeds from the sale of public lands. The law requires that the water users shall repay to the government the cost of construction, after which the works are to be turned over to the water users. The repayments are to be used for building other works, thus constituting a revolving fund. At the end of the first 10 years of operation about 3,000,000 acres were included in projects being built under this law, and about 500,000 acres were being irrigated. Works built under both the Carey Act and the Reclamation Act are to be turned over to the water users, and consequently it can be stated that in the United States nearly all of the irrigation enterprises are controlled by the water users or will be so when completed.

In India the larger irrigation works are built and controlled by the British government, which gets its returns principally by taxation of the crops grown. Approximately one-half of the land irrigated is supplied by works built and controlled by the native states or by individuals and communities. In Egypt the works are built and controlled by the government, which gets its returns there, as in India, by taxation of the crops grown. In Australia most of the works are built by the states, which levy charges for water used. In Italy some canals are controlled by the national government, some by the provinces, some by local associations, and still others by individuals. The national and provincial governments contribute to the cost of works built by local associations. Brazil has a similar scheme of aiding local agencies in the construction of irrigation works. Mexico has created a bank for aiding in the financing of irrigation enterprises, which are built by private corporations under government concessions.

The largest irrigation enterprises in Canada are owned by the Canadian Pacific Railway Company, and one of their most important projects is southeast of Calgary in the Province of Alberta. This irrigation area is on the North or Red Deer River slope of the divide, and the total irrigable area is, in round figures, some 440,000 acres. There is involved a canal system with various flumes, conduits, ditches, and laterals, with a total mileage of canals and ditches in excess of 3000. This is the largest irrigation project of the American continent and exceeded by few outside of India. The most important engineering feature of this work is the Bassano Dam, a composite structure, consisting of an earth embankment 7000 feet long with a maximum height of 35 feet, combined with an Ambursen hollow reinforced-concrete dam 750 feet between abutments and 39 feet high to the crest. There are 24 openings,

each 27 feet long, with Stoney gates 11 feet high and a reinforced-concrete headwork at right angles to the dam proper, and five 20-foot openings, each of which is closed by Stoney gates 14 feet high. This dam was designed to pass 100,000 second feet of water with 14 feet on the crest.

Irrigation in Humid Climates. Supplemental irrigation to carry crops through periods of drought has been found profitable in many cases in humid regions, especially on light, well-drained soils and with crops of high value. To what extent the practice may be extended with advantage has not been definitely determined. The rainfall of such regions is a disturbing factor. If a heavy rain occurs soon after a thorough irrigation, more serious damage may be done by excess of water than would have resulted from drought, especially if the soil be compact and poorly drained. Irrigation should therefore be attempted in such regions only on soils provided with thorough natural or artificial drainage.

Bibliography. The more important literature relating to irrigation includes publications of the United States Department of Agriculture on irrigation; Water-Supply and Irrigation Papers and other publications of the United States Geological Survey, Division of Hydrography; *Report of a Senate Committee for Irrigation and Reclamation of Arid Lands* (Washington, 1890); *Special Reports to Congress on Irrigation in the United States* (ib., 1891); Hinton and others, *Artesian and Underflow Investigations* (ib., 1892); Chittenden, *Report to Congress on Reservoir Sites in Wyoming and Colorado* (ib., 1898); Newell, "Irrigation," in the *Eleventh and Twelfth United States Census Reports*, and Teele in *Thirteenth United States Census Report* (ib., 1890, 1900, and 1910); reports and bulletins on irrigation of the agricultural experiment stations in Arizona, California, Colorado, Montana, Utah, and Wyoming, and the reports of the State engineers of these and other States in the arid regions; Baird-Smith, *Italian Irrigation* (London, 1855); Parral, *Les irrigations dans les bouehes du Rhône* (Paris, 1876); Stewart, *Irrigation for the Farm, Garden, and Orchard* (New York, 1877); Ross, *Notes on Distribution of Water of Upper Egypt* (Cairo, 1882); Stephens, *Practical Irrigator and Drainer* (Edinburgh, 1884); Llaurodo, *Tratado de aguas y riegos* (Madrid, 1884); Deakin, *Irrigation in Western Australia* (Melbourne, 1885); Hall, *Irrigation Development and Irrigation in California* (Sacramento, 1886-88); Ronna, *Les irrigations* (Paris, 1889-90); Flynn, *Irrigation Canals and Other Irrigation Works* (San Francisco, 1892); Buckley, *Irrigation Works in India and Egypt* (London, 1893); Wilcox, *Irrigation Farming* (New York, 1893); Dennis, *Reports on Irrigation and Canadian Irrigation Surveys* (Ottawa, 1894-96); Moses, *L'Irrigation en Asie centrale* (Paris, 1894); Scott, *Irrigation and Water Supply* (London, 1895); Willcocks, *Egyptian Irrigation* (ib., 1899); King, *Irrigation and Drainage* (New York, 1899); Salvador, *Hydraulique agricole* (Paris, 1900); Long, *Irrigation Law* (St. Paul, 1901); Newell, *Irrigation in the United States* (New York, 1902); Schuyler, *Reservoirs for Irrigation* (ib., 1902); Brunhes, *L'Irrigation dans la peninsule ibérique et dans l'Afrique du nord* (Paris, 1902); Mead, *Irrigation Institutions* (New York, 1903); Wilson, *Manual of Irrigation Engineering* (ib., 1903);

Risler, *Irrigations et drainages* (Paris, 1904); Newell and Murphy, *Principles of Irrigation Engineering* (New York, 1913). Bibliographies of irrigation will be found in the Annual Report of the Colorado Experiment Station for 1891 (Fort Collins, Colo.), and in the *Eleventh Annual Report* of the United States Geological Survey, 1889-90, part ii (Washington, 1890), and also in *Bulletin No. 41* of the Library of the United States Department of Agriculture by E. A. Hedrick (ib., 1902).

IRRITABILITY (Lat. *irritabilitas*, from *irritabilis*, irritable, from *irritare*, to irritate). The state or condition of the protoplasm of plants when it responds to a change in external influences or the adjacent protoplasm. The change which initiates the response is called a stimulus. When the nature of the stimulus is unknown, automatism is predicated rather than irritability. Temporarily the protoplasm may lose the power of responding to a stimulus, but when this is permanently lost the protoplasm is dead. Temporary loss of irritability may be occasioned by prolonged or repeated stimulation, in which case the loss is said to be due to fatigue; or by unfavorable conditions, such as deficient moisture, low or high temperature, lack of oxygen, anæsthetics, etc. Under such conditions the protoplasm is said to be in a state of rigor.

The agents affecting plants are extremely numerous and varied. The light changes both in intensity and direction from hour to hour; the temperature fluctuates; the moisture in air and soil is seldom the same for two consecutive days. The nature of the stimulus does not directly determine the character of the response, but this is conditioned by the mechanism which the stimulus sets in action. As there is unlikeness between stimulus and reaction, so there is disproportion between them in the energy involved. Although the stimulus stands to the reaction apparently in the relation of cause to effect, it only initiates a series of changes, in the course of which the energy liberated by increased respiratory activity produces, through the appropriate mechanism, the result observed. The stimulus is only a releasing cause, and, were the energy not provided by respiration, no reaction would occur. The only apparent exception to this is seen when a stimulus inhibits the action of an organ whose normal function requires the expenditure of energy. Here the release of energy seems to be prevented. In the absence of exact knowledge as to how this is accomplished, it may be assumed that it is by counteraction rather than by suppression.

Not all portions of the plants are equally sensitive to a given stimulus. Indeed, in many cases the sensitive regions are sharply localized and very limited. It has been shown, e.g., that sensitiveness of a root to the stimulus of gravity resides mainly in the terminal 1.5 to 2.5 millimeters. In other parts the whole growing region may be sensitive. When the sensitive region is sharply localized, it may be coincident with the region in which the response is perceived, or it may be separated from it by a considerable distance. In the latter case a propagation of the stimulus must occur. There are in plants no definite structures correspond-

ing to the nerves of animals, but the conduction is mainly through living active parenchyma cells or along such living cells as the sieve tubes or companion cells. Setting in action the mechanism of perception, the propagation of the stimulus, and the execution of the final response consume time. In some plants the final response follows in a fraction of a second after the stimulus is received, as in the sensitive plant. In most cases, however, the end reaction is separated in time from the initiation of stimulation by seconds, minutes, or even hours. This interval is known as the reaction time. When it is sufficiently long, a stimulus may be applied during a portion of the reaction time and then discontinued. After the usual interval, however, the reaction will still occur, although no stimulus is then operating. Such effects, the results of previously acting stimuli, are known as "after effects." The time during which any stimulus must act in order to call forth a response is the presentation time.

The reaction to a stimulus may consist in a growth or turgor movement, in a change in rate, or in a general change in the course of development of the organ. Further, the reaction may be either direct or induced. Induced reactions are such as will not occur in response to the stimulus acting unless some other stimulus first brings about a change; after which reaction to the first stimulus becomes possible. Thus, a plant may not respond to stimulation by gravity unless it is first stimulated by light. It is difficult, therefore, to disentangle the effects of different stimuli without extreme care in experimentation. Every living cell of the plant is in reality an irritable structure. Since movement is the most easily observed reaction, the mistake has been made of considering motor organs as being specially irritable regions. Thus, tendrils, the leaves of the sensitive plant, the peculiar motile leaves of the Venus's flytrap, the tentacles of the leaves of *Drosera*, the contractile filaments of many anthers, etc., are looked upon as sensitive organs par excellence. In reality, however, many of these are far inferior in sensitiveness to structures whose reactions are less evident. See BIOLOGY.

IR'IRITANCY (from *irritant*, from Lat. *irritare*, to render void, from *irritus*, *inritus*, invalid, from *in-*, not + *ratus*, decided, p.p. of *reri*, to think). In Scottish law, the forfeiture of an estate as the result of a breach of condition, express or implied, or the happening of an event upon which the termination of the estate is made to depend. The irritant or fatal condition, or proviso, may be an incident of the estate granted, as the duty annexed to a feudal freehold, or it may be the result of an express provision, known as an irritant clause, contained in the deed creating the estate affected by it. See CONDITION; FORFEITURE.

IR'IRITANT (from Lat. *irritare*, to irritate, annoy). An agent that causes increased circulation, pain, increased function, or muscular contraction, when applied to an animal tissue. Among the irritants are many vegetable and the mineral acids, strong alkalis, bichloride of mercury, nitrate of silver, mustard, croton oil, turpentine, etc. The term has been sometimes vaguely applied to medicines which produce irritation of nerves in distant parts when taken internally, as instanced in the action of strychnine upon the spinal cord. Heat is a mechanical or kinetic irritant. Light is also an irritant to

the retina and in diseases of the eye is often a powerful one. Electricity is an irritant when applied in certain forms. See COUNTERIRRITANTS.

IRTYSH, *ir-tish'*. An affluent of the Obi, and fourth in importance among the rivers of Siberia (Map: Asia, J 3). It rises in the southwest range of the Altai Mountains in China, frequently called here the Urungu, whence it flows in a northwest direction through Lake Zaisan-Nor, past the city of Tobolsk, until it reaches the Obi, after a course of 2633 miles. Its chief affluents are the Bukhtarma, the Om, and the Tara from the right; and the Ishim, the Tobol, and the Konda from the left. The basin of the Irtysh, comprising the governments of Tomsk, Tobolsk, Perm, and Orenburg, the territories of Akmolinsk, Turgay, and Semipalatinsk, and some Chinese territory, covers the immense area of 638,000 square miles. The Irtysh is ice-free about 200 days in the year and is navigable for nearly 2000 miles. The principal ports are Semipalatinsk, Pavlodar, Omsk, Tara, and Tobolsk.

IRUN, *ê-rōon'*. A frontier town of Spain, in the Province of Guipúzcoa, situated on the Bidassoa River, here forming the French boundary, 5 miles from its mouth in the Bay of Biscay. It is a military station and a first-class port of entry. It contains an interesting old church, restored in 1508, and has manufactures of leather, tiles, and bricks. It is also the centre of a flourishing mining and agricultural district and the terminus of a number of electric and steam railroads. Pop., 1910, 10,629.

IRVINE, *êr'vin*. A royal, municipal, and police borough and a seaport in Ayrshire, Scotland, on the Irvine, a mile above its mouth, in the Firth of Clyde, 29 miles southwest of Glasgow (Map: Scotland, D 4). It has a good town hall, an academy, and a fever hospital; also the ruins of two Norman castles. Shipbuilding, iron founding, and the manufacture of machinery, soap, chemicals, book muslins, jaconets, and checks are the chief branches of industry. Duntonknoll Quarry yields a stone largely used for the making of bakers' ovens. Neighboring coal mines yield the principal article of export. Since 1875, when its harbor was dredged, it has gradually regained its lost shipping. The principal features of the town are the municipal building, a fine bridge, and the academy, an educational institution of high repute. The town owns its water works. Mentioned in 1184, Irvine is described as a chartered burgh in the reign of Robert Bruce. Pop., 1901, 9618; 1911, 10,180.

IRVINE, WILLIAM (1741-1804). An American soldier. He was born in Ireland, graduated at Dublin University, and was surgeon on an English warship during the Seven Years' War, at the close of which (1763) he emigrated to America and settled at Carlisle, Pa. In 1774 he was a member of the Provincial Convention, and in January, 1776, was appointed colonel of the Sixth Pennsylvania Regiment. At the battle of Three Rivers, in June, 1776, he was made prisoner and, though soon paroled, was not exchanged until May, 1778. He became a brigadier general May 12, 1779, serving with Lord Stirling on his expedition against Staten Island, and with General Wayne at Bulls Ferry in July, 1780. In 1782-83 he had command at Fort Pitt of the troops for the defense of the western frontier, and in 1785 acted as agent of his State for the distribution of the public

lands among the soldiers. During his term of office he recommended the purchase of the "triangle" tract, which gave Pennsylvania her outlet on Lake Erie. He was elected to Congress in 1786 and was made one of a commission of three to adjust the accounts of the Confederation with the various States. He also was a member of the convention called to revise the State constitution, and of that by which the Federal Constitution was ratified for Pennsylvania. From 1793 to 1795 he was again a member of Congress, and in 1794, during the Whisky Insurrection (q.v.), commanded the Pennsylvania militia. He subsequently removed to Philadelphia and at the time of his death was president of the Pennsylvania branch of the Society of the Cincinnati.

IRVING, ɪr'vɪŋ, EDWARD (1792-1834). An eloquent and distinguished Scottish clergyman. He was born at Annan, Dumfriesshire, Aug. 4, 1792. He studied at the University of Edinburgh and, after completing his curriculum for the ministry in 1809, became a school-teacher at Haddington and later at Kirkealdy. At the former place one of his pupils was Jane Welsh, and at the latter began his friendship with her future husband, Thomas Carlyle. He was licensed as a preacher in 1815, but his early attempts at preaching were not successful. In 1819 he became assistant to Dr. Thomas Chalmers in Glasgow. Here he felt himself overshadowed by his more famous colleague, and in 1822 he accepted a call to the Caledonian Church, Hatton Garden, London. His success as a preacher in the metropolis was unparalleled. In brief time he transformed a poor and obscure congregation into a rich and fashionable one and exchanged the humble chapel for a handsome structure on Regent Square. In 1823 he published his first important work, *The Oracles of God: Four Orations, with an Argument on Judgment to Come*. At the close of 1825 he began to announce his convictions in regard to the second personal advent of Christ, which he declared to be near at hand. This was followed by his translation of a Spanish work, *The Coming of the Messiah in Glory and Majesty*, which professed to be written by a Christian Jew, Juan Josafat Ben Ezra, but was in reality the composition of a Spanish Jesuit, Manuel Lacunza. In 1828 appeared his *Homilies on the Sacraments*. He now began to elaborate his views of the incarnation of Christ, asserting the doctrine of His oneness with man in all the attributes of humanity. The language which he used on this subject drew upon him the accusation of heresy, to which he gave little heed. He was deep in the study of the prophecies; and when the news came to London in the early part of 1830 of certain extraordinary manifestations of prophetic power in the west of Scotland, Irving was prepared to believe them. In 1831 he published *An Exposition of the Book of Revelation*. Irving was arraigned before the presbytery of London in 1830 and convicted of heresy, ejected from his new church in Regent Square in 1832, and finally deposed in 1833 by the presbytery of Annan, which had licensed him. The majority of his congregation adhered to him, and gradually a new phase of Christian order and worship was developed, commonly known as Irvingism, though Irving had really very little to do with its development. (See CATHOLIC APOSTOLIC CHURCH.) Shortly after, his health failed, and, in obedience, as

he believed, to the Spirit of God, he went to Scotland, where he sank a victim to consumption. He died at Glasgow, Dec. 7, 1834. Irving's works were published in London (5 vols., 1864-65). Consult: M. O. W. Oliphant, *Life of Edward Irving* (2 vols., London, 1862); J. W. Carlyle, *Letters and Memorials* (2 vols., New York, 1903); Thomas Carlyle, *Critical and Miscellaneous Essays* (3 vols., ib., 1903).

IRVING, SIR HENRY (1838-1905). A distinguished English actor and manager. He was born at Keinton Mandeville, Somersetshire, Feb. 6, 1838, his name being originally John Brodribb; his stage name of Irving was legalized by royal license in 1887. He was carefully educated at a private school and then placed in a commercial situation, but he early began preparing himself for a dramatic career, and made his first appearance on the professional stage at Sunderland in 1856, as Gaston, Duke of Orléans, in *Richelieu*. After playing in Edinburgh, Glasgow, Manchester, and elsewhere, not without meeting frequent discouragements, he appeared in 1866 at the St. James's Theatre in London. He soon became noted as an interpreter of light comedy parts, and more especially as the "heavy villain" in such rôles as Robert Macaire and Bill Sikes. But his first great success was as Digby Grant in the comedy of *Two Roses* (1870), which he performed at the Vaudeville Theatre for 300 consecutive nights. In November, 1871, he was engaged by the Lyceum Theatre and increased his reputation by his appearance in *The Bells*, as Mathias (1871), in *Eugene Aram* (1873), *Richelieu* (1873), and *Hamlet* (1874). The peculiarities of his style in *Hamlet* excited great difference of opinion among the critics, which continued over his rendering of *Macbeth* (1875) and *Othello* (1876, and again with Edwin Booth in 1881), but the importance of his position constantly increased. His *Richard III* (1877) and his *Louis XI* (1878) attracted great admiration. In 1876 he made a tour through Scotland, Ireland, and the provinces. The withdrawal of Mrs. Bateman from the management of the Lyceum gave Irving, in 1878, entire control over the theatre in which he had long been the leading attraction; he secured Miss Ellen Terry, and together they inaugurated a series of brilliant performances which continued, with brief interruptions, till 1903. Irving as a manager was famous for the carefully elaborate stage setting of his productions, while as an actor he was distinguished for the psychological force of his characterizations. His theatre became in all its appointments and in the class of the plays produced there the most admirable of London playhouses, though its financial success left something to be desired. In 1899 the Lyceum passed into the hands of a limited liability company, though still under Irving's direction. In the long list of rôles which he assumed after his management began were Shylock (1879); Benedick, in *Much Ado about Nothing* (1882); Mephistopheles, in *Faust* (1885), which proved one of the most popular of his presentations, though critically less admired; Becket (1893), in Lord Tennyson's drama, which he rearranged for the stage; and Robespierre (1899), in the play written for him by Sardou.

He first came to the United States, with Miss Terry and the other members of his company, in 1883, when he made his New York debut as Mathias, in *The Bells*. The welcome which he

won on this first visit was frequently repeated, and he reproduced in the United States most of his London successes. Irving was knighted in 1895, the first actor who ever received this honor. Among his publications is *The Drama: Addresses* (London, 1892). The Irving Edition of Shakespeare (ed. by Henry Irving and F. A. Marshall) appeared in 1887-90 (London).

Irving's marriage in 1869 to Miss Florence O'Callaghan gave him two sons, Henry Brodribb Irving and Lawrence Irving (qq.v.).

Irving died suddenly in October, 1905, at Bradford, England, after a performance of *Becket* in which he had shown unusual power. His body was placed in Westminster Abbey beside the ashes of Garrick and under the shadow of the Shakespeare statue.

Bibliography. William Archer, *Henry Irving, Actor and Manager* (London, 1883); Arnold Daly, *Henry Irving in England and America, 1838-84* (ib., 1884); Hatton, *Henry Irving's Impressions of America* (ib., 1884); Scott, *The Drama of Yesterday and To-Day* (ib., 1899); P. H. Fitzgerald, *Sir Henry Irving: A Biography* (New York, 1906); H. Macfall, *Sir Henry Irving* (ib., 1906); B. Stoker, *Personal Reminiscences of Henry Irving* (ib., 1906); A. Brereton, *Life of Henry Irving* (2 vols., ib., 1908); W. H. Pollock, *Impressions of Henry Irving* (ib., 1908).

IRVING, HENRY BRODRIBB (1870-). An English actor, manager, and author, son of Sir Henry Irving. He was born in London, was educated at Marlborough and at New College, Oxford, and in 1894 was called to the bar. But as early as 1891 he had appeared on the stage in John Hare's company, and he soon gave up law to follow in his father's footsteps; in 1894-95 he was with Comyns Carr at the Comedy Theatre, in 1895 with Ben Greet's company in the provinces, in 1896 with George Alexander at the St. James's. In the latter year he married Dorothea Baird, who created the rôle of Trilby. His success as an actor was followed by success as a manager. In 1902 he took the Duke of York's Theatre; in 1906-07 toured America, in 1911-12 Australia, and in 1912-13 South Africa; and then leased the Savoy. He played Crichton in Barrie's *Admirable Crichton* in 1903, and Hamlet at the Adelphi in 1905. *The Lyons Mail* had a remarkable run in 1908, and among his later productions were *Dr. Jekyll and Mr. Hyde* and *The Bells*. His early training for the bar and his sense of the dramatic are seen in his *Life of Judge Jeffreys* (1898), *French Criminals of the Nineteenth Century* (1901), *Occasional Papers* (1906), *The Trial of Franz Müller* (1911), *The Trial of Mrs. Maybrick* (1913).

IRVING, ISABEL (1871-). An American actress, born at Bridgeport, Conn. She first appeared upon the stage in 1887, in *The Schoolmistress*, at New York, and the next year became a member of Daly's company, with which she continued till 1894. She became in 1897 John Drew's leading woman, appearing with him in *The Liars* (1898), *The Tyranny of Tears* (1899), and other pieces. At the beginning of 1902 she became leading woman in William Faversham's company. She was "starred" in 1907 in *Susan in Search of a Husband* and *The Girl who has Everything*. In 1910 she appeared in New York as Mrs. Dallas-Barker in *Smith* and in 1912 as Dulcie Anstice in *Preserving Mr. Panmure*. She was married in October, 1899,

to W. H. Thompson. Consult L. C. Strang, *Famous Actresses of the Day in America* (New York, 1900).

IRVING, JOHN BEAUFAIN (1826-77). An American genre and historical painter, born in Charleston, S. C. He was a pupil of Leutze at Düsseldorf, and after the Civil War removed from his native city to New York. He was elected to the National Academy in 1872. Among his pictures are: "The Splinter"; "Wine Tasters" (1869); "The End of the Game"; "Cardinal Wolsey and his Friends" (1876); "A Banquet at Hampton Court in the Sixteenth Century." His bright color and elaboration of detail suggest the Düsseldorf school and have caused him to be called an admirer of Meissonier.

IRVING, JOHN DUER (1874-). An American economic geologist, born at Madison, Wis. In 1896 he graduated from Columbia University (Ph.D., 1899). Joining the United States Geological Survey in 1899, he was assistant geologist in 1900-06 and geologist in 1906-07. He was acting professor of mining and geology at the University of Wyoming in 1902-03 and became assistant professor (1903) and professor (1906) of geology at Lehigh University and in 1907 professor of economic geology at the Sheffield Scientific School (Yale). In the summer of 1907 he made investigations in Alaska for the Guggenheim and Morgan interests. He became editor of the journal *Economic Geology* and is author of *Economic Resources of the Northern Black Hills*.

IRVING, LAWRENCE (SYDNEY BRODRIBB) (1872-1914). An English actor and manager, son of Sir Henry Irving. He was educated at Marlborough College and at the Collège Rollin in Paris and lived in Russia for three years while he was studying for the diplomatic service. In 1893 he appeared in Shakespearean parts in Dundee. He starred in provincial companies, acting *A Bunch of Violets*, *Trilby*, and *Under the Red Robe* in 1896-99; played in his father's company in 1900-04; toured in 1904-05 with his wife, Mabel Lucy Hackney; created the rôle of Crawshay in *Raffles*; presented his own vaudeville sketches in England and America in 1908-09; and as his own manager brought out *The Unwritten Law* at the Garrick in London in 1910. In 1912 he played Iago in Tree's production of *Othello*, at His Majesty's Theatre. On his way back to England in May, 1914, returning from a tour with his own company, he was drowned in the *Empress of Ireland* disaster when endeavoring to save his wife. He wrote several plays, *Peter the Great* (played 1898), *Bonnie Dundee*, *Richard Lovelace* (produced in New York, 1901), and *The Typhoon* (1913), after Lengyel; and translated from Gorky, *The Lower Depths* (1912).

IRVING, ROLAND DUER (1847-88). An American geologist, born in New York City and educated at the School of Mines of Columbia University. Upon graduation, he was made assistant on the geological survey of Ohio and in 1870 was appointed professor of geology and mineralogy in the University of Wisconsin, also serving as assistant State geologist (1873-79). In this connection he published *Geology of Central Wisconsin* (1877); *Geology of the Lake Superior Region* (1880); *Crystalline Rocks of the Wisconsin Valley* (1882); *Mineralogy and Lithology of Wisconsin* (1883). In 1882 he was placed at the head of the Lake Superior

division of the United States Geological Survey. His important reports, published by the government, include: *The Copper-Bearing Rocks of Lake Superior* (1883); *On Secondary Enlargements of Mineral Fragments in Certain Rocks* (1884); *The Classification of the Early Cambrian and Pre-Cambrian Formations* (1886).

IRVING, WASHINGTON (1783-1859). An American author. He was born in New York City, April 3, 1783. His mother was English, and his father had come from Scotland to New York City, where he engaged in trade. Irving studied in the schools of New York and at the age of 16 took up law. Before he was 20 he contributed, under the pseudonym of "Jonathan Oldstyle," to the *New York Morning Chronicle*, of which his brother was editor. Never in these early years in good health, he was obliged in 1804 to go to Europe, where he remained two years. Shortly after his return he published, in 1807, with his brother William and James K. Paulding (q.v.), *Salmagundi*, an undertaking in the style of Addison's *Spectator*. In 1809 appeared *A History of New York from the Beginning of the World to the End of the Dutch Dynasty, by Diedrich Knickerbocker*—a humorous, whimsical, and genially satirical sketch, which brought him reputation and money. This book had been begun with the intention of burlesquing a pretentious guidebook by Dr. Samuel Mitchell. The *Knickerbocker History*, to give it its most common name, grew as Irving's humor found more and more curiosities in the quaint and phlegmatic Dutch type, which is so strongly contrasted with the quick and more volatile descendant of British stock. He then gave up any idea of law and became a sleeping partner of his brothers, whose business house was in Liverpool, occupying himself meanwhile with literary work. Irving's reputation had preceded him to England, where his gracious manners made him a favorite in society. He met Campbell and Thomas Moore and was heartily liked by Walter Scott, who persuaded Murray to publish *The Sketch-Book*. Among other things he edited *The Poetical Works of Thomas Campbell*. During the War of 1812 he was on the staff of Governor Tompkins, of New York, and was connected with the *Analectic Magazine* of Philadelphia. In 1815 he went to Europe to look out for the business interests of the firm, the failure of which in 1818 turned him for good and all to literature.

In New York and in London (1819-20) Irving published the book by which he is most popularly known, *The Sketch-Book of Geoffrey Crayon, Gent.* It was heartily welcomed on both sides of the Atlantic, and two of the stories especially, *Rip Van Winkle* and the *Legend of Sleepy Hollow*, have become classics in American literature. The *Sketch-Book* soon went through many editions, was illustrated by Caldicott and commented by Pfundheller for the Germans. The vein of the book is one of humor, tenderness, geniality, and good-fellowship; the manner is reminiscent of Goldsmith and other English authors of the eighteenth century, to whom Irving was temperamentally drawn. The spirit that animated Irving in all of his writing, save that which was distinctly historical, is admirably expressed by his own *apologia* in the *Sketch-Book*: "It is so much pleasanter to please than to instruct—to play the companion rather than the preceptor. What, after all, is the mite of wisdom that I could

throw into the mass of knowledge; or how am I sure that my sagest deductions may be safe guides for the opinions of others? But in writing to amuse, if I fail, the only evil is in my own disappointment. If, however, I can by any lucky chance, in these days of evil, rub out one wrinkle from the brow of care, or beguile the heavy heart of one moment of sorrow; if I can now and then penetrate through the gathering film of misanthropy, prompt a benevolent view of human nature, and make my reader more in good humor with his fellow beings and himself, surely, surely, I shall not then have written entirely in vain." In 1822 appeared another volume in much the manner of the *Sketch-Book*, *Bracebridge Hall, or the Humorists*, a series of sketches, translated into German by Spiker (1826). In 1822 Irving visited the Rhine, lived for a while in Paris, and again in England in 1824. In 1824 appeared the *Tales of a Traveller*, a collection of short stories, with the same general good feeling, but with more action. In 1826 he went to Spain, remaining there until 1829, and, as a result of his stay, produced four books quite different from his former work: *History of the Life and Times of Christopher Columbus* (1828); *A Chronicle of the Conquest of Granada* (1829), an interesting narrative, but of no real historical value; *Voyages and Discoveries of the Companions of Columbus* (1831); and *The Alhambra* (1832), a series of sketches and stories associated with the author's life in the romantic ruins of Granada. Irving's book on Columbus was written with the help of Spanish archives, after Irving had given up his original purpose to translate Navarrete's recently published work on the discoverer. *The Chronicle of the Conquest of Granada* purports to be founded on the manuscripts of Fray Antonio Agapida, an imaginary chronicler. *The Alhambra* was written mainly in London, where Irving was Secretary of the United States Legation from 1829 to 1831. He returned to America in 1832, where he was welcomed with almost national honor; for the people of the United States knew that he had won recognition abroad for American literature.

In 1841 Irving was appointed United States Minister at Madrid, where he lived from 1843 to 1846, continuing his historical writing with the work on Mahomet. He passed the rest of his life, with the exception of some months of travel in the West, at Sunnyside, his country seat near Tarrytown, N. Y. From the appearance of *The Alhambra* up to 1849 his literary work was inferior to what he had previously done and is of no great charm or value. It consists of *The Crayon Miscellany* (1835); *Astoria* (1836); and *The Rocky Mountains: or, Scenes, Incidents, and Adventures in the Far West* (1837). The work which came towards the end of his life, however, added to his reputation. It was chiefly biographical and historical: *Oliver Goldsmith* (1849); *Mahomet and his Successors* (1849-50); *Wolfert's Roost* (1855); and his long-planned and affectionate *Life of Washington* (1855-59), which he completed only with the year of his death. He died at Sunnyside, November 28, 1859. Posthumously there appeared *The Life and Letters of Washington Irving* (1862-64) and *Spanish Papers and Other Miscellanies* (1866), edited by his nephew, P. M. Irving. His *Works*, in 27 volumes, appeared in New York in 1884-86.

Selections from them in English and in German, with illustrations by Ritter and Camp-hausen, were published in Leipzig in 1856. The standard *Irving* is now the 40-volume Knickerbocker Edition (New York, n. d.), which is based upon the edition revised by the author and published in the middle of the last century.

Irving is significant in the history of American letters as the first American, after the independence of the United States, to obtain real literary recognition in England. His own whimsical but keen explanation of his foreign reception is as follows: "It has been a matter of marvel, to my European readers, that a man from the wilds of America should express himself in tolerable English. I was looked upon as something new and strange in literature; a kind of demi-savage, with a feather in his hand instead of on his head; and there was a curiosity to hear what such a being had to say about civilized society." By another than the modest author, however, his success may well be attributed to the geniality of his nature, his social gifts, and his literary feeling. He was able to please an audience schooled in the manner of Addison, Johnson, and Goldsmith, and at the same time to cause no offense to the patriotic sensibilities of his countrymen. Much of his work deals directly with English life and customs and is written in the manner of a kindly, well-bred Englishman. The influence of Irving upon American letters was hence, in the main, good; it enabled writers to make use of the best English tradition and helped to rid them of the provincialism which had characterized their work up to his coming. He is perhaps best as an essayist, and he will be permanent for his charm and refinement; yet it must not be forgotten that he was practically the discoverer, for Americans at least, of the effectiveness of the short story as a form of art. Nor is Irving's place in English literature unimportant, for he was a link between Goldsmith and Dickens. Indeed, Irving seems rather like an English than like an American author; for, though there is a quaintness in his humor and freshness in his views, he is devoted to English traditions as to form. With Whitman, Bret Harte, and Mark Twain one encounters a more obviously American school.

Bibliography. A fair amount of commentary on Irving exists. In addition to the biography by his nephew, P. M. Irving, *Life and Letters* (3 vols., New York, 1909), there are: W. C. Bryant, *Discourse on the Life, Character, and Genius of Washington Irving* (New York, 1860); H. W. Longfellow, *Address before the Massachusetts Historical Society* (Boston, 1870); Laun, *Washington Irving: Ein Lebens- und Charakterbild* (Berlin, 1870); C. D. Warner, *Life*, in the "American Men of Letters Series" (Boston, 1884). Critical discussions of his work are to be found in the literary histories, such as Beers, *Initial Studies in American Letters* (New York, 1892); Barrett Wendell, *A Literary History of America* (ib., 1900); H. W. Mabie, *Backgrounds of Literature* (ib., 1904); id., *Writers of Knickerbocker* (ib., 1912).

IRVING, WILLIAM (1766-1821). An American author, brother of Washington Irving, born in New York City. He was engaged in fur trading with the Indians in the region of the Mohawk River from 1787 to 1791 and in 1793 established his business in New York City and

married a sister of James K. Paulding, one of his brother's collaborators in *Salmagundi*. He was a popular member of the literary coterie which flourished in New York early in the last century; and his many poems and contributions to *Salmagundi* mark him as among the best of early American humorists. From 1814 to 1819 he was a Democratic member of Congress.

IRVINGITES. See CATHOLIC APOSTOLIC CHURCH.

IRVINGTON. A town in Essex Co., N. J., adjoining Newark, of which it is a residential suburb, on the Lehigh Valley Railroad (Map: New Jersey, D 2). It has smelters, foundries, automobile works, lumber yards, refineries, a tannery, and manufactories of linoleum, machinery, masons' materials, and novelties. The city contains the Gladden Lodge Hospital, Bethany Home, Elks Home, a large public park, and a fine town hall. The commission form of government was adopted in 1914. Settled as early as 1666, Irvington was called Camptown until 1852, when it received its present name. It was incorporated in 1898. Pop., 1900, 5255; 1910, 11,877; 1914 (U. S. est.), 14,697.

IRVINGTON. A village in Westchester Co., N. Y., on the Hudson River, 23 miles north of New York City, on the New York Central and Hudson River Railroad. It is a beautiful place of residence. Prominent among its features of interest are the fine town hall with the Guiteau Library, and "Sunnyside," the home of Washington Irving. The waterworks are owned by the village. Pop., 1900, 2231; 1910, 2319.

IRWIN, ēr'wīn. A borough in Westmoreland Co., Pa., 22 miles southeast of Pittsburgh, on the Pennsylvania Railroad (Map: Pennsylvania, B 6). Some of the most extensive bituminous coal mines in the State are located here, and there are also iron foundries, flour mills, car shops, facing and planing mills, electrical goods and mirror factories, etc. Pop., 1900, 2452; 1910, 2886.

IRWIN, ēr'wīn, JOHN (1832-1901). An American naval officer, born in Pennsylvania. He entered the Naval Academy in 1847 and became passed midshipman in 1853. He served on the frigate *Wabash* in the Civil War and took part in the battle of Port Royal, S. C. Irwin also participated in the engagements at the forts at Hatteras Inlet and Forts Walker and Beauregard. At the capture of Fort Pulaski he received special mention in the report of the battle sent to the Navy Department. During his career he was advanced through the various ranks of the service until, in 1891, he was made a rear admiral. He retired April 15, 1894.

IRWIN, MAY (1862-). An American actress, best known in farce comedy. She was born at Whitby, Ontario, Canada, and made her appearance on the stage at Buffalo early in 1876. Coming to New York, she played for several years at Tony Pastor's Theatre; then became a member of Daly's company, with which she remained until 1887. She appeared as a star in *The Widow Jones*; *Kate Kip, Buyer*; *Mrs. Peckham's Carouse*; *Getting a Polish*; *Widow by Proxy* (1912); *The Crimson Rambler* (1914); *No. 13 Washington Square* (1915); and other light pieces. Consult L. C. Strang, *Famous Actresses of the Day in America* (New York, 1900), and Norman Hapgood, *The Stage in America, 1897-1900* (ib., 1901).

IRWIN, WALLACE (ADMAH) (1875-).

An American journalist and author, brother of Will Irwin, born at Oneida, N. Y. He graduated from the Denver High School in 1895 and studied at Stanford University (1896-99). He was special writer for the *San Francisco Examiner* in 1900, served as editor of the *San Francisco News Letter* in 1901 and of the *Overland Monthly* in 1902, wrote burlesque for the Republic Theatre in 1903 and topical verse for the *New York Globe* in 1904-05, and was staff member of *Collier's Weekly* in 1906-07. Besides his magazine articles, he is author of *The Love Sonnets of a Hoodlum* (1902); *The Rubaiyat of Omar Khayyam, Jr.* (1902); *Fairy Tales up to Now* (1904); *Nautical Lays of a Landsman* (1904); *At the Sign of the Dollar* (1904); *Chinatown Ballads* (1905); *Random Rhymes and Odd Numbers* (1906); *Letters of a Japanese Schoolboy* (1909); *Mr. Togo, Maid of All Work* (1913); *Hashimura Togo, Domestic Scientist* (1914).

IRWIN, WILL (IAM HENRY) (1873-). An American journalist and author, brother of Wallace Irwin, born at Oneida, N. Y. He graduated from Stanford University in 1899. He served as assistant editor (1899) and editor (1900) of the *San Francisco Wave*, as reporter (1901), special writer (1902), and Sunday editor (1902-04) of the *San Francisco Chronicle*, as reporter of the *New York Sun* (1904-06), as managing editor of *McClure's Magazine* (1906-07), and as writer for *Collier's Magazine* (1907-08). Thereafter he devoted himself to general magazine writing. He is author of *Stanford Stories* (1900), with C. K. Field; *The Reign of Queen Isyl* (1903) and *The Picaroons* (1903), with Gelett Burgess; *The Hamadryads* (1904), verse; *The City that Was* (1907); *Old Chinatown* (1908, 1913); *The Confessions of a Con Man* (1909); *Warrior the Untamed* (1909); *The House of Mystery* (1910); *The Readjustment* (1910); *The Red Button* (1912); *Where the Heart is* (1912); *Beating Back* (1914), with Al J. Jennings.

IS. See HIT.

ISAAC, *ī'zak* (Heb. *Yiṣḥāk*, from *sāḥak*, to laugh). One of the Hebrew patriarchs. The story of Isaac is given in Gen. xviii-xxxv. He was the son of Abraham and Sarah, born to them when Abraham was 100 and Sarah 90 years old. The connection of the name with the root "to laugh" is explained in three different versions. When the birth of Isaac is foretold by the angels, Sarah is reported to have laughed (Gen. xviii. 12); another account says it was Abraham who laughed (Gen. xvii. 17-19); the third says every one who heard of it would laugh (Gen. xxi. 6). When the child was eight days old, he was circumcised (Gen. xxi. 4), and as he grew older he was a good deal with Ishmael, his half brother. This displeased Sarah, and she had Hagar and her son driven forth (Gen. xxi. 9 et seq.). The next that we hear of Isaac is in the episode of the offering (Gen. xxii). In obedience to divine prompting, Abraham set out with his son for Mount Moriah (q.v.) and there attempted to sacrifice the lad as a burnt offering. An angel interposed, and a ram was substituted. After the death of his mother Isaac married Rebekah, his kinswoman, brought by Eliezer, the servant of Abraham, by his master's command from Mesopotamia (Gen. xxiv). Isaac was then 40 years of age. After 20 years two sons were born, Esau and Jacob. The sons were different in character, with the

result that Isaac loved Esau better, while Rebekah loved Jacob (Gen. xxv. 21-34). When a famine came upon the land of Canaan, Isaac was warned of God not to go down to Egypt, but to go to Abimelech, King of Gerar. Here he practiced the same deceit as his father before him, saying that his wife was really his sister. He prospered greatly in the land and excited the envy of the inhabitants, who twice took away the wells that he had digged. A third well was left unmolested, and he called it Beersheba (Gen. xxvi). In his old age Isaac became blind and, fearing that he was soon going to die, was anxious to bless his favorite son, Esau. By dressing in hairy garments Jacob was able to deceive his father and received the blessing intended for his brother. In consequence of this Jacob had to leave home, but not before he had received a second blessing from his father (Gen. xxvii). Isaac lived 180 years, long enough to see his son deceived by his children when they sold their brother Joseph. He was buried by Jacob and Esau in the cave of Machpelah (Gen. xxxv. 29; xlix. 31).

It is the opinion of many scholars at the present time that Isaac is either a tribal name or the name of the numen, or local divinity, of Beersheba. The theory is plausible that the full name was once Yishak-El, i.e., 'El (or god) laughs.' There is no evidence as yet, however, of a tribe bearing this name, and though the scornfully laughing (cf. Ps. ii. 4) or benignantly smiling El would not be an impossible designation of a local deity, no evidence has yet been forthcoming of the worship of a god by that name. Isaac is more especially associated with Beersheba, as Abraham is with Hebron, and Jacob with Bethel (see NEGEB); and whatever light may in the future be shed on the other two patriarchs by contemporaneous records is likely to affect also the judgment as to the character of Isaac.

Scholars who accept the composite character of the present Book of Genesis believe that the Isaac narrative contains: (a) specimens of Hebrew folklore, as the story of Isaac's birth, and the play upon his name, "the laughter"; (b) illustrations of a religious doctrine, as in the story of the sacrifice, showing the proper attitude of the Yahwe worshiper, which is also found in the Pentateuchal codes, to human sacrifice; (c) traditions of the wanderings of some of the Hebrew tribes during the nomadic period.

In the accounts of Isaac's birth there is a tendency on the part of scholars to see an attempt to modify tradition so as to make it appear that Isaac is the legitimate and "only" son of Abraham. The claims of Ishmael (q.v.), who is the older, cannot be altogether set aside; but the distinctively Jewish point of view is brought out, not only by making Isaac the offspring of Sarah—the true wife of Abraham—but by the elaborate account of the promise made to Abraham that he should have a son by Sarah, despite the latter's great age, and by the emphasis laid upon the joy that Isaac's coming occasioned on all sides. The setting aside of Ishmael to make room for Isaac reflects the separation of the Ishmaelite clan or clans from Israel and Judah. Ishmael not having formed an element in the Hebrew confederacy, the very closeness of the bond between the two as preserved by tradition even among the Hebrews becomes the motive for transforming these tradi-

tions in such a manner as to present Ishmael in as unfavorable light as possible. Hence in the most important incident of the Isaac narrative, the journey of Abraham and Isaac to the place of sacrifice, Isaac is not only called the beloved but the only son of Abraham, with the evident intent of ignoring Ishmael altogether. The story of Isaac's sacrifice may be a genuine Jewish midrash, not based at all upon popular tradition, but deliberately introduced as a *mashal* (or' allegory) to illustrate Abraham's implicit obedience to Yahwe. Abraham in this story is the type of the true and pious Yahwe worshiper who is willing to sacrifice, at divine command, even that which is dearest to him. But the point of the story is that, precious as this unflinching devotion is to the God of Israel, he is ready to accept an animal sacrifice as a substitute for human sacrifice. Similarly the commandment, "The first-born of thy sons shalt thou give unto me; likewise shalt thou do with thine oxen and with thy sheep" (Ex. xxii. 29 et seq.), the original significance of which can be subject to no question, was subsequently modified by permitting a ransom in the case of the human sacrifices. In view of the persistence of such sacrifices among some of the other Semitic nations, this sign of social progress, reflected both in story and legislation, is significant.

When we come to the wanderings of Isaac from Rehoboth to Gerar and from Gerar to Beersheba, and the quarrels over the wells, we seem to be again in the presence of popular traditions regarding the nomadic period, to which, however, a religious turn has been given by the compilers of the tradition in making Isaac a type of the mild and peace-loving Israelite; and once more the artificial (though also artistic) character of the Isaac narrative appears to some scholars to be revealed in making Isaac die at Mamre-Hebron (Gen. xxxv. 27), in order to locate his burial place in the cave of Maehpelah with Abraham, whereas Isaac's real home is Beersheba. As for the stories of Isaac's relationship to his two sons, Esau and Jacob, they reflect again the rivalry between Edom and Israel. (See JACOB.) Consult the commentaries on Genesis. See GENESIS, BOOK OF.

ISAAC I COMNE'NUS (?-1061). Byzantine Emperor from 1057 to 1059. He was the first of the line of the Comneni to ascend the throne, though his family had been for some time prominent in both military and civil capacities. In 1057 he was proclaimed Emperor by the landed aristocracy in opposition to Michael VI, whom he defeated and deposed. On his accession he found the affairs of the Empire in a very bad condition—rebellion within, aggression without, and the treasury exhausted. He succeeded in establishing a system of great economy in all branches of the administration and, in order still further to lighten the burden of taxes on the people, called upon the clergy to contribute their share. But the clergy refused to endure the imposition of any such burdens, and the Patriarch Michael is reported to have even threatened him with deposition. Death delivered Isaac from this formidable opponent, and the clergy were compelled to submit. In 1059 he repelled the Hungarians, who had encroached upon his possessions in the northwest, but soon afterward he was attacked by a violent fever and, believing his death ap-

proaching, appointed his famous general, Constantine Ducas, as his successor. He recovered from his illness, but nevertheless resigned the crown and retired to a convent, where he died after two years. Isaac was not deficient in literary attainments. We still possess his *Scholia* on Homer, his favorite author; further, a work, *Characteristics*, dealing with the Greek and Trojan chiefs mentioned in Homer; and, finally, a treatise entitled *On the Works of Homer*. Consult Finlay, *History of Greece*, vols. ii, iii (Oxford, 1877).

ISAAC II ANGELUS (?-1204). Byzantine Emperor from 1185 to 1195 and 1203-04. Delivered by a popular revolution from death, to which he had been condemned by his kinsman, Adronicus Comnenus, Emperor of Constantinople, he obtained the throne in 1185. His vices, incapacity, and military disasters rendered him unpopular, and he was dethroned, blinded, and shut up in a monastery by his brother, Alexius III, in 1195, but was restored by the Crusaders, who took Constantinople in 1203, only to be again dethroned by Alexius Ducas in 1204. He died soon after. Bulgaria was lost to the Byzantine Empire during his first period of power in 1186. Consult Finlay, *History of Greece*, vol. iii (Oxford, 1877), and Pears, *Fall of Constantinople* (New York, 1886).

ISAAC OF ANTIOCH. A poet and theologian in the Syrian church. He was probably born at Edessa in the first part of the fifth century and seems to have moved to Antioch e.450 A.D. The Chronicle of Edessa refers to him as flourishing in 451-452; the Chronicle of Michael the Syrian makes him a contemporary of Nonus, who began his bishopric in 449, and he was still living in the days of the Patriarch Peter the Fuller (470-488) and the Emperor Zeno (474-491). He was for many years abbot of a convent near Antioch. Isaac was a Monophysite, and his teacher Zenobius was a disciple of Ephraem. Many of his poems are lost; and of the 191 metrical homilies that go by his name, some may have been written by an Isaac who flourished in the beginning of the fifth century and was a disciple of Ephraem or by another Isaac living in the days of Bishop Paul (510-522). The lost poems on the classical games in 404 and the destruction of Rome by Alaric in 410 may have been by the former of these. Isaac of Antioch no doubt wrote the famous poem of 2136 lines dealing with the parrot which uttered the Trisagion in the streets of Antioch. In his denunciations of current abuses, of corrupt judges, of oppression, luxury, and licentiousness, he resembles one of the Hebrew prophets. He alludes to the invasion of the White Huns. His homilies were written in a heptasyllabic metre, and his style is forceful and rich in imagery. Bickell published in two volumes 37 of the 191 poems given in his list (Giessen, 1873-77); and 67 poems, among them 43 new ones, were published by Bedjan, *Homiliae S. Isaaci* (Paris, 1903). Consult Brockelmann, in *Die Literaturen des Ostens*, vii, 2 (Giessen, 1907). See SYRIAC LITERATURE.

ISAACS, RUFUS (DANIEL). See READING OF EARLEY, first BARON.

ISAAK, ē'zäk, IZAK, or YZAC, HEINRICH (e.1450-c.1517). A German-Italian musician. We know nothing of his life except that he was in the service of Lorenzo de' Medici for a num-

ber of years, was organist in Rome, and later was "symphonista regis" to Maximilian I at Vienna. He was a prolific composer of the contrapuntal school and was one of the first to employ the melody in the soprano. His compositions were frequently reprinted in collections, and some of his part songs and melodies (notably the choral "Nun ruhen alle Wälder") are still in use.

ISABELA, ē'sā-bā'lā. A province in Luzon, Philippines. It takes in part of the Sierra Madre and the Carballos Mountains and borders on the Pacific Ocean. The chief rivers are the Grande de Cagayán and the Magat (Map: Philippine Islands, C 2). A large part of its area is covered with thick forests peopled by savage tribes. Live stock is raised extensively, and palay, coffee, chocolate, corn, and vegetables are cultivated. Area, 5394 square miles; pop., 1903, 76,431. Capital, Ilagan (q.v.).

ISABELA. A town of Negros, Philippines, in the Province of Negros Occidental, 36 miles south of Bacólod. Pop., 1903, 12,836.

ISABELA ISLAND. See ALBEMARLE ISLAND.

ISABELINOS, ē'sā-bā-lē'nōs. In the first Carlist War, the party that opposed Don Carlos and supported the young Queen Isabella II. They were also known as Christinos or Cristinos (q.v.), from their support of Cristina, the Queen mother, in her defense of the rights of her daughter.

ISABELLA, iz'ā-bē'lā. A buff or brown color. The term originated in a story told of Isabella of Austria, daughter of Philip II, at the siege of Ostend (or of Isabella of Castile at the siege of Granada), who vowed not to change her linen before the capture of the town. Owing to the length of the siege, the linen was discolored and so gave rise to the name.

ISABELLA; OR, THE POT OF BASIL. A poem by Keats, based on a story by Boccaccio (1818).

ISABELLA I, Sp. **ISABEL**, ē'sā-bē'l' (1451-1504). Queen of Castile, known as the Catholic. She was born at Madrigal, Old Castile, the daughter of John II, King of Castile and León, by his second wife, the Infanta Isabella of Portugal. In 1454 Isabella's brother Henry ascended the throne of Castile, and in 1469 the Princess, after considerable opposition and in the face of great difficulties, married Ferdinand of Aragon. On the death of Henry IV, in 1474, Isabella and Ferdinand, jointly, succeeded to the throne of Castile and León, to the exclusion of her niece Joanna. She had won the support of a great part of the estates of the kingdom during her brother's life, and the victorious arms of her husband compelled the consent of the rest. A war with Portugal, which was waged by King Alfonso in behalf of the Princess Joanna, was terminated in Isabella's favor in 1479, and the same year Ferdinand succeeded to the throne of Aragon as Ferdinand V. This union of the two chief Spanish kingdoms laid the foundation of Spain's future greatness. The first task the allied sovereigns set themselves to perform was the pacification and consolidation of the kingdoms of Castile and Aragon. Then in 1482 they began the 10 years' war against the Moors of Granada, which culminated with the capture of the Moorish capital and the extinction of Moorish sovereignty in Spain at the beginning of 1492. It was towards the end of this struggle, the danger and hardships of which Isabella shared with her army, that the Queen of Castile earned her greatest title to fame in

the eyes of posterity, by her acquiescence in the plans of Columbus, who was then a suppliant at the Spanish court. For their successes against the Moors and their staunch Catholicism the title of "Catholic sovereigns" was conferred by the Pope on Ferdinand and Isabella. Queen Isabella was possessed of no inconsiderable beauty and much winning grace, although proud, ambitious, and exceedingly punctilious. She was always present in meetings of the council, and insisted on the use of her name with that of Ferdinand in all public documents. The consolidation of the Spanish Kingdom through the organization of the Hermandad (q.v.) and the establishment of the royal supremacy over the great military orders were in a large measure her work. In the reign of Isabella the Inquisition was organized in Castile by Torquemada, under whom its work was carried on with a barbarity bred of the most fanatical zeal. In 1492 the Jews were expelled from Castile and the rest of Spain, to the great detriment of the country. She died at Medina del Campo on Nov. 26, 1504, and was buried in accordance with her own wishes in the Franciscan monastery at Granada, whence her remains and those of Ferdinand were removed to the royal chapel of the cathedral in 1521. Of her five children, the two eldest, Isabella, Queen of Portugal, and John, her only son, died in 1498 and 1497 respectively. Of her three remaining daughters, Joanna the Mad became the wife of Philip of Austria and the mother of Charles V of Germany; Maria married Emmanuel of Portugal; and Catharine of Aragon was the unfortunate first wife of Henry VIII of England and the mother of Mary Tudor.

Bibliography. ISABELLA II (1830-1904). Queen of Spain from 1833 to 1868. She was the daughter of Ferdinand VII by his fourth wife, Maria Christina of the Two Sicilies, and was born at Madrid, Oct. 10, 1830. By a decree which set aside the Salic Law in Spain and which was confirmed by the Cortes, March 29, 1830, the Infanta Isabella became the heiress apparent to the throne, which she ascended on the death of her father in September, 1833, her mother being appointed Queen Regent. An insurrection in favor of her uncle, Don Carlos (q.v.), who according to the Salic Law would have succeeded to the throne on the death of his brother, immediately broke out and raged with great violence until 1840, when the cause of the court triumphed. In the course of the period politicians had begun to divide into the two parties of the *Moderados*, or Conservatives, and the *Exaltados*, or Liberals;

and the Queen Regent found it necessary to enlarge the Liberal constitution in 1834 and ultimately (1836) to reestablish the constitution of 1812. In 1840 Maria Christina, after making Espartero, the champion of the court in the war over the succession, Prime Minister, was reduced to the necessity of resigning the regency, which was conferred on Espartero. An insurrection broke out in 1843, which led to the overthrow of the Regent Espartero and the establishment of the military dictatorship of Narváez, who introduced an anti-Liberal policy. On Nov. 8, 1843, Queen Isabella was declared by the Cortes to have attained her majority. Although the young Queen enjoyed personal popularity, political intrigues continued, with frequent attempts at insurrection. In 1846 the Queen married her cousin, Don Francisco d'Assisi, elder son of Ferdinand VII's youngest brother. A change to almost purely absolute government in 1853 was followed by the banishment of many chiefs of the Constitutional party, as a result of which a formidable rising of the army took place in 1854 under O'Donnell (q.v.). Espartero was put at the head of an administration in which Liberal principles held sway. But the Queen disapproved of his policy, and he resigned in favor of O'Donnell, July 14, 1856, who was soon after supplanted by Narváez. For a number of years the chief power was held alternately by these two ministers. Though Liberal ministers were more than once forced upon her, the Queen, as time went on, fell more completely under the influence of the reactionary faction. She lost much of her former popularity, and the nation became impatient under her arbitrary rule. In September, 1868, a revolution broke out, headed by Serrano, Prim, and Topete, ending in the formation of a Republican provisional government and the flight of Isabella to France. In 1870 she abdicated in favor of her son, Alfonso XII, who succeeded to the throne in 1875 after the brief reign of Amadeo of Savoy and the failure of the Republic under Castelar. After 1871 the ex-Queen of Spain passed the greater part of her time in Paris. See SPAIN.

ISABELLA, ISABEAU, or ELIZABETH, OF BAVARIA (1370-1435). Queen of France. The daughter of Stephen II of Bavaria, and at 15 the wife of Charles VI of France, she was crowned Queen in 1389 and bore several children. She was noted for her remarkable beauty, and for a few years all went well; but in 1392 Charles began to have periods of insanity. He showed a great dislike for Isabella, whom he had loved madly, and a great partiality for a mistress. Isabella became very intimate with the Duke of Orléans, the King's brother, who was suspected of being the father of Isabella's seven children born between 1393 and 1407, the year of the Duke's assassination. Although frequently acting as Regent, Isabella led a scandalous life and joined first one political party, then another. She was imprisoned for a few months, but was freed by John the Fearless, after whose murder she joined in surrendering France to England, in 1420, by the Treaty of

Troyes. Her daughter Catharine she married to Henry V of England, and she had her share in the English triumphs; but she was heartily despised by the French. After the death of Charles VI, in 1422, she lived a lonely life at Paris, having grown very stout and become an object of general contempt. Consult: Vallet de Viriville, *Isabeau de Bavière* (Paris, 1859); Lavissee, *Histoire de France*, vol. iv (ib., 1902); Thibault, *Isabeau de Bavière* (ib., 1903).

ISABELLA OF BRAZIL (Portug. ISABEL), COUNTESS D'EU (1846-). A princess of Brazil, born in Rio Janeiro, the daughter of Emperor Dom Pedro II. Because of her brother's early death, she was the heir apparent during the long reign of her father. In 1864 she married Gaston d'Orléans, Count d'Eu, and in 1886 was left as Regent, with full powers, during her father's absence on a visit to Europe. An ardent opponent of slavery, and intolerant of the process of gradual abolition which was being carried out, she determined to end the institution at once. Accordingly she had her Minister introduce into the Chamber of Deputies a law for immediate emancipation without compensation, and on May 15, 1888, she issued the decree putting the law into effect and freeing forever all the slaves in Brazil. This measure caused the large planters to join with the Republicans in their opposition to the monarchy. Further, Isabella and her husband were decidedly unpopular and were thought to be under the dominance of the clergy and desirous of maintaining an autocratic rule. These conditions precipitated the revolution which overthrew the Empire and drove Isabella, her father, and the Imperial family into exile (Nov. 15, 1889). By an arrangement between the head of the French royal house and the Count d'Eu, the descendants of the Count and Countess d'Eu form an independent ex-ruling house, bearing the title Orléans-Braganza.

ISABELLA OF ENGLAND. See EDWARD II; EDWARD III.

ISABELLA THE CATHOLIC, ORDER OF. A Spanish order of knighthood, founded by Ferdinand VII, in 1815, as a reward for loyalty in the defense of Spanish-American possessions. It is now conferred for all kinds of merit. The sovereign is the head of the order, which is divided into four classes of grand cross, commanders of the first and of the second rank, and knights. The badge of the order is an eight-pointed cross of gold inlaid with red enamel, bearing a central plaque with the motto "A la lealtad acrisolada" (to proven loyalty), and suspended from a laurel crown which is held by a ribbon of orange and white.

ISABELLE (ē'zà'běl') **GAZELLE.** A gazelle of Kordofan and Sennar (*Gazella isabella*), also known as Genai, distinguished from the dorcas mainly by the sharp inward bend of the horn tips, which form decided hooks. See Plate of GAZELLES.

ISABELLITA, ē'sà-běl-lē'tà (Sp., little Isabelle). A name in the Spanish West Indies for any of the gaudy fishes of the genus *Angeliethys*, called also angel fish and emperor fish (q.v.).

ISABEY, ē'zà'bă', JEAN BAPTISTE (1767-1855). A French painter of portraits in miniature. He was born at Nancy, where he painted miniatures of the neighbors and studied with Claudot. Arriving in Paris at the age of 18, he was coldly received by his compatriot of Lorraine,

Dumont, the Queen's miniature painter. To pay his expenses, he painted buttons at 12 sous each and medallion copies of Vanloo and Boucher. Fortunately, through his roommate's father, who worked at Versailles for the tutor of the royal children, he received the commission to paint for the Queen, Marie Antoinette, miniatures of her two nephews, sons of the Comte d'Artois, who afterward reigned as Charles X. This made Isabey's fortune. The Queen liked his work, and he painted a miniature of her, after a portrait by Sicardé. He then studied with David and after the Reign of Terror became professor of drawing in a school attended by Hortense Beauharnais, who introduced him to Josephine. He was the intimate friend of both Bonaparte and Josephine and in 1805 was named First Painter to the Empress, with the additional duty of organizing the court fêtes and superintending the decorations of the Opéra. After the fall of Napoleon, Isabey stood in high favor at the courts of Louis XVIII, Charles X, and Louis Philippe, and became Commander of the Legion of Honor and Director of Fêtes under Napoleon III. He exhibited regularly at the Salon from 1793 to 1841 and during his long career painted likenesses of almost all the eminent persons of France. In the Morgan collection of miniatures loaned to the Metropolitan Museum, New York, are 13 portraits by Isabey, among them "The Duke of Reichstadt," "Queen Hortense and her Son," and "Madame Récamier." His drawing is of distinguished excellence, and his work displays to a remarkable degree the possibilities of miniature painting. Consult: Edmond Taigny, *Isabey, sa vie et ses œuvres* (Paris, 1858), containing important extracts from his diary; Williamson, *Catalogue of the Miniatures of J. Pierpont Morgan* (London, 1908); Basili-Callemani, *J. B. Isabey* (Paris, 1909), richly illustrated and exhaustive.

ISABEY, ē'zā'bā', LOUIS GABRIEL EUGÈNE 1803-86). A French genre and marine painter. He was born in Paris, the son and pupil of Jean Baptiste Isabey (q.v.), through whose influence he was made painter of the Algerian expedition of 1830. He became Chevalier of the Legion of Honor in 1832, Officer in 1852. He continued to exhibit until 1878, and towards the end of his life worked much in water colors. His works include: "Harbor of Honfleur" (1827); "Battle of the Texel" (1839), Versailles Museum; "View of Boulogne Harbor" (1843), Toulouse Museum; "Ceremony in the Church of Delft" (1847); "Marriage of Henry IV" (1848); "Embarkation of De Ruyter and De Witt" (1850) and "Roadstead of Saint-Malo," in the Luxembourg Museum; and others in the provincial museums of France and Germany. The Metropolitan Museum of New York possesses his "Banquet Hall" (1873). He was much influenced in color by Delacroix, although his art is of a lighter character. His genre pictures represent scenes of a past age and are painted in delicate and harmonious colors, especially the costumes. His marines show in an admirable manner the glittering evanescent effects of light upon the waves.

ISABNORMAL (is'āb-nōr'mal) **LINES** (from Gk. ἴσος, *isos*, equal + Eng. *abnormal*, from Lat. *abnormis*, abnormal, from *ab*, from + *norma*, rule). Lines connecting places whose temperature, pressure, etc., for any epoch have equal departures from the normal values of the respective places.

ISÆ'US (Lat., from Gk. Ἰσαῖος, *Isaios*)

(c.420-350 B.C.). A Greek orator included in the Alexandrian canon of the 10 Attic orators. Of his life little is known. He was the son of Diagoras and was probably born at Chalcis, although most of his life was spent at Athens, where he was a contemporary of Isocrates (q.v.), whose pupil he is said to have been. As he was not an Athenian citizen, he could not plead before the courts, but, like Lysias, he took up the profession of logographer, or writer of speeches for others. His specialty was the laws of inheritance. Ancient traditions say that Demosthenes was a pupil of Isæus. The ancients had 64 speeches which were attributed to him, of which 50 were held to be genuine. Of these only 10 have come down to us complete, although the single manuscript which contains them has preserved about half of another speech, and Dionysius of Halicarnassus (q.v.) has a long fragment, which is usually printed as a twelfth oration. Isæus' strength is said by Dionysius to have depended on his skill in forensic controversy. In the development of Athenian oratory he marks the transition from Lysias (q.v.) to Demosthenes (q.v.). The speeches are best edited by Bürmann (Berlin, 1883). There is an English translation by Jones, *The Speeches of Isæus* (London, 1779). Consult: Jebb, *The Attic Orators*, vol. ii (London, 1876); Blass, *Die attische Beredsamkeit*, part ii (Leipzig, 1892); Wyse, *The Speeches of Isæus* (Cambridge, 1904); Christ-Schmid, *Geschichte der griechischen Litteratur*, vol. i (5th ed., Munich, 1908). See CANON ALEXANDRINUS; LOGOGRAPHERS.

ISAG'ORAS (Lat., from Gk. Ἰσαγόρας) (c.545-c.500 B.C.). An Athenian politician. He was chosen first archon (508 B.C.) after the expulsion of Hippias (510), although Clisthenes (q.v.) had been much more influential at the time. In the quarrel which followed Isagoras was opposed by Clisthenes and the entire people, and the new constitution was victorious. But Isagoras appealed to Sparta, and Cleomenes I (q.v.), King of Sparta, insisted that Clisthenes be surrendered, since he was descended from the accursed Alcæonidæ (q.v.). The leader of the people voluntarily retired; the Spartans occupied the city; Isagoras banished 700 families and attempted to replace the democratic Five Hundred by an aristocratic Three Hundred. At this the people rose, hemmed the Spartans within the Acropolis, and after three days permitted them and Isagoras with them to retire to Sparta, but executed all Athenian partisans of Isagoras, who himself died in exile.

ISAIAH, î-zā'yā or î-zā'yā (Heb. *Yeshā'ayāhū*, help of Yahwe, or Yahwe helps). One of the most famous of the older Hebrew prophets. He was the son of Amoz and lived at Jerusalem during the reigns of Uzziah, Jotham, Ahaz, and Hezekiah. We may assume that he was born about 760 B.C., that he began to prophesy in the year in which Uzziah died (c.737 B.C.), and that he died about 700 B.C. He appears to have occupied a high social position, had easy access to Ahaz, and exerted much influence on Hezekiah. Beyond this we know little of his private life. It appears from his discourses that he was married and had at least two children, to whom (like Hosea, q.v.) he assigned symbolic names, Shear-jashub and Maher-shalal-hash-baz (vii. 3; viii. 3). It is the opinion of modern scholars that but few of the discourses in the Book of Isaiah (see ISAIAH, BOOK OF) emanate from Isaiah himself, and that it is doubtful

whether any one of these discourses has been preserved in its original form. They are found in the first part of the book, contain additions belonging to various later periods, and have been so radically rearranged that it is exceedingly difficult to fix the chronological order and to determine the political events to which they have reference. Still some of the discourses are quite clear.

The most important event in the reign of Ahaz was the combination of Pekah, King of Israel, and Rezin of Damascus against Judah (2 Kings xvi). To this event (which occurred in 734 B.C.) and its consequences several discourses of Isaiah refer, found in chaps. vii, viii, and xvii. The prophet advises Ahaz to be calm and to place his trust in Yahwe. As a matter of fact, the combination against Judah failed, but not until Ahaz had called for aid upon Tiglath-pileser IV, the King of Assyria (745-728 B.C.). This act arouses the prophet's ire. He changes his tone towards Ahaz, denounces his lack of confidence in Yahwe, and predicts havoc and misfortune to the country from these very Assyrians whom Ahaz has called in as allies. The result was that the northern kingdom of Israel was partly taken in 732 B.C. and finally conquered by the Assyrians in 723 B.C. (see SAMARIA), and incorporated in the Empire as a province, while Judah escaped only by becoming a vassal to the King of Assyria. In the days of Hezekiah the country chafed under the yoke, and a party arose in Jerusalem which formed an alliance with Egypt as a means of freeing the country from Assyrian suzerainty. Isaiah was equally opposed to this policy. Portions of his discourses during this period are preserved in chaps. xxviii-xxxi. He declares that the Egyptians and their allies will be defeated and goes so far as to intimate that Yahwe Himself will fight on the side of Assyria against His own people if they ally themselves with Egypt. Isaiah could not quell the warlike spirit which was rife in Judah, and the King watched for every chance to oppose Assyria. He not only joined with Egypt, but actually organized a revolt against Sennacherib (see HEZEKIAH), which terminated disastrously for the Judæan Kingdom, although by a fortunate turn of events it escaped being entirely wiped out. At this juncture the leading thought in what may be called Isaiah's theology reveals itself. The terrified ruler and his people in their distress hoped that by entreaties and sacrifices they might again secure the favor of Yahwe, for the calamity that befell the country was looked upon as a sign of Yahwe's displeasure. The first chapter of Isaiah (verses 5-26) gives the prophet's view of the situation. There is only one hope of salvation, and that is by a complete change of conduct on the part of the people, by upright practices, and by fair dealings, by honest government and just courts. As for sacrifices, prayers, and festivals, Yahwe hates them. This and other chapters afford an insight into the social conditions prevailing in the days of Isaiah, which is most important for understanding the attitude of the prophet towards political events. He felt deeply that there was no hope for Judah unless by a total change of conduct the people might secure once more the favor of Yahwe. Political alliances were of no avail, either with Assyria or with Egypt. He had warned Ahaz, but the warning was not heeded. His influence over Hezekiah was greater. Largely, no doubt,

at his instigation, the King undertook some religious reforms. (See HEZEKIAH.) But Hezekiah, like Ahaz, yielded to pressure and put his trust in princes instead of in Yahwe. Isaiah, no doubt sorely disappointed, lost all hope and became a prophet who foresaw only gloom and woe for his people, declaring that none, whether great or small, would escape the punishment deserved by their shortcomings.

Hence, despite the obscurity in which the personality of the great prophet is enveloped through editorial interference with his productions, enough can be determined to enable us to grasp his essential message in its full force. His contention is that through right conduct alone can a people be saved. It is because of the profound impression that this message made—not, indeed, upon his own age, but upon later generations—that Isaiah became a type of the true prophet of Yahwe and that discourses of various periods which seemed worthy to be associated with Isaiah were grouped with his utterances, and a composite Book of Isaiah was gradually evolved.

ISAIAH, BOOK OF. The first of the so-called major prophets in the English version of the Old Testament and in all other translations. In the printed Hebrew Bibles and many manuscripts, including the *Codex Petropolitanus*, it also precedes Jeremiah and Ezekiel. But the order given in the Babylonian Talmud (*Baba bathra* 14 b) is Jeremiah, Ezekiel, Isaiah, and according to Elias Levita this was followed by the German and French Jews in their manuscripts. For this arrangement the Talmud assigns as a reason that "the Book of Kings ends in desolation, Jeremiah is all desolation, Ezekiel begins with desolation and ends with consolation, and Isaiah is all consolation." The significance of this order and the reason for it have been fully discussed by Schmidt (*The New World*, ix, 656 ff.; Boston, 1900). Before larger books were made, while each prophet was copied on a separate scroll, as still was the case in the first century A.D. (Luke iv. 17), it is not probable that the question of precedence was seriously considered. When it was raised, the arrangement was, no doubt, determined by the same practical considerations of the effect upon readers and listeners in the synagogues that may be observed in the inner economy of each book, where words of comfort are apt to follow severe rebuke, and cheerful predictions denunciations of doom. The impression that the Book of Isaiah is "all consolation" was the result of the manner in which it was edited.

There is much evidence of editorial activity. Certain divisions are indicated by headings, either ascribing a section to Isaiah or describing its contents, or both. Thus, the prophecy beginning ii. 2 is introduced as "The word that Isaiah, the son of Amoz, saw concerning Judah and Jerusalem"; the narrative of the prophet's call, chap. vi, is dated "in the year when King Uzziah died"; the episode described in chap. vii is said to have occurred "in the days of Ahaz"; chaps. xiii-xiv are designated as "The Oracle concerning Babylon which Isaiah, the son of Amoz, saw"; chaps. xv-xvi are only called "The Oracle concerning Moab"; chap. xvii is called "The Oracle concerning Damascus"; chap. xix is designated as "The Oracle concerning Egypt"; chap. xx is dated in the year when "Tartan came against Ashdod, when Sargon, King of Assyria, sent him"; xxi. 1-10 is called "The

Oracle of the Wilderness," 11-12 "The Oracle concerning Duma," 13-17 "The Oracle concerning Arabia," xxii. 1-14 "The Oracle concerning the Valley of Vision" (perhaps Hinnom); chap. xxiii is said to be "The Oracle against Tyre" (probably Sidon); and i. 1 has the appearance of having been originally the heading of chap. i before it was expanded into a superscription to a larger collection of oracles. It is noticeable that headings ascribing particular sections to Isaiah and indicating the occasion are, with the exception of chap. xx, found only in chaps. i-xii; that the term *massa* (oracle) is limited to chaps. xiii-xxiii, where it is of frequent occurrence; that in these chapters the author's name is not added except in xiii. 1; and that there are no headings of any kind in chaps. xl-lxvi. The absence of any superscription in xl. 1 is all the more striking as the last 27 chapters are separated from the earlier collection of prophecies by four historic chapters (xxxvi-xxxix), which likewise have no special heading. It is also to be observed that in chaps. vii and xx, as well as in xxxvi ff., Isaiah is spoken of in the third person, while in chap. viii he speaks in the first person. A peculiarity that challenges attention is the appearance of more or less extensive sections, distinct in character, often strangely contrasting by their cheerful and comforting nature with what precedes them and yet without any special heading or ascription in any form to Isaiah. It is therefore natural to infer that the first collection of prophecies specifically assigned to Isaiah and to some definite occasion in his career has been preserved in chaps. i-xii; that the majority, if not all, of the oracles in chaps. xiii-xxiii were anonymous; that some prophecies, like those in chaps. vii and xx, were drawn from a biography of the prophet; that a second collection of Isaianic prophecies was used in chaps. xxviii-xxxii; that chaps. xxxvi-xxxix, which, with slight exceptions, are also found in 2 Kings xviii. 13-xx. 19, were taken over from the Book of Kings, or a common source; that large portions of the book were left by the final editor without any heading because they had none, among them such remarkable productions as chaps. xxiv-xxvii, xxxii-xxxv and xl-lxvi; and that the volume could not have been constituted by Isaiah himself in this manner.

Such facts did not fail to attract some degree of attention even in earlier times. Already Ibn Ezra (died 1167) hinted at later material in the book by his suggestion that it was Isaiah's in the same sense as the Book of Samuel was ascribed to this prophet. Grotius felt that many passages in Isaiah lx ff. showed that a situation in the Maccabæan period was in the prophet's mind, though he did not express any doubt as to the revelation of this situation to Isaiah; and the same attitude was apparently taken by Houbigant. Spinoza suggested that the Book of Isaiah was edited after the prophet's time. As long as it was supposed that all parts of the work must necessarily have come from Isaiah, the references to Cyrus in xliv. 28, xlv. 1, and the allusions to circumstances after the exile were explained as due to the prophetic gift which enabled Isaiah to place himself in any period in the future, even though it be separated by centuries from his own time, and to speak in view of the circumstances of that distant period. But the more clearly the historic situation was realized which is assumed to exist

in many parts of the book, the more difficult it became to harmonize such a projection into the future, even if it was thought possible, with the practical religious aims of the prophets, and serious questions began to be raised whether this or that section may not have been added in later times. It was observed that the prophets, though their eyes were always turned to the future, seem to have proclaimed their oracles in view of present circumstances, and invariably appear to have had in mind the moral effect of their messages on the people they addressed, and it was asked what purpose Isaiah, who never threatened Judah with a Chaldæan invasion, could have had in comforting Zion with the return of Judæan exiles from Babylon and the rebuilding of the temple by Cyrus, whose name could have meant nothing to his hearers; how he could have hoped to be understood at all; and what the moral influence of such a change of tone, justified by nothing in the circumstances of his own time, would have been on the attitude of the people and the reception of his repeated denunciations of sin and prophecies of doom. Finally, the psychological difficulty of such a transfer to a definite point in the distant future, without any explanation of the circumstances leading up to it, began to be felt.

Especially Doederlein (1775), Koppe (1779), Eichhorn (1780), Justi (1793), Bauer (1794), Paulus (1793), Rosenmüller (1791-93), Bertholdt (1812), De Wette (1817), and Gesenius (1821) paved the way for a wider recognition of the composite character of the book. During the last century a very large number of scholars have endeavored to determine by internal evidence what prophecies are likely to have been uttered by Isaiah himself and when the assumed additions were made. It is now generally admitted that the following passages come from Isaiah, the son of Amoz: i; ii. 6-iv. 1; v. 1-23; vi; viii. 1-18; ix. 7-x. 4; x. 5-15; xvii. 1-11; xviii; xxii. 1-25; xxviii. 1-4; xxviii. 7-xxxii. In spite of the fact that Isaiah is spoken of in the third person, and that chap. vii especially offers great difficulties, the substance of chaps. vii and xx is also regarded by most scholars as coming from him. Concerning viii. 19-ix. 6 and x. 16-xi. 9 there is a marked difference of opinion: as they seem to presuppose the Babylonian exile and voice hopes centring around some descendant of the fallen Davidic dynasty, many scholars consider them as coming from a later period, while it is argued by others that Isaiah may have looked forward to the appearance of a stronger and nobler monarch of the reigning house after a time of great depression. The hymn of thanksgiving in chap. xii is generally held to be postexilic. In spite of the ascription to Isaiah, the magnificent poem in chaps. xiii-xiv reflects so clearly the situation at the end of the exile, when the overthrow of the last King of Babylon was expected, that those who do not regard the editorial heading as correct ascribe the section to this period. The same applies to the anonymous prophecies in chap. xxi. The date of chaps. xv-xvi can scarcely be determined. Psammetichus I (663-610 B.C.) is probably the "fierce king" of xix. 4; and in view of the Elephantine papyri (q.v.) it is not improbable that there was a Jewish colony at Heliopolis as well as at Elephantine. Chap. xxiii is plausibly supposed by Duhm to be an elegy on the destruction of Sidon in 348 B.C.

The judgment of the world in chaps. xxiv-xxvii, with its elaborate eschatological programme, appears to many scholars to be very late—some think of the time of Alexander, others of the second century B.C. To the same epoch the prophecies in chaps. xxxiv-xxxv are frequently assigned, and chaps. xxxii-xxxiii are also regarded by many as postexilic. If chaps. xxxvi-xxxix were taken from 2 Kings xviii. 13-xx. 19, they are later than the exile; but even if both recensions came from an earlier source, this appears to have been a biography of the prophet, and not a collection of his oracles. It is evident that, if the sayings here ascribed to Isaiah were uttered by him, his attitude must have undergone a very marked change, which to many students seems wholly improbable. In reference to chaps. xl-lxvi it was for a long time held that these chapters were written towards the end of the Babylonian exile by an unknown prophet whom it has become customary to call Deutero Isaiah. Questions arose, however, concerning four poetical descriptions of the Servant of Yahwe—some considering these as earlier, some as later, than the main work—and the genuineness, in this sense, of a number of Songs of Zion was also doubted. Later Duhm's view gained wide acceptance, according to which chaps. lvi-lxvi were written in the middle of the fifth century by an author who has been designated as Trito Isaiah. While Deutero Isaiah was supposed to have lived either in Babylon or in Egypt or in Phœnicia, Trito Isaiah was regarded as being a citizen of Jerusalem. This solution of the problem has not been adopted by all scholars who reject the Isaianic authorship, though it is the prevalent one at present. Some still adhere to the essential unity of the whole appendix (xl-lxvi) and its origin c.540 B.C. This appears to be the position of Wellhausen (*Israelitische und jüdische Geschichte*, 7th ed., Berlin, 1914). On the other hand, doubts have recently been expressed as to the accuracy of either view. Torrey has voiced his conviction that all of these chapters were written by the same man later in the Persian period. He has not yet published his reasons for this conclusion. But they are undoubtedly connected with certain difficulties that are not satisfactorily met by the scholars who advocate the current opinions and which seem to necessitate a reconsideration from a new point of view. In the very first lines it is Jerusalem that is addressed as Yahwe's people and comforted with the hope of better conditions and the return of exiles. These are to come from the north and the south, the east and the west (xliii. 5, 6), presupposing the scattering of the Jews in all of these directions. There is no sign that the author himself belongs to the dispersed Jews. He speaks to the heart of Zion, and the exiles are always in the distance. When he refers to those living in Babylonia, he asks them to come forth from Babylon (xlvi. 20); and in speaking of the effects of Jerusalem's redemption "in the eyes of all the nations" he advises his people to "go out from thence" (lii. 11). His standpoint seems to be Jerusalem everywhere. The desire for a return of exiles from all parts of the earth is as marked in lx, lxvi. 20, as in the earlier chapters. The comforting note is found in the later chapters as well as in the earlier, and the consciousness of Israel's unworthiness, unbelief, and sin is met with in both. The mention of Cyrus in xlv.

28 and xlv. 1 has naturally led to the idea that the end of the exile is the historic situation. But in xlv. 1 "To Cyrus" is metrically redundant and looks like a later addition, and the lines referring to Cyrus in xlv. 28 have the appearance of being a homeless fragment finally interpolated here, while it once seems to have been part of an oracle ascribed to Jeremiah, as 2 Chron. xxxvi. 22, 23, Ezra i. 1, 2, suggests. Passages supposed to refer to Cyrus may in reality apply to the Servant of Yahwe or to a Judæan high priest or king. It is evident that the figure of the Servant of Yahwe, so differently interpreted in modern times, already puzzled the ancient scribes, and some of their exegesis is likely to have left traces in the text itself. The assumption that the Samaritans at the time of Ezra and Nehemiah, their sins and their heretical purpose to build a rival temple on Mount Gerizim, are alluded to in lvi-lxvi does not seem to be well founded. Such descriptions as we have, even from prejudiced sources, of the Shechemite community do not intimate that they were guilty of the practices denounced in lvii, lxv, and lxvi. A distinction seems to be made between the servants of Yahwe who tremble at His word and the sinners who in reality are apostates from the faith and have become pagans, though they hypocritically continue to participate in the official cult, and the sins enumerated seem to suggest the conditions of the Hellenizing Jews in Jerusalem in the second century B.C. It is not necessary to interpret lxvi. 1 ff. either as a condemnation of all temple service or of the attempt to build a new temple; the passage voices essentially the same feeling as 1 Kings viii. 27, and the following verses seem to denounce those who offer legitimate sacrifices, but also such as are heathenish and proscribed by the Law. The awful picture of Yahwe's vengeance on Edom and other peoples in lxiii likewise has the appearance of reflecting the victories of the Hasmonæan period. Already Grotius and Houbigant thought that this period was in the prophet's mind. From the internal evidence it would not be impossible, therefore, to maintain that the bulk of the appendix comes from the fourth century B.C., with interpolations and additions made in the second century B.C. But it should be strongly borne in mind that all such theories can only be tentative, and that a vast amount of labor and thought will have to be expended on this remarkable work before anything more can be affirmed as a fixed result of science than the bare fact that this anonymous appendix reflects conditions later than the capture of Jerusalem by Nebuchadnezzar. Eminent Catholic scholars still maintain that all parts of the Book of Isaiah come from the prophet who lived in the eighth century. Their arguments are based chiefly on the conception of prophecy as implying accurate prognostication of future situations, regardless of the needs and understanding of those immediately addressed, and partly on the similarity of certain phrases to Isaiah's style, explained by the critics as due to imitation by later writers or copyists.

Concerning the date of those passages that are ascribed to Isaiah by almost all scholars, it is generally held that chap. i originated c.705-701 B.C.; ii. 6-iv. 1, v. 1-23, and vi, c.737 B.C.; viii. 1-18, c.734 B.C.; ix. 7-x. 4, c.737-734 B.C.; x. 5-15, c.701 B.C.; xvii. 1-11, c.737-734 B.C.; xviii, c.701 B.C.; xxii. 1-14, c.701 B.C.; xxii. 15-

25, c.705 B.C.; xxviii. 1-4, c.724 B.C.; xxviii. 7-xxxii, c.701 B.C.; and the substance of vii, c.734 B.C., and of xx, c.711 B.C. The characteristic attitude of Isaiah is one of awe before the majesty of Yahwe, and fearless denunciation of all that is high and exalted on earth, of the disobedience to Jahwe's moral commands, the attempt to placate Him by sacrifice and temple worship, the dependence upon warlike preparations and political alliances rather than on Yahwe, and the lack of faith in His safe guidance. He was convinced that the mass of the people because of its infidelity would go under, and that only a remnant would turn to their God after severe affliction. So far as the people at large was concerned, he cherished no illusions as to the effect of his oracles; he realized that they would have a tendency to harden the hearts of many and goad them on to their doom. But he deposited his faithful testimony in the hearts of his disciples, and to this unknown circle of believers we probably owe the preservation of his prophecies. The terseness and vigor of his style, his command of all the resources of the language, his mastery of invective, sarcasm, and irony, the impetuosity of his speech, the grandeur and sublimity of his conceptions, and his uncompromising emphasis on the ethical demands, mark him as an extraordinarily gifted, powerful, and enlightened personality, as perhaps the greatest of all the Hebrew prophets. But the tremendous influence exercised by the book that bears his name is possibly due in even a larger measure to the remarkable prophet of an entirely different type to whom it is supposed that we owe the substance of the appendix (chaps. xl-lxvi). Some of his leading ideas became the heritage of his people and affected the development of religious thought in the Church to an extent that can scarcely be affirmed of any conception ascribed with certainty to Isaiah himself. There is no God but Yahwe, and Israel is His servant; the other gods are nothing but lifeless images; He alone can predict the future and reveal it to His prophets; He is the creator of the world, He has chosen Israel to be His people; through his knowledge and his suffering, which has redemptive value, the Servant of Yahwe, Israel, will establish Yahwe's law to the ends of the earth; the other nations are as nothing to Him; He exchanges them for Israel; He makes them lick the dust under the feet of His people, He overthrows them. These are the thoughts and sentiments repeatedly expressed. It is only necessary to remember the large place held in Judaism, Christianity, and Islam by the doctrines of monotheism, imageless worship, predestination, election for service and privilege, revelation, prophetic infallibility, and the rejection of the nations that know not God, to realize what a strong impact the grouping of these notions, whether original with the prophet or not, into a synthetic view of the world has made on religious thought in later generations. The reference to Isaiah in Ecclesiasticus xlvi. 22-25 shows that the author knew the appended chapters as a part of the book ascribed to the prophet; the Ode to Famous Men in which this reference occurs was probably written by Simeon Siracides, the son of Jesus Siracides, c.150 B.C. The book had practically its present form when it was translated into Greek in the first century B.C.

Bibliography. The earlier literature is indicated, more or less fully, in the introductions

to the Bible given under the article on "Exegesis," in Cheyne, *Introduction to the Book of Isaiah* (London, 1895), and in the commentaries, of which the following may be mentioned: Gesenius (Halle, 1820); Hitzig (Heidelberg, 1833); Luzzato (1856-67); Delitzsch (Leipzig, 1866; 2d ed., 1889); Ewald, in his *Propheten des Alten Bundes* (2d ed., Göttingen, 1867-68); Reuss (Brunswick, 1876); Lagarde, *Semitica*, vol. i (ib., 1878); Trochon (Paris, 1878); Knabebaur (Regensburg, 1887); G. A. Smith (2 vols., London, 1888-90); Hackmann, *Die Zukunftserwartung des Jesaja* (Göttingen, 1893); Driver (2d ed., London, 1893); Skinner (ib., 1896-98); Gressmann, *Ueber die Jes. 56-66 vorausgesetzten zeitgeschichtlichen Verhältnisse* (Leipzig, 1898); Cheyne (New York, 1898); Littmann, *Ueber die Abfassungszeit des Tritojesaja* (Berlin, 1899); Marti (Göttingen, 1900); Duhm (2d ed., Freiburg, 1902); Cramer, *Der geschichtliche Hintergrund von Jes. 56-66* (Berlin, 1905); Whitehouse (London, 1905); Küchler, *Jesais Stellung zur Politik seiner Zeit* (Leipzig, 1906); Sellin, *Das Rätsel des deuterojesaianischen Buches* (ib., 1908); Box (London, 1908); Gray and Peake (New York, 1912).

ISANOMALOUS (īs'ā-nōm'ā-lūs) **LINES** (from Gk. ἴσος, *isos*, equal + Eng. *anomalous*, from Lat. *anomalus*, Gk. ἀνώμαλος, *anōmalos*, uneven, from ἀν-, *an-*, priv. + ὁμαλός, *homalos*, even, from ὁμός, *homos*, same, Skt. *sama*, Goth., OHG. *sama*, Eng. *same*). Lines connecting places whose temperatures, pressures, etc., have equal departures from the average values appropriate to the respective zones of latitude. This term was first introduced by Dove.

ISAR, ē'zār. A tributary of the Danube and essentially the national stream of Bavaria. It rises in Tirol, a few miles north of Innsbruck, and, breaking through the Alps, enters Bavaria, where it flows at first north past the city of Munich and then northeast past Landshut, joining the Danube near Deggendorf (Map: Germany, E 4). Its total length is about 182 miles. Owing to its numerous falls and scarcity of water at certain points, the Isar is of little importance as a commercial waterway and is used mostly for the floating of timber.

I'SARA. The ancient name of the river now known as Isère (q.v.).

IS'ARD, or **IZ'ARD** (Fr., from Catalan *isart*, chamois, perhaps of Iberian origin). The chamois of the Pyrenees (*Rupicapra pyrenaica*), a smaller form, with shorter horns and a more foxy-red color than the typical gemse of the Alps. See CHAMOIS.

ISAROG, ē'sā-rōg'. One of the principal peaks of the island of Luzon, Philippines, situated in the southeastern part of the island in the Province of South Camarines, and occupying the isthmus between the Bay of San Miguel and Lagonoy Gulf (Map: Philippine Islands, D 4). It is an extinct volcano. Its height is 6450 feet; its base is 36 miles in circumference. Numerous streams have their sources on its slopes.

ISAU'RA. See ISAURIA.

ISAURIA, ī-sā'rī-ā (Lat., from Gk. Ἰσαυρία). The ancient name for a region in Asia Minor on the north side of Mount Taurus between Cappadocia, Lycaonia, Cilicia, and Pisidia. The Isaurians were a half-barbarous people, living by plunder. They displayed an indomitable spirit from the earliest times; with their Cilician neighbors they ravaged the Eastern waters with their piracies. In 78 B.C. they were re-

duced to a temporary submission by the Romans, but soon renewed their raids. The Romans endeavored to surround their country with a chain of fortresses. In the third century A.D. the Isaurians formed one nation with the Cilicians, and one of their number proclaimed himself Roman Emperor, but was put to death. A native of Isauria, Zeno, was Byzantine Emperor at the time of the fall of the Western Empire. The capital, Isaura, at the foot of Mount Taurus, the only important city, was a large, rich, and well-fortified place. It was burned, together with its inhabitants, by the Isaurians when unable to withstand the siege of the Regent Perdiccas, in the fourth century B.C. The country was rocky and barren, producing chiefly the vine, which was cultivated with care. Consult: Sterrett, "Wolfe Expedition to Asia Minor," in *American Journal of Archæology*, vol. iii (Baltimore, 1888); Sir W. M. Ramsay, *Historical Geography of Asia Minor* (London, 1890); and the article "Nova Isaura," in *Journal of Hellenic Studies* (ib., 1905).

IS'CA DAMNO'NIO'RUM. See EXETER.

IS'CA SIL'URUM. See CAERLEON.

ISCHIA, ēs'kyä. An island of south Italy, lying between the Bay of Naples and the Gulf of Gaeta, 7 miles southwest of Cape Miseno, the nearest point of the mainland (Map: Italy, D 4). Area, 17½ square miles. The chief industries are the manufacture of straw hats, oil, pottery, bricks, and tile. There are fisheries and shipbuilding. It is of volcanic origin, and is rocky and mountainous throughout, the highest point being the volcano Epomeo (2588 feet). Nevertheless, it is very fertile and is famous for its wine as well as for its exquisite scenery and climate, which make it one of the favorite resorts of tourists. The island is connected by steamers with the mainland. It markets white wine and fruit. It contains the towns of Forio and Casamicciola, the latter being the one most visited by tourists on account of its mineral springs, which are famous. Their populations in 1911 were respectively 5618 and 3434. Ischia, the capital, has a cathedral, a castle, a good harbor, and (1911) 7430 inhabitants. The island was first settled by Greek colonists, who abandoned it on account of its dangerous volcanic activity. It has been a number of times visited by earthquakes, especially in 1883, when the towns of Forio, Casamicciola, and Lacco Ameno were destroyed, and 1700 persons killed. Pop., 1901, 26,891; 1911, 28,000.

ISCHL, ish'l. A celebrated watering place, in the Crownland of Upper Austria, picturesquely situated in the centre of the Salzkammergut, 1533 feet above the sea level, on a peninsula formed by the rivers Traun and Ischl, 28 miles east-southeast of Salzburg (Map: Austria-Hungary, C 3). The fine parish church, built by Maria Theresa, a Kurhaus, a theatre, and a number of fine villas, including an Imperial villa, are the principal attractions. There are salt and sulphur springs, mud, pine-needle, vapor, and other baths, a whey cure, and a hydropathic establishment. Ischl is the summer residence of the Imperial family and is well patronized by the Austrian nobility as well as by foreigners, the annual number of guests being about 25,000. In the vicinity are extensive salt works, from which the brine is conducted to Ischl and there evaporated. Pop. (district), 1910, 28,611.

ISÉ, ē'sä. A central province of Japan, border-

ing on Isé Bay and adjoining Yamato on the west (Map: Japan, E 6). It is included in the Prefecture of Miye and contains several busy towns, the chief of which are Tsu, 36,408 inhabitants; Ujiyamada, 33,627; Yokkaichi, 30,140. Near Yamada are the celebrated Shinto shrines, called by the Japanese *Ryo-dai-jin-gu* (two-great-divine-temples), which rank first among all the shrines of Japan in point of sanctity, but not in point of antiquity. These shrines are annually visited by tens of thousands of pilgrims, who return with charms (consisting of chips of the wood), to be placed in the little shrine which stands on the *Kami-dana* (god-shelf) found in every Japanese house. Every six months there is a great festival, which is supposed to effect the purification of the whole nation from the sins of the preceding six months, and the possessor of a fragment of the cedar wands used in these festivals is protected from misfortune for the next six months. For a full account of the buildings, their arrangements, ceremonies, and the gods here honored, see the paper by Sir Ernest Satow in *Transactions of the Asiatic Society of Japan*, vol. ii (Yokohama, 1874).

ISEGHEM, ē'ze-gēm. A town of Belgium, in the Province of West Flanders, 23 miles by rail from Bruges (Map: Belgium, B 4). It manufactures woolen, linen, and lace. Pop., 1900, 12,172; 1910, 14,158.

ISEGRIM, ē'ze-grīm, **ISENGRIM**, **ISGRIM** (MHG. *Isengrim*, iron helmet). In German animal epos, the name of the wolf.

ISELIN, ēz'län', HENRI FRÉDÉRIC (1825-1905). A French sculptor, born at Clairegoutte, Haute-Saône. He studied under Rude in Paris and speedily made a name for himself by his portrait busts, which are distinguished for strong but sympathetic interpretation of character. He received the cross of the Legion of Honor in 1863. His "Jean Goujon" (1852) is in the Ministry of the Interior; "Picard, Dramatic Author," at the Institute; "Count Morny" and "Baron Poisson," at the Ecole Normale; "President Boileau," at the Luxembourg; "Donizetti," at the Conservatory of Music. Portrait statues by him at Versailles are "King Murat," "Prince Beauffremont," "The Duke de Morny," "Count Rambuteau," "Claude Bernard," and others.

IS'ENBRAS, or **IS'UMBRAS**, SIR. A hero of mediæval stories, originally presumptuous, but humbled by adversity.

ISEO, ē-zā'ō, LAKE, called also LAKE SEBINO (Lat. *Lacus Sevinus*). A lake in Lombardy, north Italy, 15 miles northwest of Brescia (Map: Italy, C 2). It is 605 feet above sea level, 15 miles long, from 1 to 3 miles broad, and its greatest depth is 984 feet. In shape it resembles somewhat the letter S. Through it flows the Oglio, a branch of the Po. In the middle of the lake is the island Siviano, 2 miles long, culminating in Mount Isola, 1965 feet above the sea. The population of the island in 1911 was 1167. Along the east side of the lake, over deep valleys and through lofty galleries, runs the highway from Iseo to Pisogne. North of the lake are to be seen the snow-covered Adamello Mountains. A steamer connects Sarnico and Iseo at the southern extremity of the lake with Pisogne and Lovere at the northern extremity. Iseo, which in 1911 had a population of 3521, markets wine, grain, olives, and chestnuts; it dyes and spins silk; and has several sardine and eel fisheries. There are an-

cient walls and a castle, also a communal theatre. Lovere, which in 1911 had a population of 4197, markets wine and cattle and spins silk. Its handsome church, Santa Maria in Valvendra, built in 1473 and restored in 1547, 1751, and 1888, contains frescoes by Ferramola and old paintings.

ISÈRE, ē'zâr'. A river of southeast France, rising in Savoy, at the west base of Mount Iséran (Map: France, S., K 3). It flows in a general southwesterly direction, forming great loops, through the departments of Savoie, Isère, and Drôme, past Albertville, Grenoble, the most important town on its banks, and Romans, and joins the Rhone 4 miles above Valence. The upper half of its course runs through a beautiful Alpine region around the foot of La Grande Chartreuse. A railroad follows its valley, which is the principal route to the most important Alpine passes south of Mont Blanc, and one of its upper tributaries leads to the Mont Cenis Tunnel. The entire length of the Isère is about 180 miles, for the last 90 of which, from Montmélian, it is navigable, but with difficulty, owing to its rapid flow and shoals and islands.

ISÈRE. A southeastern department of France, bounded on the north by the Department of Ain, on the west by the river Rhone, on the east by the Department of Savoie, and on the south and southeast by those of Drôme and Hautes-Alpes (Map: France, S., K 3). Area, 3179 square miles, of which nearly a half is arable land and a fifth under forest. Pop., 1901, 562,315; 1911, 555,911. The surface is level plateau land in the northwest, but mountainous in the south, where the scenery is very imposing. Pic Lory in the Oisans is 13,396 feet above the sea. The chief rivers, besides the Rhone, are the Isère, from which the department derives its name, and its affluents, the Drac and Romanche. The department is one of the richest in France in mineral products. Mines of iron, lead, silver, coal, and marble are worked. It has large forests and many mineral springs. Manufactures include gloves, silk, and paper. The vine is carefully cultivated in the valleys. Capital, Grenoble.

ISÈRE, COLOMBAT DE L'. See COLOMBAT DE L'ISÈRE.

ISERLOHN, ē'zēr-lōn'. An important manufacturing town of the Prussian Province of Westphalia, situated on the Baar, 15 miles by rail from Hagen (Map: Prussia, B 3). It manufactures chiefly needles, bronze, silver, and nickel wares, furniture, chemicals, wire (large electric cables), and machinery. Cadmium and zinc are dug from beneath the town. It has a Gymnasium and a training school for the metal industry. Pop., 1900, 27,265; 1910, 31,294.

ISERNIA, ē-zēr'nyâ. A city in the Province of Campobasso, Italy, 79 miles north of Naples, 1495 feet above sea level (Map: Italy, E 4). It has fine mineral springs. The ancient Samnite Æsernia was important because of its strong situation on an isolated hill. There are remains of huge polygonal walls and of an aqueduct. Isernia manufactures linen and pottery. It is the seat of a bishop. Pop. (commune), 1901, 9322; 1911, 9284.

ISERT, ē'sērt, PAUL EDMUND (1757-89). A Danish traveler. He went to the possessions of Denmark in Africa (1783) as chief surgeon at Fort Christiansborg, on the Guinea Coast, and three years afterward, because of having cured

the sister of the Ashanti King, he was allowed to make extensive journeyings through the King's domain. He collected interesting details of native life and manners, and also visited the Antilles before returning to Denmark (1788). He was intrusted with the establishment of a colony in Africa and made an attempt upon the island of Rio-Volta, near Malfy; but he removed to Guinea, where he had landed all his accoutrements. There he and most of his company died of fever. The letters he had written to his family and friends were published at Copenhagen (1788) under the title *Reise nach Guinea und den caraibischen Inseln in America*. They are also contained in the Danish collection of Gyldendal (iii, 1790) and translated into Danish, Dutch, Swedish, Spanish, and French.

ISEULT, ê-sōolt', **ISOLD**, **ISOLDE**, î-söld', **ISOND**, î-sönd', **ISOUD**, î-sōöd. A character in mediæval romance. The name occurs in a great variety of forms. 1. Iseult the Fair, wife of Mark, King of Cornwall, who through philtre is made to love his nephew, Sir Tristram. 2. Iseult of the White Hands, a princess of Brittany, the wife of Sir Tristram. See TRISTRAM.

IS'FAHAN'. See ISPAHAN.

I'SHAM, SAMUEL (1855-1914). An American portrait and figure painter, born in New York. He graduated from Yale University in 1875 and studied law, but after being admitted to the bar he turned to art and studied in Paris at the Académie Julian. He exhibited at both Paris salons and at the larger American exhibitions, and became a member of the National Academy in 1906. His most important achievement, however, was his *History of American Painting* (New York, 1905), the best work on the subject. It deserves high praise for its adequate treatment, sympathetic but usually just appreciations, and pleasing style.

ISHBO'SHETH. 1. In the Old Testament, a son of Saul. 2. A character representing Richard Cromwell in Dryden's *Absalom and Achitophel*.

ISHIM, ê-shēm' (Kirghiz *Isel*). A river of Siberia, the most important left affluent of the Irtysh, rising in the eastern part of the Territory of Akmolinsk. It flows in a westerly and then northeasterly direction till it empties into the Irtysh, after a course of about 1000 miles. It is free of ice about 190 days in the year, but is navigable for only 100 miles. It passes the towns of Akmolinsk, Petropavlovsk, and Ishim. The Trans-Siberian Railway crosses the river at Petropavlovsk.

ISH'IMO'TO, SHAROKU (1854-1912). A Japanese soldier. He rose in the military service to the rank of major general in 1898 and lieutenant general in 1904. For many years he had charge of the Tokyo arsenal, but in 1903 he gave up that post to become Vice Minister of War.

ISHMAEL, ish'mâ-ël (Heb. *Yishmā'ēl*, God hears). The elder son of Abraham and reputed ancestor of a number of North Arabian tribes. His story is given in Genesis xvi and xxi. It is said that Sarah, being barren, gave Hagar, her Egyptian handmaid, to her husband Abraham. When Hagar saw that she was with child, she began to despise her mistress, and as a result was harshly treated. This compelled her to seek refuge in flight; but at the advice of an angel, who foretold the birth of a son and also his character, she returned. The child was born, and at the age of 13 was circumcised. By

this time Isaac was already born, and Hagar was driven out again with her son. The provisions given her by Abraham did not last long, and she had given up hope when an angel pointed out a well of water. Ishmael grew and dwelt in the wilderness of Paran, living by hunting. He married an Egyptian woman. The Egyptian origin of both Ishmael's mother and his wife has been questioned by some scholars, who regard the term "Mizrite" as signifying that they came from the region around Wadi el Arish (the Brook of Egypt) or, less probably, a district even farther east.

Scholars generally consider Ishmael, as thus portrayed, the personification of a group of tribes who were akin to the Hebrews and who at one time proved to be serious rivals. In making Ishmael the son of a bondmaid, the tradition reflects the Hebrew point of view, and it is noteworthy that among the Arabs, who regard themselves as descendants of Ishmael, it is Hagar who is the true wife of Abraham, and Ishmael is the favored son. (See HAGAR.) The home of the Ishmaelites was the wilderness to the south of Palestine, as far as the frontier of Egypt. Hebrew tradition accounts for this by having Abraham drive Hagar and Ishmael into the wilderness. Certain phases favorable to Ishmael could not be entirely obscured. Hagar and Ishmael are under the protection of the deity revealing himself at Beer-lahoi-roi. Power is promised to Ishmael and success in war, and his name (El hears) also points to the excellent terms of his relationship to the deity. In the representations of Hebrew writers a considerable section of central and northern Arabia is occupied by Ishmaelites. Their spread over this large territory is indicated in tradition by making Ishmael the father of 12 sons (Gen. xxv. 13-18). Hence we find among the Ishmaelites representatives of both types of the Arab—the fierce Bedouin and the Arab on the road to civilization, even engaging in commerce. According to Gen. xxxvii. 25, Ishmaelitic merchants carrying spices from Gilead bring Joseph to Egypt. (See JOSEPH.) This connection of Ishmaelites with Egypt or the territory immediately east of Egypt, to which name the Mizraim seems to have been also attached, is also introduced into the narrative which records that Hagar was an Egyptian and makes Ishmael also marry an Egyptian woman. It should, however, be added that the term Ishmaelite, like the term Midianite, comes to be used vaguely by Old Testament writers, and no conclusions are to be drawn from such usage as to genealogies of Arabic tribes. In a general way it was recognized that the clans of Arabia and the clans of Palestine were closely akin, and this was represented in tradition by tracing them back to the same ancestor, just as in another stratum of tradition Hebrews and Edomites are traced back to Jacob and Esau, who unite in the person of Isaac. See EDM; JACOB; ISAAC; ESAU.

ISHPEMING, ish'pê-mīng. A city in Marquette Co., Mich., 15 miles west of Marquette, on the Duluth, South Shore, and Atlantic, the Lake Superior and Ishpeming, and the Chicago and Northwestern railroads (Map: Michigan, B 2). It is in the great Lake Superior mineral region and is the centre of the iron-mining district of the Marquette Range. Its interests are principally in iron mining, but gold and marble also are found in this vicinity and there are lumber mills. Settled about 1857, Ishpeming

was chartered as a city in 1873. Among the noteworthy features are the Ishpeming and Lindgren hospitals, a Carnegie library, and Lake Michigamme, a summer resort. The government is administered, under a charter of 1891, by a mayor, annually elected, and a common council, of which the executive is a member. The waterworks are owned by the municipality. Pop., 1900, 13,255; 1910, 12,448.

ISHTAR, ish'tär. The name of the chief goddess worshiped by the Semitic Babylonians, the Assyrians, and apparently also by the Guttians and the Lulubians. Either because of the meaning of the name, which is unknown, or the important position gained by this deity, Ishtar became a generic name for goddess. It is uncertain whether she was originally the local numen of some Akkadian community in Babylonia or a goddess worshiped by the Akkadians before they invaded this country. The latter is suggested by the fact that the name, somewhat differently pronounced, is found in all parts of the Semitic world; *Athtar* in Arabia, *Astar* in Abyssinia, *Atar* among the Aramæans, *Ashtar* in Moab, *Ashtart* in Canaan and Israel. But it has been maintained that the Ishtar cult is likely to have spread from Babylonia in different directions. The circumstance that the sex varies, so that *Athtar*, *Atar*, *Astar*, and probably *Ashtar* represent a male deity, *Ashtart* a female, and *Ishtar* either a male or a female, seems to point to an object that could be conceived of as either. Such an object is the planet Venus, which, like sun and moon, is now male, now female, and with which the Arabian *Atarsamain* and the Canaanitish *Ashtart* are closely related as *Ishtar*. In the absence, however, of a satisfactory etymology it is impossible to determine whether *Ishtar* was originally a designation of Venus, characterizing it, perchance, as the one that "musters" the heavenly hosts, or the name of a deity concerned with the fertility of the soil and of animal and human life, only subsequently identified with the planet. In either case the name seems to have been given by the Akkadians to Sumerian goddesses like *Nanai* of Erech (q.v.), *Anunit* of Akkad (see ACCAD), and others. It probably supplanted a *Nina* of Nineveh and some local goddess of *Arbela*. *Ishtar* of Erech was especially connected with the evening star, while *Ishtar* of Akkad was connected with the morning star. The latter was regarded as male (*zikarat*), in distinction from the former as female (*zinnishat*), which shows the vacillation as to sex within Babylonia itself. The goddess of Erech is represented as unmarried, but having a number of lovers, the most famous of them *Tammuz*, to whom she brings death and destruction. She is surrounded by priestesses of different grades, who symbolize their devotion to her service by rites of an obscene character. She also had male hierodules. Withal she was a goddess of a violent type, who encouraged her subjects in the fray and punished those who disobeyed her with fatal diseases. This warlike side of her nature is emphasized by kings like *Hammurapi* (2124-2081 B.C.), who appeared prominently in the rôle of conquerors. *Ishtar* of *Arbela* seems to have preserved more of the character of the stern virgin goddess of the chase and of war, while *Ishtar* of Nineveh was more of a goddess of love. The former gave, through her prophets and prophetesses, oracles to the Assyrian kings.

In the theological system Ishtar is represented as the daughter of Anu or Enlil and as the sister of Shamash, forming a part of the triad Shamash, Sin, and Ishtar, but occupying a place after the sun god and the moon god. By virtue of this pre-eminence in the heavenly host, she is known as the queen or mistress of heaven. Besides being identified with the planet Venus, she at times appears as the goddess representing the star Sirius; and as both Shamash and Sin were regarded in Babylonia and Assyria as male deities, she became the great mother goddess, the mother of mankind. In the representations of the goddess both sides of her nature, the destructive and the life-giving, are brought out. Among the Assyrians she is pictured generally as clad in flames, with a quiver hanging to both sides, a bow in one hand, and a sharp sword in the other; while in Babylonia the type that early became popular was that of the naked goddess, with prominent breasts and the organs of generation strongly emphasized, or the mother with the child at her breast. At Ras el-Ain in Mesopotamia a veiled Ishtar has been found.

Meyer, *Geschichte des Altertums* (3d ed., Stuttgart, 1913). See **ASTARTE**.

ISIAIC (ī'sī-āk) **TABLE**. The name formerly given to a bronze plate, 4 feet, 8 inches long and 3 feet wide, on which are depicted three rows of Egyptian deities inlaid in niello and silver. It seems to have been found in Italy and was sold by a soldier of the Constable de Bourbon to a locksmith, who sold it in 1527 to Cardinal Bembo. It excited much curiosity and gave rise to considerable discussion before Egyptologists had learned to decipher hieroglyphics. It is now preserved in Turin, but is almost forgotten, being considered as at best an imitation dating from the Roman period.

ISIDORE OF CHARAX, kā'rāks (Lat. *Isidorus Characenus*). A geographer of the first century A.D., born at Charax, on the Tigris, the author of *Travels in Parthia*, often quoted by Athenæus (q.v.), and of an extant work on a similar subject, entitled *Σταθμοὶ Παρθικοί*, which has survived. It is better known under its Latin title, *Mansiones Parthicae*, and is published, with a Latin translation, in the series of *Scriptores Geographici* (Paris, 1839) and by Carl Müller, *Geographici Græci Minores*, vol. i (Paris, 1855).

ISIDORE OF SEVILLE, sê-vīl', **SAINT** (?-636). An archbishop of Seville and one of the most distinguished ecclesiastics of the seventh century. He was born about 560 (or 570), probably at or near Cartagena, where his father, Severianus, had been prefect. Two of his brothers, Fulgentius and Leander, were bishops, the first of Astigi, the second of Seville; Isidore succeeded the latter in 600. The episcopate of Isidore is rendered notable by the two half-ecclesias-

tical, half-civil councils of Seville in 619 and of Toledo in 633, which were held under his presidency, and the canons of which may almost be said to have formed the basis of the constitutional law of the Spanish kingdoms down to the great constitutional changes of the fifteenth century. The decrees of councils and other Church laws anterior to his time, called by his name, are not from his hand. He died at Seville, April 4, 636. Isidore was the most learned man of his time, and his works are in the most various departments of knowledge—theological, ascetical, liturgical, scriptural, historical, philosophical, and scientific. The most complete edition is that of Arevaio (7 vols., Rome, 1797-1803), reprinted with addition of the canons and liturgy in Migne, *Patrologia Latina*, lxxxii-lxxxvi. We are indebted to Isidore for many fragments of Greek and Latin authors, among the number several of whom hardly any other remains have been preserved. In 1722 Benedict XIV made him one of the doctors of the Church. His *Sentences*, largely from Augustine and Gregory the Great, suggested Peter Lombard's *Sentences*, and his *Etymologies*, in 20 books (ed. by Otto, Leipzig, 1833), and by W. M. Lindsay (2 vols., Oxford, 1911), treating of the terms used in all the departments of knowledge in his time, was the great mediæval encyclopædia. Consult F. J. G. La Porte du Theil, "Notice de l'ouvrage d'Isidore de Seville sur les origines," in *Bibliothèque Nationale, Notices et Extraits des Manuscrits*, vol. xiv (Paris, 1798), and Ernest Brehaut, *An Encyclopedist of the Dark Ages* (New York, 1912).

ISIDORIAN DECRETALS. See **PSEUDO-ISIDORIAN DECRETALS**.

ISIDORUS (Lat., from Gk. Ἰσίδωρος), **SAINT** (c.370-c.440). A monk, often called *Pelusiota* or of *Pelusium*, from the monastery of which he was abbot. He was born probably at Alexandria, and tradition makes him a pupil of Chrysostom, but this is not certain. He is best known by his letters, of which about 2000 remain. They contain a mass of exegesis, often valuable in itself and always of importance for the construction of the early history of interpretation. They are edited in Migne, *Patrologia Græca*, vol. lxxviii (1860). Consult H. A. Niemeyer, *De Isidori Pelusiotæ Vita, Scriptis et Doctrina* (Halle, 1824), and P. B. Glück, *Isidori Summa Doctrina Moralis* (Wurzburg, 1848).

ISIN, DYNASTY OF. See **BABYLONIA, History**.

ISINGLASS, ī'zīn-glās (from MDutch *huysenblas*, Dutch *huisblad*, Ger. *Hausenblase*, isinglass, sturgeon bladder, from MDutch *huysen*, Dutch *huizen*, OHG. *hūss*, Ger. *Hausen*, sturgeon + MDutch *blas*, Dutch *blad*, OHG. *blāsa*, Ger. *Blasen*, bladder, dialectic Eng. *blaze*, pimple; associated by popular etymology with Eng. *glass*). The dried swimming bladders of several varieties of fish. The amount of gelatin in isinglass is from 86 to 93 per cent and even more. It is prepared by tearing the air bladder or sound from the back of the fish, from which it has been loosened by striking several blows with a wooden club, and washing in cold water. The black outer skin is removed with a knife, again washed, and spread on a board to dry in the open air, with the white shiny skin turned outward. To prevent shriveling or shrinking, the bladders must be fastened to the drying board. The best quality of isinglass comes from

sounds that are dried in the sun. After drying, the sound is again moistened with warm water, and the interior shiny skin is removed by hammering or rubbing. Finally, it is rolled between two polished iron rollers. If it is desired to extract the gelatin, the isinglass, while still in a moist condition, is immersed in a solution of sulphuric acid, in which it swells up to a colorless jelly which later is dissolved in warm water. On cooling and drying, a clear and colorless gelatin is obtained. The chief places of manufacture are Russia, Canada, Brazil, the West Indies, the East Indies, and Manila. The Russian varieties, which are supposed to be the best on the market, are made chiefly from the sturgeon; but elsewhere the bladders of cod, hake, and other fish are also used. Isinglass should be of a bright or light-yellow color, thin and transparent, and without any odor or taste. The latter naturally indicates the presence of impurities. When steeped in cold water and dissolved by heating, there should remain but a very small residue, and the jelly which is formed should be clear and colorless. Isinglass may be used for the same purposes as gelatin (q.v.). It is employed chiefly for clarifying beer and wine, for culinary purposes (in jellies and soups), for making cement, etc. The adhesive quality of court plaster is due to isinglass.

ISIS (Gk. Ἴσις, Egyptian, *'Ise-t*, a name of obscure etymology). An Egyptian goddess, the daughter of Seb (Earth) and Nut (Heaven) and the sister and wife of Osiris (q.v.). Herodotus identified her with Demeter and described her as the greatest of the Egyptian goddesses. After the treacherous murder of her husband by his brother Set (q.v.), Isis fled to the swamps of the Delta, accompanied by seven scorpions. On one occasion the mistress of a house in which she sought shelter, fearing the scorpions, turned the goddess from her door, and the scorpion Tefen crept into the house and stung the son of the woman so that he died. But Isis, moved by the woman's grief, laid her hand upon the child and restored him to life. Shortly after this Isis gave birth to her son Horus, whom she placed in the charge of Buto, the goddess of the north. Buto guarded him carefully, but in spite of all her care he was stung by a scorpion, and his mother found him lying lifeless on the ground. At her prayer the sun god Rê stopped his ship in midheaven and sent down Thoth, the god of wisdom, who soon brought Horus back to life. Leaving her young son in the Delta, carefully hidden by Buto from the malevolence of his uncle Set, Isis next went through the world seeking the body of her husband, Osiris, which, inclosed in a chest, had been borne out to sea by the Nile. In her wanderings she was accompanied and protected by Anubis (q.v.), the son of Osiris by his sister Nephthys (q.v.). After a long search she found the body of Osiris. The chest inclosing it had drifted ashore near Byblos, on the Phœnician coast, and had become embedded in the trunk of a great tree which had grown around it. The King of the country, ignorant of the presence of the chest, had caused the tree to be cut down and made of it a pillar for his house. Isis entered the King's service as nurse to his child and endeavored to confer immortality on the infant. Every night she burned away his mortal part with celestial fire, while she herself, in the form of a swallow, flew round the pillar lamenting her husband. One night the Queen, Astarte, came upon her while

thus engaged, and crying out in terror at the sight of the child surrounded with flames, destroyed his chance of immortality. Isis now revealed herself, drew the chest from the pillar, and conveyed the body of her husband by ship to Egypt, where she hid it and went to visit her son. Set, however, found the body of Osiris and tore it to pieces, which he scattered in every direction. Learning of this misfortune, Isis took a boat, and seeking her husband's scattered members throughout the land, found all the pieces except the phallus, which had been eaten by fishes. Wherever she found a portion of the body she buried it, and in aftertimes each of these spots was revered as the burial place of Osiris. His head, e.g., was buried at Abydos, and his backbone at Busiris, in the Delta. Isis reared her son Horus in concealment, and when he reached mature age he defeated Set and ascended his father's throne. In the legends of the sun god Rê, Isis is represented as possessing special skill in magic and in the healing art; in this character, as the "great mistress of enchantments," her aid is frequently invoked in the Egyptian magical texts. Her sacred animal was the cow, and she is sometimes represented with the head of a cow, though more frequently she wears only the horns. She is also very commonly depicted as a woman wearing upon her head a throne—the ideogram used in writing her name. In later times she is often represented as seated and holding the infant Horus to her breast.

Isis was very generally worshiped throughout Egypt, but special honor was paid to her at Abydos and Busiris. In later times the centre of her cult was in Philæ (q.v.), where magnificent temples were built to her. Here she was still revered as late as 453 A.D., long after paganism had been suppressed in other parts of the land by edict of Theodosius, her special worshipers being the savage Blemmyan tribes who constantly menaced the safety of Egypt. From Alexandria, where the worship of the triad Serapis (q.v.), Isis, and Harpocrates (q.v.) overshadowed that of all other Egyptian deities, the cult of the goddess spread throughout the whole Hellenic world, and temples were erected to her in many places. It was introduced into Rome in the time of Sulla (86 B.C.) and soon became fashionable, but was brought into ill repute by the licentiousness of its priests, and the government made occasional attempts to suppress it. Under the Empire the cult of Isis became very popular, and Domitian, Commodus, and Caracalla were among the priests of the Egyptian goddess. At the opening of spring (March 5) both Greeks and Romans held a festival in which a ship was carried in solemn procession in honor of Isis. In the Roman Calendar the day of this festival was designated as *Navigium Isidis*.

ISIS. A name sometimes applied to the upper course of the English Thames (q.v.).

ISIS AND SER'APIS, TEMPLE OF. A great temple in ancient Rome, situated on the Campus Martius near the baths of Agrippa. The temple itself, a pure Egyptian structure, was built of material transported from the Nile. It was inclosed by a peristyle dating from Domitian's time and closely resembling the inclosing wall of his forum, and was approached by a sacred avenue, on the sides of which many great works of Egyptian art were set up. At each end of the avenue stood a gateway with two obelisks, of which one now stands in the Piazza della Rotonda, one in the Villa Mattei, and one in the Piazza dei Cinquecento. Many important works of art have been discovered on the site of the temple, chief among them the Tiber statue, in the Louvre, and the Nile group, both of which were carried away by the French in 1803. The Nile was returned after Napoleon's fall and now stands in the Vatican Museum. Other important finds were the reclining statue of the Ocean, in the Naples Museum, two sphinxes, various portrait statues, relief columns, and other architectural remains. See SERAPEUM.

ISKANDER, è-skän'dēr. 1. The Turkish form of Alexander. 2. The nom de plume of Alexander Herzen (q.v.), a Russian politician and publicist.

ISKANDERUN, è-skän'dē-rōn'. A city of Turkey in Asia. See ALEXANDRETTA.

ISLA, ès'là, JOSÉ FRANCISCO DE (1703-81). A Jesuit preacher and satirist, born in Villavides, in the Kingdom of León, Spain. He was a man of acute wit and intense humor. He ridiculed a royal pageant (held, in honor of the accession of Ferdinand VI, at Pamplona in 1746) in his *Triunfo del amor y de la lealtad: Dia grande de Navarra*, an ironical eulogy so artfully disguised that at first it was regarded as an honest adulation, but upon its burlesque character becoming known he was compelled to leave the city. His most important satire was the *Historia del famoso predicador Fray Gerundio de Campazas, alias Zotes (1758)*, in whose adventure he held up to public contempt the ignorance and audacity of the itinerant friars of the time and ridiculed unmercifully their debased pulpit oratory. It was condemned in 1760 by the Inquisition on the clamor of the lower clergy, but the second part appeared surreptitiously in 1768. Of Isla's other productions may be mentioned: the *Juventud triunfante (1727)*, a work written in collaboration with Luis de Lovada, and one in which the satirical aim is most cunningly hidden; the *Cartas de Juan de la Encina (1784)*, which assails the charlatanry of Spanish physicians; his *Cartas familiares (2d ed., 1790)*; the *Sermones (1792)*, not so attractive as his satirical treatment would lead one to expect, but amply justifying his reputation as an effective preacher. Apart from the publication of the *Fray Gerundio*, Isla owes his chief fame to his translation of the picaresque novel of Le Sage, the *Gil Blas*. The text appeared in 1783, but it is now more widely read in the considerably modified arrangement by Evaristo Peña y Martín, which appeared in 1828. Consult: De Calas, *Vida de J. F. de Isla (Madrid, 1803)*; selections from his works in *Biblioteca de autores Españoles, vol. xv (Madrid, 1850)*; Policarpo Mingote y Tarrazona, *Varones ilustres de la provincia de León (León, 1880)*; Claretie, *Lesage romancier (Paris, 1890)*;

Cian, *L'Immigrazione dei Gesuiti Spagnuoli letterati in Italia (Torino, 1895)*; Alonso Cortés, *El supuesto autor del "Fray Gerundio" in Miscelánea Vallisoletana, pp. 39-47 (Valladolid, 1912)*.

ISLA DE LÉON, ès'là dà là-ōn'. An island in the Bay of Cadiz. See SAN FERNANDO.

ISLA DE PINOS. See ISLE OF PINES.

ISLA DE VIEQUES. See VIEQUES.

ISLAM, is'lam or iz'lam, Ar. pron. is-läm' (Ar., submission, from salima, to be safe). The name used by Mohammedans as the designation for their religion. It may be traced back to Mohammed. Literally, it means a causing to be sound or safe, or that which makes safe, but is commonly interpreted to mean complete and entire submission of body and soul to God (Allah), His will and His service, as set forth in the articles of faith, the commands and ordinances believed to have been revealed by God to His Prophet Mohammed. The more usual designation of the religion among Western peoples is Mohammedanism (q.v.).

ISLAMABAD, is-lä'mä-bäd'. A city of British India. See CHITTAGONG.

ISLAND (AS. iglond, eglond, Icel. eyland, Ger. Eiland, from AS. ig, eg, Icel. ey, OHG. ouwa, Ger. Au, island; connected with AS. ea, Goth. ahwa, OHG. aha, Lat. aqua, water + AS., Icel. land, OHG. lant, Ger. Land, land; connected with Ir. lann, land, Welsh llan, land, OChurch Slav. lendina, waste land, OPruss. lindan, valley; influenced by popular etymology with the unrelated isle). A relatively small body of land entirely surrounded by water. Primarily it differs from a continent only in size, although continents have a physical and biological individuality which islands do not possess. Islands are formed in various ways. Those of continental character are separated by short stretches of usually shallow water from the mainland with which they have a geological similarity. They may be formed either by marine erosion or by subsidence of the coast beneath ocean level. The small islands off Norway, Scotland, Maine, and Patagonia are to be regarded as the remnants of hills and mountains, of which the basal portions and intervening valleys have been "drowned" by a general subsidence. The British Isles, Sicily, and Japan represent larger land masses, whose former union with the mainland is indicated by submarine banks; Madagascar, on the other hand, is separated by a deep channel from the African coast. Another type of continental islands owes its origin to the constructive work of rivers, such as the islands at the mouth of the Nile and the Mississippi (see DELTA), or to ocean currents, such as the sand bars along the Atlantic coast of the United States. Islands of coral formation are usually low and limited to the warmer regions of the oceans. (See CORAL ISLAND AND CORAL REEF.) Volcanic islands, consisting of active or extinct lava cones, occur in great numbers in the Pacific and Indian oceans, while in the Atlantic they are represented by St. Helena, Ascension, and the Azores. Submarine eruptions leading to the construction of cones above sea level have taken place in recent times. The island of Johanna Bogoslava in Alaska appeared in 1796 and four years later had grown to a height of 3000 feet. In 1907 a new volcano, known as McCulloch Peak, was blown up, and its place once more oc-

cupied by the sea. Another noted instance is Graham Island (Ferdinanda) in the Mediterranean, which was thrown up in 1831, reaching a height of 200 feet and with a circumference of 3 miles. This island soon disappeared. Oceanic islands—i.e., those situated far from continental lands—with but few exceptions, are of volcanic or coral growth.

Islands are subject to changes of form and contour by various physical agencies. They may be gradually consumed, owing to the erosive action of waves and currents, until their former existence is made known only by a submarine platform. Helgoland, in the North Sea, has suffered thus for many centuries; and the eastern coast of England is wasting at a rapid rate. Volcanic islands are liable to destruction by violent explosions, such as that occurring at Krakatoa in 1883. Under certain conditions islands lying near the coasts of continents may be united to the latter; the peninsula of Shantung, once insulated, has been connected with the mainland by the growth of the Hoang-ho delta.

Island Flora. The floras of isolated oceanic islands, such as the Hawaiian Islands and Galapagos Islands, are very different from the floras of the continents. These differences in most cases affect not only species but also genera, and in one or two cases there are even distinct families which are confined to oceanic islands; in fact, island floras are the most endemic (see ENDEMISM) of all floras. The reason for these phenomena is doubtless that islands have long been isolated from continents, and the progress of evolution has been peculiar to the various islands themselves and uninterrupted by outside invasions. Not only do islands show peculiar floristic types, as has been shown, but they are also rich in certain plant families, among which the ferns have a predominant importance. It is almost certain that the abundance of ferns on oceanic islands is due to the much greater ease of migration that ferns possess as compared with seed plants, by reason of the light spores that can be carried for long distances in the wind. Islands also have a large number of plants whose seeds are scattered by birds, by water currents, or by man.

Island Fauna. For the general characteristics of the fauna of islands, see ISOLATION. Examples of individual peculiarities in island faunas will be found under GALAPAGOS ISLANDS; ETC.

ISLAND, FLOATING. See FLOATING ISLAND.

ISLAND CITY, THE. A name for Montreal.

ISLAND NUMBER TEN. An island which existed, until shortly after the Civil War, in the Mississippi River, about 40 miles below Columbus, Ky. (near the boundary line between Kentucky and Tennessee), thus named from its position in the series of islands below Cairo, Ill. After the first Confederate line in the West had been broken by the capture of Fort Henry and Fort Donelson (q.v.), the garrison at Columbus, Ky., constituting the Confederate left flank, was withdrawn to New Madrid (q.v.) and Island

Number Ten and placed in command of General McCown, who was later replaced by General Mackall. Early in March, 1862, a Federal army under General Pope and a Federal fleet under Commodore Foote advanced against these positions. On the 16th New Madrid surrendered to Pope, who then marched about 25 miles down the river, and with the assistance of transports which had been brought through a laboriously constructed channel, across a peninsula formed by a loop in the Mississippi, from a point above the island to New Madrid, succeeded in attaining the Confederate rear at Tiptonville, the Confederate batteries along the east bank having been previously silenced by the gunboats *Carondelet* and *Pittsburgh*, which, under Captain Walke and Lieutenant Commander Thompson, had successfully run by the island on April 3 and April 7 respectively. Meanwhile Foote's fleet had kept up a fairly continuous though ineffective bombardment. The Confederate garrison, which numbered between 6000 and 7000, threatened in front and rear, and completely cut off from retreat by the Federal forces and impenetrable swamps, finally surrendered on April 7; many guns and stores were also captured. The Federal loss was less than a dozen men. The cutting of the channel across the peninsula formed by the loop in the river required great labor and considerable engineering skill, while the running of the batteries by Henry Walke (q.v.) was not only one of the most dramatic deeds of the war, but completely overcame the Confederate defense of this position. After the war the old Island Number Ten was gradually washed away by the river, and a new one was slowly formed on the opposite shore. Consult A. T. Mahan, *The Gulf and Inland Waters* (New York, 1898), and Johnson and Buel (eds.), *Battles and Leaders of the Civil War*, vol. i (ib., 1901).

ISLAND OF SAINTS (Lat. *Insula Sanctorum*). A name given to Ireland in the Middle Ages, from her great number of ecclesiastics and missionaries.

ISLAND OF THE SEVEN CITIES. A legendary island settled by seven bishops and refugees from Spain and Portugal at the time of the Moorish Conquest.

ISLANDS OF THE BLESSED (Lat. *Fortunatæ Insulæ*, Gk. *Αἱ Τῶν Μακάρων Νῆσοι*, *Hai Tōn Makarōn Nēsoi*). According to an old Greek myth, certain islands situated towards the edge of the western ocean, where was the abode, not of departed spirits, but of certain favored mortals rescued from death by the gods. Here life was most easy, the climate soft and springlike, and there was abundance of all things. Homer does not refer to these islands, but speaks of the Elysian Plain, a place with like characteristics (*Odys.*, iv, 563; see ELYSIUM). Hesiod, *Works and Days*, 168, and Pindar, *Ol.*, ii, with later poets, speak of the islands. Later authors identified the islands with the Canaries, lying outside the Pillars of Hercules, in the Atlantic Ocean.

ISLAY, ī'lā. A Scottish island, one of the Inner Hebrides, included in Argyllshire, 15 miles west of the peninsula of Cantire, and southwest of the island of Jura, from which it is separated by the Sound of Islay (Map: Scotland, B 4). Area, 220 square miles, of which about 22,000 acres are under cultivation. The north of the island is hilly, and along the east shore runs a ridge rising from 800 to 1400 feet in

height of an ancient schistose character similar to the rocks of Argyll and Donegal of north-western Ireland, indicating a previous connection. The central and west districts are undulating or flat, with great peat deposits. Whisky distilling is the principal industry. Pop., 1901, 6857; 1911, 6274.

ISLE'BIUS, MAGISTER. A name sometimes applied to Luther's disciple Johann Agricola (q.v.).

ISLE DE RHONDE. See GRENADINES.

ISLE OF LADIES. A poem attributed to Chaucer, which first appeared in Speght's edition (1597) of Chaucer. It is also called "Chaucer's Dream."

ISLE OF MAN. See MAN, ISLE OF.

ISLE OF PINES, or Sp. ISLA DE PINOS, ē'slà dâ pē'nòs. An island belonging to Cuba, situated about 40 miles southeast of the south coast of the Province of Pinar del Río (Map: Cuba, C 5). It is almost circular in outline, with a diameter of about 40 miles and an area of 840 square miles. It is hilly and well forested with pine, cedar, and mahogany in the northern part, while the southern consists of a low marsh, similar to the Everglades of Florida, covered with mangrove thickets and presenting a luxuriant wealth of native flora and fauna. The soil of the northern part is sandy and favorable to the growth of pineapples and potatoes, the latter being of excellent quality. There are some mineral deposits, of which only the marble quarries are exploited. Cattle raising and the production of citrus fruits are the chief industries. Since the Spanish-American War the island has been exploited by Americans. It has been Americanized to a large extent, and unsuccessful attempts have been made to bring it under the jurisdiction of the United States. Pop., 1899, 4076; 1907, 3276, chiefly concentrated in the town of Santa Fé and the capital, Nueva Gerona, situated near the north coast.

ISLE OF THANET. See THANET, ISLE OF.

ISLE OF WIGHT. See WIGHT, ISLE OF.

ISLES, LORDS OF THE. A line of Scottish chiefs, celebrated in poetry and romance. Sir Walter Scott, in his notes to *The Lord of the Isles*, speaks of Somerled as Lord of the Isles; but it is probably more correct to speak of him as King of the Isles. The later lords of the isles traced their descent from him. He appears prominently in Scottish history in the middle of the twelfth century, during the reigns of David I and his grandson and successor, Malcolm IV. The race to which he belonged is uncertain; probably, like most of his subjects, he was of mixed descent, Norwegian and Celtic. One of his descendants, Angus of the Isles, gave his fealty to Bruce when the latter was most hard

pressed at the beginning of his reign, receiving him into his castle of Dunaverty, and afterward fought under the Great King at Bannockburn. This chief is the hero of *The Lord of the Isles*, but his name, for the sake of euphony, was changed to Ronald. John Macdonald, first Lord of the Isles, son of Angus Og, received a grant from Edward Baliol of Mull, Skye, Isla, Giblia, Kintyre, Knapdale, and other lands. He married Margaret, daughter of Robert II, founder of the Stuart dynasty. During the troubled and disastrous reign of David II, John of the Isles was able to maintain himself in a state of practical independence of the Scottish crown. He was at last, however, compelled to submit. He met David at Inverness in 1369 and gave hostages for his fidelity. He died about 1386. The most powerful of this race was Donald, eldest son of John. He set the kings of Scotland at defiance and made treaties as an independent sovereign with the kings of England. He married Mary Leslie, daughter of the Countess of Ross. Mary's brother, Alexander, Earl of Ross, by his marriage with the daughter of the Regent Albany, left an only child, who became a nun. Donald claimed the earldom in his wife's right, and when his claim was refused by the Regent he prepared to maintain it by force. Taking possession of Ross, he marched at the head of a large army from Inverness, through Moray and Aberdeenshire, and threatened to destroy the burgh of Aberdeen. Donald fought a drawn battle at Harlaw with the Earl of Mar on July 25, 1411, but was compelled to retreat and renounce his designs. He died about 1420 and was succeeded by his son Alexander. John, son of Alexander, in 1462 made a treaty with Edward IV of England, by which he promised to assist the English monarch in the conquest of Scotland.

Throughout their history the Lords of the Isles plotted against the Scottish crown and were a constant menace to the tranquillity of the realm. The last regular lord was John, who forfeited his title in 1493. After him there were several spurious claimants, and at least one who was recognized for a time as Lord of the Isles. Consult: Skene, *Celtic Scotland*, vol. iii (Edinburgh, 1880); Lang, *History of Scotland*, vol. i (ib., 1900); Skene, *Highlanders of Scotland*, edited by Macbain (Stirling, 1902).

ISLES OF SHOALS. A cluster of seven barren, rocky islands and several rocks and ledges, in the Atlantic Ocean, off the coast of New Hampshire, from 5 to 6 miles southeast of Portsmouth. The two largest are Appledore, containing 400 acres, and Star, 150 acres. On these are large hotels chiefly for summer guests, who resort there for the sea air, boating, and fishing. A steamer runs daily from Portsmouth. On White Island is a revolving light 82 feet above the sea. These islands are inhabited by a few fishermen. Consult: J. S. Jenness, *The Isles of Shoals: An Historical Sketch* (New York, 1873); C. L. Thaxter, *Among the Isles of Shoals* (Boston, 1901); id., *My Island Garden* (ib., 1904); Rufus Emery, "The Isles of Shoals," in *Magazine of History*, vol. xiii (New York, 1911).

ISLES OF THE BLESSED. See ISLANDS OF THE BLESSED.

ISLETA, ē-slā'tâ. An important pueblo of Tanoan stock, situated on the west bank of the Rio Grande, a few miles below Albuquerque, N. Mex. It ranks third among the pueblos,

coming after Zuñi and Laguna, with a population of 956. As in all other pueblos, the people are peaceable, industrious, and self-supporting, raising good crops of corn, vegetables, and fruit, all produced from an arid soil by aid of native irrigation.

Isleta del Sur is the name of a small pueblo on the north bank of the Rio Grande, about 14 miles below El Paso in Texas. It was originally established under mission auspices by refugees from the original Isleta, above noted, who accompanied the Spanish army on its retreat from New Mexico in the Pueblo revolt in 1680. Although considerably Mexicanized, the inhabitants still keep their Indian form of government, their dances, and foot races; and four or five persons remember some of the language. See PUEBLO; TANOAN STOCK.

ISLE VERTE, ēl vērt. A town, subdistrict, island, and river of Quebec, Canada. The town is the capital of Temiscouata County and stands on the right bank of the St. Lawrence at the mouth of the Isle Verte River and opposite the Isle Verte (Map: Quebec, J 2). It has a station on the Intercolonial Railway. The inhabitants are mostly French-Canadians. Pop. of census subdistrict, 1901, 2256; 1911, 2169.

ISLEWORTH, ī'z'l-wērth. A suburb of London. See HESTON AND ISLEWORTH.

ISLINGTON, īz'ling-ton. A metropolitan borough of London, in Middlesex, comprising four parliamentary divisions, 2½ miles north of St. Paul's (Map: London, D 7). In Liverpool Road is the Royal Agricultural Hall with a capacity of 50,000 persons, in which the national horse and cattle and other great shows are held. Here also are located Pentonville and Holloway prisons and the London School of Divinity. Pop. of borough, 1901, 334,991; 1911, 327,423.

IS'LIP. A town in Suffolk Co., N. Y., on Great South Bay, 43 miles east of New York City, on the Long Island Railroad (Map: New York, B 2). It is about 12 miles in length and 10 miles in width, comprising a number of villages. Islip is a summer resort with many costly residences. Great South Bay, attractive for sailing, is frequented also at other seasons for fishing and hunting. Within the limits of the town are the Central Islip State Hospital, St. Joseph's Convent, and a fish hatchery. Other points of interest are the Fire Island Lighthouse, 166 feet high, and Fire Island State Park. Blue Point oysters are shipped in great quantities. The government is vested in a supervisor, elected biennially, and a town board, made up of the justices of the peace, the town clerk, and the supervisor. Pop., 1900, 12,545; 1910, 18,346.

ISLY, DUC D'. See BUGEAUD DE LA PICONNERIE, THOMAS ROBERT, DUC D'ISLY.

ISMAIL, ēs'mā-ēl'. Capital of a district of the same name in the Government of Bessarabia, Russia, situated on the north bank of the Kilia, an arm of the Danube, and on the Rumanian frontier (Map: Russia, C 5). It carries on a considerable trade in grain and other agricultural products and has a customhouse. Its position on the frontier adds greatly to its commercial importance. Its manufacturing establishments include a large number of flour mills, brickkilns, a crockery kiln, tannery, etc. Steamships connect it with Odessa and other Black Sea and Danube ports. Pop., 1897, 33,607; 1911, 35,708. Ismail is mentioned in the sixteenth century as a fortress and was of great strategi-

cal importance under the Turkish rule. In 1632 it was sacked by the Cossacks. It was taken and destroyed by Suvaroff in December, 1790; came into the possession of Russia in 1812; was assigned to Moldavia by the Treaty of Paris, 1856, and transferred to Russia again by the Berlin Congress of 1878.

ISMAILIA, ēs'mā-ē'lē-ā. A village of Africa. See GONDOKORO.

ISMAILIA. A town in the Isthmus of Suez, on the Suez Canal.

ISMAILIANS, ēs'mā-ē'lī-anz. See MOHAMMEDAN SECTS.

ISMAIL PASHA, ēs'mā-ēl' pā-shā' (1830-95). Viceroy and Khedive of Egypt. He was the second son of Ibrahim Pasha (q.v.) and was born at Cairo, Dec. 31, 1830. He was educated in Paris and on his return to Egypt was dispatched on diplomatic missions to several European capitals. Subsequently he was appointed Regent by his uncle, Said Pasha, during his absence in Europe. In 1861 he was placed in command of the army and carried on a victorious campaign against the Sudanese tribes. On the death of Said Pasha in 1863 he succeeded him as Viceroy of Egypt. During the Civil War in America he acquired vast wealth by the production of cotton. Regarding the construction of the Suez Canal (begun under Said Pasha) as advantageous for Egypt, he actively encouraged the enterprise. In 1866 he secured from the Sultan the hereditary succession to the throne of Egypt in his direct line, and in 1867 he received the title of Khedive. Not satisfied with these privileges, he demanded more, threatening to withdraw the troops he had sent against the Cretan insurgents and to seize Crete if his demands were refused. By the advice of foreign Powers he recalled his demand. Nevertheless, by extending his rule over the regions of the upper Nile, by making foreign loans for the increase of his army and navy, and by proposing the neutralization of the Suez Canal, he made himself practically an independent sovereign. The Sultan commanded him to reduce his army, to recall his orders for ironclads and breechloaders, and to put a stop to the contraction of foreign loans, threatening him with deposition if he refused. Not receiving the expected aid from Russia and other Powers, Ismail submitted. Later he received new prerogatives, giving him control of his army and liberty to make loans and commercial treaties. By the building of public roads, the introduction of new methods of agriculture, and other innovations he endeavored to improve the economic condition of the country and to civilize the surrounding tribes. But the progressive measures of the Khedive were accompanied by a reckless extravagance which involved the country to the limit of its resources and made it dependent upon the great financial Powers. In 1879 the governments of France and England, in view of the wretched economic condition of Egypt and the large interests of their own citizens in the administration, determined to interfere in behalf of good government and united in demanding of the Porte that the Khedive should commit the portfolios of Finance and Public Works to English and French ministers. The Khedive resented any interference of the Western Powers with Egyptian affairs. The Sultan then offered to depose Ismail Pasha and to appoint Halim Pasha, Ismail's uncle, as his successor; but the Powers advised the Khedive to abdicate, promis-

ing to support his son Tewfik. The Sultan acquiesced in the course recommended, and on June 26, 1879, he signed the firman deposing the Khedive in favor of his son Prince Mohammed Tewfik. Ismail at once complied with the demand, and his son was proclaimed Khedive as Tewfik I. Ismail received an annual allowance of £50,000 and left Egypt for Naples. In 1888 he took up his residence in Constantinople, where he died March 2, 1895. See EGYPT.

ISMENE, is-mē'nē (Lat., from Gk. Ἰσμήνη). In Greek mythology, the daughter of Œdipus and Jocasta and sister of Antigone (q.v.). In character she is a sharp contrast to her sister—strong, indeed, to suffer, but not fitted for bold deeds.

ISMID, is-mēd', or **IZMID**, iz-mēd'. The modern name of Nicomedia (q.v.).

ISNARD, ês'nâr', **MAXIMIN** (1758–1830). A French Revolutionist, born at Grasse. In 1791 he was deputy from Var to the National Assembly, in which he distinguished himself by his boldness and eloquence. He was reelected in 1792 and was instrumental in forming the Committee of Public Safety. He joined the Girondists and was arrested in June, 1793, but escaped and concealed himself until the fall of Robespierre. He appeared again in the Assembly and afterward was a member of the Council of Five Hundred. From a violent radical he developed into an advocate of the coronation of Napoleon (see his *Réflexions relatives au sénatus-consulte du 28 floréal, an XII*, 1804) and served the Restoration so faithfully that he was pardoned (1816) for having voted for the death of Louis XVI.

ISOBAROMETRIC (ī'sō-bār'ō-mēt'rik) **LINES** (from Gk. ἴσος, *isos*, equal + Eng. *barometric*, from Gk. βάρος, *baros*, weight + μέτρον, *metron*, measure), or **ISOBARS**. Lines joining the places at which the atmospheric pressure reduced to a common level is the same. Ordinarily the weather maps show the isobars for sea level, and by recent decisions of the International Meteorological Congress the barometric indications must also be corrected for the influence of the variations of gravity so that atmospheric pressures may all be expressed in uniform absolute measures. Formerly meteorologists avoided the troubles and uncertainties of the reduction to sea level by using the departures of individual barometric readings from the normal reading of the instrument. These isabnormal lines were then plausibly converted into isobarometric lines by assuming that the normal pressure at sea level was everywhere the same, viz., 760 millimeters or 30 inches, and adding the departures from the normal algebraically to this assumed normal. The resulting pressures were assumed to represent closely the result that would have been given by reduction to sea level. In 1857 Ferrel showed that the normal barometric pressure at sea level could not possibly be uniform, but must be lower in the polar and higher in the tropical regions. In 1868 Buchan showed that the pressures are higher over the continents in the winter and over the oceans in the summer. Since these dates the importance of correct isobars based upon a correct method of reduction to sea level has been more and more thoroughly appreciated.

The term "isobarometric" was applied by Kaemtz, about 1830, to lines representing the oscillations of the barometer or its range from maximum to minimum during any month or

year, but this usage is now obsolete. These oscillations are greatest in regions subject to the passage of severe and numerous storms. They are greater in the northern portion of the Atlantic Ocean than in the southern portion or in corresponding latitudes on land.

The distance between two neighboring isobars is greater in proportion as the winds are less, and vice versa the distance is small when the winds are strongest. The rate of change of pressure in a unit of horizontal distance is called the gradient of pressure. This barometric gradient may be as large as 5 millimeters or 0.25 inch of barometric pressure per degree of a great circle when gales of wind prevail, and much greater in the narrow region around a storm centre within which hurricane winds prevail. The barometric gradients attending storm winds must not be considered as producing the winds. On the contrary the winds have a great influence in producing the gradients, and much steeper ones would occur if the resistances to the motion of the wind did not prevent. See METEOROLOGY.

IS'OBEL. An opera by Mascagni (q.v.), first produced in Buenos Aires, June 2, 1911; in Italy, Jan. 20, 1912 (Milan and Venice simultaneously).

I'SOBU'TANE. See BUTANE AND ISOBUTANE.

ISOHEIMENAL (ī'sō-kī'mē-nal) **LINES**. Lines that connect places having the same winter temperature. See ISOTHERMAL LINES.

ISOCHRONISM, i-sōk'rō-nīz'm (from *isochronous*, from Gk. ἰσόχρονος, *isochronos*, equal in time, from ἴσος, *isos*, equal + χρόνος, *chronos*, time). A pendulum is isochronous when its vibrations are performed in equal times, whether these vibrations be large or small; and it can possess this property by being constrained to move in a cycloidal arc. (See CYCLOID.) Huygens, who is believed to have first applied the pendulum to clocks (see CLOCK), made his pendulum isochronous by causing its string to wrap and unwrap itself round two equal cycloidal cheeks, the diameter of whose generating circle was equal to half the length of the pendulum. This device is no longer used, however, and isochronism is closely approximated in practice by causing the pendulum to describe a very small circular arc. The term is also used in connection with the balance of watches.

ISOCHRONOUS (ī-sōk'rō-nūs) **CURVE**. See CYCLOID.

ISOCLINIC, ī'sō-klin'ic (from Gk. ἴσος, *isos*, equal + κλίνειν, *klinein*, to incline), or **ISOCLINAL LINE**. A line supposed drawn on the earth's surface connecting the points at which the dip of a magnetic needle, or the magnetic inclination (q.v.), is the same. (See TERRESTRIAL MAGNETISM.) The isoclinic lines, or lines of equal magnetic inclination (q.v.), may be said to run roughly east and west. They encircle two points, one in the Northern Hemisphere and the other in the Southern, at which the magnetic inclination, or dip, is 90°. These points are defined as the "magnetic poles"; their approximate positions in 1914 were lat. 70° N., long. 97° W., and lat. 72° S., long. 153° E. There are also so-called "local magnetic poles" where, e.g., because of extraordinary local deposits of magnetic iron ore, the dip of the magnetic needle is 90°; the area of influence due to such poles is generally very restricted. The aclinic line, or line of no magnetic inclination, is usually called the "magnetic equator," as it

separates the north magnetic hemisphere (where the north end of the dip needle points downward) from the south magnetic hemisphere (where the north end of the dip needle points above the horizon or the south end points downward). Owing to the secular changes of the earth's magnetism, the isoclinic lines and the magnetic poles change their positions with the lapse of time.

ISOCRATES, i-sök'rá-tēz (Lat., from Gk. Ἰσοκράτης, *Isokratēs*) (436-338 B.C.). Though one of the 10 Attic orators of the Alexandrian Canon (see CANON ALEXANDRINUS), Isocrates was rather a publicist and a pamphleteer than an orator. His long life, as De Quincey interestingly points out in his essay on *Style*, spans the century from Pericles to Alexander. In youth he was attached to the Socratic circle, and Plato in the *Phædrus* commends him, when he was still a youth, above other orators for a certain touch of philosophy that might lead to higher things. Elsewhere Plato seems to allude to him with irony as a rival teacher and the exponent of a competing ideal of culture. His first school, opened at Chios, was probably devoted to the professional rhetoric of the law courts, and he himself wrote forensic speeches, a few of which have been preserved. These, however, he was inclined to disavow in later days when his school at Athens came to represent (after 392 B.C.) what he regarded as the more broad and liberal training in essay writing and epideictic (display) oratory on large political and Hellenic themes. From personal participation in the combats of the law courts or the assembly he was shut out by a weak voice and an invincible timidity, though he seems not to have been lacking in moral courage. Isocrates stands for three things: 1. The idea that the Greeks should unite to conquer Persia. This is set forth in his most brilliant performance, the *Panegyricus*, which cost him 10 years and is supposed to have been published at Olympia in 380 B.C. Failing to influence Athens and Sparta, he appealed to individuals—Jason of Pheræ, the tyrant Dionysius, Philip of Macedon. The legend consecrated by Milton's sonnet that the "dishonest victory at Chæroneia, fatal to liberty, killed with report that old man eloquent," is sufficiently refuted by the tone of the letter to Philip. Indeed, the conquest of Asia by Alexander, though not accomplished by a union of Athens and Sparta, was in many ways a striking fulfillment of the prophecies of the *Panegyricus*. 2. Isocrates' ideal of culture as a faculty of elegant disquisition occupying the happy mean between the narrow utilitarianism of the advocate and the unprofitable subtleties of a Plato is to us, as exemplified in his writings, a ridiculous and platitudinous thing. But nevertheless his school did as much as the Academy of Plato to make the Athens of the fourth century the schoolmistress of Greece. Dissertations have been written about his pupils. Among them were the historians Ephorus and Theopompus, and the orators Isæus, Lycurgus, and Hyperides. From that school, says Cicero, as from the Trojan horse, a company of naught but chieftains issued forth. 3. Isocrates, though not himself a great writer, holds a great place in the evolution of European prose. He was a pupil of the brilliant Sophist Gorgias (q.v.), who freely employed as ornaments of prose jingling assonance, alliteration, balanced antithesis of thought and

expression, striking metaphor, and other rhetorical features of Greek poetry. Isocrates tempered the excess of these "Gorgian figures," but retained them so far as consonant with the genius of ornate but not extravagant prose. He also practiced and taught the smooth organic structure of the long rhythmical period, the avoidance of hiatus, the conscious variation of phrase and selection of synonym. These and many other traits of style employed by him in a mechanical and monotonous way were studied in him by the world's three great masters of prose—Plato, Demosthenes, and, later, Cicero. And Cicero has made them the common property of all educated men in theory if not in practice.

Isocrates' 21 orations and 10 possibly genuine letters fill two small volumes of the Teubner texts. They have been partly translated into English by Freese, part i (London, 1894). They are not entirely free from dullness. There is an ample analysis and account of all of them in R. C. Jebb, *Attic Orators*, vol. ii (London, 1876). Consult also: F. W. Blass, *Attische Beredsamkeit* (Leipzig, 1868-80; 2d ed., 1887-93); id., *Die Rhythmen der attischen Kunstprosa* (Leipzig, 1901); W. C. Wright, *A Short History of Greek Literature* (New York, 1907); Adams, "Recent Views of the Political Influence of Isocrates," in *Classical Philology*, vol. vii (Chicago, 1912); H. M. Hubbell, *The Influence of Isocrates on Cicero, Dionysius, and Aristides* (New Haven, 1913). There is a good English annotated edition of the *Panegyricus* by Sandys, and selected orations have been edited with German notes by Schneider (Berlin, 1888).

I'SODIMORPHOUS SERIES. See ISOMORPHISM.

ISODYNAMIC (i'sō-dī-nām'ik) **LINES** (from Gk. ἰσοδύναμος, *isodynamos*, having equal power, from ἴσος, *isos*, equal + δύναμις, *dynamis*, power, from δύνασθαι, *dynasthai*, to be able). A line supposed drawn on the earth's surface connecting the points at which the intensity or strength of the earth's magnetic field has the same numerical value. There are three sets of these lines—the lines of equal horizontal intensity, the lines of equal vertical intensity, and, finally, the lines of equal total intensity. The first set show how the component (the horizontal one) of the earth's magnetic intensity acting on a compass needle varies from place to place; this component is a maximum in the equatorial regions and reduces to zero at the magnetic poles. The second set show how the component (the vertical one) acting on the dip needle varies over the earth, this component being zero along the magnetic equator (see INCLINATION) and increasing with approach to the magnetic poles. The third set map out the numerical values of the total intensity, the minimum values occurring in the equatorial regions and the maximum in the high northerly and southerly latitudes. Owing to the earth's complex magnetization, the maximum values of the vertical and of the total intensity are not found at the magnetic poles. All three sets of lines are subject to change with the lapse of years. See TERRESTRIAL MAGNETISM; ISOCLINIC.

ISOGAMY, i-sōg'ā-mī (from Gk. ἴσος, *isos*, equal + γάμος, *gamos*, marriage). A condition in plants in which the pairing sex cells (gametes) are similar, i.e., they show no evident distinction into male and female. Only the lowest plants are isogamous. The contrasting term is heterogamy (q.v.). When gametes are rec-

ognized as male and female, this means that the former is a small and active cell, while the latter is a very large and passive cell. In isogamy, however, it must be realized that the two pairing gametes are physiologically unlike, or they would not pair. The real difference, therefore, is present in isogamy as well as in heterogamy. See FERTILIZATION.

I'SOGE'OTHERMS. The name given to imaginary zones beneath the earth's surface passing through points of equal temperature.

ISOGONIC (i'sō-gōn'ik) **LINES** (from Gk. *ἴσος*, *isos*, equal + *γόνος*, *gonos*, angle), or **ISOGONAL LINE**. A line supposed drawn on the earth's surface connecting the points at which the magnetic declination, or angle which the compass direction makes with the true meridian, is the same. The line of zero magnetic declination is called the *agonic line*. See COMPASS; DECLINATION; DECLINOMETER; TERRESTRIAL MAGNETISM; ISOCLINIC.

ISOGONISM, i-sōg'ō-nizm. See ISOMORPHISM.

I'SOGRAM (from Gk. *ἴσος*, *isos*, equal + *γράφειν*, *graphein*, to write). In mathematics, a diagram meant to show graphically a relation between three variables. Also a convenient name for all those lines used on charts and diagrams to connect points characterized by equality in some respect. Among the meteorological isograms may be mentioned isotherm, isobar, isabnormals, isohyet. Consult C. F. Talman, "Meteorological Isograms," in *Scientific American Supplement*, No. 1918 (New York, 1910). See ISOPLETHS.

ISOLA BELLA, ē'zō-lā bēl'lā. One of the Borromean Islands (q.v.) in Lago Maggiore (q.v.), Italy.

ISOLA DEL LIRI, děl lē'rē. A city in the Province of Caserta, Italy, 96 miles northwest of Naples, on the rivers Liri (Liris) and Fibreno (Fibrenus), which furnish power for paper, carpet, cloth, and woolen factories and for machine works. As the name indicates, the main town is on an island in the Liri, which has magnificent waterfalls 80 feet high. Half a mile beyond the picturesque estate of M. Lefebvre, afterward the Count of Balsorano, are the twelfth-century church of San Domenico, about three-quarters of a mile north of Isola, and the tenth-century monastery where Gregory VII was once a monk. The former is supposed to rest on the site of a villa of Cicero, called Arpinas, and the Isola San Paolo is believed to be the Insula Arpinas, where the orator was born. (See ARPINO.) For a description of the villa and its neighborhood, see Cicero, *De Legibus*, ii, 3; the villa was supposed to be the scene of the dialogue *De Legibus*. Five miles west of Isola del Liri is the thirteenth-century abbey of Santi Giovanni e Paolo di Casamari, now state property. As an example of early Gothic it is rivaled in Italy only by the convent of Fossanova in Sonnino (q.v.). The name Casamari, attached to a place about 5 miles west of Isola, preserves the memory of the birthplace of Marius (q.v.). Isola has stone quarries and is lighted by electricity. Pop. (commune), 1901, 8202; 1911, 8416.

ISOLA GROSSA, grōs'sā. A long and narrow island off the coast of Dalmatia, Austria. Area, 35 square miles (Map: Austria, D 5). It is poorly watered, but nevertheless produces southern fruits, such as grapes, olives, and figs; it has also important fisheries. Pop., about 4000, mostly Croats. Its chief town, Sale,

has a harbor, a lighthouse, and a population of 846.

ISOLA MADRE, mā'drā. One of the Borromean Islands (q.v.) in Lago Maggiore (q.v.), Italy.

ISOLANI, ē'sō-lā'nē, JOHANN LUDWIG HEKTOR, COUNT (1586-1640). An Imperial cavalry general in the Thirty Years' War, born at Görz, of a noble Cypriot family. He was taken prisoner by the Turks in 1602, and after his escape became commander of a regiment of Croats and fought against Mansfield. In 1632 he was put in command of all the Croatian forces; two years later he was made Count, after deserting Wallenstein, who had treated him well. A clever leader of light cavalry and a terrible raider, Isolani fought in Picardy and Burgundy (1636), then in Hesse, Pomerania, and along the upper Rhine (1639) against Guébriant.

ISOLATION, i'sō-lā'shūn or is'ō-lā'shūn (from *isolate*, from Fr. *isoler*, It. *isolare*, from ML. *insulare*, to separate, from Lat. *insula*, island, from *in*, in + *salum*, sea, Gk. *σάλος*, *salos*, surge). In evolution, the separation or segregation of any assemblage of plants or animals in a limited area, so that the incipient varieties or species are prevented from breeding with those of adjoining regions. Through such isolation the leveling effects of free crossing or mixing with allied varieties are prevented. Thus variations or nascent species become localized, with the result that there are many thousands of local races, varieties, and species.

Besides geographical isolation there are other kinds of segregation. Darwin suggested two forms: (1) arising from organisms breeding at slightly different seasons; (2) "from varieties of the same kind preferring to pair together." To the first of these may be added the inbreeding of butterflies of two different broods, a part of one brood being belated and flying with their "nephews and nieces." See DIGONEUTISM.

Lamarck was the first to broach the subject of the doctrine of isolation as a factor in species making in referring to man. Considering organisms in general, he points out that in reproductive unions the crossings between the individuals which have different qualities or forms are necessarily opposed to the continuous propagation of these qualities and their forms. He then instances man and says that, if distance of habitation did not separate men, the intermixture by generation would cause the general characteristics distinguishing different nations to disappear. Wagner (1868) has fully proved by numerous examples the importance of migration and isolation in species making. See MIGRATION, WAGNER'S LAW OF.

As a result of 15 years' collecting in the Hawaiian Islands of land shells belonging mostly to genera found nowhere else, Gulick established the fact that in each mountain valley of the forest region of Oahu there is a great number of local species (200, represented by 700 or 800 varieties) belonging to several genera, and that each of the 20 valleys contains one or more local varieties or species restricted to that valley. On tracing this wonderfully differentiated assembly from valley to valley it became apparent that a slight variation in the occupants of a valley as compared with those of the adjacent valley becomes more pronounced in the next or third valley, still more in the fourth, and so on. Thus he was able roughly to estimate the amount of divergence between the oc-

cupants of any two given valleys by measuring the number of miles between them (Romanes). Gulick thinks the evolution of these different forms cannot be attributed to differences in their external conditions. The forest area, covering one of the mountain ranges, in which the snails live, is about 40 miles long and 5 or 6 miles wide. He states that the rainfall on the north-east side of the mountain is somewhat heavier than on the opposite side, and the higher ridges of the mountains are cooler than the valleys, but the valleys on one side of the range have a climate the same in every respect. The vegetation in the valleys differs somewhat from that on the ridges, but the vegetation of the different valleys is much the same—the birds, insects, and larger animals are the same. Though, as far as we can observe, the conditions are the same in the valleys on one side of the range, each has a molluscan fauna differing in some degree from that of any other. He also adds that a genus is represented in several successive valleys by allied species, sometimes feeding on the same, sometimes on different plants. In every such case it appeared that the valleys that are nearest to each other furnish the most nearly allied forms, and a full set of the varieties of each species presents a minute gradation of forms between the more divergent types found in the more widely separated localities. After giving reasons for the belief that this variation is not due to differences in their external conditions, Gulick concludes that the difference is due to a corresponding difference in the time of separation of each variety, and also to what he terms “cumulative segregation,” “segregate breeding,” and “independent generation.” In his interesting essay on *Physiological Selection* (1886 and 1897), Romanes states that the essence of the principle consists in *all* cases of the diversifying effect of cross-infertility, whenever and howsoever it may happen in particular cases to have been caused. (See *PHYSIOLOGICAL SELECTION*.) It is to be observed that this is but little different from Gulick’s “cumulative” or “intensive” segregation. See *EVOLUTION, Factors of Evolution; CLASSIFICATION OF ANIMALS, Species*.

After all the careful work done by Gulick it is yet to be doubted whether the chief or initial factors in the wonderful specialization which has taken place in the land shells of Oahu are not the result of migration into new regions, varying in natural conditions. For the present, then, Wagner’s factors of migration into areas with differing conditions of life and isolation, and the consequent prevention of intercrossing with the original or parent forms, may be accepted as the essential causes of the origin of perhaps two-thirds to one-half of existing, as well as extinct species.

ISOLD, ISOLDE, ĭ-söld', **ISOND**, ĭ-sönd', **ISOUD**, ĭ-sööd'. See *ISEULT*.

ISOMAGNETIC (ĭ'sō-măg-nět'ik) **LINES** (from Gk. ἴσος, *isos*, equal + μάγνης, *magnēs*, loadstone). A generic term in terrestrial magnetism for the class of lines supposed drawn on the earth’s surface connecting the points at which any particular magnetic element has the same numerical value. There are, thus, isogonies (lines of equal magnetic declination), isoclinics (lines of equal magnetic inclination), isodynamics (lines of equal horizontal intensity, lines of equal vertical intensity, and lines of equal total intensity). See *TERRESTRIAL MAGNETISM; ISOCLINAL; ISOGONIC LINES; ISODYNAMIC LINES*.

ISOMERISM, ĭ-söm'ēr-ĭz'm. See *CHEMISTRY; VALENCY; CARBON COMPOUNDS; STEREOCHEMISTRY; CYANIC ACID; ALLOTROPY*.

ISOMETRIC PERSPECTIVE. A system of conventional projection by which all three dimensions are represented to scale in a single drawing. Vertical lines are drawn vertical, and the two systems of horizontal lines at right angles to each other of a vertical cube are represented by lines at a fixed inclination, usually 30° to the horizontal, and drawn to the same scale as the verticals, or sometimes to a special scale indicated in the margin. Lines in other than these three directions are laid off by their relations to these. The term *Isometric Projection* is often used instead of *Isometric Perspective* and is more strictly correct.

ISOMETRIC SYSTEM. See *CRYSTALLOGRAPHY*, and Plate of *CRYSTAL FORMS*.

ISOMORPHISM, ĭ'sō-môr'fĭz'm (from *isomorphous*, from Gk. ἴσος, *isos*, equal + μορφή, *morphē*, form). The relationship existing between solid substances which are similar in their chemical composition and constitution, have similar crystalline forms, and are capable of forming homogeneous mixed crystals (“solid solutions”). A substance standing in an isomorphous relationship to another is capable of growing in a saturated solution of that other, the latter then forming a mantle around the first as a nucleus. Ostwald proposes to define the relationship between two isomorphous substances as the capacity of one to cause immediate crystallization in a *supersaturated* solution of another, just as a crystal of any substance is capable of causing its own supersaturated solution to crystallize immediately. It must, however, be observed that while the relationship of isomorphism certainly exists, our knowledge of its intimate nature is very vague, and neither of the above definitions gives adequate expression to all of the known facts. The ordinary carbonates of calcium (calcite), magnesium (magnesite), iron (siderite), manganese (rhodochrosite), and zinc (smithsonite), all form crystals of the same crystal system and for the most part of the same crystal class (see *CRYSTALLOGRAPHY*); and, further, their corresponding interfacial angles approach to the same values. Not all substances closely related in their chemical composition are isomorphous, and, exceptionally, substances which have no chemical relationship have similar symmetry of crystals and angles in close correspondence. (Such an

accidental resemblance of the crystal forms of chemically unrelated substances is described as isogonism.) In the case of salts the chemical component which seems mainly to condition the symmetry of the molecule is the acid radical, the metal having less influence upon the crystal's symmetry, though affecting the size of crystal angles. (See MORPHOTROPISM.) The metals of a series of isomorphous salts are said to be isomorphous elements, and it is found that for the most part they are of the same or related groups of elements. See PERIODIC LAW.

When a substance has been found to form crystals of more than one kind, it is said to be dimorphous, trimorphous, or polymorphous, the term "dimorphous" being used in a general sense to describe substances which exhibit three or more as well as two kinds of crystals. Sulphur crystallizes from fusion in long needle-like crystals of monoclinic symmetry, but from a solution in carbon bisulphide in orthorhombic crystals. Under other special conditions it assumes other kinds of symmetry. Carbonate of lime, which is generally found crystallized in nature as hexagonal (trigonal) crystals (calcite), is less frequently found in crystals of the orthorhombic system (aragonite) and with different physical properties from those of calcite. As explained above, calcite belongs in an isomorphous series with carbonate of magnesia, carbonate of iron, carbonate of zinc, etc. Aragonite, on the other hand, is a member of a different isomorphous group in which are carbonate of strontium, carbonate of barium, and carbonate of lead. A double group of this kind connected by a dimorphous substance (carbonate of lime as calcite and aragonite) is known as an isodimorphous group or series. See CRYSTALLOGRAPHY; CHEMISTRY; ATOMIC WEIGHTS.

ISOMURA, ē'sō-mōō'ra, KITTOKU (fl. seventeenth century). A Japanese mathematician.

kami, *History of Japanese Mathematics* (Chicago, 1914).

ISOND. See ISEULT.

I'SOPERIMET'RIC FIGURES (from Gk. ἴσος, *isos*, equal + περίμετρον, *perimetron*, perimeter, from περί, *peri*, around + μέτρον, *metron*, measure). Plane figures having equal perimeters. In the seventeenth century all problems which demanded the statement of a maximum or minimum property of functions were called isoperimetric problems. To the oldest problems of this kind belong especially those in which one curve with a maximum or minimum property was to be found from a class of curves of equal perimeters. That the circle, of all isoperimetric figures, gives the maximum area is said to have been known to Pythagoras. In the writings of Pappus a series of propositions relating to figures of equal perimeters is found. In the fourteenth century the Italian mathematicians also worked on problems of this kind. But Johann Bernoulli (1696) and Euler (1744) applied the calculus of variations to these problems, and Euler gave a purely analytic treatment in his celebrated work, *Methodus Inveniendi Lineas Curvas...* This theory culminated in the calculus of variations, Lagrange supplying the appropriate notation. An illustration of problems of this class is that of Jakob Bernoulli—of all curves of the same length described on a given base, to determine one such that the area of a second curve, each of whose ordinates is a given function of the corresponding ordinate or arc of the first, may be a maximum or a minimum. See MAXIMA AND MINIMA.

I'SOPLETHS (from Gk. ἴσος, *isos*, equal + πλῆθος, *plēthos*, number). These are curves connecting those points in a diagram which have the same numbers or values. This name might be logically applied to any isogram (q.v.), as it is a synonymous word. In practice it is

THERMO-ISOPLETHS FOR WASHINGTON, D. C.
Degrees, Fahrenheit.

His chief work was the *Ketsugi-shō*, which appeared in five books in 1660 and was again published in 1684. The work makes some attempt at integration and contains a number of very ingenious problems and some interesting examples of magic squares, magic circles, and sets of magic wheels. Consult Smith and Mi-

restricted to the lines drawn through points of equal value in a diagram made by inserting the proper value for any given element at the proper intersections of a coördinate net having hours along one axis (usually ordinates) and days of the year along the other axis (abscissæ). If the average temperatures for this net are prop-

erly entered thereon, the lines connecting equal temperatures would be called *thermo-isopleths*, and they would present what may be regarded as a contoured topographic map of the temperature surfaces prevailing at the locality of observation (e.g., Washington, D. C.) throughout the average or "normal" year. The figure on the preceding page presents such a diagram for Washington, D. C.

The advantages of this graphic method for presenting any climatological element are that it furnishes very characteristic, comparable, graphic pictures of the same element in different localities; it permits one to seize at a glance the distribution of the element throughout the two ranges of time, or time and space, employed and the relation it bears to time and season; and it furnishes convenient graphic interpolations and comparisons between neighboring records of differing lengths. Similar constructions are very instructive in the study of hydrologic phenomena, and they have been very useful in revealing the process of the seasonal overturning of the waters of lakes and reservoirs.

Consult: Erk, "Ueber die Darstellung der stündlichen und jährlichen Vertheilung der Temperatur durch ein einziges Diagramm," in *Meteorologische Zeitschrift* (Berlin, 1885); Fassig, *Climate and Weather of Baltimore* (Baltimore, 1907); Cox, *Weather and Climate of Chicago* (Chicago, 1914); Hann, *Lehrbuch der Meteorologie* (Leipzig, 1914).

ISOP'ODA (Neo-Lat. nom. pl., from Gk. ἴσος, *isos*, equal + πούς, *pous*, foot). An order of malacostracous crustaceans of the section Arthrostraca, mostly aquatic—some marine, some inhabitants of fresh waters—but some terrestrial, inhabiting damp places, as the wood louse and the like. They are easily recognized by the fact that the body is flattened dorsoventrally, and many of them—e.g., the sow bug or pill bug (*Porcellio*)—have the habit of rolling up into a ball with the head tucked safely inward. The first segment of the thorax is fused with the head, but the remaining seven are free and bear limblike appendages without gills. In females the basal joints of several of these appendages bear lamellæ, which form a brood pouch for the eggs. There is never any carapace. The maxillipeds, of which there is only a single pair, usually fuse to form a sort of lower lip. The abdominal appendages are biramose and serve for swimming and breathing; the most anterior pair are usually thick and form an operculum which serves to protect the more delicate appendages behind. The heart is situated chiefly in the abdomen, but extends forward a short distance into the thorax. While most of the species lead a free life, some of the marine forms (*Cymothoa*, etc.) are parasitic on fishes or on other crustaceans, or bore into wood, etc. See Illustration under GRIBBLE.

One group (Bopyridæ) are parasitic, living under the carapace of various shrimps. The females of *Bopyrus palæmoneticola* (Packard) are many times larger than the males and are much degenerated, the head being without eyes and appendages; they retain their position on their host by means of the sharp, hooklike legs around the edge of the body. The male in general appearance shows but slight modifications and is about one-fifth as large as the female, and is lodged partly out of sight under the ventral plates of its consort.

Some of these forms are notably degenerate.

The Isopoda are a comparatively small group and are generally small individuals, few species reaching a length of 1 inch, except in the colossal deep-sea *Bathynomus giganteus*, dredged in the Caribbean Sea from a depth of nearly a mile. The colors are usually dull, blackish, gray, or brown; but some of the marine forms are highly colored, red or brown, according to the hue of the seaweed they rest on.

Fossil isopods, though of little geological importance, are known from rocks as early as the Upper Devonian and Carboniferous; also from the Jurassic limestones of Bavaria and other Mesozoic formations. Most of them have some superficial resemblance to the marine *Sphæroma* and to the terrestrial wood lice of modern time. See CRUSTACEA.

I'SOQUIN'OLINE. See QUINOLINE.

ISOSPONDYLI, i'sō-spōn'dī-lī (Neo-Lat. nom. pl., from Gk. ἴσος, *isos*, equal + σπόνδυλος, *spondylos*, vertebra). An order of teleost fishes, the soft-rayed fishes. They have the anterior vertebræ simple, unmodified; the mesocoracoid arch is always well developed, and the strong shoulder girdle is connected with the cranium. There are no auditory ossicles. The scales usually are cycloid, the ventral fins abdominal. It is a large group, comprising the tarpons, ladyfishes, herrings, shads, sardines, anchovies, menhadens, salmons, trouts, whitefishes, and related families, and, in the opinion of some, the Iniomi (q.v.) also. Consult Jordan and Evermann, *Fishes of Northern and Middle America* (4 vols., Washington, 1896-1900).

ISOS'PORY. See HOMOSPORY.

ISOS'TASY. A theory of the structure of the earth that postulates that all equal areas in a surface at a certain depth below sea level (found by geodetic investigations to be about 122 kilometers, or 76 miles) are subject to the same pressure, and that below that surface the earth's materials are in a state of equilibrium. It is assumed that there is the same mass or amount of material in each unit column which extends from the actual surface of the sea or land to the depth stated. Therefore that material of a continent which is above sea level is compensated or counterbalanced by a deficiency of mass in the lithosphere (outer part of the earth) below it, while the deficiency of mass in the space occupied by the water of the oceans is counterbalanced by an excess of matter in the lithosphere under the ocean. The condition of isostasy obtains because of the yielding of the earth's materials to long-continued strains, though they may be rigid or unyielding to stress differences acting for a short time only.

The great inequalities of elevation between the continental lands and the oceanic basins, according to this theory, are maintained not so much by rigidity of the rock materials as because of differences in density—the projecting

land areas being composed of lighter materials than the depressed sea bottoms. The mountain masses which rise 15,000 feet or more above sea level are buoyed or floated, as it were, on the substratum. From a geological standpoint the most important consequence involved is that any change of load upon one part of the crust finds compensation by a movement in the substratum from the area of increased pressure towards that of diminished pressure. Thus, elevated regions which are being eroded and worn down at the surface tend to rise, while the oceanic depressions which receive the weight of sediment gradually sink. The shifting or movement of the underlying material affords an explanation for the crumbling and folding of rocks. The principle of isostasy, as explained by Dutton, has received strong support recently from the series of investigations made by the United States Coast and Geodetic Survey under Hayford. Measurements of the force of gravity at widely distributed stations show actual variations of density that, on the whole, conform with it.

Consult: J. F. Hayford, *Figure of the Earth and Isostasy from Measurements in the United States* (Washington, 1909); id., *Supplementary Investigation in 1909 of the Figure of the Earth and Isostasy* (ib., 1910); Hayford and Bowie, *Effect of Topography and Isostatic Compensation upon the Intensity of Gravity* (ib., 1912); and other publications of the United States Coast and Geodetic Survey. See DEFLECTION OF THE PLUMB LINE; GEODESY.

ISOTELUS (i-sōt'ê-lūs) **DEKAY**. A genus of trilobites belonging to the Asaphidæ and for a time considered as identical with *Asaphus* (q.v.), but distinguished from it by the smooth cephalon and pygidium, with depressed borders. Some species attain such great size that they belong to the giants among the trilobites. The most common American forms are *Isotelus gigas* and *Isotelus maximus*. The former has become widely distributed in museums, the specimens coming from the Trenton limestone at Trenton Falls, N. Y. The genus occurs abundantly in the Ordovician rocks of America, but is rare in Europe.

ISOTHERAL (i-sōth'êr-al) **LINES**, or **ISOTHERÆ**, i-sōth'êr-ê (from Gk. ἴσος, *isos*, equal + θέρος, *theros*, summer). Lines that connect together places that have the same mean summer temperature.

ISOTHERMAL, i'sō-thêr'mal (from Gk. ἴσος, *isos*, equal + θερμη, *thermê*, heat). In physics, an isothermal is a line drawn on any diagram so as to represent the successive values of the properties of a body as it undergoes certain changes, the temperature being kept constant. Thus, if the properties of the body which are to be observed and noted are its pressure and volume, the isothermal curves are drawn on a diagram having pressure and volume as ordinates and abscissæ. The isothermals of a typical substance, carbonic-acid gas, CO₂, in the form of vapor and liquid, are given in the accompanying figure. Considering any of the lower curves—i.e., the isothermals for temperatures less than 31° C.—it is seen to consist of three parts: the nearly vertical portion is the isothermal for the liquid; the horizontal portion, for the process of evaporation of the liquid, when the liquid occupies the lower portion of the containing vessel and the vapor the upper; the curve at the right, which is nearly an hy-

perbola, is for the vapor after all the liquid has evaporated. The isothermals for temperatures higher than 31° C. do not have any horizontal portion, showing that as the gaseous substance is compressed at these temperatures it never condenses and becomes a liquid—if it did condense, the curve would become horizontal, because when the temperature is kept constant

the pressure of the condensing vapor does not change. (See HEAT.) Therefore, if the gas is to be liquefied, it must be at a temperature lower than 31° C.—i.e., lower than the temperature corresponding to the first isothermal which does not have a horizontal portion. This temperature is called the “critical” temperature.

It is evident that, if the vapor at any temperature higher than the critical one is compressed, the temperature being kept constant, its volume may be made very small; and if its temperature be now lowered below the critical value, thus making its volume less, it may become a liquid. But in the actual experiment it would be impossible to tell when the change took place, because the vessel containing the vapor (or liquid) is full all the time. Not until, by a suitable increase in volume, the condition of the matter is given by a point on the horizontal portion of the isothermal, can one tell by observation that there is liquid in the vessel, for then one can see the surface of the liquid.

ISOTHERMAL LINES, or **ISOTHERMS**. In meteorology, lines that connect places having the same temperature for a day, month, or for any given interval of time. Systems of isothermal lines for daily maps, as well as for monthly and annual means, present in a very graphic manner the prevailing temperature conditions and are therefore of universal use in meteorology. They seem to have been first used by Alexander von Humboldt in 1817; but lines of equal departure from normal values were independently used by Brands in his studies of the daily weather map and the storms of Eu-

rope. Isothermal lines coincide only accidentally, if at all, with small circles of latitude, owing to the great influence of the distribution of land and water on the temperature of the air. The temperatures observed at the respective stations must be corrected or reduced to the standard level surface of the globe, in order that they may be comparable with each other. This reduction introduces discrepancies, but there are many reasons for retaining it. The rate of reduction adopted by Hann and other climatologists is 0.50° C. per 100 meters, or 1° F. for 370 feet. If a chart has been constructed using this rate of reduction, and one should desire to know the temperature at the top of a mountain, whose altitude is given, we have but to read from the chart the temperature at sea level, apply the reduction to the given altitude, and get at once approximately the temperature of the summit. The accuracy of this method is, however, limited by the fact that the rate of diminution of temperature varies so much that the adoption of an average rate is liable to lead us astray. Charts of isotherms for each month of the year and for the whole globe have been constructed, first by Buchan, and afterward by the United States Weather Bureau, and were published in full in 1900 in elegant style in Bartholomew's *Physical Atlas*.

Isothermal lines can be calculated and drawn for the upper levels of the atmosphere by using observations on mountain tops and in balloons and kites. Lines of this character were first drawn by Hergesell for Europe for certain days in 1898-1900, on which sufficient data were collected by means of balloons and kites. These lines show that large variations in temperature occur at the highest attainable levels, and that the atmosphere in general is a mixture of masses of descending cold air and ascending warm air. See charts under TEMPERATURE, TERRESTRIAL; and DISTRIBUTION OF ANIMALS; also articles CLIMATE; DISTRIBUTION OF ANIMALS; ISOPLETHS; METEOROLOGY.

ISOUARD, é'zōō'är', NICCOLÒ, known as NICCOLÒ DE MALTE in France (1775-1818). An Italian composer and musician, born in Malta. He was educated for the navy and afterward entered commercial life; but meanwhile he studied the piano under Pin in Paris, and harmony under Vella and Azopardi in Malta. Later, while in Italy, he received further instruction from Amendola, Sala, and Guglielmi. In 1795 he produced his first opera, *L'Avviso ai maritati*. The reputation gained by several works of the kind obtained for him the position of chapel-master to the Order of St. John of Jerusalem in Malta. In 1798 he went to Paris and met there Rodolphe Kreutzer, who collaborated with him in two of his operas. One of his first successes was *Michel-Ange* (1802). He also became known as a pianist. He wrote for the Opéra Comique until Boieldieu's growing popularity, and the election in 1817 of that composer to the Academy, an honor which Isouard coveted, caused him to abandon himself to dissipation. The next year he died of consumption. He had much dramatic tact; his music is always simple and gay, never trivial or vulgar, and he had the excellent librettos of Hoffmann and Etienne to work upon. Of his 33 operas, the following are the best known: *Le médecin turc* (1803); *L'Intrigue aux fenêtres* (1805); *Cendrillon* (1810); *Le siège de Mézières*, with Cherubini, Catel, and Boieldieu

(1814); *Joconde* (1814); *Jeannot et Colin* (1814); and *Aladin, ou la lampe merveilleuse*, completed by Benincori (1822).

ISOUD. See ISEULT.

ISPAHAN, is'pà-hän', or **ISFAHAN**. The former capital and one of the largest cities of Persia, situated on the Zendeh-rud (river), over 200 miles south of Teheran, the present capital (Map: Persia, D 6). The surrounding country is of remarkable natural beauty and presents a striking contrast to the half-ruined city. Only a small part of the area inclosed by the ancient and now ruined walls is inhabited, the remainder being a succession of ruined castles, mosques, and schools, which testify to the former splendor of the city. The centre of the city is occupied by a magnificent plaza laid out by Shah Abbas (1585-1628) and formerly surrounded by fine structures. Of the few buildings which have survived the ravages of time, the palace of Shah Abbas, known as Chehel Sutun, or Hall of Many Columns, is probably the finest. A row of 20 graceful cedar columns extends along the front portal, supporting a magnificently ornamented roof. Behind the columns is a spacious hall with mirror-covered walls and a fountain in the centre. Besides this hall there is a large room containing six large oil paintings depicting scenes from the life of Shah Abbas. On the southeastern side of the plaza stands the great mosque, Mesjid-i-Shah, erected in the beginning of the seventeenth century and presenting, even in its ruined state, a fine example of Eastern architecture. On the western side of the royal grounds is situated a magnificent palace known under the name of Hasht Behesht, or Eight Paradises, built by Shah Suleiman at the end of the seventeenth century. It is surrounded by beautiful gardens ornamented with fountains. On the western side is the mosque of Sheikh-Lutfallah, with its dome of enameled tiles, and at the northwestern end is the entrance to the extensive covered bazars of the city, which have a total length of over 2 miles. Another important monument is the school (medresseh) and caravansary of Mader-i-Shah Sultan Hussein, built by that Sultan 1700-10.

The Zendeh-rud, on which the town is situated, is crossed by five bridges, of which that of Allah Verdi Khan is especially remarkable, both for its size and for its architectural beauty; it is 388 yards long, with a paved roadway 30 feet broad. On the farther bank of the river is the graceful Mirror Pavilion (Aineh-Khavé), similar in style to the Chehel Sutun, but less extensive. Industrially Ispahan is still a town of some importance. Its chief products are silk, woolen and cotton goods, jewelry, arms, leather goods, and footwear. The town derives also considerable commercial importance from its position on the main route from Abushehr to Teheran. A little way south of Ispahan is situated the Armenian settlement of Julfa, which contains the entire European colony of Ispahan. It was founded in the beginning of the seventeenth century and at one time had an Armenian population of 30,000, which was reduced through persecution to about 2000. It has a number of Christian churches and several schools. Its population is estimated at upward of 80,000. It is said by Persian writers to have been founded by some of the Jews who were led into captivity by Nebuchadnezzar. It was a trading town of importance, and the capital of Irak, under the caliphs of Bagdad. It

was taken by Timur in 1392, when 70,000 of the inhabitants are said to have been massacred. During the seventeenth century, under Shah Abbas the Great, it became the capital of Persia and reached the climax of its prosperity. It is said to have had between 600,000 and 1,000,000 inhabitants; the smaller figure is given by Jean Chardin (q.v.), who long lived at Ispahan. It was then the emporium of the Asiatic world; the merchandise of all nations enriched its bazars, and ambassadors from Europe and the East crowded its court. In 1722 it was devastated by the Afghans, and towards the close of that century the seat of government was transferred to Teheran (q.v.). Its commerce has greatly declined.

ISPICA, ē'spē-kā, VAL D'. A valley in south-east Sicily, 5 miles southeast of Modica. It is 7 miles long and is famous for its grottoes, containing graves. In the fourth century, as numerous inscriptions show, these grottoes were used by Christians as tombs.

ISRAEL, iz'rā-ēl. See JACOB.

ISRAEL, KINGDOM OF. See JEWS.

ISRAEL IN EGYPT. An oratorio by Handel (q.v.), first produced in London, April 4, 1739; in the United States, Feb. 13, 1859 (Boston).

ISRAELITES, iz'rā-ēl-its. See JEWS.

ISRAËLS, ēs'rā-ēls', JOZEF (1824-1911). The foremost Dutch genre painter of the nineteenth century. He was born at Groningen, North Holland, Jan. 27, 1824, the son of a well-to-do Jewish merchant. Intended for a commercial career, he early showed a taste for art and was sent to Amsterdam, where he studied under Kruseman and Pieneman. He then spent three years in Paris, studying under Picot, and at the Ecole des Beaux-Arts under Delaroche, but frequenting the ateliers of various Romantic painters. In 1848 he returned to Amsterdam and for several years painted historical pictures which show no especial talent or individuality. His real style was not revealed until his return from Zandvoort, a fishing village near Haarlem, where he had gone for his health. There he realized for the first time the beauty of humble life, especially of the fisher folk; the tragic aspects of this life particularly impressed him. He continued to live principally at Amsterdam until he settled at The Hague in 1870. In 1862 his pictures "The Cradle" and "The Shipwrecked Mariner," exhibited in London, excited much interest. "The Cradle," with its intimate charm, and touch of agreeable sentimentality, was typical of many of the interiors, both in oil and water color, that he executed afterward. An example of this later painting is "Expectation," in the Metropolitan Museum of Art, New York. It is a moving, homely picture of the genre he made famous by "Interior of the Orphan Asylum at Katwijk" (1867); "The Frugal Meal," Vanderbilt collection (Metropolitan Museum, New York); "A Dutch Interior," Walters collection, Baltimore; "The Silent House," Glasgow Museum; "An Interior," Dordrecht Gallery; "Alone in the World," Rijks-Museum, Amsterdam (another version in Mesdag Museum, The Hague); "A Son of God's People," Municipal Museum, Amsterdam; "Before Parting"; "Through Darkness to Light"; "David before Saul"; "Children of the Sea"; "When One Grows Old"; "The Jewish Scribe"; and many others. He also painted portraits of great power, among the best of which is one

of himself (1908). He is best represented in various Dutch galleries, and many of his paintings are in the United States. As he grew older, his work gained in breadth and poetic power. The studies of fisher folk, by which he is equally well known, include the rather melodramatic "Shipwrecked Mariner"; "The Zandvoort Fisherman," in the Amsterdam Gallery; and his great canvas, "The Toilers of the Sea," which with "Between the Field and Seashore" and "The Bric-à-Brac Dealer," won medals of honor at the Paris Exposition of 1900. He received many other distinctions, was corresponding member of the French Institute and of nearly all the principal European academies. His treatment was increasingly broad and realistic, and his color, at first pronounced, was afterward modified with peculiar, misty atmospheric effects. Like Rembrandt, he was rather an artist in light and shade than a colorist, and a poet as well as a painter. He has often been compared with Millet, whom he resembles in subject as well as in a certain weakness in the purely technical sides of painting. Israëls excelled also in water color, and his etchings are notable for their simplicity and sureness of touch. He wrote a book of travels, *Spanien*, published in German translation at Berlin in 1900.

ISRAFIL, iz'rā-fēl. The archangel of music, who, according to later Mohammedan belief, will sound the last trump on the day of resurrection, standing upon the rock of the temple at Jerusalem calling mankind to the last judgment. His playing will be one of the delights of paradise. The name does not occur either in the Koran or the Hadith (q.v.). He is, however, supposed by commentators to be the angel mentioned in Suras xx, 107, 1, 40, and liv, 6. Like much of the angelology of Mohammedanism, this represents a superstructure due to later Jewish and Christian influences.

ISSA, is'ā. See LISSA.

ISSACHAR, is'sā-kār. One of the tribes of Israel, descended, according to the Book of Genesis (xxx. 17), from Issachar, the ninth son of Jacob and fifth of Leah. The name is explained as meaning "there is reward" and is interpreted by a reference to the "mandrakes" with which Leah "hired" her husband from her sister Rachel (Gen. xxx. 16), or as Leah's reward for giving her handmaid Zilpah to Jacob (xxx. 18). The subject condition of the tribe at some period of its history (cf. Gen. xlix. 14-15) may have suggested the meaning of "hired laborer." The original significance of the tribal name was probably lost at an early time, and it may have been confounded with the name of some local divinity. The tribe's lot in Palestine included the Plain of Esdraelon, but the Canaanites were but imperfectly dis-

possessed. Deborah and Barak are supposed to have belonged to the tribe, also Baasha, third King of Israel (1 Kings xv. 27). The reference to Issachar in the blessing of Moses (Deut. xxxiii. 18-19), "they [Zebulon and Issachar] to their mountain nations call; they bring right sacrifices there," has been thought to refer to Tabor, where there probably was a sanctuary visited by various peoples from whom the tribe of Issachar at one time may have drawn considerable profit. Consult Nathaniel Schmidt, *Messages of the Poets*, pp. 346-347 (New York, 1911).

ISSACHAR. A character in Dryden's *Ab-salom and Achitophel*.

ISSI, is'i. See ISSUS.

ISSLAND, is'länd. In the Nibelungenlied (q.v.), the kingdom of Brunhilda.

ISSOI, is'oi. See ISSUS.

ISSOUDUN, é'sōō'dūN'. The capital of an arrondissement in the Department of Indre, France, situated on the river Théolle, 22 miles southwest of Bourges (Map: France, N., G 6). It has a municipal college, a library, and a museum, the latter installed in an ancient building known as the White Tower. It has quarries of lithographic stone and manufactures textiles, bristles, parchment, and machinery. There are also several large breweries. The town dates from ante-Roman times, but it has preserved few ancient remains, as it has often been ravaged by wars and has been several times destroyed by fire. Pop., 1901, 14,222; 1911, 10,246.

ISSUE (OF. *issue*, *eissue*, *essue*, Fr. *issue*, from OF. *issir*, *eissir*, to go out, from Lat. *exire*, to go out, from *ex*, out + *ire*, to go). In legal procedure, the stage of an action when, in the course of pleading, the parties come to a direct conflict, i.e., a point which is affirmed by the one and denied by the other. The litigants are at issue. The term is also used to designate the point or question thus raised by the pleadings. In this sense the issue may be one either of law or of fact. If the former, it is decided by the court without the intervention of a jury; if the latter, it is, in the ordinary courts of common law, usually determined by a jury or, in equity practice, by a judge. In some of the States of the Union issues of both kinds may by consent of parties be tried by a referee. An issue of fact arises when a material matter of fact is asserted by one party and denied by the other. An issue of law arises when one party, admitting for the purposes of the issue that the facts alleged by his adversary are true, denies that they are sufficient in law to constitute a cause of action or a defense.

When a court of law or equity is sitting without a jury, it sometimes happens that a question of fact arises upon which the decision of a jury is desired. A fictitious suit is thereupon framed, involving the point in question, and brought to trial before a jury summoned for the purpose. The verdict rendered, being returned to the court, is accepted as a settlement of the issue of fact, and the trial of the cause out of which that issue grew thereupon proceeds. In some States a feigned issue in such cases is not required, the actual question as it arises being submitted to a jury specially impaneled by order of court. See GENERAL ISSUE; and consult the works referred to under PLEADING.

ISSUE. In English and American law, the

lineal (as distinguished from the collateral) descendants of a person. It comprehends grandchildren, etc., ad infinitum, as well as the immediate offspring, but does not include adoptive children. A devise of land to a person and "his issue" is deemed the equivalent of a gift to such person and "the heirs of his body" and results in the estate known as a fee tail (q.v.). The phrase "failure of issue" signifies an ultimate failure, as by the death of the last surviving lineal descendant, and, under the rules of interpretation of deeds and devises developed by the courts of common law and equity, the same signification attaches to the expression "if he shall die without issue." Thus, if lands are given to A and his heirs and, if A die without issue, to B and his heirs, the gift is regarded as vesting in B only upon a complete and final failure of A's issue, whenever this may happen. See REAL ESTATE; and consult the authorities there cited.

IS'SUS, or **ISSI** (Lat., from Gk. Ἴσσοί, Ἴσσοί, *Issos*, *Issoi*). An ancient seaport on a gulf of the same name (now the Gulf of Iskanderun) in Cilicia, Asia Minor. It possessed great strategic importance in ancient times on account of its position on the narrow defile leading from Syria into Cilicia (q.v.; see also CILICIAN GATES). At Issus, Alexander the Great overwhelmed Darius (333 B.C.). Near by, Septimius Severus overthrew Pescennius Niger, his rival for the Imperial throne (194 A.D.), and in the neighborhood the Emperor Heraclius defeated the Persians in 622 A.D. The exact site of Issus has not been determined. See BATTLE OF ISSUS; ALEXANDER THE GREAT.

ISSY, é'sé' (Fr. *Issy-les-Moulineaux*). A town in the French Department of Seine, situated about 1½ miles southwest of Paris, with which it is connected by a street railway, and on the left bank of the Seine (Map: France, N., A 2). It has a seminary, a museum, a castle, and a home for the aged. There are manufactures of silk, paint, oil, chemicals, cement, and shoes. The fortifications of Issy suffered considerably during the siege of Paris in 1870-71, but have since been restored. Pop., 1901, 16,639; 1911, 20,043.

ISSYK-KUL, é'sék-kōōl'. A lake in the Province of Semirychensk, Russia, lying to the south of Lake Balkash (Map: Asia, K 4). It is about 38 miles in width and 112 miles long, with an estimated area of over 2000 square miles, but rapidly being desiccated. It receives a number of small streams, and its water is brackish; its shores are low and sparsely inhabited. The chief settlement is Przhevalsk, situated on the east shore and named in honor of the famous explorer Przhevalsky.

ISTEL, is'tel, EDGAR (1880-). A German composer and writer on music, born at Mainz. He studied violin and composition under Fritz Volbach, at the same time attending the Gymnasium of his native town. After graduation in 1898 he went to Munich to complete his musical studies with L. Thuille and to enter the university, where he devoted himself to the science of music and to psychology, receiving the degree of Ph.D. in 1900. He wrote the operas *Der fahrende Schüler* (1906) and *Des Tribunals Gebot* (1914); a *Singspielouvertüre*; *Hymnus an Zeus* for chorus and orchestra; mixed choruses; and songs. His chief importance, however, rests upon his literary works, of which the following are the principal: *Peter*

Cornelius (1906); *Die Entstehung des deutschen Melodramas* (1906); *Die komische Oper* (1906); *Das Kunstwerk Richard Wagners* (1909); *Das Libretto* (1914).

IS'TER. The ancient name of the Danube in its lower course.

ISTHMIA, is'mī-ā, or **ISTHMIAN GAMES.** See **ISTHMUS.**

ISTHMIAN CANALS. See **NICARAGUA CANAL**; **PANAMA CANAL.**

ISTHMIAN ODES (Gk. Ἰσθμιοῖκαι, *Isthmionikai*, victors in the Isthmian Games). Poems of Pindar (q.v.) celebrating the victors in the Isthmian Games, for which see **ISTHMUS.**

ISTHMUS, is'mūs (Lat. *isthmus*, from Gk. ἰσθμός, *isthmos*, narrow neck of land between two seas). In geography, a narrow neck of land joining two portions of land. The name isthmus was by the ancients often employed without any addition to designate the Isthmus of Corinth, joining the Peloponnesus to continental Hellas. In the southeastern part of the isthmus was a sacred precinct containing temples of Poseidon and Palæmon-Melicertes, where were celebrated the Isthmian Games, one of the four great national festivals of Greece (see **INO**). According to legend, they were established by Poseidon or Sisyphus in honor of Melicertes (q.v.), or by Theseus after his victory over Sinis, in honor of Poseidon, a version which explained the right of the Athenians to the seats of honor at the Isthmian Games. The regular celebration of the games was dated from 582 B.C. The games seem to have been held every two years, in the spring of the second and fourth years of each Olympiad. The prizes were a palm branch and wreath of parsley during the Greek period, but under the Roman Empire a wreath of fir was substituted. The games were in charge of the Corinthians, and the contests seem to have been those usual at Olympia (see **OLYMPIC GAMES**), to which musical competitions were added later. After the fall of Corinth (146 B.C.) the Sicyonians continued the games, until the reestablishment of Corinth by Julius Cæsar. The contests were open to all Greeks except the Eleans. The site of the games has been excavated by the French. Near the site of the isthmian sanctuary can be seen remains of the *Diolkos* or railway by which, in ancient times, small ships were transported across the isthmus; and somewhat to the north can be traced the ancient wall by which, at various times, the Peloponnesus was protected against invasion. The extant remains belong chiefly to the later Roman Empire or the period of Venetian rule. Consult: *Gazette archéologique*, vols. ix-x (Paris, 1884-85); Ἐφημερίς Ἀρχαιολογική (Athens, 1884-85); the article "Isthmia" in Smith, *A Dictionary of Greek and Roman Antiquities*, vol. i (3d ed., London, 1890); Baedeker, *Greece* (4th Eng. ed., Leipzig, 1909). For the Isthmian Games, consult Gardiner, *Greek Athletic Sports and Festivals* (London, 1910). See **CORINTH**; **CORINTH, GULF OF**; **CORINTH CANAL.**

ISTIB, ê-stêp', or **SHTIPLIE**, shtîp'lyë. A town of southeastern Servia, situated about 18 miles east of Köprili and 110 miles south of Nish (Map: Balkan Peninsula, D 4). It has a number of mosques and a fine bazar. Its trade is of considerable importance; the population is estimated at 13,000. For over four centuries it belonged to the Turkish Empire, being included in the Vilayet of Kossovo, but during the Balkan War (q.v.) it was captured by the

Servians (October, 1912) and confirmed to them by the Treaty of Bucharest (Aug. 10, 1913).

ISTRIA, is'trī-ā. An Austrian margraviate and crownland, forming part of the modern administrative district of Küstenland (Coastland) (Map: Austria-Hungary, C 4). It consists of a peninsula, the ancient Histria, projecting into the northeast part of the Adriatic Sea, and the islands of Veglia, Cherso, and a few others, covering a total area of 1913.6 square miles. The peninsula is bordered on the north by Triest, Görz and Gradisca, and Carniola, on the east by Fiume, Croatia, and the Bay of Quarnero, and on the south and west by the Adriatic. The peninsula has well-indented coasts and is traversed by a chain of rocky mountains from north to south, culminating in the peak of Monte Maggiore, nearly 4600 feet high. The shores are generally precipitous. The chief streams are the Arsa in the east and the Quieto in the west. The climate is very warm and dry. The severe winds along the coasts are greatly feared by the inhabitants. Istria has little land adapted for tillage, but its pasture lands are extensive as well as its forests. In 1910, out of a total of about 495,600 hectares, arable land amounted to about 55,900 hectares, gardens 14,500, vineyards 29,600, meadows, pastures, etc., 214,200, woodland 165,400, lakes and marsh 630, unproductive (untaxed) 15,300. The climate is favorable to the cultivation of southern fruits, such as olives and figs. Istria also produces an excellent grape, and its wines are famous. Of mineral products it yields chiefly alum, lignite, and salt. The large forests furnish good material for ships, and shipbuilding is a very extensive industry. The sea fishing is also important. The manufacturing industries are as yet undeveloped. Owing to its numerous harbors, Istria is one of the most important commercial districts of Austria, and Pola, at the southern end of the peninsula, is the chief naval station of the monarchy. The total shipping entered at Istrian harbors amounts to about 6,700,000 tons annually. Istria has a separate Diet of 47 members and sends 6 representatives to the Lower House of the Austrian Reichsrat. For administrative purposes it is divided into seven districts and the Municipality of Rovigno. The population in 1900 was 345,050, the increase for the decade being about 8.4 per cent; in 1910 (census of December 31), 403,261, the increase being 16.95 per cent. The total was about 1.41 per cent of the population of Austria. In 1910 the inhabitants of Austrian nationality numbered 386,463, of whom Serbo-Croatian was the vernacular of 168,184 (43.52 per cent), Italian-Ladin 147,417 (38.15), and Slovene 55,134 (14.27). Of the total population present in 1910, 399,870, or 99 per cent, were returned as Roman Catholic. The principal towns include Pola (pop., 58,562), Rovigno (12,323), Capodistria (11,765), Isola (6101), Dignano (6087), and Parenzo, the seat of the Diet (4263). The ancient Istrians belonged to the stock of Illyrians, like them were pirates, and were conquered by the Romans under C. Claudius, 177 B.C. Part of their country was later united to Italy, part to Illyricum (q.v.). It fell into the hands of the Goths in the fifth century. In the seventh century Slavic peoples penetrated into the region. In the course of the Middle Ages parts of Istria were at different times under the rule of the Byzantine emperors, the Franks, the dukes of Carinthia, margraves

of various petty German houses, the Patriarch of Aquileja, the Venetians, the counts of Görz, and the house of Austria, the bulk of the peninsula finally remaining in the hands of the Venetians and the northeastern or German portion in those of Austria. On the extinction of the Venetian Republic, in 1797, the whole of Istria became an Austrian possession.

IS'TRIANS. See **ISTRIA**.

ISTURIZ, ē-stōō'rēth, FRANCISCO XAVIER DE (1790-1871). A Spanish statesman, born at Cadiz. An ardent patriot during the War of Independence (1808-14), he was a leader in the revolution of 1820, and three years later presided at the Cortes and voted against the Royalists. This stand caused his exile, and he remained in England until the amnesty of 1834. In 1836 he was made Minister of Foreign Affairs and Premier. Forced to yield his portfolio during the revolution of the following August, he became president of the Cortes in 1838. He was now devoted to the cause of Queen María Christina and continued to advance her interest and the French alliance by every means in his power. Premier again in 1846, his ministry was of short duration, but he had much to do with bringing about the marriages of Isabella II and her sister María Luisa to Francisco de Asís and the Duke of Montpensier respectively, and afterward he represented his country as Minister at the Court of St. James's (1850-54) and at St. Petersburg (1856). In 1858 he became President of the Senate and ten days later was made President of the Council and Minister of State. Sent as Ambassador to Paris (1863), he held that post until October, 1864, when he resigned and retired to private life.

IS'UMBRAS. See **ISENBRAS**.

ISWARA, ēsh'wā-rā (Skt. *īśvara*, lord). An epithet applied to different Hindu divinities, but in mythological acceptation it mostly designates Siva (q.v.).

ITA, ē-tā'. Same as **AËTA** (q.v.).

IT'ACOL'UMITE (from *Itacolumi*, a mountain in Minas Geraes, Brazil). A schistose, light-colored rock composed largely of quartz grains, but also containing mica, chlorite, talc, and other minerals. It occurs in thin plates, which commonly possess the property of flexibility and can be bent backward and forward like a piece of sole leather. The cause of this flexibility is generally assigned to the peculiar form of the quartz grains; the latter, according to some observers, are elongated and have re-entrant and projecting surfaces which articulate like joints. Itacolumite is associated with the crystalline schists of Brazil, where it covers large areas, and is also found along the southern Appalachians in the United States. The source of the Brazilian diamond has been referred to itacolumite.

ITAGAKI, ē'tā-gā'kē, TAISŪKE (1837-). A Japanese statesman, called the "Rousseau of Japan." He was born in the Province of Tosa in the island of Shikoku. He received the usual education of a samurai, or military gentleman, and when a young man became a strenuous advocate of the Mikado's supremacy as against the historic usurpation of the Shogun in Yeddo. In the Civil War of 1868 he was aid-de-camp to the Imperial general Arisugawa-no-Miya, and was especially active in the campaign against Aizu in northern Hondo. After the Restoration in Tokyo he was made one of the privy councilors to the Emperor, and held that office

from 1871 to 1873. He resigned because he, with Saigo Takamori of the Satsuma clan, advocated war with Korea on account of the refusal of the latter to continue the tribute which had been paid for centuries to the Shogun's government, and the further refusal of Korea "to acknowledge the Mikado as Emperor of Japan or to have any official relations with his government, which it held to be in league with the Western barbarians." The war party failed, however, and Itagaki, believing that his countrymen would have favored such a war had any political machinery existed for making known their views, became an ardent advocate of representative government based on the system of Great Britain or the United States. When, in 1877, the Satsuma Rebellion broke out under Saigo, Itagaki made fresh efforts, by peaceful agitation, for constitutional government. He organized the first political party in Japan (*Jiyu-to*, or Liberals), contending that in the constitution promised by the Emperor it should be provided that the ministry should be responsible to the Parliament and not to the throne. In 1878 he was Minister of Public Works, and Minister of the Interior in 1880. After much hesitation he accepted the title and decoration of Count in 1887. In 1898 the Liberals, under Itagaki, united with the Progressives under Okuma, and the fusion was called the Constitutional party, which had a large majority in the Lower House. The Emperor thereupon invited Counts Okuma and Itagaki to form a cabinet (Itagaki holding the portfolio for Home Affairs), which, however, lasted but six months, when the ministers resigned and the party resolved itself into its old elements. Itagaki was an uncompromising advocate of the adoption of the British or United States constitutional system as against that based on the German, drafted by Ito and adopted in 1889. He became a Christian and was long an officer of the Church.

ITALA, it'ā-lā. The name given to the Latin versions of the Bible current before the famous Latin version by Jerome (q.v.). Consult Schanz, *Geschichte der römischen Literatur*, part iii, § 772 (2d ed., Munich, 1905). See **BIBLE**: (IV) *The Versions—The Latin Version*.

ITALIAN ARCHITECTURE. A term used by certain English writers to designate the Renaissance style of architecture because it originated in Italy. More properly it designates the architecture of Italy since 1800, as all that precedes that date is called by particular names of styles and periods. Modern Italian architecture displays few important works of original design, owing partly to political and industrial conditions, but more to the overwhelming influence of the past. Hence the best Italian work has been archæological in character, like the splendid façade of Florence Cathedral by De Fabbris. The most ambitious of recent works is the gigantic monument of Victor Emmanuel at Rome; stupendous in size and cost, but suffering from a lack of simplicity and restraint, a lack which is apt to characterize Italian work, as is seen also in the great Palace of Justice in the same city. See also **GOTHIC ARCHITECTURE**; **RENAISSANCE ART**.

ITALIAN ART. According to the general plan of the **NEW INTERNATIONAL ENCYCLOPÆDIA**, the art of modern European countries, which is essentially international in character, is treated under the headings of the great epochs

of its development. (See ART.) The art of Italy, therefore, falls under various headings: the ancient under ETRUSCAN ART and ROMAN ART; the mediæval under EARLY CHRISTIAN, ROMANESQUE, and GOTHIC ART. The architecture of the Renaissance is likewise treated under the collective heading RENAISSANCE ART; but Italian sculpture and painting, which during this period became independent of architecture, are best treated under the general articles PAINTING and SCULPTURE, which cover the entire modern development. The local aspects of Italian painting are noticed in special articles like FLORENTINE, VENETIAN, and UMBRIAN SCHOOLS OF PAINTING (and others). The decorative arts of Italy are treated under such separate headings as DECORATIVE ART; FURNITURE; TAPESTRIES; JEWELRY; PLATE; ETC.

ITALIAN BAND. See AUGUSTUS' BAND.

ITALIAN LANGUAGE. A term used generically to denote those modern types of Latin speech spoken in the Italian peninsula, in Sicily, Sardinia, Corsica, and Malta, along the north-eastern Adriatic shore (Istria, Dalmatia, Illyria), and on the southern watershed of the Alps as a whole (including the Münster, Gardena, and Gardera valleys). The Italian language on the Continent thus extends beyond the political boundaries of Italy into Austria, Switzerland, and France (Savoy). In Adriatic Austria and Italian Friuli Italian has for some decades been yielding to Slavic pressure, finding compensation in the gradual extinction of the German communes in Venetia and in strong colonies in South America (Argentina), in the United States, and in Libya (Africa).

Specifically the term denotes that type of language which is the common medium of expression in these different regions—a language of which the minuter characteristics cannot be rigidly defined, but in which the predominant element is the dialect of Tuscany (Florence, Siena, Pisa, Lucca) or, more strictly still, of Florence. In this sense the term "Italian language" is relatively modern (sixteenth century), replacing the term "Tuscan," which was, as it still sometimes is, inaccurately used to distinguish the literary language from other dialects; and the term "vulgar" (*volgare*), formerly used in opposition to school Latin.

Italian is one of the *Romance* (also called *neo-Latin*, or *Romanic*) languages (q.v.). The others are French, Provençal, Spanish, Portuguese, Rumanian. The Italian dialects of the eastern Alps are so peculiar, however, that they are sometimes classified as a separate language, *Rhæto-Romanic* or *Ladin* (from *Latinum*). A great Italian philologist, Ascoli, wished similarly to isolate the western Alpine dialects as the *Franco-Provençal* language. Still others would so treat *Sardinian*.

THE ITALIAN DIALECTS

In proportion as the Roman Empire extended, the language of the city of Rome was imposed upon her conquered territories. In Italy Latin came to supplant the Gallic languages in the north, Etruscan in the centre, Oscan, Umbrian, and allied types as well as Greek in the south. But meanwhile the language of Rome was undergoing many internal changes. Contact with the culture of the Gauls, Germans, and Greeks introduced many new words into Latin. The ancient dialects of Italy (*Italic dialects*) as they disappeared left traces behind them in the

language of the capital. A certain proportion of modern Italian vocabularies is derived from these ancient sources, often anterior to the barbaric invasions. Furthermore, in Rome itself there had been from early times more or less rigid class distinctions. Economic and clannish antagonisms isolated various groups from each other. The cultivated patrician spoke a language somewhat different from the uneducated plebeian and the cosmopolitan mob. This cultivated language came to be adorned with imposing literary monuments which established standards of taste and ultimately shackled itself with a preceptualistic grammar. Conservatism thus became the rule in the literary tongue, while the populace went on adapting its linguistic expression to the most varied national and regional influences. As early as the late Empire there is a wide gap between popular, vulgar Latin and that of classic literature. It was this vulgar tongue that merchant, soldier, and colonist spread over the non-Roman Latin world in a pronunciation, a morphology, a syntax, that Cicero and Vergil would not have recognized.

This vulgar Latin, spoken by the vast hordes of the Roman populace, survived the fall of the Roman Empire and is still spoken in its Italian and other Romance forms. With the fifth century classic pagan culture, essentially aristocratic, succumbs to Christian culture, in its origins popular. The Latin of Christianity shows extensive concessions made by the classic tongue to the vulgar speech. But neither of these cultures possessed adequate machinery for educating the poorer classes, who developed their own languages without disturbance from above. The ancient cultural tradition remained, however, strongest in Italy. This fact, together with the relatively slight racial changes in Italy, perhaps explains the greater similarity of Italian to ancient Latin types.

Nevertheless, the destruction of national life broke down the intimate mutual relations of the provinces of the Empire. Regional traits in language became accentuated. Diversity increased as intensity of communication lessened. The parish differentiated itself from the town as a whole, the town from the surrounding country, one geographical or economic unit from another. Thus, the Latin tongue, which proceeded from Rome with more or less unity, broke up into thousands of types. We may classify these types for convenience into languages, dialects, and patois; but such delimitations have no absolute value. Were we to take account of all the slightest variations of speech, there would be almost as many types as there are speaking individuals. In the city of Venice there are two distinct linguistic "spheres"; the language also of a Venetian proper differs from that of a citizen of the Venetian mainland, who would in turn find even difficulty in talking with a Lombard or a Furlano and be driven to despair or to delight in Genoa and Palermo. Time has much the same effect as distance. In Italy, however, there is not so great a gap between the old dialects and their modern forms as is found in France.

For the characteristics of vulgar Latin as opposed to the classic tongue, see the article on ROMANCE LANGUAGES. Here we shall outline summarily the general linguistic types that show more or less widely distributed developments from this vulgar Latin.

I. Dialects showing more or less dependence on Romance types outside of Italy.

1. Franco-Provençal dialects (Savoy, Wallensia, the upper valleys of the two branches of the Dora, of the Orco and the Stura). Distinctive characteristics: (a) Latin palatal + *a* = *e* or *i* (capream = *zevra*). (b) Preservation of Latin pluperfect indicative and imperfect subjunctive (portaveram = *portaro*; haberem = *avre*). (c) Preservation of *t* in third person singular of verbs (portat = *portet*). (d) Lat. *ca* = *ehe* or *ehe*, as in French (carum = *zir*).

2. Ladin dialects (Swiss Grisons, Münster, valleys of Gardena and Gardera, Noce, Avisio, Corievole, Boite, upper Piave, the Province of Friuli, the upper Ticino, upper Mera, Val Fiorentina, and Cadore). Characteristics: (a) Lat. *ca* and *ga* are palatalized (capillum = *chavel*). (b) Lat. groups *pl*, *cl*, *gl*, etc., remain intact (claves = *clcfs*). (c) Plurals are formed with *s* (rami = *rames*). (d) Lat. accented *a* = *e* (canem = *zen*). (e) Lat. accented *ū* = *ü*, as in French (mulos = *müles*). (f) Diphthongization of the other accented Latin vowels in position (before two consonants): *e* = *ie*; *e* and *i* = *ei*; *ō* and *ō* = *ue* = *ue*, *ö* (like French *eu* and *œu*) (nivem = *neif*; oculi = *oeje*; modum = *möd*; infernum = *infiern*).

II. Dialects independent both of French and strictly Italian systems. These embrace the group formerly called *Gallo-Italian* (Ligurian, central in Genoa; Piedmontese, central in Turin; Lombard, in Milan; Emilian, in Bologna). Here belongs also Sardinian, with three types corresponding to the regions of Logudoro, Campidano, and Gallura.

1. Gallo-Italian group. Characteristics: (a) Final unaccented Lat. vowels drop in Pied., Lom., and Emil. (retem = *red*; vocem = *votsh*). (b) Pretonic Lat. vowels drop in Pied. and Emil. (dinerum = *dnê*), sometimes developing a prosthetic vowel (rumorem = *armor*). (c) Lat. accented *ū* = *ü* and *ō* = *ö* in Pied., Lig., and Lom. (durum = *dür*; novum = *növ*). (d) Lat. accented *ē* and *ī* = *ei* in Pied., Lig., Emil. (habere = *aveir*); the diphthong *ie* from Lat. *ē* does not, however, appear. (e) Lat. accented *a* = *e* generally, except in Lig. (andare = *ander*). (f) Nasalization of *n* generally (panem = *pân*). (g) Vocalization of palatal in Lat. group *ct* (factum = *fait* and *fatch*), which is also confused with *pt* (scriptum = *screihtor*). (h) Disappearance of intervocalic *d* generally and in Lig. of *l* and *r* (ridere = *rie*; dolorem = (in Genova) *durur* = *dü* through step *duu*). (i) Lat. *g* between back vowels (*a* or *o*) = *j* (in Piedmontese) (braga = *braja*). (j) In Lig. *pl* (Lat.) = *ch* (as in Eng. *church*), *bl* = Eng. *j* (as in *joy*), *fl* = *sh* (plus = *chü*; rabies = *rajja*; florem = *shü*). (k) In Lig. a final Lat. *s* often becomes aspirate *h*, as is regular in Sanskrit and as occurs also in the dialect of Bergamo (grossum = *groh*). (l) A Latin final *i* causes umlaut generally (bonum = *bön*, but boni = *boin*). (m) In Emil. verbs show large use of present subjunctives in *-pa* (siam = *sipa*) and of preterits in *-p* (fuit = *fop*). (n) Subject pronouns are triplicated or duplicated generally (cantas = *ti te cantet*, that is really Lat. *te te cantas tu*).

In these dialects the presence of nasal vowels and of the French *ü*, the summary justice done to unaccented vowels and the reduplication of pronouns have been ascribed to ancient Celtic influences. Their unintelligibility is a standing

joke among educated Italians, who see their sonorous *fiore* and *dolorc* reduced to squeaky monosyllables, *shü* and *dü*.

2. Sardinian group. Characteristics: (a) The Latin accented vowels are all preserved, i.e., *ī* and *ū* do not blend with *ē* and *ō* (nucem = *nughe*; pilum = *pilu*). (b) Similarly the unaccented final vowels (see ib.). Sardinian thus furnishes corroboration of the derivation of Romance nouns from Latin accusatives, since the treatment of accusative *-um* and ablative *-o* is different, whereas in Italian generally they would be the same. (c) Final *t* and final *s* survive (plantas = *plantas*, amat = *amat*). (d) Lat. *c* and *g* remain hard before *e* and *i* (facis = *faghes*). This phenomenon, of questionable antiquity however, has been held as proof of the Latin pronunciation of *c* and *g* in this situation. (e) Initial *cl*, *bl*, etc., survive (clarum = *claru*). (f) Lat. *ny* = *nzh* (melius = *mezhus*). (g) Lat. *qua*, *gua*, *eu*, and *gu* = *bba* or *bb* (aquam = *abba*). (h) Lat. *ll* = *dd* (bellum = *beddu*). (i) Lat. *s* + consonant prefixes, when initial, a permanent *i*-, which is movable in Italian generally (stellam = *istella*). (j) Phonetic changes are widely determined by position of words in the sentence (*Satzphonctik*): *su ove* = *the ox*, but *sos boves* = *the oxen*, the *b*, i.e., dropping between vowels. (k) The definite article derives from *ipsum* (= Sard. *su*, plural *sus*), not from *illum* (= It. *il*, *lo*, Fr. *le*, etc.). (l) Lat. imperfect subjunctive survives in verbs (cantarem = *canterc*). (m) Preference of preterits in *-si* (cantavi = *cantesi*). (n) Future formed by Lat. *habere* + preposition *ad* + infinitive (habeo ad manducare = *hapo a mandigarc*, I shall eat). This is conclusive corroboration of the etymology of the Romance future.

Sardinian in general seems to represent an earlier stage of vulgar Latin than other Romance languages. It is one of the most important and interesting for linguistic study.

III. Dialects with pronounced affinity to the Tuscan system.

1. Venetian (Venice, the Venetian estuary, and mainland as far as the Adige, the Alps, and Friuli). Characteristics: (a) Loss of intervocalic *d* (crudum = *cruo*). (b) Intervocalic *k* = *g* (amicum = *amigo*). (c) Lat. *cl* = *ch* (as in Eng. *church*) (ecclesia = *cesa* for It. *chiesa*). (d) Lat. *sc* before *e* and *i* = *ss* (piscem = *pesse*). (e) Intervocalic *ly* = *j* (like *z* of Eng. *azure*) (familia = *famegia*). (f) Third singular replaces third plural in verbs (cantant = *i canta*). (g) Preference for participles in *-csto* in second and third conjugations (vedutum = *vedesto*). (h) The *s* of Lat. second person singular is preserved in interrogation (habes = *ti a*, but habes tu? = *astu*). (i) Intervocalic *l* tends to disappear in contemporary dialect (insalatam = *insaaa*). (j) Lat. *est* = *xe*. (k) Double consonants become single (bellum = *belo*). The great similarity of this dialect to the literary tongue has given its literature a ready diffusion outside of Venetia.

2. Corsican. There is a Sardinian trend and a Tuscan trend: (a) Lat. *gu* = *bu* (gunna = *bunna*, It. *gonna*). (b) Lat. first conjugation is sometimes attracted to third (laxare = *leche*). (c) Unaccented vowels survive, with *u* for *o* and *i* for *e* (lactem = *latti*, pilum = *pilu*). (d) Lat. accented *ar* + cons. = *e* (carnem = *chern*). (e) Lat. *ll* = *dr* (bellum = *bedru*, It. *bello*). (f) The suffix *-one* is diminutive, as in French (fratellonem = *fratedronu*, little brother).

3. South Italian dialects—Sicilian, Neapolitan, Roman (Umbria, Marche, Roman Province). General characteristics: (a) Intervocalic *t* survives (setam = *seta*). (b) Intervocalic *d* = *r* (ad duos = *a roi*). (c) Lat. *nd* = *nn* (discendere = *scennere*), so also *mb* = *mm* and *nv* = *mm*. (d) Lat. *pl* = *ky*, *bl* = *j* (Eng. *joy*), *fl* = *sh* (plus = *chiu*, rabiem = *raggia*, florem = *sciuri*, It. *fiore*). So also for *py*, *by*, *fy* (sepia = *secchia*). (e) Lat. *ce*, *ci* = *tts* (glaciem = *iazzu*). (f) Dropping of initial vowels (intendere = *'ndennere*). (g) Double consonants are preserved, and many single consonants are doubled (de post = *doppu*). (h) *Satzphonetik* (see above) is prevalent (dominam = *donna*, but unam dominam = *'na ronna*). Special characteristics:

A. Sicilian. (a) Lat. *i* and *ũ* survive, but Lat. *é* = *i* and *ó* = *u* (pilum = *pilu*, credere = *crediti*, solem = *suli*). (b) Intervocalic *ly* = *ghy* (filiam = *figghia*). (c) Intervocalic *ll* = *dd* (bellum = *beddu*).

B. Neapolitan (principal variations: Calabrian, Abruzzese, Otrantine, Leccese, Basilisk for the Basilicata, Neapolitan for region of Naples). (a) All Sicilian characteristics more or less prevalent (filium = *figghiu*, vocem = *vuci*, caballum = *cavaddu*). (b) Lat. *fl* = *hy* (florem = *hyuri*). (c) Lat. *õ* = *ue* (corem = *cueri*) and unaccented often = *au* (honorem = *anaure*). (d) Accented Lat. *a* = *e* (capum = *ghepe*). (e) In Abruzzese a general dropping or weakening of unaccented vowels (satisfactionem = *sfaziaune*), which is limited more usually to finals (bonum = *buone*). (f) Neapolitan follows the Romance tendency for Lat. *i* = *e* (venis = *viene*), following Sicilian, however, for accented Lat. *o*, *u* and *e*, *i*. (g) Accented Lat. *ě* and *õ* diphthongize in position, i.e., before two consonants (apertum = *apierte*, mortem = *muorte*). (h) Creation of consonants between vowels in hiatus (alterum = *avotre* through steps *autro*, *aultro*). (i) General diffusion of Lat. pluperfect indicative (feceram = *faceru*). (j) Traces of ending *t* in third singular of verbs (habuit = *ebbeti*). (k) In Abruzzese third singular replaces third plural. (l) Lat. neuter plurals in *-ora* survive (tempora = *tempora*).

C. Roman and Umbrian. (a) Lat. *ld* = *ll*, *nd* = *nn*, *mb* = *mm* (plangendum = *piannenne*, calidum = *callu*, plumbum = *piommo*). (b) Diphthongization of *ě* and *õ* in position (tempus = *tiempi*, dominam = *duonna*). (c) Survival of Lat. *intus* and *apud* influencing prepositions *ad* and *in* (*ad* = *ta*, *in* = *me* before article). Here also a wide diffusion of Tuscan elements on the one hand and Neapolitan on the other.

IV. The Tuscan dialects (Florentine, Pisan, Lucchese, Sienese, and Aretine). Characteristics: (a) Lat. *c* between back vowels = *h* (illam casam = *la hasa*). (b) Lat. *ly* = *gghi* (filiam = *figghia*) or disappears (alium = *aio*). (c) Lat. *l* + consonant = *i* and *u* (alterum = *ailtro* and *autro*). (d) Intervocalic *t* = *h* (adripatum = *arrivaha*). (e) In Lucca *tj* = *ss* (plateam = *piassa*). (f) Also Lat. *s* = *th* (preso = *pretho*). (g) Lat. *-unct* = *-ont* (unctum = *onto*). (h) Unaccented *e* = *e* (te = *te*, It. *tu*). (i) Frequent interchange of *l* and *r* (mortem = *molte*). (j) Assimilation of pretonic vowel to the tonic, and of post-tonics to the final (utilem = *utele*, ridiculam = *ridiquala*). (k) Palatalization of *t*, *d*, *l*, *n*, before a final *i* (quarti = *quarkye*, cani = *kegne*). (l) Metathesis of *i* between vowel and consonant (medie-

tatem = *meità* = *metià*, vocitum = *voito* = *votio*).

THE LITERARY TONGUE AND THE "QUESTION OF LANGUAGE"

While Latin held almost undisputed sway in the written document and in interregional communication, these dialects reigned undisturbed in their respective territories. The earliest popular Italian documents (tenth century) are dialect in language. And when, in imitation of the popular literature of France and Provence, the Italians set about conscious artistic production, each Italian thought of writing only in his native dialect. Thus, in the thirteenth century the poetry of the court of Frederick II is notably Sicilian and at any rate Southern in language; the epic poetry of the north is markedly Venetian, while Umbrian forms the base of the splendid Franciscan dialogues in verse. Had Venetian imperialism, e.g., succeeded in unifying Italy politically, doubtless Venetian would to-day be the Italian language just as the language of the Capetian estates of the Ile de France became the French tongue. But Italy was destined to attain cultural unity long before political independence, though the linguistic hegemony of Tuscany has never been as undisputed as the present political leadership of the house of Savoy.

Its earliest rival was the hybrid Southern language of the Sicilian court, which was raised to some dignity by a fairly extensive literature in the thirteenth century. But this language, in this literature, rested on the artificial foundations of the culture that characterized the court of Frederick II; and its development ceased with the dispersion of that court. A variety of causes gave, already at this early date, the predominance to the Tuscan dialect. Tuscany occupies a central position in Italy. Its dialect of all the Italian group departs least in phonology and morphology from classic Latin, and therefore best of all the dialects it harmonized with the traditions of Latin culture. The aggressiveness of Florentine commerce is only secondary in its influence to the great fact in the history of the Italian language that Florence developed a local culture worthy of taking up the heritage of the Sicilian poets and capable of producing the three literary artists who summarize Italian thought and feeling of the early Renaissance and late Middle Ages—Dante Alighieri, Francesco Petrarca, and Giovanni Boccaccio.

The *Divine Comedy* of Dante was the only book of its age able to hold in popular culture the position of Vergil in the Latin tradition. It alone was sufficient to turn the whole current of cultivated expression into one channel. But Tuscany was fortunate again in producing Petrarch, whose cosmopolitan training and distinctly modern outlook were likewise able to cast in a Tuscan mold all the intellectual aspirations of a new age that might have found Dante outworn. While thus the two supreme models of Italian poetry were Tuscan, Boccaccio came to complete the series with the brilliancy of his prose. Italians who saw in Dante and Petrarch poets equal to Vergil and Horace and in Boccaccio a rival of Cicero readily came to see in the language of these men a peer of Latin. As early as 1435 the doctors of Pope Eugene's court were debating on the "regularity" of the vulgar tongue (Tuscan), and the *certame coro-*

nario (poetic contest) of Florence (1441), though its productions cast little glory on the Italian language, at least signifies the existence in learned circles of the conviction that the language of the "Three Crowns" (Dante, Petrarch, and Boccaccio) was as "noble" as Latin. It was to demonstrate this equality, particularly to show that the categories of Latin grammar were applicable with the same preceptual force to Italian, that the earliest grammars were written (Lorenzo il Magnifico (?), c.1490; F. Fortunio, 1516).

But the examination of the linguistic question in Italy soon revealed a very troublesome situation. Italians outside of Tuscany, as they attempted to write in the language of Petrarch and Boccaccio, could not free themselves from the consciousness of their own native dialects. Dialectical tendencies in the literary tongue were especially strong in the regions closely kindred to Tuscany (Venetia, Rome, South). Moreover, in Tuscany itself Latin culture had eliminated from the literary language the most prominent and "barbarous" dialecticisms ($s = h$, $ly = gghi$, $st = sht$, $l = r$, $unct = ont$, etc.; see above). What theoretically was to be the status of these different elements? The Italian grammarians of the Renaissance had, as their most effective instrument in answering this question, the rhetorical theory of imitation, and they grouped themselves into schools according to the manner in which they applied it. The most fortunate of these early groups was that of classic purism, headed by Cardinal Pietro Bembo, whose book of *Prose* (1525) rigidly defined Italian as the language of the Three Crowns, which Bembo brilliantly illustrated in his own writings. This theory, in effect, made Italian really a "dead" language, since in vocabulary and syntax it was not to exceed the limits of Dante, Petrarch, and Boccaccio, in which triad Petrarch and Boccaccio for their cosmopolitanism in language were recognized as primates. This weakness was soon discerned and violently combated by the Tuscan school (Machiavelli, Claudio Tolomei, G. B. Gelli, and P. F. Giambullari), who recognized the Tuscanity of the Three Crowns and concluded that a living language, in harmony with the cultural tradition, should follow the living Tuscan speech as spoken by cultivated Tuscans. This group also had a Sienese wing (C. Cittadini, O. Lombardelli, S. Bargagli), originators of the apothegm "lingua fiorentina in bocca senese," which succeeded definitively in coupling Siena with Florence as the fountain of "pure" Italian. But the pretensions of these Tuscan schools ran contrary to the regional sentiments of most other Italians, and their resentment at the very term "Tuscan" first gave currency to the term "Italian language," previously called either "vulgar" or "Tuscan." Nevertheless, all grammarians, whatever the color of their doctrine, accepted the theory of imitation, and it was the theory of Bembo, modified by admitting to parity with the Three Crowns all "good writers" (e.g., Sannazaro, Bembo himself, Ariosto, Tasso, Della Casa), that ultimately triumphed. This wider classicism, first codified by Salviati on a Florentine basis, has been the guiding principle of the Accademia della Crusca, which since its foundation in 1583 has in its successive dictionaries pretended with some success to the rôle of arbiter in Italian linguistic matters. In the seventeenth and eighteenth

centuries the Crusca had several antagonists: its theory of the authority of classical usage was attacked in the individualistic system of G. B. Vico, in the doctrine of "logic" and analogy which gained currency under the influence of French philosophy, more subtly again in the theories of "gallantry" and "taste" that filled the pre-Revolutionary academies. The Crusca itself has been profoundly modified in the last 50 years by the Manzonian theory of Italian. Alessandro Manzoni, in his criticism and in the polishing of his famous romance *I promessi sposi* (The Betrothed), compromises between the doctrine of classic purism and Tuscan usage, correcting the "barbarisms" of Tuscany by means of the classic tradition, but reconciling the inconsistencies of the classic authors and providing for growth by adopting such usage as is justified by the living language as spoken in Florence. This is the doctrine that at present is forming the literary Italian language and that is exemplified in the grammar of Luigi Morandi-G. Cappelletti that the Italian government has imposed upon elementary schools.

In this literary tongue the intensely Latin quality of the Florentine dialect is preserved. Italian *accented* vowels follow in general the simpler changes of vulgar Latin ($a = a$, $\bar{u} = u$, $\bar{i} = o$, $i = i$, $\check{i} = e$, $\bar{o} = o$, $e = e$). Of the diphthongs from \check{e} and \check{o} (*ie*, *uo*) in free position (followed by one consonant), the second (*uo*) is tending to revert to *o* (*pedem = piede*, *novum = nuovo* and now frequently *novo*). The simple vowel changes occur also in unaccented vowels, where, however, pretonic *e* is often *i*, and where the influence of labials is often felt (*demandare = dimandare*, but regularly *domandare*). The most radical of the consonantal changes affects the groups *bl*, *cl*, *pl*, which become *bi*, *ki* (spelled *chi*), *pi* (*clamare = chiamare*, *planum = piano*, *blondum = biondo*); but assimilation of other groups is general: *ct = tt*, *pt = tt*, *gd = dd*, etc. (*factum = fatto*). This phenomenon is most disfiguring of Latin when the assimilation takes place after the loss of an intervening unaccented vowel (*venire habeo*, I shall come = *venirò = venrò = verrò*). As in other Romance tongues, the Lat. groups *ce*, *ci*, and *ge*, *gi* have palatalized ($c = ch$ in Eng. *church*, $g = g$ of Eng. *gem*). Purely Latin, on the other hand, is the preservation of double consonants (*gallum = gallo*, i.e., *gal-lo*). In morphology, Italian has reduced the Latin noun cases to two, accusative singular and plural, and the total number of verb tenses and moods to eight simple and seven compound tenses, supplying the deficiency by means of prepositions (*homini = all' uomo*, to the man) and auxiliary verbs (*fecerat = aveva fatto*, he had done). While the vocabulary of Latin has been made to meet all the conditions of Italian life in its changing history, the simplicity of the phonetic and morphological changes, coupled with a fairly perfect phonetic orthography, has made the acquisition of Italian easy for a person who knows Latin or any of its modern Romance forms.

Bibliography. The classification of the Italian dialects most convenient for their systematic study is that of G. I. Ascoli, "Italia dialettale," in *Archivio glottologico italiano*, vol. viii (Turin, 1882-85). For dialects and history of the language, see bibliography of ROMANCE LANGUAGES. Fundamental are the series *Archivio glottologico italiano* (Turin,

1874—) and Monaci, *Crestomazia italiana dei primi secoli* (Città di Castello, 1912). For bibliography of modern dialect publication, the *Zeitschrift für romanische Philologie*, Supplementhefte (Halle, 1874—); dialect dictionaries, Alberto Bacchi della Lega, *Bibliografia dei vocabolari nei dialetti italiani* (Bologna, 1876–77). Useful elementary books: Paolo Savj-Lopez, *Altitalienische Chrestomathie* (Strassburg, 1893), and D'Ovidio and Meyer Lübke, *Grammatica storica della lingua e dei dialetti d'Italia* (Milan, 1906), both with bibliography. Question of the literary language: Trabalza, *Storia della grammatica italiana* (Milan, 1908). Grammars: Morandi-Cappelletti, *Grammatica italiana* (Milan, 1906), and in English, C. H. Grandgent, *Italian Grammar* (Boston, 1904). Dictionaries: in Italian, Petrocchi, *Novo dizionario italiano* (Milan, 1906); Pianigiani, *Vocabolario etimologico della lingua italiana* (Rome, 1907); in English: A. H. Edgren, *Italian Dictionary* (New York, 1902); Giuseppe Baretta, *New Dictionary of the Italian and English Languages* (2 vols., London, n. d.).

ITALIAN LITERATURE. The literature written in the Italian language (q.v.). [In view of the necessarily restricted space allotted to minor authors in our biographical articles, we shall treat Italian literature, especially the earlier period, with somewhat greater detail and length than the corresponding portions of English and French literature.] Two salient facts characterize the early history of Italian literature: its relatively late beginning (as compared with French, Spanish, and the Germanic literatures) and its extraordinarily rapid rise in less than a century to the heights of Dante, Petrarch, and Boccaccio. Both these facts are due to the tenacity of the Latin tradition in Italy. From Boëthius and Cassiodorus (sixth century) down through the Middle Ages, Italians read the Latin classics and wrote Latin even with elegance—all the more because the barbaric invasions did not cause ethnological and social disturbances so violent and thoroughgoing as those beyond the Alps. There was in Italy no central political power. Life developed regionally and municipally rather than nationally; there was no national spirit to develop an Italian epic literature, no feudalism to foster a Provençal chivalry. The cultivated classes turned rather to the history of their ancient glories, to science and philosophy, and their productions in these fields were for the learned public rather than for the populace. Here Latin was the traditional and the efficient tongue. This culture, moreover, had roots in the laity as well as in the clergy. By the middle of the thirteenth century science and philosophy had attained a high degree of excellence, with all the vigor of civic and intellectual life attendant upon them. Early Italian literature reflects this culture rather than the untaught emotions of a naïve and ignorant populace. So in a sense Italian literature was born full grown.

Thus until the first half of the thirteenth century Latin continued to serve in Italy for the writing of chronicles, historical and narrative poems, heroic legends (many of them introduced from France; e.g., the story of Charlemagne and his knights, of Arthur and his Round Table, the mediæval account of the fall of Troy, and the history of Alexander the Great), religious legends and lives of the saints (cf. the famous collection of the Bishop of Genoa, Jacopo da

Voragine (1230–98), known as the *Legenda Aurea*), didactic and scientific works (grammars, encyclopædias, and treatises on morals and philosophy), religious lyrics (hymns like the “Stabat Mater” and the “Dies Iræ”), and liturgical plays and mysteries (the prototypes of the first Italian dramas, the *rappresentazioni sacre*). But Latin was not the only language written in Italy before the time when Italian was thought dignified enough for literary use. The poets of southern France had already wandered into Italy before the end of the twelfth century, and when the Albigensian Crusade drove them forth in the early years of the fourteenth century, the troubadours crossed the Alps in still greater numbers and sang throughout the land of the Apennines their Provençal songs of love and political strife. There soon arose a school of Italian poets who imitated the methods of these Provençal troubadours and, disdaining their native tongue, wrote in the foreign Provençal. Prominent among them were Alberto Malaspina (c.1165–1210), Lanfranco Cigala (c.1200–c.1260), Bonafacio Calvo (c.1200–70), Bartolomeo Zorzi (c.1250), and especially Sordello (c.1200–c.1270), made immortal by Dante. Like the speech and song of southern France, the speech and verse of northern France also entered Italy at an early date. The jongleurs brought the *chansons de geste* into the north of Italy, and there, especially in the domain of Venice, great currency was given to the stories of Charlemagne, of his mother Berte, of his knights, like Ogier le Danois, and the heroes of the Carolingian cycle. The *chansons de geste* were introduced in their native speech. Soon, however, Italians took them up and told the stories in an Italianized form of French (cf. Niccolò da Verona's *Prise de Pampelune*), and later still certain of the *chansons* were related by Italians in a mixed speech, in which Italian predominated. The epic matter thus worked over in Italy was to become of great importance for the history of the poems of chivalry in the fifteenth century. From northern France there were imported also the *fabliaux*, the stories of Reynard the Fox, and the great allegorical and satirical *Roman de la rose*, all of which played a part in the formation of the literature of Italy.

The great popularity of such literature in the thirteenth century, especially of Provençal poetry, seems first to have impressed upon Italians the possibility of doing similar things in Italian. We have, indeed, specimens of written Italian that date back almost to the middle of the tenth century, but they have no literary significance. Nor does the eleventh century show anything of importance, and the more substantial documents ascribed to the twelfth century, such as the *Cantilena bellunese*, the *Ritmo cassinese*, and the *Cantilena di un giullare toscano*, have even less artistic worth than the isolated attempt at writing Italian verse on the part of a foreigner, the Provençal poet Raimbaut de Vaqueiras, in his jocular bilingual *contrasto*. With the thirteenth century, however, Italian assumes literary significance. In all parts of Italy the popular language is now used for the composition of verse, which for half a century remains much more important than prose in the vernacular.

It was at the court of Frederick II (1194–1250) in Sicily that the Provençal lyric manner was first imitated in Italian. Hence the early

Italian poets are generally grouped together as the Sicilian school, although in point of fact they were not all Sicilians, but had Apulians and Tuscans among them. Chief among their number were the Emperor Frederick himself, his son Enzo (c.1225-72), his Chancellor, Pier della Vigna (died 1249), and Giacomo da Lentino, who, one of the most fertile of all, was regarded by Dante as one of the best of the school. These and the other members of the movement simply wrote Provençal poetry, but in their native tongue, so true is it that, aside from the language, there is nothing Italian in their verses, as indeed there was nothing Italian in the society this school reflects. It was unfortunate, too, that the poetry of Provence had by this time itself passed from the spontaneous character of fresh psychological analysis into a decadent conventionalism. Here and there one may find among these Italians a trace of the warm gentleness that was the discovery of Provençal chivalry, but more often they sing with a gallant banality. They adopted the *canzone* (q.v.) as their stock poetic form, and from them the manner spread into central Italy and Tuscany, finding acceptance especially in the towns having close relations with Frederick's court. Thus Arrigo Testa in Arezzo, Folcacchiero de' Folcacchieri in Siena, and many more reëchoed the Sicilian note. In at least one writer of this class, Buonagiunta Orbicciani, there is manifest a tendency to depart somewhat from the methods of the Sicilian school and to introduce elements of Tuscan origin. This tendency becomes a certainty about 1260-80, in the lyrics of two sets of poets, the one belonging to Tuscany, the other to Bologna, and both representing a transition period during which prominence is given to the sonnet as well as to the *canzone*.

In this second phase the Provenzalizers (*Provenzaleggianti*), as they are called, read into the hackneyed praises of their ladies philosophical and religious meanings. Human love is studied as to its origin and nature and its resemblances in cause and effect to divine love. So the lady who inspires human love comes to symbolize the divine power that inspires love of God, and thus to assume a part in the process of salvation itself. So at this early date Italian poetry tends towards erudition and intellectuality, characteristics that are permanent. Aristocratic and impersonal, it is nevertheless henceforth associated with the national culture.

Of the Tuscan poets the most important was Guittone del Viva of Arezzo (1220-94), one of the noncelibate friars called *Frati godenti*. In his earlier poems he adhered closely to the strict Provençal manner. In the later ones, replete with Latinisms in vocabulary and construction, he introduces speculation of a moral, religious, and philosophical nature, and, with a new and healthy outlook, he addresses to his fellow citizens remarks on matters of contemporary political interest. This attention to political matters of the day is stressed also in other members of the Florentine group, of whom Monte Andrea and Frescobaldi may receive a passing mention. The greatest departure from the mannerisms of the Sicilian school was made by the Bolognese group of writers, and the best of all these was Guido Guinicelli (c.1230-76). From his *canzone* beginning *Al cor gentil ripara sempre amore* may be said to date the manner called the *dolce stil nuovo*, or sweet new style,

which reached its height of excellence in the sublime poetry of Dante. Love and nobility (*gentilezza*), says Guinicelli, are as inseparable as light and fire. So the loved one, bearing the semblance of an angel, awakens nobility in the heart (inherently noble) through love. It remained still for Dante's idealism to proclaim that love could create nobility even in the ignoble heart. The methods of Guittone and Guinicelli were adopted by the Florentine Chiaro Davanzati (c.1230-?), whose conception of love is, however, rather a matter of Christian symbolism than of philosophy. Among the Tuscans the most Tuscan of all for direct contact with life are Rustico di Filippo (c.1220-c.1280) and Cecco Angioleri (1255-?), who have some affiliations with Provençal idealism, but who also wrote satirical sonnets of a high order of humor.

Meanwhile the influence of Northern French literature was also making itself felt in Italy. But yielding the lyric to Provence, it is rather in didactic literature that this other foreign model prevailed. From Milan, Gherardo Patechio (Girardo Pateg, c.1228) explained the "Proverbs of Solomon." If he takes anything from Provence, it is still the biting, moralizing satire of his *Noie* (Ennuis). The catechism is turned into verse by Uguccione da Lodi (Uguccion de Laodho). More pretentious in scope was the didactic poetry of Bonvesin da Riva and Giacomino da Verona, of whom the latter contributed to vision literature the *Libro delle tre scritture* (black for hell, red for redemption, and gold for salvation). Of the same class is an anonymous poem, styled vaguely as *Atrovare* from Reggio d'Emilia. A similar dreary didacticism appears again in the *Sermoni* of Pietro de Barsegapé. Thus early the practical unimaginative character of the north stands out against the more idealistic tendencies in the south. And the two trends, likewise permanent characteristics of Italian literature, meet in Florence for their perfection. For the best writer in this didactic genre is Brunetto Latini (c.1220-c.1294), whom a too literal interpretation of a statement made by Dante (*Inferno*, xv) has caused to be considered as the latter's tutor. He was certainly a great factor in promoting culture in his own time. To Brunetto Latini, in addition to prose works and certain minor poems, there must be ascribed the allegorical poem called the *Tesoretto*. He intended this to be a sort of preface to his encyclopædic work, *Li livres dou tresor*, which he wrote in French. The initial motive to Brunetto's poem was probably furnished by the *Consolations* of Boëthius, but here, as in all this literature, the great formative influence was the *Roman de la rose*.

To northern Italy, a favorite haunt of the wandering jongleurs, belongs also at this time much narrative verse in Italian showing the Northern French material of the *chansons de geste* (cf. the *Buovo d'Antona*, almost wholly Italian in treatment) and the beast epic (cf. *Rainardo e Lesengrino*, in two Venetian versions), thoroughly acclimated in Tuscany, as we shall see, after having passed through Franco-Italian intermediary forms. This epic material, though borrowed from abroad, was essentially popular in appeal. But it had to combine with another native Italian tradition, substituting the octave stanza for the ponderous French *laisse*, before it lost its savor of ex-

oticity. Proofs are not lacking of the early existence and independent origin of a thoroughly popular Italian poetry, occasional in its nature and dealing with love or matters chiefly of local significance. For samples of this poetry we must go to the works of more consciously artistic poets who imitated it, or else judge of it from similar productions of later date. Thus Giacomino Pugliese adopted some of its forms, and a charming bit of it has come down to us attributed to Cielo d'Alcamo, one of the Sicilian group. This is a *contrasto*, or dialogue, between lover and lady: his passion is impudently spurned by a coquetry that is only too ready to yield. These characters, clearly objectified, spar back and forth with delicious humor.

But for really great, and at the same time thoroughly native, poetry we must turn to the Umbrian school of popular Franciscan poets. Drunk with the religious fervor of St. Francis of Assisi, these monks carried the good message to the multitude in its own language and its own poetic forms. They brought the Holy Office from the church to the market place, not with the cumbersome machinery of the French mystery, but in the simple narrative of the Gospels condensed into its most tragic and human essences. The *laudi* (Praises) of the Umbrians have an historical importance for the Italian theatre, especially in relation to Lorenzo il Magnifico and Poliziano. But the *Crucifixion* and the *My Lady Poverty* of Jacopone da Todi are masterpieces in their own right.

Italian prose of literary moment did not appear until the second half of the thirteenth century. As has been said, many narrative and didactic works were written in Latin. Moreover, like Brunetto Latini, certain other Italians adopted French for their productions; thus, Aldobrando, a Tuscan, composed in French prose his little treatise *Le régime du corps* (1256), and Rusticiano da Pisa employed the same language in his compilation of tales about Arthur and his knights (c.1270) and in his account of the journey of Marco Polo. Italian prose was first used to any great extent in translations of Latin didactic, moral, and historical works, and of French legends of an heroic or a religious nature. Original prose works began to appear later. Among them were the letters of Guittone d'Arezzo (1220-94), which display an unmistakable attempt to create a sort of poetical prose in Italian; the didactic works of Guidotto da Bologna (c.1266), of Tommaso Gozzadini (second half of the thirteenth century), of Ristoro d'Arezzo (1282), and especially the *Introduzione alla virtù* of Bono Giamboni (second half of the thirteenth century); certain chronicles and historical accounts; and, most interesting of all, certain collections of tales. Already in the thirteenth century professional tellers of tales (*favolatori*, *novellatori*) wandered about northern and central Italy relating stories derived from all possible sources. Written collections of their tales or of similar ones were the *Conti di antichi cavalieri* (second half of the thirteenth century), consisting at least in part of rather free versions of matter originally French and Latin, and the *Novellino*, worked over in many versions even before the end of the thirteenth century and displaying no little skill in the art of storytelling, which Boccaccio was to develop to the fullest before another century had passed.

This summary review of the pre-Dantesque Italian literature makes clear the fact that by this literature alone we are entirely unable to explain the genius of Dante. Had he left only his minor works he might be intelligible on the basis of the literary tradition: the poetry of Guinicelli, Davanzati, and Fra Guittone leads up to the *Vita nuova* (c.1290) and the *Canzoniere*. Had Dante stopped here he would have been noteworthy among the fairly ordinary poets of the sweet new style: Guido Cavalcanti, Dante's first friend, who philosophizes on the nature of love with a graceful idealism, Lapo Gianni, Dino Frescobaldi, Gianni Alfani, and Guido Orlandi, who likewise sing of ladies angelified and form a manner that hastens to a conventional degeneration in their immediate and younger followers. The *Convito*, too, would be notable, simply for its unusual competence, alongside of the commentaries of Francesco Barberino (1264-1348) and the treatises of Domenico Cavalca (1270-1342). The *De Monarchia*, in Latin, might in part seem probable after the chronicles of Dino Compagni (q.v.) and in connection with those of Giovanni Villani (1275-1348), both of whom reflect the political temper of Dante's age. But what shall we say of the *De Vulgari Eloquentia*, of which the philological acumen has no parallel till we reach the eighteenth century in Italy, and then in the isolated case of Giambattista Vico? Or of the *Commedia*, which stands on a solitary pinnacle not only in Italy, but in the civilization of the world? The *Comedy* of Dante is an allegorical poem, and we might cite in a similar category the *Intelligenza* or the *Fiore*, anonymous poems in the sequence of the *Roman de la rose*, which might lead rather to poems of the calibre of the Dantesque imitations of Cecco d'Ascoli (Francesco Stabili, 1257-1327), who wrote the *Acerba*; of Dante's son Jacopo, who wrote the lumbering *Dottrinale*; or Francesco degli Uberti, author of the *Dittamondo*. To understand the possibility and the full meaning of Dante's *Comedy* we must go outside the field of Italian belles-lettres and penetrate into the essence of all mediæval culture. We must follow him into the scientific movement shown in part in the works of Albertus Magnus, into philosophy that had been treated with synthetic vision by Thomas Aquinas, into the mysticism of St. Bonaventura and the democratic exaltation of St. Francis of Assisi. Nor could we stop here. There would still remain the plastic sensibility and imaginative sweep of concept of a Giotto or a Niccola Pisano, the serene splendor of the Ducal Palace in Venice, the simple elegance of Santa Croce. There would still remain the civic life of Florence that was pushing upward out of feudal anarchy into proletarian democracy on the basis of an industrial wealth, developing for itself vast lines of foreign trade. If, then, we take the essential elements of each of these aspects of mediæval life, isolate its basic problems of science and philosophy, catch its political and social emotions at fever heat, visualize its exterior traits with luminous clarity, and then conceive of them all as coordinated into a unit by the dominance of an unclouded intellect, and expressed with a training chastened and beautified by a sense of classic form, we shall have arrived at some appreciation of the *Comedy* of Dante.

The *Comedy* of Dante is the complete and crowning expression of mediæval culture. The

Canzoniere of Francesco Petrarca looks, on the other hand, towards the future and expresses the feeling, even if it does not with equal completeness exhaust the mind, of Italians for four centuries to come. Between the two men there were certain affiliations. Petrarch may have met Dante at Pisa in 1311, when Petrarch was seven years old. He knew, admired, and felt a certain emulation of the *Comedy*. Petrarch's poetry has more than one reflection of the manner of the sweet new style, and he was in personal contact with the later poets of that school, some of whom were equally intimate with Dante. Here especially we must recall Cino da Pistoja (Sinibaldi), a jurist of Siena (died 1336), known particularly to Americans in the tales of Maurice Hewlett. He shows the philosophizing acumen of Dante's school as regards love, becoming most distinctive, however, in his poems on the death of his lady Selvaggia. Petrarch also felt high regard for Sennuccio de Bene (died 1349) and Franceschino degli Albizzi (died 1348), contemporaries of Matteo Frescobaldi, who make up the principal figures in the later period of the school. Petrarch's Latin works, too, show indebtedness to the same religious spirit, the same aprioristic concept of ethics and of the supreme objects of life that we find in Dante. This spirit was producing a rich literature in the fourteenth century. The sermons of Fra Giordano da Rivalto (died 1311) have come down, with the treatises of Jacopo Passavanti, as florid specimens of ascetic eloquence; but richer than these in philosophical depth, classic elegance, and contact with contemporary life are the works of Domenico Cavalca (*Medicina del cuore*, treatises on foolishness, sin, patience, spiritual discipline, etc.). Noteworthy are the letters of the beatified Giovanni Colombini, though far less famous in England and America than the burning religious epistles of St. Catharine of Siena (1340-87) and the *Fioretti* [Little Flowers] *di San Francesco*, a collection of Franciscan legends compiled about 1350.

But there are vast differences between the asceticism of Petrarch and that of these authors or of Dante. Otherworld preoccupations are indeed strong in the poet of Arezzo, but they are combated, as we see not only in the famous *Confessions* but in the *Canzoniere*, by a spirit which is less of skepticism than of intense love of this life itself. Whereas Dante strives to abstract from his love of Beatrice a vision of universal experience and truth, Petrarch is content with the enjoyment and pain of love as a simple human experience; and his sense of the beauties of human impulses as it comes in contact with the ascetic ideals which sought to repress them, and in which as a devout Christian of his own age he believed, creates a mood of tender melancholy, of impatient sensualism, with flights towards exaltation and plunges into profound despair. Historically the most important trait that detaches itself from these conflicting states of mind in Petrarch is his individualism. The *Canzoniere* revealed to Italians the existence and richness of their own individualities. Human emotions came to have a value per se without reference to the perspective of eternity. And this new field of artistic exploitation was made all the more attractive to aristocratic society by his mastery of polite manners, his delicate sense of chivalric gallantry, his urbane banalities, his language, sin-

gularly close to the classic Latin, free from obtrusive Tuscanity, and therefore far more cosmopolitan in tone than the picturesque idiom of Dante. With the fourteenth century Italian society was passing from a bourgeois, democratic stage into an individualistic, aristocratic temper. This new society was dominated in poetry by the *Canzoniere* and the *Trionfi* of Petrarch.

Much, perhaps, of this new feeling in Petrarch was stimulated by his passionate devotion to antiquity. As a humanist his part in Italian culture is even greater than his rôle as an Italian poet. He was one of the first to bring into classic studies the critical attitude, reconstituting imperfect texts, weighing conflicting authorities, reconstructing ancient personalities as distinctive psychologies. But especially in his own voluminous Latin works he sets the standard of humanistic Latin composition. Mediæval Latin was in a sense a living language in that it adapted itself to new conditions by enlarging its vocabulary and conforming syntax to the vulgar tongues. Petrarch strives for the purest Latin of the best classic authors, keeping closely to them in locutions, syntax, and vocabulary. This tendency, if it did tend to develop the scientific spirit, nevertheless came to make Latin composition a mechanical mosaic of phrases borrowed from the ancients, thereby stressing erudition over imagination, exalting the grammarian over the thinker, and turning Latin into a dead language.

In political theory there is a distinct break between Dante and Petrarch: the one with his theory of universal empire under God, with his two independent agents, Emperor and Pope; the other characteristically a republican. Dante sees the foundation of the Empire as the beginning of Rome's glory, which for Petrarch ended with the fall of the Republic. But the civic spirit of Petrarch has a much less practical bearing than that of Dante: he is always the visionary, enthusiastic, e.g., at the prospects of Rienzi's republic, or the erudite, who tries in vain to weigh classic memories, as in his pleas to the Venetian Senate, against actual interests of state. For something of Dante's grasp of events we have to turn in the fourteenth century to Dino Compagni (1257-1324) and Giovanni Vallani (died 1348), the vigorous style of which is in strong relief amid the many similar productions of the time, some mere compendia of Villani (Malespini, A. Pucci, Marchione Stefani), others of more personal tone (Donato Velluti, 1313-70), most, finally, of the older mediæval style (Simone della Tosa, *Le istorie pistolesi*).

With Giovanni Boccaccio's *Decameron* this, the most glorious period of Italian letters, is perfected. Only in the sonorous involution of his prose—not without tremendous and generally bad influence on later writers—does Boccaccio contribute to the Petrarchian tendency that gradually divorced literature in Italy from fresh contact with life. Appreciated as a genius by Petrarch, he became in his later years one of Petrarch's dearest friends—perhaps the most remarkable relationship recorded between writers of supreme rank. On Dante he published one of the most authoritative of the early biographies. His humanistic work, composed late in life after a deep religious experience, is not of the high quality of Petrarch's and is more mediæval in method and tone. The minor works

of his youth, on the other hand, the sentimental psychological romances and lyrics based to an important degree on personal experiences in love, have great interest in the history of literary forms—the prose romance, the pastoral romance, the octave poem, the allegory, etc.—as well as for inherent artistic qualities. From the thirteenth century there continued into the fourteenth all manner of popular tales recited in verse and prose, and from French and Latin this fund of material was being widely enlarged. Important here for the extent and the social significance of their appeal are the vulgarizations of Ovid (e.g., of G. Buonsignori, Arrigo Simintendi, Domenico da Montecchiello, C. Figiovanni, etc.). Domenico Cavalca was epitomizing sacred writings. Filippo Ceffi translated the story of Troy of Guido delle Colonne, Guido di Pisa wrote the “Life of Æneas,” Bosone da Gobbio that of Cæsar. Bartolommeo da San Concordio considered with wealth of illustration cases of conscience. Add to these the anonymous *Book of the Seven Counselors* (*Libro dei sette savi*) and the *Libro di Fioravanti*, the latter from the French, and other importations from the romances of the *Matière de Rome la grant*. All this literature shows its effects in the earlier productions of Boccaccio, who, in this regard, finds his nearest rival in Antonio Pucci, though Pucci is essentially a popular and Boccaccio more of a court writer. But the interest of the *Decameron* is far different and greater. Its dominance in Italy as the model of prose writing, its almost encyclopædic illustration of the possibilities of situation in story-telling, the far-reaching sources from which it was drawn, its reflection of contemporary Italian manners and life, all give it great historical importance. But, writing with the clearest powers of visualization, Boccaccio has created therein characters that are alive and complete in their reactions to situations that occur in the lives of all humanity. In this sense Boccaccio, in his own world, is as great as Dante—the world of the everyday life of Florence, minutely objectified by the artist and as frankly described with a sense of humor that dominates everything, even the sense of pathos which is the important undertone in the *Decameron*.

In his reflection of private life Boccaccio is the most brilliant example of an important tendency in this literature of the fourteenth century. An occasional flash of Boccaccio's manner appears in his imitator, Franco Sacchetti (1330–1400), who has left some proverbial types in Italy: Basso della Penna, symbol of the *loica piacevole*, or stickling on literal meanings of words, Dolcibene, the practical joker, and Gonnella the buffoon. Other imitators of Boccaccio are Giovanni Fiorentino in the *Pecorone* and Giovanni Sercambi (1347–1424), who was utilized by Shakespeare. Pieraccio Tedaldi (c.1300–1350) is remembered best for his satires on matrimony, just as Cecco Angiolieri, earlier in the century, expressed in eternal form all the rebellion of wayward youth against parental authority. So Alessio Donati, Francesco Landini (1325–97), Antonio Pucci, Pietro Fattinelli, in their verse and prose, help to complete the picture of that social order which soared to paradise with Dante and laughed and tumbled in brothel and wineshop with Boccaccio—just as its chivalric aspects appear in the beautiful *Months* of Folgore di

San Geminiano and its national aspirations in the lyrics of Fazio degli Uberti (Pisa), Francesco di Vannozzo (panegyrist of the Italic ambitions of the Visconti), Antonio Beccari (1315–63), a whimsical genius who boldly substituted the worship of Dante to that of Christ, Simone Serdini (1360–1420) from Siena, not to speak of local groups, the Venetians (Giovanni Quirini) and the Aretines (Braccio Bracci). In this minor production of the trecento (fourteenth century) it is worth while to mention several poetic forms that have become famous: the *cantari* (narrative ballads) illustrated particularly by Pucci and Piero Caterino da Siena; the *serventesi*, verse in the general rhyme scheme AAAb, BBBc (11 and 7 syllabled lines), used in poetry of occasion; the *frottole* (irregular poems using great variety of verse length: 11, 7, 5, and even 3 syllables). And especially in popular literature we find the lament, the prophecy, the legend, the *novella* (tale in verse or prose), the *noie* (Provençal *enuech*), humorous satires on the petty irritations of life, cultivated especially by Pucci, the *caccia* (hunt), a variation of the *frottola*, not to omit the chivalric romance destined to such glory later, and in dramatic literature the *lauda* that in the next century was to attain the splendor of the *sacra rappresentazione* of Florence.

The Renaissance, heralded by Petrarch and Boccaccio, becomes all-important in the fifteenth century, when the humanists, aided by the recently invented printing press, diffused a knowledge of the literature of ancient Greece and Rome through the length and breadth of the land and ultimately through the whole Occident. Florence is still to the fore in this period, but there are now other important centres of learning and literary productivity, such as Naples, where the house of Aragon ruled; Ferrara, where the dukes of Este were the patrons of men of letters; Rome, Mantua, Venice, Bologna, and Milan. In other words, although the Florentine influence still remained predominant, the literature of this period is more truly a national one in that it is not confined to a single region, but comes into being all through the peninsula. Here we cannot enumerate the many writers engaged in translating from Greek and Latin or writing only in the latter language. The connecting link between them and Petrarch is Coluccio Salutati (1331–1406), the leading figure in the first generation of humanists, in whom mediæval forces, as regards methods and ideas, are strong. In the first half of the century scientific classicism triumphs in Poggio Bracciolini (1380–1459), Niccolò Niccoli (1364–1437), Leonardo Bruni (1370–1444), and Antonio Traversari (1386–1439), all working principally in Florence, where Cosimo dei Medici was laying the groundwork for the brilliant tyranny of Lorenzo the Magnificent. Outside of Tuscany we have the Istrian Pier Paolo Vergerio (1370–1444), Antonio Loschi (1360–1441) at Milan; from Bergamo came Gasparino Barzizza (1359–1431), and from Verona, Vittorino da Feltre (1378–1446). It is not only that in these men the passion for antiquity becomes dominant over everything else, but that passion comes in their followers to modify the whole view of life. Pagan ideals assail Christian ethics, and a sensuous and elegant æstheticism replaces the ascetic aspirations of the previous age. Scientific research calls in question the documentary bases of religion. More than one

humanist actually laid aside his faith. In letters, humanism at first aggressively despised the traditional literary forms of the vulgar tongue, leveling an attack even at Italian itself. But the popular traditions soon asserted themselves against this aberration: the *certame coronario* (poetic competition) of 1441, in which even humanists (Leone Alberti, Leonardi Dati) participated, signaled the reconciliation between Italian and Latin letters, though the classic spirit was destined to dominate productions in the vulgar tongue for generations.

In fact the Italian literature of this century shows much the same happy compromise between the old and the new that we see in painting and sculpture. The ancient dramatic *lauda* takes on a classic brilliancy in the sacred representations of Lorenzo il Magnifico, while the same popular form clothes the purely classic *Orfeo* of Poliziano. Meanwhile in the universities and courts the scholars were examining the memories of the ancient stage, and Vergerio, Bruni, Alberti, and others were writing plays in Latin in imitation of Seneca and Plautus, whose actual works were occasionally reproduced before audiences—all this preparing the way for the imitative erudite comedy and the classic tragedy of the following century. Similarly the chivalric romance, which had thoroughly Italianized itself in the readings of men like Andrea Barberino (c.1370-c.1432), passes from the purely popular style of the *Reali di Francia*, *Rinaldo di Montalbano*, *Buovo d'Antona* to the artistic elaboration of the *Morgante maggiore* of Luigi Pulci (1432-84). Here Pulci preserves much of the naïve, elementary exuberance of the popular legends of Charlemagne, but as a man of the elegant world he laughs at his own creation throughout, so that his work remains as a masterpiece of humorism. Humor, too, is an important motive in the *Orlando innamorato* of Matteo Maria Boiardo (1434-94), but his view of the subject is essentially different from that of Pulci. On the Carolingian materials he grafts the spirit of the legends of the Round Table: the love motive comes into the foreground and with it richer psychological exposition. Classic allusions bedeck his octave stanzas with reminiscences and imitations of beautiful passages in the Latin poets, and a savor of actual life pervades his poem from his use of frequent situations from the very human popular tales. All this is to suggest the method, as indeed to furnish the subject matter, of the great masterpiece of Ariosto a half century later. The lyric also shows progression, for it is the skilled humanist Leonardo Giustiniani (1388-1466), who, in the popular forms of the *strambotto* and the so-called *giustiniane*, strikes some of the sweetest harmonies in Italian poetry. In this century, however, we begin the series of the famous Italian learned ladies with Isotta Nogarola (1418-66), Costanza Varano (1426-47), and, most famous of all, Cassandra Fedele (1465-1558), all of them humanists and pedants, all of them frail attempts to incarnate the new spirit of idealism that was growing in the aulic views of woman. The manifesto of this idealism was Gerolamo Benivieni's *Canzona dello amore celeste et divino* (1488), pedantically illuminated by the notes of Pico della Mirandola and inspired by the Platonism of Marcilio Ficino (died 1499). In one of its aspects this revival of Plato represents a healthful reaction against the dead codifications of

the mediæval theology of the Aristotelians. But in its reflections in polite society—the society of eleemosynary poets and idle courtiers—it becomes merely the cloak for a sophisticated and hypocritical sensualism, from which only the French Revolution could free aristocratic Europe. The love lyric follows woman into this atmosphere of denaturalized love, and the great master is Petrarch. Petrarchists were Antonio Tebaldeo (1463-1537), Serafino Aquilano (1466-1500), Cariteo (Benedetto Gareth, 1456?-1514), and Bernardo Accolti; and Petrarchists with different degrees of nearness but of similar insipidity will be all the Italian lyrists for three centuries thereafter. It is true that in the preciousness of this age there were elements of seriousness—respect for intellect, admiration of wit, love of social grace; and some even of its deeper emotional moods are present in the *Arcadia* of Jacopo Sannazaro (1458-1530), which has great historical importance as a mirror of its time, though it remains for our age one of the dreariest books in Italian literature. This pastoral romance tries to create the mood of naïve simplicity—one of the hypocritical ideals of this age sated with refined splendor.

It is perhaps by reaction from this aristocratic delicacy that the popular literature presents almost a studied coarseness, as in Burchiello (1404-49) singing with special gusto of "fleas, bedbugs, and many lice" in a cryptic dialect now unintelligible. This burlesque poetry had numerous cultivators (Alessandro Braccese, T. Baldinotti, Luigi Pulci, Matteo Franco), of whom the most famous for variety of subject and vividness of observation is Pistoia (Antonio Cammelli, 1440-1502). Some of Boccaccio's malice, if not of his power, runs on in the *novella* (tale), which counts among its principal exploiters Poggio Bracciolini (*Liber facetiarum*), Giovanni Mainardi (1396-1483, *Le facezie dell' Arlotto*), Gentile Sermini, Masuccio Salernitano, Sabbadino delli Arienti, and Antonio Manetti (*Novella del grasso legnaiuolo*). Whatever the inclinations of the humanists towards skepticism, there was no dearth of religious literature, whether in prose (Feo Belcari, 1416-84) or poetry. This was the age of Savonarola (1452-98). But read the *De partu virginis* of Sannazaro, the sacred poems of Filelfo, of Jacopo Gradenigo and Candido Buontemponi, and the extent of the transformation of the religious consciousness from the time of Dante will become apparent.

As regards mental temper, the quattrocento best reveals itself in Lorenzo Valla (1407-57), a mind inquisitive, hostile to tradition in science, philosophy, and literary scholarship, original in every sense, and finding a permanent place in the history of civilization from his attack on the principle of authority. So also the best illustration of its æsthetic temper might be found in the personality of Lorenzo il Magnifico, especially in the *Stanze per la giostra*. The cinquecento (sixteenth century) continues and develops the preceding age in all its essential characteristics, but with an intellect more aggressive and conscious of its own power. Machiavelli deliberately sets aside the search for conditions that "the imagination might conceive as ideal"—thus he disposes of the otherworld morality of Dante—and seeks in "facts as they are actually observed" the laws to govern conduct in statecraft. Leonardo da Vinci abandons memorization of the physics of Aristotle for

actual studies from nature. Pomponazzi considers not the immortality, but the mortality, of the soul. From an obscure monastery near Naples, Giordano Bruno disputes the triune nature of God and goes on to the acceptance of the Copernican system. The spirit of religious reform comes over the Alps from Germany and flames in Naples, Ferrara, and Lucca. Catholicism itself is overhauled and repaired, receiving a new ardor in Vittoria Colonna, a new austerity in the order of the Capuchins, a new and encyclopædic intellectual outlook in the Italian counter-reform that crystallizes in the Council of Trent.

The cinquecento had a predominating admiration for the active intelligence and for originality. But if this spirit led on the one hand to the experimental method, it was conditioned on the other by its too eager expression in erudition and its tendency towards generalization. In literature we find an outreaching to embrace the whole of life, but at the same time a growing belief in definite absolute forms capable of definition both as to their essential character and as to the means of attaining to them. *Arte* came to have a precise meaning, "the way of doing things," and it was the function of the *ingegno* "constructive intelligence," which was a purely intellectual faculty. Aristotle furnished the limits of these forms, and the rules of the *arte* were deduced not only from ancient theorists (Aristotle, Horace), but from classical authors who were presumed to have applied them (Homer, Vergil, Seneca, Plautus). Latin and Greek literature presented, accordingly, forms that appeared fixed and language that appeared regular, or at least reducible to rules. If the quattrocento had vindicated the right of Italian letters to exist side by side with the classics, the cinquecento had to demonstrate that Italian literature should be evolved along the same lines and the Italian language restricted within the same grammatical categories. Thus came about the triumph of classicism in æsthetics and of preceptualism in language, and the aggressive originality of the cinquecento mind spent itself in ingenuity of imitation with Dante, Petrarch, and Boccaccio as models, instead of rushing out, as did the Romanticists of a later age, into all the infinitude of human nature.

So the sixteenth century, which believed in the *genres*, marks the appearance of regular epics, regular tragedies and comedies, regular lyrics, and even its best thought comes to express itself in the Platonic dialogue. Of all this production, most brilliant is the chivalric epic, relatively free from the disturbance of classic rules in Lodovico Ariosto (1474-1533) and consciously regular in Torquato Tasso (1544-95). Ariosto's *Orlando furioso* marks the apogee of chivalrous poetry in Italy. Starting where Boiardo's *Orlando innamorato* ends, and presupposing that the reader is acquainted with the story there unfolded, Ariosto develops still further the love affair of Orlando and Angelica, interweaving with it many other romantic episodes, especially that of Ruggiero and Bradamante. For his idealistic, ethical subject matter Ariosto is indebted to French poems and romances of the Middle Ages, to Latin classic verse, and to Italian writers of the Renaissance period; but he is most original in the way in which he has breathed new life into the old material, analyzing in various moods, pathetic, humorous, sen-

suous, ribald, the various reactions of humanity to love. His style has a charm due in no slight degree to the skill with which he has combined the pomp of classic diction with a simplicity of expression peculiarly his own, and his versification is satisfactory because of the ability with which he has handled the *ottava rima*. Ariosto had many imitators, but their poems, like that of his predecessor Boiardo, are now little read. Several attempts were made to remodel the *Orlando innamorato*, the most successful being that of Francesco Berni (c.1497-1535), a master of style.

Ariosto's contemporaries, who were entranced by his genius, were, however, not slow to perceive his "irregularity." To avoid this fault was the purpose of the critic Gian Giorgio Trissino (1478-1550) in his *Italia liberata dai Goti*, the first classic epic, which scholars remember for the perfection of its regularity, and which every one else has forgotten for its perfect insipidity. Through the *Amadigi* of Bernardo Tasso (1493-1569), the *Girone cortese* of Luigi Alamanni (1495-1556), the *Ercole* of Giraldo Cinthio (1504-73), we arrive at the *Gerusalemme liberata* of Torquato Tasso, the son of Bernardo, the greatest Italian writer of the second half of the sixteenth century, who sums up many of its tendencies and creates much of the mood of the two following generations. A man of extraordinary genius, which reveals itself in all his works, as well in his masterpiece, *La Gerusalemme liberata*, as in his lyrics, dramas, dialogues, and letters, he suffered at times from a mental disorder which, though it necessitated placing him under restraint, did not impair his literary productivity. His poem, *Rinaldo*, is a youthful work of the category of chivalrous poems, dealing with the adventures of the Carolingian hero Renaut de Montauban. But Ariosto had uttered the supreme word in chivalrous story, and Tasso was to gain his laurels by perfecting a new *genre*, that of the crusading or Christian epic. This he did with his *Gerusalemme liberata*, a poem of markedly serious intent, primarily concerned with the Crusades in which Godfrey of Bouillon played a part. The author did not disdain to admit as subordinate elements certain features of the chivalrous romance, especially in connection with the love episodes, just as he also drew from his favorite authors of classic antiquity. Like Ariosto, whom he resembles very much in his imitation of passages of ancient writers, he uses the *ottava rima* with ease and grace. An individual note in Tasso's work is that of melancholy, which, springing in several episodes (*Sophronia*, *Clorinda*) from the juxtaposition of love and death, is really an echo of the man's personal experience and of his mental anguish. Nevertheless, in its most characteristic aspects this epic interprets with masterly vision the highest religious aspirations of the Italian counter-reform, and the poem is otherwise remarkable for the sustained dignity and poise of its execution. Although contemporaries, like posterity, applauded the *Gerusalemme liberata*, Tasso was not satisfied with his work, and, yielding to religious impulses of an ascetic nature, he published a remodeled form of it, *La Gerusalemme conquistata*, which is much inferior to the original poem and is, therefore, neglected, while the *Gerusalemme liberata* remains dear to the whole Italian people.

In lyric verse the impulse of the sixteenth century towards originality declared itself in revolt against the too conventional nature of the Petrarchistic verse of the preceding period. In his *Rime*, Pietro Bembo (1470–1547) showed how better results could be obtained in lyric song by going directly to Petrarch for inspiration, and Bembo's example was followed by a host of poets. But the true animus of the Bemboistic reform is made apparent in his *Prose della volgare lingua*, where he stresses the importance of having a general literary speech for the land, that unity of style may be attained and the character of the literature be made national. This he does by promoting the theory or rigid classicism on the basis of imitation in general and of Dante, Petrarch, and Boccaccio in particular. Bembo's charming personality, his exalted ecclesiastical rank, his powerful friendships gave his ideas great weight. Their culminating triumph appears in the manifesto of Arcadia nearly two centuries later, where the whole devastating force of his doctrine becomes apparent in the motto "not nobility of substance, but excellence of imitation." Central in Venice, Bembo's native city, and in Urbino, where he long resided, this movement caused a revived worship of Petrarch which amounted almost to a religion. Its earliest and most distinguished poetic converts were, in Venice, Domenico Venier (1517–82), Girolamo Molin (1500–69), and Bernardo Capello (1498–1566). But the fervor spread generally through the peninsula. The vast mass of production in verse that ensued—mediocre always and generally arid—need be mentioned only in some of its curious manifestations: the *centoni*, patchwork poems, made entirely of verses of Petrarch rearranged; the "replies of Laura," imaginary answers to each of Petrarch's sonnets; the *spiritualizations*, in which, in tone with the Catholic reaction, the earthly love of Petrarch is retreated, sonnet by sonnet, as of religious character and import. Typical authors are Angelo di Costanzo (1507–91) and Bernardino Rota (1509–75); less typical, for an occasional flash of originality, are Luigi Tansillo (1510–68), whose verses were plagiarized and "philosophied" by Giordano Bruno, Galeazzo di Tarsia (1520–53), Cardinal Giovanni della Casa (1503–56), and Annibale Caro (q.v.). On a solitary eminence for a lyric expressing his own vigorous personality is Michelangelo Buonarroti (1475–1564), and with him is associated, for a tender and beautiful friendship, Vittoria Colonna (1490–1547), the death of whose husband, the Marquis of Pescara, inspired in her a poetic vein remarkable for its religious intensity. In this Petrarchistic movement the learned woman stands out even more conspicuously than in the preceding century: Laura Terracina, Lucia Bertani, Laura Battiferri have been forgotten beside the happier fortunes of Tullia d'Aragona (1506–56), Veronica Franco (1546–91), courtesans both, and of the gentlewomen Veronica Gambarà (1485–1550), Gaspara Stampa (1523–54), and Barbara Torelli. The Platonic idealism which accompanied and glorified for its authors the Petrarchistic conception of love and which expresses itself most tritely in the *Asolani* dialogues of Bembo, most subtly in the *Dialogo di amore* of Tullia d'Aragona, and most philosophically in the *Eroici furori* of Giordano Bruno, had a strong appeal for all the aristocratic circles of Europe. Its influence appears

in the poetry of the *Pleiade* (Ronsard, Du Bellay, De Baif, Saint-Gelais) in France, of Juan Boscán, Garcilaso de la Vega in Spain, of Francisco de Sâ in Portugal, and of Wyatt and Philip Sidney in England. There were, to be sure, some discordant voices in this Petrarchian adoration: Giordano Bruno, who rebelled against everything, rebelled against this also, but his genius had no special fecundity in verse; Pietro Aretino satirized the new movement with some positiveness; Antonio Broccardo, with an admiration for the popular poetry of the quattrocento, and, more deliberately, Cornelio Castaldi, lacked only genius in their reactions against it in verse. The revolt that manifests itself in the attempts to revive Latin and Pindaric metres—the blank verse of Trissino, the odes and *selve* of Bernardo Tasso, the elegies of Ariosto, B. Tasso, and L. Alamanni—was scarcely thoroughgoing, inasmuch as it too was a form of imitative classicism.

Towards the century's end lyric verse runs completely into a slough of despond, when, with the Catholic reaction losing its fervor and tending towards a caducous conventionalism in faith, poetry is turned largely into religious channels. But this verse belongs in spirit to the age that follows. For the best work in Italian poetry, if we wish to leave the masters Ariosto and Torquato Tasso, we must turn to the burlesque and the satire, to the irrepressible laughter of Francesco Berni (1497/8–1535) in his jocose sonnets which created the style called *bernesque*, or to that of his imitator Anton Francesco Grazzini (called *Il Lasca*), the first in a long series of *bernesque* poets (Giovanni Mauro, Gianfrancesco Bini, even Tansillo and L. Dolce), worthy all, to adapt a phrase of Pietro Aretino, of crowns "of four kinds of sausages." Teofolo Folengo (1496–1544), immortal under his pseudonym Merlin Cocai, and for his numerous affiliations with Rabelais, is in a different category; for in his Latinized Venetian-Italian, called *macaronic* Italian (or Latin, as you will), in his rollicking *Baldus*, followed in joyous succession by the *Zanitonella*, the *Orlandino*, the *Chaos del Triperuno*, the burlesque epic is informed by a spirit of deep artistic seriousness and no mean ethical ideal, which was notably lacking in the *pasquinades* of Pietro Aretino (1492–1556), a curious specimen of the cynicism of this period, who achieved fame in this type of epigram (so styled from the statue of Pasquino in Rome, where they were posted as public libels). The *pasquinades* of Italy, collected by the German Ulric von Hutten, spread through Europe all the motives of Latin wit and satire, and the ultimate sources of the stock in trade of all modern comic journals are to be found in them. Nor should we, if we seek vitality alone, neglect the narrative verse inspired by the wars against the Turk and particularly by the battle of Lepanto (1570), and, in quite a different field and in Latin, the *Syphilis* of Girolamo Fracastoro (1483–1553), and, to turn to popular poetry, the *canti carnascialeschi*, as well as the *stanze* of the Tuscan Campagna; whereas the definitive value of the classical satire (Ariosto, Pietro Nelli, Luigi Alamanni, Ercole Bentivoglio) is more difficult to fix, since it shows on the one hand all the pedantry of cinquecento classicism, and on the other some of the vigor of the *sermoni* of the fifteenth century, from which, in a certain sense, it springs.

One sad result of the æsthetic theory of the

Renaissance was the contempt of the aristocrats for the old dramatic form known as *representazioni sacre*, which disappeared from the towns in the early part of the sixteenth century and withdrew to the cloisters and the country districts. Its place was taken by prose translations of ancient dramas, which paved the way for Italian imitations of the works of antiquity. The first Italian tragedy, and in fact the first regular tragedy, in all modern literature, was the *Sofonisba* (1515) of Gian Giorgio Trissino. This was followed by many tragedies, one sadder than the other and nearly all modeled on the works of Euripides, Sophocles, and Seneca, e.g., the *Rosmunda* and the *Oreste* of Giovanni Rucellai, the *Canace* of Sperone Speroni (1500-88), the *Orbecche* of Giraldo Cinzio (1504-73), the *Orazia* of Pietro Aretino (1492-1556). Even Torquato Tasso perpetrated the *Torrismondo*, which deals with matter of Germanic origin. Most of the tragedies were composed in blank verse (*versi sciolti*). Something better may be said for the regular comedies of the time, nearly all based on Plautus and Terence, and a few original, which were written sometimes in verse and, more often and more successfully, in prose. The masterpiece among the comedies was the *Mandragola* (1513) of Niccolò Machiavelli (1469-1527). Let us say this in deference to the opinion of Macaulay; and, moreover, the theme of the *Mandragola* has survived to this day as a universal tale. But the *Candelaio* of Giordano Bruno had a literary fortune no less remarkable, as did the *Pedant* of Francesco Belo, the comedies of Pietro Aretino, and *Gli intronati* of the Academicians of Siena. Aristotle, too, is historically of much importance as the first cultivator of the regular comedy and because his *Suppositi* is as little of a mere name as, let us say, *Ralph Roister Doister* in English literature. But read any play you wish of Giambattista della Porta (1535-1615)—the reading will not be entirely wearisome—or any one of the recent Bari anthology (Bari, Laterza, 1912) of cinquecento comedies; there is present there, in an alloy not overrefined to be sure, much of the wit of the *pasquinades*, much of the elementary sense of action that has been the true base of comedy in every age. What is dead, on the contrary, is the Plautan type personage, who substitutes linguistic play for realistic self-revelation. But even these are not entirely dead: the braggart soldier was a distinctive figure in sixteenth century society; the doctor, too, with his colleague the pedant, recurs in life even to-day; and in these written comedies (*commedie erudite* they were sometimes styled) much interest attaches to them from the fact that they are the clearest presentation we possess of similar figures, similar *masks*, who died on the stage of the improvised play (*commedia dell'arte*, professional comedy) with the voices of the actors who created them. The *commedia dell'arte*, which originated during this century, is one of the most important phenomena in the history of the modern theatre. Produced from a simple outline (*scenario*), with lines largely extemporized, though each character had his specialty thoroughly conventionalized, this type of comedy enjoyed in Italy a life three centuries long. In its stock personages—Pantaloon the merchant, Gratiano the doctor, Arlecchino the sly servant, Lelio the lover, etc.—the Italians saw the idiosyncrasies of their varying regional life portrayed, satirized, with a perennial life

and humor. Their wandering troops of actors wandered into Spain and France; in Paris they established a permanent theatre; and if not, assuredly, from their philosophic depth, at any rate from their *dramatic* vision, Molière learned his trade as comedian and playwright, and from them sprang in a still more intimate relation the immortal productions of Carlo Goldoni.

Poetry succeeded in expressing possibly some of the moods and certainly all the affectations of the Italian cinquecento. Its real spiritual and intellectual life appears in prose. It is the current fashion of literary historians to ignore thinkers as thinkers; we must ignore the dialogues of Giordano Bruno (1542-1600) as pre-eminently philosophical and the treatises of Leonardo da Vinci (1452-1519) as predominantly scientific. But somehow the lucid intellect of Niccolò Machiavelli (1469-1527) has made politics a department of literature; since his wonderful style is, after all, only the incisiveness of his grasp of political science, based on a rigidly empirical method, which he applies with merciless disregard of aprioristic ethics to the successful formation of tyrannies in the *Prince* and, with the same merciless disregard, in the *Discorsi sopra la prima deca di Tito Livio*—a work too often overlooked, especially by our own time—to the successful formation of republics. As a historian Machiavelli (*Istorie fiorentine, Vita di Castruccio Castracani*) has the virtues and defects of a method: that of writing of facts with a too general regard for their bearing on the principles of conduct in which he is interested. But this method, as followed out by him, has been of inestimable influence on modern thought; for by virtue of it his two principal works are of service to-day, many of his general inferences have withstood the test of modern history, and though Machiavellianism has come to be synonymous with selfish opportunism, Machiavelli, one of those least tainted with Machiavellianism, by directing attention to the materialistic forces that govern human events, established also the study of the processes that control them, and in actual effect has contributed as much as any other modern thinker to all libertarian movements after him. Francesco Guicciardini (1483-1540), in his *Storia fiorentina*, his *Discorso del reggimento di Firenze*, his diplomatic reports, memoirs and critique on Machiavelli, was a more orderly historian and possessed as well most of Machiavelli's ideas, lacking only the emotional fervor and the aggressive intensity of his greater contemporary. Close in their footsteps followed Donato Giannotti (1492-1573) in works on Florence and Venice, which show greater interest in minute details of political history, but less originality and clarity of thought, though something of Machiavelli's spirit. The writings of these men, taken with those of the less powerful Benedetto Varchi (1503-65) and Paolo Paruta (1540-98), an anti-Machiavellian idealist, form the most portentous contribution of Italy to modern thought, the most glorious monument to Italian mentality, of this period.

One other body of prose production has proved scarcely less influential in its own field—that of literary criticism and applied æsthetics. As regards insight into the nature of art, there is probably more value in the first dialogue of Bruno's *Eroici furori* and in a few verses of Aretino than in all the voluminous theoretical

production which begins with the *Prose* of Pietro Bembo and the Italian grammar of Fortunio (Regole) and runs down through Lodovico Castelvetro (superb as a philologist), Girolamo Muzio, Cinzio Giraldi, Benedetto Varchi (who definitely codified the Italian classic tongue), Sperone Speroni (who was plagiarized by Du Bellay in his famous *Défense de la langue française*), Giovanni Minturno, and Francesco Patrizi to the establishment of the Academy of the Crusca, to the poetic codes of the Academy of Arcadia of the next century, and to Giambattista Vico, the founder of æsthetic science, who wrote in the eighteenth century. The work of this literature we have briefly characterized above; suffice it here to note that it established, one may say, for the whole of Europe, down through Lessing to the Romantics of the nineteenth century, the principles of neoclassicism, which experience has indeed modified in part and even as regards rigorous precept destroyed, but which nevertheless have deeply enough colored the æsthetic thought of the modern world as to resist the assaults of German philosophy and the more self-conscious attacks of our own contemporary Benedetto Croce, the rejuvenator of Vichian æsthetics.

But if we restrict ourselves to the narrower view of belles-lettres, the prose of the sixteenth century is no less remarkable. For here, not to mention Giorgio Vasari's (1511-74) *Lives of the Painters and Sculptors*, we have the autobiography of Benvenuto Cellini (1500-71), an astonishingly frank self-revelation of one of the most interesting of men, a book, moreover, that is even to-day as much read as any other of the century in any language. More academic is the vogue of the *Cortegiano* of Baldassare Castiglione (1478-1529), who there expounds the theory of court taste as the norm of good usage in language, but whose most interesting aspect, aside from the value of his work as a source for cultural history, is in his reflection of the Platonic idealism that lies behind much of the aristocratic poetry and the aristocratic art of his time. Only less comprehensive is the *Galateo* of Cardinal della Casa, which enjoyed an even more extensive fortune as a practical guide to good manners. The tales of Matteo Bandello (c.1480-c.1562) are not without some artistic merit, but their chief value is, again, historical, whether from their reflection of manners or from their influence on later writers (Shakespeare), to which latter consideration the importance of the *Hecatombithi* of Giraldi is almost exclusively due. And much the same might be said of the *Piacevoli notti* of Gianfrancesco Straparola, of Parabosco (*Diporti*), of Firenzuola and Fortini. The *Diaries* of Marin Sanudo (1466-1535) stand, both for substance and form, in a class by themselves. Meanwhile epistolography became in the sixteenth century a fine art, with Pietro Aretino, who in his letters completely exposes the dark recesses of his personality, as a typical example. It is a racier, but no less individual, flavor that we find in the correspondence of Andrea Calmo (1510-71).

It has been the fashion for some generations past to ridicule the manner that rules Italian literature in the seventeenth century, and which has been dubbed with an opprobrious term, *seicentismo*. The unanimity of the lamentation which invariably saluted its mention was only slightly disturbed by the recent publication from Bari (1911) of Croce's *Lirici marinisti*, and

perhaps rightly so; for surely it would be strange if, out of the endless flood of poetry from veritably thousands of poets, some 600 passable pages could not be selected. Nevertheless, the phenomena of *seicentismo* have been too summarily derided, as indeed they have been too mechanically explained. Obscenity, arrogance, a lack of logic approaching aberration, hostility to real thought, ponderous and misapplied erudition, slavish adherence to tradition and authority coupled with almost impudent boasts of originality, these are the ethical traits that underlie this century's most distinct characteristic in art: the *conceitto*. But this age, which burned Bruno and gagged Galileo, produced also Thomas Campanella and Fra Paolo Sarpi; and if it worked the *conceitto* to death, it also invented the telescope and realized the experimental scientific method. It was primarily an age of intellectual unsettling and struggle, full of contrasts in emotion and thought, which in architecture it expressed by adorning Parian marble with the black *pietra di paragone*, and from the gloom of which it took refuge in an unbridled sensualism.

To grasp this age in its historical sequence we must return to the later aspects of the cinquecento: it is foreshadowed, as regards literary technique, in the accentuated preference for antithesis in the style of the *Gerusalemme liberata* and, as regards mood, almost to perfection in the delicate, sophisticated, but none the less intense, sensualism of Tasso's *Aminta*. It is useless to call this the first great pastoral drama; its closest affinity spiritually is found in the *lascivia* (sensualism) of the *Adonis* of Giambattista Marini. So its religious hypocrisy appears already in the pious songbooks of the sixteenth century, and we may begin—if Aretino's asceticism seems sacrilegious—with the *Tears of Saint Peter* of Tansillo. As for literary theory, there is nothing new, save an extraordinary increase in the number of the *genres* and a new statement of an old quibble hacked over as a quarrel between ancients and moderns. So the lyric is subdivided into love, moral, trivial, obscene, piscatory, marinesque, and forest poetry, and each new *genre* has numerous claimants for the credit of inventing it. Tommaso Stigliani struts about as the first "to sing Spanish deeds in Tuscan accents." Tassoni invents the mock-heroic epic as though Folengo had never existed. Out of all this dross one thing of beauty—the musical drama, the opera, in its special aspect called the *melodramma*, which in music by Francesco Cavalli and Claudio Monteverdi, with librettos by Gian Francesco Busenello and others, still survives. In prose the *conceitto* is rampant likewise, rolling out from church pulpit, academic parlor, and senatorial chamber in sonorous vacuity. The comedy sleeps in Cicognini, waiting for Goldoni to make over the *commedia dell'arte* into artistic comedy. The tragedy sleeps even sounder still. What had happened to the vigorous outreaching after life that characterizes the great Italian Renaissance? Some answer: Spanish influence; but Spain owed as much to Italy as did Italy to the Spanish occupation. Others answer: the Renaissance theory of ornamentation as the essence of art; but this theory the cinquecento itself possessed. Others, again: the progressive divorcing of literature and life by theories of imitation, by admiration for erudition, by the establishment of oversophisticated cultural

ideals, that operated all through the sixteenth century. Others, finally: the Italian counter-reform in faith, the very rigidity of which stifled individual religious feeling, rewarded demonstrative hypocrisy, and generally tended towards ritualism and formalism. There is some truth in all of these explanations and much in their combined effect. Except that *seicentismo*, as a manner, is not confined to the Italian seicento: it is paralleled in the preciousness of France, the Gongorism of Spain, the euphuism of England. It breaks out in late Latin literature, in mediæval poetry, in Persian poetry, in folklore of all ages and peoples—all of which suggests that *seicentismo* is a phenomenon recurring in a certain set of intellectual circumstances, of which perhaps the most cogent trait is the restriction of the intellectual outlook by dogmatic boundaries of various, of any kinds, which force the aggressive mind to turn inward upon its own past achievements instead of going on to new discovery, and thus substitutes ingenuity of recombination for creative originality.

Let us ignore for the seicento the literature that merely repeats the previous age: the numerous followers of Tasso in the epic—of Tasso who reigns in the seventeenth and eighteenth centuries, as had Petrarch before him; the thousands of Petrarchists of varied hue of doctrine; the hundreds of academies, all equally pretentious and equally insipid; the hundreds of playwrights, of whom scarcely one, save here and there a brilliant extemporizer of the Andreini family, feels a breath of life; the petty polemics of myriad critics equipped with astonishing erudition and equally astonishing lack of common sense. For the seicento did a few things well. It enjoyed Gabriello Chiabrera (1552–1638), who left some enduring flashes of tenderness in his *canzonette*, though a pedant in his metrical exercises in classic forms. It understood and visualized every phase of sensualism, as witness the brilliant production and the interesting career of Giambattista Marini (1569–1625), author of the *Adone*, which his age, with the reserved assent of posterity, has called the “marvelous poem.” It surprised itself in producing one litterateur of serene intellect and sober judgment, Trajan Boccalini (1556–1613), whose *Dispatches from Parnassus* are a classic of humoristic social, political, and literary criticism. Its humor, in fact, is as vital as its sensualism: it is still possible to read the *Rape of the Bucket* of Alessandro Tassoni (1565–1635), whose national spirit burns nobly in the *Philippics* against Spain, and who illustrates the curious mental perversity of his age in his *Pensieri diversi*. While Galileo was breaking ground for Isaac Newton, Francesco Redi was founding modern bacteriology in his studies on parasites (1626–98), and Fra Paolo Sarpi (1552–1623), author of the fundamental *History of the Council of Trent*, was establishing with definitive precision the legal relations of church and state, sustaining laic jurisprudence against an effete canon law, vaunting freedom of speech against ecclesiastical interference. What of the tyrannical rationalism of Tommaso Campanella’s (1568–1639) *City of the Sun*, the manifesto of a socialistic communism? In it as in his stately verses there is something of the emancipated intelligence which the pyre of Bruno could not destroy. Dialect literature never quite lost its intimate touch with reality in Giambattista Basile, in Maggi, in Busenello. Historians of art

assert that out of the florid, the exuberant experimentation of the roccoco style, so absurd in itself, sprang much of the discovery of modern technicians. So underneath its grotesque literary expression one feels in the seicento an impatient, a palpitating, however disoriented, intellectual vigor. It comes to the surface in these men, of whom any age might well be proud, whom the seicento even admired, but whose trail it refused to follow in order to give birth with volcanic contortions, to that mouse of literature, the Academy of the Arcadia.

Christina of Sweden founded it in 1690 around the elegant personalities of Giovannaria Crescimbeni (1663–1728) and Gian Vincenzo Gravina (1664–1718), the latter, in his way, no mean thinker. It aimed to react against *seicentismo*, a term which its later devotees invented, as illustrated in the followers of Marino; it actually clarified the atmosphere of the final manifestations of Petrarchistic idealism, now at last running in decadence to expire in the French Revolution. Its mood may be described best in its method: if the lover fixed his eyes on eternity and filled his mind with platitudes on divine love, he could attain to the maximum of sense stimulation with a modicum of sex indulgence. This is the spirit that finds its social reflection in the institution of *cicisbeismo*, the system of the serving cavalier and Platonic soul mate, which needed constant demonstration to itself of the truth of its idealistic convictions, by daily seeking out the temptations of the boudoir, which, as is asserted and as a little good will may readily believe, they successfully resisted. Once more in Italian poetry—flaccid echoes of the age of Dante—we find ladies angelified, descending from heaven to lift the humble lover to an exalted eternity. There is the quintessence of gallantry, revealing itself not in the bald superlative of the duecento, but in an involved intellectual tour de force that shuns every shock of crudity, every suggestion of materiality. Meanwhile the vocabulary of Petrarch and the sixteenth-century poets (and grammarians too) must be learned by rote; every head must be stuffed, till it could hold nothing else, with classic quotations; no gentleman worthy of the name but could give offhand any rhyme series in Italian with completeness. So Arcadia, which bridges the seventeenth and eighteenth centuries and becomes predominantly typical of the latter, marks the age of facile composition and—to us miraculous—extemporization; for could not Corilla Olimpica (Maria Maddalena Morelli) treat offhand and viva voce in any metric form any problem from the nature of God to whether feather beds are more conducive than beds of straw to the attainment of a well-ordered temperament? No age, not even the cinquecento, ever laid greater store on cleverness. Fortunes were won by a witticism and careers were made with a sonnet, as well as ruined by a single faux pas. Let us bundle together here the Perfettis, the Bertolas, the Crudelis, the Frugonis. The Arcadian virus was both fertile and tenacious. Even Vincenzo Monti, in an age that ought to have known better, began in its manner, as did the Metastasios, the Goldonis, the Gozzis, the Parinis. Let us signalize only Jacopo Vittorelli, at once typical and individual, for the melancholy sweetness of his Anacreontics to Irene.

For the eighteenth century in Italy looks not

only backward to Petrarch, but forward to Napoleon Bonaparte. And this renaissance of mentality appears even in some of the traditional literary forms. Or rather, if not mentality, it is at least a clear artistic vision that comes into the melodrama with Apostolo Zeno, a fine scholar and a fair poet (1668-1750), and in that most settecentistic of all the writers of the settecento, Pietro Metastasio, who, discovered by Gravina, was supported by Marianna Bulgarelli, who carried the splendor of Italian poetry to Vienna as court dramatist, who in his serious melodramas shows the utter inability of his century to be serious, and finally leaves to the folk music of Italy many a melancholy or sensuous air culled from his opera librettos. The *Didone*, the *Clemenzia di Tito*, the *Attilio Regolo*, even the *Siroe* with its involved intrigue, are, in their genre, masterpieces, not of the gigantic outlook, but of the delicate sentiment, intensely felt, perfectly apprehended by the creative spirit. Dignity, if not compelling passion, sustains the classic tragedies of Scipione Maffei, especially the *Merope*, well worthy to stand beside Racine's better, and above Voltaire's best, dramatic poems. Pier Jacopo Martelli (1655-1755), imitating the French Alexandrine verse, hits on the languid yet fecund rhythm of the 14-syllabled *martellian couplet*, which has ever since resounded on the Italian stage. Jocose poetry, too, sensed from a distance the new burst of life, though none will exaggerate the value of Forteguerra's *Rieciardetto* or of Casti's *Animali parlanti*, both famous enough in their own day. But the Bernesque poetry of the settecento has too often behind it the spirit of gossip and malice, not the animal violence of the sixteenth century or of Boccaccio. A gossip was Bartolommeo Dotti, a tattletale was Pietro Buratti, and is even Carlo Gozzi any too free from such things? Meanwhile, even in the most reactionary writings, the spirit of rebellion rumbles: there is an aggressive tone in the reactionary *Lettere Virgiliane* of Saverio Bettinelli; the *Granelleschi* of Venice, in their defense of antiquated forms, had, in the nature of things, to be fighters; and Carlo Gozzi, to demonstrate the value of the old, has to give it a novelty that in his *Fiabe* (folklore dramas) has a vitality as fresh in the Germany of the nineteenth century as on the New York stage in 1914.

In contradistinction to the monotonous mediocrity of the seicentisti, towards the end of the eighteenth century strong personalities begin to come forward. There are the adventurers, with lives more involved in reality than romance would dare invent in fiction. Lorenzo da Ponte slept with beggars and stood before kings, got a living on his wits, and died at peace, a professor in Columbia University. Giacomo Casanova, genius that he was no less in swindling than in love and literature, saw every grade of fortune and every recess of life in the gay century which he portrays with photographic accuracy in his memoirs. His autobiography is more interesting simply in quantity and scope of experience than that revealed in the *Memorie inutili* of Carlo Gozzi and the memoirs of Goldoni. Giambattista Vico (1668-1744) has had to wait till the twentieth century for the recognition of the originality and intrinsic worth of his *Scienza nuova* in the fields of anthropology, æsthetics, and sociology. The Christian socialism of Antonio Muratori (1672-1750) is less

important than his scholarship in the *Rerum Italicarum Scriptores*, a work more vast surely, but certainly not more useful, than Forcellini's Latin lexicon, in which Zeno, Maffei, and Muratori all had a hand. England for a moment seemed disposed to hang Giuseppe Baretti (1719-89), to whom it came to owe some insight into Italian culture. Baretti is one of the first critics in the modern sense, fighting in his *Frusta letteraria* the vacuities of Arcadia, hailing the return in literature to serious substance, and hitting on moments of definitive vision in his artistic appreciation. Gasparo Gozzi (1713-86), in his *Osservatore*, was a follower of Addison, more tainted than Baretti with tradition, but nevertheless quite as gifted with common sense; and the changing mood of the century is apparent especially in his *Difesa di Dante*. This return to the spirit of the Middle Ages is paralleled by a whole movement towards *exotism*: some interest is manifested in German poetry, the relations with France become extremely intimate; most important of all, Melchiorre Cesarotti (1730-1808) translates Ossian (Macpherson) from English, and in him the first seeds of Italian romanticism are sown. The French philosophic spirit was more immediately productive: it appears particularly in historical writing, in the attempt to organize all human experience, as revealed in jurisprudence, governmental forms, the arts and sciences, manners and customs, into logical, coherent systems with fixed universal principles. This method, which is after all a retrogression from Machiavelli's empiricism, goes often astray in Gravina (*De Origine Juris*) and is too mechanical even in Giannone (*Storia del regno di Napoli*); but from it Vico derived much of his impetus, and it produced that most human of all libertarian documents, the *Treatise on Crimes and Punishments* of Cesare Beccaria. This work grew out of the vigorous intellectual movement in Milan, central in the group which edited the *Caffè*, of which the public-spirited Alessandro Verri, author of *Le notti romane*, was a leading figure.

But Goldoni, Parini, Alfieri—in these names the Italian eighteenth century was crowned and epitomized. The smile of Goldoni belongs as much to America as to Venice, his native city. For *Mirandolina* has charmed us in the creation of Mrs. Patrick Campbell; *Giannina* has rippled and pouted from many a university stage; and now the most comprehensive production in the literature around Carlo Goldoni has come from Chicago in the biography written by Mr. Chatfield-Taylor (New York, 1914). Goldoni's plays, unsubsidized by the academic world, are more often acted on their own merit than those of any author anterior to 1800. In them there is much of the old: Goldoni's comedy gushes florid from the essence of the *commedia dell'arte*, but Pantaloon incarnates the morality of Venice and the good sense of all the world. Goldoni is best, to be sure, in his native element, the life of the lagoons, which he seizes in its characteristic traits and portrays with brilliant reality. *I rusteghi*, *The Quarrels of Chioggia*, *Sior Tonin Bonagrazia*, *Noble of Torcello*, *Le donne euriose* (this too an American favorite) are his most genial inspirations, but *The Liar* has a perennial vogue. *The Family of the Antiquary*, *The Mistress of the Inn*, *The Café*, *The Friend*, *A Strange Occurrence*, while they show little of Molière's philosophic grasp

of life—the comparison, after all, is unfair to both—possess an even superior excellence of visualization, of characterization. In this respect Goldoni overshadows all his predecessors and obsesses perhaps to an excess the next generations of comedy in Italy. His conscious fight for the comedy of character—so misunderstood by the Gozzis, the Pietro Chiaris, the Granelleschi as a group—did not, after all, destroy the *commedia dell' arte*. What it did destroy, and effectually, was the classic imitative comedy; the popular extemporized play, rather, it transformed with a serious purpose and vivified with a transplantation of its roots into the fresh ground of observation of life. In this sense Goldoni fulfilled, rather than betrayed, the promise of the *commedia dell' arte*.

In Goldoni's lashing of aristocratic vices and his propaganda for middle-class virtues some have seen the rise of a revolutionary consciousness. Goldoni himself would have been shocked at this interpretation of his work. His satire is the reaction of common sense to social phenomena as they are; and in this respect he is like another good-natured and frank-souled contemporary, Giuseppe Parini (1729-99). Surely the social cancer that the French Revolution was cutting out with the sword was never explored with a more cutting probe than in the *Giorno* of this Milanese cleric. But, again, it is rather a clear and sincere confidence in the ethics of the past than a programme for actual reform that we have in this vigorous satire. Parini, in fact, was taken completely aback by the storm that swept across the Alps. And in the midst of the turmoil of 1797 he fled with a sigh of relief to the academic harmlessness of his sculpturesque odes, dictating the lines of mellow sadness to the *Inclita Nice*, and returning with delight to the classic imagery of *L' Educazione*. Vittorio Alfieri was, on the other hand, a fighter, as witness many a passage in the *Misogallo*, the autobiography, and his classic tragedies themselves. His dramatic works for a half century taught to Italian youth hatred of tyrants and love of liberty and justice—emotions that to us have become both unimaginative and trite in their more universal forms. As unimaginative and trite we should probably now characterize much of Alfieri's work. *Saul* alone has passed, with a few lyrics, into world literature, for its noble and stately portrayal of a soul that, through sin or error, has lost its grip on life and stands face to face with a self-created despair.

Napoleon's proclamation of Rimini in 1797 brought Italians, as from a dream of idleness and gayety, into the tragic reality of a new order of things. And the dominant question was what, as Italians, they were going to do about it. Vincenzo Monti (1754-1828) was one of the many not ready with an answer and one of several distinguished intellects who never really found a satisfactory one. His panic-stricken disorientation, that appears in his life, shows also in his literary work, largely indebted to Arcadia, now rushing out to the Napoleonic vision, now reacting against Revolutionary excesses, settling down finally to a contemplation of democracy, but feeling most safe in the uncompromising atmosphere of classic translations. Himself quite satisfied with escaping unharmed, his vacillation was rewarded with a reputation for exquisite artistry in his tragedies, in the satirical *Bassvilliana* and his ver-

sion of the *Iliad*. Stendhal, better than any one else, has understood the conflicting trends of feeling at this period. What we see in his *Letters from Rome, Naples, and Florence* is a society passing from a static, gay, complacent, aristocratic system to the tumultuous aggressiveness of an ambitious middle class. A giddy intoxication overcame the suppressed social strata with the first descent of Bonaparte, but after Waterloo came the restoration of the old régime. The national consciousness was strong, but its hopes had been cruelly deluded. It is this hope and this delusion that give distinctive character to Italian literature in the first half of the nineteenth century.

Its production was vast and much of it has a cogent vitality. But its most dominant tendencies are best expressed in three men: Ugo Foscolo (1778-1827), Alessandro Manzoni (1785-1873), and Giacomo Leopardi (1798-1837). Foscolo was a man of the backward outlook upon the grandeur of ancient Italy, surrounded with the hazy splendor of Grecian islands. He came from Zante, the ancient Zacinthos, and the hopes of the present were for him realized in the Venetian Republic, considered not as a finality, but as a promise of a great Italian future. He hailed in a strong ode the Napoleon that spoke at Rimini, and he lashed the tyrant that betrayed at Campo Formio. Turning to violence for a moment, he was swept by defeat into an exile full of bitter reflection and despair. It is true that the earlier redaction of the *Letters of Jacopo Ortis* is preëminently sentimental, going not much beyond the horizon of Goethe's *Werther*, by which it was inspired. But in the second form of this romance the patriotic motive is much more powerful: it is a deluded national consciousness, as well as an unhappy love, that leads to suicide. As a matter of fact Foscolo found solace for his disappointment in the elegance of classic art, expressing itself in his tragedies and in his masterpiece, the *Sepolcri*. Here there is a mood made up not only of classicism, but of a spirit steeped in English romanticism (particularly Ossian). In the hymn to the *Graces* classic æstheticism holds uncontested sway.

The refuge that Foscolo found in art, as a national heritage, Manzoni found in religion, as an institution no less national. For surely the intense religious devotion that characterizes especially the Milanese school of the early ottocento satisfied not only a craving for security of spirit, but a patriotic pride in the Church as well. This feeling, in fact, was strong enough to form a political party and create a slogan under Pius IX. It meant everything to Manzoni. In the *Cinque maggio* the conqueror of Europe, dying at St. Helena, finds peace from the turmoil of life in the arms of faith. In the ode on *Pentecost*—this is the real gem of the *Inni sacri*, which, though surely competent, attain elsewhere no exceptional heights of inspiration—he again returns to the portrayal of the confidence in life, the impregnability of hope, that comes over the soul entirely submissive to the consciousness of God's presence within. And thus made sure of himself, Manzoni goes on to grapple with immediate practical problems: he was too big a man to be restricted within one mood and too vigorous to exhaust himself with Foscolo in a contemplative inaction. He attacks the philosophical problems presented by the new age in science and in the new outlook

on ethics. The national culture attracts him as an æsthetician and critic. So he throws himself particularly into the question of the national language, and the Manzonian theory is triumphant to-day. His doctrine reconciles the prevalent Tuscanity of the Italian language with the cultural tradition as a whole; for he favors a liberal standard of speech, recognizing additions from dialectical or literary sources, but, where questions of alternative are involved, choosing the usage of the spoken language of Florence. The principal instrument in this propaganda has been his famous romance *I promessi sposi* (The Betrothed). This novel rests on a remarkable historical study of the seventeenth century, particularly of the conditions surrounding the plague of 1630. It aimed to express also the idealism of the Italian romantics. In some of its aspects Italian romanticism is only a reflection of the ideas of the romantics in France and Germany—thus so far as the attitude towards preceptual classic forms and limitations of subject are concerned. In other respects it is distinctively Italian, Italian in that it identified itself with the political unification of Italy and with Catholic ideals. It crystallized as a school in the group that published the journal *Conciliatore* at Milan. Its manifesto was written by Giovanni Berchet (1783–1851), who, in the famous *Letter of Grisostomo*, announced its æsthetic principles and who illustrated its methods in his ballads. Here let us stress the *Hermit of Mont Cenis* as the most enduring, though it was Berchet's patriotic poems that endeared him to his own and the following generation. Manzoni's tragedies, too, violated consciously the classic unities; but their revolt is superficial, for his mind was here dominated by the classic dignity of Alfieri, which permeated the tragedy down through S. Battista Nicolini (1788–1855) and Pietro Cossa (1830–81) and is not wholly inefficacious to-day. *I promessi sposi* is, however, the great masterpiece of this movement: intrinsically, because of its graphic description of the plague, the portrait of the vicious and repentant noble called the Innominato, for the unswerving monk Fra Cristoforo, the human, vacillating Don Abondio; historically, for its numerous epigones, the romances of Massimo d'Azeglio (1798–1866, *Ettore Fieramosca*, *Niccolò de' Lapi*), of Francesco Domenico Guerrazzi (1804–73, *L'Assedio di Firenze*, *Battaglia di Benevento*, *Beatrice Cenci*), Cesare Cantù (*Margherita Pusterla*). Everybody wrote historical romances, inspiring hatred of oppression, love of Italy, and, more often than not, religious resignation, as indeed everybody wrote his *Memoirs*. This is particularly true after 1850, when liberty was no longer a dream; but though composed in later periods, they reflect the temper of the first half of the century. Here the best specimen—worth more than an army corps for the cause of freedom—was *Le mie prigioni* of Silvio Pellico (1789–1854), an Alfierian in his tragedy *Francesca da Rimini*, who here narrates the horrors of an Austrian prison system with a sobriety that compels conviction and a religious humility that explains much. It is a good-natured and thoroughly moral bourgeois that D'Azeglio described in himself in *I miei ricordi*. Historical and philosophical writings did not go much beyond the limits that Manzoni embraces in his own personality: dominated by the method of the eight-

eenth century, it set as its main problem the vindication of Catholic idealism against the eighteenth-century philosophic rationalism, attempting at the same time to free Catholicism itself from Jesuitical control and ideas. Thus the historian Carlo Botta (1766–1837), thus the critic Pietro Giordani (1774–1848), thus the philosopher Rosmini, and, in a higher order still, Vincenzo Gioberti (1801–52), whose writings, collected under the title *Nuova protologia*, exhaust the middle-class mind of the early nineteenth century.

Leopardi's delusion was a delusion not to be anaesthetized in the art of Foscolo nor cajoled by the religion of Manzoni. He considered it rather the vindication of his dignity as a human being to look his delusion in the face and, finding his life problem—whether as an Italian or as a man—unanswerable, to live and die with consciousness alive in the fullest possible measure to his delusion. This is the anguished nobility that cries in the ode to the *Ginestra*. And with the same melancholy, even desperate, determination he looks in his idylls and *canzoni* upon love, upon patriotism, upon the life around him. The triumphant middle class of the last decades, that has passed out of oppression to material prosperity, and in that prosperity has found the justification of its ethical ideals and metaphysical formulas, finds Leopardi a problem. Whence this morbidity of temperament, this insanity that all is genius? And the answer has been found in his diseased and distorted body, his unfortunate experiences in love and life, even in the sentimentality of his grandfather. But is there not, at least, the chance that some other criticism may come to take Leopardi at his own evaluation and see in his work the expression of a serene intellect, that before the problem of human destiny will accept no compromises, content, like the Vergil of Dante's *Purgatory*, in the presence of the enigma to bow its head?

There was in Leopardi as much of plastic vision and æsthetic sincerity as in Foscolo; and in Leopardi's philosophy there was even more inaction. The freedom of Italy was won not so much by such men as by men like Giuseppe Giusti (1809–50), whose smashing satire—read the galloping verses of the *Stivale* (The Boot), the *Steam Guillotine*—filled the Italian youth with the eagerness to leave philosophic meditation to their grandfathers and go out and make Italy. This had been done virtually by 1860, though, to cite a famous epigram, when Italy had been made, there still remained the problem of making Italy. With this latter task, in its intellectual bearings, contemporary Italian literature is still engaged. Production has been enormous in bulk and high in quality, though we are still, perhaps, too near it to keep all its aspects in true proportion. Two figures at least stand out with permanent distinctness: Giosuè Carducci (1836–1907) and Gabriele d'Annunzio (1864–). Carducci, above all, represents the attainment by the Italian middle class to its own self-consciousness. He has the Leopardian strain and the Manzonian strain, and his Hellenism—is it not already foreshadowed in definite outline in Foscolo? His mind is obsessed by Italy's past, which for him reaches back to Hellenic origins, of whose culture ancient Rome was the legatee and of which modern Italy will be the transmitter to the civilization of the future. Or rather, Carducci's

atavism is not exactly an obsession, so completely is it dominated by his spirit, assimilated by his intellect, and directed towards action by his will. The revival of ancient glory presented itself at first to Carducci polemically as a reaction against romanticism; polemically also, later, as a question of form: in the *Odi barbare* he leaves rhyme and traditional metrical forms for old Greek and Latin measure. But the notion of propaganda is soon swallowed by his artistic vision itself. The ode to *Aurora* drips with light in which Carducci revels for its own glory. With this splendor he clothes all the past of Italy and Greece. In its behalf he fights the ascetic gloom of Christianity. The *Hymn to Satan* (Satan is progress; Jehovah, the Church, is reaction, darkness) is lacking, perhaps, in depth. But the odes *To the Springs of the Clitumnus*, *In a Gothic Church* are immortal poems to faith in national destiny and faith in the joy of life, as opposed by "impious" religious terror. In the *Church of Polenta* he sings the palinode, recognizing the unifying force of the Church in Italian consciousness. The ode *At the Station*, the sonnet *The Ox*, the poems *Before San Guido*, *Niccola Pisano*—their number could be much increased—are each masterpieces for objectivity and aspiration.

D'Annunzio's Hellenism is even more intense, as indeed it rests on a vaster Hellenic culture, though less pedantic, than Carducci's. In his indefatigable production, as varied as his life has been troubled, one trait seems always to appear: it has well been called a sensualistic dilettantism. D'Annunzio has often gone out to ideas from abroad: Tolstoy left a trace on the *L'Innocente*, Nietzsche on the *Triumph of Death*. He has felt German philosophy as well as English, French, and Greek poetry. For it is his task in life to *feel* everything. He revels in sensation of every sort, in color, in sound, in smell, in touch, and he is fascinated by, just as he thoroughly understands, the minutest emotional reactions to sensation. *Il piacere* (Desire), for all its ugly theme, is in this respect one of the most solidly packed romances since Thackeray in England and Flaubert in France, just as *Fuoco* (Fire) is one of the most remarkable for lyric splendor. Fortuitous circumstances largely have stressed the importance of his dramas (*La gioconda*, *La città morta*, *La gloria*, *Francesca da Rimini*, etc.), that almost never go beyond the scope of his earlier poetry and romances, which remain most truly representative of his surprising genius.

In sharp contrast with D'Annunzio's pagan sensualism stands the Catholic idealism of Antonio Fogazzaro (1842-1909), who shows will triumphant over passion in the beautiful romance *Daniele Cortis*, but who more comprehensively in a trilogy of novels—*Piccolo mondo antico*, *Piccolo mondo moderno*, *Il santo*—tries to deal with the paramount questions of modern Italian life. There he sustains nationalism, patriotism, as the fundamental necessity, but also a progressive nationalism broadening out the prospects of the individual life, integrating everything in faith and Christian ethics, stripped of formalism and lived in action.

Around these men we may group a host of less distinct personalities and systems, the poets Giovanni Prati (1815-84) and Aleardo Aleardi (1812-78) of the older group, classic in manner, romantic in substance; Mario Rapisardi (1844-1911), Arturo Graf (1848-1913), Ada

Negri (1870-); among the more recent. Giovanni Pascoli (1851-1913) has attained greater distinction, perhaps, for his brilliant classicism; Lorenzo Stecchetti (1845-) for his method called realism or verism. Domenico Gnoli has recently shifted the classic elegance of his earlier poetry to a manner of exquisite romantic tenderness. In the novel, from Ippolito Nievo (1832-61), who may be said to have begun the serious psychological study of contemporary problems, through Edmondo de Amicis (1848-1908), who struck the ethical keynote for the younger generation, through Enrico Castelnuovo (1839-), with his subtle humor, through the Barrilis, the Farinas, the Rovettas, the Seraos, we come down to the contemporary field, where we may say the short story of regional life shares with the drama the place of chief interest in contemporary literature. Regional life has in Italy always found a free-flowing channel of expression in dialect literature: one thinks, e.g., of Meli for Sicily, of Porta for Milan, of Ruzzante, Calmo, Maffio Venier for Venice, of Burchiello for Florence—all these from the older literature. The sonnets of Giuseppe Gioachino Belli in the Roman dialect of the epoch around 1850 set the method for the flourishing contemporary schools. Its dean is Renato Fucini, who, in his tales *Le veglie di Neri* and *All' aria aperta* and in his Pisan sonnets, has portrayed the life of the Tuscan Campagna with consummate art. Trilussa and Pascarella have been, again in Roman dialect, doing the same for Rome. One may say that the Neapolitan plays and poems of Salvatore di Giacomo are among the most beautiful productions of recent Italian literature. But the output has been both rich and solid in the tale in Italian: Grazia Deledda for Sardinia, Giovanni Verga for Sicily, Antonio Beltramelli for Umbria. Luigi Pastonchi and Ugo Ojetti are doing splendid work of the same sort, largely as journalists. The Italian comedy long felt the influence of Goldoni. It left its imitative manner for a time in Paolo Ferrari (1822-89) and in Vittorio Bersezio, who reflects the life of Piedmont. It came to great excellence in Giuseppe Giacosa (1847-1904), whose *Come le foglie* (Like Falling Leaves) has enjoyed a permanent vogue. Giacosa most deeply felt the problems occasioned by the spirit of commercialism in its fight with the sounder middle-class virtues. For these in a sense he fought, while it is again the cause of faith and Christian morality that inspires the deeply serious drama of E. A. Butti (1875-1910). Butti has written comedies and romances of a high order on contemporary aristocratic life, but perhaps his most charming and intense play is *Fiamme nell' ombra*. The Neapolitan Roberto Bracco is, on the other hand, an observer who holds no thesis, but catches with wonderful sense of situation what he sees. *Astray in the Dark*, *Ghosts*, *The Saint*, *Don Pietro Caruso*, *Snow-Storm*—these are all gems of literature that enable Italy to compare well with other European nations on the contemporary stage. Italian criticism has in the nineteenth century felt the full force of the historical method; with Alessandro d'Ancona (1835-1914) the most venerable figure of this school has passed away. Its greatest name is Francesco de Sanctis, well qualified to stand beside Sainte-Beuve and Taine for the value, if not for the bulk, of his work. The method and ability of De Sanctis descended

upon Benedetto Croce, who, through the splendid essays in his journal *La Critica*, is exerting at present perhaps the most pronounced influence upon æsthetic theory and critical method of any one in Europe. Cesare Lombroso (1836-1908) has similarly developed Italian criminology, and his broad outlook stimulated to a great degree Guglielmo Ferrero, who, after important works on jurisprudence and Roman history, has been an important international figure through his criticism of contemporary life in Europe and America.

Italian literature to-day is national still rather than cosmopolitan in character: its chief function is the consolidating of the different regional tempers into a national Italian unit; its chief materials are the memories of a great cultural history in the past, a great spiritual institution, the Church. In this work its besetting danger is atavism. The more violent elements of the bourgeoisie have sensed this danger and created *futurism*. It remains to be seen whether the new nationalism, which for some years now has been conscious of itself, can turn into new channels the deep-lying artistic sense of the people, its ready hospitality to new ideas, its belief in literature. As it stands, Italy's most influential contributions to world literature have been the *Comedy* of Dante and the Italian Renaissance.

ITALIC LANGUAGES. A group of closely related languages of which Latin and the modern Romance tongues are the best-known representatives. At the dawn of history the group was confined to Italy, unless, as some scholars suppose, the language of the Siculi was Italic.

Many of the languages anciently spoken in the peninsula were not Italic languages; the Greek dialects which were in use at many points along the southern coast, the Messapian of Iapygia, the Gallic in the north, and the Etruscan in the centre are certainly to be excluded from the group, and so probably are the Ligurian and Venetian of the north. Next to Latin and its descendants the most important Italic language is Oscan, which in the fourth and third centuries before Christ was spoken in Samnium, including the country of the Frentani and Hirpini, northern Apulia, Lucania, Bruttium, and the Sicilian city of Messana. North and northwest of the Oscan terrain and south, east, and northeast of Rome were spoken Pæignian, Marucian, Vestinian, Volscian, Marsian, Æquian, Sabine, and some other less important dialects. In the immediate neighborhood of Rome were spoken Prænestine, Lanuvian, and other dialects of the Latini, while a few miles to the north of the city, surrounded by Etruscan territory, was the Italic language of Falerii (Faliscan). The northernmost member of the group was Umbrian, the language of Umbria; our knowledge of it is almost exclusively based upon documents from the town of Iguvium, and we do not know how numerous or extensive the local variations from Iguvian usage were.

The Italic languages form a branch of the Indo-European languages (otherwise called Aryan or Indo-Germanic, q.v.). They are more closely related to the Celtic languages (q.v.) than to any other known group of Indo-European. Although there is very little obvious resemblance between Latin and any one of the Celtic languages of which we have extensive documents, this is due partly to the fact that these are known only from comparatively recent times and partly to the unusually numerous changes which the Celtic languages have suffered; if we had documents as early as the earliest we have for Indian and Iranian, Italic and Celtic might appear almost identical. At any rate there is no doubt that Italic and Celtic are to be grouped together as forming the Italo-Celtic branch of Indo-European. Among the most striking of their common features are the following: (1) abstract nouns formed by the suffix *ti* with an extension in *n*, e.g., Lat. *ment-ion-em*, OIr. *ermi-ti-u*; (2) superlatives in *is-omos*, e.g., Lat. *ægerrimus* from **ægri-isomos*, Gall. *ov̄ξισάμη*, 'highest'; (3) the use of the *o*-stem locative in *ei* (Lat. *ī*, Celt. *ī*) as a genitive, e.g., Lat. *agri*, OIr. (Ogam inscription) *maqi*, 'of a son'; (4) the fusion of the Indo-European aorist and perfect; (5) the formation of passives and deponents in *r*, e.g., Lat. *sequitur* = OIr. *sechithir*; (6) the formation of the preterit passive from the past passive participle in *to*, e.g., Lat. *monitus*, 'he was advised,' OIr. *roléiced*, 'he was left.' A remarkable fact which may or may not be significant is that the Celtic languages, like the Italic, are divided into two groups, one of which represents Indo-European *qu* by *p* and the other by *qu* (later *c*). The resemblances between Latin and Greek, which formerly led scholars to assume a close relationship between the Italic and Hellenic (see GREEK LANGUAGE) branches of Indo-European, are due chiefly to extensive borrowing within historical times, and partly also to the fact that Greek and Latin are the only languages of the western grand division (*centum* languages) of the family from which we have ancient documents.

Features which distinguish the Italic languages from Celtic are the following: 1. The original diphthong *eu* became *ou*, while in the earliest-known Celtic (Gallic) the two were still distinct, e.g., OLat. *douco*, Goth. *tiuhan*, Indo-European **deuk*-. 2. The Indo-European aspirates (*bh*, *ph*, *gh*, *kh*, etc.) became spirants (*f*, *h*, etc.), whereas in Celtic they lost their aspiration and became *b*, *p*, *g*, *k*, etc., e.g., Lat. *fert*, OIr. *berid*, Skt. *bhárati*. 3. The ablative suffix *d* was extended from the *o* stems to the other declensions, e.g., OLat. *sententiad*, Osc. *toutad*, "civitate." The case system of the known Celtic languages is so meagre that one cannot say positively that early Celtic did not share in this innovation. 4. The Indo-European interrogative pronoun came to be

rescued a type of speech that was apparently on the verge of extinction and spread it over half the civilized world. Oscan-Umbrian is divided into two main branches, one of which consists of Umbrian, while the other includes Oscan and the minor dialects which occupy the territory between Oscan and Umbrian. These minor dialects are sometimes grouped together under the name Sabellian, but they do not seem to have any closer affinity with each other than with Oscan. The Latin-Faliscan includes Latin, the other dialects of the Latini, of which Prænestine and Lanuvian are the best known, and the Faliscan of Falerii. From Latin are descended the modern Romance languages. The mutual relationship of the Italic languages is roughly represented by the following table:

used as a relative; Celtic relative clauses are so different from anything else in Indo-European that one may suppose that there was no relative pronoun in the Italo-Celtic period. 5. The extensive changes of the Indo-European verb which yielded the four Latin conjugations are most of them common to all the Italic languages, but only a few of them are to be found in Celtic. 6. Italic formed a gerundive in *ndo*, e.g., Oscan *úpsannam*, "faciendam." 7. In the realm of syntax we may mention especially the construction of the accusative with the infinitive.

The Italic languages fall into two groups, the Oscan-Umbrian and the Latin-Faliscan. The most obvious and convenient mark of distinction between the two groups is their treatment of the Indo-European labiovelars *qʷ* and *gʷ*, which appear in Latin as *qu* and *v* (*gu* after nasals), but as *p* and *b* in Oscan-Umbrian. At the beginning of our records Latin-Faliscan was confined to the Roman Campagna, the Alban Hills, and the town of Falerii, while Oscan-Umbrian covered all the rest of the Italic territory. There is reason to suppose that dialects of the Latin-Faliscan type had once been spoken through a much wider region, and that they had been supplanted by the invading Etruscan and Oscan-Umbrian. The rise of Rome, then,

Alphabet. The Italic dialects employed several different alphabets, all of them based on the Greek alphabet of the Chalcidian colonies in Italy, especially on that of Cumæ. Two forms were derived from this source, the Latin-Faliscan and the Etruscan-Oscan-Umbrian. The Oscan and Umbrian alphabets consisted of 21 and 19 letters respectively, and were read, like the oldest Latin and Greek, from right to left. The letters were as follows:

Oscan

Ɐ Ɀ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ
 a e i í u ú v n m r l k t p g d b s f h z

Umbrian

Ɐ Ɀ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ ⱼ ⱽ
 a e i u v n m r l k t t p b s f h í ç z

Oscan ⱽ is a modification of V, which is used in the later inscriptions to represent the *o* sound. This sound is represented in early Oscan and in Umbrian by the unmodified V. Oscan Ɀ represents an open *e* sound. There were a few numerical signs, Oscan-Umbrian | for 1, X for

10, Oscan V for 5,) for 100. Both Oscan and Umbrian, however, frequently employed the Latin alphabet. In modern linguistic works the words in Oscan-Umbrian script are usually printed in bold-faced or spaced Roman type, those in Latin letters are represented by italics, as Oscan **faksiad** or **faksiad**, 'let him make,' *fefacust*, 'he will have made.' In addition the oldest Italic inscriptions are in many cases written in the Greek alphabet. Punctuation in the inscriptions is capricious and frequently neglected; the usual system, however, is one or more dots.

Oscan-Umbrian. The Oscan-Umbrian languages possess many features in common besides their treatment of the Indo-European labiovelars: *nd* became *nn*, e.g., Osc. *úpsannam*, "operandam"; *s* was retained before nasals and liquids, e.g., Ose. *físnam*, "fanum"; *f* from Indo-European *bh* and *dh* was retained even in the interior of a word, e.g., Umb. *tefe*, "tibi"; final *ā* was changed in the direction of *ō*, e.g., Osc. *molto*, "multa"; the nominative plural of the first and second declensions retained the original endings *ās* and *ōs*; the genitive singular of the first declension retained the original ending *ās*, and the genitive singular of the third declension was *eis*, the original ending of the *i* stems. In all of the common features of Oscan-Umbrian which we have mentioned those languages differed from Latin; in many of them, however, Oscan-Umbrian merely retained the Italic form or usage, while Latin suffered some change. In some cases of the latter sort Prænestine, Lanuvian, and Faliscan, or some of them, were like the Oscan-Umbrian group in retaining the primitive state of affairs; thus, *f* appears in the interior of the word in Faliscan *carefo*, "carebo," and Prænestine *nefrones*, "kidneys." Early Latin as well as Prænestine seems to have retained *s* before nasals, for the Duenos inscription which was found at Rome has the word *cosmis*.

Oscan. As already stated in detail, Oscan was spoken in a very large part of central and southern Italy. Although a few local dialectic peculiarities have been detected, the language is remarkably homogeneous in view of its wide extension. The system of writing is very clear and regular; it is the sort of writing that one expects for a highly cultivated language, and in some details it shows unmistakable traces of the work of the schoolmaster. Oscan was the official language of the powerful Samnite state, and it was spoken in the wealthy and highly civilized cities of Campania, where early Greek influence upon Italian civilization was strongest. We have, in short, all the conditions for the production of a literature, and we find some of the effects which a literature might exert upon the language. It is not surprising, then, to learn that the Romans got their *fabella Atellana* from the Oscans (Livy, 7, 2, 12: *quod genus ludorum ab Oscis acceptum*; cf. Cicero, *Fam.*, 7, 1, 3, and Tacitus, *Ann.*, 4, 14). Strabo tells us (5, 3, 6, p. 233) that even in his day the Oscan language was to be heard on the stage. The poet Ennius boasted that he had three souls because he spoke Latin, Greek, and Oscan (Gellius, 17, 17, 1); he did not boast of a Messapian soul, although Messapian was his native language, doubtless because there was no Messapian literature. Oscan was still in use at Pompeii when that town was destroyed in 79 A.D.

The Oscan inscriptions number about 230. Most of them, however, contain exclusively, or

almost exclusively, proper names, and only four—the Bantine tablet, the Cippus of Abella, the tablet of Agnone, and the Curse of Vibia—are of any considerable length. The first of these, the Tabula Bantina, discovered in 1793, is the longest. It is a mutilated bronze plate about 15 by 10 inches and bears on one side an inscription of 38 lines in Oscan and on the other a Latin text 32 lines long. The tablet deals with legal regulations concerning the city of Bantia in Lucania. The Cippus of Abella, found near Avella in 1745, is a block of hard limestone 6 feet, 5 inches high, 1 foot, 8 inches broad, and 11 inches thick. It contains in 58 short lines of letters about 1½ inches high an agreement between the towns of Abella and Nola concerning the joint use of a temple of Hercules. The tablet of Agnone, discovered in 1848, is of bronze, with a handle and chain by which it may be hung up, and measures 11 × 6 inches. It is inscribed on both sides with 47 very short lines, which contain the names of the deities to whom statues in a certain sacred grove belonged. The Curse of Vibia, found at Capua in 1876, consists of 13 lines, written on a lead plate about 8¾ × 3 inches. As a specimen of Oscan, the following passage may be taken from the Bantine tablet, 5-7:

Oscan: *deiuatud sipus comenei perum dolom mallom, siom ioc comono mais egm(as touti)cas amnud pan pieisum brateis auti cadeis amnud, inim idic siom dat sena(teis) tanginud maimas carneis pertumum.*

Latin: *iurato sciens in comitio sine dolo malo, se ea comitia magis rei publicæ causa quam cuiuspiam gratiæ aut inimicitia causa, idque se de senatus sententia maximæ partis perimere.*

The most striking peculiarity of Oscan is the conservatism of its vowel system. If extensive remains of the language are ever discovered, it will be as important as Greek as a witness to the vocalism of Indo-European. The long diphthongs are shortened, but the original quality of all diphthongs is retained, except that *eu* becomes *ou* and *əu* and *əi* become *au* and *ai*. Intervocalic *s* remains a sibilant which in the native alphabet is not distinguished from *s* in other positions, but is written *z* in the Latin alphabet, e.g., the genitive plural ending *azum*, Umb. *aru*, Lat. *arum*. Anaptyctic vowels are developed between liquids or nasals and mutes, e.g., *aragetud*, "argento." After a dental *u* becomes *iu*; e.g., *tiurri*, "turrim."

Pæignian was spoken in a small mountainous district north of Samnium. More than 30 Pæignian inscriptions are known, but the only one of any length is the Herentas inscription. It was unearthed in a grave at Pentima, the ancient Corfinium, in 1877. It is written on the side face of a block of travertine, 2 feet, 7 inches long, 2 feet, 5 inches from front to back, and about 11¼ inches high, and is the epitaph of a priestess named Vibia. As a specimen of Pæignian, we may cite from the Herentas inscription, 5-6:

Pæignian: *sua aetatu firata fertlid praicime Perseponas af ded.*

Latin: *suam ætatem feneratam fertiliter in regnum Persephonæ abdidit.*

Pæignian agrees with Oscan more closely than any other known dialect. It shares the retention of the intervocalic sibilant and the development of anaptyctic vowels.

Marrucinian. This dialect, spoken to the northeast of Pæignian, seems from its very scanty remains to be closely akin to the latter. It is known from two inscriptions, one from

Teate, the centre of the Marrucinian territory, containing merely two proper names, and the other from Rapino, written in 12 short lines on a rusty bronze tablet about 6 inches square. This dates from about 250 B.C. and is concerned with certain sacrificial rites. Lines 1-5 of the bronze of Rapino may be quoted to give an idea of this dialect:

Marrucinian: *aisos pacris totai Maroucai lixs. asignas ferenter auiatas toutai Maroucai.*

Latin: *dis propitiis civitati Marrucæ lex. Proscizæ feruntur auspicaetæ civitati Marrucæ.*

Marsian. The remnants of the Marsian dialect, spoken around Marruvium, on Lake Fucinus, are contained in a few very brief inscriptions. The dialect shows, in its monophthongization of original diphthongs, a close resemblance to Umbrian. In other respects Marsian seems to have been very similar to Pælignian and Marrucinian.

Æquian. Of the dialects of the Æqui, who centred around Cliternia and Nerea, no inscription has been preserved which is free from suspicion. If *prufatted* (Latin *probavit*) is really an Æquian form, the dialect would seem to have shown a marked affinity to Oscan (cf. Osc. *prúfatted*).

Sabine. Of Sabine also the remains are too scanty to give any information regarding the dialect. Only one inscription, which is very brief, has been preserved. It has been shown from literary evidence that *d* sometimes became *l* in Sabine, and that such Latin words as *lacrima* (Gk. *δάκρυ*), *olor* (beside *odor*), *solium* (beside *sedeo*) are Sabine loan words. The considerable number of such words in Latin indicates that the Sabine dialect exerted a powerful influence upon Latin; but our almost complete ignorance of the tongue makes it impossible to detect Sabine elements in our Latin documents, except in the case of words with *l* from *d* and words such as *catus*, which the Romans themselves call Sabine. Another peculiarity of Sabine was the conversion of *gh* into *f* where Latin has *h*.

Volscian. The Volsci, whose capital was Velitræ, have left one inscription of four lines, known as the Tabula Veliterna, discovered in 1784 and inscribed on a bronze $1\frac{3}{8} \times 9\frac{1}{8}$ inches. If we may draw conclusions from this tablet, Volscian stood the nearest of all the Sabellian dialects to Umbrian. The scantiness of our sources, however, forbids any hard and fast conclusion. As a specimen of Volscian, the third line of the tablet of Velitræ may be quoted:

Volscian: *sepis toticu couehriu sepu ferom pihom estu.*

Latin: *siquis publico conventu secutus erit (?) ferre pium esto.*

The resemblance to Umbrian consists in (1) the monophthongization of diphthongs, e.g., *toticu*, Umb. *totar*, Osc. *touto*; (2) the loss of final *d*; and (3) the assibilation of *k* before *e* (?) and *i*, e.g., *fajia*, Umb. *façia*, Osc. *fakiiad*.

Umbrian. The remains of Umbrian are of far greater extent than those of any other ancient Italic language except Latin. Practically all the texts in this dialect are contained in the Iguvine tablets, discovered in 1444 at Gubbio, on the site of the ancient town of Iguvium or, as it was called in the Middle Ages, Eugubium. The Iguvine tablets were originally nine, although but seven are now preserved. The tablets are of bronze, inscribed, with the exception of the third and fourth, on both sides. They vary in size, the first two being about 22×15 inches, the third and fourth about

16×12 inches, the fifth about 18×14 inches, and the last two about 33×22 inches. The entire number of lines is 449. The first four and about two-thirds of the fifth are written in the national Umbrian alphabet, while the last third of the fifth tablet, as well as the sixth and seventh, are written in Latin characters. It seems tolerably certain, both on epigraphical and linguistic evidence, that the portion in the Roman alphabet is later than that in the epichoric script. The date of the inscriptions, however, apart from this relative one of the several parts with each other, is doubtful. Possibly one will not be far astray in dating them between the third and first centuries B.C. The difference between the Old Umbrian, which is written in the national script, and the New Umbrian, which was inscribed in Latin letters, was probably more apparent than real. Since the Umbrian alphabet lacked signs for *o*, *g*, *d*, *b*, they used instead *u*, *k*, *t*, *p*. On the other hand the Latin script could represent the sound of the Umbrian *ř* only by *rs*. New Umbrian showed, however, a marked deviation from Old Umbrian in the change of final *s*, retained unchanged in the earlier form of the dialect, to *r*, as OUm. *tutas*, 'of the city,' but NUmb. *totar*. There are a few other distinctions which are of minor importance, such as the more closed pronunciation of *ē* in New than in Old Umbrian (as NUmb. *habitu*, 'let him have,' but OUm. *habetu*; NUmb. *verir*, *vereir*, 'at the gates,' but OUm. *veres*). The Iguvine tablets are ritualistic in subject. The texts I a (which is reproduced on the accompanying plate) to I b, and VI a to VI b 47 deal with the purification of a high place near Iguvium, while the remainder of I, VI, and all of VII a treat of the purification of the city itself. The last two tablets, however, are much more detailed than the Old Umbrian. The second tablet is concerned with a lustral sacrifice for the priestly college of the Atiedii, with an optional sacrifice to an infernal deity, and with the rites to be performed at the semiannual gathering of decuries from 10 towns or clans. The third and fourth tablets give in detail the rites for sacrifice to Jupiter, Pomonus, Vesuna, and certain other deities, while the fifth is devoted to resolutions of and enactments concerning the same college of Atiedii, who figure so prominently in these inscriptions. To show the difference between Old and New Umbrian, the following passage, taken from I a 11-13 and VI b 1-2 may be cited:

Old Umbrian: *preveres Tesenakes tre buf fetu Marte Krapuvi fetu ukripe Fisiu, tutaper Ikuvina. arviu ustentu vatuva ferine fetu, puni fetu, kutef pesnimu.*

New Umbrian: *pre verir Tesenocir buf trif fetu Marte Grabouei ocriper Fisiu, totaper Iiouvina. arvio fetu, uatuo ferine fetu, poni fetu, tases persnimu.*

Latin: *pro portis Tessinacis tres boves facito Marti Grabovio pro arce Fisia, pro civitate Iguvina. frumenta facito, exta in ferculo facito, posca facito, tacitus precator.*

Umbrian, like Latin, is characterized by a large number of phonetic changes; some of these are found also in one or another of the related languages, while others are peculiar to Umbrian alone. We have already noticed the parallelism between Umbrian and Volscian in the simplification of diphthongs, the loss of final *d*, and the assibilation of *k* before *e* and *i*. Faliscan and Prænestine agree in part with Umbrian in the simplification of the diphthongs, while Latin follows a different method of simplification, and most of the other dialects retain the diphthongs

unchanged. Umbrian is like Latin in converting *s* between vowels to *r*; e.g., genitive plural *aru*, Lat. *arum*, Osc. *azum*. Intervocalic *d* became a sound which was written *rs* (*r̄* in the Umbrian alphabet), e.g., *persi*, *peṛi*, Lat. *pede* (cf. the Sabine change of *d* to *l*). Initial *l* became *v*, e.g., *vutu*, Lat. *lavito*. Several other changes were scarcely less important than these.

Latin-Faliscan is distinguished from Oscan-Umbrian in (1) the treatment of the Indo-European labiovelars, e.g., Lat. *quando*, Falisc. *cuando*, Osc. *pūn*, "cum"; (2) the retention of final *a*, e.g., Lat. *multa*, Falisc. *Pola*, "Paulla," Osc. *molto*; (3) the formation of the genitive singular of the third declension, which in Latin shows *is* (from *es*) or *us* (from *os*), in Faliscan *o* (from *os*), but in Oscan *eis*, e.g., Lat. *nominis*, *Cæsar*, Falisc. *Arunto*, "Arruntis," Osc. *aeteis*, "partis"; and (4) the formation of futures in *f*, which in Latin becomes *b*, e.g., Falisc. *carefo*, Lat. *carebo*. If the remains of Faliscan and the dialects of Latium were more extensive, it would no doubt be possible to point out other features common to all Latin-Faliscan dialects but not possessed by Oscan-Umbrian. In the main, however, the divergence of Latin from Oscan is due to relatively late changes in Latin itself, and the somewhat wider gap between Latin and Umbrian is due to still later changes in both Umbrian and Latin.

Latin is usually said to be the language of Latium, and that is no doubt the original meaning of the word. The Latin of the Roman Empire, however, the language in which the Latin literature is composed, was originally the language merely of the city of Rome. The rest of Latium was occupied by a considerable number of other dialects, some of which probably differed from Latin almost as widely as did Faliscan. In fact Prænestine seems to have resembled Faliscan rather more closely than it did the language of Rome. It seems best, therefore, to restrict the name Latin to the language of the city of Rome and the later language of the Roman Empire, and to regard the other ancient dialects of Latium as coördinate with it.

Faliscan was the language of the ancient town of Falerii, situated about 30 miles north of Rome and about 2 miles west of the Tiber. Although the town belonged to the Etruscan confederacy from the beginning of our records, its language and some of its customs were Italic. The 37 inscriptions are very brief and consist for the most part of proper names, excepting the younger Faliscan texts, which, although longer, contain so large an element of Latin that they are of no linguistic importance. The following inscription on the patera found near Civitã Castellana, the ancient Falerii, in 1887 is a good example of this dialect:

Faliscan: *foied uino pipafō cra carefo.*
Latin: *hodie vinum bibam cras carebo.*

Faliscan was differentiated from Latin by the following features: (1) the retention of medial *f*, which Latin and some of the dialects of Latium changed to *b*, e.g., *carefo*, Lat. *carebo*; (2) the representation of initial Indo-European *gh* by *f*, where Latin and also Oscan-Umbrian had *h*, e.g., *foied*, Lat. *hodie*; (3) the change of initial *f*, from Indo-European *bh* or *dh*, to *h*, e.g., *haba*, Lat. *faba*; (4) the retention of intervocalic *s* as a sibilant, written sometimes *s* and sometimes *z*, e.g., *Folcozeo*, *Folcosio*, *Halæsus*, *de zenatuo sententiad*. (5) To some extent at least Falis-

can corresponded with Umbrian rather than with Latin in the simplification of the diphthongs; *loferta*, "liberta," shows *o* for Italic *ou* (Pælgianian *loufir*), whereas Latin changed *ou* to *ū*.

Prænestine. The dialect of Præneste is known from a number of early inscriptions. These texts consist for the most part of lists of names of deities inscribed on brass mirrors and cylindrical caskets found in Prænestine tombs. The most interesting relic of the dialect is the famous Prænestine fibula, a gold brooch of about the sixth century B.C., which gives, therefore, one of the earliest of all Italic inscriptions. It is as follows:

Prænestine: *Manios med fhefhaked Numasioi.*
Latin: *Manius me fecit Numerio.*

We do not know that this inscription contains any feature which did not belong to Latin of the same date. In other Prænestine documents, however, we find medial *f* for Latin *b* and initial *f* for Latin *h*, as in Faliscan (e.g., *nefrones*, *Foratia*, "Horatia"). Prænestine, like Faliscan, shows the Umbrian method of simplifying the diphthongs, e.g., *losna* for *lūna* (from **louksnā*), *Hercole* for *Herculi* (from **-ei*). Like Faliscan again is the extensive Etruscan influence to be seen in the confusion of the voiced and voiceless mutes in *Alixentros* for *Alexander*, *Casentera* for *Cassandra*, etc.

Other Dialects of Latium. We know even less about the other dialects of Latium than we do about that of Præneste. Lanuvian *nebrundines* beside Prænestine *nefrones* shows that the Latin change of medial *f* to *b* was not entirely confined to the city of Rome. The grammarians cite "rustic" forms such as *prētor* for *prætor*, *spēca* for *spīca* from **speica*, *ōrum* for *aurum*. A fair inference is that the Umbrian method of simplifying the diphthongs was rather widespread in Latium.

Latin is treated under LATIN LANGUAGE; see also GRIMM'S LAW; VERNER'S LAW; INDO-GERMANIC LANGUAGES. It is necessary here only to point out the extensive influence which the other Italic languages have had upon the dialect of the city. In case a Latin word displays a feature that is known to be foreign to Latin and native to one or several of the related idioms, we may safely conclude that the word in question has been borrowed. Thus the name *Pompeius* is related to Oscan **pompe* instead of to the equivalent Latin *quinque*, which yielded the genuine Roman names *Quin(c)tius*, *Quin(c)tilius*, etc. *Albius* is the Latin form of the dialectic *Alfius*. *Rūfus* must come from a dialect which retained medial *f* but changed *ou* to *ū* as Latin did; the synonym *rōbus*, on the other hand, implies a dialect which changed medial *f* to *b* but which changed *ou* to *ō* in the Umbrian fashion. Very likely both words came from dialects of Latium. Plautus's *monerula* for *monedula*, and *dispennite* and *distennite* for *dispendite* and *distendite*, display Umbrian sound changes.

The modern Italian dialects preserve some traces of the ancient Italic languages. Neapolitan *attrufe* comes from Oscan **octufer*, not from Latin *October*. The modern Italian assimilation of *nd* to *nn* covers about the territory once occupied by the Oscan-Umbrian languages.

Bibliography. The most convenient and reliable work on Oscan and Umbrian is C. D. Buck, *Grammar of Oscan and Umbrian* (Boston, 1904). The fullest grammatical discussion of Oscan-Umbrian, including the minor dialects, but not

Faliscan or the dialects of Latium, is Von Planta, *Grammatik der oskisch-umbrischen Dialekte* (Strassburg, 1892-97). The fullest collection of material, with brief discussion and including Faliscan, is R. S. Conway, *The Italic Dialects* (2 vols., Cambridge, 1897). A full but uncritical treatment of Faliscan is Deeke, *Die Falisker* (Strassburg, 1888). The influence of the other Italic languages upon Latin is discussed in Ernout, *Les Éléments Dialectaux du Vocabulaire Latin* (Paris, 1909).

ITALIENS, é'tá'lyän', BOULEVARD DES. The most frequented and fashionable of the boulevards of Paris, named from the old Théâtre des Italiens.

ITALIENS, LES. See THÉÂTRE DES ITALIENS.

ITALY. The central of the three great peninsulas of south Europe. It stretches out in a southeast direction and is bounded on the north by Switzerland and Austria-Hungary; on the east by Austria-Hungary, the Adriatic, and the Ionian Sea; and on the southwest and west by the Mediterranean and France. It is separated from the Balkan Peninsula by the Strait of Otranto, 47 miles in width, and is nearly walled off from the great body of the continent by the lofty ranges of the Alps. With its continuation, the island of Sicily, it nearly reaches across the Mediterranean and is thus exceptionally favored with convenient commercial routes in all directions. Its position also especially adapts Italy for a large sea trade, because it is in the line of the shortest route from west and central Europe to Oriental countries. Although Italy is separated from the northern lands by the Alps, they are no longer a barrier to Italy's commerce, for several lines of railroad cross the mountains. Extending from northwest to southeast about 700 miles, and with an average breadth, except in the extreme north, of 100 miles, the mainland has an area of 91,161 square miles; to this Sicily, Sardinia, Elba, and smaller islands add 19,389 square miles, making the total area of the kingdom 110,550 square miles. The mainland is about twice as large as Pennsylvania or New York and extends from lat. 38° N. to lat. 46° 40' N. and from long. 6° 30' E. to long. 18° 30' E.

Topography. The coast, 4160 miles in length (inclusive of the islands), is easily accessible from every part of the country. No settlement is remote from salt water, four-fifths of Italy being within 62 miles of the sea. In the north of the Adriatic the coast is low and sandy, bordered by shallow waters, and, except at Venice, not easily accessible to large shipping. Farther south, near Rimini, spurs from the Apennines reach the shore, which becomes high and rocky. The south and west coasts are generally high, rocky, and picturesque, with many bold promontories. The middle of the west coast, however, has three stretches of low and marshy land, known as the Maremma, the Campagna, and the Pontine Marshes. The west coast is varied by bays, gulfs, and other openings, and is therefore most favorable for commerce. In the northwest is the Gulf of Genoa, on which the wealthy city of Genoa stands. About the middle is the deep embayment with the fortress port of Gaeta. Next is the Bay of Naples, celebrated for its beauty. Beyond this is the Gulf of Salerno, at the head of which stands the port of Salerno. The southeast end of the peninsula is deeply indented by the Gulf of Taranto, which cuts off the so-called heel of

Italy (ancient Calabria) from the toe (modern Calabria). The population is dense on all coasts where fever does not prevail, about 17 per cent of the inhabitants of Italy living within 3 miles of the sea.

The Kingdom of Italy falls geographically into three parts, differing from each other in surface features and climate and, as a consequence, in productions. One part to the north is continental, another to the south is peninsular, and the third is insular. The north portion contains the great plain of Lombardy, the valley of the Po, bordered on the west and north by the Alps. The Italian Alps are usually named after the provinces of the neighboring plains, as Piedmont, Lombardy, and Venetia. The peninsula is almost completely filled by the Apennines, which stretch through central and south Italy and are continued through Sicily.

The Alps, beginning at the Gulf of Genoa, extend first to the west, then to the north, and finally to the east, towering in lofty summits covered with snow fields. Their slopes are deeply scored by valleys, and they present a very abrupt face towards the plain of the Po. The rainfall on them is, as a result, rapidly transferred to the plain, making protective works along the river banks necessary in order to restrain the periodical floods.

The northern Apennines, which touch the Ligurian Alps, curve round the Gulf of Genoa and extend to the source of the Tiber. Their highest summit is Monte Cimone, 7110 feet. The central Apennines, beginning at the source of the Tiber, soon divide into several chains, forming the rugged mountain district of the Abruzzi, on the eastern verge of which is the Gran Sasso (9580 feet), the highest peak of the Apennines. The southern Apennines stretch to the southeast from the Abruzzi to the coast of the Gulf of Taranto, where they assume a southerly direction, with summits culminating in Monte Polino 7450 feet. The rugged and unfertile Apennines form the watershed of the peninsula; they are bordered, especially on the west side, by lower and more productive mountain districts that are grouped under the name of the sub-Apennine region. A number of passes through the Apennines are utilized by the highways across the peninsula. The Italian peninsula contains the only active volcano on the continent of Europe, Vesuvius.

The mountain regions of Italy, with their ruins, cloisters, storied castles, towered cities, the quietude of their rural scenes, and their picturesque aspects, are among the great charms that draw tourists to the country. Italy's beauty is enhanced by the singular clearness of the air, which causes the lines of tower and church and castle to stand out with clear-cut perfection and makes mountains that are miles away appear to be almost within touch.

The Italian islands are also mountainous. Sicily, nearly filled with the continuation of the Apennines, has the loftiest volcano in Europe (Mount Etna, 10,740 feet). It has not, however, figured so prominently in the history of volcanoes as Vesuvius, near Naples. The mountains of fertile but unhealthy and neglected Sardinia rise only a little over 5000 feet in height. The Lipari Islands are wholly volcanic in character.

Only about one-third of the surface of Italy is made up of plains, most of it being the great plain of Lombardy, or the plain of the Po.

This plain is encircled by a steep mountain wall in the form of an arch. The largest and richest farming area and the greatest industrial development belong to this low, almost flat plain. It is watered by the rivers of the Po system, which are fed by many Alpine and Apennine streams, with which the cereal and other crops are irrigated. The plain is a long narrow trough formed by subsidence between the Alps and Apennines and built up by the alluvial deposits of streams from the Alps and Apennines. It is steadily encroaching on the sea, because the Po for centuries has been extending its delta into the Adriatic. During six centuries the Po delta has increased 198 square miles in area. Recent surveys show that the increase is actively maintained at the present day. According to the calculations of Professor Marinelli, it will take over 100 centuries at the present rate of increase for the Po to fill up the whole of the north Adriatic north of lat. $40^{\circ} 45' N$. The former port of Adria, which gave its name to the Adriatic, now stands about 15 miles inland. The Lombard plain has a more dense population and far more active manufacturing and business interests than the peninsula. Among the small plains of the peninsula are those of Tuscany and Apulia, the fertile plain to the north of Naples (the Campania of the ancients), that bordering on the Gulf of Manfredonia, and the Roman Campagna.

Hydrography. Italy has many streams, although it has only one great river, the Po. The most important streams, the Po and the Adige, flow into the Adriatic Sea. The Po is fed on one side by the snows of the Alps, on the other by the heavy rains of the Apennines, and drains an area of about 30,000 square miles, of which nearly 11,000 are level and, indeed, almost flat. Its course marks the line at which the sediment and débris from the Alps meet the sediment and débris from the Apennines. The Po is navigable to Turin and with its tributaries affords about 600 miles of navigation. The Adige enters Italy from Tirol and flows eastward to the Adriatic. The beds of both these rivers are constantly but very slowly being elevated by the alluvial deposits brought down from the mountains. The rivers of the peninsula are of little importance for navigation or industry. The beds of most of them are dry in summer, so that they cannot be relied upon for water power. The most important among them are the Arno, which rises in the Apennines and flows west past Florence and Pisa through a lovely and well-cultivated valley. It has a short course of only 150 miles. The Tiber rises not far from the sources of the Arno, the two rivers being connected by a canal through the tributary called the Chiana, whose waters flow partly into the Arno and partly into the Tiber. The canal system is thoroughly developed in the basin of the Po and is utilized not only for transportation, but also for the irrigation of hay and rice, so that the farmer in the great plain is almost independent of rain. There are many lakes where the mountains merge into the great plain; also a considerable number in the peninsula, some of which are crater lakes. The chief lakes of north Italy are, in the order of their size, Garda, Maggiore, and Como. These are not only important as pleasure resorts, but they form the great reservoirs for the rivers of the plain. Lago di Garda covers an area of 140 square miles and is very deep. Lago Maggiore is longer than Como, but not so large as Garda; a part of this lake is in

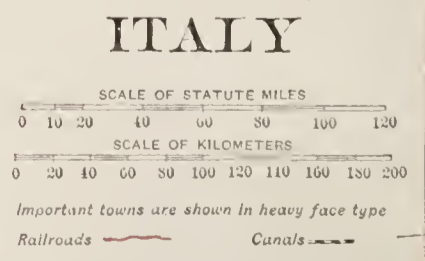

Switzerland. Lago di Como is one of the loveliest lakes in the world. Other considerable lakes are Lugano and Iseo.

Climate. Italy may be divided into four climatic regions—northern, eastern, western, and southern. The first, coinciding with the valley of the Po, has a warm summer and a large daily range of temperature. The greatest extremes of temperature are in the Po basin; but even here, except in Piedmont, the mean winter temperature does not descend below $35^{\circ} F$. The great wall of the Alps protects it from the north winds and continental influences. Peninsular Italy is divided climatically into the eastern and western regions. The extremes of temperature diminish towards the south; on the east slope of the Apennines the mean annual temperature is about $57^{\circ} F$., while the west slope is a trifle warmer. South Italy, Sicily, and Sardinia form the last climatic division, with a mean annual temperature varying from $61^{\circ} F$. to $64^{\circ} F$., the difference between summer and winter being only 25° . The mean summer temperature at any station in the whole kingdom does not exceed $80^{\circ} F$., and, except in the elevated valleys of Piedmont, it is nowhere lower than 70° . As in all the Mediterranean countries, the largest rainfall occurs in the fall and winter months, after the growing season, when the westerlies prevail, so that irrigation is required in nearly all parts of the kingdom. The soils are excellent, particularly in the Lombard plain, which is among the richest agricultural lands in the world. Many once fertile parts of the Apennines, however, have been denuded of their soil.

The greatest climatic drawback of Italy is found in the swampy lands of the lower Po, the Maremma, the Campagna, the Pontine Marshes, and some other regions where intermittent malarial fevers prevail during the summer months. Only six of the provinces, including Genoa and Florence, are wholly free from malaria. Large sums of money have been spent in attempts to overcome this evil by means of drainage canals and pumping machines and by draining the breeding places of the mosquito. The extensive planting of the eucalyptus is believed also to have had a favorable effect upon the salubrity of these malarial regions.

Flora. The flora of the central and southern lowlands is typical of the Mediterranean countries, with the olive as the most characteristic tree. The great extent of the mountains and highlands, however, causes the myrtle, olive, and other evergreens to be confined to the coasts, especially in north Italy, where the olive is excluded from the plain by the colder winter weather. In the northern plain are maize, wheat, vines, and mulberries. Rice is grown on the irrigated fields near the Po. The flora of the Apennines is very much like that of central Europe. The shores of the Tyrrhenian Sea present almost a continuous growth of orange, olive, and lemon trees. In the extreme south the vegetation is subtropical; the sugar cane, the Indian fig, and the date palm are found. Forests have almost everywhere been destroyed, but the chestnut tree clothes the sides both of the Alps and the Apennines, the nut in some districts supplying the chief food of the inhabitants.

Fauna. Italy is very low in the scale of European countries with regard to its fauna. The bear, genet, weasel, and some rodents are almost the only conspicuous examples in the way

D Longitude 11 East from E Greenwich 16

of mammals. The Alps and Apennines, and the swampy marenme of Rome and Tuscany, afford some refuge for wild life; but otherwise almost everything above an insect is killed for food or wantonly by the people. This has been the rule so long that the country is nearly bare even of small birds. Upon certain great estates a few animals, such as the native fallow deer, are preserved. Were not Italy, by its extension towards the south, a highway of migration to and from Africa for the birds, their absence would be still more complete. The autumn flight of quails from Tunis is a period of feasting. The sea life along the shores of the southern part is wonderfully varied and plentiful.

Geology. In its geological structure Italy represents a portion of the great system of mountain folds which extend across the Eurasian continent, and which are here diverted from the normal east and west direction to north and south. There is reason for believing that the peninsula once formed a continuous land bridge across the Mediterranean, thus uniting the ranges of the Alps with the Atlas. The uplifting of the Apennines took place at a comparatively recent geological period; Mesozoic and Tertiary strata including limestones, marls, and sandstones are the predominant formations. The islands off the coast of Tuscany, together with Corsica, Sardinia, and northeast Sicily, represent a much older land mass (Tyrrhenia), which, previous to the Tertiary period, occupied a large part of the depression now filled by the Tyrrhenian Sea. The great crustal movements that have determined the present configuration of Italy were accompanied by volcanic eruptions on an enormous scale. Evidences of these ancient outbursts are found in the Euganean and Brescian hills, near Padua; in the numerous vents along the west coasts of middle Italy, including Monte Amiata and the Alban Hills; and in the Phlegrean Fields of Campania. On the mainland Vesuvius is the only volcano now active, although eruptions have occurred in the Alban Hills within historical times. Sicily contains the great cone of Mount Etna (q.v.), and the Lipari Islands are dominated by Stromboli—both active volcanoes.

Mineral Resources. Italy has no great mineral wealth. A small quantity of anthracite is mined in Piedmont, and lignite in Umbria, Tuscany, and Sardinia; the total output of coal in 1912 was 663,812 metric tons, valued at \$1,179,000. The most important mineral is sulphur, the output of which constitutes in value nearly one-third of all the mineral products, though the production has declined considerably. The richest sulphur mines are in the Sicilian provinces of Girgenti, Catania, and Caltanissetta; smaller deposits occur on the mainland, in the provinces of Forlì, Ancona, Avellino, and Pesaro e Urbino. Over 17,000 persons are engaged in extracting this mineral. The methods employed in procuring the sulphur range from the most primitive to the latest and most improved. Almost the entire world's supplies of this mineral are drawn from the Italian mines. In 1911 the production amounted to: sulphur ore, 2,682,766 metric tons, valued at \$6,002,000; raw sulphur, 414,161 tons, valued at \$7,775,000; refined sulphur, 166,802 tons, valued at \$3,592,000; and powdered sulphur, 158,977 tons, valued at \$3,847,000. The island of Elba yields an especially good quality of iron ore, which is largely exported to other countries. In 1912 the output

of iron ore was 582,066 tons, valued at \$2,395,000. Rich deposits of zinc ore are worked in Lombardy and Sardinia; the output of this mineral ranks second in value to that of sulphur, the total in 1912 being 149,776 tons, valued at \$3,529,000. Quicksilver is mined in Tuscany, copper in Piedmont, Tuscany, and the Venetian Alps, and lead in the provinces of Genoa, Lucca, and in Sardinia. Small quantities of gold, silver, and antimony are also produced. Sicily and Calabria contain deposits of rock salt, while sea salt is made along the coast of Sicily and Sardinia. The marble quarries of Carrara, Massa, and Serarezza have a worldwide reputation. The quarries of Italy employed in 1912 nearly 71,000 persons, and their total output, including marble valued at \$5,000,000, was valued at \$12,402,000. The petroleum deposits of the Apennines, near Piacenza and other places, have been exploited since about 1893. The output of crude oil in 1911 reached 22,906,000 pounds.

Mineral waters suited for medicinal and bathing purposes are found at numerous localities in the Apennines and the volcanic regions. Among the popular resorts are Abano, Acqui, Bonino, Bagni di Lucca, Ischia, San Giuliano, San Pellegrino, Montecatini, and Posetta.

Fisheries. The sea and fresh-water fisheries of Italy are considerable and give employment to about 130,000 persons. The number of fishermen officially reported for the year 1911 was 127,792, of which total 6477 were engaged in deep-sea or foreign fishing, the remainder chiefly in the Mediterranean and gulf waters adjacent to the shores of Italy. The number of vessels and boats engaged in the same year was 28,402. The Mediterranean furnishes immense quantities of tunny, anchovies, sardines, mullet, pilchards, and mackerel. The Italian fisheries yielded about \$4,830,000 in fish in 1911, but the imports of fish exceed the exports. The value of fish imported in 1912 was \$11,020,000. This consisted almost entirely of fish dried or prepared in oil. Coral fishing formerly netted over \$400,000 per annum; in 1910 it yielded only \$14,500. It is carried on mainly along the coasts of Sicily and Sardinia. Sponges are obtained around Trapani and off the coast of Tunis. Tunny fishing produced \$793,000 in 1910.

Agriculture. Agriculture is the principal industry. The area of Italy comprises 70,820,197 acres, only 7.4 per cent of which is unproductive land; 45.4 per cent being tilled land, 25.6 per cent pasture land, 4.9 per cent vineyards, orchards, etc., and 16.2 per cent forests. The most fertile and best cultivated lands are in the northern plain, drained by the Po, in Tuscany, in Campania, and in north Sicily, near Palermo. The poorest agricultural sections are in the country east of the Apennine Mountains, the marshy lowlands of south Tuscany and Rome, the plains of Apulia, and the hilly interior of Sicily. Extensive swamp areas, and the large, unproductive stretches of arid land which could be turned into fertile gardens and fields with proper irrigation, have made it necessary for the government to undertake large drainage and irrigation works, which have added about 6,000,000 acres to the productive area of the country.

The agricultural lands are, as a rule, divided into comparatively small holdings, though large farms exist in the vicinity of Rome, Milan, Pavia, and Cremona. Peasant proprietorship of the

lands is common in Piedmont and Liguria, while in Tuscany, Umbria, and the Marches a system of partnership between owner and cultivator is practiced. In Lombardy and Venetia the rental system prevails.

Crops. Italy is favored above most countries by climatic conditions and is comparable to California in the great range of crops that can be grown, including both temperate-zone and tropical varieties. Like Florida, its peninsular position gives it the advantage of an insular climate, and though it is in a more northern latitude (Naples being on the same parallel with New York), it is not subject to severe freezes such as sometimes occur in Florida, the Alps to the north protecting it from the southward sweep of cold north winds. From the agricultural table appended it will be seen that wheat production has materially increased, the product of 1913 being nearly 50 per cent greater than in 1900. The production does not meet the domestic demand, and annual importations are necessary. Corn is also raised throughout the kingdom, the two most important districts being the provinces of Milan and Caserta. The other important

the eye of the traveler in Sicily and Sardinia, adorn the coasts of Liguria, and thrive in the coast provinces of south Italy. The provinces of Messina, Palermo, Catania, Syracuse, Trapani, Calabria, Salerno, Catanzaro, Foggia, Caserta, and Naples are famous for the delicious fruit they produce. In 1911 the orange and lemon orchards had an area of 110,456 acres. Almonds are grown in south and insular Italy, and other fruits, such as figs, dates, melons, and pistachio nuts, are produced in large quantities and exported. Silk culture is no less prominent, giving Italy first place in Europe as a raw-silk producer and second only to China and Japan in the world. Its output makes up 80 per cent of the total European production and nearly one-fifth of the world's product. In 1913 the production of silk cocoons amounted to 72,312,000 pounds, which, however, was materially less than that of 1900. Silkworms are raised chiefly in north and middle Italy. The cultivation of mulberry trees is extensive, having developed in connection with the silk industry. The following table shows the fluctuations in the chief crops since 1870:

YEAR	Wheat (bushels)	Corn (bushels)	Rice (bushels)	Wine (gallons)	Olive oil (gallons)	Silk cocoons (pounds)	Tobacco (pounds)
1870-74*.....	144,448,524	88,471,812	27,806,724	727,497,763	87,783,691	8,340,974
1879-83*.....	132,142,956	84,188,018	20,663,478	971,088,920	89,553,630	91,651,636	13,531,281
1890.....	131,456,160	74,974,284	17,887,914	778,165,569	81,522,862	89,890,360	5,057,815
1900.....	127,795,140	86,275,200	16,886,100	789,868,300	39,440,581	111,342,300	12,401,148
1910.....	153,405,000	101,723,000	21,457,000	773,841,000	36,577,000	95,520,000	16,100,000
1912.....	165,721,000	98,669,000	21,532,000	1,165,599,000	24,172,000	91,933,000	39,683,000
1913.....	199,498,000	108,388,000	26,612,000	1,579,736,000	72,312,000

* Annual average.

provinces are Brescia, Cremona, Udine, Treviso, and Padua. This crop also shows an increase as compared with earlier years, but does not fully supply the home consumption, necessitating some importations. The cultivation of rice has somewhat increased within recent years and amounted in 1913 to 26,612,000 bushels. Oats, barley, and rye are also important cereal crops. Potatoes, turnips, beetroot, and sugar beet are of considerable importance. The production of hay, both from the natural grass meadows and the various cultivated varieties, is very extensive. Some hemp and flax are grown, but cotton cultivation has been reduced to insignificance.

In the agricultural economy of Italy fruit plays a more important part than cereals. The vines covered (1912) 11,002,368 acres. The government is spending large sums of money in combating the phylloxera and maintaining schools for teaching the art of wine making. The vine is grown all over the country, especially in the provinces of Bari, Alessandria, Lecce, Foggia, Rome, Catania, and Florence. The wines of Italy are of many kinds, but, owing to the defective methods of preparing them, they deteriorate with age and are to a great extent unfit for export. The best-known wines are the Marsala of Sicily, the Chianti of Tuscany, and the Asti of Piedmont. These are quite largely exported. The wine crop of 1913 was nearly double that of 1900. The olive tree thrives best in Liguria and throughout central and south Italy, as well as on the islands of Sardinia and Sicily. It occupies an area nearly one-half as large as that under the vine.

Luxuriant groves of orange and lemon delight

The agricultural methods prevailing in north Italy are essentially the same as in other countries of western Europe, being characterized by intensive cultivation, the use of modern machinery, and the employment of the best methods of irrigation and fertilization. On the contrary, south Italy, though essentially an agricultural country, suffers from crude, primitive methods of cultivation. The Italian peasant is among the poorest in Europe. The prevalence of large estates and the presence of tenants and hired laborers who cultivate the land are characteristic features of Italian agriculture. No definite statistics are gathered on the subject, but it is estimated that the agricultural producers are made up of 40 per cent laborers, 40 per cent tenants, and 20 per cent owners. Since about the year 1900 a system of collective farming, i.e., leasing of farms by groups of laborers, has spread quite rapidly in the north, particularly in Emilia.

Stock Breeding. This industry is in a backward state. The only branch that may be said to be carried on in a rational way is the breeding of horses and horned cattle in the northern part of the country. The exports of horses, cattle, sheep, and swine, though small, exceed the imports. The production of wool is not sufficient to satisfy the domestic demand. Sheep raising is carried on most extensively in the poorer provinces of south Italy. In north or continental Italy extensive methods of cattle raising are followed, and stall feeding is common, but in peninsular and insular Italy open-field grazing prevails. In the north there is a considerable trade in dairy products, especially

cheese—Gorgonzola, Parmesan, and Stracchino being among the famous brands. Coöperative methods are extensively used in the dairy industry. The raising of goats is confined to the hilly regions. Poultry and eggs are produced in large quantities and exported. The following table shows the number of live stock in Italy at different periods:

YEAR	Horses	Mules	Asses	Cattle	Sheep	Goats	Swine
1875-76.....	657,544	293,868	498,766	3,489,125	6,977,104	1,688,478	1,553,562
1881-82.....	660,123	302,428	674,246	4,783,232	8,596,108	2,016,307	2,064,000
1890.....	720,000	300,000	1,000,000	5,000,000	6,900,000	1,800,000	1,800,000
1908.....	955,878	1,238,060	1,238,060	6,198,861	11,162,926	2,714,878	2,507,798

The value of the products of the live-stock industry of Italy is estimated at about \$285,000,000 per annum.

Forestry. About 11,277,000 acres, or 16.2 per cent of the total area of Italy, are under forests. Of this total area, 1,611,000 acres are in chestnuts. Only 129,095 acres of forests belong to the government, but a great part of the forest land is under government supervision, which is exercised by the Ministry of Agriculture through a staff who are unable, however, to prevent the devastation of forests. Since 1867 the government has been trying to offset the loss by planting new trees. The total value of the forest products is nearly \$30,000,000 per annum.

Manufactures. The manufacturing industries of Italy have materially improved, owing to the utilization of the plentiful water power, especially at the north, by which electricity is rendered available for the operation of factories and small workshops. The industrial census of 1911 showed a total of 243,988 establishments employing 1,305,000 persons in the provinces having each as many as 5000 establishments. The most important branch of manufacture is the production of raw silk, which has been referred to under *Agriculture* in this article. The industry thrives especially in Piedmont, Lombardy, and Venetia. More than 500,000 people are employed in the raising of silkworms. Silk spinning and weaving are carried on mostly in the north—Lombardy, and especially the Province of Como, being the centre of the industry. The spinning and weaving of wool and cotton are on the increase, but the production is not sufficiently large to satisfy the home demand. The same is true of the manufacture of linen and jute articles. In 1911 the textile industries employed 657,190 persons. The iron and steel industry employs about 100,000 people exclusive of those employed in the mines. While it has reached such proportions, no great progress can be recorded in regard to its growth, owing largely to Italy's lack of sufficient mineral deposits.

In the manufacture of small metal ware, and especially of finer articles of bronze, silver, and gold requiring high artistic skill, Italy has long enjoyed a wide reputation, the beautiful work turned out by the workshops of Milan, Venice, Genoa, Rome, and Naples finding ready purchasers among lovers of art throughout the world. The same may be said of the finer varieties of pottery and glassware, especially the terra cotta, majolica, and faïence, and the mosaic, enamel, and pearl work of Venice, Genoa, Leghorn, Florence, and Rome. The marble and

alabaster products are no less famous. Altogether some 90,000 people are employed in the above industries. The chemical industry employs over 6000 persons and turned out in 1912 about \$55,000,000 worth of products, the most important single article of that industry being sulphuric acid. The paper and leather industries employ about 25,000 people, and the manu-

facture of straw hats and other straw-plaited goods gives employment to several thousand persons.

The manufacture of tobacco and of salt are government monopolies. The annual output of the former fluctuates between 37,500,000 and 40,000,000 pounds; that of the latter increased from 267,000 tons in 1871 to 389,000 tons in 1881, 419,000 tons in 1891, and 521,453 tons in 1911. The manufacture of alcohol, beer, and liquors, sugar, glucose, chicory, powder and other explosives, mineral oils, matches, gas, and electricity is subject to government supervision. None of these industries, however, has reached any large proportions. The sugar industry shows more signs of vitality than any other, although but of recent date in Italy. In 1898 there were only four sugar refineries, with an annual output of 8000 tons; in 1912 their number increased to 37, and the output to 159,000 tons.

Transportation. In 1913 Italy had a railway system with a total length of 11,015 miles. The mileage is the smallest of any leading country in Europe and is less per square mile of area than is common in western European countries. As a result of the peninsular position of Italy, the traffic of its railroads is mainly local, which has not justified the construction of a large mileage and is partly responsible for the financial difficulties which have overtaken the operation of the system, as below described. The Apennines, extending through the length of Italy, divide the railway system into two distinct groups, called the Mediterranean and Adriatic respectively. Each of these, as well as the respective lines of Sicily and Sardinia, was operated under the Law of 1885 by separate companies until July, 1905, when the government resumed the management of the state lines. The first railway in Italy was built in 1839, to connect the city of Naples with Portici, a distance of 5 miles. In 1860 there were 1118 miles, about one-fifth of which belonged to the state, the remainder being owned by seven railway companies. In 1869 the state undertook the construction of new railways and by 1870 owned nearly two-thirds of the total, 3962 miles. By 1879 the mileage had increased to 5228 miles, and as the growth of the system did not keep up with the needs of the country, there was a popular clamor for a more rapid construction of railways by the government. In 1879 a law was enacted with a view to meeting this demand, providing for the construction of upward of 3728 miles, at an expense of about \$240,000,000. As the government found insuperable financial difficulties in trying to carry out this provision,

it was compelled to give up the undertaking in a few years.

In 1885 an agreement was reached with three private railway companies, whereby the latter were to take over the three principal lines of the kingdom and were to be designated as the Mediterranean, the Adriatic, and the Sicilian Railway companies. By virtue of this agreement these companies were to have the operation of the government lines for a period of 60 years, either side, however, to have the right to terminate the contract at the expiration of 20-year periods. The companies paid the government the total sum of \$53,000,000—\$28,800,000 to be rebated by the latter for the extension and improvement of existing lines, and the remainder to be spent for the purchase of additional rolling stock and the construction of new lines. The companies paid all operating expenses, and, in addition, from 10 to 15 per cent of the gross revenue of each road was put into the reserve fund to offset the wear and tear on roads and rolling stock. The state received, moreover, 27½ per cent of the gross revenue of the continental roads, and 3 per cent on the Sicilian roads as rent, besides an equal share of all profits in excess of an annual dividend on the capital stock of 7½ per cent. The government might demand from the companies an annual expenditure of not more than \$20,000,000 for new railway construction. The money was raised by issuing 3 per cent bonds guaranteed by the government. Upon the reversion of the lines to the government the companies were to be reimbursed the sums originally paid by them for the railways, with due allowance for the depreciation of the property.

This scheme had not resulted in a more rapid development of the railway system of Italy, the cost of construction having proved so high that it involved the government in financial difficulties. A parliamentary commission appointed in 1895 to investigate the method employed in the construction of nine lines elicited the information that the actual expense incurred exceeded the amount originally authorized by \$30,000,000, the respective figures being \$70,600,000 and \$40,600,000, making an excess of 74 per cent over the sum authorized.

The length of the state lines now under government management is 8540 miles. The number of passengers carried annually increased from 34,040,515 in 1881 to 64,898,078 in 1902 and 82,407,600 in 1910.

Highways. Italy has an elaborate system of highways, divided into national, provincial, and communal, according to the source of their maintenance. In 1910 the length of the roads was about 92,200 miles, of which 5160 miles were national, 27,757 provincial, and 59,283 communal.

Communication. The postal and the telegraph systems are both in the hands of the government, though certain concessions are granted to railway and tramway companies in the telegraph service. For the year ending June 30, 1911, the number of letters and post cards transmitted, not including the governmental official letters, was 470,251,000. The number of private telegrams inland for the same year was 13,593,000, and an additional 3,322,000 were sent or received from abroad. The telegraph system includes a large number of submarine cables which connect different parts of the country. A net revenue is realized annually from the operation

of the postal and telegraph systems. Both systems have been greatly extended and their use increased in recent years. The number of radiograms received by the wireless stations in 1911 was 14,129; number sent, 4470.

Commerce. The volume of Italian commerce was in 1913 more than double that of 1900. The remarkable growth is shown by the table which follows:

FOREIGN COMMERCE OF ITALY

YEAR	Imports	Exports
1871.....	\$192,739,688	\$217,091,913
1880.....	245,128,834	226,457,838
1890.....	275,457,286	192,520,070
1900.....	340,047,133	267,649,250
1905.....	369,209,000	308,221,000
1910.....	626,473,360	401,435,634
1913.....	702,089,724	483,255,329

The above figures apply to special commerce only, i.e., imports for home consumption and exports of domestic products. The transit trade is equal to about one-tenth of the special commerce. In 1888 a law was passed regulating the foreign commercial relations of Italy. This law, with some additional clauses, has remained in force down to the present time and is of a protectionist character. In 1891 and 1892 special treaties were concluded with Germany, Austria-Hungary, and Switzerland. They have proved beneficial to Italy. On the other hand, the commerce with France fell off considerably. Coal, raw cotton, wheat, and other cereals constitute over three-tenths of the import trade. Next in importance are machinery, silk (unbleached, raw, or twisted), timber for building purposes, hides (raw or dried), woolen manufactures, raw wool, and fish. Silk constitutes nearly one-fifth of the total exports. Next in the order of importance are cotton manufactures, fruit, wines, cheese, hides, raw hemp, eggs, sulphur, and olive oil. Germany occupies the first place in the Italian import trade, furnishing about one-sixth of its total imports. The United Kingdom and the United States follow with about one-seventh each. Then come France, Austria-Hungary, and Russia. The largest exports go to Germany and Switzerland, about 13 per cent and 11 per cent respectively. Switzerland secures its high rank in the export trade of Italy by virtue of its large importation of raw silk. Next in order of importance are the United States, France, Austria-Hungary, Great Britain, and Argentina.

In our own foreign commerce Italy holds the tenth place in the import trade and the sixth place in the export trade. The table below shows the development of Italian-American commerce since 1890:

YEAR	Exports to United States	Imports from United States
1891.....	\$21,678,208	\$16,046,925
1895.....	20,851,761	16,363,125
1900.....	27,924,176	33,256,620
1901.....	24,618,384	34,473,189
1903.....	36,246,412	35,032,680
1905.....	38,628,579	38,740,067
1910.....	49,868,367	53,467,053
1913.....	54,107,364	76,285,278
1914.....	56,407,671	74,235,012

The largest items of export to the United States are raw silk, sulphur, macaroni and vermicelli, olive oil, oranges and lemons, conserves, dry fruits, and marble. Unmanufactured cotton annually makes up about one-half of the total imports from the United States.

Shipping and Navigation. Italy has a large and active merchant marine. In 1911 it numbered 757 steamers of 697,000 tons capacity, and 4713 sailing vessels of 411,000 tons. The tonnage of sailing vessels is on the decrease, while the steam tonnage is increasing, as is shown by the table below. The peninsular position of Italy fits it admirably for a commercial nation. In the mediæval times, when the Oriental trade was prominent in European commercial life, the Italian ports attained the first rank. But with the decreasing relative importance of the Mediterranean traffic, when new trade routes were opened and new commercial fields became important, the Italian cities ceased to play a leading part in the world's commerce, and the Italian merchant marine is now inferior to that of either Germany or France.

THE MERCHANT MARINE OF ITALY

YEAR	Total vessels	Net tonnage	STEAMERS		SAILING VESSELS	
			No.	Net tonnage	No.	Net tonnage
1878...	8,590	1,029,000	152	63,000	8,438	966,000
1890...	6,732	821,000	290	187,000	6,442	634,000
1900...	6,074	873,000	409	315,000	5,665	558,000
1905...	5,596	1,032,614	513	462,259	5,083	570,355
1910...	5,459	1,107,187	718	674,497	4,741	432,690
1911...	5,470	1,107,985	757	696,994	4,713	410,991

These figures show at first a decline, which was not checked until 1897. Even the increased tonnage in 1900, viz., 873,000 tons, was far below the tonnage of 1878, which was not attained again until 1904. Still, Italy does a much larger part of its own shipping than some nations having a larger maritime trade. In the foreign oversea trade of Italy England has the first place, carrying (1912) nearly 36 per cent of the incoming and over 15 per cent of the outgoing merchandise. Italy itself controls about 21 per cent of the incoming and 41 per cent of the outgoing tonnage in the foreign trade. The remainder is distributed chiefly among Greece, Austria-Hungary, Germany, Norway, Spain, Holland, and Denmark. In coastwise shipping Italy controls about 98.6 per cent of all the merchandise transported. About 340,000 persons are employed in the merchant marine—an increase of more than 12 per cent in the last five years. Millions of dollars have been ineffectively paid out of the Italian treasury in ship subsidies to shipowners. The chief ports are Naples, Genoa, Palermo, Leghorn, Messina, Catania, and Venice. Ancona and Brindisi are also well-known seaports.

Banking. The banking system of Italy has been very unsatisfactory, owing to the general financial distress of the country and to mismanagement. Previous to 1893 there were six banks of issue—the National Bank of the Kingdom, the Bank of Naples, the National Bank of Tuscany, the Tuscan Bank of Credit, the Roman Bank, and the Bank of Sicily. In 1892 disclosures of illegitimate manipulations of bank funds

and the collapse of the Bank of Rome precipitated a financial crisis. This institution was put into liquidation in 1903, and by the law of that year the National Bank of the Kingdom and the two Tuscan banks were consolidated as the Bank of Italy. The right of issuing bank notes was limited to this bank, the Bank of Naples, and the Bank of Sicily, which were chartered for 20 years from January, 1894. By the Law of Dec. 31, 1907, the amount of bank-note circulation, to be covered by a metallic reserve of 40 per cent, allowed to these banks was fixed at \$175,244,000. The allotment to the Bank of Italy was \$127,380,000, or 72 $\frac{2}{3}$ per cent of the total, the remainder being divided between the other two banks. The banks, however, may issue notes in excess of their allotment when they have sufficient security in bullion or when advancing money to the government. The Bank of Italy was soon charged with the gratuitous handling of all the fiscal transactions of the Treasury in the provinces, saving to the state \$240,000 annually. Thus, without being really a state bank, it performs some of the functions usually intrusted to such banks in other countries of Europe and is under strict government control and regulation. The capital stock of the Bank of Italy is nominally \$60,000,000, although the paid-up capital amounts to only about \$42,000,000, part of the difference having been absorbed by the losses of the Bank of Rome. The combined capital of the other two banks exceeds \$21,000,000. The financial condition of the three banks of issue at the beginning of 1914 was as follows: cash and reserve, \$291,400,000; deposits, \$587,500,000; notes in circulation, \$440,700,000; total assets and liabilities, \$1,250,000,000.

In addition to these Italy has developed, with great success, a system of popular coöperative banks. These are associations of people of small means who combine their savings for mutual loans and credit and do a general banking business on a comparatively small scale, discounting commercial paper, workmen's liens, treasury checks, etc.; keeping current accounts, and advancing loans "on honor," i.e., without any security whatever, to needy people who can bring recommendations of two members of the association.

The first bank of this kind was opened in 1865 in Milan as the result of the agitation of Signor Luzzatti. Ten years later there were 82 such banks with a membership of more than 77,000 and a capital and reserve fund of more than \$9,000,000. In 1886 their number increased to 516, the membership to more than 250,000, and their working capital to nearly \$18,400,000. In 1912 they numbered 862, with a proportionately increased capital and membership. Other banks operating in Italy are credit banks, agrarian credit companies built on the plan of the popular coöperative banks, credit-foncier banks, savings banks, and government postal savings banks.

In 1912 there were 9799 post-office savings-bank offices, with 5,780,010 depositors and total deposits amounting to \$376,072,000. There were in the same year 186 offices of the ordinary savings banks, with 2,363,832 depositors and deposits aggregating \$480,965,000. At the beginning of 1913 the savings deposited with the coöperative savings banks and ordinary credit companies amounted to \$244,423,000.

There are seven clearing houses in Italy, which

increased in volume of business in the four years 1907-11 from \$9,942,358,000 to \$11,833,218,000, or about 19 per cent.

Finances. The finances of Italy are in a somewhat unsatisfactory state owing to the heavy interest payment on the large national debt and the heavy expense of its standing army and modern navy. Although the annual budgets of the government usually show a surplus, this is often achieved with the help of loans and always through burdensome taxation. It is an undoubted fact that Italians are heavily burdened with taxes of all kinds, and yet they apparently prosper and accumulate wealth. The indirect taxes include excise, customs, and octroi duties. To these should be added the revenues derived from the tobacco, salt, quinine, and lottery monopolies. These taxes and revenues altogether yield more than 45 per cent of the total revenue. The direct taxes, including a land, an income, and a house tax, furnish about 21 per cent of the total revenue. The inheritance tax, registration and stamp duties bring in about 13 per cent more. The remainder (21 per cent) is obtained from incomes from all kinds of public property and government works, such as public domains, railways, telegraphs, posts, etc.

The largest item of expenditure is the interest on the public debt—over \$100,000,000 per annum, or about one-fifth of the total ordinary expenditure. The next largest item is the army and navy, which reached \$206,500,000 in 1912-13 (or nearly two-fifths of the total expenditure). By contrast the expenditure on public instruction during the same year was \$28,717,000 (or about 5 per cent), and on agriculture, industry, and commerce combined, but \$6,098,000 (or slightly more than 1 per cent). Since 1885 the revenue and expenditure of the government have remained practically the same until recently, as is shown by the following table of the budget since the existence of the kingdom in its present limits:

YEAR	Revenue	Expenditure	Surplus (+) or deficit (-)
1871.....	\$249,847,591	\$241,243,022	+\$8,604,568
1881.....	303,707,093	293,529,645	+10,177,447
1891-92.....	349,590,318	359,218,079	- 9,627,761
1895-96.....	367,950,702	368,277,331	- 326,629
1899-1900....	349,585,629	348,543,552	+ 1,042,097
1901-02.....	362,384,902	358,191,956	+ 4,192,946
1906-07.....	387,905,000	382,672,000	+ 5,233,000
1911-12.....	477,743,438	499,326,729	-21,583,291
1912-13.....	488,072,566	537,768,532	-49,695,966

The figures for the last two years show "effective" revenues and expenditures only. By means of financial operations the budget for 1911-12 was made to balance at \$557,444,004, while the final accounts for 1912-13 showed a surplus of \$633,802. To what an extent all other public interests have been neglected for the sake of military expenditure may be seen from the table in the next column, which shows the increase of expenditure for military purposes, for the payment of the debt, and the total expenditure.

The expenditure for military purposes decreased since 1896, when it reached \$86,000,000, owing to the defeat of the troops in Africa and the consequent contraction of military operations. But the increase of expenditure on that item in recent years has been enormous, to the detriment of such vital interests as public insti-

tutions, sanitation, industry, agriculture, commerce, etc. The expenditure of the state for public instruction amounts to about \$26,000,000 annually, mostly on higher education.

YEAR	Expenditure army and navy	Service of public debt	Total expenditure
1871.....	*33	*88	*241
1881.....	45	97	293
1891-92.....	67	128	359
1901-02.....	77	138	358
1906-07.....	80.4	128.8	382.7
1911-12.....	163	98.4	499.3
1912-13.....	206.5	101.3	537.8

* Millions of dollars.

Local Finances. In both commune and province expenditure is classified as "obligatory" and "optional," the former including the maintenance of roads, education, police, and matters considered indispensable. In 1899 the revenue of the communes of Italy amounted to \$128,401,829, while that of the provinces was \$26,335,265. No complete data are available for later years. In 1907 the ordinary revenues of the communes amounted to \$97,386,107. The largest items in the communal revenue are (1) the gate tax, or octroi, which is partly a duty on certain articles not otherwise taxed, and partly a surtax not to exceed 50 per cent of that levied upon certain commodities at the frontier; and (2) a surtax upon lands and buildings, also limited to a maximum of 50 per cent of that levied by the state. Of less importance are the levies made upon family incomes, live stock, etc. The bulk of the provincial tax is secured from a surtax upon land and buildings, which is likewise limited to 50 per cent of the state assessment. The expenditure and indebtedness of both the communes and the provinces have greatly increased during the last two decades.

As an illustration of the immense tax burden in Italy may be cited the land tax, which altogether, national, provincial, and communal, amounts to nearly one-fourth of the landowner's revenue. Under the cadastral survey which served as the basis of the land assessment prior to 1886, the burden of this tax fell with great inequality upon different parts of the country. But a law passed in 1886 authorized a new survey, which was quickly made in the provinces which were unjustly burdened, thereby securing a measure of relief. But the provinces which would not profit by the survey have been slow to make it (in some provinces the increase amounted to over 90 per cent). Hence the revenue yielded by the land was lessened in consequence of the law. The income tax, which is proportional, does not apply to incomes obtained from the land, but only upon those from movable capital and from labor.

Public Debt. The growth of Italy's debt and interest charges thereon since 1870 has been as follows:

YEAR	Debt	Interest
1870.....	\$1,663,744,800	\$77,682,800
1890.....	2,413,513,400	111,468,600
1900.....	2,529,057,800	115,967,000
1904.....	2,403,772,000	110,785,000
1913.....	2,754,420,000	96,585,000

(The seeming discrepancy between the interest figures in the above table and the one preceding

is due to the fact that the one gives the interest charges only, while the other gives the total service of the debt, which includes amortization.) The table shows that the debt increased more than 65 per cent in the period indicated, making it the fourth largest public debt in the world. It is next to that of France, of Great Britain, and of Russia, all of which countries have far greater resources than Italy. In fact the per capita debt of Italy, \$78.16 in 1913, is greater than that of any of the countries mentioned except France, where it was \$160.25 during the same year. It is, however, less than in some countries, e.g., Spain, where the figure is \$90.97; Portugal, \$174.74; Belgium, \$108.92.

Navy. The Italian navy was formed by the consolidation of the fleets of Sardinia and the Two Sicilies (1861). The importance of naval power to the newborn kingdom was fully appreciated. A dozen armor-clads and a large number of cruisers and smaller vessels were built in the next half-dozen years. The largest of the armor-clads, the *Re d'Italia* and the *Re di Portogallo*, of 5700 tons, were built at Webb's Yard, New York. Of the others, six were of about 4000 tons, two of 2700, and two of 2200.

The overwhelming defeat at Lissa in 1866 was a severe blow to Italian naval development. But early in the next decade the reorganization and rebuilding of the navy began. From that time until the present the Italian navy has led the way in many of the greatest advances in battleship construction. The *Duilio*, launched in 1876, was not only larger than any existing warship, but she carried much heavier armor and enormously larger guns. The *Duilio* was quickly followed by a sister ship, the *Dandolo*, and a little later by two larger and faster vessels with less armor. In some respects these may be regarded as the prototype of the battle cruiser of to-day.

By 1890 the Italian navy had advanced to third place in fighting strength, and the annual expenditure to nearly \$25,000,000. The financial condition of the nation then demanded economy, and no more large ships were launched until 1897. The cessation of building caused the Italian navy to decline in relative power. At present it is sixth in strength and is very nearly equal to that of Japan. In 1901 two battleships were put in the water, two in 1904, one in 1905, one in 1907, and four heavy cruisers in 1907-08. In 1910 the first dreadnought was commenced, followed by three in 1911 and two in 1913; two have been commenced, and two more will be laid down before the middle of 1915.

The present building programme, approved by the Italian Parliament, provides for the immediate laying down of four battleships to be completed in 1917 and thence onward to begin one each year. This programme will result in the permanent maintenance of a fleet of 20 first-class battleships of less than 20 years of age. The necessary numbers of cruisers, destroyers, submarines, auxiliary vessels, and air craft are included in the programme.

The head of the navy is the Minister of Marine (an admiral), who is assisted by the superior council of the navy, which is composed of one vice admiral (or admiral) president, three vice admirals (or rear admirals), one director general of the civil *personnel*, members; one rear admiral (or captain) who is a member and secretary; and lastly, the chief of the bureau or office whose affairs are under con-

sideration. The Navy Department is divided into the following branches: (1) cabinet of the Minister, which coördinates the branches; (2) general staff, which has charge of the preparation of plans and arrangements for everything that pertains to the readiness of the fleet for war, including operations, exercises, manœuvres, strategy, tactics, organization, mobilization, etc., and it is also concerned with the composition of forces afloat, building programmes, and design of ships—as many of these matters are determined by special boards, the chief of the general staff is a member of the boards; (3) *personnel*; (4) naval construction; (5) armament and equipment; (6) merchant marine; (7) hydrographic service; (8) medical department; (9) military engineering (fortifications, works, etc.); (10) office of revision; (11) accounts. The naval academy and college are located at Leghorn. The principal dockyards are at Spezia, Castellamare, Venice, Taranto, and Naples, and there are naval stations at Genoa, Messina, Licata, Cagliari, and Palermo.

The fleet is organized as follows:

[NOTE. Displacements are given in thousands of tons; thus, 12.5d is 12,500 tons; 4g12 means that 4 12-inch guns constitute the main battery; 30k means 30 knots' speed; 3t, 3 torpedo tubes; a.c., armored cruiser; b.s., battleship; c., cruiser; des., destroyer; sub., submarine; * means dreadnought b.s. or c.]

Two battleships of 9600 tons are placed in reserve and three older ones (12d to 15d) relegated to coast defense. There are 14 small cruisers available for service, some in commission, others in reserve. There are 43 destroyers completed, 3 building; 20 submarines, 6 building; 75 small torpedo boats, many unfit for service; and 37 large merchant steamers are subventioned and may be taken into service in case of war. An aviation service was organized in 1912.

The *personnel* of the navy consists of 1 admiral, 18 vice admirals, 14 rear admirals, 131 captains and commanders, 1331 other line officers (including engineer officers, recently combined with the line), 257 medical officers, 239 pay officers, 110 naval constructors, 1136 warrant officers, and 38,000 enlisted men. The naval estimates for 1914-15 are 260,284,575 lire (\$50,234,922.98), which sum is slightly less than that voted for the previous year. The outbreak of the Great European War may cause a considerable increase in these figures. See NAVIES.

Army. The Italian military system is complicated and requires a careful study of the conditions of service to arrive at a nearly correct estimate of the number of fully trained men available for the initial mobilization. Owing to the custom of granting unlimited leave to large numbers of men, the regular army is often short, by several thousand, of the full number provided by law for the peace establishment. Owing to insufficient budgets, the training of the several categories of militia has often been incomplete or altogether omitted.

Service, though universal and compulsory, is not the same for all the men of military age. Liability extends from the 20th to the 39th year. The men of 20 each year are divided into three classes and disposed of as follows: first, those that fill the vacancies in the regular army, in which service is for two years; then six years in the reserve on unlimited leave; then four years in the mobile militia; then seven years in the territorial militia, making a total liability for service of 19 years, ending at the age of 39. Second, the eligible men of 20 for whom there are no vacancies in the regular army are assigned to the *complementary force*

for eight years, where they receive from only two to six months' training for the entire period. They then pass to the mobile militia and then to the territorial militia for four and seven years respectively, which completes their 19 years' service. Third, the men of 20 who are exempted from active service are assigned direct to the territorial militia, where they receive only 30 days' training. The men who have passed through the regular army are supposed to receive about 30 days' training per year while in the reserve and mobile militia and a less amount while in the territorial militia.

Higher Organization.—These are 12 army corps (25 divisions) and 3 cavalry divisions organized in peace.

Infantry.—Typical formations are 4 companies to the battalion, 3 battalions to the regiment, 2 regiments to the brigade, 2 brigades to the division. To each division is attached 1 regiment of field artillery (5 batteries of 6 guns each). Total war strength of the division, about 14,000 men, 1400 horses, 30 field guns. To the army corps of two divisions are attached 6 light batteries, 3 heavy batteries, a regiment of cavalry, and a regiment of light infantry (Bersaglieri), having 4 battalions, one of which is a cyclist battalion. In addition to the above there are 26 battalions of Alpine infantry, to which are attached 36 mountain (pack) batteries. The war strength of the infantry company varies from 120 to 150 in Bersaglieri and Alpine troops to 250 men in the line companies. Total peace strength of infantry (389 battalions and 88 district headquarters), 7627 officers, 162,000 men.

Cavalry.—There are 3 independent cavalry divisions, each consisting of 2 brigades of 2 regiments each and 2 horse batteries. Total cavalry, 150 squadrons and 29 depots, making a total of 1006 officers, 27,416 men, 25,467 horses. A regiment in peace consists usually of 5 squadrons of about 150 men each, with 4 officers.

Artillery.—There are 263 field batteries (light, heavy, and mountain) and 110 companies of coast and fortress artillery, also 51 artillery depots; total, 2359 officers, 49,256 men. The light field-artillery regiment may have 5 or 6 batteries and 2 battalions; the battery, 6 guns. The strength of batteries varies from 3 officers and 90 men to 5 officers and 150 men; companies from 3 officers and 107 men in peace to 5 officers and 200 men in war. All artillery officers are on one list, from which they are assigned to field, fortress, and seacoast artillery.

Engineers are organized as 6 regiments: 2 of pioneers, 1 each of pontoon troops, telegraph troops, sappers, and railway troops. The 82 companies and 10 train companies amount to a total of 630 officers and about 11,000 men. The companies vary in strength from 3 officers and 110 men in peace to 5 officers and 250 men in war.

Sanitary Troops.—There are 12 companies. Total, 769 officers and about 3700 men.

Supply Train.—There are 12 companies, one for each of the 12 army corps. Total, 452 officers and about 4000 men.

Military Police.—The Carabinieri are organized as 12 legions, with a total of 709 officers and about 30,000 men. About 4000 are mounted. In war they would furnish about 1 infantry brigade of 7000 officers and men for field service.

Special Formations.—For administration, staff duty, military schools, etc., there are 1284 officers and about 1900 men.

Aëronautical Service.—This is being developed and at the end of 1914 is to supply 30 field squadrons of 7 aëroplanes each, or a total of 210, for use with the field army. In addition there are about 10 serviceable airships. The *personnel* is organized into sections, battalions or squadrons, in accordance with the duties required. There are a specialist battalion of 5 companies, an experimental section, a flying battalion of 2 companies, and the field squadrons above mentioned.

Total Peace Strength.—According to the latest data available in 1914, this amounted to 15,172 officers, 289,500 men, 64,345 horses. Owing to the system of giving unlimited leave to men supposed to be serving with the colors, it is doubtful if more than 250,000 men were actually with their regiments at any one time.

Total War Strength.—The complex system, insufficient budget, and indefinite leaves to individuals of all the categories, before training is completed, render it difficult to estimate Italy's strength in *fully trained* men. On paper she could mobilize 3,500,000 men, actually not more than 1,500,000 *fully trained*. Assuming that the *initial mobilization* would be confined to existing organizations of the regular service, the fighting strength of the three arms on initial mobilization would be: infantry rifles, 325,000; cavalry sabres, 25,000; field guns (all calibres), 1600.

Arms.—Infantry, Mannlicher Carcano rifle, 6.5 mm. calibre, using a magazine. The territorial militia uses the old Vetterli. The field artillery is being rearmed (1914) with the De Port gun and carriage, considered the best in Europe. See FIELD ARTILLERY.

Colonial Troops.—In addition to the troops already mentioned Italy maintains colonial troops in her African possessions, as follows: in Libya (Tripoli and Cyrenaica), about 3000 Italian and 10,000 native troops; in the Colony of Eritrea (Erythræa), about 600 Italian and 8000 native troops; in Italian Somaliland, about 4700 soldiers in all, mostly native. The native troops have a proportion of Italian officers.

Budget for 1913-14, \$71,110,000.

The critical political position of Italy between the opposing influences of the Triple Alliance and the Triple Entente, in the European War of 1914, undoubtedly induced Italy to put her military house in order for any eventuality.

Frontiers.—The total land frontier adjacent to France, Switzerland, and Austria-Hungary is about 1200 miles. The coast line, including Italy proper, Sicily, Sardinia, Elba, and other small islands, is a little over 4000 miles. Land fortifications are located in the principal passes of the Alps and in the basin of the river Po. Among the latter are Casale, Piacenza, Verona, Mantua, Venice, and Alessandria. On the coast of the peninsula and islands there are Vado, Genoa, Spezia, Monte Argentaro, Gaeta, all strongly fortified. Taranto, in the Strait of Messina, is also fortified. The naval station of Maddalena consists of a number of fortified islands. Rome is also protected by forts.

Government. The existing constitution of the Kingdom of Italy is the *Statuto fondamentale del Regno*, which was originally issued (March 4, 1848) as the constitution of the Kingdom of Sardinia. When Sardinia expanded into united Italy, its organic law was adopted by the new nation. This constitution has never been formally changed or revised; in fact, no

provision exists for its amendment, and constitutional changes have been made by the ordinary methods of legislation, as in England, which has been the political model of the Italians.

The throne is hereditary in the house of Savoy on the principle of the Salic Law; the King attains his majority at the age of 18. The official residence of the royal family is the Palazzo del Quirinale in Rome. The King's salary is 16,050,000 lire a year, from which he returns to the government 1,000,000 lire. His person is declared inviolable. Like the King of England, the Italian monarch's powers are great in theory, but very much limited in practice; for Italy, according to her constitution, is a "representative monarchical government." The King does not veto any bills passed by Parliament, although he has a theoretical right to do so, and very seldom does he attend cabinet meetings. Only in the field of foreign affairs does he exercise any real influence. The reigning monarch, Victor Emanuel III, is very democratic in his ideas and manners and is popular amongst all classes of Italians, even with the Republicans and Socialists.

The cabinet consists of 11 members and their undersecretaries. These are: Foreign Affairs, War, Marine, Finance, Education, Internal Affairs, Treasury, Public Works, Justice and Ecclesiastical Affairs, Commerce, Industry, and Agriculture, Posts and Telegraphs. According to the constitution an Italian citizen does not need to be a member of Parliament to be chosen a cabinet minister, although it is customary to choose only members of Parliament, particularly from the Lower House. Like the British and French cabinets, the Italian is directly responsible to the Chamber and must resign on an adverse vote. The Premier is generally the leader of the most powerful political group. In theory it is the King who chooses the cabinet; in practice it is the influential politicians in the Chamber. The cabinet administers the laws, appoints officials, conducts foreign affairs, and initiates all important legislation. In no country, not even in England, is the cabinet so powerful as it is in Italy, where it dominates Parliament, which has not the same prestige as it has in England and in France. Frequently administrative ordinances issued by the cabinet take the place of parliamentary legislation.

The Senate is at present composed of 383 members, appointed for life by the King on nomination by the cabinet. A seat in the Senate is not hereditary, and it is required by law that appointments should be made from certain categories, like high officials in church and state, men distinguished in art, science, or literature, and wealthy property owners. No man below 49 years old can be appointed. The Senate is a body of great dignity and influence, but of little legislative authority, as the parties in power often resort to swamping the Senate with their friends and adherents. Seldom does it initiate legislation or even seriously oppose bills sent up from the Chamber; it contents itself mainly with revising, amending, and suggesting. In legislative authority it is inferior even to the French Senate. Proposals to reform the Italian Upper House are constantly being made, and an elaborate report on this subject was submitted to Parliament in 1910, which suggested the inclusion of an elective element and a widening of its powers. The President and Vice President of the Senate are named by the King, i.e.,

the ministry. The Senate is empowered to act as a High Court of Justice to try cases of treason and impeachment.

The Lower House, or Chamber of Deputies, is composed of 508 members chosen by the legally qualified voters as determined by the Franchise Law of 1912. At first the suffrage was restricted to those having property and education, but it has been gradually extended until now there is virtually universal suffrage. The great electoral reform carried through by the Giolitti ministry in 1912 gave a vote to all male citizens over 21 years of age who can read and write and to all illiterates over 30 years old. Many Italians abstain from voting partly because they are not as yet accustomed to parliamentary government and partly because of the attitude of the Catholic church towards the nation. In 1883 Pope Pius IX issued the decree *Non Expedit*, which forbade faithful Catholics to participate in the elections, in order not to recognize what the Pope claimed as a "usurping" government. In recent years the growth of Socialism in Italy has so frightened the papacy that Pius X issued a decree in 1905 permitting voting by the faithful, but only by the special consent and direction of the hierarchy. The Chamber is elected by secret ballot in single-member constituencies. Candidates must receive a majority of all the votes cast in order to be declared elected. If not, second balloting takes place one week later between those who came out on top of the poll. Although the term of office is five years, the Chamber may and often is dissolved before its term has expired. Sessions are public. Interpellations are frequent, but a vote on the question must be taken only after an interval of several days. This has prevented frequent changes of ministry.

In Italy, as in all other countries of continental Europe, there are no two powerfully organized political parties striving for the control of the government; instead, there are a number of loosely organized groups that combine and recombine whenever it suits their temporary interests, which are largely personal in character. A striking feature of Italian politics is the absence of a historical conservative party, because in 1870 the most conservative elements of society were opposed to the unification of Italy. Hence the Liberal party is split into Right and Left wings. In recent years, because of the fear of Socialism, a conservative clerical party has been organized. There is still in existence a Republican group advocating the ideals of Mazzini, but it exerts very little influence in Italian politics. The popular parties, like the Radicals and Socialists, are a rapidly growing force, particularly the latter, which rose from 12 seats in the Chamber in 1895 to 78 in 1913. The petty and personal character of Italian politics disgusts many electors, who either do not vote at all or are glad to give their support to comprehensive principles as embodied in Socialism, which is most ably expounded by distinguished writers like Labrioli and Ferri. As no single party has a majority in the Chamber, the government must find its support in a coalition of groups, which is called a *blocco*. This at present consists of Liberals and Radicals.

The administrative system, both central and local, is fashioned largely after that of France. Historical subdivisions have been replaced by artificial areas, and local self-government is

superseded by a centralized administration. The power of the higher administrative officials to issue ordinances for the purpose of supplementing the statutes has been carried even further than in France and in many cases has the effect of suspending or displacing the statutes. An organ of restraint upon the action of the government in this respect is found in the Council of State and the several courts of accounts. The former is chiefly an advisory organ, but it also has power to prevent arbitrary action of the central government in the removal of local officials; the courts of accounts exercise supervision over various activities of the administration, and their approval is necessary to the validity of all decrees and orders which involve the expenditure of more than 2000 lire. The seat of government of Italy is Rome. From 1865 to 1871 the capital was Florence, which had superseded Turin.

For the purpose of local government Italy is divided into artificial circumscriptions called provinces, *circondari*, *mandamenti*, and *comunes*. The chief executive officer in each province is the prefect, appointed by the King, and under the control of the Minister of the Interior. He is therefore the agent of the central government, and in this as in other respects corresponds to his French prototype. He is charged with the publication and execution of the laws, takes measures for the public safety, disposes of the armed forces, issues police ordinances, and supervises and directs the subordinate officials of the province. To advise and assist him in the discharge of his duties a prefectural council over which he presides is provided. The deliberative assembly of the province is the Provincial Council, chosen for five years by an electorate which is somewhat restricted, but which has been extended. The size of the Council varies according to the population of the province. It meets at the capital of the province once a year, it elects its own officers, and all resident taxpayers are eligible to its membership. Its sessions are opened by the prefect, who has the right to preside over them and to suspend them for a limited period. It has a wide power of local legislation relating to such matters as the creation of highways, establishment of societies, public institutions, the care of provincial property, schools, poor relief, the budget, loans, besides a supervisory authority over the civil service. There is also in each province a provincial deputation elected by the Provincial Council and presided over by the prefect. It represents the Council during its recess, superintends the enforcement of its resolutions, prepares the budget, exercises a disciplinary control over inferior officers, and performs a variety of local duties under the direction of the Council.

The *circondario* plays an unimportant part in the local administration. Its chief officer is an underprefect, who represents the central power. The *mandamento* is a judicial district for the pretor, and, like the *circondario*, is of little consequence as an administrative area.

The *comune* is the lowest administrative unit, and, like the province, has its own elected council. The chief executive officer in the *comune* is the *syndic* or mayor. By a recent law the *syndics* of all the *comunes*, irrespective of their population, are chosen by the communal councils from their own membership. The functions of the *syndic* are twofold: he is the local

municipal magistrate and at the same time the agent of the central government in the commune. As mayor, he presides over the Council, executes its ordinances, is the custodian of communal property and institutions, and takes measures for the public health and safety. As agent of the central government, he publishes and executes the national laws and ordinances and performs various duties which relate to matters of central concern. The Communal Council is chosen by the same electorate as that which selects the Provincial Council and for the same term. It meets ordinarily twice a year and is presided over by the syndic. It is subject to central control and may be dissolved by the King. Its duties include a large control over the communal civil service, the care and management of communal property and institutions, and the administration of a large number of purely local matters. In each commune is also an organ known as the municipal junta, composed of the syndic and a number of assessors elected by the Communal Council. It corresponds to the deputation in the province, i.e., it conducts the affairs of the commune when the Council is not in session.

The judicial system of Italy, like the administrative system, is modeled largely on that of France. The lowest judicial functionaries are the *consiglieri*, one of whom is appointed by the King for each commune. He serves for three years and without pay. His jurisdiction extends to civil actions in which only a small amount is involved. Above this officer is the pretor, whose territorial jurisdiction is the *mandamento*, a district comprising several communes. His competence in civil matters extends, among others, to all actions in which the amount involved does not exceed 1500 lire, and he has an appellate jurisdiction over the decisions of the *consigliatore*. In criminal matters his jurisdiction extends to all misdemeanors and crimes punishable by imprisonment for a period not exceeding three months, or banishment not exceeding one year, or by fine not exceeding \$200. Above the Court of the Pretor is the Civil and Correctional Tribunal, which is divided into chambers, one of which sits in each of the most important cities of Italy. Its jurisdiction in civil matters extends to appeals from the decisions of the pretor and to those civil actions for which neither the pretor nor the *consigliatore* is competent. Together with a number of men prominent in trade and commerce, it sits as a court for the adjudication of commercial disputes. It is also a criminal court for offenses not cognizable by the pretor and has appellate jurisdiction over appeals from the decisions of the pretor.

There are 20 courts of appeal in Italy, each of which is divided into chambers. Their appellate jurisdiction extends to decisions of the civil and correctional tribunals. In each appellate court district there are one or more courts of assize, composed of a judge of the Court of Appeal and two assessors, and generally a jury of 14 men. The criminal jurisdiction of the Court of Assize extends to crimes punishable by imprisonment for a long period of time, to offenses against the security of the state, and to press offenses.

The highest judicial tribunals in Italy are the courts of cassation, of which there are five—one at Florence, one at Naples, one at Palermo, one at Turin, and one at Rome. Each is com-

posed of a first president, several presidents of sections, and from 8 to 16 judges. Each is divided into two chambers—one civil, the other criminal. Each is the court of last resort within its own district, but, unlike the Supreme Court of the United States, has power only to quash the decisions of the lower courts on account of errors in law and send them back for rehearing. Like all European courts, they have no power to declare statutes null and void on account of their repugnance to the constitution. As in France, the so-called separation of justice from administration exists, and a series of administrative tribunals, modeled after those of France, have been created. The highest of these is the judicial section of the Council of State. A source of danger to the Italian judiciary is its lack of independence as over against the administration. The judges are irremovable after three years of service, but they may be transferred to less desirable judicial stations by the Minister in the "interest of the service." It is claimed that this power has been abused to the detriment of the judicial service.

Colonies. The history of the colonial expansion of Italy is the same as of its military expansion—an attempt to keep abreast with the Great Powers in the most costly and ruinous of activities without having first developed the productive sources at home. The colonial policy has been advocated by Italian statesmen as a means of increasing foreign commerce, because in other countries it has served as an outlet for overflowing industry and trade. The result has been disastrous to the government and country alike. After spending about \$75,000,000 on the African possessions Italy has been forced to abandon most of its ambitious schemes. See section *History* in this article.

In September, 1911, after a quarrel with Turkey, Italy invaded Tripoli. Turkey ceded the territory to Italy by the Treaty of Ouchy, signed Oct. 18, 1912. The area of the territory annexed is estimated at about 406,000 square miles; native pop., 523,176 (census of 1911). According to a recent statement by the Minister of the Treasury, the Libyan campaign, the occupation of the Ægean Islands, and precautionary measures cost the government \$222,000,000 up to Dec. 31, 1913. The other Italian possessions include the Colony of Eritrea on the Red Sea, with an area of about 45,800 square miles and a population of about 450,000; and Italian Somaliland, with an area of 139,000 square miles and a population of 400,000. The government has to contribute more than \$1,000,000 annually to cover the deficit of the administration.

Money, Weights, and Measures. As a member of the Latin Union, Italy has the same monetary system as France (so far as the standard of money and coinage is concerned, not the method of issuing paper money). The amount of fractional silver coinage to which Italy is entitled under the provisions of the Union has been fixed at about \$46,000,000. The coins are the same in value, size, and fineness as those in France, except that the name "lira" (pl. lire) is substituted for "franc," and "centesimo" for "centime." The metric system applies to all weights and measures.

Population. Italy ranks sixth among the countries of Europe with respect to population, coming after France. The following table shows the area and population by provinces in 1881, 1901, 1911, and estimates for 1913:

PROVINCES AND COMPARTIMENTI	Area in square miles	Population 1881	Population 1911	Population 1913 (est.)

Kingdom of Italy	110,688	28,459,628	34,671,377	35,238,997

The following list shows the increase of population, during the nineteenth century, within the present territory of the kingdom:

1816.....	18,383,000
1848.....	23,618,000
1862.....	25,000,000
1872.....	26,801,154
1882.....	28,459,628
1901.....	32,475,253
1911.....	34,671,377

Thus, there has been an increase of 6,211,749 people, or over 21.8 per cent, in 29 years. With respect to density of population, 318.8 people per square mile in 1913, Italy ranks third among the countries of continental Europe, coming after Belgium and the Netherlands. In general, the northern portion of Italy, extending as far south as Florence, is more densely populated than the remaining portions. The population is remarkably homogeneous, the number of distinctly non-Italian inhabitants being small and concentrated in a few districts; as, e.g., the 80,000 people of French origin in the Province of Turin, 90,000 Albanians in Sicily and southern Italy, 30,000 Greeks in Calabria and on the Adriatic coast, 30,000 Slavs in northeast Italy in the vicinity of the Austrian frontier, 11,500 Germans living mostly in the north, and some 10,000 Spanish in Sardinia.

The number of foreigners residing temporarily in Italy is very small—about 61,600 in 1901. There is a slight excess of males over females in Italy.

The following table includes all towns having a population of over 100,000 in 1911:

	1901	1911
Naples.....	564,000	678,000
Milan.....	491,000	599,000
Rome.....	463,000	542,000
Turin.....	336,000	427,000
Palermo.....	310,000	341,000
Genoa.....	235,000	272,000
Florence.....	205,000	233,000
Catania.....	150,000	211,000
Bologna.....	152,000	173,000
Venice.....	152,000	161,000
Messina.....	150,000	127,000
Leghorn.....	98,000	105,000
Bari.....	77,000	104,000

Emigration. The unsatisfactory condition of public affairs is responsible for the enormous

tide of emigration. More than 5,500,000 Italian emigrants are living in foreign countries, and their number increases from year to year by hundreds of thousands. The growth of emigration in the last four decades was as follows:

1876.....	108,771
1880.....	119,901
1885.....	157,193
1891.....	293,631
1896.....	307,482
1900.....	352,782
1905.....	726,331
1910.....	651,475
1911.....	538,844
1912.....	711,446

It will be seen that the emigration increased more than fivefold in the period indicated. As the conditions responsible for this exodus from the country do not seem to improve much, there are no reasons to expect any decline of emigration in the near future. The region contributing most to the emigration is the less productive and more poorly developed southern portion of the peninsula from Naples southward, and the emigrants are chiefly peasants or representatives of other lower classes. The Province of Genoa contributes more than any other province in the north to the stream of emigration. The country most vitally interested in this question is the United States. As late as 1888 less than 12 per cent of all the Italian emigrants went to the United States, while more than 33 per cent went to Brazil, and about 23 per cent to Argentina, Uruguay, and Paraguay. In 1910 the proportion was reversed, the number of emigrants to the United States, Brazil, and Argentina being 263,000, 19,000, and 105,000, or 40.3 and 16 per cent respectively. By a ministerial Decree of July 30, 1911, immigration to Argentina was suspended until Aug. 24, 1912. The result was that in 1911 only 32,719 emigrants, or 6.13 per cent of the total, went to Argentina. About four-tenths go to European countries, especially France, Switzerland, Austria, and Germany. The majority of these ultimately return home, and the remainder finally embark for America.

Births, Deaths, and Marriages. The birth-rate of Italy, although fully up to the normal, has been slowly declining. While it annually exceeded 37 per 1000 inhabitants prior to the last decade of the nineteenth century, in 1911 it was only 31.54. On the other hand, the death rate has declined much more rapidly, having decreased from 28.1 per 1000 inhabitants in 1887 to 21.42 in 1911, the Italian government justly priding itself on the sanitary improvements which have made such results possible. The excess of births over deaths, which was only 7.19 per 1000 inhabitants in 1872, increased to 10.12 in 39 years.

Religion. The great bulk of the inhabitants of Italy belong to the Roman Catholic church. Especial prominence attaches to the church in Italy from the fact that the seat of the central administration of the church is in Rome. The welfare and harmony of the church, however, suffered greatly through the bitter contention that arose over the question of temporal power of the Pope and the possession of property by religious orders. There is still a Clerical party, the influential portion of which consists of the clergy, who would have the temporal power of the church reestablished. Pius IX refused to recognize the validity of the claims of the Italian government to the possession of the pa-

pal territories, and always insisted upon the rights of the papacy to the States of the Church. Leo XIII steadily pursued the same course, and declined the consideration of any *modus vivendi* which did not admit the papacy's rights to the temporal power. Pius X followed, and Benedict XV is following, the same policy. This unyielding attitude against compromise has considerably hampered the political work of the government in internal affairs and weakened it in its policy against the alarming aggressiveness of the Socialist party. The great majority of the upper classes are strongly opposed to the realization of the claims of the Clerical party. It is probable that the antipathy to the political ambition of the Clericals is largely responsible for the indifference which the majority of the better classes show towards all religious principles and for the widespread prevalence of free thought. The clergy, however, have a very considerable following from the ranks of the ignorant classes of the population. Miracles and mysteries play an important part in the worship of the lower classes, particularly in south Italy. In 1866 a law suppressing all religious houses was passed, applicable to the entire kingdom. Their property was sold by the state, the greater part of the proceeds being turned into an ecclesiastical fund for the support of public worship, though a part of the proceeds is granted as pensions to some members of the suppressed religious institutions. In 1899 there were still over 13,000 persons receiving pension funds. Although their property was taken from them, the religious orders still have a large membership. The last census figures available (1901) return 65,595 Protestants and 35,617 Jews. Over a third of the Protestants were Waldenses. They are strongest in Piedmont. The Greek Orthodox church also has a small representation in Italy.

Social Betterment. The agricultural class, forming the greater part of the population, during the last decades of the nineteenth century suffered from all the ills that come in the wake of poor soil, antiquated methods of cultivation, defective land system, burdensome taxation, and want of capital. Since that time much has been done to improve conditions. After long and persevering efforts on the part of the people, strikes, and food riots, laws have been passed for the reclaiming of land by irrigation, for afforestation, and for the draining of the swampy district, in the endeavor to stamp out malaria. The most important work, however, has been done by the village banks (see *Banking*) and the coöperative agrarian societies. The former provide the capital, often on credit; the latter have an extensive and varied programme. They supply the people with modern implements, seed, and manure almost at cost price; they encourage the founding of agricultural schools and especially of traveling agricultural professorships. Emigration to North and South America has had a good effect on labor conditions in rural districts. By lessening competition it has raised the wage; and, better still, emigrants returning from America have brought with them new ideas and a higher standard of living, together with increased demands.

The position of the industrial worker in Italy is worse than that in any other western European country, except Spain. But he has raised himself considerably by economic organization and political action. The unit of activity is

not so much the trade-union, which, however, is growing to occupy a more important place, as the chambers of labor. The chambers are the foci of labor organizations and are usually subsidized by the municipalities. In 1898 most of them were dissolved by the conservative government. They were soon reestablished, however, stronger and more numerous than ever. They fight on all occasions in the interest of the workmen. In this way wages have been increased and hours have been shortened. Labor legislation is still backward, though much has been done through the efforts of the Socialists and Radicals in Parliament.

Laws have been passed forbidding children under 12 to be employed in factory or workshop; boys under 13 and women are not allowed to work underground or in unhealthy and dangerous trades; night work for women and boys under 15 is strictly forbidden. Women are required to abstain from work for one month after childbirth and receive maintenance during abstinence. Besides laws of this type there has been constant extension of accident-insurance funds and old-age and invalidity pensions. The laws are excellent, but, as there is very little provision for enforcing them, they are to a great degree violated and evaded.

Italy now needs more thorough economic organization, legislation putting less of a burden of taxation upon the people, more labor legislation, and especially more rigid enforcement of laws, to come up to the level of the other European countries.

Charities. The extreme poverty of the population in Italy has given occasion for much activity in order to prevent distress. Formerly the income derived from the property of the religious orders was liberally, though not always wisely, spent for charitable purposes. Indeed, the belief that the sort of charity which the religious orders dispensed tended to foster pauperism was one of the motives which led to the selling of their possessions. The responsibility for the care of the poor now falls more definitely upon the state, which has become very active not only in the usual sphere of charitable endeavor, but also in the matter of improving the industrial and social conditions. (See below.) A large part of the government's annual expenditure for charitable purposes is by grants to charitable institutions which have permanent charitable endowments. In the course of years a large number of these have been established, the investigation of 1900 showing 27,078, with an aggregate capital of about \$425,000,000. Large additions have been annually made since that time. The sum at their disposal that year amounted to \$23,308,000. The charitable institutions include different kinds of hospitals and asylums, almshouses, workhouses, etc. Outdoor relief is also extensive and includes assistance in food or money, medical attention, and other objects, one of the most important being the giving of marriage portions. The Minister of the Interior is at the head of the charitable administrative system, the larger institutions being directly under charge of the provincial governments and the smaller ones in charge of the communes.

Education. Italy compares very unfavorably with north European countries in respect to the general diffusion of education. Since the nation is overburdened with debt and is lacking in national wealth, the educational system has not

had the financial support necessary to its proper development. It would have been difficult to establish a high educational standard even had the government not been financially handicapped. It required much effort and time to do away with the extremes of illiteracy existing in some of the provinces when the present kingdom was established. In whole regions two-thirds of the population were illiterate, and in Reggio di Calabria and Catania the illiterates amounted to 93 per cent of the total population. A better condition generally prevailed throughout the north of Italy. The government, desirous of improving the educational status, made elementary education free and in 1877 passed a law making education compulsory between the ages of six and nine years. This has had a very beneficial influence, although, excepting in the northern provinces of Piedmont and Lombardy, the law has not been strictly enforced. Attendance is much the greatest in the winter months, when the schoolhouses are often overcrowded. The reduction of illiteracy has been aided by the introduction of the policy of giving elementary instruction to illiterate conscripts. The percentage of illiterates married decreased for males from 57.73 in 1871 to 24.8 in 1910, and for females from 76.73 in 1871 to 36.8 in 1910. In Basilicata the male illiterates at the time of marriage were still in 1910 over one-half of the total.

The national scheme of education comprehends the entire scope of education, including kindergarten, primary, secondary, technical, and higher instruction. In 1907-08 there were 343,563 children in attendance at kindergartens. Private societies and citizens, besides the communes, support the kindergartens. The primary course of instruction is divided into two grades. The first grade corresponds to the compulsory period, or the first three years of a child's school life. The second grade is a supplementary course of two years, but comparatively few pupils continue in this grade, the enrollment being less than a tenth of that in the lower grade. The attendance at the public primary schools in 1907-08 was 3,002,168, and at the private schools of the same rank 148,081. The private schools are required to follow the same programme as do the state schools. Many of the communes have established night or Sunday schools for the special benefit of children who do not continue into the second grade of the primary course and also for the benefit of adults. The enrollment at these schools in 1907-08 was 182,373. A still higher grade of schools has been established for the benefit of girls who wish to prepare for normal schools or for a practical career, the instruction including bookkeeping and technical branches. The attendance at these in 1910-11 was 19,678.

The elementary school buildings are generally throughout the rural districts of a very inferior and inadequate kind. Often rooms are rented for school purposes, and their selection is not infrequently made by officers who are incompetent or who subserve their personal interest. In many cities, however, the buildings and their equipment are of the most approved type. In 1877 religion was eliminated from the state schools. Religious instruction is only given when demanded by parents of the pupils. The private schools are generally in charge of religious orders. In the last years of the nineteenth century much progress was made in the

introduction of agricultural courses into the elementary school system. The communes bear the main burden of elementary education, although the state assists and to a small extent the provinces assist also. The state, provinces, and communes share in varying proportions in the support of other branches of education, the local Chamber of Commerce also sometimes aiding in the support of special schools. A large number of the secondary institutions are supported by religious denominations.

The attention given to higher education is remarkable, considering the backward condition of elementary education. In the last quarter of the nineteenth century the gain in graduates from the 21 Italian universities was about seven times the corresponding rate of increase of the Italian population. This result is largely due to the fact that public offices must be entered by way of the universities. Recently, however, the attendance has fallen off somewhat. The state maintains 17 universities, as follows: Naples, Turin, Rome, Padua, Bologna, Palermo, Genoa, Pavia, Pisa, Catania, Modena, Messina, Parma, Cagliari, Siena, Sassari, Macerata, which, together with the four free universities in Perugia, Camerino, Urbino, and Ferrara, had a total enrollment of 21,436 in 1911-12. The first eight of these exceeded an enrollment of 1000 each, and Naples had 4281. Besides the foregoing, there are separate university courses. Italy is known internationally for its art institutions, of which there were 13 government and 13 nongovernment in 1910-11, with aggregate enrollments of 2566 and 1162 respectively. There are five government and a number of private music conservatories. There are also a number of commercial, agricultural, and other industrial schools of academic rank.

For the training of teachers there are about 130 normal schools, the greater part of them being under the control of the government. The attendance at these in 1910-11 was 37,912, nearly all of it female. Compared with American or even north European standards, the teachers are underpaid, but their salaries do not compare unfavorably with those received by other classes of the Italian population. Male teachers of a superior degree receive from \$200 to \$264 a year in the cities, while female teachers of an inferior degree receive from \$112 to \$130 in the country. The provision of the law that calls for an increase in salary every six years of uninterrupted service is evaded by dismissing teachers before the expiration of that period. Provisions are made for the pensioning of teachers, both the communes and the teachers' salaries being levied upon for the pension fund.

The secondary educational system is divided into two groups—the classical and the technical, the latter having greatly increased in popularity during recent years. There are two kinds of classical schools—the *ginnasi* and the *licei*, the former being a five years' course and receiving pupils of the age period 10 or 11 to 15 or 16. The latter is only a three years' course. A few of the *licei* have recently reformed their curriculum by substituting mathematics and a modern language at the expense of Greek and the sciences. In 1910-11 there were 291 *ginnasi*, with 38,053 pupils, and 159 *licei*, with 14,342. The technical instruction is given at technical schools, of which there were 331 in 1910-11, with 82,406 pupils, and at technical institutes, of

which there were 77 in the same year, with an attendance of 20,712. See MONTESSORI.

Ethnology. Of the Paleolithic epochs of culture stages of Europe there are few relics in Italy, yet the northern slopes of the Apennines are said to be rich in chipped implements of the *coups de poing* type. Scrapers also abound, and leaf-shaped objects of Solutrian type, but little of later Paleolithic forms. In places favorable to such life cave dwelling is not without its witnesses. The stone workers of the earliest human occupation of Italy were followed in the Neolithic period by dolichocephalic pottery makers and builders of pile dwellings on the lakes of the northern borderland, and by mound builders in the Po valley, who on the marshy lowlands built tumuli, called *terramare* (q.v.), with level tops, and on them erected dwellings and villages, which were protected by ditches. The germ of Italian culture lay in this epoch. The peoples were many, though in the regions separated by the Po they belonged to only two races. Industrialism had taken the place of savagery. The polished axe, the scraper, weights, and spindles of terra cotta, coarse and fine pottery, slate ornamented with etchings, toilet articles and domestic utensils of bone and antler, linen fabrics, acorns, hazelnuts, and seeds of flax, wheat, barley, poppies, and apples, all show that a mixed people then existed. The most ancient peoples of Italy known to the historian belonged to a dolichocephalic race. They may be classed in the Mediterranean species and called Ligurians. They were akin to the Iberians of Spain and the Pelasgians of Greece, a colony of whom, greatly modified by local mixture, became Etruscans. Towards the close of the Neolithic period there came into the north of Italy a brachycephalic people who brought with them copper and occupied most of the Po valley, founding there the Umbrian dominion. This short-headed race modified the biological characters, the customs, and the speech of this northern region. Thus arose a sharp division of the peninsula into two distinct ethnic areas—that of the broad-headed Alpine or Celtic type of central Europe, north of the Apennines, and the true long-headed Mediterranean or Ligurian type in the south. Later on appeared the tall, blond race from what is Germany and from the regions farther east, Cimbri, Goths, Ostrogoths, Visigoths, Saxons, and Lombards. These conquerors were long-headed also, like the Pelasgians. They did not profoundly modify the physical characters of the population. The skulls of the peoples along the Po are varied from place to place. Biologically the two divisions of Italy exist as they did before the Teutonic invasions. Venetians are 1.666 meters or 65.5 inches in stature, and the proportion of head width to head length among the Piedmontese is 0.86. In the other ethnological division of Italy Sardinian soldiers are only 1.619 meters or 63.68 inches in stature, and the ratio of head width to head length is 0.77.

History. For the history of Italy down into the fifth century A.D., see ROME, *History*. When Metternich, in 1845, said that Italy "represents simply a group of independent states, united under the same geographical term," he was describing a state of affairs which had existed ever since the downfall of the Roman Empire in the fifth century. This lack of unity makes it almost impossible to present the history of Italy under one head, but necessitates a study

of the separate states. (See especially the articles on VENICE; FLORENCE; GENOA; MILAN; LOMBARDY; SAVOY; TUSCANY; NAPLES; ROME; SICILY; PAPAL STATES.) Through the repeated invasions of the barbarians into Italy during the fifth century (see especially ALARIC; AT-TILA; GOTHS; HUNS) many portions of the country had been depopulated and government had become very weak. The old free population had long since disappeared, and the land was chiefly in the hands of powerful nobles, who were able to maintain bands of retainers by means of which they could protect themselves against marauders. Finally in 476 the last independent Emperor of the West, Romulus Augustulus, was dethroned by Odoacer (q.v.), a chief of the German tribe of the Heruli. This event is usually taken as marking the end of the Roman Empire and the beginning of the Middle Ages. As a matter of fact, there was no abrupt transition; for Odoacer and his Germanic successors continued the old constitution, which, however, had ceased to be effective for some time before 476 and gradually disappeared, though for centuries it was invoked by all rulers of Italy. Odoacer did not enjoy his crown long, but was treacherously murdered in 493 by Theodoric the Great (q.v.), under whose leadership the Ostrogoths had invaded Italy. For the last time in many centuries Italy was prosperous; for Theodoric was just and wise, and the natives were treated mildly, being judged equitably and allowed to retain to a large extent their property. But the Italians, who were largely Catholics, were discontented under their Arian masters. The result was that, forgetting or underestimating Byzantine despotism, they welcomed the attempts of Belisarius (q.v.) and Narses (q.v.), the generals of the Byzantine Emperor Justinian, to drive out the barbarians after the death of Theodoric, in 526. In 552 the last of the Gothic kings, Teias or Teja, fell in the terrific battle at Mount Vesuvius, and the remainder of the Goths disappeared among the Italians.

The Byzantine sway was of short duration; for after the recall of the capable Narses in 565, the Lombards (q.v.), a Germanic people, invaded Italy, according to the account of Paulus Diaconus (q.v.), called in by Narses himself in revenge for his recall. Their King was Alboin, who made Pavia his capital, and from that city as a starting point expeditions were sent in all directions, so that soon nothing was left to the Byzantine Empire except the south and the Exarchate of Ravenna. After the death of Alboin, in 573, the Lombards for a time had no King, but separate bands united under various leaders, known as "duces." They were Arians, as the Goths had been before them, and hence there was continuous strife between them and the native Italians, which increased as the popes became more powerful and the real rulers of Rome. Finally a new King, Agilulf, who ruled from 590 to 616, became a convert to Catholicism, and for some time comparative harmony prevailed. But the Lombards from political necessity were driven to seek possession of the city of Rome, and thereupon the popes called in the Franks to aid them. These under the vigorous leadership of Pepin (q.v.) and Charles the Great conquered the Lombards, and finally in 774 Desiderius, the last King of the Lombards, was sent to die in a monastery, and Charles the Great had himself crowned with the Iron Crown

(q.v.). This proved to be little more than a change of rulers, for, as generally in the Middle Ages, the laws of the victors were not imposed upon the conquered. Out of gratitude for the royal title which the Pope had bestowed on him after the deposition of the last of the Merovingian kings, Pepin granted to the holy see the possession of a strip of territory in central Italy, comprising the Exarchate of Ravenna, the March of Ancona, and the Romagna, the former two conquered from the Lombards. This donation of Pepin (q.v.), later confirmed by the donation of Charles the Great, was momentous for the history of Italy in that it marked the beginning of the temporal rule of the popes and introduced into Italy one of the most powerful factors of national activity. On Christmas Day, 800, Charles the Great was crowned Emperor by Pope Leo III, and for centuries the history of Italy turned upon the conflict and interrelation between the two great powers which disputed with each other the primacy in mediæval life, the empire and the papacy. By the Treaty of Verdun (843), in which the Frankish realm was partitioned between the grandsons of Charles the Great, Italy was included in the share given to Lothair. During the years of confusion that followed, the Saracens overran south Italy and even threatened Rome. The history of Italy for many years is nothing but the rise of one petty king after another, many of them aspiring to the Imperial title. Among these may be mentioned Guido of Spoleto, Berengar of Friuli, and Hugo of Provence. With them the papacy intrigued and plotted, for the successor of Peter was now the puppet of different factions in Rome.

The period of anarchy ended in 962, when Otho the Great (q.v.), after obtaining possession of north Italy and the Lombard crown, was crowned Emperor. This marked the establishment of the Holy Roman Empire of the German Nation (see HOLY ROMAN EMPIRE), and until the end of the Middle Ages the Emperor theoretically ruled over Italy, though the Imperial authority was completely set aside by the beginning of the fourteenth century. For a long time the emperors came to Rome to be crowned by the Pope, and until that had been done their title was not considered to be complete. Meanwhile the south of Italy was still in the possession of the Byzantines and Lombards, whom the German emperors were unable to oust, until finally in the eleventh century they were driven out by the Normans, who in 1127 united their conquests in Italy with Sicily, which they had wrested from the Saracens. (See SARACENS; NORMANS; GUISCARD, ROBERT.) In the time of the Emperor Henry IV (1056-1106) the papacy had become strong and powerful again, and the great investiture struggle broke out, the papacy finding an indomitable champion in Gregory VII. See INVESTITURE.

Simultaneously with the increasing power of the popes a great barrier to the continued rule of the Germans was being erected in the rising city states. In Italy the feudal system had never attained the high development so characteristic of France and Germany, which was due to a great extent to the survival of Roman traditions and the many cities in Italy, for feudalism was chiefly rural, not urban. The cities of Lombardy defied the power of the Emperor Frederick Barbarossa, of the house of Hohenstaufen, who waged bloody wars with them to

no purpose. In 1167 the Lombard League (q.v.) was formed. In 1176 Frederick was vanquished at Legnano, and in 1183, in the Peace of Constance, the cities secured the recognition of their liberties. A last attempt to crush both the papacy and its allies was made by Frederick II, the last great ruler of the house of Hohenstaufen (1215-50); but, though he controlled Naples and Sicily, as well as the Empire, even his great ability was unable to change the state of affairs. Italy itself was rent by the struggles between the opponents and the partisans of Imperial rule, known respectively as Guelphs and Ghibellines (q.v.), names which continued to be the designation of fiercely contending parties long after the emperors had lost their hold on the country.

In the second half of the thirteenth century a new foreign power came to play an important rôle in Italian affairs. Charles of Anjou, brother of Louis IX of France, summoned by the Pope to aid him against the Hohenstaufen, undertook the conquest of the Kingdom of Sicily and Naples (The Two Sicilies), and overthrew Manfred, the son of Frederick II, in 1266. Conradin, the last of the Hohenstaufen, was defeated in an attempt to recover the Kingdom in 1267 and put to death. But in 1282 (see SICILIAN VESPER) Sicily rose against the French and placed itself under the power of Aragón.

In the north the cities, having secured independence from the central authority, entered into contests with the nobles, who claimed authority over them. Gradually the various nobles were defeated, compelled to abandon their castles in the country, and to live in the cities. By commerce the cities had grown very wealthy and had established oligarchical governments, which were tending to become democratic. Venice by her share in the Fourth Crusade had secured extensive possessions in the East. (See BYZANTINE EMPIRE; DANDOLO.) Pisa, Genoa, Milan, and Florence had acquired great power. In 1278 the Emperor Rudolph of Hapsburg recognized the Papal States, which included Emilia, Romagna, the March of Ancona, the Patrimony of St. Peter, and the Campagna of Rome. In 1284 the naval power of Pisa was crippled by Genoa. Before this Genoa had engaged in a fierce struggle for ascendancy with her rival, Venice, which finally ended in favor of Venice towards the close of the next century. In every city of north and central Italy the population was divided into Guelphs and Ghibellines. In a general way the former may be said to have represented the progressive party; the latter, the conservative. In the cities civil strife was incessant, and the triumph of either party frequently resulted in the expulsion of the hostile faction from the city. Often the exiles attempted to regain power with the aid of other cities, and city warred against city, producing throughout the later Middle Ages a shifting succession of alliances, conquests, and temporary truces. This condition of affairs was inimical to commerce and manufacturing, which were the chief interests of the citizens in the north. In the cities the *podestà* (q.v.), who had been created as an arbitrator between the different parties, had proved inefficient and now became mainly a judicial officer. His place as head of the city was taken by a "captain of the people," representing the dominant party. As military skill was essential in this position, it was held usually by a noble. The people, desir-

ous of peace, acquiesced in the establishment of a strong power. Hence there arose in almost every city a "despot," or absolute ruler, an office which in many cases came to be hereditary in some noble family—with the Scalas at Verona, the house of Este at Ferrara, the Malatestas at Rimini, the Visconti and later the Sforzas at Milan. This period has been called fittingly "the age of the despots." Under their rule the arts prospered, literature flourished, life became more luxurious, wealth greater. But the people, who had fought so valiantly in the past, became unwarlike, and the cities placed their reliance in mercenary troops. (See CONDOTTIERI.) Gradually the smaller cities passed under the influence of the stronger states. By the middle of the fifteenth century Italy had reached a position of great prosperity and comparative tranquillity. She was in the van of European countries in all that pertained to culture, having led the way in the great revival of the arts and letters. (See RENAISSANCE.) Tuscany, which had produced Dante and Giotto, was preëminent in this revival. Amid all this splendor began a terrible period of foreign aggression in 1494.

Modern History. From the close of the Middle Ages until the nineteenth century there is no history of Italy as a united nation, but only of the different cities and states which composed it, their rivalries and their combinations with foreign powers. Chief among these states were the Duchy of Milan (which came to an end in 1535), and the republics of Florence, Genoa, and Venice in the north; the States of the Church, stretching, a bar to political unity, across the middle of the peninsula; and the Kingdom of Naples in the south. In addition to these more important political divisions there were many minor courts distinguished throughout Europe for their magnificence and intellectual brilliance. Some families, of whom the Medici of Florence are the most notable example, having amassed great wealth in banking or commerce, rose to the highest power in church and state. But at the close of the fifteenth century Italy entered an age of invasion in which she became the scene of fierce wars waged by France, Spain, Austria, and the Italian states and princes, culminating in the ascendancy of the Spanish and Austrian Hapsburgs. The discovery of America, which destroyed the commercial supremacy of Venice and therewith her political power; the fall of Granada, which increased the influence of Spain by giving it a free hand; the death of Lorenzo de' Medici in Florence—hastened this catastrophe. In 1494 Charles VIII of France undertook to conquer the Kingdom of Naples, then misruled by the house of Aragón. He was tempted by Ludovico Sforza, the Milanese usurper, and by the Florentines, who were ripe for rebellion against the tyranny of the Medici. He invaded Italy, made a treaty with Florence, which expelled the Medici, brought the Pope to submission, and marched on Naples, which was taken. Charles was, however, forced by a league formed against him by Venice, Spain, Milan, the Emperor Maximilian, and the Pope, to retire from Naples and fight his way out of Italy (1495-96). This French invasion had an importance transcending its political results in the dissemination of the Italian culture over the rest of Europe. Michelet has described it as "the revelation of Italy to the nations of the North." Louis XII,

the successor of Charles VIII, assumed the titles of King of Naples and Duke of Milan and entered upon a policy intended to support these pretensions. Allying himself with Venice, Louis invaded the territory of Milan in 1499 and was soon master of it. In 1501 a partition treaty was arranged between Louis and Ferdinand of Spain, by which the latter was to have Calabria and Apulia, with the title of Duke, and the King of France was to have the remainder of the Neapolitan Kingdom, with the title of King of Naples and Jerusalem. This treaty, which was on the part of Spain an act of the most cold-blooded treachery towards an ally, was immediately carried out by force of arms. Quarrels soon arose between the two allies, and in 1502 France and Spain were again at war on Italian soil. Through the generalship of Gonsalvo de Córdoba (q.v.), the French were driven out and made a disastrous retreat to France. (See CERIGNOLA; GARIGLIANO.) But France was soon in the field again in north Italy. In 1508 the League of Cambrai was formed against Venice, which was reduced to great straits by the victory of the French at Agnadello in 1509. But in 1511 the Holy League formed by the militant Pope, Julius II, with Spain and Venice, was arrayed against France, whose forces were driven out of Italy in 1513. Two years later Francis I (q.v.), continuing the policy of his predecessors, reconquered Milan; but it was lost again in 1521, immediately after the outbreak of the great struggle between that monarch and his rival, the Emperor Charles V. Francis I was defeated and captured at Pavia in 1525. In 1527 the forces of the Constable de Bourbon (q.v.) took and sacked Rome, and Pope Clement VII (Giulio de' Medici) became the prisoner of Charles V.

A new invasion of Italy by the French under Lautrec in the same year, with the Florentines, Genoese, and Venetians as allies, was at first attended with success, but in the end resulted disastrously, and in the Peace of Cambrai of 1529 Francis renounced all claims to territory in Italy. He renewed the struggle with Charles V, but the hold of the Hapsburgs on Italy could not be shaken. In 1535, on the extinction of the Sforza dynasty, Charles V took possession of Milan, which became part of the Spanish realm. Naples was governed by Spanish viceroys and remained for over 200 years in the hands of the Spanish Hapsburgs. Of all the free city states of Italy only four survived, of which only Venice and Genoa are worthy of mention. In north Italy the authority of the Hapsburgs (Austria supplanting Spain) was not thrown off until after the middle of the nineteenth century.

The reactionary bigotry of Spain fell heavily upon the whole Italian peninsula. In pursuance of the energetic anti-Hapsburg policy of Richelieu (q.v.), France from 1635 to 1659 waged war against Spain in north Italy, having for its allies Parma, Mantua, and Savoy, which had become an independent state again in 1574 under Emanuel Philibert, who transferred the capital of the duchy to Turin, which thus became the nucleus of the unified Italy of to-day. Under Mazarin's administration France gave some assistance to the Neapolitan revolt, begun under Masaniello and continued under the inefficient leadership of Henry, Duke of Guise. The War of the Spanish Succession (1701-14) and the decline of France at the end of the reign of

Louis XIV established the Spanish-Austrian rule in Italy without opposition. Lombardy and Naples passed from Spain to Austria, which also obtained Sardinia, and the house of Savoy received the island of Sicily, wrested from Spain. In 1720 Sicily was exchanged for Sardinia, and the Duke of Savoy took the title of King of Sardinia. The growth in strength and influence of the house of Savoy was the beginning of an efficient national power in Italy. Piedmont became the real centre of life of the new kingdom. In 1734-35 the Bourbons established themselves on the throne of The Two Sicilies, and in 1748 they obtained possession of Parma and Piacenza. The 45 years following the Treaty of Aix-la-Chapelle (1748), which terminated the War of the Austrian Succession, were years of peaceful development in all parts of Italy, which was better governed than it had been for some centuries. Many reforms were introduced, especially in Lombardy, Tuscany, and Sardinia, and although free institutions were not among them the people made economic progress under enlightened despotism. But the spiritual awakening of Europe which preceded the French Revolution had found expression in Italy in men like Alfieri, Beccaria, and other political philosophers. The events following the French Revolution meant the renewal of the struggle between France and Austria for the domination of Italy, but at the same time the revival of the consciousness of strength and unity in the Italian people. In 1792 Savoy and Nice were seized by the French. In 1796-97 the army of Bonaparte swept through north Italy, driving the Austrians before it. Through the Peace of Campo Formio in 1797 Lombardy, part of Venetia, Modena, the Romagna, etc., were constituted into the Cisalpine Republic (later known as the Italian Republic), and the Genoese dominions into the Ligurian Republic. The Venetian Republic, which had existed for 1100 years, was extinguished, and the bulk of its territories handed over to Austria. In 1798 a revolt was organized by French conspirators in Rome, and General Berthier (q.v.) proclaimed the Roman Republic, the Pope, Pius VI, being imprisoned in the French fortress of Valence, where he died the following year. The Neapolitan court, supported by Austria, having undertaken hostilities against the French in Italy in 1798, Naples was taken by the French, Jan. 23, 1799, and the Parthenopean Republic was erected. Piedmont and Tuscany had already been seized by the French. The two southern republics were short-lived. In 1799 the French were expelled from south Italy by the Second Coalition and were forced back in the north. The influence of the French Republic, which had aroused the democratic element in all the Italian states, was ended and was to give place to that of a purely military conqueror, Napoleon, to whom all Italy finally became subject. In 1800 the First Consul, having established his power in France, crossed the Alps and opened his second and most memorable campaign in Italy. The victory of Marengo forced the Austrians to sign an armistice followed by the Peace of Lunéville, 1801, which left Napoleon a free hand for his reorganization of Italy on a military basis. Popular movements which had sprung up under the inspiration of the ideas of the French Revolution were henceforth sharply repressed. Certain reforms were, however, introduced, such as the Code Napoléon. In 1805 Napoleon was

crowned with the Iron Crown of Lombardy as King of Italy, this Italy including the northern regions. In 1806 Napoleon took possession of the Kingdom of Naples, which was given to his brother Joseph, and, when the latter became King of Spain in 1808, to Joachim Murat. In 1808 Rome became part of the French Empire. The breakdown of the domination of Italy by Napoleon followed his defeat at Leipzig (1813). The Austrians invaded northern Italy, and an English force occupied Genoa and exhorted the Italians to rise in behalf of their freedom. Murat, having joined the allies, was allowed to retain his throne, but in 1815 he took up arms for Napoleon and was defeated and expelled. The Congress of Vienna led to a restoration of the pre-Napoleonic order with only slight modifications and left Italy at the mercy of Austria and the papacy. The Sardinian Kingdom, augmented by the territory of the Genoese Republic, was returned to the house of Savoy; Austria recovered Lombardy and Venetia (having been stripped of the latter in 1805); Modena was restored to the house of Este (q.v.); the Duchy of Parma was conferred on Maria Louisa of Austria, wife of Napoleon, and Lucca was erected into a duchy for the dispossessed Bourbon dynasty of Parma; the Grand Duchy of Tuscany passed again to the house of Lorraine-Hapsburg; the Bourbon dynasty (which had maintained its rule in Sicily) was restored in the Kingdom of Naples; the tiny Republic of San Marino and the Principality of Monaco retained their independence. The period following the Napoleonic rule and extending to the final unification of Italy in 1870, was characterized by a constantly growing movement for Italian unity and independence, which has been named the *Risorgimento*.

The dominion of Austria and the rule of autocratic princes, upheld by the Hapsburgs and the Holy Alliance, could not endure in Italy forever. Crushed under an iron despotism, the country was pervaded by a network of secret societies, which kept up a constant agitation for constitutional government. (See *CARBONARI*.) The French rule had introduced into the country certain liberal and progressive ideas which made their impression upon the people. But the princes, strong in the support of Austria, refused all concessions and by means of an elaborate police system succeeded in checking the progress of liberalism. Risings promoted by army officers took place in Naples (1820) and Piedmont (1821). In Naples Ferdinand I was forced to grant a constitution, but yielded to Metternich at the Congress of Laibach, and in May, 1821, was reëstablished in his despotic sway with the aid of Austrian troops. He now entered upon a course of vindictive persecutions against the Liberals. In Naples Francis I, the son and successor of Ferdinand I, continued the iniquitous policy of his father. The government of the Papal States under Leo XII was oppressive, reactionary, and incapable. Tuscany alone, during the decade of 1820-30, enjoyed a fair measure of freedom and prosperity under its Grand Duke, Leopold II. The July revolution of 1830, which drove the Bourbons from the throne of France, had its echoes in Italy. In 1831 insurrections broke out in Modena and in the Papal States, and in Bologna a congress of representatives from the revolted Papal States, excepting Rome and a few cities in the March of Ancona, adopted a constitution

establishing a Republican form of government. Austria promptly intervened, suppressed the revolutionary movement in the dominions of the Pope, and placed a garrison in Bologna. Upon the death of Charles Felix, in 1831, the succession in the Kingdom of Sardinia passed to Charles Albert (q.v.), Prince of Carignan, representative of the younger line of Savoy. There had been in Piedmont already a suggestion of national independence in the agitations of 1820-21. Now, the patriot Giuseppe Mazzini issued an address to the new King, who was known to hold more liberal views than others of his house, calling upon him to become the leader and liberator of Italy. From this time the idea of Italian unification and independence grew in strength and found its hope in the Sardinian monarchy, for it had become apparent that the cause of reaction had its strongest support in Austria, which must be driven from the peninsula by some power strong enough to assume the leadership in Italy. Mazzini at the same time founded the secret political society, Young Italy (q.v.), organized to support the principles of the Carbonari, whose propaganda was Republican, but also Nationalist, as Mazzini realized that freedom was only possible with unity. The impulse to a national uprising was afforded by Pope Pius IX, the first Pope to be elected without the influence of Austria. Immediately after his election in 1846, he entered upon an extensive series of reforms in the Papal States. An amnesty was proclaimed for political offenders, political exiles were permitted to return, the liberty of the press was established, the highest offices were opened to laymen, and a Council of Notables was summoned to initiate new reforms. The example of the Pope was followed by several Italian princes. Reforms were introduced in Lucca and Tuscany, and, above all, in Piedmont, where a great advance was made towards constitutional government (1847). Reform, however, was only preparatory to revolution. In January, 1848, the people of Palermo rose and drove out the Neapolitan garrison, and on February 10 Ferdinand II granted his people a constitution and summoned a separate parliament for Sicily. At the same time Leopold II issued a constitution for Tuscany, although his motive was rather hatred of Austria than sympathy with liberalism, and Pius IX, who had now begun to feel alarmed at the rapidity with which the course of reform was progressing, consented unwillingly to a constitution for the Papal States (March 14, 1848). The revolutionary outbreak in Vienna on March 13, 1848, which drove Metternich from power, was the signal for a rising in Milan (March 18). The Austrian troops, under Radetzky, were driven from the city after a five days' battle with the populace. On March 22 Venice rose under Manin and expelled the Austrians, and on the following day the Republic of St. Mark was reëstablished, with Manin at its head. The rulers of Parma and Modena were forced to flee. In Piedmont there was a clamor for war to drive the Austrians from Italy, and Charles Albert, after long hesitation, decided to mobilize his army and go to the assistance of Lombardy, which he entered March 25, acclaimed as the liberator of Italy. He was joined by 13,000 Neapolitan troops and contingents from Tuscany and Lombardy. On July 25 the Piedmontese suffered an overwhelming defeat at Custoza, and on August 6 Radetzky reëntered

Milan. An armistice was concluded on August 9, by the terms of which Charles Albert was to evacuate Lombardy, Venetia, and the duchies of Parma and Modena. Charles Albert, however, considered it his duty not to abandon the Lombards without making another effort to free them from Austrian domination, and in March, 1849, the armistice was suspended. The Austrians under Radetzky crossed the Ticino, and on March 23 overwhelmed the Piedmontese army at Novara. On the night after the battle Charles Albert abdicated in favor of his son, Victor Emmanuel II. In central and south Italy reaction was triumphant. Pope Pius IX, who saw that the revolutionary movement was fast getting beyond his control, became conservative, but a rising under Mazzini drove him from Rome. On Feb. 5, 1849, the temporal power of the Pope was abolished, and Rome was constituted a republic. In April a French army of 8000 men was dispatched under Marshal Oudinot to suppress the Roman Republic. Oudinot entered Rome in July, in spite of the heroic resistance of Garibaldi, and the papal authority was reestablished.

The Kingdom of Sardinia, with the liberal constitution which Charles Albert had granted in 1848, remained the only refuge of nationalism and liberalism, though with its diverse and mixed population, alien to the rest of Italy, it was not the most promising ground for the national propaganda. Victor Emmanuel II adhered firmly to the constitution, retained the tricolor flag, the symbol of free Italy, continued the liberty of the press, and encouraged political refugees from the other states to make Piedmont their asylum. The advent of Cavour (q.v.) as head of the ministry (1852) opened a vigorous, aggressive policy, in which the Minister was fully supported by the King. Cavour contrived that Sardinia should enter into an active alliance with England and France, and, after she had rendered them effective assistance in the Crimean War (q.v.), he was able to urge, in the Congress of Paris in 1856, the necessity of the consideration of the condition of Italy as a matter of international concern and to secure an acknowledgment of the claim, in spite of the protest of Austria. He effected an understanding with Napoleon III in a meeting at Plombières in July, 1858, after the attempt of Orsini upon the life of the Emperor had impressed upon him the intensity of the Italian desire for freedom and his own responsibility for intervention, and proceeded to increase the armed strength of Piedmont, acting boldly with a view to bringing on a war with Austria. France came to the aid of Sardinia, and the allied armies won with some difficulty the battles of Magenta (June 4) and Solferino (June 24). All north Italy was preparing to join Sardinia, when Napoleon, through the influence of the Empress Eugénie and the Clerical party in France, deserted his ally and concluded the preliminary Treaty of Villafranca, July 11, 1859. By the Treaty of Zurich, November 10, between France, Austria, and Sardinia, Austria ceded Lombardy, with the exception of Mantua and Peschiera, to France, which was to transfer them to Sardinia. The people of the duchies and the Romagna in a plebiscite (March, 1860) declared for a union with Sardinia. As the price of French assistance, Napoleon exacted the cession of Savoy and Nice, which became a part of France. The situation created by the victories in the cause of

national freedom in the north half of Italy invited the great patriot leader Garibaldi to undertake the task of liberating the south. In April, 1860, Palermo rose against Francis II, the successor to the odious Ferdinand II on the throne of The Two Sicilies. On the 6th of May Garibaldi, with about 1000 volunteers, embarked at Genoa, bent on the conquest of Sicily and Naples. After performing miracles of valor Garibaldi succeeded in conquering Sicily and declared himself dictator of Sicily in the name of Victor Emmanuel, "King of Italy." On July 20 he defeated the Neapolitans at Milazzo. Messina, the last stronghold of the Bourbons in Sicily, fell on July 25, and Garibaldi with 5000 men crossed into Italy (August 20-21), meeting with no resistance. On September 7 he entered Naples with a small escort, Francis II having fled to Gaeta, after making a vain attempt to save his throne by the grant of a constitution and the promise of many reforms. The liberator proclaimed the reign of Victor Emmanuel. The Sardinian government had been openly in sympathy with Garibaldi, but had carefully abstained from affording any pretext for the intervention of the foreign Powers. This diplomatic position, however, seemed to be threatened when Garibaldi, not satisfied with conquering The Two Sicilies, prepared to invade the States of the Church. In the meanwhile, the Sicilies, Umbria, and the Marches declared by plebiscite for annexation to Sardinia (October, 1860), and on Feb. 18, 1861, the first Italian Parliament was opened in Turin by Victor Emmanuel. On February 26 the Parliament conferred the title of King of Italy upon Victor Emmanuel, who formally assumed it on March 17.

The death of Cavour, June 6, 1861, at this crucial period, was a heavy loss to the new kingdom. A ministry under Baron Ricasoli had a brief term of office, and was succeeded, March 31, 1862, by the ministry of Rattazzi, whose subserviency to France caused much distrust among the Italian Liberals. The restlessness of Garibaldi, who was impatient of delay in the acquisition of Venetia and Rome, and had even had under consideration for this end a plan for raising a revolt in the Balkans and Hungary, was a grave cause of disquiet for the government, as it was highly important that the new state should not hastily involve itself in a new struggle without outside support. After traveling about Italy, engaging in the organization of "rifle clubs," the irrepressible patriot went to Sicily with the avowed intention of organizing an expedition against Rome. A royal proclamation (dictated by the fear of French intervention) declaring him to be in rebellion did not deter the Sicilians from rallying around the Garibaldian standard, and on Aug. 22, 1862, Sicily was declared in a state of siege, the Liberal clubs were dissolved, and an armed force was dispatched to disperse the volunteers, since the advance of Garibaldi was considered to be a danger to the Monarchist cause. Garibaldi, having landed in Calabria, was met by the Sardinian troops at Aspromonte (August 29), and after a slight engagement, in which he was severely wounded, was forced to surrender. In spite of the temporary check to the conquest of the Papal States, their acquisition was inevitable. In 1865 Florence became the capital of Italy. This was but a step nearer towards Rome. In 1866 Italy allied herself with Prussia against Austria, and although her army was defeated at

Custoza (June 24), and her fleet at Lissa (July 20), she was enabled to participate in the Prussian triumph, and in October Venetia became part of the Kingdom of Italy. (See SEVEN WEEKS' WAR.) The protection of the papal territory by France alone stood in the way of that completion of unification which required for its fullest expression the establishment of the government in the Eternal City. In 1867 Garibaldi headed a new expedition against the papal territory; but Napoleon III, from motives of policy, refused to permit the extinction of the temporal power of the Pope. A French force defeated the Garibaldians after a severe engagement at Mentana (November 3), and this event destroyed the good feeling which had prevailed between Italy and France since 1859. At last, in 1870, the urgent necessities of the Franco-German War compelled the Emperor Napoleon to withdraw his forces, and once more Italy profited by Prussia's victories. The Italian forces entered the lands of the church on September 11, and on the 20th made their entry into Rome. The Roman people declared for union with Italy in October by 133,000 votes against 1500, and on July 2, 1871, Rome became the capital of United Italy.

The problems of the new state were not simple ones. The task of political organization and consolidation was complicated by the great diversity in economic, cultural, and social conditions between the north and the south. The inhabitants of southern Italy, kept for centuries under a burdensome despotism, showed themselves, on the whole, deficient in training for self-government, which comes more naturally to the Tuscans, Lombards, Piedmontese, and Venetians.

The six years which followed the first Italian Parliament in 1871 witnessed the disintegration of the moderate conservatism which had characterized the policy of Cavour and the other great leaders in the struggle for national unity, and the new monarchy found itself confronted with sectional, social, and ecclesiastical problems of the greatest complexity, in addition to that of securing the newly created nation a voice in the councils of Europe. The ecclesiastical problem was that of a satisfactory settlement between the papacy and the monarchy. The Pope had refused to be reconciled to the arrangement of 1870 whereby the papacy was to be indemnified for the loss of its temporal power by the acquisition of certain privileges and immunities and the receipt from the state of a generous annual income. The papacy has ever since maintained its irreconcilable attitude, and the Pope has considered himself a prisoner in the Vatican, while Catholic citizens have been encouraged to abstain from active participation in political affairs. Within the last 10 years, however, there have been signs of a change of policy upon this last point. See ROMAN CATHOLIC CHURCH.

A more complex problem was that of the economic development of the country and the adjustment of the social and sectional difficulties connected therewith. With small resources in coal and other minerals, Italy is, and bids fair to remain, despite all efforts to develop its industries, chiefly an agricultural country, with the exception of the north, where a more intelligent population has taken up the ideas of co-operation, rural banks, and improved methods of cultivation; in the south, and especially in Sicily, agricultural progress has been slow for various reasons. The high percentage of illiter-

acy, the overtaxation, and the antiquated land system, in which absentee landlordism is combined with a high rate of emigration among the agricultural workers, have united to produce a state of poverty and unemployment which has been aggravated at frequent intervals by disasters of appalling magnitude, volcanic eruptions, landslides, and earthquakes, such as that at Messina in December, 1910, when 170,000 people perished. The large emigration has created peculiar economic conditions: on the one side whole populations are being largely supported by the money sent from relatives in America, on the other side a new form of usury is being created to supply passage money and landing capital to emigrants. The bad economic conditions are accompanied by social and political degeneracy, as exemplified in criminal societies such as the Mafia and Camorra (qq.v.).

With the development of factory industry and the growth of towns a large body of industrial workers was created whose dissatisfaction with their wages and conditions of labor has been the source of constant industrial disturbances. This industrial dissatisfaction combined with the agrarian unrest has found expression in a strong Republican movement, whose growing strength has been shown in frequent strikes and riots both industrial and agrarian, whereas the attitude of the government has grown continually more lenient. A serious agrarian insurrection in Sicily in 1893-94 was suppressed arbitrarily by Crispi. In 1898 riots occurred at the funeral of the Radical leader Cavallotti in Milan and Rome and spread quickly over several provinces. In the so-called "Three Days" at Milan 82 people were killed. The Zanardelli-Giolitti ministry was the first cabinet which abstained from the former attitude of repression and adopted the policy of nonintervention in labor troubles, which was severely strained by the gas strike in Turin in 1902 and a threatened general strike of railway men. The measures taken by the government in the face of a general strike in Rome in 1903 were applauded by the Conservatives and resented by the Extreme Left, which brought about the downfall of the cabinet by starting an agitation against the Czar's proposed visit to Italy and by preferring charges of maladministration in the Navy Department. An attempted reconstruction of the cabinet was met by the Radicals by the appointment of a committee of resistance to declare a general strike and bring about the cabinet's resignation in 1904. The threat was not taken seriously, and the general strike broke out, paralyzing the cities of Milan, Venice, Genoa, and Turin, and disturbing Rome, Florence, and Naples. Railway lines were destroyed, and flags were torn down in denunciation of the monarchy. Giolitti succeeded in mastering the situation by a clever handling of the troops without committing bloodshed. The terrorized middle class, however, joined hands with the clergy, and in the next elections radicalism was completely routed. There have been recurrences of industrial and agrarian disturbance since that time, especially in 1907, 1908, 1910, 1911, and 1914; but, although the social aims of these movements have remained as serious as before, the position of the monarchy seems to be less threatened. Victor Emmanuel I died Jan. 9, 1878, and was succeeded by his son Humbert (Umberto), who inherited his father's courage but not his genial

personality and force of character. He was well-meaning and loyal to his coronation oath; but his political outlook was a narrow one, and towards the end of his reign he suffered a small clique of military and reactionary politicians to blind him to the signs of the times. Moving freely among the people in a rather excited period regardless of warning, he was murdered, on July 29, 1900, at Monsa by Angelo Bresci, an Italian anarchist from America. The Prince of Naples, who ascended the throne as Victor Emmanuel III, while steadily opposing any reduction in armaments, has frankly accepted the more enlightened policy that the country demanded and has by this and by the simplicity of his manners and the sincerity of his character improved the somewhat sinister outlook for monarchical rule in Italy.

At the same time a certain amount of democratic progress has been peacefully won by the electoral reforms of 1881 and 1912, which considerably enlarged the electorate. The reform of 1912 granted the franchise to illiterates who had reached the age of 30 and had performed military service. The elections held in 1913 on the basis of this reform indicated a notable movement of the Italian people in the direction of the programmes and the principles of the radical parties—the Liberals having won 16, the Socialists 40, votes.

Other domestic reforms have been the nationalization of railways, attempted somewhat rashly in 1905 and not without some economic maladjustment. More successful in the field of public finance proved Luzzatti's conversion of the debt from 4 to 3½ per cent; but the serious problem of taxation, involving the questions of securing a general relief from overtaxation and a more equitable regional distribution of taxes, the south being at present heavily overtaxed, has proven difficult, owing to the large expenditure for armaments, in which Italy has tried to keep a middle course between the great Powers and the small.

Colonial Policy. The colonial policy of Italy started as a consequence of the forward policy of France in Africa and of England in Egypt. Secured by the Triple Alliance from attack by land and by agreement with Great Britain from attack by sea, the government decided upon a forward policy in Africa. Early in 1885 Beilul and Massowah were occupied by an Italian expedition, but subsequent operations on the mainland evoked protests from King John in Abyssinia. In the anarchy that followed the death of the latter, in 1889, one of the Abyssinian pretenders was promised Italian aid against his rival in an ambiguous treaty which was interpreted by the Italian government to involve the suzerainty of Italy over Abyssinia, and money was coined with the impress of King Humbert wearing the Ethiopian crown. In 1890 the African possessions were consolidated into a colony, Eritrea. Led on by the first brilliant victories over the dervishes in 1893 and 1894, Crispi planned a vast African Empire; but in 1896 an Italian expeditionary force met with complete disaster at Adowah, and the suzerainty over Abyssinia had to be abandoned. In February, 1890, an Italian protectorate was established over the Somali Coast south of British Somaliland. After unsuccessful attempts by two private companies to administer the colony, the government took over the whole control in 1905. In 1906 an agreement was signed by

Italy, France, and Great Britain. It was also with the connivance of France and Great Britain that Italy undertook the annexation of Tripoli in 1911. The international situation being favorable to Italian action, the government took advantage of the agreements relating to north Africa concluded with Great Britain and France, and an ultimatum was delivered in Constantinople September 27 which gave the Porte 48 hours in which to accept the occupation of the provinces of Tripoli by Italian troops and an Italian administration, with the provision that the Sultan's sovereignty should be secured and an annual subsidy paid by the new protectorate to the Porte. The Porte declined, and Italy proceeded to the occupation and blockade of the Libyan coast, while the Turks retreated into the interior, taking up the offensive and harassing the Italian lines. Austria deprecated any attack on the eastern coast of the Adriatic, and Russia took the same position with respect to the Dardanelles. As a result of the Italo-Turkish War, Turkey bound herself to withdraw her troops from Tripoli, but did not recognize the sovereignty of Italy. She was to have a representative to look after the interests of the Mohammedans in Tripoli, while Italy pledged herself to restore to Turkey the Ægean Islands occupied by the Italian troops and to pay that part of the Ottoman public debt which is guaranteed by the revenue of Tripoli and the Cyrenaica.

Foreign Policy. In foreign policy the prevailing tendency of Italian diplomacy in the decades following the unification of Italy was in the direction of an alliance with Germany. This was due in part to the attitude of France, because, until the defeat of the clerical and monarchical parties, there was always the danger of a French reoccupation of Rome. Furthermore, the energetic naval policy of Italy was held by France to endanger her interests in the Mediterranean. Italian ambitions with regard to Tunis, first stimulated by Austria and Russia at the Congress of Berlin (1878), were frustrated by the French occupation of that region as a colony in 1881 with the connivance of Great Britain and Germany. As the latter fact was unknown at the time in Italy, Bismarck contrived to utilize the strong resentment of Italy against France to bring about a rapprochement between Italy and Austria in spite of the strong Irredentist (see IRREDENTISM), anti-Austrian feeling in Italy, and, May 20, 1882, the famous Triple Alliance was concluded which has been renewed at various periods and for the last time in 1912 for 1912-17.

Relations with Austria, which had always been difficult on account of the movement for the restoration of the Italian provinces still held by Austria and the conflict between Austrian clericalism and Italian anticlericalism, were complicated still further after 1897 by the Italian distrust of the Balkan policy of Austria. The Austrian annexation of Bosnia and Herzegovina in October, 1908, agitated public opinion greatly, and the storm of indignation was only reduced slightly by economic arrangements for Italian railways in the Balkans. The menace of an Austrian Albania which often arose was settled by the agreement between the Powers for the preservation of Albania's independence in 1912. But the efforts made by Germany to reconcile Austria and Italy proved only of temporary value, and upon the outbreak

of the war between the Triple Entente and the Dual Monarchy and Germany in 1914 loud demands were made upon the Italian government to fulfill the wishes of the Italian Irredentists and take Trieste and Trent for Italy. As Italy had not been consulted in the negotiations leading to the Great War of 1914, she decided to remain neutral and not join Germany and Austria. This attitude of Italy was of great value to France because no troops were necessary to protect the Italian frontier. See WAR IN EUROPE.

On the other hand, the relations between Italy and the western European Powers have gradually improved in recent years. Since the close of the tariff war with France in 1898 and after the agreement of France on the Italian policy in Tripoli, a strong current of popular opinion expressed itself in sympathy with closer relations with France. As a result, agreements on Mediterranean and African affairs between Italy, France, and Great Britain were arranged, and in 1902 the French Ambassador at Rome declared that a conflict between the two Latin nations was no longer possible. The visit of President Loubet to Rome in 1904 confirmed these friendly relations, and Italian diplomacy supported France at the Algeiras Conference, although this antagonism to the aims of Germany in Morocco was rather resented by the latter. This same popular sentiment for France seems to have had a strong influence on the attitude of Italy at the outbreak of the European War of 1914. See NATIONAL COATS OF ARMS; NATIONAL FLAGS.

For the period after Charlemagne: Gregorovius, *History of the City of Rome in the Middle Ages*, translated by Hamilton (8 vols. in 13, London, 1894-1902), which in spite of its name gives a good account of the struggles in the rest of Italy; Hartmann, *Geschichte Italiens im Mittelalter* (Leipzig, 1897); J. C. Simonde de Sismondi, *History of the Italian Republics in the Middle Ages*, edited by William Boulting (New York, 1906); Chalandon, *Histoire de la domination normande en Italie et en Sicile* (2

vols., Paris, 1907); Pasquale Villari, *L'Italia da Carlo Magno alla morte di Arrigo*, vol. vii (Milan, 1910; Eng. trans., London, 1910); id., *Medieval Italy from Charlemagne to Henry VII* (New York, 1910); H. D. Sedgwick, *Italy in the Thirteenth Century* (2 vols., Boston, 1912), contains a bibliography. For the relation of the Empire and Italy: Wilhelm von Giesebrecht, *Geschichte der deutschen Kaiserzeit* (6 vols., Brunswick, 1855-95). For the fifteenth and sixteenth centuries: Jacob Burckhardt, *The Civilization of the Period of the Renaissance in Italy* (London, 1898); J. A. Symonds, *The Renaissance in Italy* (7 vols., ib., 1877-1904); Stanley Leathes, "Italy and her Invaders," in *Cambridge Modern History*, vol. i (New York, 1902). On the nineteenth century: Mistrali, *Da Novara a Roma* (5 vols., Rome, 1870-79); H. von Treitschke, *Historische und politische Aufsätze*, vol. ii (5th ed., Leipzig, 1886); Tivaroni, *Storia critica del Risorgimento* (9 vols., Turin, 1891-96); W. R. Thayer, *Dawn of Italian Independence* (2 vols., Boston, 1893); Bolton King, *History of Italian Unity, 1814-1871* (2 vols., London, 1899), contains a bibliography; W. J. Stillman, *Union of Italy, 1815-95* (New York, 1909). For the period 1849-70: E. Quinet, *Revolution d'Italie* (Paris, 1857); Hermann Reuchlin, *Geschichte Italiens von der Gründung der regierenden Dynastien bis zur Gegenwart* (4 vols., Leipzig, 1859-73); Grattina, *Storia d'Italia* (1882); R. de Cesare, *Last Days of Papal Rome, 1850-1870* (Boston, 1909). For the period 1866-80: Cesaresco, *The Liberation of Italy, 1815-70* (London, 1895); Arangio-Ruiz, *Storia costituzionale del regno d'Italia, 1848-98* (Florence, 1899); Pietro Orsi, *Modern Italy, 1748-1898*, translated from the Italian and published in "Stories of the Nations Series" (New York, 1900; 3d Ital. ed., Milan, 1912), contains a bibliography. For recent histories: Johnston, *Napoleonic Empire in Southern Italy and the Rise of the Secret Societies* (2 vols., London, 1904); Gori, "Il regno d'Italia, 1860-1900," in *Storia Politica d'Italia* (Florence, 1904); King and Okey, *The Italy of Today* (2d ed., New York, 1904); F. M. Crawford, *Southern Italy and the Rulers of the South* (London, 1905). Reale Accademia dei Lincei, *Cinquanta anni di storia italiani* (3 vols., Milan, 1911); M. C. Fraser, *Italian Yesterdays* (2 vols., New York, 1913). For bibliography: Langlois, *Manuel de bibliographie historique* (Paris, 1896); *Cambridge Modern History*, vol. i (New York, 1902).

ITALY, FREE CHURCH IN, known also as the EVANGELICAL ITALIAN CHURCH. An organization established by the Italian patriot and reformer Alessandro Gavazzi (q.v.) in 1870. He brought together 23 scattered independent congregations in a General Assembly. In 1874 a confession of faith was prepared, and the name Free Church in Italy was adopted. This confession was a declaration of the principles held by all evangelical Christians, and the Free Church is in harmony with the Waldensian and other Protestant churches. The constitution is partly Presbyterian and partly Congregational or Independent, the General Assembly being composed of deputies from the churches, and each church independent of all the others in local affairs. The General Assembly appoints the committee that superintends the entire work, and the funds collected by the commissioners are remitted directly to that committee. In 1891, by royal

decree, the title Chiesa Evangelica Italiana was given to the church. It has spread rapidly. The church is divided into 10 districts, embracing about 40 congregations and 2000 communicants. It maintains elementary and Sunday schools. Among its buildings is the old church of San Jacopio in Florence, bought and presented by friends in Great Britain. The theological seminary, in which Gavazzi was professor of sacred rhetoric, was originally near the Vatican in Rome, but in 1891 was removed to Florence. The city of Florence gives an annual bounty to one or more of the Free Church schools.

ITASCA, ĭ-täs'kà, LAKE (so named by Henry R. Schoolcraft, from the barbarous Lat. *veritas caput*, true head or source; Indian name, *Omuskosesagauegoum*). The largest of several small lakes, lying in a basin in Beltrami Co., Minn. (Map: Minnesota, B 3). It consists of three long, narrow arms—one extending to the north, from which emerges the Mississippi River (q.v.); one to the southeast; and one to the southwest. The arms are of about equal length; their combined shore length is about 13 miles, and the area of the lake is 1130 acres. The lake was discovered in 1832 by Henry R. Schoolcraft (q.v.). Itasca State Park, a tract including 19,700 acres, was created by an Act of the Minnesota State Legislature in 1891. For a detailed description of this region and its history, consult J. V. Brower, *Itasca State Park* (St. Paul, Minn., 1904).

ITA'TA (ĕ-tä'tà) **AFFAIR**. In American history, an affair rising from the seizure by the United States in 1891, for an alleged infraction of her neutrality laws, of a vessel, the *Itata*, owned by insurgents against the government of Chile. In April, 1891, this vessel was ordered to California for the purpose of receiving a large quantity of arms and munitions which an agent of the insurgent party had purchased in the United States with a view to sending them to Chile for the use of the insurrectionary forces. During her voyage to California the *Itata* had on board several small cannon and a few old muskets and at a Chilean port took on board 12 soldiers to serve as stokers. At Cape San Lucas the cannon and ammunition, together with the arms and uniforms of the soldiers, were packed in the hold of the vessel. The arms and ammunition purchased in New York, having been shipped to San Francisco, were loaded on a schooner, afterward were transferred to the *Itata* off the southern coast of California, and in due time the vessel proceeded on her way to Chile. By direction of the Attorney-General of the United States an effort had been made to detain her, on the ground that the neutrality laws of the country were being violated, but she succeeded in escaping from the officers left in charge of her. The cruiser *Charleston* was then sent in pursuit. The *Itata* was overtaken on June 4, was compelled to surrender to Rear Admiral Brown, and was given over to the custody of the United States District Court at San Diego for trial, on the charge of violating the neutrality laws of the United States. Upon trial it was held that the facts, as set forth above, did not constitute the fitting out of a hostile expedition against a government with which the United States was at peace, and that the mere purchase and transportation of arms to a party of insurgents in a foreign country in the ordinary course of trade was not a violation of the neutral duty of the United States or a violation

of her neutrality laws. The affair aroused considerable excitement in the United States, and loud complaints were made of the manner in which the authority of the United States was defied by the officers of the vessel at San Diego.

ITATIAIA, ē'tā-tyī'ā. The highest mountain in Brazil. It is 9739 feet high.

ITCH (AS. *gycþa*, from *giccan*, OHG. *jucchan*, Ger. *jucken*, to itch), also called **SCABIES** and **PSORA**. A parasitic disease of the skin, due to the presence of the larvæ or mature specimens of the *Acarus* (or *Sarcoptes*) *scabiei*, which burrows into the integument. The lesions are caused more by the scratching of the patient than by the presence of the insect. The resulting eruption is multiform, papules, vesicles, and large encephalomatous pustules occurring, besides crusts and scratch marks. In mild cases or early in an attack the symptoms are itching, which is worse at night, and a few papules or vesicles. The diagnosis is established by the discovery of the *caniculus*, or burrow, left by the female insect in the skin in the course of depositing her eggs. This appears as a minute, dotted, brownish-black line, curved or sinuous, from $\frac{1}{8}$ to $\frac{1}{2}$ of an inch long, rarely several inches long. These burrows may easily be seen by rubbing a little ink over the surface and then wiping the skin clean. The male insect remains on the surface. The female enters the skin at once and may advance $\frac{1}{20}$ of an inch a day. See **ITCH MITE**.

Scabies is said by Bulkley to be fairly common in the United States, forming 4.05 per cent among 200,000 cases of skin disease collected by the American Dermatological Association. It is more common in Europe, especially among the poor and uncleanly, though found in all classes. The disease is conveyed by direct bodily contact or by means of infested clothing or bed linen. Though other places may be first attacked, the earliest lesions are commonly found between the fingers and on the palmar surface of the wrist. The genital region, abdomen, thighs, anterior fold of the axilla, as well as all parts where there are warmth and pressure (as the waist and buttocks), are generally attacked, and in women the neighborhood of the nipples is early invaded by the eruption. The eruption may be looked for wherever the skin is thin. The dermatitis resulting from the parasite and from the scratching caused by the itching is a simple inflammation of the skin, resembling that caused by heat, cold, or mechanical irritants. The entrance of microorganisms into the abraded surface may cause pustular lesions. The treatment for the condition is first directed to killing the insects and their eggs. This result is effected by the use of sulphur. Naphthol, ichthyol, oil of eade, and carbolic acid are also used to allay the itching and reduce the inflammation. Reinfestation from the patient's own gloves, muffs, bedding, etc., is possible—an accident which may be obviated by baking or boiling the articles.

DHOBIE ITCH, also called *Indian*, *Chinese*, or *Burmese ringworm*, is a form of tinea which attacks the opposite and inner sides of the thighs and the region of the genitals, the folds of the buttocks, the skin under the breasts or in the axilla, causing great suffering from the extreme itching and tenderness which accompany the appearance of the eruption. This variety of tinea (*Tinea trichophytina cruris*) occurs commonly in warm climates, though found in the United States. The treatment, which seldom

fails, is the use locally of genuine sulphurous acid. The application of this remedy is to be followed by an ointment of tar and zinc, or compound tincture of green soap. See also **BARBER'S ITCH**; **PRURIGO**; **RINGWORM**.

ITCH. A parasitic disease of horses, dogs, and other animals. See **MANGE**.

ITCHANG. See **ICHANG**.

ITCHEN, ïeh'en. A growing town and suburb of Southampton, England, on the estuary of the Itchen. Pop., 1901, 13,097; 1911, 19,484.

ITCH MITE, *Acarus scabiei*, or *Sarcoptes scabiei*. Although the iteh was undoubtedly known both to the Greeks and Romans, there is no certain evidence that a mite was recognized as the cause of the disease earlier than by Avenzoar, an Arabian physician of the twelfth century. Throughout the Middle Ages and till the nineteenth century the necessary connection between the disease and the mite was universally recognized. During the early part of the last century the existence of the iteh mite was distrusted, until in 1834 Renucci, a Corsican student, demonstrated the existence of the creature. A case reported in 1892 by Dr. Robert Hessler, of Indianapolis, attracted much attention. The skin of the patient was estimated to contain 7,000,000 eggs and 2,000,000 mites.

The iteh mites of the lower animals were formerly considered to be distinct from the species affecting human beings; but Raillet, the latest authority, believes them to be only varieties, and it seems therefore that human beings may be infested from certain of the domestic animals. The true human iteh is *Acarus scabiei*, now known as *Sarcoptes scabiei hominis*; the Norway iteh, *Sarcoptes scabiei crustosæ*; that of the horse, *Sarcoptes scabiei equi*; of the sheep, *Sarcoptes scabiei ovis*, etc. All stages of the parasite occur on the host, upon which it is absolutely dependent for existence.

The adult female mite is considerably larger than the male; it is visible to the naked eye and forms a roundish, grayish-white corpuscle, not unlike a starch granule; it is about $\frac{1}{5}$ of a line in length and $\frac{1}{7}$ in breadth. When seen under the microscope, it presents a truncate tortoise-like shape and is seen to be studded with hairs and bristles. The head terminates in two pairs of mandibles, and these mandibles afford good characteristic distinctions of the species. The males are much scarcer than the females.

Consult Raillet, *Zoologie medicale* (Paris, 1895), and Osborn, *Insects Affecting Domestic Animals* (Department of Agriculture, Washington, 1896). See **ITCH**; **ACARUS FOLLICULORUM**.

ITCHWEED. A North American marsh plant with poisonous properties. See **HELLEBORE**.

ITENEZ, ê-tā'nāz. A river of Brazil. See **GUAPORÉ**.

ITH'ACA. An island in the Ionian Sea, the home of Ulysses (q.v.). See **ITHAKI**.

ITHACA. A city and the county seat of Tompkins Co., N. Y., at the head of Cayuga Lake, 56 miles northwest of Binghamton, on the Delaware, Lackawanna, and Western, the Lehigh Valley, and the Central New York Southern railroads, and on a branch of the New York State Barge Canal (Map: New York, D 6). The State in 1913 constructed in Ithaca a canal terminal basin. The city's situation is one of natural beauty. In addition to the scenery of Cayuga Lake that of numerous

gorges and waterfalls in the vicinity adds to its attractions, the most noted of the falls being Ithaca, Triphammer, Buttermilk, Enfield, and Taughannock. The last, 215 feet in height, is the highest waterfall in the United States east of the Rocky Mountains. Cornell University (q.v.), which includes the New York State College of Agriculture and the New York State Veterinary College, is picturesquely situated on East Hill, about 400 feet above and overlooking the lake and the city. Other features are preparatory schools, the Cornell Library and reading room (founded by Ezra Cornell, q.v.), Ithaca Conservatory of Music, the United States Weather Bureau Station, and Renwick Park. Ithaca is in a productive farming and fruit-growing region. Its industries include the manufacture of chains for power transmission, guns, castings, calendar clocks, advertising signs, paper, gasoline engines and boats, bricks, and cement. There are also several plants for the manufacture of salt, which is derived from driven wells. The city owns and operates the water works. Under the charter of 1909 the government is vested in a mayor biennially elected, a council, a board of public works, and administrative officials, who, with the exception of the board of education, which is chosen by popular election, and of the city clerk, who is appointed by the board of public works, are appointed by the mayor. Among the public buildings are a city hospital, homes for aged women and children, and the public library. There are a charities association and a civic association organized for the purpose of affording playgrounds for children and of making the streets and parks of the city more attractive. Pop., 1890, 11,097; 1900, 13,136; 1910, 14,802; 1914 (U. S. est.), 15,510. Settled in 1789, Ithaca was variously called The Flats, The City, and Sodom, until about 1806, when Simeon De Witt gave it its present name. In 1821 it was incorporated as a village and in 1888 was chartered as a city. At Buttermilk Falls, near Ithaca, stood the Catawba Indian village Coreogonol, built about 1753 and destroyed in 1779 (September 24) by a division of Sullivan's army. A bronze tablet now marks the location of one of Sullivan's encampments. Ithaca was for many years an important canal port because of its early connection with the Pennsylvania coal fields by the Cayuga and Susquehanna Railroad and its situation at the head of Cayuga Lake. It was a port of lading for barges carrying coal cargoes westward on the Erie Canal. Its traffic declined as through lines of railroad were built. Consult Selkreg (ed.), *Landmarks of Tompkins County* (Syracuse, 1894).

ITH'AKI (formerly *Ithaca*, Gk. Ἰθάκη, *Ithakē*). One of the Ionian Islands, situated east of Cephalonia, from which it is separated by a narrow channel (Map: Greece, B 5). It is oblong in shape and has an area of about 38 square miles. Its surface is generally mountainous, rising in the northern part to an altitude of 2600 feet. The coasts are well indented, and the mountain slopes are covered with vines, olives, and other southern fruits. Besides the production of currants and oil, the natives also engage in seafaring and fishing. Administratively Ithaki forms a part of the Greek Nomarchy of Cephalonia and had in 1907 a population of 13,000. The chief town, Vathi, is the seat of a Greek bishop and in 1907 had a population of 6837. Ithaki is celebrated as the

home of Ulysses, and some cyclopean ruins near Porto Molo are popularly reputed to be the remains of the castle of Ulysses.

ITHOME, i-thō'mē (Lat., from Gk. Ἰθώμη). In Greek mythology, one of the nymphs by whom the infant Zeus was nursed. The Messenian hill and fortress of the same name, known now as Vurkano, were called after her. See **MESSENI**A. Consult Pausanias, 4, 33, 1, with the notes on the passage by Metzsig-Blümner.

ITHURIEL, i-thū'ri-ēl. 1. In Milton's *Paradise Lost*, one of the two angels sent by Gabriel to discover Satan, who had secretly entered the Garden of Eden to beguile Adam and Eve. Ithuriel accomplished this by his magic spear, which revealed deceit. 2. In Klopstock's *Messiah*, the guardian angel of Judas Iscariot, and, after his fall, the second angel of Simon Peter.

ITIN'ERANCY (from *itinerant*, from Lat. *itinerari*, to journey, from *iter*, OLat. *itiner*, journey, from *ire*, Gk. *lévai*, *ienai*, Skt. *i*, to go). A term applied to the system of limited pastorates in the Methodist church. It originated with Wesley. To accomplish what he considered necessary for the revival of religion in England, he traveled from town to town and, remaining but a day or two in a place, adopted the plan of commissioning a few competent men to preach in the societies which he had organized. These helpers, as he called them, rapidly increased; but, the societies increasing still more rapidly, he found it necessary to extend and methodize their labors and accordingly appointed them to definitive circuits for a year. At first the whole country was divided into seven of these itinerant districts, and at Wesley's death there were 72 in England, 3 in Wales, 7 in Scotland, and 28 in Ireland. The circuits were long, and the preachers were changed from one circuit to another every year or two. The system was well adapted to conditions in America among the feebler churches and generally among the frontier settlements of the West. In course of time it came to be looked upon with disfavor by many in the Methodist Episcopal Church North of the United States. The length of time that a minister might remain in one place was lengthened from six months to a year, then to two years, next to three years, and then five years, and at the General Conference held in Chicago in 1900 the time limit was removed; but preachers are still appointed from year to year by the bishop.

ITINERA'RIUM. See **ITINERARY**.

ITIN'ERARY (Lat. *itinerarium*, from *iter*, OLat. *itiner*, journey). The name given by the Romans to a table of the stopping places between two cities of importance, with the distances from one to another. The itineraries of the ancients contribute much to our knowledge of ancient geography, and all seem to date from the later period of the Roman Empire. Of these the most important are the *Itineraria Antonini* and the *Itinerarium Hierosolymitanum*. The *Itineraria Antonini* are two in number, the *Itinerarium Provinciarum* and the *Itinerarium Maritimum*—the former containing the routes through the Roman provinces in Europe, Asia, and Africa; and the latter the principal routes of navigators, who then sailed mainly along the coasts. They take their name from Antoninus Caracalla, by whom they were first published, as corrected up to his time, but they seem to have been originally prepared at an earlier date. The *Itinerarium Hierosolymitanum*,

or *Burdigalense*, was drawn up 333 A.D., for the use of pilgrims from Burdigala (Bordeaux) to Jerusalem. Among other examples is the *Itinerarium Alexandri*, in which the route of march of Alexander the Great is laid down; this was prepared in connection with the expedition of Constantius against the Persians (340-345 A.D.). A collected edition of ancient *Itineraria* was published in Paris in 1845 by D'Urban, *Recueil des itinéraires anciens*. Besides, the Antonine and Jerusalem itineraries are edited by Parthey and Pinder (Berlin, 1847); the *Itinerarium Alexandri* by Volkmann (Naumburg, 1871); that of *Antoninus Placentinus* by Gildemeister (Berlin, 1889). The itineraries thus far named belong to the *Itineraria Adnotata* or *Scripta*; they are in the nature of books, without maps. The famous so-called *Peutingerian Table* (q.v.) should be mentioned here as the chief example of the *Itineraria Pieta* (Illustrated Itineraries); it is a traveler's map of all the great highways of the Roman Empire. It exists in a manuscript of the thirteenth century, but was originally compiled in the third or fourth century A.D., and is published by Miller, *Die Weltkarte des Castorius* (Ravensburg, 1888). At the mineral springs *Aquæ Apollinares*, near Vicarello in Tuscany, were found four silver cups in the form of milestones, inscribed with lists of the stopping places on the journey from Gades (Cadiz) to Rome. See ANTONINUS, ITINERARY OF.

IT IS NEVER TOO LATE TO MEND. A novel by Charles Reade (1856).

ITIUS PORTUS, ish'i-ūs pôr'tūs. The place whence Cæsar (54 B.C.) set out on his second expedition to Britain, probably the modern village of Wissant or Duessant, on the coast of France, near Boulogne. Consult T. Rice Holmes, *Ancient Britain and the Invasions of Julius Cæsar* (Oxford, 1908), and "Last Words on Portus Itius," in *The Classical Review*, vol. xxiii (London, 1909); the latter article corrects and supplements the earlier discussion.

ITO, ē'tō, HIROBUMI, MARQUIS (1841-1909). A Japanese statesman, born in the Province of Choshu. Under the patronage of the progressive daimyo Mori, he, with Inouye (q.v.) and others, eluded the vigilance of the Yeddo spies and in 1861 reached England, where they spent two years as students, but hurried home to dissuade the Choshu officers from war with the combined fleet of British, United States, Dutch, and French men-of-war at Shimonoseki (1864). Though unable to prevent hostilities, he assisted in the negotiations which followed, and helped to open the eyes and set the faces of his beaten clansmen to a new goal, the unity of all Japan under the Mikado, with enlarged powers and with new forms of civilization patterned after Western models. In 1871 he studied the coinage system of the United States, and his report resulted in the adoption of a decimal system of money and the establishment of the mint at Osaka. As one of the vice ambassadors, he accompanied Iwákura (q.v.) round the world in 1872, in an effort to obtain from the Powers some modification of the treaties. He was made Minister of the Interior in 1878, and in 1882 visited Europe and the United States for the purpose of familiarizing himself with representative institutions preliminary to the establishment of a parliamentary régime in Japan. In 1885 the cabinet was reconstructed according to modern ideas, and in 1886 Ito became Min-

ister President of State and carried out radical economic reforms. In 1888 he retired to prepare the long-promised written constitution, and on Feb. 11, 1889 (the anniversary of Jimmu Tenno), this magnificent instrument, more liberal in its provisions than some European governments allow, was promulgated. Ito is well called "The Father of the Constitution," and his volume of *Commentaries*, in illustration and defense of Japan's fundamental law, is worthy to rank with the *Federalist*. As Premier, he carried the nation through the Chino-Japanese War of 1894-95, and, on resigning in favor of the Yamagata régime in 1896, was created Marquis. He was again Premier from January to June, 1898, and from October, 1900, to June, 1901, and in the last year traveled in Europe and the United States, receiving the degree of LL.D. from Yale University. In St. Petersburg he is believed to have labored for an understanding with Russia and, failing, set on foot negotiations which resulted in the alliance with Great Britain in 1902. In 1903 he became President of the Privy Council. After the outbreak of the Russo-Japanese War he went to Korea as special adviser to the Emperor in accordance with the treaty of alliance between the two countries concluded Feb. 23, 1904. During the progress of the war the advice of Marquis Ito was largely effective in shaping the course of diplomatic events. To his influence was generally attributed the action of the government in concluding peace at Portsmouth on terms profoundly distasteful to the great mass of the Japanese nation. In November, 1905, he negotiated with Korea a convention by which the foreign affairs of that country were placed under the control of a Japanese resident general, receiving the appointment in 1906. On Oct. 26, 1909, he was assassinated by a Korean at Harbin. Consult: J. W. Foster, "Marquis Ito, the Japanese Statesman," in *International Quarterly*, vol. ix (New York, 1904); G. T. Ladd, *In Korea with Marquis Ito* (ib., 1908); J. H. Longford, "Reminiscences of Prince Ito," in *National Review*, vol. liv (London, 1909); K. Nakamura, *Prince Ito, the Man and Statesman* (New York, 1910).

ITO, YUKO (or SUKENORI), COUNT (1843-1914). A Japanese naval officer, born in Satsuma Province. He studied at the Kaisei Naval College in Tokyo and entered the Imperial navy in 1868. In the civil war of 1877 he commanded the *Nisshin*. He was promoted captain in 1882, rear admiral in command of the standing squadron in 1886, and vice admiral and chief of the Yokosuka naval station in 1892. In the war with China, as commander in chief of the combined squadron, he fought the battle of the Yalu. He was made Viscount in 1895 and Count in 1907, having been chief of the naval general staff from 1895 through the war with Russia and being appointed fleet admiral in 1905.

ITONAMAN, ē'tō-nä'man. A stock of north-east Bolivia, South America. Consult Chamberlain, in *Journal de la Société des Americanistes de Paris*, vol. vii (n. s., Paris, 1910).

ITRI, ē'trê. A town in the Province of Caserta, Italy, 90 miles southeast of Rome, about 6 miles northwest of Formia. It has a ruined castle and houses built from the masonry of the ancient Via Appia. It was the native place of Fra Diavolo, whose history is echoed in Auber's opera and in Washington Irving's *The*

Inn of Terracina. Cicero was murdered near Itri, and a large tower on the outskirts of the town is supposed to be his tomb. Pop. (commune), 1901, 5797; 1911, 6077. Consult Baedeker, *Southern Italy and Sicily* (16th Eng. ed., Leipzig, 1912).

I-TSING, ē'tsing', or YI TSING (635-713 A.D.). One of the three great Chinese Buddhist travelers in India. The names of the other two were Fa-Hien and Hiuen Tshang (see HWEI-SANG). I-Tsing was born in the year 635 at Fan-Yang, near Peking, and he became a devoted follower of the Buddhist religion. In 671 he went on a pilgrimage to India in order to journey through the holy land of Buddhism, and he spent nearly 25 years visiting scenes connected with Buddha's life, at the same time collecting texts and material relating to the faith. He returned to China in 695 and devoted the remainder of his life to translating, in more than 100 volumes, the treatises and books which he had gathered. In this way he became the founder of a school for the study of Buddhist literature in China. His work is of special importance also as a record and description of India and the Malay Archipelago at the time when he lived. His death occurred in 713. His account of India has been translated by J. Takakusu, *A Record of the Buddhist Religion as Practiced in India and the Malay Archipelago* (Oxford, 1896). Another work giving an account of the travels in India of 60 Chinese pilgrims of the seventh century B.C., was published by Chavannes, *Les religieux éminents qui allèrent chercher la loi dans les pays d'occident* (Paris, 1894).

ITSUKUSHIMA, it'su-kush'ê-mâ. See MIYAJIMA.

ITÚ, ê-tōō'. A town in the State of São Paulo, Brazil, situated in a fertile region on the Tieté River. It has a Franciscan monastery, a hospital, iron and bronze foundries, cotton manufactures, and a trade in coffee; it is one of the most important industrial centres of Brazil. Pop., 11,000.

ITUCALEAN, ê-tōō'kâ-lâ'an. A stock on Rio Chambera, Ecuador and Brazil, South America. Consult Chamberlain, in *Journal de la Société des Americanistes de Paris*, vol. vii (n. s., Paris, 1910), and Beuchat and Rivet, in *Zeitschrift für Ethnologie* (Berlin, 1909); the latter suggest that the Itucalé may be Panoan.

ITURÆA (it'û-rê'à) **AND THE ITURÆANS**, it'û-rê'anz. A border people and district between Syria and Arabia, referred to frequently by classical writers, by ancient historians, and mentioned once in the New Testament (Luke iii. 1). The people doubtless go back to Jetur, one of the sons of Ishmael (Gen. xxv. 15; cf. 1 Chron. i. 31, v. 19). Because of their seminomadic character they had for a long time no permanent region of abode, so that it is not until the fourth century of the Christian era that we find any reference to a specific district, *Ituræa*—Luke's phrase (iii. 1) describing an undefined border region, partly Ituræan and partly Trachonitic, as in Acts xvi. 6. At the same time these people moved within a somewhat defined territory, located in the Anti-Lebanon country, with Chalcis as their capital—a territory which in 105 B.C. spread southward to the borders of Galilee and doubtless southeastward towards Trachonitis, as indicated in the Lukan phrase (iii. 1). They were Arabians, whose old home was to the northwest of

Medina, but who at a very early period moved northward in search of new quarters. Some time before the exile they came in conflict with Israelites east of the Jordan. In the second century B.C. Aristobulus I, King of Judæa, conquered some of their bands and annexed their territory to Judæa. Their first-known ruler was Ptolemy, son of Mennæus (c.88-40 B.C.). He controlled the valley between the Lebanons, and his influence extended nearly to Damascus. Later he was conquered by Pompey, from whom he secured immunity by a payment of 1000 talents. In 40 B.C. he was succeeded by his son, Lysanias, whom Mark Antony confirmed in his position, but afterward (36 B.C.), at Cleopatra's instigation, put to death, and gave his dominions to the cruel and covetous Queen. The extensive domain was leased to Zenodorus, as tetrarch, but, because of his implication in the robber raids of Trachonitis, a part of his tetrarchy was taken from him and given to Herod, a grandson of Herod the Great. Another portion, with its capital at Abila (see ABILENE), was placed under the rule of the Lysanias mentioned in Luke iii. 1. On the death of Zenodorus (20 B.C.) what remained of his domain was added to Herod's kingdom. At Herod's death (4 B.C.) it fell to his son Philip (Josephus, *Ant.*, xv, 10, 3), who is called by Luke (iii. 1) tetrarch of the Ituræan and Trachonitic region. Philip held this region until his death in 34 A.D. In 37 A.D. Caligula gave the two tetrarchies to Agrippa I, with the title of King. Agrippa was confirmed in this possession by Claudius (41 A.D.) and secured from him in addition the entire kingdom of his grandfather Herod. On Agrippa's death (44 A.D.) his dominion was incorporated into the Roman Province of Syria. The Ituræans were warlike, famed as archers, and from the days of Cæsar many of them served in the Roman armies. Cicero accused Mark Antony of seeking to terrify the Senate with his Ituræan guards (*Philippics*, ii, 19, 112; xiii, 18), and cohorts of Ituræan troops are frequently mentioned in the inscriptions of the first and second centuries. Consult Schürer, *History of the Jewish People in the Time of Jesus Christ*, vol. i (New York, 1896), and G. A. Smith, *Historical Geography of the Holy Land* (11th ed., ib., 1904).

ITÚRBIDE, ê-tōōr'bê-dâ, AGUSTÍN DE (1783-1824). Emperor of Mexico. He was the son of a nobleman of Navarre, who emigrated to New Spain shortly before the birth of his son, who was born at Valladolid (since 1828 known as Morelia), Sept. 27, 1783. Don Agustín entered the army in 1798 and during the insurrection of 1810 fought for the Spanish cause. He was advanced to the position of commander in chief of the provinces of Guanajuato and Michoacan in 1815, but this post was soon taken away from him.

From 1816 to 1820 Itúrbide was out of the military service. When in this latter year, and by order of the Cortes, the constitution of 1812 was proclaimed, the Viceroy gave him command of the Spanish Army of the South, with orders to proclaim the absolute power of Ferdinand VII; but Itúrbide began a series of intrigues with the revolutionary leaders, which culminated in his proclamation of Feb. 24, 1821, the so-called Plan of Iguala, wherein complete independence of Spain under a prince of the royal family was offered to the people. This plan rapidly gained adherents. From a small

force of some 2500 men, with which he had left Mexico in November, 1820, his army had increased, by the spring of 1821, to 6000. He gained possession of Vera Cruz and Puebla, and on September 21 entered the city of Mexico at the head of 16,000 men. The Viceroy signed a treaty with the insurgents, providing for the adoption of the Plan of Iguala, and stipulating, in addition, that in case of the refusal of the princes of the royal family to occupy such a position, the Mexicans should choose an emperor for themselves. A regency was formed, with Itúrbide at its head, and he was at the same time appointed commander in chief of the army. A national congress was convened at Mexico. The new government avoided harsh measures and succeeded in establishing peace, but dissensions broke out in the regency, the troops became clamorous for pay, and the congress refused to meet their wishes. Itúrbide turned to the monarchical party and was by them proclaimed Emperor on May 18, 1822. He was crowned, with the title of Agustín I, July 21, 1822. Harsh measures of repression led to open rebellion. On Dec. 2, 1822, Santa Anna, colonel of a regiment stationed at Vera Cruz, declared for a republic, and his example was followed by Guerrero and Bravo in the south. Itúrbide saw himself deserted by those in whom he had placed most confidence, and sought to make his peace with the country by summoning the congress which he had shortly before dissolved. His influence, however, had disappeared, and in March, 1823, Itúrbide offered his abdication to the congress. He received a pension of \$25,000 and was ordered to reside in Italy. He accordingly left Mexico, spent the next year in Italy and England, and in May, 1824, sailed for Mexico from London, unaware that the Republican government had outlawed him, and led by the representations of his partisans to believe that Mexico would rise in arms to welcome him. He landed at Soto la Marina, July 14, but was immediately arrested, taken before the provincial congress of Tamaulipas, condemned as a traitor by that body, and shot in the public square of the town of Padilla, July 19. The Mexican government provided a pension for his wife, who resided for a number of years in Philadelphia, died there, and was buried in St. John's (R. C.) Church. His grandson, Agustín, was adopted by the Emperor Maximilian as his heir in 1864. Consult, for a full account of Itúrbide, with descriptive lists of authorities cited, H. H. Bancroft, *History of Mexico*, vol. iv (San Francisco, 1890); Agustín de Itúrbide, *Statement of Some of the Principal Events in the Public Life of Agustín de Itúrbide*, translated by M. J. Quin (London, 1824; Fr. trans. by J. T. Parisot, Paris, 1824); C. M. de Bustamente, *Historia del Emperador Itúrbide hasta su muerte, y sus consecuencias, y establecimiento de la República Federal* (Mexico, 1846). See MEXICO.

ITURUP, ē'tu-rōōp'. An island of Japan. See ETOROFU.

I'TYS (Lat., from Gk. Ἴτυς). In classical mythology, the son of Tereus and Procne, killed by his mother and served in a dish to his father. See PHILOMELA.

ITZÁ, ê-tzá'. An important people of Mayan stock, occupying the country about Lake Petén, in northern Guatemala. Their dialect is the Maya proper. The ruined city of Chichén-Itzá (q.v.) in Yucatan takes its name from them, and, according to their own tradition, they re-

moved thence on the breaking up of the Maya kingdom about 1420 and built a new city on an island in the lake. They were visited by Cortés in 1525, but maintained their independence until 1697, when their country was invaded by the Spaniards under Ursua, who stormed their island capital, slaughtering or driving into the lake great numbers of their people, and razing to the ground the 21 temples on the island. Among other spoils taken from the house of the King was a library of sacred books, written in hieroglyphics upon bark fibre, and containing their historical traditions, calendars, and rituals, all of which were probably destroyed by the conquerors. The earlier history of the Itzá is closely woven into that of the great Maya civilization. The Maya chronicles, called Books of Chilán Balam, relate to them more than to any other tribe and carry their records back into the fifth century A.D.

ITZAMNÁ, it'sám-ná'. The mythic culture hero of the Maya of Yucatan, who, according to their traditions, ruled over them as King at an early period, building cities, devising a code of laws, and inventing their calendar and hieroglyphic system. He was also claimed as a teacher of agriculture, a miraculous healer, and the ruler of the winds and rains. His shrine at Izamal was a noted resort of pilgrims throughout the whole territory occupied by the tribes of Mayan stock. From the fact that he is said to have come from the East, and from an analysis of his various titles, among which are Lord of the Eye of the Day, Lord of the Wheel of the Months, etc., some scholars conclude that Itzamná is a personification of light. In the objective studies which have been made on Maya manuscripts and sculptures there is a very important god who appears in the guise of a benevolent old man and who is called God D, or the Roman-nosed God. This is probably to be identified as Itzamná, whereas the equally important Long-nosed God may be Kukulcan. Consult Shellhas, "Representation of Deities of the Maya Manuscripts," in *Papers of Peabody Museum*, iv, no. 1 (Cambridge, Mass., 1904), and Spinden, "Maya Art," in *Memoirs of Peabody Museum*, vi (ib., 1913).

ITZCOATL, ē't'skō-ä't'l, **IZCOHUATL**, ēs'kō-wä't'l, or **IZIOCATL**, ē'sē-ō-kä't'l (?-1440). First Emperor of the Aztecs. He began to reign in 1427 and joined with the princes of Acolhua and Tlatelulca in an attempt to throw off the yoke of Maxtla, Emperor of Tepanec. They succeeded after a campaign of nearly four months and captured the tyrant, of whom they made a sacrifice. Itzcoatl afterward did much for the mental and material improvement of his own state and people. Consult H. H. Bancroft, *Native Races*, vol. v (San Francisco, 1882).

ITZEHOE, it'se-hō. A town in the Province of Schleswig-Holstein, Prussia, situated on the Stör, 32 miles northwest of Hamburg (Map: Prussia, C 2). It contains a twelfth-century church, a Rathaus dating from 1695, a memorial to Kaiser Wilhelm I, and a home for the aged, founded in 1240. There are manufactures of sugar, nets, Portland cement, soap, carpets, textiles, dyestuffs, machinery, iron, chicory, and cigars; it also builds ships. There is an extensive trade in cereals, cattle, lumber, and wine. Pop., 1900, 15,649; 1910, 16,547. Itzehoe, the oldest city of Holstein, had its origin in a castle erected in 809 during the reign of Charlemagne as a barrier against the Danes. The

town received Lübeck rights in 1238 and was the residence of the counts of Holstein.

IUKA, i-ū'kā. A city and the county seat of Tishomingo Co., Miss., 114 miles east by south of Memphis, Tenn., on the Southern Railroad (Map: Mississippi, J 1). It is known for its mineral springs and has a coeducational normal institute. There are some lumbering interests. The electric-light plant is owned by the city. Pop., 1900, 882; 1910, 1221.

On Sept. 19, 1862, during the Civil War, it was the scene of a battle between a Federal force of about 10,000 under General Rosecrans and a Confederate force of about 12,000 under General Price, the latter retreating during the night, though neither side gained any decisive advantage. The Federal loss in killed, wounded, and missing was between 700 and 800, and the Confederate loss was about the same.

IU'LUS, i-ū'lūs. The son of Æneas, later called Ascanius. (Consult Vergil, *Æneid*, bk. i.) According to some, the son of Ascanius also bore the name of Iulus. See ASCANIUS.

IVAN, *Russ. pron. ē'van'* (Russ., John). The name of a number of Russian grand dukes and czars, of whom the most notable were the first, third, and fourth.

IVAN I KALITA (?-1341) laid the foundations of the Muscovite Kingdom. Though one of the younger princes by birth, he obtained through extreme subserviency to the Tatars the title of Grand Prince (1328). His influence was still more strengthened when he was appointed by the Khan collector of the Tatar vikhod (tax) for all the principalities of Russia. In this capacity he became practically the Khan's plenipotentiary in his relations to the Russian princes, and he made use of his position to weaken his antagonists. He also managed to accumulate great wealth (hence his nickname Kalita, i.e., bag of money). He extended considerably the limits of his originally small principality by the purchase of land, villages, and even of entire town districts (like Bieloe, Ozero, Galitch, etc.), as well as by conquest and diplomatic negotiations. His high position with the Tatars helped him to accelerate this process and to raise Moscow from the position of an obscure village to that of the leading city of Russia. The *Chronicle* calls him "the first to knit the Russian soil together" and particularly praises him for having stopped the Tatar raids and thus having brought peace to the land. He was also strong enough to "rid the country of robbers" and to secure public safety. The introduction into Russia of the Byzantine criminal code and of agrarian laws (the "Law of Landowners") is also attributed to Ivan Kalita. One of his achievements was the transference of the seat of the Metropolitan to Moscow (in 1326), which made it the religious as well as the political centre of Russia. This act greatly increased the prestige of the Moscow government, whose acts henceforth seemed to be sanctioned by the chief religious authority of the country.

IVAN III THE GREAT (1440-1505) was coruler of his father Vasili the Dark and succeeded him as Grand Prince in 1462. He successfully continued the policy of his predecessors which aimed to unite all Russia under the leadership of Moscow and to strengthen the power of the princely dynasty. He suppressed the appanage principalities and the democratic commonwealths, threw off the Tatar yoke, abolished the

privileges of the boyars (see BOYAR), and entered into a long struggle with Lithuania in order to regain some of the Russian districts which had joined the latter country. The free city of Novgorod had already been devastated by Ivan's father and predecessor Vasili, who had exacted from the city 15,000 rubles and an oath of loyalty to Moscow. To find protection against Muscovite oppression, the leading political party of Novgorod had sought the help of Lithuania. A treaty was concluded in 1471 with the Lithuanian King, Kasimir, which secured for Novgorod all its former privileges and liberties under the protection of a Lithuanian viceroy. Ivan III grasped this opportunity to declare the people of Novgorod strangers and traitors to "orthodoxy," and in two punitive expeditions of 1475 and 1477 he conquered Novgorod and annexed it to Moscow. The democratic institutions of the ancient free city were abolished, thousands of its best families were transported into the interior parts of Muscovy, and Muscovites were settled in Novgorod. With its freedom Novgorod also lost its commercial significance. The independent princes of Yaroslav and Rostov voluntarily joined Moscow, while Iver and Viatka were conquered by force of arms in 1485 and 1489. The people of the minor principalities at this period often desired union with Moscow, and the territorial extension began to assume a national and religious character. In 1480 submission to the Golden Horde (q.v.) was completely cast off, though it had been but nominal for some time; somewhat later the once terrible Golden Horde was demolished by the Crimean Khan (1502). The wars with Lithuania (1492-94 and 1500-03) resulted in the annexation to Russia of the cities of Chernigov, Rilsk, and Starodub in the ancient Russian territories of Smolensk and Sieversk. This territorial extension brought Muscovite Russia face to face with Poland and western Europe. The external relations of the country, hitherto confined within the circle of the various principalities of Russia, developed now into important diplomatic relations with western Europe—with Poland, Lithuania, Sweden, the Teutonic and Livonian Order of Knights, the Emperor of Germany, the Pope, etc. The forcible and successful foreign policy resulted in the strengthening of the idea of national unity under the leadership of an absolute monarch. The second marriage of Ivan III with Sophia Paleologue, niece of the last Byzantine Emperor, in 1492, favored the growth of these ideas. Sophia never gave up her title of Byzantine Princess, transferred her prestige to Moscow, sharing it with her husband, and "taught him to penetrate the secrets of autocracy." From this time on, the double eagle took its place in the Russian arms and Russia claimed to be the legitimate successor of Constantinople as head of the Empire and Greek church. Ivan's full title now read: "Ivan, by the Grace of God, Emperor of all Russia, Grand Duke of Vladimir and Moscow and Novgorod and Pskov and Tver and Perm and Urga and Bolgari and the rest." Ivan took great interest in internal improvements. In 1497 he issued the *Sudebnik* (q.v.), a uniform code of laws for the country which laid down definite rules of judicial procedure. He invited also artists and craftsmen from Italy to encourage Russian industry and art and embellished Moscow with buildings, the most famous of which is the Uspensky Sobor

(cathedral of Assumption). Ivan III died in 1505 and left to his eldest son and successor, Vasili, 67 of his towns and districts and but 30 to all his other sons. In his will Ivan set forth a new rule of succession according to which the domains of all his kinsfolk after their death were to pass directly to the reigning grand duke instead of reverting, as before, to the prince's heirs.

IVAN IV THE TERRIBLE (1530-84), son of Vasili, was born in 1530 and was three years of age when his father died, his mother, Elena Glinski, being left as Regent. The government fell into the hands of the turbulent boyars and passed from the hands of one notable family of boyars to those of another. This gave rise to struggles which were marked by atrocities and numerous executions. These impressions of his youth and his "wretched" education turned Ivan into a dissolute, unbalanced, and cruel man, who was however swayed from time to time by good and noble impulses. These circumstances and his education were also responsible for his hate of the boyars. The Archbishop Macarius, author of the famous *Chetee Minei* (Lives of the Saints), was the only enlightened man near Ivan. He inspired Ivan with love for reading, developed his intellect, suggested to him the idea of Moscow being the third Rome, and encouraged him in his ambition to raise the Grand Duchy to an "Orthodox Czardom." Ivan had hardly reached his majority when he declared his desire to marry and to be coronated as Czar (q.v.). The solemn act was performed in 1547; the same year he married Anastasia of the house of Romanov (q.v.). The great fire of Moscow and the ensuing revolt of the people "brought fear into Ivan's soul"; he took new councilors, chief among whom were a priest Silvester, a nobleman Adashev, and several notable princes, as Kurbsky, Vorotinsky, etc. By this "chosen council" the government was directed for 13 years, which form the first successful and happy period of the reign of Ivan IV. In 1550 the first Zemski Sobor (q.v.), or National Assembly, was summoned. The Sobor considered and sanctioned a new and improved code of laws. In 1551 an Ecclesiastical Sobor codified the rules of church administration and of religious life in general in a book of 100 chapters. As a result of these Sobors, local self-government and administration were radically reformed and developed. In 1552 Kazan was conquered, and in 1556 the conquest of Astrakhan followed. The subjugation of these Tatar Khanates secured peace for the eastern frontier of Muscovy and opened up the gates to the east beyond the Ural Mountains by way of the rivers Kama and Viatka. In 1560 the young wife of Ivan died and Silvester, Adashev, and his "chosen councilors" lost their influence on the Czar; some of them were exiled or imprisoned, others entered the service of Lithuania. Ivan began a life and death struggle against the boyars. In 1564 the Czar left Moscow for the suburb Alexandrovo, and in 1565 he addressed to the capital two gramotas (letters, edicts)—one to the clergy and boyars, and the other to the "Orthodox Christians" of Moscow City. In his first gramota the Czar enumerated "the treasons of the boyars, the voyevodas (chiefs of town districts) and of all prikaznikh (officials)." In his second gramota, which was read in the public forum, Ivan thanked the people for their loyalty. The ap-

peal to the people had its effect: a deputation of Muscovites, headed by the clergy, succeeded in gaining Ivan's consent to return to Moscow, on the condition, however, that he should be free to deal with his enemies as he saw fit, and to establish an oprichnina, a sort of separate estate for himself and his household administered by his bodyguard, or oprichniki. With the oprichnina well organized the Czar began his campaign of making the boyars "harmless." One by one he subjected to the jurisdiction of the oprichnina the cities and districts which were situated in the territories of the former udiels (appanages), transferring the descendants of the princely families to the borderlands, where there were no appanage traditions. Their hereditary estates were distributed among his favorites and loyal bodyguards, who thus became landowners. For nearly 20 years, to his very death, Ivan continued this policy, reducing nearly half of the country to the status of oprichnina. The other half, called, in distinction of the oprichnina, zemchina, continued to be governed as formerly by the Boyarskaya Duma (council of boyars). The oprichnina accomplished the task of humiliating the ancient nobility of princely origin and of reducing them to the status of "men of service." The process was accompanied by many cruelties, which gained for Ivan the sobriquet "Terrible." The oprichnina strengthened absolutist tendencies, but it weakened the country and may be held responsible for the disastrous end of the wars with Lithuania and Sweden. The subjugation of Kazan and Astrakhan by the Russians brought Russia into contact with the Sultan of Turkey, who repeatedly demanded the return of the Khanates. In 1571 the Crimean Khan, a vassal of Turkey, entered and burned Moscow. But when the Tatars appeared the following year near the river Oka, they suffered a terrible defeat. These events, however, led the Russian government to consider the defense of its southern frontier. Heretofore the southern frontier of Muscovy had been along the middle Oka. During the reign of Ivan many Russians settled beyond the Oka on the "ukraina" (border), or in the "wild field." These colonists were known as "free Cossacks"; they did not recognize any governmental authorities, except their own elected atamans (chiefs). In 1571 the Muscovite government began to settle her own colonists and to fortify the "wild field." Towards the end of the sixteenth century the entire field to the rivers Vorskla and northern Donetz was dotted with towns and fortresses and became an integral part of Muscovy. This secured protection against Tatar raids and opened the way for the colonization of the rich black-soil territory of modern middle Russia. The "free Cossacks," however, to avoid submission to Muscovite authorities, left these places and settled in the country at the mouth of the river Don, where they gave rise to the Cossacks of the Don. (See COSSACKS.) The decline of Novgorod made it necessary for Russia to have a port on the Baltic Sea. The Knights of Livonia handicapped the commercial and industrial development of Russia by prohibiting Russian merchants from passing through their territory and preventing foreign merchants, artisans, and artists from going to Russia. In 1558 Ivan began a war with Livonia. To avoid annexation to Muscovy, Livonia divided and in separate parts joined Sweden, Lithuania, and Poland (1560-

61). In 1576 Stephen Bathory was elected to the Polish-Lithuanian throne and defeated the Muscovites several times. In 1581 peace was concluded through the mediation of the papal emissary, Possevin. Ivan had to give up all his claims in Livonia and to return to Lithuania all the territory formerly conquered by his armies. In 1583 a treaty was made with Sweden according to which Russia had to give up several cities (Yam, Koporie, and Korelu). Two other important events took place during the reign of Ivan IV. In 1553 an English expedition, headed by Chensler, seeking a northwest passage through the Arctic Ocean, made its appearance at the mouth of the northern Dvina. Chensler found his way to Moscow, was favorably received, and returned two years later as the first English Envoy to Russia. In 1584 the city of Archangel was built, and commercial relations with England were entered into. The other important historical event was the beginning (1582) of the conquest of Siberia (q.v.) by Yermak.

Some historians, like Professors Chistowitz and Kovaleoski, find in Ivan the Terrible signs of insanity. In a fit of fury he killed his eldest son, Ivan (1580). Ivan was married seven times. He died in 1584, leaving only two young sons. Consult Kazimierz Waliozewski, *Ivan the Terrible* (Philadelphia, 1904), containing a bibliography, and A. S. Rappoport, *Mad Majesties, or Raving Rulers and Submissive Subjects* (London, 1910).

IVANGOROD, ê-vân'gô-rôt. A fortified town at the confluence of the Wieprez with the Vistula in the Province of Sedle, Russian Poland, about 60 miles southeast of Warsaw (Map: Russia, B 4). With Warsaw, Novo-Georgievsh, and Brest-Litovsk, it forms the important Polish "quadrilateral." Pop., 1912 (est.), 5500. Ivangorod was the high-water mark reached by the Germans during their first drive on Warsaw in the European War which broke out in 1914. Here the Russians stopped the combined Austro-German offensive movement, compelling them gradually to retire from Russian Poland. See **WAR IN EUROPE**.

I'VANHOE. A novel by Sir Walter Scott (1819) and the name of the hero.

IVAN IVANOVITCH, ê-vân' ê-vâ'nô-vîch (Russ., John Johnson). See **NATIONAL NICKNAMES**.

IVANOVO-VOZNESENSK, ê-vâ'nô-vô vâz'-nyë-syënsk'. A manufacturing town of Russia, in the Government of Vladimir, situated on the river Uvod, 25 miles by rail north of Vladimir (Map: Russia, F 3). It consists of the village of Ivanovo on the right bank of the river and Voznesensk on the left bank, incorporated in 1871 as the town of Ivanovo-Voznesensk. It is the second important centre of the Russian cotton manufacture, which gives employment to a great part of the inhabitants, not only of the town, but also of the surrounding district. There are also large cotton-printing and chemical establishments in the town, as well as large ironworks both in the suburbs and in the town. Ivanovo-Voznesensk is connected by a branch line with the Moscow and Nizhni Novgorod Railway. Pop., 1897, 53,900; 1912, 167,726.

IVARA. See **JUVARA**, **FILIPPO**.

IVERACH, ê've-râk, JAMES (1839-). A Scottish philosopher and theologian, born in Caithness. He was educated in Edinburgh at the University and New College; was ordained

minister of the United Free Church at West Calder in 1869; was minister at Ferryhill, Aberdeen, from 1874 to 1887; and in the United Free Church College at Aberdeen was professor of apologetics from 1887 to 1907, then professor of New Testament language and literature, and principal after 1905. Iverach was moderator of the United Free church in 1912-13. He contributed many articles to the *Spectator* and published: *Evolution and Christianity* (1884), *Life and Times of St. Paul* (1890), *The Truth of Christianity* (1895), *Theism in the Light of Present Science and Philosophy* (1899), *Descartes, Spinoza, and the New Philosophy* (1904).

IVER'NA. See **HIBERNIA**.

IVES, ivz, FREDERIC EUGENE (1856-). An American inventor, born at Litchfield, Conn. In 1874-78 he had charge of the photographic laboratory at Cornell University. He did much pioneer work in developing photographic processes, with special reference to orthochromatic and trichromatic photography and to photo-engraving. Among many devices invented by Ives is the parallax stereogram. He received the Cresson and Scott Legacy medals of the Franklin Institute, Philadelphia, the Progress and Science medals of the Royal Photographic Society, London, and the Rumford medal of the American Academy of Arts and Sciences.

IVES, HALSEY COOLEY (1846-1911). An American artist and museum director, born at Montour Falls, N. Y., and trained at South Kensington, London, and under Piatowski. He had charge of the Art Department at the Chicago World's Fair in 1893, and in 1904 of the corresponding department at the St. Louis Exposition, where he received a grand prize for services to art education. He several times represented the United States government as a commissioner abroad with reference to art matters. In 1896 he became director of the Museum and School of Fine Arts at St. Louis.

IVES, LEVI SILLIMAN (1797-1867). An American theologian. He was born at Meriden, Conn.; was brought up on his father's farm in Turin, N. Y.; served during the first year of the War of 1812 and studied at Hamilton College; but in 1819 left the Presbyterian for the Episcopal church, and after study in New York was ordained in 1823. He preached at Trinity Church, Philadelphia, from 1823 to 1827; at Christ Church, Lancaster, Pa., in 1827; and in Christ Church, New York, until 1831, when he became Bishop of North Carolina. There his Tractarian views brought him into trouble; he recanted, but again embraced them, and was declared deposed by his act of submission to the Pope in 1852. His apologia, *The Trials of a Mind in its Progress to Catholicism*, was published in 1854. Ives spent his last years as a professor in St. Joseph's Seminary.

ÍVIZA, or **ÍBIZA**, ê'bê-thâ. The larger of the two Pityusæ Isles of the Balearic group, belonging to Spain (Map: Spain, F 3). It is situated about 60 miles from the mainland and 56 miles southwest of the island of Majorca. Area, about 230 square miles. The island is mountainous and well wooded, with fertile valleys. The principal industry is the production of salt by the evaporation of sea water led into large shallow lagoons. Pop., 1900, 23,556; 1910, 24,608. The chief town, Iviza, on the southeast coast, has a fair harbor and a large trade in salt. Pop., 1900, 6327; 1910, 6225.

IVO OF CHARTRES, shâr'tr', SAINT (c.1040-

1116.) A mediæval Churchman, Bishop of Chartres, sometimes called Yvo Carnotensis. He was born in Beauvais, studied at Bec, where he was a companion of Anselm, rose to the provostship of the canonry of Saint-Quentin in Beauvais, and in 1090 was consecrated Bishop of Chartres by Pope Urban II. Ivo is one of the heroic figures in French mediæval history; appearing now as the dauntless opponent of royal injustice and now as the determined foe to clerical wrongdoing. He figures in the investiture controversy of his time as one of the mediating and mollifying forces, endeavoring to see that both church and state were properly treated. (See INVESTITURE.) He compiled a collection of canon law which is one of the most important precedents to Gratian's, edited by Fournier (Chartres, 1896-97). His letters are one of the sources for the history of his time; a French translation, edited by Merlet, was published at Chartres, 1885. His works are in J. P. Migne, *Patrologia Latina*, vols. clxi, clxii (Paris, 1854-55).

IVORY (OF. *ivurie*, *ivoire*, Fr. *ivoire*, It. *avario*, ML. *ebureum*, from Lat. *ebur*, ivory, from Egypt, *ābū*, *āb*, Copt. *ebou*, *ebu*, elephant). The name formerly given to the main substance of the teeth of all animals, but it is now restricted to that modification of *dentine*, or tooth substance, which in transverse sections shows lines of different colors running in circular arcs and forming by their decussation minute lozenge-shaped spaces. By this character, which is represented by every portion of any transverse section of an elephant's tusk, true ivory may be distinguished from every other kind of tooth substance and from every counterfeit, whether derived from tooth or bone. Although no other teeth, except those of the elephant, present this characteristic, many other animals, such as the walrus, narwhal, and hippopotamus, possess teeth, horns, or tusks which, from their large size and from their density, can be used for the same purpose in the arts as those for which true ivory is employed. In the case of the elephant the tusk is formed by the prolongation of the upper incisor, while the tusk of the hippopotamus and other animals is a prolonged canine. Perhaps with the ancients "ivory" was used in the broader sense, for Pliny tells us that in Ethiopia ivory was so plentiful that it was used for doorposts, fences, and cattle stalls. The ivory of the tusks of the African elephant is held in the highest estimation by the manufacturer, on account of its greater density and whiteness. The tusks are yellow or brown on the outside, but inside are snowy white. The tusks are of all sizes from a few ounces in weight to more than 100 pounds each. Russia, and especially Siberia, obtains large quantities of ivory from the tusks of fossil elephants. This product, called fossil ivory, is composed of calcium phosphate, 64; organic matter, 24; water, 11.15; calcium carbonate, 0.10. There are various chemical processes by which it may be dyed various colors, as black, blue, green, yellow, red, and violet. Ivory articles can be made flexible and semitransparent by immersion in a solution of phosphoric acid of specific gravity 1.130, till they become translucent. They are then to be taken out, washed with water, and dried with a soft cloth, when they are found to be as flexible as leather. They harden on exposure to dry air, but resume their pliancy when immersed in hot water. The opac-

ity and elasticity of old ivory may sometimes be restored by boiling it in gelatin, but no satisfactory method for restoring its whiteness has yet been discovered.

The tusks of the elephant have from very early periods constituted an important article of trade, in consequence of their great beauty as a material for ornamental manufactures and even works of fine art. Ivory is frequently mentioned in the Old Testament. Solomon had a throne of ivory and gold. The Egyptians and Assyrians made much use of this material in ornamental work. With the Greeks it became a most important material, and by the hands of the sculptor Phidias a statue was produced of the Olympian Jupiter of such marvelous beauty and imposing majesty that it was considered a misfortune to die without having seen it. The pupils of Phidias made many of these colossal images (chryselephantine statues), the bodies being in ivory and the drapery in gold. It was also extensively used by the Romans, who were supplied from Africa, and by them its use was diffused over the whole of Europe. In fact it was through the consular diptychs or carved ivory tablets, joined by hinges, containing within a wax record on which are inscribed official names and portraits, that the traditions of classical art were passed along to more barbarous times, while later they figured in Christian art as covers of missals and reliquaries.

During the Renaissance ivory was much used for inlaid work in furniture, and the art of carving it was brought to a high state of skill. Caskets, statuettes, mirror cases, chessmen, and many other articles were made of this material. The town of Dieppe in France has had its ivory factories since the fifteenth century. At present the demand for ivory is increasing, owing to the great taste and skill of some of the artists who work in this material, and, as the supply increases but very slowly, it is likely to become very costly. The art of working in ivory doubtless had its origin in India, where it has always been a much valued material. In China and Japan, especially the former country, the decorative value of ivory is highly prized, and infinite care and patience are shown by the Chinese in his carving on this material. Piano keys supply the principal use of ivory, and unless the imitation products were drawn upon, the natural article would not suffice to meet this single demand. Ivory is difficult to cut, requiring the hardest and sharpest tools, but it is easily sawed or filed. Large plates of veneer are obtained by cutting a spiral shaving round the tusks with what is known as a reciprocating saw. It is polished with various powders. Every scrap of material is saved in the manufacture of ivory, the scraps, shavings, and dust being converted into ivory black or artists' pigments.

The tusks of the African elephant furnish at once the greatest and best parts of the ivory of commerce, and for this purpose it is estimated that annually some 70,000 elephants are killed. At the same time there are many old tusks that find their way into commerce. In addition to tusks obtained from killing elephants and those derived from various old supplies, fossil ivory derived from Siberia, China, Alaska, and elsewhere figures prominently, though statistics as to its amount are not available. African tusks sometimes reach a length of 9 feet and weigh 200 pounds or more, one pair from German East Africa weighing 459 pounds and the larger

measuring 10.16 feet in length. The tusks are sold on the basis of weight. Those of the Indian elephant are smaller, averaging under 50 pounds, the largest tusks measuring not over 4 or 5 feet in length outside curve and about 16 inches in circumference at the gum and weighing about 74 pounds.

Prime ivory consists of tusks, each of more than 20 pounds' weight. Scrivelloes are tusks weighing less than 20 pounds each; ball scrivelloes are suitable for the manufacture of billiard balls; bagatelles, not large enough for the production of balls; while the other classes are hollows, cores, and defectives. Walrus teeth, an inferior class of ivory substitute, commands relatively a very low price and is derived in large amounts from Alaska. Tusks of extinct mammoths have been found 12 feet long and weighing 200 pounds. The three great ivory markets of the world are Antwerp, London, and Liverpool, the first named being since 1895 the most important, and the receipts usually exceeding those of London.

On account of the opening of the Congo Free

extermination of the elephant, and at the same time its uses grow, so consequently various substitutes must be employed, such as celluloid and vegetable ivory (qq.v.), the latter being a product of increasing use. The world's production of ivory fluctuates greatly.

Germany is the greatest consumer of ivory and is usually followed by India, where ivory working is considered as a religious rite, in addition to being an important industry carried on in Mysore, Travancore, Burma, in the town of Murshidabad, and in Bengal and Delhi. In 1913 India imported 243,941 pounds of unmanufactured ivory valued at \$663,613, most of it from Africa, as except in Burma this product is preferred to that of India or Ceylon.

Germany imports largely from England, and in 1912, of total imports of 315.7 tons of raw ivory, 102 tons came from England. In the United States a tariff of 20 per cent imposed by the Act of 1913 on raw ivory affected the American industry. Recent imports of ivory by the three countries are indicated in the accompanying tables.

East Indian teeth and scriveloes, per hundredweight (112 pounds), ranged from \$403.91 to \$428.25 for sound tusks weighing on the average 80 pounds and over, to \$194.66 to \$199.52 for soft defective tusks of from 3 to 5 pounds. Egyptian and Malta teeth and scriveloes brought, per hundredweight, \$389.32 to \$408.78 for soft sound tusks of 80 pounds and over, down to \$214.12 for average-weight tusks of from 3 to 5 pounds. Gabun, Congo, Niger, and other West African teeth and scriveloes brought, per hundredweight, for sound tusks averaging 70 pounds or over, \$296.85 to \$330.92, while several tusks averaging from 3 to 5 pounds brought from \$107.06 to \$111.92. Consult Maskell, *Ivories* (New York, 1905). See ELEPHANT; VEGETABLE IVORY.

IVORY, SIR JAMES (1765-1842). A Scottish mathematician, born at Dundee and educated at the University of St. Andrews, where he exhibited special proficiency in mathematics and graduated M.A. in 1784. In 1786, after further study at Edinburgh, he abandoned the theological career for which he was preparing, taught in the Dundee Academy for three years, and from 1789 to 1804 engaged in commercial pursuits as manager and partner of a flax-spinning mill. In his leisure hours, however, he continued his mathematical studies; became known by learned contributions to the Royal Society of Edinburgh; and in 1804 received the appointment of professor of mathematics in the Royal Military College, then at Marlow, Buckinghamshire. He retired in 1819 on a pension which was augmented in 1831, when he was knighted. His essays and memoirs, published from 1796 to 1842, in the *Transactions* of the Royal Societies of Edinburgh and London, evince remarkable and acute analytical power. His resolution of the attractions of ellipsoids, enunciated in 1809, has been known ever since as "Ivory's theorem." In 1814 he received the Copley medal from the Royal Society for "a new method of determining a comet's orbit"; in 1826 the Royal medal for a paper on refractions, which was eulogized by Laplace for its masterly analysis; and again in 1839 the Royal medal for his "Theory of Astronomical Refractions." He was elected to honorary membership in several learned societies of Great Britain and other lands.

IVORY, VEGETABLE. The fruit of a handsome palm, *Phytelephas macrocarpa*, which grows in the Peruvian Andes, on the banks of the river Magdalena, and in other parts of South America. The stem is short and procum-

spadix and have neither calyx nor corolla. The fruit, which is as large as a man's head, consists of six or more four-celled aggregated drupes and contains numerous somewhat triangular nuts as large as a hen's egg. The kernels of

THE IVORY-NUT PALM.

these nuts, called *corrozzo* nuts in commerce, are so hard and white, and resemble ivory so greatly, that the name "vegetable ivory" is particularly applicable. They have of late come into extensive use with turners in the manufacture of buttons, umbrella handles, and small trinkets.

a, NUTS IN HUSK; b, A SHELLED NUT.

The imports into the United States in 1913 were 29,206,278 pounds valued at \$977,525. See also ATTALEA; COQUILLA NUT.

I'VORYBILL'. The great Southern woodpecker (*Campephilus principalis*), now confined to the cypress swamps of the Gulf States and nearly extinct. It is one of the largest of the

tribe and so impressed Linné by its size (length, 20 inches) and grandeur that he called it "prince." Its plumage is glossy black, with the secondaries and shorter primaries pure white, and a white stripe down each side of the neck and along the scapulars, meeting in the middle of the back. The long crest of the male is

HEAD OF IVORYBILL.

scarlet, but that of the female is bluish black; the bill is ivory yellow, straight, and chisel-like, capable of drilling holes in hard wood and reaching the deeply buried grubs upon which it mainly feeds. This fine species was formerly a resident from the Potomac and Ohio rivers southward, and the early ornithologists have much to say of it. Audubon says its food included grapes, and that its nest was a hole, like that of other woodpeckers, dug by the alternate labor of both mates, always in a living tree. He remarks its graceful flight—the bird seems merely to swing itself from the top of one tree to that of another in an elegantly curved line—and describes its notes as clear, loud, yet very plaintive. These birds were never very numerous, since they were constantly killed by the Indians, who valued highly their heads as ornaments and as symbols of dignity and courage. The frontiersmen, with barbaric love of color, copied the custom and adorned their shot pouches and caps with the gaudy crests, and ignorant Southern farmers killed them and all woodpeckers under the mistaken notion that they were destroying the forest trees.

IVORY CARVING. Under this head must be included sculpture in bone, in vegetable, in walrus or narwhal ivory, and in fossil ivory, as well as that carved in the ivory of the elephant. It is therefore the whole subject of delicate and minute ornamental carving, except as done in wood and in fine hard stones. At all ages of artistic development it seems to have been practiced. The earliest specimens, chiefly from the Dordogne in France, are the work of cave dwellers and date from the time when the mammoth and the reindeer roved in southern Europe. They show considerable artistic skill, manifested in a restrained realism and an astonishing comprehension of life and movement.

Ancient Ivories. The earliest Egyptian ivories go back at least to the first and second dynasties (3400–2980 B.C.). In later Egyptian tombs there have been found statuettes, handles of weapons, boxes, and the like, very delicately sculptured; and others have been found in Nineveh, especially tablets, now in the British Museum, carved with significant figures in low relief, dating from the tenth century B.C. The Greeks used ivory for a great variety of decorative purposes; but its most famous use in antiquity was in connection with the chryselephantine (q.v.)

statues, which were the most magnificent and sacred in Greece. Among the many uses which the Romans, particularly during the late Imperial times, made of carved ivories, the most important was the consular diptychs, tablets of ivory given by the consuls as mementos to their patrons and friends. A number of private diptychs, some of fine artistic quality, also survive. The luxury of the later Empire, particularly in the East, made use of carved ivory as panels for doors, in chairs, etc. The dwellings of the wealthy were filled with furniture of ivory and silver.

Byzantine Ivories. It was in fact in the Eastern Empire that ivory carving attained its most perfect development, especially in connection with ecclesiastical usage. The history of sculpture from the fourth to the eighth century can best be studied by means of these small but highly finished works. The diptych was developed into the wonderful carved book covers which adorn many ancient manuscripts and into devotional tablets with interior instead of exterior carvings. Ivory was also used for pyxes, shrines, crosiers, crucifixes, panels to ornament doors, seats, especially thrones, like that of Archbishop Maximianus in the cathedral of Ravenna. The earliest period of Byzantine ivories closed with the iconoclastic movement (726–842 A.D.). At this time secular ivories became the rule: caskets, of which there is a fine ninth-century example in the Victoria and Albert Museum, London; delicately carved hunting or drinking horns, called oliphants, and usually showing Oriental influence; mirrors, combs, seals, chessmen, and a variety of other objects. The Macedonian and Comnenian periods (from 842 till the sack of Constantinople by the Crusaders, 1204) form a second golden age of Byzantine ivories, of which a fine example is the triptych d'Harbaville in the Louvre. Even the last period of Byzantine art, terminating with the capture of Constantinople by the Turk in 1453, produced works of great excellence. Throughout its career Byzantine ivory carving was imitated by the craftsmen of the West, and this lasted until the advent of the Gothic period. This is true of the Carolingian Renaissance (ninth century) in Germany and France, which produced fine book covers, and of German ivory carving in the time of the Ottos (tenth century). During this period and even in the eleventh century ivory carving was the most important form of sculpture, and was often determinative for the stone sculpture, particularly of the façades of Romanesque cathedrals in southern France. But with the revival of sculpture in stone during the late Romanesque epoch ivories gradually began to lose their unique importance, and from about the close of the twelfth century they in turn become subordinate to sculpture in stone.

Gothic Ivories. In the mighty revival of all art during the Gothic epoch ivory carving had an important share, rivaling in its achievements the Byzantine epoch. All the objects of ecclesiastical use mentioned above, and others besides, were produced in great numbers. Diptychs, and especially the more popular triptychs, were marvels of minute workmanship or of delicate openwork and traceries. The most popular subject, however, was the Virgin and Child, of which numerous specimens survive in all the principal collections. One of the finest known of ivory carvings is a Madonna of unusual size, gilded

and tinted, in the little church of Villeneuveles-Avignon. During the fourteenth century secular ivories were increasingly produced—elaborate mirror cases, caskets carved with scenes from the mediæval romances, plaques for thrones, like the delicately carved fragment of the throne of Jayme I, King of Aragon and Minorca, in the Morgan collection (Metropolitan Museum, New York). Practically all Gothic ivories, like the Byzantine before them, were polychrome, producing a rich, enamel-like effect. France, and in especial Paris, was the great centre, till the close of the fourteenth century, when Burgundy rose into prominence. Germany and England, much less productive, were influenced by French models; southern Europe was comparatively inactive, except that in Italy, at the close of the fourteenth century, fine altars and caskets were carved of bone, and in Spain the Moors carved caskets and other objects of great beauty.

Modern Ivories. Although a few fine examples were produced during the later fifteenth and sixteenth centuries, ivory carving gradually sank into disuse. But during the baroque period it was again abundantly practiced, especially in Germany and the Netherlands. Of particular interest are the rich and elaborate German tankards, to be seen in all museums; while in Flanders the infant bacchanals of Francis Duquesnoy achieved a wide reputation. During the eighteenth century France, where an important school was established at Dieppe, again took the lead, but by c.1750 the art ceased to attract men of talent. The school of Dieppe continued a desultory activity; and in the early nineteenth century James Pradier (q.v.), among other sculptors, carved many figures in ivory. But the real revival came about 1890 in connection with the goldsmith's art; for the rich mellow tint of ivory lends itself admirably to combination with the nobler metals and with precious stones. "Objets d'art," as such sculptures are generally called, were first introduced and have been designed most of all in Paris, where prominent artists like Vever, J. Dampt, Théodore Rivière, and especially Lalique, have made a specialty of them. In Belgium, also, the acquisition of the Congo territory by King Leopold II, who offered important medals for carving the ivory it produced, led to an important revival, in which artists like Constantin Meunier, van der Stappen, Hoscman, and Rombeaux participated. The Belgian expositions and the activity of local centres and schools gave an impetus to the art in Germany, where the sculptor Lewin-Funcke deserves especial mention. In the recent revival of decorative art in Great Britain ivory carving also played a part. Its most notable use, however, has been in the polychromatic sculpture of great artists like George Frampton and Alfred Gilbert.

The Orient. In India the art of ivory carving has been practiced from earliest times. The innumerable figurines of the Hindu pantheon have little besides a decorative interest; but beautiful caskets and similar objects were made in the south. On the east coast of India the inhabitants of Goa and other Portuguese possessions produced interesting hybrid wares for the European market. All the Saracenic peoples made use of the ivory, especially in their remarkable inlay work. But by far the best known and the most valuable Oriental ivories are those of China and Japan. Japanese art seems indeed to have followed its strong predi-

lection for minuteness in undertaking the artistic treatment of very small masses of these hard materials. The little netsukes (see NETSUKE) are more often of ivory than of any other substance, and their almost infinite variety and their spirited character are well known. Less known are the highly wrought boxes carved with reliefs, both high and low, and adorned with little figures in the round which serve as knobs for the cover or the feet of the piece.

Important Collections. Among the museums richest in ivories are those of Vienna, Berlin, Dresden, and Munich; the Musée de Cluny and the Louvre, Paris; the Victoria and Albert Museum and the British Museum, London; the municipal museums of Bologna, Brescia, Milan, and Ravenna; the Museo Nazionale, Florence; the Museo Kircheriano, Rome; and the Museo Cristiano of the Vatican. The treasuries of certain cathedrals like Milan, Monza, Ravenna, possess rich specimens of the art. Ivory book covers are generally preserved, often along with other ivories, in the important libraries, such as the British Museum, the Bibliothèque Nationale, Paris, the Royal libraries of Berlin and Munich, at Saint-Gall, and especially in the Vatican. The most important collections in the United States are those of the late George A. Hearn and J. P. Morgan, the latter (on exhibition in the Metropolitan Museum, New York) one of the most important and representative in existence.

Bibliography. The best general account of the diverse and scattered aspects of this subject is by Emile Molinier, *Histoire générale des arts appliqué à l'industrie*, vol. i (Paris, 1896). The most complete English manual is Alfred Maskell, *Ivories* (London, 1905), which contains a full bibliography and many photographic reproductions of noted pieces, including a discussion of consular diptychs. Indispensable to a thorough study of the subject are the important researches and photographic publications of Dr. Hans Graeven, published, as well as elsewhere, in *Jahrbuch der kunsthistorischen Sammlungen des allerhöchsten Kaiserhauses*, vols. xx, xxi (Vienna, 1899-1900); id., *Frühchristliche und mittelalterliche Elfenbeinwerke in photographischer Nachbildung* (Rome, 1898-1900); G. C. Dutt, *Monograph on Ivory Carving in Bengal* (Calcutta, 1901). The best work on the antique period is also by Hans Graeven, *Antike Schnitzereien in Elfenbein und Knochen* (1st series, Hanover, 1903). For mediæval ivories, consult: William Maskell, *Ivories, Ancient and Mediæval* (New York, 1876); A. M. Cust, *Ivory Workers of the Middle Ages* (London, 1902); O. M. Dalton, *Byzantine Art and Archaeology* (Oxford, 1911). For the Renaissance and modern: Scherer, *Elfenbeinplastik seit der Renaissance* (Leipzig, 1903). The catalogues of the ivories of the great collections are valuable by reason of good introductory sketches as well as descriptions; such as those of the Berlin Museum by Vöge (Berlin, 1900), the Hearn collection (New York, 1908), the British Museum by Dalton (London, 1909), the Hoentschel (now J. P. Morgan) collection by Pératé (Paris, 1911), and those of the Metropolitan Museum of Art, New York.

IVORY COAST (Fr. *Côte d'Ivoire*). A colony constituting a part of the Government-General of French West Africa, bounded on the north by the French Colony of Upper Senegal and Niger, on the east by the British Colony of the

Gold Coast, on the south by the Gulf of Guinea, and on the west by Liberia and the Colony of French Guinea (Map: Africa, D 4). The boundary with Upper Senegal and Niger varies from about 9° 30' N. to about 10° 40' N., the western part extending farther north than the eastern. The most southerly portion is at the western limit of the coast, about 4° 20' N. On the northeast the boundary is formed by the Black Volta River; the southern part of the western boundary, by the Cavally River. The coast line is about 380 miles in length. The area of the colony is estimated at 325,200 square kilometers (125,560 square miles). The coastal strip, averaging about 35 miles in width, is flat and contains the well-known lagoons, which for the most part are navigable. Beginning on the east, these lagoons are: Aby (sometimes called Assinie), Tendo, Frambo, and Assinie (properly so called); Ebrié (called also Grand-Bassam), which is about 90 miles long and has branches known as Lagoon Potou and Lagoon Ono—on it are situated the towns of Grand-Bassam, Bingerville, Abidjan, Dabou, and Jacquville; Lahou, north of the port of Grand-Lahou; and Fresco. The rivers are not of very great commercial importance, though there is some navigation on the Comoë, Bandama, Bia, Sassandra, and Cavally. North of the low-lying coastal strip the land rises, but no great elevations are found except in the west. Here a range about 30 miles in length, with an east-and-west direction, culminates near Nzô in Mount Nimba, on the boundary with French Guinea a little north of the Liberian line. Nimba has an altitude of 1644 meters (5393 feet) and is the highest mountain of French West Africa. South of this range, between the deep valleys of the Sassandra and Cavally, is a second mountainous region, where the highest peak reaches about 1400 meters (about 4600 feet). The colony is notable for its vast and dense forest, which has been its chief material resource and at the same time the most formidable obstacle to exploration and development. In extent the forest is not quite so great as was formerly believed. Beginning near the shore of the sea or the lagoons, it extends in the west to 8° N. and in the east to about 7° 30' N., while in the centre of the colony it is indented by a large area between the N'zi and Bandama rivers (which are confluents). North of the forest region wooded areas may still be found, especially along the streams; but there are large savannas, where grazing and agriculture are somewhat developed. This Sudanese region is too remote from centres of communication to attract the enterprise of whites, but it holds out fair promise to native development.

The climate is generally hot and, at least in the coastal and forest regions, unhealthy. Rains are excessive (they are more frequent in the forest than on the coast), and the humidity is always great. There are four seasons: the main dry season (with a mean temperature of over 82° F.), from mid-December to mid-April; the main wet season, from mid-April to mid-July; the short dry season, from mid-July to September; the minor season of rains, from September to mid-December.

The colony produces mahogany and other woods, palm kernels, palm oil, rubber, manioc, and ground nuts; some corn and rice are cultivated by the natives. Imports and exports (general commerce) amounted to 7,619,000 and

8,052,000 francs respectively in 1900; in 1905, 13,895,000 and 7,636,000; in 1910, 16,049,000 and 15,750,000; in 1911, 20,567,000 and 18,249,000; in 1912, 17,534,000 and 17,616,000. In 1912 imports from France were valued at 6,316,000 francs, and from the United Kingdom, 7,200,000 francs; exports to France, 6,853,000 francs, and to foreign countries 10,763,000 francs. The chief imports in 1912 were: cotton tissues, 4,642,000 francs; rice, 1,111,000 francs; machinery and iron manufactures, 1,058,000 francs; distilled liquors, 942,000 francs. The principal exports are palm oil and rubber, while palm nuts and mahogany are important. The chief ports are Grand-Bassam, Grand-Lahou, and Assinie.

A railway is projected to extend through the colony from south to north. It starts from Abidjan on the north shore of Lagune Ebrié and passes through Dimbokro (183 kilometers), near the confluence of the N'zi and Bandama; in September, 1912, it was opened to traffic as far as Bouaké in the centre of the colony, 316 kilometers (196 miles) from Abidjan. Telegraph lines connect the principal towns and extend to adjoining colonies.

The colony is divided into 17 circles. It is administered by a Lieutenant Governor, under the Governor-General of French West Africa. The capital is Bingerville. The budget for 1914 showed an estimated revenue and expenditure of 7,265,000 and 6,093,000 francs respectively.

The population of the Ivory Coast was estimated in 1911 at 1,132,941. For 1913, the indigenous population is reported at 1,416,043, divided as follows: Agni, 357,212; Senoufo, Dioula, and Malinki, 334,932; Bete, Gouro, Dan, and races of the upper Cavally, 312,608; Attié, Abbey, and other races of the lagoons, 62,386; Krumen, 19,056; Ashanti-Fanti, 3098; various races, 332,751. Of the total, 1,329,568 were returned as fetishists, 79,334 as Mohammedans, 4139 as Protestants, and 3002 as Roman Catholics. The Agni, who comprise some 15 tribes (including the Baule), are allied ethnologically to the Ashanti and inhabit, roughly speaking, the southeastern quarter of the colony. They probably came from the north of the present Gold Coast Colony about 1730. They are fetishists; their society is patriarchal and admits polygamy. The Dioula and Senoufo are comprised in a group known as Mande. The Dioula, a conquering race, are Mohammedans; the Senoufo, probably autochthonous, are fetishists. The various races of the lagoons, some of whom are related to the Ashanti, are in a state of savagery, being much inferior to the Agni or the Mohammedans of the north. The inhabitants of the southwest quarter of the colony, the Krumen, Bete, Gouro, etc., are in a low state of civilization. The Ivory Coast has no large towns. In 1913 Grand-Lahou had a population of 3050 indigenes and 78 Europeans; Grand-Bassam, 2832 and 164; Tiassalé, 1548 and 17; Aboisso, 1241 and 38; Assinie, 1135 and 38; Bingerville, 780 and 38; Abidjan, 613 and 110.

The French occupation of the Ivory Coast dates from 1842, when treaties were concluded placing the inhabitants about the Lagune Ebrié under the protection of France. In 1850 factories were established at Grand-Bassam and Assinie, and two years later a fort was erected at Dabou. The factories were abandoned in 1871. In 1878 a French Resident was appointed,

but the hold of France on the country was slight until 1893; in that year, as a result of the explorations of Binger and Treich-Laplène in the eighties and of Marchand in 1892, a decree was issued organizing the Colony of the Ivory Coast. With the subjugation of Samory's kingdom in the northwest, which began in 1893 and ended with the capture of Samory in 1898, French authority became paramount. Subsequently assassinations of French officials were not infrequent, and in 1910 the Abbey revolted; but French supremacy is practically established throughout the country. Consult: Binger, *Du Niger au Golfe de Guinée par le pays de Kong et le Mossi, 1887-1889* (2 vols., Paris, 1892); Clozel and Villamur, *Les coutumes indigènes de la Côte d'Ivoire* (ib., 1902); Maurice Delafosse, *Les frontières de la Côte d'Ivoire, de la Côte d'Or, et du Soudan* (ib., 1908); official monograph, *Côte d'Ivoire* (ib., 1908); Sonolet, "Lettres d'Afrique Occidentale," in *Journal des Débats* (ib., 1909-11); F. Lambert, "La Côte d'Ivoire," in *Société de Géographie d'Alger et de l'Afrique du Nord, Bulletin*, vol. xvii (Algiers, 1912).

IVORY SHELL. A gastropod of the genus *Eburna*, so called from its white, solid, smooth shell. The epidermis is usually wanting. The white shell is sometimes spotted with dark red, and the animal is spotted like the shell. The species inhabit the Red Sea and Indian Ocean, as well as the coasts of the Cape of Good Hope, Japan, China, and Australia.

IVREA, ê-vrâ'â. An episcopal city in the Province of Turin, Italy, 38 miles north-northeast by rail of the city of Turin, on the left bank of the Dora Baltea, which is crossed here by a Roman bridge (Map: Italy, A 2). It has an extensive castle (now used as a prison), a tenth-century cathedral, a ruined abbey, a lyceum, and a town hall. Its educational institutions include a Gymnasium, a technical school, and a theological school. Ivrea markets wine, grain, and fruit, spins silk and weaves cotton, and has ironworks and dye works. On this site stood the ancient town of Eporedia, a place of importance because of its position at the junction of various roads; there were gold mines, too, near by. It was colonized by the Romans in 100 B.C. to command the roads over the Great and Little St. Bernard. The town of Ivrea was the capital of the Margraviate of Ivrea which Charlemagne substituted for the Lombard Duchy. The margraves of Ivrea, Berengar II, his son, Adalbert II, and Arduin of Ivrea, were raised to the Italian throne. The last was finally obliged to yield before Henry II, who in 1019 annexed the margraviate to the Empire. In 1248 Ivrea was given as a fief to Count Thomas of Savoy, to whose posterity it descended. The French captured the town in 1554, 1641, and 1704. From 1800 to 1814 it was the capital of the French Department of Doire (Ital., Dora). Pop. (commune), 1901, 11,696; 1911, 11,330. Consult Baedeker, *Northern Italy* (14th Eng. ed., Leipzig, 1913).

IVRY-LA-BATAILLE, ê'vrê'-là-bâ'tî'y'. A village of France in the Department of Eure, on the river Eure, 40 miles west of Paris. Though it has a ruined abbey, and manufactures of musical instruments, combs, and leather goods, its chief interest is as the scene of the great victory of Henry IV of Navarre, March 14, 1590, over the Duke of Mayenne. The battle has been commemorated by an obelisk as well as a poem by Macaulay. Pop., 1901, 1034; 1911, 1190.

IVRY-SUR-SEINE, sur-sân'. A manufacturing town in the Department of Seine, France, on the left bank of the Seine River, 1 mile south-southeast of the fortifications of Paris (Map: Paris and Vicinity). Its forts form part of the defenses of the capital. It has increased rapidly in industrial importance. Here are located the great workshops of the Orléans Railroad; and there are manufactures of machinery, pottery, organs, wall paper, and rubber. Much garden truck is produced. Its principal manufactures are musical instruments, soap, and chemical products. Pop., 1901, 28,585; 1911, 35,445.

IVY (AS. *ifig*, OHG. *ebarvi*, *ebah*, *ebahewi*, Ger. *Epheu*, of uncertain origin). A name applied to a number of climbing, creeping, and trailing plants, among them the English or common ivy, Boston or Japanese ivy, Virginia creeper, ground ivy, and poison ivy. The common or English ivy (*Hedera helix*) is a well-known native of Europe, rare in the northern countries, which has been extensively introduced into the eastern United States between latitudes 30° and 40°. Its long, creeping, branched stem, which climbs on trees and walls to a great height and closely adheres to even very hard substances by means of abundant rootlets which it develops along its whole length, acquires in very aged plants the thickness of several inches. Its five-lobed, shining, stalked, evergreen leaves, clothing bare walls with green luxuriance, serve to throw off rain, and the rootlets of the stem extract moisture from the

COMMON OR ENGLISH IVY.

walls to which they cling, contrary to a common prejudice that ivy tends to produce dampness in walls. The flowering branches of ivy have ovate, entire leaves, very different from the others. Its small greenish flowers are produced in the beginning of winter, and the small black berries are ripened in the following year. The berries are eagerly eaten by many birds, although they have a pungent taste and contain a peculiar bitter principle called hederin and an acid called hederic acid, which are also found in a gummy exudation obtained by incisions from the stem and occasionally used in varnish mak-

ing and in medicine as a depilatory and a stimulant. In Egypt the ivy was sacred to Osiris, in Greece to Bacchus (Dionysus), whose thyrsus was represented as surrounded with ivy; the Romans mingled it in the laurel crowns of their poets.

Several of the 60 or more horticultural varieties of ivy are planted for ornamental purposes, of which that generally known in Great Britain as Irish ivy and on the European continent as English ivy is particularly esteemed for its large leaves and luxuriant growth. The Boston or Japanese ivy (*Psedera tricuspidata*) and the Virginia creeper (*Psedera quinquefolia* or *Ampelopsis quinquefolia*) belong to the same family as the grape. They are shrubby, hardy ornamental climbers, cling by tendrils opposite the leaves, and are especially attractive in their autumnal coloration. The Boston ivy has three-lobed or trifoliate leaves, the Virginia creeper five leaflets upon rather long petioles. The Boston ivy clings closely to walls, is of rapid growth, and is one of the best hardy vines for city growing. Both the common and Boston ivy grow readily from cuttings. The ground ivy (*Nepeta glechoma*) is a plant of the mint family that trails over the ground. The poison ivy or poison oak (*Rhus toxicodendron*) somewhat resembles the Virginia creeper in the appearance of its leaves and is sometimes mistaken for it. Its leaflets, however, are three in number and are not palmately arranged upon a common leafstalk. This plant possesses an irritant poison, and bathing the affected parts in an alcoholic solution of lead acetate is highly recommended as a remedy. The German ivy (*Gynoxys cordifolia*, or *Senecio mikanioides*) is a plant belonging to the family Compositæ. The Kenilworth ivy is *Linaria cymbalaria*. The name "ivy" is also applied in the southeastern United States to *Kalmia latifolia*, an evergreen shrub.

IVY GERANIUM. See PELARGONIUM.

IVY LANE CLUB. A club founded in 1749 by Dr. Johnson. Its meetings were held at the King's Head, in Ivy Lane, London. See CLUB.

IVY OWL. A fanciful name for the English tawny owl (*Syrium*, or *Strix, aluco*), which frequents ivy-grown ruins. See OWL.

IVY POISONING (DERMATITIS VENENATA). An inflammation of the skin produced by poisonous plants, chiefly poison ivy or oak (*Rhus toxicodendron*) and poison sumach or dogwood (*Rhus venenata*). Individuals differ very widely in their susceptibility to this form of poison. Some appear to be entirely immune even after handling the plants, while others are affected by the mere neighborhood of poison ivy, without actual contact. An attack may come on in a few hours or days after exposure. The skin becomes red and swollen, innumerable vesicles and blebs then appear, and there is severe burning, tingling, or itching. The eruption is carried to other parts of the body by auto-inoculation. The disease lasts from one to four weeks. Treatment consists in the application of mildly astringent and sedative lotions; hyposulphite of sodium, boric acid, fluid extract of grindelia robusta, and zinc, being favorite remedies. When large areas of the body are affected, alkaline baths are grateful. See IVY.

IWÁKURA, ē-wá'kōō-rá, TOMOMI, PRINCE (1835-83). A Japanese statesman, born in Kyoto, of one of the illustrious families of the great Minamoto (q.v.) clan. He became a

chamberlain in the Imperial household of the Mikado Komei (1847-66), father of the late Emperor, Meiji Tenno (q.v.). He was one of the 88 out of the total number of 136 kugé, or court nobles, who opposed the opening of the ports to foreign commerce. In the ebb and flow of the troubled politics of the time Iwákura fell into disgrace and was banished. Later he became the agent and firm ally of the revolutionary leaders, and was the means of carrying through the palace revolution of January, 1868, by which the men in the progressive party got possession of the person of the Emperor and reconstructed the government. In this Iwákura became one of the highest officers, and thenceforth one of the chief progressive leaders of the Empire, carrying through the abolition of the feudal system with vigor and wisdom. He never saw a foreigner until middle life; yet as Minister of Foreign Affairs he proved himself a match for the foreign envoys, and in 1872 led the great embassy to the treaty powers of the world to secure if possible some modification of the treaties with them. On his return he opposed the proposed war with Korea, and carried through the measure which commuted the hereditary pensions of the samurai (q.v.), by which the Treasury was relieved of heavy financial burdens and the nation enabled to enter upon a new phase of development. On the night of Jan. 14, 1873, an attempt was made by nine assassins to kill him, but he escaped. He remained the Mikado's chief councilor until his death. His son, Prince Iwákura Tomosada, became one of the chief officers of the court.

IWAO, OYAMA. See OYAMA, IWAO.

IWEIN, ē'wán. 1. A knight of Arthur's Round Table, whose story was used in the twelfth century by Chrestien de Troyes in his *Chevalier au Lion*. 2. The most important and complete work of Hartmann von Aue. It is an independent and free adaptation of Chrestien de Troyes's *Chevalier au Lion*. Consult Chrestien de Troyes, *Sämtliche Werke*, edited by W. Foerster (Halle, 1884-99).

I. W. W. See INDUSTRIAL WORKERS OF THE WORLD.

IXI'ON (Lat., from Gk. 'Ιξίων). In Greek legend, a king of the Lapithæ (q.v.). He married Dia, the daughter of Deïoneus, and later by treachery caused the death of his father-in-law. When no one would purify him from the murder, he prayed to Zeus, who pardoned him, invited him to his table, and gave him immortality. Intoxicated by the nectar, he sought to seduce Hera, but was deceived by a cloud in her image, and by this became father of the centaurs (q.v.). As a punishment, he was fastened by serpent bonds to a fiery wheel perpetually rolling through the air. Later writers transferred the scene of his punishment to Tartarus. The story is later than the Homeric and Hesiodic poetry.

IXTACCIHUATL. See IZTACCIHUATL.

IXTAPALAPA, ē'stá-pá-lä'pá. A suburb of Mexico City (Map: Mexico, D 9). It was an important place at the time of the conquest by Cortés. Pop., about 5000.

IXTLILXOCHITL II, èst-lèl'sô-chè't'l (c.1500-c.1529). A chief of the Tezcucans, the most civilized among the primitive races of Mexico. Ixtlilxochitl was the son of the famous King Netzahualpilli, and at his father's death (1516) he disputed the right of his elder brother to the throne, seeking help to establish

himself as King (1520) from the Spaniards, who had arrived to begin their career of conquest. He supported them throughout, thus gaining the hatred of other native princes, of his kindred, the Aztecs, and even of his own people.

IXTLILXOCHITL, FERNANDO DE ALBA (c.1568–c.1648). A Mexican historian. He was a grandson of the last native chief or King of the Tezcuco tribe and of his principal wife, who was a daughter of Cuitlahuatzin, the successor of Montezuma. After graduating at the College of the Holy Cross (Santa Cruz) at Tlaltelolco, he was appointed interpreter to the viceregal court for trying native cases, a position in which he was able to render great assistance to the former subjects of his family. His birth and position enabled him to gather a great amount of invaluable information relating to the past history of the two native peoples from whom he was descended. He mastered the hieroglyphics of Anahuac, made large collections of manuscripts, familiarized himself with the traditions and folklore of the country, and drew his information in some instances from those who had come into contact with the *Conquistadores*. All these data he carefully preserved in his numerous *Relaciones históricas*, which to a large extent are repetitions and condensations of each other. The *Historia Chichimeca* is the most important of his writings and was completed in 1616. His works, edited by Señor Alfredo Chavero, were published by the Mexican government, *Obras de Ixtlilxochitl*, vol. i, *Relaciones*, vol. ii, *Historia Chichimeca* (2 vols., Mexico, 1891–92); but in manuscript form they were used by Prescott in his *Conquest of Mexico*. Furthermore, the *Historia* had appeared twice before the aforesaid edition by the Mexican government, and the *Relaciones* once: *Voyages, relations, et mémoires originaux pour servir à l'histoire de la découverte de l'Amérique, publiés pour la première fois en français par H. Ternaux-Compans* (trans. from the Spanish manuscript and containing only the *Historia*, 2 vols., Paris, 1840); and Edward King, Viscount Kingsborough, *Antiquities of Mexico* (9 vols., London, 1830–48; vol. ix, pp. 197–468 containing the Spanish text of the *Historia* and of the *Relaciones*).

IYEMITSU TOKUGAWA, ê-yā'mīt'su tō'-kōō-gā'wā (1604–51). A Japanese statesman of the seventeenth century, grandson of Iyeyasu, the founder of the Tokugawa line of shoguns. He succeeded to the title in 1624 and proved himself the ablest, after Iyeyasu, of the 15 shoguns of the line. He continued, and completed in 1638–41, the policy of his grandfather in excluding all foreign influences, not only expelling all foreigners and eradicating every trace of Christianity, but also forbidding all natives, under penalty of death, to leave the country; and, the better to secure this end, he ordered the destruction of all seagoing vessels. The Dutch were confined to the little artificial island of Deshima in Nagasaki harbor, and their intercourse with the outer world was limited to two ships a year. The English had already retired from Hirado. The persecution of the Christians was fierce and bloody, and, in 1638, 37,000 of them were hurled from the precipitous cliffs of Pappenberg near Nagasaki, and hundreds more were tortured to death. He rebuilt and greatly enlarged Yeddo and erected the gorgeous shrines at Nikko, where he lies beside his illustrious

grandfather. Consult W. E. Griffis, *The Mikado's Empire* (11th ed., New York, 1906).

IYEYASŪ (or **IEYASŪ**) **TOKUGAWA**, ê-yā'yā-s' tō'kōō-gā'wā (1542–1616). A famous Japanese general and statesman, the first shogun of the Tokugawa line, and the founder of the peace and order under which the Japanese lived from the year 1604 to 1868. Though a descendant of the famous Minamoto clan, his father was a humble peasant. He served with distinction under both Nobunaga and Hideyoshi (qq.v.). On the death of Hideyoshi, in 1598, great dissensions arose among the territorial barons or daimyos in regard to his successor. Many, including Iyeyasu, had sworn to protect Hideyoshi's son Hideyori, then a child of six, and to secure his succession; but many more opposed his claim as the son of a person of low birth, and sided with Iyeyasu when a movement against him compelled him to take up arms. In a bloody battle at Sekigahara, on Oct. 16, 1600, Iyeyasu utterly routed his enemies, killing 10,000 of them. Wholesale confiscations followed, and with these lands he rewarded his adherents in such a way as to secure his own authority throughout the country. Later he captured the castle at Osaka, where the child Hideyori was with his mother, and in 1603 reported to the Mikado, receiving from him the appointment of head of the Minamoto clan, and that of Seii-Taishogun (or Barbarian-quelling-great-general). Not long after he received the submission and homage of the barons at Yeddo, which he made his capital. The better to maintain his authority, he ordained that each of the daimyos should, with a certain number of his armed retainers, remain in Yeddo six months of the year, and their wives and families should be left as hostages when they visited their own domains. He then began extensive internal improvements; he enlarged the castle at Yeddo, made streets and canals, built bridges, erected buildings, drained marshes, constructed the great highway called Tokaido, which runs along the eastern coast from Yeddo to Kyoto, and effected many other great and lasting improvements for the betterment of the country. In 1605 he concluded peace with Korea, reestablished friendly relations with China, and retired in favor of his son Hidetada, reserving to himself, however, a large measure of control. He then took up his abode in his castle at Sumpu (now Shidzuoka), in the Province of Suruga, occupying himself with the collection of books and manuscripts, and the composition (as is believed) of the document, in 100 sections, known as *The Legacy* (or Testament) of Iyeyasu, containing laws or rules to be observed in governing the country. His policy, which aimed at the unification of the country, included as one of its features the exclusion of aliens and the alien religion, Christianity. In 1614 he issued a proclamation ordering all Romish propagandists and leaders of churches to be deported, their churches to be destroyed, and compulsory recantation of the faith by the converts. Large numbers were deported, and thousands were massacred in the persecutions that followed. The Portuguese and Spanish were expelled, but the Dutch and English, who first arrived in Japan during this period, received commercial privileges—the former being allowed to settle at Nagasaki and the latter at Hirado.

Iyeyasu died at Sumpu and was buried at Kunosan in Suruga, but later his remains were

interred in a mausoleum at Nikko. He was canonized as To Sho Dai-Gongen, but is commonly spoken of as Gongen Sama. His festival falls on the 17th day of the fourth month. Consult: Lowder, *The Legacy of Iyeyasu* (Yokohama, 1874); Grigsby, in the *Transactions of the Asiatic Society of Japan*, vol. viii (Tokyo, 1875); J. J. Rein, *Japan: Travels and Researches* (London, 1884).

IZABAL, è'sà-bäl'. Capital of the Department of Izabal, Guatemala, situated in a mountainous but very fertile district on the south shore of Lake Izabal (or Golfo Dulce), which is connected with the Caribbean Sea by the Río Dulce (Map: Central America, C 3). The river is not navigable for large vessels, and Livingston, at the mouth of the river, has become the port through which Izabal exports ebony, rosewood, and other fine cabinet woods, sarsaparilla, cacao, and coffee. Pop., about 4000.

IZABAL, LAKE. An inlet of the Gulf of Honduras in the eastern part of Guatemala, Central America (Map: Central America, C 3). It extends in a southwestern direction for 36 miles and has a width of about 11 miles. Its depth is sufficient for large steamers, but the bar at the mouth makes it difficult of navigation.

IZAK, HEINRICH. See ISAAC, HEINRICH.

IZALCO, è-säl'kô. A remarkable volcano, near the Pacific coast, 36 miles northwest of the city of San Salvador, Guatemala. It suddenly burst out of the plain in 1770 and since then has been active at regular intervals. Great quantities of material have been ejected, and the cone has gradually risen to the height of about 6000 feet. It is one of the series known as the San Salvador group of volcanoes that forms a prominent feature of the Guatemalan coast.

IZAMAL, è'sà-mäl'. A town in the State of Yucatan, Mexico, situated 41 miles by rail east of Mérida (Map: Mexico, P 7). It is noted chiefly for its ancient ruins, which have interested many eminent archæologists, among others Charnay and Bourbourg. Pop., about 6000.

IZ'ARD, GEORGE (1776-1828). An American soldier, son of Ralph Izard. He was born at Richmond, Surrey. He graduated at the College of Pennsylvania in 1792; then went to England, where he entered the military school at Kensington, and after a short stay there studied at Edinburgh, Marburg, and Metz. He was lieutenant of engineers in the United States Army (1794-96); returned finally to America (1797); was sent to Charleston as the engineer of Castle Pinckney, and later commanded Fort Mifflin and West Point. He was then for a short time Secretary of the American Legation at Lisbon. He resigned from the army in 1803, but at the beginning of the War of 1812 re-entered it as colonel of the Second Artillery and rose to the rank of major general (1814). He was ordered to the northern frontier, where he served at first under Gen. Wade Hampton and later (in August, 1814) relieved General Brown in the command on the Niagara frontier. In October he crossed the Niagara with about 8000 men and moved against General Drummond, on the Chippewa. After a sharp skirmish (October 19) near Cook's Mills, on Lyon's Creek,

General Drummond withdrew his troops to Fort George and Burlington Heights. Izard failed to follow and retired to Black Rock; and this conduct, though approved by the government, aroused popular criticism. This led to his publishing in 1816 a volume entitled *Official Correspondence with the War Department, 1814-15*. President Monroe appointed him Governor of Arkansas Territory in 1825, a post which he held until his death.

IZARD, RALPH (1742-1804). An American patriot of the Revolutionary period, born near Charleston, S. C. He inherited a large estate, was educated at Cambridge, England, and on his return to America passed his time chiefly in New York as a young man of fashion. Returning to England in 1771, he lived in London until 1774, when he went to the Continent because of the impending war between England and her American Colonies. From 1776 to 1779 he was nominally Commissioner of the United States to Tuscany, but remained during the greater part of this period at Paris and took an active part in the controversy between Franklin and Arthur Lee, siding with the latter and vigorously attacking the former. In 1780 he returned to America and soon afterward pledged his valuable estate to enable Congress to procure ships of war from Europe. He was instrumental in securing the appointment of General Greene to the command of the southern army. He was a delegate to the Continental Congress (1782-83), and was a member of the United States Senate from 1789 to 1795. His correspondence was published by his daughter in 1844.

IZCOHUATL, ès'kô-wä't'l. See ITZCOATL.

IZ'DUBAR'. See GILGAMESH.

IZIOCATL. See ITZCOATL.

IZMAILOV, èz'mä-è'lôf, ALEXANDER EFIMOVITICH (1779-1831). A Russian poet and writer of fables, born in Moscow. He was educated at the School of Mines and shortly after was appointed Governor at Archangel, then at Tver. He is chiefly known by the 120-odd fables in which he portrays Russian characteristics. A collection of them was published in 1814. He also contributed to periodical literature and wrote romances such as *Biednaia Matcha* (1801). The seventh edition of his poems appeared in 1849, and his complete works were issued in 1849.

IZMID, iz-méd'. See NICOMEDIA.

IZRAIL, iz'râ-îl. See AZRAEL.

IZTACCIHUATL, ès-täk-sè'hwä't'l, or **IX-TACCIHUATL**. A lofty mountain in Mexico, just north of Popocatepetl, 40 miles southeast of the city of Mexico. It is of volcanic origin, but has no crater. It is oblong in shape, and its summit is covered with perpetual snow; its profile resembles a woman lying wrapped in a white shroud, whence its name, which means White Woman. Its height is about 17,000 feet. On a clear day, from the valley of Mexico, it is a most impressive and inspiring sight.

IZÚCAR, è-sōō'kär. A city and district of Puebla, Mexico, situated 35 miles southwest of the city of Puebla, at the base of Popocatepetl (Map: Mexico, K 8). It is in the midst of a rich sugar region and has railway communication with Puebla. Pop., about 12,000.

J

J The tenth letter of the English alphabet, and the latest letter added to our script. In form *J* was at first merely a variation of *I*, and both characters were used interchangeably for either vowel or consonant. A differentiation later followed in the value of the symbols. *J* was appropriated to represent the consonant sound, *I* was confined to the vowel. In English this usage did not become established until the seventeenth century. In the minuscule letter the dot over the *j* is a proof of its original identity with *i*. The Latin *I* came from the Greek *ἰῶτα*, *iota*, which itself was derived from the North Semitic *Yod*. This latter originally represented the consonantal sound *y*, but later was used also to indicate the vowel *i*.

Phonetic Character. In English *j* has the composite sound of *d* + *zh*, as in *judge*. It is thus a combination of the voiced dental explosive and the voiced palatal spirant. In French, however, the spirant value (*zh*) alone is given the letter, as in *jour* (*j* pronounced as the *z* in English *azure*); in German *j* has the original *y*-sound of the Latin *i*-consonant; in Spanish the *j* has a sound resembling a guttural *ch*. As to its source, the English *j* appears chiefly in words derived from the Romance languages, and hence from the Latin *j* (*i*) or *di*. Thus, the English word "to judge" has its *j* from the OF. *jugier*, Lat. *judicare*; on the other hand, Eng. "journal" is through the Fr. *journal* from the Lat. *diurnalis*. Before the differentiation of *J* and *I* in English the combination *Gi* for *J* was sometimes used in Middle English, as in *Giwes* for *Jews*, no doubt under Romance influence; cf. Ital. *Giovanni*, from Lat. *Johannes*.

JA'BAL. A son of Lamech and brother of Jubal and Tubal Cain, according to Gen. iv. 20. He is said to be the father, or ancestor, of those who dwell in tents and with cattle. The name is supposed to designate him as shepherd or herdsman and has been connected with the Hebrew and Phœnician word *jobel*, 'ram.' It is also supposed by some scholars to be another form of Abel (q.v.), to which the same meaning is naturally assigned; but the evidence for this is not conclusive. Jabal's brother Jubal is said to have been the father, or ancestor, of such as handle the harp and pipe.

JABALPUR, jüb'ül-pōor', or **JUBBULPORE.** A division of the Central Provinces (q.v.), British India. (Map: India, D 4). It comprises the districts of Jabalpur, Saugor, Damoh, Seoni, and Mandla and has an area of 18,953 square miles. Pop., 1901, 2,081,480; 1911, 2,421,064. Capital, Jabalpur.

JABALPUR, or **JUBBULPORE.** The capital of a district and division of the same name in the Central Provinces and one of the most important railroad junctions of British India, near the Nerbudda River, 200 miles southwest of Allahabad (Map: India, D 4). It is 1306 feet above the sea, picturesquely situated in a hilly, rock-encircled basin marked with numerous gorges. Education is carried on in a government college, the law school, an engineering school, normal schools for both sexes, and an industrial school. The town has wide and straight streets, and a garrison is stationed here. It manufactures cotton goods, carpets, wire netting, brass work, and statuary, and its export and import trade is of considerable importance. It was formerly the great centre of the Thugs (or stranglers), who were eventually suppressed by the British government. The Marble Rocks, 11 miles distant, is a favorite excursion place and a scene of great natural beauty and interest. Pop., 1901, 90,533; 1911, 100,651.

JAB'BOK (Heb. *yabbōk*, copious river, probably from *bākak*, to pour forth). A stream of the East Jordan country, which rises near Rabbath Ammon and after a course of about 65 miles, not taking into account its numerous windings, empties into the Jordan 23 miles north of the Dead Sea (Map: Palestine, D 3). The modern name is Nahr ez-Zerqa (blue river). It affords some of the most picturesque scenery of Palestine. Before the conquest of Canaan it separated the territories of Ammonites and Amorites (Josh. xii. 2) and later flowed through the Land of Gad. On its banks Jacob is represented as having had his encounter with the mysterious antagonist (Gen. xxxii. 24-25).

JAB'IRU (Brazilian name). 1. A large stork (*Mycteria americana*, or, as modern taxonomy has it, *Jabiru mycteria*), common in tropical America and occasionally found as far north as Texas. It is about 4 feet long and 7 feet across the wings. The plumage is pure white, but the head and neck are destitute of feathers and are black, with a reddish or flesh-colored ring around the base of the neck. The bill is a foot long, very thick at the base and slightly bent upward at the tip. The jabiru is the only true stork (sub-family Ciconiinae) found in North America. 2. Two other storks, one Oriental and the other African, which are so closely allied that, were they not widely separated, they would probably be considered as members of a single genus. The former is the black-bellied jabiru of Australia (*Xenorhynchus asiaticus* or *australis*), represented in south-

eastern Asia by a similar species or variety; and the latter is the handsome "saddle-billed" stork (*Ephippiorhynchus senegalensis*) of the Sudan, one of the most common and conspicuous wading birds of the marshy region of the upper Nile.

JABLOCHKOV, yä'blöch-kôf, PAUL (1847-94). A Russian electrical engineer and inventor, born at Serdobsk in the Government of Saratov. In 1871-75 he was director of the telegraph lines between Moscow and Kursk, and in 1876 he moved to Paris, where he devoted himself to experiments with electric arc lamps. He succeeded in inventing the "candles" known by his name, that were in general use for a few years. He returned to Russia in 1894 and there died in poverty.

JABLOCHKOV CANDLE. See ELECTRIC LIGHTING.

JABLONOWSKI, yä'blö-növ'skê, JOSEPH ALEXANDER PRUSS, PRINCE (1712-77). A Polish-German patron of letters. He was Waywode (administrative chief) of Nowogrodek, and left his fatherland in 1768. He went to Leipzig, where he endowed the Jablonowski Scientific Association and offered three prizes for monographs on Polish history, economics, and mathematics or physics. This association began its work in 1774 and after an interval of inactivity was revived in 1828. It published *Acta Societatis Jablonovianæ* (1772-73), *Nova Acta* (1802-45), and the series of prize monographs (1847 et seq.).—STANISLAS (1634-1702), of the same family, was one of the conspirators against King Michael, and a leader of the Poles in the war with Turkey. He was made a German prince by the Emperor Leopold for his services at Vienna. Jonsac's *Histoire de Stanislas Jablonowski* was translated into Polish by a second PRINCE STANISLAS (1799-1878), a Polish artillery officer.

JABLONSKI, yä-blön'skê, DANIEL ERNST (1660-1741). A Polish Protestant theologian, born at Nassenhuben, Prussia. He studied at the University of Frankfort and in England and the Netherlands. In 1683 he took charge of the Reformed Church in Magdeburg, where he distinguished himself as a preacher. From 1886 to 1891 he was rector at the Moravian College, Lissa. Frederick I chose him for his chaplain (1691-93), and by 1699 he was the leading bishop of the Moravian church. That year he published his *Hebrew Bible*, and he also brought out an edition of the *Talmud* (1715-21), besides translating into Latin Bentley's sermons on "A Confutation of Atheism," which formed the first course of the Boyle lectures. His knowledge of Oriental languages was one of his qualifications for the presidency of the Berlin Royal Academy of Sciences (1733), and he labored long, though unsuccessfully, to bring about a union between the Swiss, German, and English Protestants.

JABON, hä-bön', or **JABONCILLO**, hä'bôn-the'lyô. See SOAPFISH.

JAB'ORAN'DI. A name given in South America to several species of plants used as diaphoretics. The plants grow chiefly in Brazil and are most known in the neighborhood of Pernambuco. Those recognized by the Pharmacopœia of the United States are *Pilocarpus seloanus* and *Pilocarpus jaborandi*. (See ALKALOIDS.) When bruised, the leaves are aromatic and taste somewhat bitter. The important constituents are a volatile oil and two alkaloids

called pilocarpine and jaborine. The latter alkaloid somewhat resembles atropine in its action. An infusion of the leaves or a fluid extract or tincture may be given internally; or one of the salts may be administered with a hypodermic syringe. When an infusion of 90 grains of the dried leaves is swallowed, it produces in the course of two or three minutes a flushing of the face, and in the course of five or six minutes drops of sweat appear on the forehead and soon afterward on other parts of the body and limbs. When sweating is established, the face becomes pale, and a profuse secretion of saliva and nasal and bronchial mucus is poured out upon the mucous surface, and often there is an abundant secretion of tears. The salivation is often so profuse as to interfere with speech. The average duration of sweating is about one hour and a half, and the temperature usually falls 1° F. The average loss of fluid by sweating is nearly two pints, but the loss is said sometimes to be four quarts if the salivary and mucous secretions are included. Sometimes, though rarely, sweating does not take place, but salivation is more frequently absent than sweating. When one of these is diminished, the other is increased. Vomiting is a usual occurrence, but the nausea is not great. The quantity of urine secreted during the sweating is diminished and is passed with pain. Urea appears in the perspiration and saliva. The pulse is quickened at first and later slowed, and the arterial tension is increased. Larger doses later cause marked cardiac depression. The sight frequently becomes dimmed—an effect attributed to the action of the drug on the muscles of accommodation belonging to the lens. (See EYE.) Jaborandi is an effective galactagogue, or promoter of the lacteal secretion. The hypodermic injection of one-sixth or one-fifth of a grain of pilocarpine or the hydrochlorate produces much the same effects as the internal administration of the infusion of the leaves, but the action is more prompt as well as more lasting. With the hypodermic injection sweating always takes place, and vomiting is less frequent. Applied locally to the eye, it causes marked contraction of the pupil and diminution of intraocular tension. In general it may be said that the action of pilocarpine is antagonistic to that of atropine.

The medical uses of jaborandi are few, and it should be used internally only with caution, on account of its depressing action upon the heart. It has been employed to cause absorption of effusions into the serous cavities, either those of inflammatory origin, such as pleurisy, or those due to circulatory failure or insufficient action of the kidneys, such as hydrothorax and dropsy. It may be said that other remedies may be found which are quite as efficacious and lack the depressing effect. In uræmia and eclampsia it has been used, but *Veratrum viride* is now preferred. In conjunction with morphine it is employed as an antidote in atropine poisoning. Its chief use, however, is in glaucoma (q.v.), in which its local application to the eye causes diminution of the intraocular tension. It is generally given as pilocarpine hydrochloride for this purpose. It is sometimes employed to break up adhesions of the iris by contracting the pupil. For this purpose it is alternated with atropine, which causes dilatation. It is used internally and locally to cause a thicker and coarser growth of hair.

JABOTICABA, zhâ-bô'tê-kä'βά. An edible

fruit produced by the Brazilian tree *Myrciaria cauliflora* and other species. The trees attain a height of 35 to 40 feet and produce on their trunks and larger branches large numbers of maroon-purple fruits $\frac{1}{2}$ to $1\frac{1}{2}$ inches in diameter. The fruits resemble grapes somewhat, but have a thicker, tougher skin. The trees flower several times during the year, depending on rains or water supply, and the fruit ripens within three or four months. An attempt has been made to grow the trees in Florida, but the introduction was so recent that its adaptation cannot be affirmed.

JACA, jä'kä. A tropical tree, closely related to the breadfruit. See JACK TREE.

JAC'AMAR (Fr., Sp. *jacamar*, from Brazilian *jacamarica*). One of the birds of the tropical American family Galbulidæ, of which about 26 species are known, all inhabitants of the region east of the Andes. They are comparatively small, are brilliant in plumage, resemble the bee eaters of the Old World, and in their habits are like the arboreal insectivorous kingfishers. The Brazilians call them "foolish" on account of their stupidity. Jacamars nest in holes in banks or stumps and lay only two white eggs.

JACANA, jäk'ä-nä, Portug. pron. zhä'sä-nä' (Brazilian *jacaná*). One of the small, raillike plovers of the family Parridæ, remarkable for their carpal spurs and for the extraordinary length of their toes and claws, adapted to the bird's habit of seeking its food (green sprouts of rice and the like, insects, and small aquatic animals) by walking on the floating leaves of the water plants in weedy lakes and slow rivers. They belong to the tropics of various parts of the world. The common species of South America (*Jacana spinosa*), abundant in Guiana and Brazil, is about 10 inches long; black, except the back and part of the wings, which are of a bright chestnut color. Another species is found in tropical America and extends its range as far north as Texas. The prevailing color of the plumage is rich purplish chestnut. Their general habits are much like those of the gallinules, which they resemble in bodily appearance. The strong spur with which the bend of each wing is armed is a formidable weapon in the fighting that seems incessant among them.

Of the 10 or 12 Old World species, one or two need special mention. The pheasant-tailed jacana, or water pheasant (*Hydrophasianus chirurgus*), is a familiar bird throughout the Oriental region and, like another species (of northern Australia), is often called lotus bird, because of its fondness for places where that plant prevails. Its colors are pleasing, and its tail is prolonged by four very long feathers, which suggest those of a pheasant. During the rains, in their favorite haunts, each pair forms a rude flat nest of weeds and grass, interwoven beneath with the long shoots of aquatic plants, which support it buoyantly on the surface. All the family lay rich olive-brown eggs, closely marked with dark lines. This bird is a favorite subject for representation in the native art of all the countries from India to Japan. The genus *Metopedius*, hardly different from the American jacana, has representatives in Africa, Madagascar, and India; and the genus *Hydrolector* belongs to northern Australia and the neighboring islands. Consult authorities for South America, India, and the East, mentioned under BIRD. See Plate of RAILS, ETC.

JAC'ARAN'DA WOOD (Brazilian name).

A hard, heavy, brown South American wood, which from its faint odor is also called rose-wood. It is derived from several species of *Jacaranda*, of the family Bignoniaceæ. Several species, locally called caroba, etc., are employed medicinally in many South American countries.

JACARÉ, jäk'ä-rä', Portug. pron. zhä'kä-rä' (Portug. *jacaré*, *jacareo*, from the Brazilian name). Any of the caymans or alligators (qq.v.) of tropical America, the species of which are distinguished by some qualifying word. Thus, the jacaré tinga is the small six-foot *Caiman trigonatus*, with the slender muzzle and black-banded tail; jacaré nassu is the great *Caiman niger*, sometimes 20 feet long. Used alone, the name usually means the common, or spectacled, cayman (*Caiman sclerops*), which is very numerous from southern Mexico to northern Argentina. It is of medium size and is distinguished especially by the fact that the upper eyelid is rugose, partly ossified, and often produced into a small horn. All these alligators spread into the flooded forests in the wet season and congregate in the river courses during the dry season. They do vast damage to stock and kill many human beings; but their hides are of commercial value, and their flesh is eaten by all the Amazonian Indians.

JACCOUD, zhä'köö', FRANÇOIS SIGISMOND (1830-1913). A French physician, born at Geneva. He went to Paris about 1850 as a music teacher; studied medicine, winning a gold medal in 1859 and his degree in the same year; and in 1863 became assistant in the medical faculty. He was appointed titular professor of pathology in the faculty of medicine in 1876, became permanent secretary of the Académie de Médecine in 1877, and in 1883 began to teach in the medical clinic at the Pitié. He wrote: *De l'organisation des facultés de médecine en Allemagne* (1864), a report on his official investigation; *Leçons de clinique médicale* (1867-88); *Traité de pathologie interne* (7th ed., 1883); *Du froid comme cause de pneumonie* (1887); and a translation from Graves, *Clinique médicale* (1861-62); and he edited the *Nouveau dictionnaire de médecine et de chirurgie* (1864-86).

JACHIN (jä'kin) **AND BOAZ**. The names of the two brazen pillars which Solomon set up in the porch of the temple (1 Kings vii. 15-21).

JACHMANN, yäg'män, EDUARD KARL EMANUEL (1822-87). A Prussian naval officer, born at Danzig. He entered the service in 1845 and became a captain 14 years later. In 1862 he took part in the expedition to East Asia and China, and in 1864 defeated the Danes near Jasmund, on the island of Rügen, whereupon he was promoted to be rear admiral. Placed at the head of the Navy Department in 1867, he was made vice admiral in the following year, and in the Franco-German War was commander of the Prussian fleet in the North Sea. He was Minister of the Navy in Von Stosch's cabinet (1872), but retired a year later.

JACINI, yä-chē'nē, STEFANO, COUNT (1827-91). An Italian economist and statesman. He was educated in Switzerland, in German universities, and at Milan. During the Austrian rule of Lombardy in 1849-59 he engaged in economic investigation, writing *La proprietà fondiaria in Lombardia* (1856) and *Sulle condizioni economiche della Valtellina* (1858). For his writings on the evils of Austrian rule, he was made Minister of Public Works under Cavour in 1860-

61 and later held the same office in 1864-67. He helped to bring about the alliance with Prussia for the war against Austria in 1866, participated in the organization of Italian railroads, and was president of the Agricultural Commission of 1881-86. He was made Senator in 1870 and Count in 1880.

JACITARA (jäs'î-tä'rà) **PALM** (South American Indian), *Desmoncus macroacanthos*. A palm found in the lowland forests of the Amazon. It has a slender, flexible stem which often climbs, by means of hooks, to a height of 60 or 70 feet. The outer part of the stem, cut into long strips, is much used to make the plaited cylinders in which grated cassava root is squeezed in the process of extracting the starch. These wicker cylinders, which are very durable, will outlast two or three made from other fibers. The material seems suitable for many other purposes.

JACK. A piece of mechanical apparatus for raising heavy weights short distances. Jacks are made in a variety of forms, but may be divided into lever jacks, screw jacks, hydraulic jacks, and geared jacks. The lever jack is the device used from a remote antiquity for lifting wagon axles so as to free the wheel from the ground. A long lever swings upon a pin in a post as a fulcrum, and the short arm goes under the axle. There is a device like a ratchet or a linked chain to hold the axle from falling when the lever is no longer depressed. In the screw jack a nut is similarly supported on a hollow post, and a lever turns the screw in the nut and, the latter being held from turning, the screw is advanced with great power, owing to the slow motion axially through the nut. Hydraulic jacks are portable forms of hydraulic presses. In geared jacks a combination of levers and gearing takes the place of the simple lever or screw of the other jacks and the water of the hydraulic jacks. The essential requirement of a jack is that it shall be of compact and sturdy construction and shall be conveniently portable. The ordinary screw jack is an excellent illustration of all these qualities. Jacks are much used in railroad wrecks or accidents and in house moving and shoring and in erecting machinery. See **HYDRAULIC PRESS**.

JACK. In the United States navy, a blue flag with white stars, corresponding in all respects to the similar portion of the national flag, which is sometimes called the *union*. In Great Britain and Germany the *jack* is a flag which is similar to the upper quarter of the man-of-war flag which is nearest the staff. In countries which have no union in their man-of-war flag, the jack more nearly resembles the colors carried at the stern except in size. It is set on a staff at the stem, or on the bowsprit cap of rigged ships. It has no particular significance at the present time, but is usually hoisted in port. The United States naval jack is carried in the bow of a boat when an ambassador, minister, or chargé d'affaires of the United States is being carried by it. See **FLAG**, and **Colored Plates** with the articles **NATIONAL FLAGS** and **UNITED STATES**.

JACK, or **JACKFISH**. A name applied, often in connection with some qualifying word, to many fishes, usually marked by liveliness of action. 1. A pickerel, especially the Eastern green pickerel. 2. One of the Californian rock fish (*Sebastes paucispinis*). 3. Either of two West Indian amber fishes (*Seriola lalandi* or

Seriola dumerili), more often called amber jacks. 4. Any of various scads and crevalles, especially the jurel (q.v.).

JACK, CAPTAIN. A picturesque character in American frontier life about the middle of the eighteenth century, called also the Black Hunter or Black Rifle. After the massacre of his family and burning of his home on the Juniata by Indians, he devoted himself unceasingly to vengeance and gathered about him a band of daring men who in Indian dress engaged in a relentless pursuit of all Indians and in the defense of white settlers.—The name is applied also to **KI-ENT-POOS**, the principal leader of the Modoc Indians (q.v.) in northern California in the War of 1872-73. He acquired notoriety by the deliberate murder of General Canby while attending a peace conference, for which he and others concerned in the attack on the commissioners were hanged, on the final suppression of the outbreak.

JACK-A-GREEN. See **JACK-IN-THE-GREEN**.

JACKAL, jāk'al (OF. *jackal*, *jakal*, Fr., Sp. *chacal*, from Ar. *jaqāl*, from Pers. *shaghāl*, from Skt. *srgāla*, *jackal*). The common name of a number of species of the genus *Canis*, abounding in Asia, Africa, and southeastern Europe. They agree in all their most important characters with wolves and dogs (see **CANIDÆ**), although the form and tail are somewhat foxlike. The head is narrow and the muzzle pointed. The ears are erect and rather large. The tail is not so long as in foxes, but is almost equally bushy. All the jackals are of small size, as compared with wolves, seldom exceeding 15 inches in height at the shoulder. Their colors are buff and tawny, more or less grizzled; the tip of the tail is always dark. They make holes for themselves in the ground, or take possession of such as already exist among rocks or ruins; and in these they spend the day, not venturing abroad, as a rule, till the dusk of evening. They hunt during the night in troops, and their howlings are described by all who have heard them as peculiarly unpleasant. The notion that the jackal is the "lion's provider" is one of the exploded fables of natural history, although it may have some foundation in the lion occasionally following a troop of jackals in full cry and appropriating "the lion's share." Jackals are not only ready to devour any animal which they can run down, but any carrion that they may find. They follow armies; they dig up the ill-buried dead; they rob henroosts and outhouses; but they are as omnivorous as domestic dogs, and eat farinaceous or other vegetable food when it comes in their way; they are even said, like foxes, to enter vineyards and devour the grapes. They have a very offensive smell, which, however, is said to diminish through domestication, and they are domesticated without difficulty. Everywhere jackals interbreed with native dogs, and doubtless they contributed essentially to the early stock. The foregoing applies especially to the "common" jackal (*Canis aureus*), which is spread, with many variations, throughout the semidesert region from the Sudan to Afghanistan, India, and Burma, and also is common in Europe as far north as Heves Comitatus, Hungary, and on the plains of Greece and European Turkey. In northern India it is known as pheal, and in southern India as bhalu, and many weird stories are told of it and its relations to the tiger. The African variety is rather larger and grayer than the Asiatic.

The black-backed jackal or tenlie (*Canis mesomelas*) is a very distinct species, of bright coloration. The sides and limbs are red to reddish yellow; the back and end of the tail are black. It is widely distributed throughout eastern and southern Africa, and its handsome fur is highly prized. A third African species, the side-striped jackal (*Canis adustus*), called rubuyo on the West Coast, and canduc eastwardly, is widely scattered south of the equator and differs from the others in having rather shorter and much darker ears and the sides marked with one or more curving light bands bordered with black—a feature, however, which is highly variable. Cf. DOG; FOX; WOLF; and see Plate of FOXES AND JACKALS.

JACK-A-LANTERN. See IGNIS FATUUS.

JACK-AMEND-ALL. A nickname given to Jack Cade (q.v.).

JACK AND JILL. A nursery song. The name Jill is a corruption of the Norman Julienne, once common in England in the form Gillian. The prototypes of Jack and Jill in Norse mythology are two children rescued by the moon from their father, who forced them to draw water all day. The Scandinavian peasantry still see in the spots on the face of the moon the children with their pail.

JACK AND THE BEAN STALK. A nursery legend found in the folklore of many peoples. The harp has been interpreted as the wind, the bags of treasures as the rain, the red hen as the sun.

JACKASS. A domestic donkey; often abbreviated into jack, especially to designate an entire male. See *Donkey* under ASS.

JACKASS KINGFISHER. See LAUGHING JACKASS.

JACKASS PENGUIN. Any penguin of the genus *Spheniscus*, so called from their cry, which is similar to the braying of a donkey. See PENGUIN.

JACK BRAG. A pretentious character in Theodore Hook's novel of the same name (1837).

JACK'DAW. A familiar Old World crow (*Corvus*, or *Colæus*, *monedula*), very widely distributed in Europe, Asia, and North Africa. It is 13 or 14 inches long and deep black in color, appearing dark gray on the neck, but with a steel-blue gloss elsewhere. It frequents towns and villages and makes its home in towers, steeples, old chimneys, and similar places. It is more or less gregarious and social, is easily domesticated, and exhibits great shrewdness in all its actions. Like other crows, it has considerable power of mimicry and makes an interesting and often an amusing pet. It builds a large nest of sticks and twigs, lined with wool and other soft substances, and lays four to seven eggs, similar to those of American crows.

JACKDAW OF RHEIMS, RĒNIZ, THE. One of the best known of the *Ingoldsby Legends*, the story of a jackdaw which stole the ring of a cardinal and, through the curse laid by the cardinal on the thief, was afflicted until he restored the ring. It has been made into a "comic cantata" with very effective music by George Fox.

JACK'ET (OF. *jaquette*, *jaquet*, dim. of *jaque*, Sp. *jaco*, It. *giaco*, Eng. *jack*, cheap coat of mail). A long cylinder of steel surrounding the tube of a gun for about half its length from the breech end and projecting slightly beyond the latter. See ORDNANCE; GUNS, NAVAL.

JACKFISH. See JACK.

JACK FROST. The personification of frost or cold in nursery tales.

JACK HORNER. An old and familiar English nursery rhyme. Various explanations of its origin have been given. It is said that the abbot of Glastonbury sent to Henry VIII or to the commissioners, when the estates of the monasteries were seized, the title deeds to certain manors, and for safety inclosed them in a pasty, which was intrusted to a messenger. The latter opened the crust and extracted the deeds of the manor of Wells, and the abbot was punished for having withheld them. The rhyme is said by Halliwell to be derived from "Jack and his Stepdame," an older production.

JACKING. A form of night hunting and fishing formerly much resorted to, but now generally discountenanced by American sportsmen and forbidden by statute in most of the United States. Jacking deer was done from a rowboat or canoe, preferably the latter, because a paddle can be used noiselessly. Any light which could be kept concealed until it was needed would serve. Sometimes this light was arranged in the bow of the craft, sometimes it was a lamp fitted into a specially made helmet-like hat. Such a light flashed suddenly at a deer heard feeding or drinking at the water's edge will almost always cause the animal to stand still for a few moments, either in terror or out of curiosity, and its eyes will show plainly in the rays of the jack. Under such conditions it is practically impossible to be certain of killing the animal outright, even with a shotgun. Similar devices are used at night to lure fish to the surface, where they are speared.

JACK-IN-THE-GREEN. The name of one of the principal characters in the May Day festivities in England. The part is usually taken by a boy, whose costume is profusely adorned with wreaths of flowers or greens. Sometimes called *Jack-a-green*. Consult Joseph Strutt, *Sports and Pastimes of the English People*, edited by Hone (London, 1830) and often revised since then. See MAY.

JACK-IN-THE-PULPIT.

JACK-IN-THE-PULPIT, INDIAN TURNIP (*Arisæma triphyllum*). An American perennial

herb of the family Araceæ, common in moist, shady woods. It has a rather large, flattish corm or tuber noted for its acridity, due to the mechanical effects of needle-like crystals called raphides, and often used in domestic medicine; usually two leaves of three leaflets each; and a club-shaped spadix covered by a green or purple spathe which falls away in early summer and exposes the conspicuous red berries at maturity. When properly cooked, the corm resembles in flavor a well-boiled Irish potato. When planted in cool, moist, rich soil, the plant succeeds well in gardens.

JACK KETCH. A former familiar title for the hangman in England, dating from the time of John Ketch (died 1686), public executioner during the reign of James II. At the time of its origin the title was also often closely associated with the notorious Judge Jeffreys. The name is said to be a corruption of Jaquet's, from the name of the lord of the manor of Tyburn. In France the headsman is euphemistically styled M. de Paris.

JACK-O'-LANTERN. See IGNIS FATUUS.

JACK PUDDING. The English equivalent of the German Hanswurst.

JACK RABBIT. See HARE.

JACK ROBINSON. A name occurring in the phrase "Before you can say Jack Robinson," with the meaning of "instantly." The origin of the phrase is unknown. It has been referred to a humorous song by Hudson, a London tobacconist; to a Jack Robinson distinguished by the briefness of his visits to his neighbors and his hasty departures; and by Halliwell to an old play, in which it is cited under the form "as easie . . . as tys to saye *Jacke! robys on.*"

JACKS, LAWRENCE PEARSALL (1860-). An English theologian. He was born in Nottingham, was educated at the University School there and at the University of London, Manchester College, Göttingen, and Harvard. He entered the Unitarian ministry in 1887, was an assistant at Bedford Chapel to Stopford A. Brooke (whose daughter he married in 1889), preached at Renshaw Street Chapel, Liverpool, and at the church of the Messiah, Birmingham, and in 1903 became professor of philosophy in Manchester College, Oxford. From its foundation in 1902 he was editor of the *Hibbert Journal*, an important Unitarian review. Among his brilliant sketches and essays are: *Mad Shepherds, and Other Human Studies* (1910); *The Alchemy of Thought* (1910); *Among the Idol-makers* (1911); *All Men are Ghosts* (1913).

JACK SALMON. The wall-eyed pike. See PIKE PERCH.

JACK SNIPE. 1. A sportsman's name in America for the pectoral sandpiper (*Tringa*, or *Pisobia, maculata*) of the books, also called meadow snipe and grass snipe. It is 8½ to 9 inches long; the wing 5 to 5½ inches. Its color is yellowish brown, striped with blackish above; the scapulars have chestnut edgings; belly and chin white; throat and breast ashy, shaded and sharply streaked; rump blackish; bill and feet greenish. It is migratory in the United States, winters to the southward, and as a rule breeds only in sub-Arctic Canada and Alaska, where it is very numerous in summer west of the Mackenzie, growing rare towards the east. It is very abundant, however, in Labrador in summer. Its course of migration seems to be mainly eastward of the cordillera and plains, for it is never numerous west of

Manitoba. It is different from most sandpipers in its snipe-like behavior; i.e., it does not go much in flocks, but appears upon the marshes singly or in pairs.

2. The jack snipe or half snipe (*Gallinago*, or *Limnocyptes, gallinula*) of Great Britain is a true snipe (q.v.), about half the size of the common typical species of Europe. It is rather infrequent in England and is noted for lying so close as almost to be trodden upon before rising. See PECTORAL SANDPIPER, and Colored Plate of SHORE BIRDS.

JACKSON. A city and the county seat of Jackson Co., Mich., 76 miles by rail west of Detroit, on the Grand River and on the Michigan Central, the Lake Shore and Michigan Southern, the Grand Trunk, the Michigan United Traction, and the Cincinnati Northern railroads (Map: Michigan, E 6). It is built on both sides of the river; the principal streets are paved with brick; and among more prominent features are the State prison, an Odd Fellows Home, a Carnegie library, fine parks, and a fine government building. Jackson is the centre of a productive farming region, and coal and fire clay exist in the vicinity. It has a considerable trade in agricultural produce, and is also an important wholesale distributing point, especially for reaping and mowing machines. Its extensive manufactures include foundry and machine-shop products, agricultural implements, automobiles, stoves, refrigerators, brass, steel, and iron castings, automobile accessories, drop forgings, milling machinery, flour, sewer pipe, fire brick, paper, corsets, etc. The Michigan Central Railroad has large car and machine shops here. The city owns and operates its water works. In 1914 it adopted the commission-manager plan of municipal government. Jackson was settled in 1829, but it did not develop rapidly until after railroad communication was opened by the Michigan Central in 1841. It was chartered as a city in 1857. Pop., 1900, 25,180; 1910, 31,433; 1914 (U. S. est.), 34,097.

JACKSON. The capital of the State of Mississippi, on the Pearl River, 181 miles north of New Orleans, La., on the Illinois Central, the New Orleans Great Northern, the Alabama and Vicksburg, the Yazoo and Mississippi Valley, and the Gulf and Ship Island railroads (Map: Mississippi, E 6). Besides the State capitol, some prominent structures are the Governor's mansion, government building, Millsaps College (Methodist Episcopal), founded in 1892, Bellhaven College for young ladies, Jackson College, Campbell College, State institutions for the deaf and dumb, the blind and the insane, hospitals and sanitariums, James Observatory, a Carnegie library, and the State library. Among the points of interest are the remains of fortifications erected at the siege of Jackson in 1863, the old capitol, a Confederate monument, and a statue of Jefferson Davis. The city is in a cotton-growing region, with very fertile soil, but not far from the sandy, long-leaf-pine region, and has considerable trade and valuable manufactures, including cottonseed products, lumber and lumber products—staves, hubs, spokes, etc.—brooms, machinery, plows, and harrows. Jackson adopted the commission form of government in 1913. The city owns its water works. Settled about 1830, Jackson was incorporated 10 years later. During the Civil War it was occupied in 1863 by General Grant, and in 1864 was for the most part destroyed by General Sherman.

Pop., 1900, 7816; 1910, 21,262; 1914 (U. S. est.), 26,990.

JACKSON. A city and the county seat of Jackson Co., Ohio, 95 miles south by east of Columbus, on the Hocking Valley, the Baltimore and Ohio Southwestern, and the Detroit, Toledo, and Ironton railroads (Map: Ohio, E 7). There are coal and iron mines, iron furnaces, foundries, a shoe factory, pipe works, auger-bit factory, railroad shops, plow works, etc. Jackson, settled as early as 1795 and incorporated in 1847, is governed by a mayor, elected every two years, and a council. Pop., 1900, 4672; 1910, 5468.

JACKSON. A city and the county seat of Madison Co., Tenn., 85 miles by rail north-east of Memphis, on the south fork of the Forked Deer River and on the Nashville, Chattanooga, and St. Louis, the Illinois Central, the Birmingham and Northwestern, and the Mobile and Ohio railroads (Map: Tennessee, B 3). Union University, Lane College (colored), and the Memphis Conference Female Institute are situated here, and there are Carnegie and collegiate libraries, an Elks Home, two hospitals, and several court buildings. Highland and Lancaster parks are places of scenic interest and summer amusement resorts. The city is an important truck-shipping centre, carries on an extensive cotton trade, and among its industrial establishments are large cotton and cottonseed-oil mills, railroad shops, boiler and engine works, furniture, heading, spoke, skewer, and plow factories, grain mills, and manufactories of porch columns, overalls, veneers, tile and brick, automobiles, etc. Settled in 1819, Jackson was incorporated in 1854 and adopted the commission form of government in 1915. The city owns and operates its water works and electric-light plant. Pop., 1900, 14,511; 1910, 15,779.

JACKSON, ABRAHAM REEVES (1827-92). An American physician, born in Philadelphia. He graduated at the Pennsylvania Medical College in 1848; practiced in Stroudsburg, Pa., and Chicago, Ill.; founded and became surgeon-general of the Woman's Hospital of Illinois; was made professor of gynecology in the Rush Medical College, Chicago, in 1872; later became president of the College of Physicians and Surgeons in Chicago; and at the time of his death was president of the American Association of Gynecologists. He was an honorary member of several medical societies and author of numerous papers, among which may be mentioned *Removal of Large Urethro-Vesical Calculus* (1858); *Successful Removal of Both Ovaries* (1866); *Removal of Fibrous Tumor of Uterus* (1872).

JACKSON, ABRAHAM VALENTINE WILLIAMS (1862-). An American Indo-Iranian scholar, born in New York City. He graduated at Columbia in 1883, there held a fellowship in letters from 1883 to 1886, and was instructor in the Anglo-Saxon and Iranian languages from 1887 to 1891. After advanced study at the University of Halle, Germany (1887-89), he was appointed adjunct professor of English language and literature in Columbia (1891). In 1895 he was selected to occupy the chair of Indo-Iranian languages, then newly founded. He became well known as a lecturer on various subjects appertaining to English literature and the Orient, and in 1901, during a visit to India and Ceylon, received special attention from the Parsis, who presented to Columbia a valuable collection of Zoroastrian manuscripts in recognition of the

instruction there given by him in their ancient texts. In 1903, 1907, and 1910 he traveled in Persia and Central Asia, and in 1911 again visited India. He was elected a director of the American Oriental Society and published *A Hymn of Zoroaster* (1888); *An Avesta Grammar in Comparison with Sanskrit* (1892); *An Avesta Reader* (1893); *Zoroaster, the Prophet of Ancient Iran* (1898); *Die iranische Religion* (1900); *From Constantinople to the Tomb of Omar Khayyam* (1911); *A Catalogue of the . . . Persian Manuscripts Presented to the Metropolitan Museum . . . by A. S. Cochran* (1914), with A. Yohannan.

JACKSON, ANDREW (1767-1845). An American general and seventh President of the United States. He was born March 15, 1767. There has been much controversy between North Carolinians and South Carolinians regarding the place of his birth. There is a tradition that he was born at the Waxhaw Settlement in Union Co., N. C., but Jackson himself thought that he was born near the Waxhaw Creek in Lancaster Co., S. C., and in the opinion of his most thorough biographer "the weight of evidence seems to favor the South Carolinians." His father, Andrew Jackson, a poor farm laborer of Scotch-Irish stock, emigrated from Carrickfergus, Ireland, with his wife in 1765 and settled on Twelve Mile Creek in North Carolina. In 1767, a few days before his son's birth, the elder Jackson died, and his widow immediately removed to the home of her sister, Mrs. James Crawford, in South Carolina. In his boyhood Andrew was a leader among the wild youths of his neighborhood and easily surpassed them in quick temper, quarrelsomeness, and enthusiasm for such sports as cockfighting and horse racing. He had little or no schooling except such as is acquired from rough contact with the world. Though but eight years old when the battle of Lexington occurred, before the war was over he had taken some part, being once captured by the British. The death of his mother from a fever, caught while nursing Americans held in prison at Charleston, and of his two brothers at the hands of the British, left him alone in the world. It is not certain what means of support he had, but after working a few weeks at the saddler's trade, in 1784 he began to study law at Salisbury, N. C. While he was yet under 20 he was admitted to the bar as attorney and counselor, and in 1788 was appointed public prosecutor in the region now forming the State of Tennessee. It was a new and wild country, and in the prosecution of his duties Jackson needed chiefly force and persistence, qualities which gained him strong enemies, but equally strong friends. In 1791 he married Mrs. Rachel Robards, a daughter of John Donelson, one of the pioneer settlers of Tennessee. The marriage was the cause of considerable severe comment, from the fact that the bride had been divorced under peculiar circumstances. The parties took what was only a legislative warrant for a trial to be an actual divorce, and were married two years before the actual divorce was granted. They were married a second time, but the unfortunate matter was a sensitive point to Jackson all his life.

In 1796 he was a member of the convention to frame a constitution for Tennessee. In the same year he was chosen to Congress. His political sympathies were with Jefferson, and he went so far as to incur the condemnation of

being one of the 12 who opposed the address to Washington at the close of his administration. While in the House, he secured the payment of a claim which Tennessee had for expenses in an Indian war, adding thereby greatly to his popularity. In 1797 he was elected to a seat in the Senate, but he resigned the next year, having little pleasure in political life. From 1798 to 1804 he was a "Judge of the Supreme Courts" of Tennessee. In 1802 Jackson was chosen major general of the militia over ex-Governor Sevier. On the purchase of Louisiana (1803) Jackson was an unsuccessful applicant for the appointment of Governor. From 1804 to 1811 he was engaged in business, storekeeping, and planting. The abuses of credit in the border State, where there was little money and much land speculation, got him into embarrassments, and his own self-centred personality caused him many quarrels. Besides a quarrel with Sevier he had two duels, in one of which he killed Charles Dickinson, who had been drawn into a quarrel originating in a proposed horse race, and received himself a wound which maimed him for life.

When Burr appeared in the Southwest in 1805, he received cordial support from Jackson until the latter suspected that some disloyalty to the United States was involved. Jackson gave no further help to the enterprise, though he was later convinced of the innocence of Burr's motives, for he appeared as a witness for him at his trial and made a public speech against Jefferson relative to the matter.

The declaration of war against Great Britain in 1812 brought Jackson his opportunity. As soon as he heard the news, he offered his own services and the coöperation of 2070 militia under his control. In January, 1813, he set out under orders for New Orleans, which was regarded as a probable point of attack. In March he was at Natchez, organizing his force with great energy and skill, when suddenly he received orders to disband his forces, neither pay nor rations being furnished for these men, 500 miles from home. Jackson hired transportation on his own responsibility and led his men home in a body. His friend Thomas H. Benton, afterward the Missouri Senator, secured the repayment of this expense, but a slight discord which this good turn might have eased was aggravated by Jackson's standing second for another man in a duel with Jesse Benton, brother of Thomas H. After a fiery quarrel Jackson threatened to horsewhip Thomas H. Benton, and when he met the two brothers in a tavern in Nashville, a bloody fracas took place. Jackson was shot twice, and Jesse Benton was badly stabbed.

Ever since the earliest attempts to remove the Georgia Indians from their territory, there had been intermittent wars. Emboldened by the war between the United States and England, the Creeks in 1813 made further trouble and committed many outrages, the chief of which was the massacre at Fort Mims (q.v.) on August 30. Intense excitement followed, and the whole Southwest was aroused. The Tennessee Legislature called for volunteers and resolved to exterminate the troublesome tribe. In spite of the wound which Jesse Benton had given him, Jackson was soon in the field, and with Colonel Coffee, his former partner, defeated the Indians severely at Talladega and at Tohopeka or Horseshoe Bend on the Tallapoosa River. Jackson distinguished himself in these military opera-

tions by his boundless energy. Besides the foe, Jackson had to contend with discord among the officers, insubordination among his men, and scarcity of food, and he manifested not only a sympathetic understanding of the situation, but a great decision of action. This campaign began Jackson's national career; in August, 1814, he was in command at Mobile, a major general in the regular army.

The British attacked Fort Bowyer on Mobile Point, September 14, and were repulsed. They then, entering Spanish territory, retired to Pensacola, which Jackson had already asked orders to attack; acting now on his own responsibility in default of an answer from Washington, Jackson stormed the town with 3000 men. His success was very important, for it now rendered possible the defense of New Orleans, where Jackson arrived Dec. 1, 1814. The place was without defenses, and but for their own slowness and Jackson's almost frenzied energy, the British might easily have taken the town. Jackson proclaimed martial law, made the utmost of his means, and inspired his men with his own enthusiasm. The army was a motley one, being composed of regulars, militia from the neighboring States, a few pirates, and a battalion of negroes. On Jan. 8, 1815, the British made their grand assault on Jackson's works and were repulsed with great slaughter, the Americans having not only the better leadership, but remarkably good fortune due to various accidents. The British withdrew with the loss of their commander, Sir Edward Pakenham, and more than 2000 men. The American loss was only 8 killed and 14 wounded. The treaty of peace had been signed at Ghent, Dec. 24, 1814, two weeks before the battle. This victory was the greatest American success on land during the War of 1812, and the position it gave Jackson was pre-eminent. Besides his personal popularity among the frontier people, whom he so thoroughly understood, he had now a national reputation. A mutiny in September, 1814, arising from a misunderstanding as to enlistment, resulted finally in the execution of six men in February, 1815. This unprecedented sternness seems to have been justified, but when an attempt was later made to manufacture out of it political capital, Jackson, contrary to his usual method of action, disavowed responsibility. For the arrest of a Judge Hall during the prevalence of martial law Jackson was fined \$1000 for contempt, but 30 years later this was refunded by Congress.

In April, 1815, Jackson was appointed commander in chief of the Southern Division, and Congress voted thanks for his services. His next active work was in the war against the Seminoles in Florida, in the course of which occurred another of his acts which created no little excitement. He arrested and put to death, on the charge of inciting the Indians, two British subjects, an English adventurer, Ambrister, and a Scotch trader, Arbuthnot. At the same time Jackson hanged two Indian chiefs and then seized Pensacola (1818), in spite of the remonstrance of the Spaniards. These proceedings created intense excitement in England, but after much angry correspondence there was a peaceable settlement. In Congress Jackson's conduct was very generally condemned, but all attempts to pass a vote of censure failed. On the cession of Florida to the United States he was appointed Governor (1821), and during his brief term of office had some serious difficulties in consequence

of the arrest of a judge for issuing a writ of habeas corpus. Efforts in Congress to pass censure for this act were not successful.

The Seminole War closed Jackson's military career, and with no inclination of his own he was again taken into political life. He was elected to a seat in the United States Senate in 1823. In 1822 and again in 1824 the Legislature of Tennessee nominated him for President. At the election the latter year there were four candidates, who received electoral votes as follows: John Quincy Adams, 84; William H. Crawford, 41; Henry Clay, 37; Jackson, 99. No one having a majority, the House of Representatives elected Adams, and Jackson retired to private life. But four years afterward he was supported by all the opponents of the administration and elected by an immense majority, the vote being Jackson, 178; Adams, 83. Calhoun was re-elected Vice President. The contest was one of the most personal and bitter in American political history, because Jackson, taking as a personal matter the party slander which accused Adams of buying Clay's support in the preceding election by the promise of the portfolio of State, threw his whole force into the struggle. Jackson was re-elected in 1832, his principal opponent being Henry Clay. In his second term Van Buren was Vice President.

Jackson's eight years' administration of the government meant the rise of the people to power. Jefferson, Madison, Monroe, and even J. Q. Adams had also been affiliated with the Democratic Republican party, but they had been trained statesmen, who administered the government in the interests of all classes. Now a man sprung from the people, relying upon them and thoroughly representing them, held the reins of power. He happened to be more or less of an autocrat, but it was inevitable that his successors would become more and more servants of the people or of the politicians who controlled the people. A new régime much more purely democratic had begun, and it was the people of the Union as a whole, not of the States as units, that had risen to power.

A prominent feature of the new régime was the large number of removals from office, which Jackson may have believed to be necessary to the cleansing of the public service from the corrupting influence of executive patronage. Unfortunately, however, many of his appointments showed that he was not always a good judge of men, and in the pursuit of this policy he unwittingly promoted the evils of the spoils system. (See CIVIL-SERVICE REFORM.) The leading events of Jackson's two administrations were the scandal concerning Mrs. Eaton (see EATON, MARGARET), whereby the cabinet was broken up; the veto of the United States Bank charter; the removal of the deposits of public money from that bank; and particularly the prompt and complete crushing of the nullification movement in South Carolina in 1832. This movement was started in opposition to a high tariff, and Jackson himself was opposed to such a tariff, but he gave South Carolinians to know that while the laws remained unrepealed they should be enforced at any hazard. Before any serious conflict had occurred the matter was settled, chiefly through the influence of Henry Clay. During his second term Jackson was engaged in the bank war. He ordered the Secretary of the Treasury to stop making deposits of public money in the United States Bank and its

branches. The cabinet was not favorable to such a policy, and Jackson put William J. Duane at the head of the Treasury; but as he declined to do the required services, he was displaced, and Roger B. Taney was appointed. Taney obeyed Jackson's order, and, in retaliation, the Senate refused to confirm his nomination as Secretary, and he was subsequently made Chief Justice of the United States Supreme Court. Feeling ran so high in this bank war that the Senate passed a resolution of censure on the President, a proceeding unheard of till then. In 1837 this resolution was by vote expunged from the record. The bank war closed in 1836-37; the old bank was not rechartered; and after some time the independent treasury or subtreasury system was invented to take its place as a depository for public money. During Jackson's terms the national debt was entirely paid off; the Indians were removed from Georgia and nearly all of them from Florida; and two States, Arkansas and Michigan, were admitted to the Union. The chief disturbing element was the question of slavery, and the great financial panic of 1837 was just beginning when he left the chair. His personal ascendancy allowed him without opposition to name his successor, Martin Van Buren, who had skillfully won his friendship. On quitting office he published a farewell address and retired to the Hermitage, as his home near Nashville was called, where he passed the remainder of his life, always, however, taking a deep interest in public affairs. He died June 8, 1845.

Jackson seems to have been very amiable when things were going his way, but when opposition arose his violence of temper and action was ungovernable. He was essentially a man of action and not a thinker, although in his often-assailed bank policy he seems to have been nearer right in some respects than his critics. He was, take him all in all, one of the most commanding personalities in American history, but it seems clear that many of his decisions were determined by the way of manipulation by friends—known as the Kitchen Cabinet—who shrewdly used his force and popularity.

Bibliography. The best biography of Jackson is that by J. S. Bassett (2 vols., New York, 1911). Consult also: J. H. Eaton, *Life of Andrew Jackson* (Philadelphia, 1828); William Cobbett, *Life of Andrew Jackson* (New York, 1834); J. T. Headley, *Lives of Winfield Scott and Andrew Jackson* (ib., 1852); Benton, *Thirty Years' View* (ib., 1854); C. E. A. Gayarre, *Sketch of General Jackson by Himself* (New Orleans, 1857); James Parton, *Life of Andrew Jackson* (3 vols., New York, 1861); S. K. Bolton, *Famous American Statesmen* (ib., 1888); Oliver Dyer, *General Andrew Jackson, "Old Hickory"* (ib., 1892); James Parton, *General Jackson* (ib., 1893); Peck, *The Jacksonian Epoch* (ib., 1899); W. G. Sumner, *Andrew Jackson*, in the "American Statesmen Series" (ib., 1899); W. G. Brown, *Andrew Jackson* (Boston, 1900); A. C. Buell, *Life of Andrew Jackson* (2 vols., New York, 1904); A. S. Colyar, *Life and Times of Andrew Jackson* (2 vols., Nashville, 1904); C. T. Brady, *True Andrew Jackson* (Philadelphia, 1906); MacDonald, *Jacksonian Democracy* (New York, 1906); A. H. Lewis, *Andrew Jackson* (ib., 1907); T. E. Watson, *Life and Times of Andrew Jackson* (Thomson, Ga., 1912). The best-known monuments to Andrew Jackson are those by Clark Mills, in Washington with

replicas at New Orleans and Nashville, and by John Frazee, in Memphis, Tenn.

JACKSON, BENJAMIN DAYDON (1846-). A noted British botanist, born in London and educated at private schools. He is perhaps best known as the compiler of *Index Kewensis* (q.v.), a reference book on which he worked for nearly 14 years, which appeared from 1893 to 1895 (supp., with Durand, 1901-06), and which was long a standard authority for the names of flowering plants. From 1880 to 1902 he was secretary of the Linnean Society, and then became general secretary. Among his other works are: *Guide to the Literature of Botany* (1881); *Vegetable Technology* (1882); *Glossary of Botanical Terms* (1900; 2d ed., 1905); *Life of George Bentham*, in "English Men of Science" (1906); *Darwiniana* (1910); *Index to the Linnean Herbarium* (1912); *Catalogue of Linnean Specimens of Zoölogy* (1913). He also edited works by C. B. Clarke and wrote numerous articles for botanical journals.

JACKSON, CHARLES (1775-1855). An American jurist. Born at Newburyport, Mass., he graduated at Harvard in 1793, studied law with Chief Justice Parsons, and began to practice in 1796 at Newburyport. In 1803 he removed to Boston, where, associated with Judge Hubbard, he had the most lucrative practice in the State. He was judge of the Massachusetts Supreme Court from 1813 to 1824, a member of the State Constitutional Convention of 1820, and one of the commissioners to revise the State laws in 1833. His *Treatise on the Pleadings and Practice in Real Actions* (1828) is a standard work on the law of property.

JACKSON, CHARLES LORING (1847-). An American chemist, born in Boston and educated at Harvard, Heidelberg, and Berlin. In 1868 he became assistant, in 1871 assistant professor, and in 1881 professor of chemistry at Harvard. In 1911 he retired. He published a number of papers, mainly on topics of organic chemistry, in the *Proceedings of the American Academy* and in the *American Journal of Science*. He studied the organic compounds of selenium, the preparation of borneol, of the fluorine derivatives of benzoic acid, of benzene-trisulphonic acid, and other important organic substances.

JACKSON, CHARLES THOMAS (1805-80). An American scientist, born at Plymouth, Mass. He graduated at the Harvard Medical School in 1829 and during the last two years of his course made a mineralogical and geological survey of Nova Scotia in company with Francis Alger of Boston. An account of this expedition is contained in the *Memoirs of the American Academy of Arts and Sciences*. He went to Europe in 1829 and spent three years studying in Paris, varied by occasional trips to Germany and Italy. In 1833 he began the practice of medicine in Boston, but soon abandoned it to devote himself to chemistry, mineralogy, and geology. He was State geologist of Maine in 1836, of Rhode Island in 1839, and of New Hampshire in 1840. In 1837 he had a violent controversy with Morse, to whom he claimed to have given the idea of the telegraph. He explored the wilderness on the southern shore of Lake Superior in 1844, and from 1847 till 1849 was United States surveyor of mineral lands in Michigan. He claimed to be the discoverer of the anæsthetic properties of ether, and this involved him in a dispute with Dr. W. T. G. Morton. His claim was supported by many

Boston physicians, and a committee appointed by the French Academy of Sciences to investigate the matter decided that both men were entitled to recognition. Dr. Jackson published elaborate reports of his work as a State geologist and as a member of the United States Geological Survey; contributed articles to the *American Journal of Science and Arts*, to the *Comptes Rendus*, and to the *Bulletin de la Société Géologique de France*; and wrote a *Manual of Etherization, with a History of its Discovery* (1863).

JACKSON, CYRIL (c.1858-). An English sociologist and educator, educated at Charterhouse and at New College, Oxford. He studied law; worked at Toynbee Hall from 1885 to 1895, becoming a member of the London School Board in 1891; was inspector general of schools for Western Australia in 1903-06; acting agent general for Western Australia in 1910-11; and in 1913 became an alderman of the London County Council. His important published works are reports on educational and industrial subjects, notably those on "boy labor" and "assistance to the unemployed" in the Report of the Royal Commission on Poor Laws; he also wrote *Unemployment and Trade Unions* (1910) and *Outlines of Education in England* (1914).

JACKSON, DUGALD CALEB (1865-). An American electrical engineer. He was born at Kennett Square, Pa., graduated as civil engineer from the Pennsylvania State College in 1885, and studied at Cornell University in 1885-87. He was then vice president and engineer of the Western Engineering Company at Lincoln, Neb., until 1889, for a time was connected with the Edison interests, and then entered private practice as a consulting engineer. In addition to professional duties, from 1891 to 1907 he was also assistant professor of electrical engineering at the University of Wisconsin, and thereafter had charge of the department of electrical engineering at Massachusetts Institute of Technology. In 1905 he was elected president of the Society for the Promotion of Engineering Education, and in 1910 president of the American Institute of Electrical Engineers. He is author of *A Text-Book on Electricity and Magnetism and the Construction of Dynamos* (2 vols., 1893-96) and *Electricity and Magnetism* (1895), and coauthor of *Alternating Currents and Alternating Current Machinery* (1896; rev. ed., 1913) and *An Elementary Book on Electricity and Magnetism and their Applications* (1902).

JACKSON, FORT. See FORT JACKSON.

JACKSON, FREDERICK GEORGE (1860-). A British Arctic explorer. He completed his education at the University of Edinburgh. His earliest polar experiences were those of a whaling voyage in 1886-87. In 1893 he made a sledge journey of about 3000 miles, during which he crossed the Siberian tundra (frozen, marshy prairies) between the Obi and the Pechora rivers. In 1894 he was given command of the expedition sent by Mr. Alfred Harmsworth (later Baron Northcliffe) to explore Franz Josef Land exhaustively and to attempt to reach the North Pole. Although the *Windward* was carried farther north than any vessel previously in these waters, the polar attempt was abandoned when Nansen met Jackson on his remarkable retreat from the *Fram*. Remaining at Franz Josef Land from 1894 to 1897, Jackson explored the archipelago between long. 42° and 56° E. and to lat. 81° 20' N. His observations of the fauna, flora,

and physical conditions of Franz Josef Land were extensive and valuable. For this work he was awarded a gold medal by the Geographical Society of Paris and was made Knight of the Royal Order of St. Olaf. Serving in the Boer War, he attained the grade of captain and was later promoted major. His narratives of Arctic travel appeared under the following titles: *The Great Frozen Land* (1895); *A Thousand Days in the Arctic* (1899).

JACKSON, FREDERICK JOHN FOAKES. See FOAKES-JACKSON.

JACKSON, GEORGE (1864-). A Canadian Methodist clergyman and educator. He was born in Grimsby, England, and was educated at the Wesleyan Methodist College, Richmond, and at London University. He began pastoral work in 1887 on Clitheroe Circuit, but in 1888 removed to Edinburgh, where he was pastor of a mission church until 1906. In the latter year he removed to Ontario, and in 1906-09 was pastor of the Sherbourne Street Methodist Church, Toronto. In 1909 he was appointed professor of the English Bible in Victoria University. He resigned in 1913. His publications include: *Judgment, Human and Divine* (1902); *Young Man's Religion*; *The Old Methodism and the New*; *Memoranda Paulina: The Teaching of Jesus* (1903); *The Fact of Conversion* (1908); *Studies in the Old Testament* (1909); *The Preacher and the Modern Mind* (1910); *In a Preacher's Study* (1914).

JACKSON, GEORGE THOMAS (1852-1916). An American dermatologist, born in New York City, a brother of Samuel Macauley Jackson. He studied at the College of the City of New York, for two years in Berlin, Vienna, and Strassburg, and in 1878 graduated from the College of Physicians and Surgeons, Columbia University. Until 1884 he was in general practice. After that he devoted himself exclusively to dermatology, a subject which he taught at the Woman's Medical College of the New York Infirmary (1890-99), the University of Vermont (1895-1900), and Columbia (instructor, 1890-1908; professor, 1908-13). He is author of: *Diseases of the Hair and Scalp* (1887, rev., 1893); *The Ready Reference Handbook of Diseases of the Skin* (1893; 7th ed., rev., 1914); *Treatise on Diseases of the Hair* (1912), with C. W. McMurtry.

JACKSON, HELEN FISKE HUNT (1831-85). An American poet and novelist, better known by her pen name of H. H. She was born at Amherst, Mass., Oct. 18, 1831. Her father was Prof. N. W. Fiske. At 21 she married Major Edward B. Hunt of the United States Engineers, who died in 1863. She married afterward (1875) William S. Jackson, a banker of Colorado Springs, Colo. She died at San Francisco, Aug. 12, 1885. Helen Hunt was educated at Ipswich, Mass., and in New York and began to write for periodicals during her residence as a widow at Newport, R. I. Her poems won her friends, and in 1870 she published a volume of "Verses by H. H.," which was read widely. From this time her pen was constantly employed. The most ambitious of her works are the novels *Mercy Philbrick's Choice* (1876), *Hetty's Strange History* (1877), both in the "No Name Series"; *A Century of Dishonor* (1881), a plea for better treatment of the Indians; and the romance on the same theme entitled *Ramona* (1884). Mrs. Jackson also wrote some books for children, and several posthumous volumes were brought out

shortly after her death, among them *Sonnets and Lyrics* (1886). The "Saxe Holm Series" are said to be hers. Her poems probably constitute her best claim to remembrance, and such good judges as Emerson—in the preface to *Parnassus* (1874)—and Thomas Wentworth Higginson have admired her lyrics. For an appreciation of her genius, consult T. W. Higginson, *Contemporaries* (Boston, 1900).

JACKSON, HENRY (1839-). An English classical scholar. He was born in Sheffield and was educated at Cheltenham and at Trinity College, Cambridge, of which he became fellow in 1864. From 1875 to 1906 he was prælector in ancient philosophy at Cambridge and then became Regius professor of Greek. He received honorary degrees from St. Andrews, Aberdeen, Glasgow, Oxford, Manchester, Sheffield, and Berlin. His special field being Greek philosophy, particularly Aristotle (the Ethics) and Plato, he contributed articles on Greek philosophers to the *Encyclopædia Britannica* and to classical periodicals and edited the fifth book of Aristotle's *Nicomachean Ethics* (1879) and *Texts to Illustrate the History of Greek Philosophy from Thales to Aristotle* (1901).

JACKSON, HENRY ROOTES (1820-98). An American diplomat and soldier, born in Athens, Ga. He graduated at Yale in 1839 and in the following year was admitted to the bar in Georgia, where he was for several years United States district attorney. During the Mexican War he commanded the First Regiment of Georgia Volunteers. He was judge of the Superior Court from 1849 to 1853, when he was sent as the United States chargé d'affaires to Vienna. There he was Minister Resident from 1854 until his resignation in 1858. After his return to Georgia he aided the United States district attorney in prosecuting the owners of the slaveship *Wanderer*. Jackson was one of the Democratic delegates who seceded from the Charleston convention in 1860. When his State seceded, he became a colonel on Governor Brown's staff and was active in securing the United States arsenal at Augusta with its stores of arms and ammunition. He was then appointed major general by the Governor and was placed in command of all the State troops, but soon resigned this commission to accept one as brigadier general in the Confederate service and went to western Virginia, where he succeeded General Garnett upon the latter's death. Recalled by Governor Brown to aid in the defense of Georgia's seacoast, and unable to obtain leave of absence from the Richmond authorities, he resigned his Confederate commission and was reappointed by the Governor major general and commander of all the State troops. This office he held until the Georgia State troops were turned over to the Confederacy in 1862, when he was left without a commission. He was not again received into the Confederate service until near the close of the war, when he was made a brigadier general in Hood's army and, after taking part in the battle of Franklin, was captured with his whole brigade in the battle of Nashville (q.v.) and was a prisoner during the remainder of the war. He was appointed United States Minister to Mexico in March, 1885, but resigned about a year later because of his disagreement with the government in the matter of the seizure and sale by the Mexican authorities at Tampico in January, 1884, of the American schooner, *Rebecca*. Secretary Bayard held that the charge

against this vessel of attempted smuggling was not substantiated. He published *Tallulah and Other Poems* (1851).

JACKSON, HOWELL EDMUNDS (1832-95). An American jurist, born at Paris, Tenn. He graduated at the University of Virginia in 1854 and at the law department of Cumberland University in 1856 and then began to practice law in Jackson, Tenn., removing to Memphis in 1859 and returning to Jackson in 1876. He was strongly opposed to secession, but went with his State, and after the establishment of the Confederacy was appointed receiver for West Tennessee property confiscated by the new government. At the close of the war he became a member of the Tennessee Court of Referees, a provisional Supreme Court created to hear the cases which had accumulated during the Civil War. In 1880 he was elected to the Tennessee Legislature and the next year to the United States Senate, where he served until April, 1886. He resigned to accept the appointment of United States Circuit Court judge for the Sixth Federal Circuit, and in February, 1893, President Harrison appointed him an associate justice of the United States Supreme Court. When stricken with fatal illness, he forced himself to attend the second hearing of the income-tax law, and his vote would have caused it to become effective had not Justice Shiras (q.v.) reversed his previous decision.

JACKSON, JAMES (1757-1806). An American soldier and political leader, born at Moreton-Hampstead, Devonshire, England. He went to Georgia in 1772 and began the study of law. He joined the "Liberty Boys," took part in the defense of Savannah in 1776, was a member of the first constitutional convention of Georgia in 1777, was made brigade major of the Georgia militia in 1778, and again engaged in the defense of Savannah. After its surrender he went to South Carolina, served with Sumter, Pickens, and Morgan, and was publicly thanked by the last named after the battle of Cowpens. He participated in the siege of Augusta and was left in command after the capture in 1781. Later he organized a partisan legion, which he commanded. When Savannah was recaptured, the Legislature voted him the forfeited house of a Tory. In 1788 he was elected Governor, but declined on account of youth and inexperience. He sat in the First Federal Congress and was elected United States Senator in 1793. This office he resigned in 1795, and was elected to the State Senate in order to force the revocation of the Yazoo land grants. He was an influential member of the constitutional convention of 1798 and was elected Governor the same year. In 1801 he returned to the United States Senate and sat until his death. He was a follower of Jefferson in politics.

JACKSON, JAMES (1777-1867). An American physician, brother of Charles Jackson the jurist. He was born in Newburyport, Mass., graduated at Harvard in 1796, and studied medicine with Dr. Holyoke of Salem and in London. In 1800 he began practice in Boston. He was the first physician of the General Hospital in Boston, which, with Dr. Warren, he had established. In 1810 he was chosen professor of clinical medicine in Harvard and in 1812 professor of theory and practice there. He was several times elected president of the Massachusetts Medical Society. He wrote: *On the Brunonian System* (1809); *Remarks on the*

Medical Effects of Dentition (1812); *Letters to a Young Physician* (1885). Consult Putnam, *Memoir of Dr. James Jackson* (Boston, 1905).

JACKSON, JAMES STRESHLY (1823-62). An American soldier, born in Madison Co., Ky. He was graduated at Jefferson College in 1844 and in 1845 at Transylvania University, where he had studied law. He practiced in Kentucky before and after the Mexican War, in which he fought as a lieutenant of volunteers enlisted by himself. He served in the Thirty-seventh Congress from March, 1861, until the following December, when he resigned to enter the Federal army, for which he raised a company of cavalrymen. He became colonel of the Third Kentucky Cavalry on Dec. 13, 1861, and brigadier general of volunteers the following July, and was killed on Oct. 8, 1862, at the battle of Perryville, where he was one of the division commanders under General McCook in the Army of the Ohio.

JACKSON, JOHN (1778-1831). An English portrait painter, born at Lastingham, Yorkshire. His father was a tailor, who brought him up to the same trade; but Lord Musgrave, who met the youth at Whitby, was impressed by his artistic talent and gave him encouragement. Another patron, Sir George Beaumont, lent him a Reynolds to copy and in 1805 gave him £50 a year to study at the Royal Academy, of which he was elected a member in 1817. Between 1804 and 1830 he exhibited 146 pictures at the Academy and 20 at the British Institution. His best portrait is considered to be that of Flaxman. In the National Gallery, London, are his portraits of the Rev. William Holwell Carr and of James Northcote, R.A.; in the National Gallery of British Art, a portrait drawing of David Wilkie, in red chalk on gray paper; in the Print Room of the British Museum, a collection of his drawings. His portraits are better in color than in drawing or characterization.

JACKSON, SIR JOHN (1851-). An English contractor, born in York and educated at Edinburgh, being trained as a civil engineer. He built many public works, including the last section of the Manchester Ship Canal, with C. J. Mills (completed 1893), the London Tower Bridge (1894), the Dover harbor works, the Keyham dockyard extensions at Devonport (1907), the Simons Town (South Africa) harbor works. Jackson was knighted in 1895 and made a Companion of the Victorian Order in 1911. In 1910 he was elected as a Unionist to the House of Commons from Devonport.

JACKSON, JOHN ADAMS (1825-79). An American sculptor, born at Bath, Me. He studied first in Boston and later with Suisse in Paris, opening a studio in New York on his return to America. At Florence, Italy, in 1853, he modeled busts of Adelaide Phillips and T. Buchanan Read. In 1854, at Boston, he made bust portraits of Wendell Phillips, George S. Hilliard, and Dr. Lyman Beecher. In 1860, being commissioned to make a statue in bronze of Kane the Arctic explorer, he went to Florence to execute the work and continued to reside in Italy. There he produced most of his ideal subjects; among them "Cupid Stringing his Bow," "Peace," "Musidora" and "Il Pastorello," an Italian shepherd boy. His "Eve and the Dead Abel" in the Metropolitan Museum represents him at his best, but lacks strength and originality.

JACKSON, JOHN HUGHLINGS (1834-1911).

A distinguished English neurologist. He received his early medical education in York Medical School; this was followed by a period of study at St. Bartholomew's Hospital, where he received the degrees M.R.C.S. and L.S.A. in 1856. In 1859 he became connected with the London hospital and in 1886 received his master's degree at the University of St. Andrews, where he became lecturer on physiology in 1864. Four years later he delivered the Croonian lectures of the College of Physicians, on "The Evolution and Dissolution of the Nervous System." In 1890 he was Lumleian lecturer, when he took for his theme "Convulsive Seizures," a subject which he had made his own. (See EPILEPSY, a certain type of which disease bears his name.) He received honorary degrees from the universities of Glasgow, Edinburgh, Leeds, Bologna, and Ireland. His literary work was extensive and solid and took the form generally of papers delivered before medical societies or published in medical journals. From a list of more than 200 titles the following may be cited: "Convulsions and Epilepsy," contributed in 1868 to *Reynolds' System of Medicine; Cases of Disease of the Nervous System in Patients the Subject of Inherited Syphilis* (London, 1868); *Clinical and Physiological Researches on the Nervous System* (London, 1873); *A Study of Convulsions* (1870); *Some Remarks on the Routine Use of the Ophthalmoscope in Cerebral Disease* (1879). Consult the obituary sketch in the *Lancet* (London, 1911).

JACKSON, MERCY BRISBEE (1802-77). An American physician. She was born at Harwich, Mass., and graduated at the New England Female Medical College in 1860, though she had previously practiced at Plymouth and Boston for more than 30 years. She was admitted to the American Institute of Homœopathy in Philadelphia in 1871 and was the first woman to obtain that honor. She afterward became a member of the Massachusetts and the Boston Homœopathic societies and in 1873 was made professor of the diseases of children in the Boston University School of Medicine, which position she was filling at the time of her death. She was married twice—first to the Rev. John Brisbee, and after his death to Capt. Daniel Jackson, of Plymouth. She delivered many lectures on the subjects of temperance and woman suffrage and was a contributor to the *Woman's Journal*.

JACKSON, PATRICK TRACY (1780-1847). An American cotton manufacturer, born at Newburyport, Mass., brother of Dr. James Jackson. He was apprenticed to a merchant, made several voyages to the Far East, and engaged afterward at Boston in the India trade, in which he acquired a fortune. With his brother-in-law, Francis C. Lowell, of Boston, he engaged in cotton manufacture and after several experiments succeeded in producing a model from which a power loom was constructed in 1814 by Paul Moody. They purchased their first mill in 1813 at Waltham—the first that converted the raw cotton into cloth. In 1821 he purchased land on the Merrimac River, on which the Merrimac Manufacturing Company erected a number of mills under his auspices. This was the nucleus of the present city of Lowell. In 1830 he obtained a charter for a railroad from Lowell to Boston, which under his direction was completed in 1835. He took a deep interest in the moral and intellectual welfare of his operatives.

JACKSON, SAMUEL MACAULEY (1851-1912). An American editor, born in New York City, a brother of George Thomas Jackson. He graduated in 1870 at the College of the City of New York, in 1873 at Union Theological Seminary, and in 1873-75 studied at the University of Leipzig. From 1876 to 1880 he was pastor of the Presbyterian Church at Norwood, N. J., and from 1895 to 1912 professor of Church history in New York University. He was connected as editor or contributor with a number of dictionaries and encyclopædias, including the first edition of the *NEW INTERNATIONAL ENCYCLOPÆDIA*. He was editor in chief of the *Concise Dictionary of Religious Knowledge* (1891), of the "Heroes of the Reformation Series" (9 vols., 1898-1906), of *Handbooks for Practical Workers in Church and Philanthropy* (9 vols., 1899-1904), and of the new *Schaff-Herzog Encyclopædia of Religious Knowledge* (12 vols., 1907-11). For the "Heroes of the Reformation Series," he wrote *Huldreich Zwingli* (1901, 1903), supplemented by *Zwingli Selections* (1901), and by *The Latin Works and the Correspondence of Huldreich Zwingli, together with Selections of his German Works*, in English translation, vol. i (1912).

JACKSON, SHELDON (1834-1909). An American Presbyterian missionary and educator. He was born at Minaville, N. Y., graduated from Union College in 1855 and from Princeton Theological Seminary in 1858, and, entering home mission work, organized the first Presbyterian churches in Wyoming, Montana, Idaho, Utah, and Arizona, and was especially prominent in Alaska. He was made government agent of education in Alaska in 1885; published the *First Annual Report on Education in Alaska* (1886); and conceived and carried out the plan of introducing reindeer into Alaska, working first with private and later with government support. In 1898 he was United States special agent to procure a Lapp colony in Alaska. Jackson was a successful speaker on missions, was moderator of the Presbyterian General Assembly in 1897, was author of *Alaska and Missions on the North Pacific Coast* (1880), and in 1896 assisted in the foundation of a missionary college in Utah. Consult R. L. Stewart, *Sheldon Jackson* (New York, 1908).

JACKSON, STONEWALL. See JACKSON, THOMAS JONATHAN.

JACKSON, THOMAS (1783-1873). An English Wesleyan clergyman and author, born at Sancton, Yorkshire. He entered the ministry in 1804. From 1824 to 1843, as editor of the *Wesleyan Methodist Magazine* and of the publications of the Methodist Book Concern, he accomplished an immense amount of work. From 1843 to 1862 he was theological tutor at the Richmond Theological Institution. He was twice president of the British Conference. A complete list of his own works includes 40 titles, and the works which he edited 12 more. An authority on all matters pertaining to Methodism and Methodist history, to him we owe the rescue of the manuscripts of the journals of John and Charles Wesley. A large library which he collected relating to early Methodism and especially rich in Wesleyana was presented by William Deering to Garret Biblical Institute, Evanston, Ill. Jackson's principal works are: *The Life of John Goodwin* (1822); *The Centenary of Wesleyan Methodism* (1839); *The Life of Charles Wesley* (2 vols., 1849); *The Journal of Charles*

Wesley (2 vols., 1849); *The Life of R. Newton* (1855). He edited the works of John Wesley (14 vols., 1829-31); *A Collection of Christian Biography* (12 vols., 1837-40); *The Journals of John Wesley* (4 vols., 1864); *The Lives of the Early Methodist Preachers* (6 vols., 1865). Consult his autobiography, *Recollections of my own Life and Times*, edited by B. Frankland (London, 1876).

JACKSON, SIR THOMAS GRAHAM, first BARONET (1835-). An English architect, born in Hampstead. He was educated at Brighton and at Wadham College, Oxford, of which he was a fellow in 1864-80. He studied architecture under Sir George Gilbert Scott and is best known for his academic buildings—e.g., Brasenose College, Lincoln, Corpus Christi, and Trinity at Oxford, the Law Library and Law School, the Archæological Museum, and the Psychological Laboratories at Cambridge, and buildings at Eton, Harrow, Rugby, and Uppingham—and for his restorations, notably, Winchester Cathedral, the Bodleian Library and St. Mary's and All Saints churches, Oxford. He designed bookplates and table glass, doing much to develop English glass blowing. Honorary degrees were conferred on him by Cambridge (1910) and Oxford (1911), and he was made Baronet in 1913. He wrote: *Modern Gothic Architecture* (1873); *Dalmatia, the Quarnero, and Istria* (1887); *Wadham College, Oxford* (1893); *Reason in Architecture* (1906); *Byzantine and Romanesque Architecture* (1913).

JACKSON, THOMAS JONATHAN, generally known as STONEWALL JACKSON (1824-63). A famous American soldier, born Jan. 21, 1824, of Scotch-Irish-English stock, at Clarksburg in western Virginia (now West Virginia). At an early age he was left to the care of an uncle, a farmer and miller, under whom he was trained in business methods and received some opportunity for study. When only 18, he became sheriff of the county, and soon after was admitted to West Point, where in 1846 he graduated No. 18 in a class of 70, which included McClellan, Reno, Gibbon, Pickett, Maury, A. P. Hill, and Wilcox. He was assigned as second lieutenant to the First Artillery, ordered to join Magruder's Battery (then serving in Mexico), almost immediately achieved prominence in the operations under General Scott, and was brevetted captain and major for gallantry at Contreras, Churubusco, and Chapultepec. From 1848 to 1851 he was stationed at Fort Hamilton and first became noted for that strong religious tendency which afterward caused him to be known as the Havelock of the Confederate army. On March 27, 1851, he resigned from the army and became professor of natural and experimental philosophy and artillery tactics in the Virginia Military Institute, at Lexington, Va. He was not a good teacher, but his influence on his students and on those with whom he was closely associated was profound. In 1856 he visited Europe. On April 21, 1861, soon after the outbreak of the Civil War, Jackson was ordered by direction of the Governor of Virginia to report with his corps of cadets at Richmond for active service. He was commissioned a colonel, was placed in command of the Virginia forces, and was sent to Harper's Ferry. In July of the same year his troops were organized into a brigade (afterward the Stonewall Brigade), and he was appointed a brigadier general. When the Confederates under Johnston moved from

Harper's Ferry towards Manassas, Jackson's brigade was in the van and among the first to get into position. In the first battle of Bull Run the South Carolinians were sorely pressed, and their commander, General Bee, seeking to encourage them, is said to have cried out, "Look at Jackson—there he stands like a stone wall," thus originating the historic sobriquet. In September Jackson was promoted to be major general and was assigned to command the Confederate forces in the lower Shenandoah valley. The duty assigned him is thus described by General Johnston: "After it became evident that the valley was to be invaded by an army too strong to be encountered by Jackson's division, that officer was instructed to endeavor to employ the invaders in the valley, but without exposing himself to the danger of defeat, by keeping so near the enemy as to keep him from making any considerable detachment to reënforce McClellan, but not so near that he might be compelled to fight." In pursuance of this plan Jackson fell back up the valley before Banks, who occupied Winchester. Late in March, 1862, the Federal forces were withdrawn to Manassas, as an outpost of the defenses of Washington, and were closely followed by Jackson. Underestimating the strength of the Federal rear guard under General Shields, he made a sharp attack (March 23) upon that officer's position at Kernstown, 3 miles south of Winchester, but after a severe struggle of three hours was repulsed, retiring in good order, with the loss of several hundred men and one piece of artillery. While this affair was a reverse to the Confederates, the boldness shown by Jackson confirmed the Federal authorities in the determination to retain McDowell in front of the capital in spite of McClellan's protest. Jackson finally retired to Staunton, from which point (having increased his available force to 16,000 men) he confronted 30,000 men under Banks and Frémont with three columns, attacked the Federal detachments in detail, and succeeded in outmanœuvring them, particularly in the affair at McDowell (May 8). Banks, finding his communications threatened, fell back across the Potomac, closely followed by Jackson. Soon afterward Jackson reoccupied Winchester. About May 30, finding his communications with Richmond threatened by a fresh Federal force under McDowell, he began a rapid and masterly retreat up the valley, halting at certain favorable points and engaging his pursuers successfully, particularly at Cross Keys and Port Republic (June 6, 8, and 9). Jackson's valley campaign was a conspicuous illustration of his characteristics as a leader, the extraordinary mobility of his infantry earning for it the title of foot cavalry.

Early in April, 1862, the Confederate army, under Gen. J. E. Johnston, was lying in front of Richmond. McClellan, at the head of the Army of the Potomac, was marching up the peninsula to invest that city, meeting with but little opposition save at Yorktown and Williamsburg (qq.v.). Gen. R. E. Lee was placed in command of the Confederate forces after the battle of Seven Pines or Fair Oaks (May 31-June 1), in which Johnston had been severely wounded, and one of his first acts was to order General Jackson to join him with his corps. The junction was effected with Jackson's customary promptness and skill, and he suddenly appeared (June 26) at Mechanicsville, upon the right flank of the Federal army, which fell back

after a smart engagement to Gaines's Mill, where on the following day the battle was renewed. Jackson's corps took part in the movements attending McClellan's "change of base" and was especially prominent at Malvern Hill (July 1). Soon afterward Jackson confronted General Pope, who with the combined forces of Banks, Shields, and Frémont was assuming the offensive in northern Virginia. He first defeated Banks at Cedar Mountain, near Culpeper, Va., on August 9, and by a rapid and daring flank movement gained Pope's rear and his depot of supplies at Manassas Junction. On August 29-30 the Confederates under Lee and Jackson achieved a decisive victory over Pope in the second battle of Bull Run, which forced him to fall back upon the Potomac. In Lee's invasion of Maryland, which immediately followed, Jackson was detached to capture Harper's Ferry, which fell into his hands, together with more than 11,500 prisoners and considerable material of war. At Antietam, on September 17, he commanded the Confederate left wing, his corps bearing the brunt of the battle. At Fredericksburg, December 13, Jackson, who had recently been promoted to be lieutenant general, commanded the right of the Army of Northern Virginia and repelled the attack made by Burnside's left grand division under Franklin. In the following spring the new commander of the Army of the Potomac, General Hooker, crossed the Rappahannock and attempted to interpose his command between Lee and Richmond, sending nearly all his cavalry under Stoneman to cut the Confederate communications with Richmond. The Federal forces, drawn up at Chancellorsville, were greatly superior in strength and were strongly intrenched, excepting on the extreme right of their line. Taking advantage of this weakness, Jackson, on May 2, with Lee's consent, withdrew his corps from the front, made a long and rapid detour, came in unobserved on the enemy's right flank (Howard's corps), and, screened by the dense wood, advanced in three lines and burst like a tornado upon the unsuspecting Federals. After a slight effort at resistance the greater part of Howard's corps fled panic-stricken to the rear, hotly pursued by Jackson's men, who were, however, greatly impeded by the underbrush and lost their formation. With a small escort Jackson advanced in front of his lines, between eight and nine o'clock P.M., to reconnoitre. As he was returning, his party was mistaken for Federal cavalry and was fired upon by the Confederates. Jackson was severely wounded in the left arm and right hand. On the following day his left arm was amputated, and he seemed in a fair way to recover; but pneumonia set in, from which he died at Guinea Station, May 10, 1863. Jackson was conspicuous not only for his military ability but also for his personal virtues. Like Cromwell, he blended the devoutness of the Puritan with the severity of the soldier. He never began a battle without a prayer and after a victory publicly gave thanks to God. He was very gentle in his social relations, and he believed in making war with consideration for all noncombatants, but to the bitter end, relentlessly, against all enemies of his cause. He resembled Sheridan in the soundness of his judgment, quickness to seize an advantage, and personal magnetism, but, like that general, the full measure of his capacity was never tested. When Lee heard of his wounds, he exclaimed:

"General Jackson has lost his left arm; I have lost my *right* arm."

In accordance with his own wishes, he was buried at Lexington, Va., where a statue and a memorial hall commemorate his connection with the place. There is a monument to his memory in one of the public parks in Richmond, erected by his English admirers; and the spot where he received his death wound is marked by a plain granite shaft bearing his name. Jackson was twice married—first to Miss Eleanor Junkin (died 1854), and second to Miss Mary A. Morrison.

JACKSON, WILLIAM LAWIES, first BARON ALLERTON (1840-). An English politician. He was born in Yorkshire, was educated privately and at a school conducted by the Moravians, and entered upon a business career. In 1876 he sought election to the House of Commons as member for Leeds in the Conservative interest, but was defeated. In 1880 he was successful in North Leeds and was returned for that constituency until 1902. His abilities were recognized in 1885 in his appointment as Financial Secretary to the Treasury in Lord Salisbury's first administration, and he held the same office in the second administration of that statesman, formed in 1886. In 1890 he was appointed Privy Councilor and in 1891-92 served as Chief Secretary for Ireland. In 1902 he was created Baron Allerton of Chapel Allerton. While engaged in politics, he maintained his connection with business enterprises and was for many years chairman of the Great Northern Railway Company.

JACKSON SQUARE. A public square of New Orleans, La., formerly the Place d'Armes, and renamed for Andrew Jackson, who in 1815 defeated the British at New Orleans.

JACKSONVILLE. A city and the county seat of Duval Co., Fla., 14 miles from the Atlantic Ocean and 138 miles by rail southwest of Savannah, Ga., on the St. Johns River, the Florida East Coast Canal, and on the Seaboard Air Line, the Georgia Southern and Florida, the Atlantic Coast Line, the Southern, and the Florida East Coast railroads (Map: Florida, E 1). Connected with New York, Charleston, and other Atlantic coast ports by steamship, it has, since the completion of the improvements in the river, become an important shipping point for lumber, shingles, crossties, cotton, phosphates, kaolin and clay, oranges, garden produce, naval stores, etc. The city has also a considerable wholesale and retail trade and important fruit-growing interests. Prominent among the industrial establishments are the Union Stock Yards, cigar factories, lumber and planing mills, mattress and palmetto-fibre factories, a fertilizer plant, carriage works, iron foundries, brick-yards, shipyards, and steam-engineering works. Jacksonville has long been a popular winter

resort. It has ten public parks and is well paved, 75 miles of its streets with macadam and vitrified brick. Among the more notable buildings are the government building, city hall, county courthouse, armory, Union Depot, St. Luke's Hospital, United States Marine Hospital, Confederate Soldiers' Home, Daniel Memorial and St. Mary's orphan homes, several fine hotels, a high school, a Carnegie library, and the Central Grammar School. Hemming Park contains a Confederate monument. There are also large ostrich and alligator farms, and a Government Weather Bureau Station. The government is vested in a mayor and city council. A board of nine bond trustees have charge of all municipal plants, but appropriations are fixed by the council. Jacksonville has a 30-foot channel at mean low water to the sea. Work was begun in 1914 on the construction of municipal docks and terminals, which are to cost \$1,500,000. The water works and electric-light plant are owned by the municipality. Jacksonville, named in honor of Gen. Andrew Jackson, Florida's first Territorial Governor, was founded in 1822. On May 3, 1901, a fire swept over 148 blocks of the city (450 acres), causing a loss of over \$10,000,000. Pop., 1900, 28,429; 1910, 57,699; 1914 (U. S. est.), 70,173.

JACKSONVILLE. A city and the county seat of Morgan Co., Ill., 93 miles north of St. Louis, Mo., on the Chicago and Alton, the Chicago, Peoria, and St. Louis, the Wabash, and the Chicago, Burlington, and Quincy railroads (Map: Illinois, D 6). Primarily a residential place, Jacksonville has numerous colleges and public institutions. It is the seat of Illinois College, founded in 1829 (the first institution of higher learning in the State); Routt College (Catholic); the Illinois Woman's College (Methodist Episcopal), opened in 1847; Illinois Conservatory of Music, connected with Illinois College; Illinois College of Music, connected with Illinois Woman's College; the Jacksonville State Hospital for the Insane; and State institutions for the blind and the deaf and dumb. There are also the Passavant Memorial Hospital, Hospital of Our Saviour, and a Carnegie library. Duncan Park and Nichols Park are here. The city hall, courthouse, and high school are prominent buildings, and Morgan Lake is of interest. The principal industrial establishments include railroad-car shops of the Chicago, Peoria, and St. Louis, woolen and planing mills, brickyards, several large cigar factories, and bridge works. Jacksonville, named in honor of Gen. Andrew Jackson, was founded as the county seat in 1825 and was first incorporated in 1867, this charter being still in operation. The government is of the commission form, the elective officers being a mayor and four commissioners. There are municipal water works and electric-light plant. Pop., 1900, 15,078; 1910, 15,326; 1914 (U. S. est.), 15,431.

JACKSONVILLE. A town in Cherokee Co., Tex., 118 miles southeast of Dallas, on the International and Great Northern, the Texas and New Orleans, and the St. Louis Southwestern railroads (Map: Texas, E 4). It is the seat of the Alexander Collegiate Institute (Methodist) and of the Jacksonville Baptist College. The city is in a fertile agricultural district, is an important fruit and truck-shipping centre, and has oil, saw and planing mills, and basket and crate factories. The water works are owned by the municipality. Pop., 1900, 1568; 1910, 2875.

JACKSON WHITES. A settlement of mixed-blood Indians in northern New Jersey.

JACK SPRAT. A familiar English nursery rhyme, occurring in Halliwell's *Nursery Rhymes*, where Archdeacon Pratt occupies the place of the later hero, Jack Sprat.

JACK'STONES. A game played with five small pebbles, marbles, or pieces of specially shaped metal (iron). The popular forms of the game are as follows: (a) All five stones are tossed into the air and caught, so far as is possible, on the back of the hand; or else one of the stones at a time is tossed up and caught in various methods agreed upon. (b) Ones.—In this exercise the stones are at first held in the hand; the jack (any one of the five) is then tossed into the air; the remaining four are laid upon the floor, and the jack is caught before it can land. In *Twos*, *Threes*, and *Fours* the stones are picked up, while the jack is in the air, by twos, threes, or fours, as the case may be. Other games with jackstones are *Riding the Elephant*, *Set the Table*, *Peas in the Pod*, and *Horses in the Stable*. According to Aristophanes, jackstones was a girls' game and exceedingly popular. Other ancient writers say the game was originally played with the knucklebones of sheep.

JACK'STRAWS. A game played with from 20 to 100 little sticks of ivory or wood, of uniform size and between 4 and 6 inches in length, carved (with the exception of a few jackstraws which are left perfectly plain) to resemble weapons, implements, tools, etc. The game consists in letting the sticks fall together in a loose heap, each player in turn extricating as many straws as possible (one at a time) without moving perceptibly any other straw. The decision is in favor of the player with the most straws. Originally the name of the game was jerkstraws, and in England it is also called spillikins. In Germany it is known as *Federspiel*, and in France as *Jonchets* or *Honchets* (from *joncher*, to strew).

JACK-TAR. A common term for a sailor, derived from his tarpaulin garments, and frequently shortened to tar.

JACK THE GIANT KILLER. A nursery tale, the subject of which appears in various legends. The English version is adapted from an old British story of Corineus the Trojan, translated by Geoffrey of Monmouth. The theme of the tale is the superiority of skill to force.

JACK THE RIPPER. A name given to the unknown perpetrator of a series of 10 brutal murders which occurred in the East End of London between April and September, 1888.

JACK, jāk, **JAK**, or **JACA**, zhä'kä, **TREE** (East Indian *jaca*), *Artocarpus integrifolia*. An East Indian tree of the same genus as the breadfruit (q.v.), but larger. The fruit, which is very large and weighs from 5 to 50 pounds, sometimes 70 pounds, is produced in great abundance. It resembles the breadfruit, but has a pulp of somewhat unpleasant flavor. It forms a great part of the food of the natives in some parts of India, Ceylon, etc. The seeds, which lie immediately under the rind, are very palatable when roasted. The timber, which is yellowish, strong, and ornamental, is used for almost every purpose and is exported for making musical instruments, cabinetwork, the backs of brushes, marqueterie floors, etc. To supply the demand of it, the tree is being planted in many tropical countries.

JACMEL, or **JACQUEMEL**, zhāk'mēl'. A seaport town on the south coast of Haiti, situ-

ated on a bay of the same name, 30 miles southwest of Port-au-Prince (Map: West Indies, D 3). The streets are generally very narrow, and the houses mostly of wood. The bay is open, and vessels anchor about half a mile from shore and discharge and load by means of lighters. It has a considerable trade with the United States and is visited regularly by the English Royal Mail steamers. The population of the commune is estimated at from 30,000 to 50,000. Jacmel is the residence of a United States consular agent.

JA'COB (Heb. *Ya'akōb*, probably 'he supplants,' or 'he deceives,' 'El' being understood as the subject; connected by Gen. xxv. 26 with 'akeb, 'a heel,' and by Gen. xxvii. 36 with the root meaning 'to deceive'). One of the Hebrew patriarchs. The story of Jacob, with numerous insertions, is found in Gen. xxv-1 and is as follows: He was one of the two sons born to Isaac and Rebekah. His character, quiet, peaceful, and home-loving, appealed to Rebekah, and she loved him more than she did Esau. Taking advantage of his brother's hunger, he bought his birthright (Gen. xxv. 29-34). Later, instigated by his mother, who had heard of Isaac's purpose to bless Esau, he impersonated his brother and received the blessing intended for the latter. As a consequence, Jacob had to flee from home, receiving another blessing from his father before his departure. By his father's command he went to Padan-Aram, to the house of Laban (Gen. xxvii-xxviii. 5). Here he served seven years for Rachel, but Leah was given to him instead. Undaunted, he served seven years more for Rachel (Gen. xxix). Of his two wives and two maids, Bilhah and Zilpah, Jacob had 12 sons and one daughter (Gen. xxix. 31-xxx. 24; xxxv. 16-18). Finally Jacob made up his mind to return home. His wives readily agreed, and they stole away from Laban, who pursued and caught up with Jacob, but did him no harm (Gen. xxx. 25-xxxi). On the way home he met Esau, who behaved magnanimously (Gen. xxxii-xxxiii. 16). After having put away the strange gods found in his camp, Jacob came to Bethel and made an altar on the place where God had appeared to him when he fled from his brother (Gen. xxxv. 1-15). He finally settled in Palestine, but afterward went to Egypt, where his son Joseph (q.v.) had preceded him (Gen. xxxvii, xlvi). Jacob died in Egypt at the age of 147, but was buried by his sons in the cave of Machpelah (Gen. xlix. 33; l. 13). In the course of his career there were three distinct places in which Yahwe or His messengers appeared to him. When fleeing from Esau, he halted at Bethel (Gen. xxviii) and was there assured in a dream, in which God Himself appeared standing beside a ladder on which heavenly beings ascended and descended, that he should come safely back to his native land. After his return he again visited Bethel, and God once more appeared to him, changed his name to Israel, and announced the future greatness of the Hebrew nation (Gen. xxxv). At Mahanaim he encountered angels of God (Gen. xxxii. 1, 2). Lastly, at Peniel he had an encounter with a divine being, who first fought with him and, when subdued, blessed the patriarch and announced that his name should henceforth be Israel, interpreted as one who prevails in the conflicts with gods and with men (Gen. xxxii. 24-32).

The first notable feature of the undoubtedly

composite narrative, viewed as a whole, is the greater abundance of incidents than in the narratives of Abraham and Isaac, and the second is the various cycles of tales embodied in the Jacob narrative. We have in the first place (a) a series of Jacob-Esau stories; (b) Jacob-Laban stories; (c) a series of incidents connected with sanctuaries, Bethel, Mahanaim, Peniel, and Shechem; (d) stories of Jacob's children. There are good reasons for supposing that the Jacob-Esau and the Jacob-Laban stories existed independently, but have subsequently been combined. In this process the various incidents have been separated and inserted in the story of Jacob's career at points where they seemed best to fit in. It thus happens that the Jacob-Esau stories are not told consecutively; but after the account of the birth of Jacob and Esau it is explained how Esau lost his birthright, and the flight of Jacob is related (chaps. xxv-xxvii); the Jacob-Laban tales are then introduced (chaps. xxviii-xxxi), ending with a second flight of Jacob, this time from Laban; then the combination of the Jacob-Esau stories is again taken up and brought to a close (xxxii-xxxiii. 17), after which we have a series of miscellaneous incidents in Canaan and Egypt. Interspersed in these three sections of the narrative we encounter the incidents at the sanctuaries Bethel and Mahanaim; the marriages of Jacob and the birth of his children; incidents in the careers of his children, leading to the introduction of an entirely independent cycle of Joseph stories (Gen. xxxvii-xlvi. 1).

The elaborate and complex character of the narrative points to the union of various streams of tradition, and under the circumstances it is not easy to determine the centre to which Jacob belongs. That, like Israel, he is not an individual, but either represents some clan as the eponymous ancestor, or is the name of a local divinity, is thought to be certain; and the fact that in the name of one of the Hyksos kings, Jacob-her (Jacob is satisfied), Jacob appears to be a divine name has been quoted as favoring the latter alternative. The prominence of Bethel in the Jacob-Esau cycle points to this place as at one time at least the home of the tribe or the worshipers of the god. Some scholars think that the figure of Jacob was originally connected with the southern Bethel, or Bethuel, the modern Halasa. (See NEGEB.) The rivalry between Jacob and Esau is more easily understood if this is the case. It reflects the hostility between Hebrews and Edomites (see ESAU; EDM) which marks the relation between those two groups, conscious throughout their history of the close genealogical ties that bound them together. Just as in the case of Ishmael (q.v.) features are found which place him in a more favorable light than Isaac, so in the Jacob-Esau cycle there is at bottom a series of traditions which originated in the Esau groups, and which Jewish tradition had to reshape so as to remove all features unfavorable to Jacob. The attempt, however, did not succeed altogether; and accordingly Jacob appears actually in the light of a deceiver and, what is more, is obliged to flee from Esau. This flight, if it means anything, points to the discomfiture at some time of the Jacob clan driven from its district by the more powerful Esau. An alliance is entered upon between Jacob and a distinct Aramæan clan, Laban. The marriages of Jacob into four groups and the birth of

numerous children indicate the gradual growth and extension of the Jacob clan until it feels itself powerful enough to cut loose from Laban and return to its former haunts.

But the old popular traditions have been made to serve the historical pragmatism. It was deemed necessary to connect the 12 sections of the Hebrew confederacy with patriarchal history, and hence the extension of the Jacob clan is depicted as though the confederates all sprang from him, whereas, as a matter of fact, the Hebrew confederacy represents the combination of heterogeneous elements having less in common than many of the groups have with others who did not join the confederation or were never incorporated into it. The adjustment of tribal traditions to the later religious and historical theory did not proceed without encountering hindrances. To secure the number 12 and make it work right on all occasions was especially difficult, and the narrators are not at all consistent in their method of obtaining this number. It is this attempted adjustment of popular stories, legends, and myths to later theory that accounts for the identification of Jacob with Israel, the eponymous ancestor of the *Bene Israel*; and in this process of elaboration and transformation of old stories it is also important to note the alternating traces of northern and southern Hebrew writers. It was the northern kingdom, formed of 10 tribes, that represented the real Israel; and the identification of Jacob with Israel and the favoritism shown by Jacob to Joseph (the father of Ephraim and Manasseh) represent the work of northern writers, who thus turn out to have had the larger share in the process of reshaping traditions. Rightly interpreted, the story of Jacob thus becomes the key to the history of Jewish tradition. In its details it not only conceals a large amount of valuable material for the earlier traditions of many of the clans forming the Hebrew confederation, but also enables us to trace the gradual progress of the transformation of the material and its adaptation to the purpose of writers imbued with strong likes and dislikes, who viewed the past from a very subjective point of view. To this point of view there must be added a religious theory which is the outcome of an uncompromising confidence in Yahwe and the zealous and exclusive devotion to His service. This theory is, in brief, that Yahwe established His covenant with the patriarchs, and that the history of the people back to its beginnings is an illustration and proof of this covenant. In some respects Jacob is a more important prop to this theory than even Abraham, certainly more important than Isaac. Indeed, it would seem that the story of Jacob thus worked out represents by itself a complete illustration of the theory, and that Abraham and Isaac are tacked on to it as appendices or links by means of which the theory can be joined to another originally independent series of traditions, again reshaped, elaborated, and made to take a definite direction.

Bibliography. For full discussion of the investigations of the Jacob narratives, consult the commentaries on Genesis of Dillmann, Holzinger, Gunkel, Skinner, and Driver, and the Hebrew histories of Wellhausen, Stade, Guthe, Kittel, and Piepenbring; also Stärk, *Studien zur Religions- und Sprachgeschichte des alten Testaments* (Berlin, 1899 et seq.). For the later Jewish legends about Jacob, consult the article

"Jacob," in Hamburger, *Real Encyklopaedie für Bibel und Talmud* (Leipzig, 1897), and in The *Jewish Encyclopaedia* (New York, 1904). Winckler, in his *Geschichte Israels* (Leipzig, 1895-1900), Stucken, *Astralmythen der Hebräer* (ib., 1896), and Jeremias, *Das alte Testament im Lichte des alten Orients* (ib., 1906), propose a mythological explanation of Jacob; but the theory as a whole has not been accepted, though it may be admitted that some mythical elements may have crept into the narrative.

JACOB, GILES (1686-1744). An English compiler, born at Romsey, Hampshire. He studied law and published a great number of technical works, such as *The Accomplished Conveyancer* (3 vols., 1714) and the *Compleat Chancery-Practiser* (1730), besides his dissertations on rural life, *The Compleat Court-Keeper* (1713), *The Country Gentleman's Vade-Mecum* (1717), *The Compleat Sportsman* (1718), and *The Land Purchaser's Companion* (1720); but his most important work was his *Poetical Register, or Lives and Characters of the English Dramatic Poets* (2 vols., 1719-20).

JACOB, JOHN (1812-58). An English soldier and military author. He was born at Woolavinton, Somerset, Jan. 11, 1812, and was educated at Addiscombe. He entered the Bombay Artillery in 1828, served in the Afghan War in 1839, and in 1841 took command of the Sind (or Jacob's) irregular horse, with which he enforced order in Upper Sind and Cutch, and under Napier distinguished himself at Miani and elsewhere. The injustice of William Napier's *Conquest of the Sind* roused Jacob to his own defense and to Outram's. In 1852 he became commandant of the native police of Upper Sind; negotiated a treaty with the Khan of Khelat (1854); in 1857 served under Outram; and, after his departure, was in sole command of the army in Persia. He died Dec. 5, 1858, at Jacobabad, which had been named in his honor. Jacob was a splendid organizer of native troops, an excellent cavalry officer, and the inventor of a rifle and an explosive bullet. He wrote many tracts on the defects of the British army and civil service in India; collected by Pelly, *Views and Opinions of General Jacob* (2d ed., 1858). Consult Shand, *General John Jacob* (London, 1900).

JACOB, zhá'kôb', LOUIS LÉON (1768-1854). A French admiral. He was born at Tonnay, Charente, was educated at Rochefort, and volunteered from a clerkship in the marine bureau to the navy (1784). He was promoted to ensign in 1793, commanded the *Ça Ira* in her brave fight against a superior English force (1795), and was taken prisoner. After his release he distinguished himself (1798) against Sir John Warren's fleet and was again captured but soon exchanged. He took part in the campaign in Santo Domingo in 1801, was commandant at Granville (1805) and at Naples (1806), and shared in the battle of Sables d'Olonne. He was made a rear admiral in 1812 and in 1814 defended Rochefort. He was retired on the Restoration, reentered active service in 1820, was Governor of Guadeloupe from 1823 to 1826, prepared the expedition against Morocco and Algiers (1827), served on the Admiralty Board until 1834, when he became Minister of Marine, and was aid-de-camp to Louis Philippe until 1848. He introduced in 1805 a system of semaphores which was long used in the French navy.

JA'COB, RICHARD TAYLOR (1825-1903). An American soldier, born in Oldham Co., Ky. He was educated for a lawyer, but after travels in South America went West in 1846, and there enlisted a body of mounted men to assist General Frémont in taking possession of California. He served in the Civil War as colonel of the Ninth Kentucky Cavalry Regiment, raised by himself. For a time he was with Major General Buell and afterward he joined in the pursuit and capture of Gen. John Morgan. He accompanied General Shaekelford on the Tennessee expedition that resulted in the capture of 2500 men under General Fraser at Cumberland Gap and was in the desperate struggle at Bean's Station. He was elected Lieutenant Governor of Kentucky in 1863, bitterly opposed the Emancipation Proclamation, and advocated the election to the presidency of General McClellan. His public criticism of the administration was so violent that he was arrested and conducted to Richmond, but was afterward unconditionally released by President Lincoln.

JACOBA, yá-kō'bä, COUNTESS OF HOLLAND (1401-36). The daughter and heir of William II, Duke of Bavaria and Count of Holland, she was first married to John, Duke of Touraine and son of Charles VI of France. In 1417 her father and husband both died. Her possessions were disputed first by her uncle, John of Bavaria, Bishop of Liège, and then by John IV, Duke of Brabant, her second husband, whom she married in 1418. Humphrey, Duke of Gloucester, the third husband, whom she married in 1422, at first supported her claims, but three years later deserted her. Her cousin, Philip V, Duke of Burgundy, then claimed the inheritance, and although she rebelled against him in 1432 with the aid of her fourth husband, Francis of Borselen, she was defeated and thereafter had to live in retirement. Consult Paul Lacour, "Une princesse héroïque au XVe siècle," in *Nouvelle Revue*, vol. vii (n. s., Paris, 1900).

JAC'OBÆ'A, **JACOBE**, yá-kō'be, or **JACOBINE**, zhá'kō'bën' (1558-97). A duchess of Jülich, daughter of the Margrave Philibert of Baden-Baden. Brought up a Catholic by her uncle, Albert of Bavaria, she married in 1585 John William, who, seven years later, succeeded his father as Duke of Jülich and soon after became insane. Jacobæa was accused of dissolute conduct and brought to trial before the Emperor by her enemies; but before he gave sentence she was found murdered in her bed. A German play by Kugler, *Jakobäa* (1850), dramatizes the story. Consult Stieve, *Zur Geschichte der Herzogin Jakobäa von Jülich* (Bonn, 1878), and Max Lassen, "Die Verheiratung der Markgräfin Jakobe von Baden mit Herzog Johann Wilhelm von Jülich-Cleve-Berg, 1581-85," in *Akademie der Wissenschaften, philosophisch-philologische und historische Klasse, Sitzungsberichte* (Munich, 1895).

JAC'OBÈ'AN ARCHITECTURE. The phase of English Renaissance architecture which developed during the reign of James I (1603-25) was a natural outgrowth of the Elizabethan style and, like it, found its chief expression in manor houses and collegiate buildings. The classic orders were more generally used, but in strangely fantastic and denatured versions; the *gaine*, which in the Elizabethan style was confined to interior decoration and furniture, appeared in place of pilasters on the exterior, together with strapwork and openwork in

stone; while all distinctively Gothic details finally disappeared. Bramshill House in Hampshire is a typical example. The interior decoration shows an advance towards Renaissance types, but there was not yet any really classic feeling, and the change from this style to the Palladian introduced by Inigo Jones (q.v.) was abrupt. Consult: C. J. Richardson, *The Architectural Remains of the Reigns of Elizabeth and James I* (London, 1840); R. T. Blomfield, *A Short History of English Renaissance Architecture* (ib., 1897); A. T. Bolton, *Jacobean Architecture and the Work of Inigo Jones in the Earlier Style* (ib., 1911). See ELIZABETHAN ARCHITECTURE.

JACOB EV'ERTZEN. A quaint book name applied to the small, brightly colored grouper-like West Indian fishes of the genus *Bodianus*, otherwise known as guativeres and by other names. According to Bloch, the fish was named for Jacob Evertzen, a noted Dutch pilot in the middle of the eighteenth century, whose pock-marked face suggested to his fellow sailors the dark-spotted and freckled fishes (especially the *Bodianus guttatus*, the type of the genus). See GUATIVERE.

JACOB FAITHFUL. A novel by Capt. Frederick Marryat (1839), appearing first in the *Metropolitan Magazine*.

JACO'BI, jä-kō'bī, ABRAHAM (1830-). An eminent German-American physician, born at Hartum, Westphalia, Germany. He studied at the universities of Greifswald, Göttingen, and Bonn, obtaining his degree in medicine from the last-named institution. Because he had been an active participant in the struggle for free Germany in 1848 and thereafter, Jacobi was prosecuted for treason and was kept in Prussian prisons from 1851 to 1853. In the latter year, after spending a few months in Manchester, England, he came to America and established himself in New York City. He took an active part in founding the German dispensary (1857); was chosen (1860) to fill the first chair of diseases of children instituted in the United States, that of the New York Medical College; from 1865 to 1870 filled a similar chair in the medical department of the University of the City of New York (later University and Bellevue Hospital Medical College); helped found the German Hospital of New York (1868); and from 1870 until his retirement in 1902 was clinical professor of the diseases of children in the College of Physicians and Surgeons (Columbia University). He was the first to establish in New York City systematic and special clinics for the diseases of children, and very largely to him is due the recognition of pediatrics as a distinct branch of medicine. In 1895 he was urged to leave New York and become professor of pediatrics in the University of Berlin, but he declined the honor. He was for many years consulting physician to the New York City Department of Health, to the J. Hood Wright Memorial Hospital, and to the New York Skin and Cancer Hospital, and visiting physician to the Nursery and Child's Hospital. He served as physician to the Mount Sinai Hospital from 1860, to the Hebrew Orphan Asylum from 1868, to Bellevue Hospital from 1873, and to Roosevelt Hospital from 1898. In 1896 he was president of the Association of American Physicians and in 1912 president of the American Medical Association.

Dr. Jacobi's writings are very numerous. A

great number of his papers, principally on diseases of women and children, were published in medical and other periodicals in America and in Germany. His books include: *Cogitationes de Vita Rerum Naturalium* (1851); *Dentition and its Derangements* (1862); *Infant Diet* (1873; 3d ed., 1875); *A Treatise on Diphtheria* (1880); *The Intestinal Diseases of Infaney and Childhood* (1887); *Therapeuties of Infaney and Childhood* (1895; 3d ed., 1903). His contributions to Noeggerath and Jacobi's *Midwifery and the Diseases of Women and Children* (1859) and his "Hygiene und Pflege der Kinder," in Gerhardt's *Handbuch der Kinderkrankheiten* (1877), are most noteworthy. In 1893 he published two volumes of miscellaneous essays and addresses on a variety of subjects, mostly medical, under the title *Aufsätze, Vorträge, und Reden* (1893); and in 1909 another collection of miscellaneous papers, entitled *Collectanea Jacobi*, was published in 8 volumes. In 1873 he married Miss Mary C. Putnam (see JACOBI, MARY PUTNAM); his daughter married George McAneny (q.v.).

JACOBI, yā-kō'bè, FRIEDRICH HEINRICH (1743-1819). A German philosopher. He was born at Düsseldorf, Jan. 25, 1743, and was educated at Frankfort and Geneva with a view to preparing himself for a mercantile career, which he began in 1762. In 1772 he was appointed councilor of finance for the duchies of Berg and Jülich and, having married a woman of wealth, was enabled to devote himself to literary pursuits. In 1794 he moved to Holstein and in 1804 to Munich, where he had been appointed a member of the newly instituted Academy of Sciences, of which he became president in 1807. He died on March 10, 1819. His writings consist partly of romances and partly of philosophical treatises. The principal are *Woldemar* (2 vols., 1779) and *Eduard Allwills Briefsammlung* (1781), both philosophical romances which attracted much attention in their day, but have now no claim to special recognition, while his philosophical work has still considerable interest. *Ueber die Lehre des Spinoza in Briefen an Mendelssohn* (Breslau, 1785) is a polemic against logical methods of speculation in the search after the higher class of truths; and *David Hume über den Glauben, oder Idealismus und Realismus* (ib., 1787) continues the polemic and makes an attempt to demonstrate that the mind or nature of man possesses another faculty—viz., faith, or intuition—by which the higher truths are as firmly grasped and in the same way as the material world is grasped by it, since sense is incompetent to witness to the independent reality of that world. His collected works, including letters, appeared at Leipzig (6 vols., 1812-24). Further letters were published by Rudolf Zoeppritz (Leipzig, 1869) and by Leitzmann (Halle, 1892). Consult: Deycke, *F. H. Jacobi im Verhältniss zu seinen Zeitgenossen* (Frankfort, 1848); Fricker, *Die Philosophie des Friedrich Heinrich Jacobi* (Augsburg, 1854); Zirngiebl, *F. H. Jacobis Leben, Dichtungen und Denken* (Vienna, 1867); Harms, *Ueber die Lehre von F. H. Jacobi* (Berlin, 1876); Holtzmann, *Ueber Eduard Allwills Briefsammlung* (Jena, 1878); Lévy-Bruhl, "Jacobi et le Spinosisme," in *Revue Philosophique* (Paris, 1894); id., *La philosophie de Jacobi* (ib., 1894); Wilde, *F. H. Jacobi: A Study of the Origin of German Realism* (New York, 1894); Crawford, *Philosophy of F. H. Jacobi*

JACOBI, HERMANN GEORG (1850-). A German Sanskrit scholar, born at Cologne. He was educated there and at Bonn and Berlin, where he devoted himself to Sanskrit under Gildemeister and Weber. In 1889 he was made professor at Bonn, after serving as professor extraordinary at Münster (1876-85) and professor at Kiel (1885-89). Possibly his most important work is in Indian chronology: "The Computation of Hindu Dates in Inscriptions," published in *Epigraphia Indica* (1892). His dating of the Rig-Veda, *Ueber das Alter des Rigveda* (1893), on astronomical grounds, puts the time much earlier than the usual estimate. His other works, on comparative philology, Prakrit grammar, Sanskrit literature, and Jainism, include, besides contributions to various publications: *Kalpasūtra of Bhadrabāhu* (1879); *Aeārānga Sūtra of the Çvetāmbara Jains* (1882); *Sthavirāvali Charita* (1883-91); and translations of the *Aeārānga*, *Kalpa*, *Uttarāhyayana*, and *Sutrakṛtānga Sūtra*, in the *Sacred Books of the East*, vols. xxii and xlv (1884-95); *Ausgewählte Erzählungen in Māhārāshtri* (1886; Eng. trans., *Hindu Tales*, 1909); *Das Rāmāyaṇa* (1893); *Das Mahābhārata* (1903); *Kompositum und Nebensatz. Studien über die indogermanische Sprachentwicklung* (1897); an edition of the *Samarādityu Sankhsepa* (1905); translations, published in the *Zeitschrift der deutschen morgenländischen Gesellschaft*, such as *Anandavardhanas Dhvanyāloka* (1903), *Umasvati's Tattvarthadighama* (1906), *Ruyyaka's Alamkarasarvasva* (1908), and many others.

JACOBI, JOHANN GEORG (1740-1814). A German poet, brother of Friedrich Heinrich, born at Düsseldorf and educated at Göttingen. He was appointed professor of philosophy and oratory at Halle (1766) and soon afterward made the acquaintance of Gleim (q.v.), with whom he edited *Iris* (1774-76), to which Goethe, Heinse, Lenz, Sophie La Roche, and others were contributors. He was made professor at Freiburg in 1784. Jacobi's poetic style was sentimental and effeminate, save in a few of his last works. His collected works, with a biography by Von Ittner, one of his friends, were published at Zurich (8 vols., 1807-22); his correspondence with Gleim appeared in 1786; and Martin edited *Ungedruckte Briefe von und an Johann Georg Jacobi* (Strassburg, 1874). Consult: J. A. von Ittner, a biography in J. G. Jacobi, *Sämmtliche Werke*, vol. viii (Zurich, 1822); Georg Ransohoff, *Ueber Johann Georg Jacobis Jugendwerke* (Berlin, 1892); Joseph Longo, *Laurence Sterne and J. G. Jacobi* (Vienna, 1898).

JACOBI, KARL GUSTAV JAKOB (1804-51). A German mathematician, the brother of Moritz Hermann Jacobi the physicist. He was born in Potsdam, studied in Berlin, and began his teaching there as privatdocent in 1824, but soon after went as professor of mathematics to Königsberg. He became a member of the Prussian Academy of Sciences in 1836 and in 1842 took up his permanent residence in Berlin, lecturing at the university. Jacobi's great work was in the theory of elliptic functions, of which he and Abel (q.v.) were the founders. He also contributed to the theory of numbers, to analytical mechanics, and to the study of determinants.

A very important determinant bears the name Jacobian. (See DETERMINANTS.) He also founded the theory of Abelian functions. The following important works appeared in his lifetime: *Fundamenta Nova Theoriæ Functionum Ellipticarum* (1829); *Canon Arithmeticus* (1839); *De Formatione et Proprietatibus Determinantium* (1841; ed. by Stäckel, 1896); *Mathematische Werke* (3 vols., partly posthumous, 1846-71). His *Vorlesungen über Dynamik* was published posthumously (1866; 2d ed., 1884). His *Gesammelte Werke* (7 vols. and suppl., 1881-91) were published by the Berlin Academy. His essay, *Über die vierfaeh periodischen Functionen zweier Variabeln*, etc., was translated from the Latin and edited by Weber (1895). Consult Lejeune-Dirichlet, "Gedächtnisrede auf Jacobi," in the *Abhandlungen der Berliner Akademie* (Berlin, 1852; printed in Jacobi's *Gesammelte Werke*, vol. i, ib., 1881), and Königsberger, *Carl Gustav Jacob Jacobi* (Leipzig, 1904).

JACOBI, jā-kō'bī, MARY PUTNAM (1842-1906). An American physician, born in London, England, the daughter of George P. Putnam (q.v.). She was the first woman to graduate from the New York College of Pharmacy, in 1862, and from the Women's Medical College of Philadelphia, in 1864. After teaching in New Orleans and writing for a year, she went to Paris, spent 18 months in hospitals there, was admitted by the Minister of Public Instruction to the Ecole de Médecine, and graduated in 1871, receiving the second prize for her thesis. She returned to New York to begin practice and to act as lecturer on therapeutics in the new Women's Medical College of the New York Infirmary. In 1873 she was married to the physician Abraham Jacobi (q.v.). Upon the founding of the New York Post-Graduate Medical School (1881) she became clinical professor of diseases of children; she served as visiting physician to the New York Infirmary and to St. Mark's Hospital; in 1874 she organized, and became president of, an association for the advancement of the medical education of women; and she was the first woman admitted to the New York medical societies and to the American Medical Association. Her writing on medical subjects was considerable and important. Harvard University awarded her the Boylston essay prize in 1876, and in 1891, when she contributed to *Women's Work in America*, she could record for herself, in the bibliography devoted to the writings of American women physicians, more than 40 titles of papers and treatises. Her books include: *The Question of Rest for Women during Menstruation* (1877); *Acute Fatty Degeneration of New-Born* (1878); *The Value of Life* (1879); *Cold Paek and Anæmia* (1880); *The Prophylaxis of Insanity* (1881); *Hysteria and Other Essays* (1888); *Common Sense Applied to Woman's Suffrage* (1894).

JACOBI, yā-kō'bē, MORITZ HERMANN (1801-74). A German physicist and architect, brother of Karl Gustav Jacobi. He was born at Potsdam. In 1835 he became professor of architecture at the University of Dorpat. Two years later he was called to St. Petersburg, where he became a member of the Academy of Sciences in 1842. He carried out numerous important researches in physics and suggested as a practical unit of resistance a copper wire of given dimensions. He also discovered (1850) that

the action of the dynamo was but the converse of the motor. He wrote *Mémoire sur l'application de l'électromagnétisme au mouvement des machines*, a remarkable essay published in 1835, and *Die Galvanoplastik* (1840). Consult Wild, *Zum Gedächtnis an Moritz Hermann Jacobi* (St. Petersburg, 1876).

JAC'OBIN. A small, highly artificial pigeon, resembling the capuchin, in which the prolonged upright feathers of the neck and head form a sort of cowl about the face. See PIGEON, and Colored Plate of PIGEONS.

JACOBINE. See JACOBÆA.

JACOBINI, yā'kō-bē'nē, LUDOVICO (1832-87). An Italian cardinal and diplomat of the Roman Catholic church, born at Genzano. He was nephew of the Papal Minister of Public Works and was rapidly advanced in ecclesiastical honors. In 1870 he became Undersecretary of State, and in 1874 was made Archbishop of Thessalonica (Saloniki) in partibus. In the same year he was Nuncio to Vienna, where he first showed his diplomatic abilities. In 1879 he met Bismarck to obtain the revocation of the Falk laws passed by the Prussian Diet against the Catholics in 1873, a mission in which he was ultimately successful. He was appointed Cardinal in 1879, and in 1880 was made Papal Secretary of State.

JACOBINS, jāk'ō-bīnz, *Fr. pron.* zhā'kō'bān'. A political club in France which exercised a profound influence on the progress of the French Revolution. It was organized at Versailles in May, 1789, by the representatives from the provinces to the States-General. It comprised in the beginning about 75 members; of whom some two-thirds belonged to the Third Estate and the rest to the clergy, and included among its members some of the most prominent leaders of the time, like Mirabeau, Barnave, Sieyès, Robespierre, Pétion, and the brothers Lameth. It met very frequently and in secret session for the purpose of deciding upon common action to be taken in the National Assembly, and it is probable that the great event of Aug. 4, 1789—the abolition of feudal privileges—and the enunciation of the Rights of Man were planned beforehand in the sessions of the club. Upon the removal of the National Assembly to Paris the sessions of the club were suspended for a time. In the winter of 1789-90 they were resumed in the refectory of the Jacobin convent in the Rue Saint-Honoré, whence the members of the club were derisively called by their opponents Jacobins. The name was changed from Club Breton to Société des Amis de la Constitution. Membership in the club was limited at first to deputies of the National Assembly, but soon the club was thrown open to prominent Parisians in the various walks of life whose sympathies were with the Revolution, and such men as Marie-Joseph Chénier, La Harpe, Cabanis, Lacépède, David, and Fabre d'Eglantine now joined the Jacobins. At this time the club was rather moderately radical, favoring merely constitutional monarchy. After May, 1791, the meetings of the club were held in the chapel of the convent. In November, 1791, its membership numbered more than 1200. The proceedings of the club were published after October, 1791. It had been the intention of the founders to make the club a nucleus for similar societies to be organized throughout France, and this object was speedily carried out. Affiliated societies sprang up in all the towns and in many

villages, and these at all times remained in close touch with the mother society. In May, 1791, the number of such societies was more than 400, and in the spring of 1794 it verged closely on 1000. The Jacobin leaders in Paris were able in this manner to carry on a most effective propaganda throughout the country, and, in fact, the perfection of their organization was such as to give the Jacobins the aspect of a political machine.

The attempted flight of Louis XVI in 1791 produced the same effect upon the Jacobin Club as it did upon the nation at large. The radical element began to gain the upper hand, and though it was still professedly monarchic in tone, the question of the deposition of Louis XVI was seriously raised. Upon this point the club split. In the hall of the Jacobins was drawn up the petition demanding the deposition of Louis XVI which brought about the massacre in the Champ de Mars on July 17. Although the leaders of the Jacobins disavowed all responsibility for the document, which they declared had been drawn up by a crowd that invaded the hall, the sanguinary outcome produced a schism in the club. The majority of members, including the most prominent leaders, seceded to form the club of Feuillants (q.v.), and of those who remained, Robespierre and Pétion were the most prominent. The Jacobins now entered upon a new phase, that of violent Republican propaganda. Together with the Girondists (q.v.) they planned the uprising of Aug. 10, 1792, the object of which was the overthrow of the monarchy. With the meeting of the Convention (September, 1792) the strife of parties began, Jacobins against Girondists. The former, as the representatives of uncompromising democracy, showed themselves the more fit to cope with the dangers of foreign invasion and internal insurrection which now confronted France. In the struggle against the Girondists they brought to bear upon the Convention the force of organized public opinion skillfully directed by the various societies throughout the country acting in implicit obedience to the mother society in Paris. With the fall of the Girondists the Jacobins became the practical rulers of France. No important action was taken in the Convention which had not been previously discussed in the sessions of the club, and, as a matter of fact, the meetings of the club came to be popularly regarded with greater interest than the sessions of the Convention. Of equal importance with the influence which it exercised upon the legislative activity of the Convention was the supervision which it exercised over the representatives of the government in the provinces. Its spies were constantly on the watch against treason to the Republican cause, and in many places where the action of the government officials seemed to lack the requisite revolutionary fervor the local Jacobin societies assumed virtual control. By this time the club, of course, had become thoroughly democratic, though perhaps the character of its members raised it above the mob contingents of Hébert and Collot d'Herbois. Robespierre became its master after the overthrow of Danton, and, with the Committee of Safety, it was one of the most efficient instruments in carrying out the Terror. The success of the Jacobins was due mainly to the fact that it always knew what to do and hesitated at nothing in order to do it. In the series of crises

that confronted France during the Revolution, the Jacobins presented a solid front to the enemies without and to the traitors within. Success condoned many of their terrible deeds in the eyes of the patriotic revolutionaries. With the fall of Robespierre the importance of the Jacobins ceased. Its sessions were suspended for a time, resumed, and again abandoned. On Nov. 11, 1794, its hall was closed by order of the Convention. Once more reconstituted and meeting at the Panthéon, its sessions were forbidden by the Directory in February, 1796. In the provinces there was a short revival of Jacobin activity in 1799.

Bibliography. A great mass of literature concerning the Jacobins appeared between the years 1790 and 1796, the most important contributions being the *Journal des Amis de la Constitution* (Paris, 1790-93), the *Journal de la Montagne* (ib., 1794-95), and William Playfair, *History of Jacobinism* (2 vols., Philadelphia, 1796). There were also numerous pamphlets and poems published, such as *La Jacobinade*, *Le secret des Jacobins*, *Les crimes des Jacobins*. Of modern authorities, the best and most detailed is F. V. A. Aulard, *La Société des Jacobins* (4 vols., Paris, 1889-95). Consult also: Augustin Barruel, *Mémoires pour servir à l'histoire du Jacobinisme* (5 vols., Hamburg, 1803); Zinkeisen, *Der Jakobinerklub* (2 vols., Berlin, 1852-53); W. A. Schmidt, *Tableaux de la Révolution française* (3 vols., Leipzig, 1867-70); F. V. A. Aulard, *The French Revolution: A Political History, 1789-1804*, translated from the French by B. Miall (4 vols., New York, 1910). See FRANCE; ROBESPIERRE; DANTON; together with the works cited under these titles.

JACOBITES (from Lat. *Jacobus*, James). The name given to the adherents of the male line of the house of Stuart in Great Britain and Ireland after the revolution of 1688. Many of the more devoted royalists followed James II into France, but the greater part of the Jacobites remaining in their native land made a show of submission to the new government, while secretly supporting the cause of the Pretender. Their intrigues and conspiracies were incessant till the middle of the eighteenth century. Their hostility to the house of Hanover broke out in rebellions in 1715 and 1745, in consequence of which several of them lost their lives upon the scaffold, titles were attainted, and estates confiscated. After the overthrow of the Young Pretender at Culloden in 1746 their cause became so hopeless that it was not long before their activity ceased altogether; those who still retained their attachment to the exiled family finally acquiesced in the order of things established by the Revolution. In Scotland, where they were most numerous, the hopes and wishes of the Jacobite party were expressed in many spirited songs, which form an interesting part of the national literature. The Jacobites of England were also called Tories. They were generally distinguished by warm attachment to the Church of England, as opposed to all dissent, if they were not members of the Catholic church, and held very strongly the doctrine of nonresistance, or the duty of absolute submission to the King. The Jacobites of Scotland were also generally Episcopalians and Roman Catholics. In Ireland the Jacobite cause was that also of the Celts as opposed to the Saxons, or the native race against the English colonists, and of the Roman Catholics against

the Protestants. These diversities prevented a complete union and greatly weakened the Jacobites.

Bibliography. James Hogg, *Jacobite Relics* (Edinburgh, 1819-21); Chambers, *Jacobite Memoirs* (ib., 1824); J. Allardyce (ed.), *Historical Papers Relating to the Jacobite Period* (Aberdeen, 1895-96); Terry, *The Rising of 1745, with a Bibliography of Jacobite History* (London, 1900); F. W. Head, *The Fallen Stuarts* (Cambridge, 1901); Marquis de Ruvigny, *Jacobite Peerage* (Edinburgh, 1904); Vaughan, *The Last of the Royal Stuarts* (London, 1906); Hale, *James Francis Edward, the Old Chevalier* (ib., 1907); Grew, *The English Court in Exile* (ib., 1911).

JACOBITES. A name given to the Oriental sect of Monophysites (q.v.), belonging more especially to the Monophysites of Syria, Mesopotamia, and Babylonia, or the Old Syrian church. It is derived from a Syrian monk called Jacobus Baradaeus (*Baradai*, 'ragged,' because he often traveled in the guise of a ragged beggar), who formed the Monophysite recusants of his country into a single party. He was chosen Bishop of Edessa in 541 and for more than 30 years traveled through Asia Minor and the East, organizing churches and ordaining bishops, priests, and deacons. The Jacobites were the Syrian national church, and during the Middle Ages were strong. Later many went to the Roman church (see *Uniats*), and now these number only about 80,000. At their head is the separate Patriarch of Antioch, whose choice must be confirmed by the Sultan. Under him are eight metropolitans and three bishops. Of the former, one, the Metropolitan of Jerusalem, called the Maphrian, ranks higher than the others. Both Patriarch and Maphrian live at the monastery of Zaferan, near Mardin. The Jacobites have monks, but no nuns. Their Monophysitic views make them heretics to the Greek church, but they have only minute ceremonial differences from the latter. They are in fellowship with the Coptic church. (See *COPTS*.) Since 1874 the Church of England has carried on mission work among the Jacobites. Consult W. F. Adeney, *The Greek and Eastern Churches* (New York, 1908), and F. J. Bliss, *The Religions of Modern Syria and Palestine* (ib., 1912).

JACOB OF EDES'SA (c.640-708). An eminent theologian and Syriac writer. He was born near Antioch. In early life he entered the monastic order and studied for a while in Alexandria. He was appointed Bishop of Edessa about 686, but resigned his office after four years, because of the insubordination of some of his clergy. He retired first to a monastery near Edessa and then, after 11 years, to one near Antioch. He applied himself to the study of the Syriac version of the Old Testament, revising the text and making many annotations. He had a thorough knowledge of Hebrew, Syriac, and Greek, and for his able translation of Syriac works into Greek he received the surname of "Interpreter of the Books." In his own country he was best known as a grammarian. In 708 he was induced to resume his see, but died four months later. Consult Kayser, *Die Kanones Jakobs von Edessa übersetzt und erläutert* (Leipzig, 1886), with biographical sketch, and William Wright, *Short History of Syriac Literature* (London, 1894).

JACOB OF HUNGARY. See *PASTORELS*.

JACOB OF SARUG (SĒRŪGH) (451-521).

A Syriac writer, born at Kurtam on the Euphrates. When Amid was captured by the Persians in 503, he was a visiting presbyter at Haura in Sarug, and in 519 he became Bishop of Batnān in the same district. He is chiefly remembered as the author of some 763 metrical homilies. Most of his works are in manuscript, but in 1903-08 four volumes of his *Homiliæ Selectæ* were published at Paris and Leipzig.

JACOB OF TODI, tō'dē. See *JACOPONE DA TODI*.

JACOB OF VITRY, vē'trē', or **JACQUES** (c.1180-1240). Bishop of Acre and Cardinal Bishop of Frascati. He was born probably at Vitry, northern France. He studied in Paris, and was consecrated a priest there in 1210. For several years he lived at Oignies, a place in the present Belgian Province of Namur, attracted by the fame for piety and holiness of the Beguine Maria of Oignies. At Oignies he joined the Order of St. Augustine. At the request of the Pope he preached against the Albigenses, and afterward he preached a new crusade. His preaching was so successful that he was chosen Bishop of Acre in 1214 and consecrated in 1216 by Pope Honorius III. He fulfilled the duties of his bishopric with energy and success, in particular buying Christian slaves from the Saracens and caring for Mohammedan children who had fallen into Christian hands. Difficulties arising with the secular officials, he resigned his bishopric in 1225 and returned to Oignies. In 1227 Gregory IX made him Cardinal Bishop of Frascati. He died in Rome, May 1, 1240. Jacob was justly famed as a preacher in his own time and in later times is remembered as an historian and authority for manners and social conditions of the early thirteenth century. His great work was the *Historia Orientalis*, also called *Historia Hierosolymitana Abbreviata*. He also wrote a life of St. Maria of Oignies. His letters are interesting and valuable recitals of events of the Fifth Crusade, and his sermons have served as the model for many a preacher. A French translation of his *Historia* is in Guigot, *Collection des mémoires*, vol. xxii. Consult Barroux, *Jacques de Vitry* (Paris, 1885).

JACOB OM'NIUM. The pen name of the English essayist Matthew James Higgins (q.v.).

JACOBS, yä'köps, ALBERT MICHEL (1812-79). A Belgian marine painter, born at Antwerp. He studied at the Antwerp Academy, where in 1843 he was appointed professor. The National Gallery in Berlin contains his "Grecian Archipelago" (1848); the New Pinakothek in Munich, "Foundering of the Emigrant Ship *Floridian* on the Coast of Essex," "Sunrise in the Archipelago" (1852), and "View of the Harbor of Constantinople"; and the Museum at Brussels, "Waterfall of the Glommen in Norway" (1855).

JACOBS, yä'köps, CHRISTIAN FRIEDRICH WILHELM (1764-1847). An eminent German classical scholar, born at Gotha. After studying at the universities of Jena and Göttingen, he was made an instructor in the Gymnasium at Gotha (1785). After 1802 he held a position in the public library of the same city. In 1807 he was appointed a teacher of classical literature at the Munich Lyceum, and a member of the Academy of Sciences of that city, but returned to Gotha in 1810 as chief librarian and director of the collection of numismatics and antiques. From 1831 to 1842 he was director

of the art collections of Gotha. Besides many editions of ancient writers, including the *Antehomericæ* of Tzetzes (1793), *Ælian* (1832), *Achilles Tatius* (2 vols., 1821), and the *Imagines* of Philostratus (1825), with Welcker, his numerous works include an edition of the *Anthologia Græca* (13 vols., 1794-1814), his most important classical work, remarkable for its profound learning and elegance of style, followed by a revised text, in three volumes, made from the Palatine manuscript (see ANTHOLOGY, 1); metrical translations of 700 poems of the *Anthology*, published under the title of *Tempe* (2 vols., 1803); translations from Demosthenes, *Staatsreden und Rede für die Krone* (1805); an elementary book on Greek, *Elementarbuch der griechischen Sprache* (1805; frequently republished); and numerous miscellaneous essays on classical philology, collected under the title *Vermischte Schriften* (vols. i-iii, 1823-24; vols. iv-viii, 1829-44). Of the later works, his *Geschichte des weiblichen Geschlechts* (vol. iv) is best known. Consult his sketch of himself in his *Personalien* (Leipzig, 1840); Wüstemann, *Friderici Jacobsii Laudatio* (1848) and *Hellas* (Berlin, 1852); Sandys, *A History of Classical Scholarship*, vol. iii (Cambridge, 1908).

JA'COBS, HENRY EYSTER (1844-). An American educator and Lutheran theologian, born at Gettysburg, Pa. He graduated from Pennsylvania College in 1862 and from the Lutheran Theological Seminary at Gettysburg three years later. Between 1870 and 1883 he was professor at Pennsylvania College, successively of Latin and history, ancient languages, and Greek. He was then appointed professor of systematic theology in the Mount Airy Seminary, Philadelphia, where he also assumed the office of dean in the following year. He served as president of his church's board of foreign missions (1902-07), of the General Conference of Lutherans (1899, 1902, 1904), of the American Society of Church History (1907-08), and of the Pennsylvania German Society (1910-11). Besides translating various German theological works and editing the *Lutheran Church Review* (1882-96), a *Lutheran Commentary* (1895-98), and a *Lutheran Encyclopædia* (1899), he wrote: *The Lutheran Movement in England* (1891); *History of the Lutheran Church in America* (1893); *Elements of Religion* (1894); commentaries on Romans (1896) and 1 Corinthians (1897); *Life of Martin Luther* (1898); *The German Emigration to America, 1709-40* (1899); *Summary of the Christian Faith* (1905).

JACOBS, JOSEPH (1854-1916). A British-American author, born at Sydney, Australia. He graduated from St. John's College, Cambridge, in 1876, traveled in Spain (1888) and in the United States (1896), and is best known for his work in history and folklore. In 1900 he came to New York to become an editor of the *Jewish Encyclopædia*, which was completed in 1906. He served as president of the Jewish Historical Society and from 1906 to 1913 was professor of English literature and rhetoric in the Jewish Theological Seminary of America. Among his publications are: *English Fairy Tales* (1890); *Celtic Fairy Tales* (1891, 1894); *Indian Fairy Tales* (1892); *Æsop's Fables* (1894); *As Others Saw Him* (1895), a life of Christ from the Jewish standpoint; *Reynard the Fox* (1895); *Literary Studies* (1895); *Jewish Ideals* (1896). His scholarly

editorial work includes Carton's *Æsop* (1889); Day's *Daphnis and Chloe* (1890); Painter's *Palace of Pleasure* (1891); Howell's *Familiar Letters* (1892). In addition, he translated Gracian's *Art of Worldly Wisdom* (1892) from the Spanish and (1899) certain tales from Boccaccio; for some time he edited *Folk-Lore*, and was editor of the *Jewish Year Book* (1896-99), the *Literary Year Book* (1898-99), and the *American Hebrew* (1906).

JACOBS, MICHAEL (1808-71). An American Lutheran clergyman and educator, born near Waynesboro, Franklin Co., Pa., and educated at Jefferson College, Canonsburg, where he graduated in 1828. In 1829 he became an instructor in Gettysburg Gymnasium (later Pennsylvania College) and was professor from 1832 till his retirement in 1865. He also entered the Lutheran ministry in 1832 and was prominent in the West Pennsylvanian Synod. A man of varied attainments, Jacobs invented (1845) a new method of canning fruit, made original studies in meteorology, contributed to the publications of the Smithsonian Institution, and wrote *The Rebel Invasion of Maryland and Pennsylvania* (1863).

JACOBS, yä'köps, VICTOR (1838-91). A Belgian statesman and leader of the Clericals, born at Antwerp and educated in France, at the Jesuit College at Vaugirard, and the University of Brussels, where he studied law. He was elected deputy in 1863, having taken advantage of the popular disaffection to compulsory service in the army to strengthen the Catholic party; became Minister of Public Works and of Finance in 1870; and in 1884 received the portfolio of Interior and Public Instruction. While he held this post, Jacobs passed the denominational education bill which put the religious orders again in power and which forced its author from the government. But he was still manager and head of the Clerical party and presided at the Catholic congress at Malines only a short time before his death. He wrote several legal studies, including *Le droit maritime belge* (2 vols., 1889-91).

JA'COBS, W. W. (1863-). An English novelist of seafaring people, born in London and educated at private schools. In 1883 he entered the Civil Service, Savings Bank Department. During this period and after he wrote: *Many Cargoes* (1896); *The Skipper's Wooing* (1897); *Sea Urchins* (1898); *A Master of Craft* (1900); *Light Freights* (1901); *At Sunwich Port* (1902); *The Lady of the Barge* (1902); *Odd Craft* (1903); *Dialstone Lane* (1904); *Captains All* (1905); *Short Cruises* (1907); *Salthaven* (1908); *Sailors' Knots* (1909); *Ship's Company* (1911); *Night Watches* (1914). With Louis N. Parker he wrote also a three-act play, *Beauty and the Barge*, in which Cyril Maude played in New York in 1913.

JACOBS CAVERN. A natural cave, about 2 miles east of Pineville, McDonald Co., Mo., named in honor of its discoverer, E. H. Jacobs, of Bentonville, Ark. In 1903 the cavern was carefully examined by Jacobs and Profs. W. K. Moorehead and Charles Peabody. The surrounding rock formation was found to be St. Joe limestone, of the Subcarboniferous age. The opening is slightly more than 21 meters long by about 14 meters deep; the height of the roof from 1.20 meters to 2.60. Lines of stratification show plainly in the walls; the roof is of solid limestone. Dripstone appears in the

walls and in the deep bed of ashes on the floor. In these ashes were found a number of hammerstones, horn or bone awls, flint knives, charcoal, six human skeletons, and the bones of various large and small mammals, none of them yet extinct. The occupants are believed to have antedated the mound builders. Examination of the stalagmite formations indicates that the implements had been lying in the ashes for about 1900 years. Some of the relics found in the cavern are deposited in the Museum of Phillips Academy, at Andover, Mass., and are described by Professors Moorehead and Peabody in *Bulletin No. 1* of the Department of Archaeology of that institution. Consult also the articles by Professor Peabody in the *American Anthropologist* for September, 1903, and by C. N. Gould in *Science* for July 31, 1903.

JACOBSEN, yä'køb-sen, JENS PETER (1847-85). A Danish novelist, born at Thisted in Jutland. He first became known as a botanist and as a translator of Darwin. In 1872 he published his novel *Mogens* (republished in a collection, 1882), followed by *Et Skudd i Taagen* (1875), and then *Fru Marie Grubbe* (1876), a fine study of seventeenth-century life. *Niels Lyhne* (1880) is modern, skeptical, and realistic. His last book was *Mogens og andre Noveller* (1882). The mixture of philosophy, science, and powerful imagination in his novels has made Jacobsen a favorite and influential writer. He created a new prose style for his native tongue. Consult: his *Letters*, edited by Georg Brandes (2d ed., Leipzig, 1899); Vilhelm Anderson, "Jens Peter Jacobsen," in his *Litteraturbilleder*, part ii (Copenhagen, 1907); Johannes Mayerhofer, "Jens Peter Jacobsen: sein Leben und seine Werke," in *Frankfurter Zeitgemässe Broshüren*, vol. xxxiii (Hamm, 1914).

JACOBSEN, JOHAN ADRIAN (1853-). A Norwegian traveler and ethnographical collector, born in Risö, near Tromsö. From 1867 to 1874 he sailed on a whaling ship along the Finmarken, Spitzbergen, and Murman coasts; in 1876-77 he visited Valparaiso and Patagonia; and for several years, while representative of Karl Hagenbeck of Hamburg, he traveled in the Arctic regions and returned with reindeer, families of Lapps and Eskimo, and various objects of interest. Between 1881 and 1888, for the Museum für Völkerkunde in Berlin, he traveled along the coast of America from Mexico to Bering Strait; through Siberia, Sakhalin, Korea, Japan, Borneo, Celebes, and Timor. In all he collected for the Berlin museum alone 18,000 ethnographical specimens. In 1889 he made collections in Germany, and in 1892 in Norway for the museum at Bergen. At the Chicago Exposition (1893) he exhibited collections from 25 non-European races. These became the foundation of the Field Columbian Museum in Chicago. His costly private collections he donated (1908) to the Ethnographical Museum in Christiania, Norway. He wrote *Reise an der nord-westküste Amerikas* (1884), *Eventyrlige farter* (1894), and *Reise in der inselwelt des Banda-Meeres* (1896).

JA'COB'S LADDER. 1. A ladder, reaching from earth to heaven, seen in a vision by Jacob (Gen. xxviii. 12). 2. On shipboard, a short rope ladder with iron or wooden rungs, to give easy access to the lower rigging, tops, etc. It is also the name of an apparatus for raising light weights a considerable height. One form, much used in breweries and distilleries, is an

endless revolving chain of buckets, filling themselves at the bottom of the chain and emptying themselves at the top.

JA'COBSON, JOHN CHRISTIAN (1795-1870). A Danish-American Moravian bishop and educator, born in Burkall, Denmark. After completing his education at the German Moravian College, he came to the United States, at the age of 21, and occupied various positions till he became principal of the female seminary at Salem, N. C., in 1834. The academy grew and flourished under his control, but he left it to superintend a boys' boarding school in Nazareth, Pa., and to take the leadership of the Northern Moravian church, which made him a bishop in 1854. He retired three years before his death.

JACOB'S STAFF. 1. A kind of staff carried by pilgrims to the tomb of the Apostle James the Elder. The term is also applied to a dagger or sword concealed in a staff of this kind. 2. The three stars in a straight line in the Girdle of Orion. 3. Any stick used as a temporary mount for an instrument in preliminary surveys.

JACOB'S STONE, or JACOB'S PILLOW. The Stone of Scone, said to have served Jacob as a pillow when he had the vision of the ladder reaching into heaven. The stone is now preserved in the coronation chair (q.v.) of England.

JACOB'S WELL. The scene of the conversation of Jesus with the woman of Samaria. The well is near Nablus, in Syria, and is said to have been hewn in the rock by Jacob. A church built over the well is mentioned in the fourth century, but was destroyed during the period of the Crusades.

JACOB TOME INSTITUTE. An institution of secondary education at Port Deposit, Md., founded by Jacob Tome and opened in 1894. It comprises a kindergarten and junior school for boys and girls, a high school for girls, and a boarding school for boys, including two years of grammar school and four years of high school. It prepares for college, technical schools, professional schools, and business. Residents of Maryland are exempt from the annual tuition fee of \$100. There are 20 buildings in a campus of over 160 acres. The library contains 10,000 volumes. The endowment exceeds \$2,000,000, and the grounds and buildings of the institute have cost over \$900,000.

JACO'BUS. A current but not official name for an English gold coin of the reign of James I (Lat. *Jacobus*), originally in 1603 valued at 20 shillings. The issue of a lighter sovereign of this denomination in 1604 increased the value of the Jacobus to 22 shillings, while in 1612 the value of the new coin was made 22 shillings, and the early coin rose to 24.

JACOBUS, MELANCTHON WILLIAMS (1816-76). An American Presbyterian minister and author, born at Newark, N. J. In 1834 he graduated from Princeton College and four years later from Princeton Seminary, where he was instructor in Hebrew for the year preceding his acceptance of the pastorate of the First Presbyterian Church in Brooklyn, N. Y. (1839). While absent in the Holy Land (1850-51), he was elected professor of Oriental and biblical literature in the Western Theological Seminary at Allegheny, Pa. This chair he held from 1852 until his death. He was pastor of the Central Presbyterian Church, Pittsburgh, Pa., from 1858 to 1870. In 1869 he was moderator of the last

General Assembly of the old-school branch of his church, and in 1870 presided, conjointly with Dr. Philemon H. Fowler, at the opening of the first Assembly of the reunited church. He was secretary of the Sustentation Committee of the Presbyterian church from 1871 to 1874 and received the degrees of D.D. from Jefferson College, Pennsylvania (1852), and LL.D. from Princeton (1867). He published: *Notes on the New Testament* (4 vols., 1848-59); an *Address to the Churches* (1861); *Genesis* (2 vols., 1864-65); *Exodus* (shortly before his death).

JACOBUS, MELANCTHON WILLIAMS (1855-). An American theologian, born at Allegheny City, Pa., a son of the preceding. He graduated at Princeton in 1877, at Princeton Theological Seminary in 1881, from 1881 to 1884 studied at the universities of Göttingen and Berlin, and from 1884 to 1891 was pastor of the Presbyterian Church at Oxford, Pa. In 1891 he was appointed to the chair of New Testament exegesis and criticism in Hartford Theological Seminary (Congregational). He also served as acting president of the seminary in 1902-03 and as dean of the faculty after 1903. At Princeton Seminary he was Stone lecturer (1897-98) and at Mount Holyoke College lecturer on the New Testament (1901, 1903-04). In 1899-1900 he was acting pastor of the Centre Congregational Church at Hartford. The degree of D.D. was conferred on him by Lafayette College (1892) and Yale University (1910). His Stone lectures were published (1900) as *A Problem in New Testament Criticism*. He had charge of the New Testament department of the NEW INTERNATIONAL ENCYCLOPÆDIA, was chairman of the editorial board of the *Standard Bible Dictionary* (1909), edited an English translation of Zahn's *New Testament Introduction* (1909), and prepared a *Commentary on the Gospel of Mark*, for "The Bible for Home and School Series" (1914).

JACOBUS BAR'ADÆ'US. See JACOBITES.

JACO'BUS DE BENEDIC'TIS. See JACOPONE DA TODI.

JACO'BUS DE VORAG'INE (c.1230-c.1298). An Italian writer, Archbishop of Geneva, and author of the celebrated Golden Legend (q.v.).

JACO'BY, HAROLD (1865-). An American astronomer, born in New York City. In 1885 he graduated at Columbia University, where he served as assistant, instructor, and adjunct professor from 1888 to 1904. He was appointed professor in 1904 and director of the observatory in 1906. In 1889-90 he was assistant astronomer on the United States eclipse expedition to West Africa in the United States steamship *Pensacola*. He became also a counselor of the New York Academy of Sciences, treasurer of the American Mathematical Society, editor of the *Transactions* of that society, and fellow of the Royal Astronomical Society of London. His technical papers on astronomical photography, star clusters, parallaxes, and other subjects appeared in the publications of the New York Academy of Sciences, the Academy of St. Petersburg, the Académie des Sciences of Paris, the Academy of Helsingfors, and the Royal Astronomical Society of London. He published *Practical Talks by an Astronomer* (1902), a collection of interesting essays, written in untechnical style, on "Navigation at Sea," "Galileo," "Photography in Astronomy," "The Moon Hoax," and other special topics. The depart-

ment of astronomy in the first edition of the NEW INTERNATIONAL ENCYCLOPÆDIA was edited by him. He is also author of *Astronomy: A Popular Handbook* (1913).

JACOBY, yà-kō'bè, JOHANN (1805-77). A German politician, born in Königsberg, Prussia, of Jewish parents. He studied at Königsberg and Heidelberg, became a practicing physician at Königsberg in 1830, and wrote numerous pamphlets on questions of the time. His *Vier Fragen* (1841), in justification of the demand for a Prussian constitution, brought upon him accusation of high treason and a sentence to two and a half years' imprisonment, but in 1843 he was released and almost immediately came into conflict with the censor again. In 1848 he was elected to the Vorparlament of Frankfort as a reform member, and to the National Assembly of Prussia, where by his incisive speeches he identified himself with the Left. He was elected to the German National Assembly in 1849, took part in the Rump Parliament, and again was accused of high treason against the King personally. In 1863 he became a member of the Prussian Lower House, and both there and in the *Zukunft* journal, established by him, was an increasingly violent opponent of the government. He even styled German unity the death of freedom. In 1864 and again in 1870 he was sentenced to imprisonment. He retired from political life in 1871. His publications include a biography of Heinrich Simon (1865) and his *Gesammelte Schriften und Reden* (1872; an additional volume, 1877). *Der Geist der griechischen Geschichte* was published under the editorial supervision of F. Röhl in 1884.

JACOPO DA PONTE, yä'kō-pō dà pōn'tā. An Italian painter commonly known by the title JACOPO BASSANO. See BASSANO.

JACOPO DEI BARBARI, dā'ē bār'bā-rē (c.1440-50-c.1515). An Italian painter and engraver, called also the 'Master of the Caduceus' from the sign on his plates, and by contemporary Germans Jacob Walch. He was one of a family of painters and was brought up and worked in Venice, where he was probably a pupil of Bartolommeo Vivarini. About 1490 he went to Nuremberg and remained there for several years, exercising a strong influence upon Dürer and Hans von Kulmbach. By 1500 he was back in Venice, for at this time he executed a large bird's-eye view of the city, engraved on wood. From 1505 to 1510 he was active in various cities of Germany, as court painter to Emperor Maximilian, then in the service of Count Philip of Burgundy, and finally (1510) he became valet de chambre and court painter to the Regent Margaret of the Netherlands. He is mentioned as dead in 1516. There has been much discussion about the life and works of this artist. He was one of the first to engrave on metal and left 30 plates, of which some are of mythological and some of religious subjects. His paintings are of less importance, and he is also said to have been a sculptor. The interest of Barbari is largely on account of the curious union in him of the German and Venetian styles of art, most uncommon at that date. Consult the monographs by Galichon (Paris, 1861) and Ephrussi (ib., 1876). Reproductions of all his engravings and woodcuts are given in the admirable folio edited by Kristeller for the International Chalcographical Society (Berlin, 1896).

JACOPO DELLA QUERCIA. See QUERCIA, JACOPO DELLA.

JACOPONE DA TODI, yä'kô-pō'nâ dá tō'dê, JACOBUS DE BENEDICTIS (c.1230-1306). An Italian mystic and poet. He was born at Todi in Umbria, was a lawyer and successful in his profession. The sudden death of his wife, about 1268, wrought a complete change in his life. He abandoned his profession, distributed his goods among the poor, and sought the world's scorn by his strange behavior. At the same time he vigorously denounced the corruptions of the times and the ambitions of the lofty. After 10 years of penance he became a Franciscan monk, expressing his humility by remaining a lay brother. He joined the opponents of Boniface VIII, was captured at Palestrina in 1298, and kept in prison till the Pope's death in 1303. He died at Collazzone on Christmas night, 1306. Jacopone's poetry was most of it written in the Umbrian dialect. His hymns are characteristic of his time, full of the fervor and the same exalted enthusiasm which are to be found in those of St. Francis of Assisi. The hymn "Stabat Mater Dolorosa" is generally attributed to Jacopone, perhaps incorrectly. Consult: Sorio, *Poesie scelte di Fra Jacopone da Todi* (Verona, 1859); D'Ancona, "Jacopone da Todi, il giullare di Dio del secolo XIII," in *Studi sulla letteratura italiana de' primi secoli* (Ancona, 1884); Gebhart, *L'Italie mystique* (Paris, 1890); Macdonnell, *Sons of Francis* (London, 1902); Bruguali, *Fra Jacopone da Todi* (Assisi, 1907). He is the hero of a novel by Dorsey, *The Mad Penitent of Todi* (Notre Dame, Ind., n. d.).

JACOTOT, zhà'kô'tô', JEAN JOSEPH (1770-1841). The originator of a 'universal' method in education, born at Dijon, France, in 1770. He turned his attention at first to philology and, after having studied that subject for some time, became a teacher of the classic languages in his native town. Subsequently he took up the study of law and became an attorney. In 1792 he entered the army and rose to the rank of captain of artillery; he was then made secretary to the Minister of War, and finally a substitute director and professor of mathematics at the Polytechnic School in Paris. In 1815 he went to Brussels and three years later accepted the position of professor of French language and literature at the University of Louvain. In 1827 he became a director of the advanced military school in that city. He returned to France in 1830 and died in Paris.

His system of universal instruction was empirical, propounded in general rules which are unintelligible without his own explanation. It consists in directing the student's exertion to particular subjects, encouraging and exciting him in every possible manner to make use of his mental powers. The teacher is not to become an expounder, but, after setting the student on the right track, is to leave him to explain away his own difficulties. His ideas were an outgrowth of his own intellectual development and of his experience at Louvain, where he, though French and understanding no Flemish, taught the Flemish boys by books having French and Flemish in parallel columns, largely through one book, the *Télémaque*. There he saw that the pupils learned, though he did not teach them. This plan was applied to other subjects, with the idea that one could teach all subjects, even those of which he might have no knowledge himself. There were four steps insisted upon in the process of learning: first, learn; second, repeat; third, reflect; fourth, verify.

His famous maxims, "Pupils must learn something and refer to that all the rest" and "All is in all," meant that all things in nature are united in one great whole, the knowledge of which may be acquired through any of its parts. His ideas are empirical approaches to the ideas of concentration, interest, etc., of Herbart, though expressed in exaggerated or paradoxical form. His method of language teaching is quite similar to the popular plans of Hamilton and of Ollendorf.

Jacotot expounded his ideas in *Enseignement universel* (1822) and in the *Journal de l'Emancipation Intellectuelle*. Others of his works are *Musique, dessin et peinture* (1824) and *Mathématiques* (1828). For his life and works, consult his English disciple Payne, *Lectures on the History of Education* (London, 1892), and Quick, *Educational Reformers* (New York, 1907).

JACQUARD, zhà'kär', JOSEPH MARIE (1752-1834). A French inventor, born at Lyons. He was the son of a weaver and at first followed his father's trade, but afterward was a bookbinder and typesetter. Still later, after the death of his father, he began experimenting with looms and lost his small inheritance (1772). In 1793 he fought in the Army of the Rhine, on the Rhone and Loire, and then went back to Lyons, where he completed his invention, known as the Jacquard loom, for which he was awarded a bronze medal at the Industrial Exposition of 1801. He continued to improve his loom despite the hostility of the Lyons silk weavers, who feared that his labor-saving device would throw them out of employment. In 1806 his invention was bought by the state and declared public property. Jacquard was rewarded with a pension and a royalty on each loom, and in 1840 a statue of him was erected at Lyons. See LOOM, for an account of his invention.

JACQUE, zhák, CHARLES EMILE (1813-94). A French animal and landscape painter and etcher, one of the most eminent of the nineteenth century. He was born in Paris, was apprenticed to an engraver at 17, then worked in Antwerp and for two years in London, where he designed wood engravings, illustrating Shakespeare and a *History of Greece*. Returning to France, he joined the Barbizon group and became known as its great sheep painter, just as Troyon was its painter of cattle. Another favorite subject was poultry yards, on which he himself wrote a book entitled *Le poulailler* (1869). In 1867 he was decorated with the cross of the Legion of Honor and in 1889 received the Grand Prix for etching and a gold medal at the universal exposition of the same year for his paintings. His canvases, small in size, are big in conception, conscientious and virile in execution, and show mastery of landscape, especially the sky. But he is even more important as an etcher, by reason of his powerful influence upon the development of the art in France. His technique is well-nigh faultless in its delicate yet vigorous line, its mastery of chiaroscuro, and its harmonious tonal effects. In this medium the scope of his art was wider, including admirable landscapes and peasant subjects. Under the influence of Millet, whose most intimate friend he was, his art, which at first inclined to prettiness, became increasingly virile. His painting is represented in the Louvre by an imposing "Flock of Sheep" in the midst of a firm landscape and by three other examples;

in many French provincial collections; and in the Metropolitan Museum, New York, by four sheep subjects, including one in the Vanderbilt collection.

JACQUELINE, zhák'lén'. The name given to grotesque mugs, in the shape of a woman seated, first made in Desvres, France, and later in Holland, Germany, and England.

JACQUEMART, zhák'mär', HENRI ALFRED MARIE (1824-95). A French sculptor, born in Paris. He studied painting there under Paul Delaroche, but forsook it for sculpture, which he studied with Klagmann. He exhibited animal groups at the Salon from 1847 to 1879. His most important works are the equestrian bas-relief of Louis XII at Compiègne, the bronze statue of Mehemet Ali in Alexandria, the four colossal lions upon the bridge in Cairo, two griffins at the Fountain of Saint-Michel, Paris, and the statue of Mariette Bey at Boulogne-sur-Mer. He received the decoration of the Legion of Honor (1870).

JACQUEMART, JULES FERDINAND (1837-80). A French etcher, born in Paris. While he painted at least 110 water colors, of which three—"Japanese Art Objects," "Landscape near Nice," and "Flowers"—are in the Metropolitan Museum, New York, his reputation depends upon his etchings, the best of which were published in the *Gazette des Beaux-Arts*. The same magazine also reproduced many of his wood engravings and pen drawings. He was, first of all, an illustrative artist, etching 27 plates for the *Histoire de la porcelaine* (Paris, 1862) by his father, Albert Jacquemart; 12 plates for his father's *Histoire de la céramique* (ib., 1873); the series of 47 plates published by Techener (ib., 1864) under the title *Histoire de la bibliophile*; 60 for Barbet de Jouy's *Les gemmes et joyaux de la couronne* (ib., 1868); 88 for Loubat's *Medallic History of the United States of America* (New York, 1878), reproducing many medal portraits of famous Americans, among them George Washington, Horatio Gates, Anthony Wayne, Benjamin Franklin, John Paul Jones. Among the many famous paintings etched by Jacquemart were 12 owned by the Metropolitan Museum (London, 1871). He was one of the founders of the Société des Aquarellistes (Water Color Society), and almost from the moment he made his début in 1859 enjoyed an immense reputation. His etchings rank high as finished works of art, but lack boldness and strength. For a descriptive list of 395 of his etchings, with biographical and critical notes and many illustrations, consult Louis Gonse, "Jules Jacquemart," in *Gazette des Beaux-Arts* (Paris, 1875, 1876, 1880, 1881).

JACQUEMEL. See JACMEL.

JACQUEMINOT, zhák'mé'nô', JEAN FRANÇOIS, VISCOUNT (1787-1865). A French general. He was born at Nancy, studied at the Ecole Militaire, entered the army in 1803 and, rising to the grade of colonel, distinguished himself at Austerlitz, Essling, Wagram, and the Beresina. When Napoleon returned from Elba, Jacqueminot was made commander of lancers. He made a brilliant charge at Quatre Bras and after Waterloo refused transfer to the service of the Bourbons, was imprisoned for a month, and after his release established at Bar-le-Duc a great silk factory, which gave employment to many of the veterans of the Republic. Elected to the House of Deputies in 1827, he joined in

the protest of the Two Hundred and Twenty-one against Polignac, and with Pajol directed the Rambouillet expedition which led Charles X to leave France. In 1842 he succeeded Chaud as commander of the National Guards of the Seine. Louis Philippe made him Viscount in 1846. His indecision at the head of the Guards made possible the revolution of 1848, and he was retired in that year.

JACQUEMONT, zhák'môn', VICTOR (1801-32). A French traveler and botanist, born in Paris. He traveled in the West Indies in 1826 and two years later was appointed by the authorities of the Royal Gardens to undertake a voyage of exploration in India. After several delays caused by an insufficient outfit, he crossed the Himalayas, explored a portion of Tibet, and reached Chinese Tartary. He brought back many specimens of new plants. Shortly after his return he died in Bombay. Guizot edited his scholarly and entertaining *Voyage dans l'Inde* (1836-44), which contains much information on a variety of subjects. His *Correspondance* (1833) is particularly interesting from his gift for observation and the easy, familiar style in which he wrote.

JACQUERIE, zhá'krè' (from *Jacques Bonhomme*, the common epithet bestowed by the nobles in derision on the French peasant). The name given to the insurgent peasants in France in the middle of the fourteenth century, in the reign of John the Good. The insurrection of the Jacquerie broke out in the year 1358, when the French King was a prisoner in England and France in a state of the greatest disorder and anarchy as a result of the invasions by the armies of Edward III. The immediate occasion of it was a collision between adherents of some nobles and the peasants in the month of May in the neighborhood of Beauvais; but it was really caused by long-continued oppression on the part of the nobles. Suddenly rising against their lords, the peasants laid many castles in ruins, murdered some nobles, and pillaged the country—acting, as they said, on the principle of doing as had been done to them. For some days the region of the lower Marne and the Oise was entirely at their mercy, and the peasants were joined by the bourgeoisie in some of the towns; but the magnitude of the danger induced the quarrelsome nobles to make common cause against them, and on June 10 the peasants were defeated with great slaughter near Meaux by Charles the Bad of Navarre. This put an end to the insurrection. But the nobles took a terrible revenge, burning the villages and killing the peasants. In two weeks 20,000 are said to have been murdered. Froissart, who had no sympathy for the peasants, undoubtedly drew too dark a picture of the atrocities committed by the Jacquerie, while minimizing the sanguinary vengeance exacted by the nobles. Consult Flammermont, in the *Revue Historique*, vol. ix (Paris, 1879), and Luce, *Histoire de la Jacquerie* (ib., 1895).

JACQUES DE CUJAS. See CUJACIUS.

JACQUES OF VITRY. See JACOB OF VITRY.

JACQUIN, zhá'kän', NIKOLAUS JOSEPH, BARON (1727-1817). An Austrian botanist, born at Leyden. He studied medicine in his native city and in Paris and afterward went to Vienna, where he made a catalogue of the plants in the garden at Schönbrunn for Emperor Francis I. From 1755 to 1759 he traveled in South America. Some years after his return

he became professor of botany and chemistry at the University of Vienna. He was ennobled in 1774. Some of the more important of his works are: *Hortus Botanicus Vindobonensis* (1770-76); *Flora Austriaca* (1773-78); *Icones Plantarum Rariorum* (1781-93); *Plantarum Rariorum Horti Cæsarei Schönbrunnensis* (1797-1804).—His son, FRANZ JOSEPH (1767-1839), was also a botanist.

JAC'TITA'TION (ML. *jactitatio*, from Lat. *jactitare*, to utter, frequentative of *jactare*, to agitate, discuss, frequentative of *jacere*, to throw; connected with Gk. *ιάπτειν*, *iaptein*, to throw). The legal offense of falsely and maliciously asserting a legal claim or right to the detriment of another. The offense is not generally dealt with by the law as a crime, nor does it come within the class of wrongs, denominated torts, which are remediable by an action for damages, but it may by appropriate process be suppressed, and the rights of the injured party established by a decree. In English law the offense is cognizable only by the ecclesiastical courts and by the Probate, Divorce, and Admiralty Division of the High Court of Justice, and is confined to the false assertion of a right to tithes and to a seat in a church and to the false claim of marriage to another. In the last-named case the process is called *jactitation of marriage*. The action is of rare occurrence in England, but is more common in Scotland. It has never existed in the United States. Consult Sir William Blackstone, *Commentaries on the Laws of England* (4th ed., 2 vols., Chicago, 1899).

JACUARU, jä-kōō'ä-rōō. A Brazilian lizard. See TEJU.

JADASSOHN, yä'dä-sōn, SALOMON (1831-1902). A German musical composer and theorist, born at Breslau. He studied the pianoforte under Hesse and Liszt, the violin under Lüstner, and in 1848 entered the conservatory at Leipzig, in which institution he subsequently (1871) became professor of harmony, pianoforte composition, and counterpoint. He studied under Liszt in 1849, but his career as a teacher dates from 1852, after a course of private study under Hauptmann. His various works on the science of music have continued to be used as textbooks throughout the world. He is the composer of about 150 works in nearly every musical form, all written in faultless style. Although he will be remembered as a great theorist rather than as a great composer, many of his compositions bear evidences of permanent value. He was appointed conductor of the Psalterion Choral Society in 1866, and from 1867 to 1869 was kapellmeister of the Euterpe organization. Among his textbooks the following are noteworthy: *Harmonielehre* (Leipzig, 1883; Eng. trans., New York, 1893); *Kontrapunkt* (Leipzig, 1884); *Kanon und Fuge* (ib., 1884); *Lehrbuch der Instrumentation* (ib., 1889) (the above have also been translated into English at Leipzig); *Elementar-Harmonielehre* (ib., 1895).

JADE (Fr., Sp. *jade*, from Sp. *yjada*, *ijada*, side, from Lat. *ilium*, flank, groin; ultimately connected with Gk. *είλειν*, *eilein*, Lat. *volvere*). A name applied to various tough, compact minerals of the pyroxene and amphibole groups, chiefly jadeite and nephrite, of a white to dark-green color. These minerals were used by primitive man for utensils and ornaments, and among the Chinese they are highly prized as material for vases and other carved objects,

which now are frequently seen in museums and art collections in Europe and America. Specimens of jade have been found among the remains of the lake dwellers of Switzerland, at various points in France, and in Mexico, Greece, Egypt, and Asia Minor. The chalchihuitl (q.v.) of the early Mexicans has been supposed by some to have been jade, but the present belief is that this name refers to the turquoise found in the mines in New Mexico. Consult H. R. Bishop, *The Bishop Collection, Investigations, and Studies in Jade* (2 vols., New York, 1906).

JADE, yä'de, or **JAHDE**. An inlet of the North Sea in the Grand Duchy of Oldenburg (Map: Germany, C 2). It owes its origin to coastal sinking combined with storm floods between 1218-1511. It is about 10 miles in diameter, and the greater part is shallow, with exposed mud flats at low tide; but at the narrow inlet it is deep enough for the largest men-of-war, and here a small territory a little over a mile in extent was acquired by the Prussian government from Oldenburg in 1854. On it was built the fortified port and naval station of Wilhelmshaven (q.v.).

JADLOWKER, yät-lōf'kēr, HERMAN (1879-). A Russian tenor, born in Riga. In order to escape from a commercial career into which his father wished to force him, he ran away from home as a lad of 15 and finally went to Vienna, where he studied singing with Gänsbacher. In 1899 he made his début at Cologne in Kreutzer's *Nachtlager von Granada*. He then secured engagements in Stettin and Karlsruhe. Here Emperor William heard him and was so impressed that he offered him a five-year contract at the Royal Opera in Berlin. From there he went to Vienna. In 1910 he appeared at the Metropolitan Opera House, where he was one of the most versatile and reliable artists. In 1912 he returned to Berlin.

JADWIGA, yät've-gä. See HEDWIG.

JAD'WIN, EDGAR (1865-). An American military engineer, born at Honesdale, Wayne Co., Pa. He studied at Lafayette College in 1884-86 and graduated from the United States Military Academy at the head of his class in 1890. He was in local charge of the enlargement of Ellis Island, New York harbor (1890-91); was on duty with engineer troops and at the United States Engineer School (1891-95); and between 1893 and 1902, except during the Spanish-American War, was an assistant on government engineering works in connection with rivers, harbors, and fortifications. In the Spanish-American War he served as major and later as lieutenant colonel, Third Regiment U. S. V. Engineers, and was in command of the detached Third Battalion of the regiment at Matanzas, Cuba. From 1902 to 1907 Colonel Jadwin was in charge of river, harbor, and fortification work, first on the Pacific coast south of San Francisco and later on the Texas Gulf coast, having charge of the construction of the sea wall at Galveston. From 1907 to 1911 he worked on the Panama Canal, at first in the Chagres division; later he was in charge of breakwater construction at Colon, of the excavation of the sea-level canal from the Atlantic Ocean to Gatun, and of the rock and sand supply for the Gatun locks and spillway. He was promoted to a lieutenant-colonelcy in 1913. He contributed articles on military engineering to the first and second editions of the NEW INTERNATIONAL ENCYCLOPÆDIA.

JAEGER. See JÄGER.

JAEGER, or JÄGER, GULL. See SKUA.

JAEGERS, jā'gērz, ALBERT (1868-). An American sculptor. He was born in Elberfeld, Germany, came to America as a boy, and was self-taught in his art. He was represented at the Buffalo and St. Louis expositions and modeled statues for the new customhouse, New York, and the Fine Arts Building, St. Louis. He also executed a number of cleverly composed reliefs and fine portrait busts and won frequent competitions, including that for the Baron von Steuben Monument in Washington. A replica of the latter was presented by Congress to the German Emperor, who thereupon decorated Jaegers. He became a member of the National Sculpture Society.

JAÉN, há-ān'. A former kingdom in Andalusia, south Spain, now the Province of Jaén, which includes a somewhat larger area (5205 square miles) than the old kingdom (Map: Spain, D 4). It is bounded by New Castile on the north, Murcia on the east, Granada on the south, and Cordova on the west. It lies in the upper basin of the Guadalquivir. The northern part is traversed by the Sierra Morena, now deforested and almost barren, while in the south and east are the rugged, lofty, and well-forested Sierras de Segura and Cazorla. The mineral wealth, especially of the northern mountains, is considerable, including lead, iron, copper, zinc, and salt. Though iron ore is plentiful, argentiferous lead is the only metal extensively mined, the production amounting to over 80,000 tons of ore annually. Agriculture is confined to the valley of the Guadalquivir; cereals and olives are grown; other industries are unimportant. The population of the province in 1900 was 474,490 and in 1910, 526,718. The largest city is Linares, and the capital is Jaén.

The Moorish Kingdom of Jaén arose in the eleventh century at the time of the dissolution of the Caliphate of Cordova. It was short-lived and of little importance. The region was conquered by Castile early in the fourteenth century.

JAÉN. The capital of the province of the same name, Spain, situated in the valley of the Guadalquivir, at the foot of Mount Jabalcuz, 58 miles east of Cordova and on a branch of the railroad between Madrid, Cordova, and Seville (Map: Spain, D 4). It is surrounded by the remains of old Moorish walls, with numerous towers and pinnacles. There are several old Gothic churches, a cathedral, and a few interesting remains of its heyday as a Moorish capital; the only really handsome buildings of the town, however, are among its private palaces, e.g., those of the counts of El Villar del Prado and of the Suárez family. The town has a high school or institute containing extensive art galleries and a fine library; it has also a theatre and a bull ring. In the neighborhood are the sulphur springs and baths of Jabalcuz. Pop., 1900, 25,566; 1910, 26,894.

JAFFA, yäf'fä (Ar. *Yafa*). A seaport town of Syria, Asiatic Turkey, situated in the Sanjak of Jerusalem, on a rocky coast, 35 miles northwest of Jerusalem, of which it is the port and with which it is connected by a railway line 54 miles long (Map: Palestine, B 3). It is irregularly built and possesses few points of interest. Its mosques and monasteries are of slight archi-

tectural merit, and its harbor is far from safe. The coast is skirted by a dangerous reef, through which the entrance is exceedingly narrow. In stormy weather it is often impossible to land for days at a time. As the port of Jerusalem, however, Jaffa is not without commercial value, and its importance is increasing with the development of the surrounding region. The chief exports of Jaffa are soap, fruits, wine, oil, and sesame, while the imports consist chiefly of cotton goods, rice, sugar, petroleum, tobacco, lumber, etc. The oranges of Jaffa are justly reputed the finest in the world. Jaffa is the seat of many consular agencies, including one from the United States. In the city is a German colony founded by the Friends of the Temple (q.v.); another templar colony is at Saron, about 1 mile northeast of the city. In the vicinity of Jaffa is a Jewish colony of the Alliance Israélite, with a school of agriculture. There are several missionary hospitals and schools. The population is estimated at over 45,000, mostly Mohammedans, but it includes a colony of some 8000 Jews. See JOPPA.

JAFFÉ, yäf'fä, PHILIPP (1819-70). A German historian, born at Schwersenz in Posen and educated at Berlin under Ranke. He became an active editor of the *Monumenta Germaniae Historica* and published *Geschichte des deutschen Reichs unter Konrad III.* (1845) and the very valuable *Regesta Pontificum Romanorum* (2d ed., 1881-86). Dissatisfied with his academic advancement, he took up the study of medicine. After passing his examination in medicine, he returned to his former scientific studies. His excellent contributions to the *Monumenta* were broken off in 1863, a year after his appointment to a chair in Berlin, by a quarrel with Pertz. He became a Christian in 1868, lost many of his earlier friends, and committed suicide at Wittenberg. His most important work was the *Bibliotheca Rerum Germanicarum* (1864-73).

JAFFNA, jäf'nä, or **JAFFNAPATAM,** jäf'nä-pä-täm'. A fortified town situated on an island of the same name, lying off the northern coast of Ceylon, of which it is an administrative dependency, and from which it is separated by a narrow strait (Map: India, D 8). It has an old fort erected during the Portuguese occupation, a few interesting temples, and an old Dutch church. The natives engage in considerable trade in tobacco and Palmyra timber. Jaffna is identified with the Galiba of Ptolemy. Pop. (largely native), 1900, 33,860; 1911, 40,539.

JAFFRAY, jäf'rä, ROBERT (1832-1914). A Canadian legislator and capitalist. He was born near Bannockburn, Scotland, early engaged in business in Edinburgh, and went to Toronto, Ontario, in 1852. For 31 years he was in the grocery trade and afterward in a large number of financial, railway, insurance, and industrial undertakings, becoming president of, or director in, many corporations, including the Globe Printing Company. He was a Liberal in politics and in 1906 was appointed a member of the Dominion Senate. While not prominent in politics in the common acceptance of the term, he was the trusted adviser of Liberal leaders and by personal integrity and farsighted views exerted a strong influence upon their policy and legislation.

JAGANNATH, jüg'à-nät, **PURI,** pōō'rē, or **JUGGERNAUT** (Skt. *Jagannātha*, lord of the world, from *jagat*, world, going, pres. p. of *gam*,

to go + *nātha*, lord, from *nāth*, to seek help). 1. The name of a town on the coast of Orissa, Bengal, in lat. 19° 48' N., long. 85° 50' E., Puri being now the official name (Map: India, F 5). It is celebrated as one of the chief places of pilgrimage in India. For many centuries the Golden Tooth of the Buddha was preserved at Puri, but it owes its reputation now to a temple erected there in honor of Vishnu, under his aspect as Jagannath. 2. The deity of Jagannath is essentially a god of all people, and this fact, combined with the peculiarly attractive nature of Krishna, also an incarnation of Vishnu, is the chief cause for the reverence paid him. It seems probable that the "lord of the world" was originally a local godling of non-Indian origin, who was absorbed into the Vishnuitic form of Hinduism, which holds sway especially in eastern India. Jagannath has a magnificent temple in Puri and is exposed to view three days each year. On the first of these days (the *Suan jattrā*, or bathing procession) the god is publicly bathed. Ten days later, on the *Rath jattrā*, or car festival, he is drawn on an enormous and floridly ornate car to some neighboring temple, whence he returns in somewhat diminished pomp after a week. The fact that in the press and excitement of the enthusiastic multitude fatalities occasionally occur has given rise to the erroneous popular idea that devotees seek to be crushed to death beneath the car. Consult: Sir William Hunter, *Orissa* (London, 1872); Wilkins, *Modern Hinduism* (ib., 1887); *The Imperial Gazetteer of India*, under "Puri," vol. xx (Oxford, 1908); James Fergusson, *History of Indian and Eastern Architecture* (2 vols., London, 1910).

JAGELLONS, yā-gēl'lonz. The name of an illustrious dynasty which reigned in Lithuania, Poland, Hungary, and Bohemia. This name is derived from Jagello or Jagellon, the last of a long line of hereditary grand dukes of Lithuania, who succeeded to his patrimonial possessions in 1381. Jagello in 1386 married Hedvig, daughter of Louis the Great, King of Poland and Hungary, who had succeeded her father on the Polish throne, and he was recognized as King by the Poles. He embraced Christianity and is known as Ladislas (Wladislaw) II of Poland. He died in 1434.—His son, LADISLAS III (q.v.), King of Poland (1434–44), was also elected King of Hungary after the death of Albert of Austria, in 1440, mainly through the agency of John Hunyady. He was succeeded in Poland by his brother, CASIMIR (1444–92), whose three sons, JOHN ALBERT (1492–1501), ALEXANDER (1501–06), and SIGISMUND I (1506–48), reigned in succession.—SIGISMUND II AUGUSTUS (1548–72), the son of this last and one of the wisest of the Polish monarchs, added Livonia to his kingdom. With him the male line of the Jagellons ended, but through his sisters descendants of the Jagellons ruled from 1587 to 1668.—LADISLAS, the son of Casimir IV of Poland, was elected King of Bohemia in 1471, on the death of George Podiebrad, and also succeeded Matthias Corvinus in Hungary in 1490. Ladislas died in 1516 and was succeeded in both kingdoms by his son, LOUIS II, who was defeated and slain by the Turks at Mohacs (Aug. 29, 1526), and with whom terminated the male line of the Jagellons of Bohemia and Hungary. His sister ANNA married Ferdinand I. See POLAND. Consult Rœppl and Caro, *Geschichte Polens* (Hamburg, 1840),

and Andrassy, *Development of Hungarian Constitutional Liberty* (Eng. trans., London, 1908).

JAGEMANN, yä'ge-mán, CHRISTIAN JOSEPH (1735–1804). A German scholar, born at Dingelstedt. After two years in Denmark, he spent several years in Italy, where he studied Italian literature. In 1774 the Elector of Mainz made him director of the Catholic Gymnasium of Erfurt, and afterward he was appointed private librarian of the Duchess Anna Amalie at Weimar, where he became a Protestant and married. His principal works were *Geschichte der freien Künste und Wissenschaften in Italien*, a revision of Tiraboschi's *Storia della letteratura italiana* (1777–81), and *Magazin der italienischen Litteratur und Künste* (1780–85), in which his translation of Dante's *Inferno*, in unrhymed iambic pentameter, appeared. His four-volume Italian-German and German-Italian dictionary appeared in 1790–91.

JÄGER, yä'gēr, GUSTAV (1832–). A German naturalist and hygienist, born at Bürg in Württemberg. He studied at the Theological Seminary of Urach, at the Stuttgart Polytechnic, and at the Tübingen Hochschule. For about 10 years he was a teacher of zoölogy in Vienna. From that time until 1884, when he began to practice medicine, he was a director of zoölogical gardens or a teacher in various German schools. He wrote a number of books on natural science, but his fame rests chiefly on his advocacy of the use of none but wool clothing. His publications include: *Die Darwinische Theorie und ihre Stellung zu Moral und Religion* (1869); *Lehrbuch der allgemeinen Zoologie* (vol. i, 1871; vol. ii, 1878); *Die Normalkleidung als Gesundheitsschutz* (1880; 4th ed. as *Mein System*, 1885); *Die Uniform im Licht der Gesundheitslehre* (1887); *Ein verkannter Wohltäter* (1891); *Selbstarznei im Heilmagnetismus* (1908); *Leben im Wasser* (3d ed., 1908).

JÄGER, OSKAR (1830–1910). A German historian and educator, son of the scientist Georg Friedrich Jäger, born at Stuttgart and educated at Tübingen. He taught in the Gymnasia of Stuttgart, Ulm, and Wetzlar, and was rector and director at Mörs and Cologne. After being pensioned in 1901 he was made honorary professor of pedagogy at Bonn. His pedagogical works are: *Aus der Praxis, ein pädagogisches Testament* (1885–97); *Das humanistische Gymnasium* (1890); *Didaktik und Methodik des Geschichtsunterrichts* (1895; 2d ed., 1904). His more important historical works are: *John Wycliffe* (1854); *Geschichte der Römer* (6th ed., 1901); *Geschichte der Griechen* (6th ed., 1900); *Die punischen Kriege* (1869–70); *Weltgeschichte* (last ed., 1899); new editions of Schlosser, *Weltgeschichte für das deutsche Volk* (5th ed., 1904); *Auswahl wichtiger Aktenstücke zur Geschichte des 19. Jahrhunderts* (1893), with Moldenhauer.

JÄGERNDORF, yä'gērn-dōrf. A frontier city in the Austrian Crownland of Silesia, on the Oppa, 14 miles by rail northwest of Troppau (Map: Austria, E 1). It is finely situated, 1018 feet above the sea, has a castle built by the Prince Liechtenstein and a beautiful church. There are also several technical schools. The town is a centre of the woolen industry and has manufactures of paper, organs, machines, cordials, woolen and woven goods, and vinegar. It is an important market for the surrounding country. Pop., 1900, 14,675; 1910, 16,681,

chiefly of German descent. Jägerndorf was plundered by the Tatars in 1241. In 1745 it was the scene of two battles between the Prussians and the Austrians.

The town was the capital of the Principality of Jägerndorf, which was bought in 1523 by the house of Hohenzollern, but in 1623 it was given by the Emperor to Prince Charles of Liechtenstein, because its Prince, John George of Hohenzollern, had supported Frederick of Bohemia in his fight against the Emperor. The house of Hohenzollern, however, did not resign its claims, and by the Peace of Breslau (1742) Frederick the Great obtained from Austria the cession of a small portion of the principality, which now forms Prussian Jägerndorf.

JAG'GAR, THOMAS AUGUSTUS (1839-1912). An American Protestant Episcopal bishop. He was born in New York City, graduated at the General Theological Seminary, New York, and was ordained priest in 1863. He was rector of Anthon Memorial Church, New York (1864-68); of St. John's, Yonkers (1868-70), while there founding St. John's Riverside Hospital; and of Holy Trinity, Philadelphia (1870-75). For 30 years (1875-1905) he was Bishop of southern Ohio. After he had retired from charge of this diocese he still retained his seat and vote in the House of Bishops, and from 1908 until his death he was Bishop in charge of American churches in Europe. He published *The Personality of Truth*, Bohlen lectures for 1900, besides various essays, sermons, and addresses.

JAG'GERY (Anglo-Ind., from Hind. *shakkar*, from Prak. *sakkara*, from Skt. *śarkara*, sugar). The name given in the East Indies to the sugar obtained from palm sap. In the Philippines it is called pakaskas. In obtaining the sap the flower spathe is cut in the ease of the coconut and nipa, or with the buri the head of the palm is tapped. The juices of the palms contain about 15 per cent of sugar. The sugar is generally consumed in the countries where it is produced and is very impure. Chemically much of it is identical with cane or beet sugar, but its production on a commercial scale has never succeeded. More recent experiments tend to show, however, that with modern sugar-making machinery the nipa palm may yield considerable amounts of a comparatively pure sugar. See CARYOTA.

JAGIĆ, yä'gich, VATROSLAV (1838-). A Slavic philologist, born at Warasdin and educated at Vienna. In 1860 he was appointed a teacher at Agram, and in 1870 he was elected member of the South Slavic Academy. But in the same year he was dismissed from Agram and became professor of comparative philology at Odessa. He resigned this position in 1874 to take the new chair of Slavic philology at Berlin, where he founded (1875) the *Archiv für slawische Philologie*. In 1880 he succeeded Sresnevski at St. Petersburg, and six years afterward became professor of Slavonic philology at Vienna. He retired in 1908. Jagić was chosen member of the Royal Servian Academy of Belgrade, of the Imperial Academy of Cracow, and of the Imperial Academy of St. Petersburg. His works, besides contributions to *Književnik*, *Rad*, *Starine*, the *Proceedings of the Vienna Academy*, and his *Archiv*, bear chiefly on the early history of the Slavs, on their languages and literatures; they are too numerous to mention, but a complete bibliography will be

found in the *Festschrift (Sbornik)*, written by his former pupils in 1908. Jagić is the editor of the *Slavic Philological Encyclopedia (Entzyklopediia Slavionskoi Filologii)*, published at St. Petersburg (1909 et seq.), to which he contributed a *History of Slavic Philology* (ib., 1910).

JAGO, jā'gō, RICHARD (1715-81). An English poet, born at Braudesert, who, after taking his B.A. and M.A. degrees at Oxford, became curate (1737) and then rector (1754) of Snitterfield, Warwickshire, where, although he received other and richer preferments, he mainly resided and where he died. Shenstone, his friend from university days, admired his poetry, especially his elegy "The Blackbirds." His poems, which had made their appearance in various ways and places, were finally posthumously published, as revised by the author, under the title *Poems Moral and Descriptive* (1784). Aside from his poetry, Jago's work is quite insignificant. Consult the notice of Jago prefixed to the 1784 edition of his poems, mentioned above, and F. L. Colville, *Warwickshire Worthies* (London, 1870). Some of his poems will be found in A. Chalmers's *English Poems*, vol. xvii (ib., 1810).

JAGOW, yä'gō, GOTTLIEB VON (1863-). A German statesman, born in Berlin, son of the hereditary master of the hunt. He was educated at Bonn. In 1886-95 he held different local offices and then became attaché at Rome and in 1896 at Munich. In 1897 he was made Secretary to the German Embassy in Rome, where (after a year as Minister to Luxemburg) he became Ambassador in 1909 and in December, 1912, assisted in the renewal of the Triple Alliance. When he became Minister of Foreign Affairs early in 1913, succeeding Von Kiderlen-Waechter, it was supposed that his relations with Italy would assure Germany of that power's complete coöperation; but the next year the outbreak of the Great European War proved his plans faulty. Consult F. W. Wile, *Men around the Kaiser* (London, 1913). See WAR IN EUROPE.

JAGUA, Hä'gwá. See CIENFUEGOS.

JAGUAR, jā-gwār' (from Brazilian *jaguara*), *Felis onca*. The largest, fiercest, and most interesting of all the wild cats of the New World. It is decidedly heavier than the puma, though the measurements usually given do not serve to bring out the difference. An average jaguar is 6 or 7 feet long, of which one-third or more is tail; the girth back of the shoulders is about 3 feet; the head is disproportionately large, and the limbs are massive. In color there is a very wide range of diversity, from a ground of dirty white or yellowish to almost black, southern animals being the lightest. In all cases, however, there are distinct and very characteristic markings, not unlike those of the leopard; but in the jaguar the rings cover more ground, are inclined to be more angular and broken, and each ring incloses one or more dark spots. See **PLATE** of WILD CATS, accompanying article CAT.

The jaguar is found distributed very generally throughout South America, except in the colder parts of Patagonia (beyond lat. 40° S.) and on the highest mountains; it extends northward (or recently did) as far as Texas and possibly even into Louisiana and Arkansas, but apparently it has never crossed the Mississippi—at least not so as to get any foothold. The black variety is most common in Guiana, where

it is sometimes called "tapir tiger," from its supposed fondness for tapirs as an article of food. The skull may easily be distinguished by a prominent tubercle on the anterior or nasal edge of the orbit.

The jaguar is essentially an animal of the forest and remarkably fond of water; so that the half-flooded jungles of the Amazon valley are its true and most suitable home, and there, in the season when large districts are submerged, it easily maintains for weeks together an almost entirely arboreal life. Nevertheless, a race of jaguars exists on the Pampas, a cold, treeless, and waterless desert, where they lurk in the tall grass or river-side thickets, working destruction among the ranchmen's horses, cattle, and sheep, and pouncing upon deer and the smaller mammals and reptiles of the region. Another curious fact is the enmity between the jaguar and the puma of the plains (and perhaps elsewhere), leading to constant battles in which the jaguar is likely to be worsted by its more active and aggressive antagonist. Foxes and wolves torment the big beast also, by following it about in hope of feeding upon the remains of its feasts, as jackals attend the African lion.

Jaguars are likely to remain in certain localities, in the vicinity of which they prowl at night, lying asleep or in ambush most of the daylight hours, and they seldom attack man unless provoked. They feed chiefly upon mammals and large reptiles. Monkeys and capybaras make a large part of the diet. Deer, sloths, tapirs, and manatees are also hunted, but peccaries are seldom attacked. The jaguar is sometimes killed by the great anteaters, whose sabre-like claws tear its bowels open even while the anteater itself is in the throes of death. Along the tropical rivers the jaguars wait for and seize turtles that come ashore to lay their eggs, turn them over, and gnaw them out of their shells. Even alligators and boas are occasionally seized, killed, and devoured, and jaguars are expert at snatching fish from overhanging banks. Much of this prey requires hard chasing; but the animal prefers to lie upon the low limb of a tree, or the top of a rock commanding some game trail or drinking place, and thence to leap upon its victims. The female jaguar usually produces two or three kittens at a birth, which are as beautiful and playful as young leopards. These have sometimes been tamed; but this species is perhaps the most savage and intractable of the great cats, and the kittens become dangerous with increasing years. See HUNTING BIG GAME.

The fullest account of this cat is by J. H. Porter in *Wild Beasts* (New York, 1894). Consult also: Alston, "Mammals," in Selater and Salvin's *Biologia centrali-americana* (London, 1879-92); A. R. Wallace, *Travels on the Amazon* (ib., 1889); H. W. Bates, *The Naturalist on the Amazon* (7th ed., ib., 1895); W. H. Hudson, *The Naturalist in La Plata* (4th ed., ib., 1903).

JAGUARONDI, jä'gwä-rön'dê, or **YAGUARONDI**. A tropical American wild cat (*Felis jaguarondi*), remarkable for its very long body and tail in proportion to the limbs and for its uniform coloration, also for its isolated habitats. It inhabits Guiana, eastern Brazil, and Paraguay, and also northeastern Mexico, but, so far as known, is not to be found in the countries between. Its body is about 30 inches long and its tail fully 25 inches. The skull is elongated and flattened, the pupil of the eye round, and the

nose is, as it were, strongly pinched in laterally. Its fur is gray, varying in some individuals towards brown, in others towards red, and is wholly unspotted. Compare EYRA.

JAHDE, yä'de. An inlet of the North Sea. See JADE.

JAHN, yän, FRIEDRICH LUDWIG (1778-1852). A Prussian patriot and hero of the common people, an ardent advocate of German unity, and the father of popular gymnastics (Volks- or Vereinsturnen). He was born in the village of Lanz, developed a passion for Prussian and German history and the German language and literature during six years at the universities of Halle, Jena, and Greifswald, and interrupted his studies by frequent excursions to all parts of the country. His chief literary work, *German Nationality* (*Deutsches Volkstum*, 1810), falls in the period between the battle of Jena and the outbreak of the War of Liberation and gives fitting expression to his dominant idea. The years 1810-18 mark the culmination of his career. As a teacher in Berlin, he began to meet schoolboys outside the city gates on half-holiday afternoons for games and simple exercises, and then, as the numbers grew, an outdoor gymnasium was constructed and new exercises were devised, until in 1816 and 1817 more than 1000 "turners" were in attendance. Jahn saw in this active, wholesome, common life an opportunity to develop harmony and to kindle public spirit. Numerous gymnasia of the Berlin type were opened elsewhere in Prussia and other German states, with the help of Jahn's pupils and of *Die Deutsche Turnkunst* (1816), which he and they prepared. But the reactionary policy adopted by the Holy Alliance led to the general closing of these Turnplätze, and to Jahn's arrest (1819) on suspicion of "secret and most treasonable associations." Although finally acquitted (1825), he passed the remaining years of his life in comparative obscurity, most of them in the Thuringian town of Freyburg-on-the-Unstrut. There the Turnhalle has been built over his grave, and a Jahn Museum is near by. The Turnvereine in their present form began to appear after 1840, but they reflect the spirit and aims of Jahn.

JAHN, JOHANN (1750-1816). A distinguished Roman Catholic Orientalist and biblical critic. He was born at Tasswitz, Moravia, June 18, 1750, received his early education at Znaim and Olmütz and in 1772 entered the Premonstratensian convent of Bruck, where he took his vows in 1774 and was appointed professor of Oriental languages and biblical criticism. On the suppression of this convent, in 1784, Jahn was transferred to the same professorship in Olmütz, and finally (1789) to the University of Vienna, where after 1803 he also held the chair of dogmatic theology. So far as regards the modern Catholic literature of Germany, Jahn may be regarded as the father of biblical criticism. But the boldness of some of his opinions in his *Einleitung* aroused the alarm of the ecclesiastical authorities, and he was honorably removed from his chair in the university by being promoted to a canonry of St. Stephen's at Vienna in 1805. He continued, however, to pursue the same studies till his death, in Vienna, Aug. 16, 1816, and published many works in both departments, the most important of which, passing over his grammars, lexicons, and elementary books of the Hebrew, Syriac, Aramaic, and Arabic languages, are his *Einleitung in die*

göttlichen Schriften des alten Bundes (2 vols., 1792; and again in 4 vols., 1802-03; Eng. trans. by Turner and Whittingham, New York, 1827); *Biblische Archäologie* (5 vols., 1797-1805; Eng. trans. by Upham, 3d ed., Andover, 1832); *Enchiridion Hermeneuticæ* (1812); an appendix of dissertations to this work (1813-15); and an edition of the Hebrew Bible (4 vols., 1806). Five years after his death a collection of *Remains* was published at Tübingen, the genuineness of which, although seemingly without reason, has been called in question. In 1822 his *Introduction, Archæology, Enchiridion, and Appendix Hermeneutica* were put on the index.

JAHN, OTTO (1813-69). A German philologist and archæologist. He was born at Kiel and studied at Kiel, Leipzig, and Berlin. In 1837 he visited Paris, in 1838 Italy, and in 1839 became privatdocent in Kiel, but was in 1842 called to Greifswald, where he remained till 1847, when he became professor at Leipzig. His activity in the revolutionary movements of 1848-49 offended the Saxon government, and in 1851 he was deprived of his chair at the university; but he remained at Leipzig until 1855, when he was appointed professor of classical philology and archæology and director of the Academic Museum of Art at Bonn. Here he remained until in 1867 he was called to succeed Eduard Gerhard at Berlin. But before he could enter upon his new duties his health gave way, and he died in Göttingen, Sept. 9, 1869. Jahn was a many-sided scholar and produced valuable works in many fields. In classical philology may be mentioned his editions of *Persius* (1843); *Censorinus* (1845); *Juvenal* (1851; 4th ed. of Juvenal, Persius, and Sulpicia by Leo, 1910); Sophocles' *Electra* (1861; 3d ed. by A. Michaelis, 1882); *Pausaniæ Descriptio Arcis Athenarum* (1860; 3d ed. by A. Michaelis, 1901); Plato's *Symposium* (1864; 2d ed. by H. Usener, 1876); and the *Treatise on the Sublime*, attributed to Dionysius or Longinus (1867; 2d ed. by J. Vahlen, 1887). He published also a collection of essays on music, *Gesammelte Aufsätze über Musik* (1866), and a very important *Life of Mozart* (1856-59; 3d ed. by Deiters, 1889-91; Eng. trans. by Townsend, 1891). But it was in the field of classical archæology that Jahn's influence was most strongly exerted as a teacher and writer. His writings are for the most part short articles, which appeared in periodicals as university programmes, or in the proceedings of learned societies, especially in the *Berichte der königlichen sächsischen Gesellschaft der Wissenschaften zu Leipzig*. Some were collected in *Archäologische Aufsätze* (1845), *Archäologische Beiträge* (1847), and *Aus der Altertumswissenschaft* (1868). Among his more important works were: *Die Ficoronische Cista* (1852); *Beschreibung der Vasensammlung König Ludwigs* (1854), with an epoch-making introduction on Greek vases; *Ueber den Aberglauben des bösen Blicks* (1855); *Darstellungen des Handwerks und Handelverkehrs*, three papers dealing with reliefs, vases, and paintings (1861, 1867, 1868); *Griechische Bilderchroniken*, published after his death by A. Michaelis (1873). Jahn's importance in the study of classical archæology is due to the stress he laid on exact and scientific method, and recognition of the limits of exact knowledge, in opposition to the symbolical school of interpretation, which had led to the wildest hypotheses, and of which the chief representa-

tives were Panofka, Gerhard, and Braun. Consult Michaelis, *Allgemeine deutsche Biographie*, vol. xiii (Leipzig, 1881), and Sandys, *A History of Classical Scholarship*, vol. iii (Cambridge, 1908).

JÄHNS, yāns, FRIEDRICH WILHELM (1809-88). A German composer and musical critic, born at Berlin. He was educated for the operatic stage, but became a teacher of vocal music and founder and head of a musical Verein. Of his compositions his songs are best known, but his most valuable work was his criticism of Weber, *K. M. von Weber in seinen Werken* (1871), which is the most authoritative of the biographies of Weber and includes a complete thematic catalogue of his works together with critical comments. Jähns's splendid collection of Weberiana is now in the Berlin Royal Library.

JAI-ALAI, hī'ā-lī'. See PELOTA.

JAIL DELIVERY, COMMISSION OF (OF. *jaiole, geole*, Fr. *geôle*, from Lat. *caveola*, dim. of *cavea*, cavity, cage, cave, from Lat. *cavus*, hollow, Gk. *κύαυ, kyar*, hole, from *κύνειν, kyein*, to swell, to contain). One of the four royal commissions issued to judges of assize in England, under which they discharge their duties on circuit. The commission empowers the judges to try and deliver every prisoner who shall be in the jail when they arrive at the circuit town. It is directed to the judges, with whom are coupled the sergeants at law and king's counsel on the circuit, the clerk of assize, and the associate. Similar authority is conferred upon courts of oyer and terminer in the United States by general statutes. See ASSIZE; OYER AND TERMINER; and consult the authorities referred to under CRIMINAL LAW.

JAIL FEVER. See TYPHUS FEVER.

JAÍME. See JAMES.

JAÍME, hī'mā (JAÍME-JUAN-CARLOS-ALFONSO-FELIPE DE BORBÓN-ANJOU), DON (1870-), DUKE OF MADRID. A Carlist claimant of the Spanish throne, son of the Bourbon Prince called Don Carlos (1848-1909) and of Marguerite of Parma. He was born in Vevey, Switzerland, received a military education in Austria and England, and entered the Russian army, in which he became a colonel. He made his residence at Frohsdorf, near Vienna. His father's death in July, 1909, left him the head of the royal Spanish house of Bourbon-Anjou, and for a time in 1909 and 1910 the apparent lack of harmony between the Vatican and the Spanish government gave rise to rumors of a new Carlist uprising.

JAINISM, jīn'iz'm (from Skt. *jāina*, from *jina*, conqueror, a name given to the founder of the religion, from *ji*, to conquer). The name given to a schismatic religion of early India, which arose as a protest against Brahmanism about the same time as did Buddhism and became an important rival of the latter, although resembling it in many respects. It still retains a position as one of the most important among the living sects of the Hindus and claims over 1,000,000 believers. Many adherents to its teachings are found in every province of Upper Hindustan, in the cities along the Ganges, and in Calcutta, but more especially to the westward, in the states of Mēwar and Merwara, in Gujarat, and southward along the upper part of the Malabar coast and scattered throughout the peninsula. The Jains are among the wealthiest and most influential members of the Hindu com-

munity, as they are devoted largely to mercantile pursuits. Accordingly their temples, the most famous of which are those of Mount Abu, are among the finest in India. In their way of living they are refined and simple, and in their manners they are gentle and attractive. It is now generally believed that Jainism antedated Buddhism in its beginnings, and that its chief expounder, Vardhamāna Mahavira, was an older contemporary of the Buddha. The name *Mahāvira* itself is appellative and means 'the great hero.' He is also called *Kevalin* or *Sarvajna* (omniscient), *Siddha* (accomplished), *Tirthakara* (finder of the ford), etc. Another name given to the deified saints of the faith is *Arhat* (venerable, holy); accordingly the followers of these spiritual leaders are sometimes called *Arhatas*. Mahavira, the founder of Jainism, arose in the sixth century B.C. in the region not far from the holy city of Benares, which was the territory likewise that gave birth to Buddhism. His family name was Jnātriputra, and he is referred to in the Buddhist writings as Nataputta, which was the form of the name in his own dialect of Magadha (q.v.). His father's name in the same vernacular appears as Siddhattha; his mother's as Trisala. It is said that on their death, in his thirtieth year, he renounced his home and petty kingdom, gave up his wife and his daughter, and became a religious devotee and recluse. For 12 years he practiced the most rigorous kind of asceticism and then devoted the remaining 30 years of his life to preaching and teaching and, like Buddha, to organizing his faith and the religious order of his community. His death must have occurred before Buddha's, as the latter refers to that event. The reputed teacher of Mahavira was Parśva or Parśvanatha, who belonged to the pre-Buddhistic sect of the Nirgranthas (without bonds, free from ties, emancipated), and this religious master must have flourished not later than the seventh century B.C. There is evidence also of Mahavira's having also been influenced by a stern ascetic named Gosala, who was for a time his associate and pupil, but afterward his rival and the leader of another sect of minor importance.

The tenets of the Jainas or Arhatas are in several respects analogous to those of the Buddhists (see BUDDHISM), and like them go back to the principles of the Sankhya and Yoga (qq.v.) philosophy; but they resemble in others those of the Brahmanical Hindus. With the Buddhists they share in the denial of the divine origin and authority of the Vedas, and in the worship of certain saints, whom they consider superior to the other beings of the pantheon. They differ, indeed, from them in regard to the history of these personages, but the original notion which prevails in both worships is the same. With the Brahmanical Hindus, on the other hand, they agree in admitting the institution of caste, in performing the ceremonies called *Samskaras* (see SAMSKARA), and in recognizing some of the subordinate deities of the Hindu pantheon, at least apparently, as they do not pay especial homage to them, and as they disregard completely all those Brahmanical rites which involve the destruction of animal life. Their teaching, however, transcends the bounds of the Aryan world, being intended also for the despised Sudras and Mlechhas (Europeans). It deserves notice, too, that though rejecting in general the authority of the Vedas, they admit

it and quote Vedic texts if the doctrines of the latter are conformable to the Jaina tenets. The Jainas are thoroughgoing hylozoists, recognizing a psychic element (*jīva*) in every material object. Apart from this they have no well-rounded-out metaphysical theory, as they hold the doctrine (*syād-vāda*) that "yes" and "no" may at the same time be predicated.

According to their doctrine, all objects, material or abstract, are arranged under nine categories, called *tattvas*, truth, or principles, of which the ninth and last is called *mōkṣa*, deliverance or liberation of the vital spirit from the bonds of action, i.e., final emancipation, salvation. It is identical with the Nirvana of the Buddhist. To reach such an emancipation the most stringent asceticism and self-mortification for 12 years are essential. Salvation can be obtained only through such observances and the "Three Gems," which are the treasures of the faith. These are "right knowledge, right conception, and right actions." These latter, which are synonymous with virtue, are fivefold: (1) noninjury (*ahiṃsā*); (2) kindness, and true but pleasant speaking; (3) uprightness, especially shown by nonstealing; (4) purity in thought, word, and deed; (5) renunciation of worldly interests. This freeing of the spirit from the bonds of material things will come through successive reincarnations; it will mean true release, but the spirit will retain its individuality.

The principles of faith, as mentioned before, are common to all classes of Jainas, but some differences occur in the practice of their duties, as they are divided into religious and lay orders, *Yatis* (which among the Svetambaras include women), and *Srāvakas* or *Upāsakas*. Both, of course, must place implicit belief in the doctrines of their saints; but the *Yati* has to lead a life of abstinence, silence, and continence. He should wear a thin cloth over his mouth to prevent insects from flying into it, and he should carry a brush to sweep the place on which he is about to sit, to remove any living creature out of the way of danger. Their highest law of duty is not to harm any living creature, and their doctrine of metempsychosis does not stop at animal existences, but it includes the inanimate world as well. The saintly *Yati* may dispense with all acts of worship; while the *Srāvaka* has to add to the observance of the religious and moral duties the practical worship of the saints and a profound reverence for his more pious brethren. The secular Jain must, like the ascetic, practice the four virtues—liberality, gentleness, piety, and penance; he must govern his mind, tongue, and acts; abstain at certain seasons from salt, flowers, green fruits, roots, honey, grapes, tobacco; drink water thrice strained, and never leave a liquid uncovered lest an insect should be drowned in it; it is his duty also to visit daily a temple where some of the images of the Jain saints are placed, walk round it three times, make an obeisance to the image, and make offerings of fruits or flowers, while pronouncing some such formula as "Salutation to the Saints, to the Pure Existences, to the Sages, to the Teachers, to all the Devout in the world." The reader in a Jain temple is a *Yati*, but the ministrant priest is not seldom a Brahman, and the presence of such Brahmanical ministrants seems to have introduced several innovations in their worship. In Upper India the ritual in use is often intermixed with formulas belonging more properly to the Saiva

and Sakta worship, and images of Siva and his consort have their place in Jaina temples. In the south of India they appear, as mentioned before, to observe also all the essential rites or Samskaras of the Brahmanical Hindu. The festivals of the Jainas are especially those relating to events in the life of their deified saints; but they observe also several common to other Hindus, as the spring festival, the Sripanchami, and others.

The Jainas are divided into two principal divisions, *Digambaras* and *Svetambaras*. The former word means 'sky-clad,' or naked, and it is thought that the Gymnosophists, or naked devotees, to whom the Greek writers allude, were Jainas; but this is not quite certain. (See GYM-NOSOPHISTS.) They seem to be identical with the Niganthas (Nirgranthas) mentioned in Buddhist Pali writings and in an inscription of Asoka. If this identification is correct, Nataputta, a leader of the Nigantha sect, is identical with Jnātriputra Mahāvira. At the present day ascetics of the Digambara class wear colored garments and confine the disuse of clothes to the period of their meals. *Svetambara* means 'one who wears white garments'; but the differences between these two very ancient divisions are far from being restricted to that of dress; it is said to comprehend a list of 700 topics, of which 84 are considered to be of paramount importance. In the south of India the Jainas are divided into two castes; in Upper Hindustan they are all of one caste. It is remarkable, however, that among themselves they recognize a number of families between which no intermarriage can take place, and that they resemble in this respect also the ancient Brahmanical Hindus, who established similar restrictions in their religious codes.

As regards the pantheon of the Jaina creed it is more fantastic than that of the Brahmanic sects, whence it is borrowed to a great extent, but without any of the poetical and philosophical interest which inheres in the gods of the Vedic time. The highest rank among their numberless hosts of divine beings—divided by them into four classes, with various subdivisions—they assign to the deified saints, whom they call *Jina*, *Arhat*, or *Tirthakara*, i.e., prophet, besides a variety of other generic names. The Jainas enumerate 24 Tirthakaras of their past age, 24 of the present, and 24 of the age to come; and they invest these holy personages with 36 superhuman attributes of the most extravagant character. Notwithstanding the sameness of these attributes, they distinguish the 24 Jinas of the present age from each other in color, stature, and longevity. Two of them are red, two white, two blue, two black; the rest are of a golden hue or a yellowish brown. The other two peculiarities are regulated by them with equal precision, and according to a system of decrement, from Rishabha, the first Jina, who was 500 poles in stature, and lived 8,400,000 great years, down to Mahavira, the twenty-fourth, who had degenerated to the size of a man and was no more than 40 years on earth, the age of his predecessor, Parśvanatha, not exceeding 100 years. The present worship is almost restricted to the last two Tirthakaras; and these may be considered as historical personages. As, moreover, among the disciples of Mahavira there is one Indrabhati, who is called Gautama, and as Gautama is also a name of the founder of the Buddha faith, it has been thought that Gautama

Sakyamuni, the Buddha, is alluded to; but this is not accepted, although Buddha calls himself by the title of Jina (the conquering one), and the Buddhist scriptures also sometimes speak of him as the twenty-fifth Buddha or Jina.

Jainism, in contrast to Buddhism, never spread beyond the bounds of India; on the other hand, it has lived longer than Buddhism in the land that gave it birth. Prakrit is the canonical speech of Jainism, but the sacred literature of the Jainas is uninteresting or stupid.

Bibliography. Among the best older essays on the tenets, mythology, observances, and literature of this sect are those of Wilson, *Essays*, vol. i (London, 1862), and Colebrooke, in his *Miscellaneous Essays*, ed. by Cowell, vol. ii (ib., 1873). More recent and important is the sketch by Monier-Williams, in the *Journal of the Royal Asiatic Society*, vol. xx (London, 1888); Jacobi (q.v.), "Jaina Sutras," in the *Sacred Books of the East*, vols. xxii, xlv (Oxford, 1884-95); Bühler, *On the Indian Sect of the Jainas*, translated from the German by Burgess (London, 1903); "Eine Jaina Dogmatik," in *Deutsche Morgenländ. Gesellsch., Zeitschrift*, vol. lx, pp. 287-325, 512-51 (Leipzig, 1906); the excellent outline by Hopkins, "Jainism," in *Religion of India* (Boston, 1895); Schubring, *Acārāṅga-sūtra, erster Srutaskandha*, text and glossary (Leipzig, 1910); Jhaverī, *The First Principles of the Jain Philosophy* (London, 1910); Warren, *Jainism in Western Garb as a Solution to Life's Great Problems* (Madras, 1912). On Jaina literature, consult: Weber, *Sacred Literature of the Jainas*, translated by Smyth (Bombay, 1893); Barodia, *History and Literature of Jainism* (ib., 1909). On Jain architecture: Fergusson, *Cave Temples of India* (London, 1880), and Burgess, *Buddhist and Jaina Caves* (ib., 1881-83). On Jaina epigraphy: Guérinot, *Répertoire d'épigraphie Jaina précédé d'une esquisse de l'histoire du Jainisme d'après les inscriptions* (Paris, 1908). For a bibliography, consult the *List of Sanskrit and Hindi Manuscripts Purchased by Order of Government and Deposited in the Sanskrit College, Benares, during the Years 1902, 1905-06, and 1909* (Allahabad, 1904-10); Guérinot, *Essai de bibliographie Jaina* (Paris, 1906); Hüttemann, *Die Jnataerzählungen im sechsten Anga des Kanons der Jinisten* (Strassburg, 1907); Barnett, *The Antagaḍa-dasāo and Anuttarovavāiḍya-dasāo*, translated from the Prakrit (London, 1907); Guérinot, "Notes de bibliographie Jaina," in the *Journal Asiatique*, vol. xiv, pp. 47-148 (Paris, 1909).

JAINTIA (jīn'tī-à) **HILLS.** A mountainous region of Assam, British India, covering an area of about 2000 square miles. With the Khasi Hills it gives its name to a governmental district. Coal and limestone are the chief mineral products; rice is grown. The hill villages are inhabited chiefly by Panars, a race which differs in language and creed from the Khasis, who call them Syntengs.

JAIPUR, jī-pōor', or **JEYPORE**, -pōr'. A native Rajputana state, India, bordering on Bikanir, Bhartpur, Gwalior, Jodhpur, and other regions (Map: India, C 3). Area, 15,579 square miles. The surface is generally level except to the north and northwest, where it is broken by a spur of the Aravalli Mountains. It is sparsely watered, but this defect is gradually being overcome by extensive irrigation works. Corn, wheat, barley, cotton, tobacco, sugar cane, and the poppy are cultivated, and cattle are raised.

Woolen and cotton cloths, chintz, statuary, pottery, brass and lacquer work are manufactured. Copper, cobalt, black and white marble are found in the hills. Capital, Jaipur. Pop., 1901, 2,658,666; 1911, 2,636,647.

JAIPUR, or **JEYPORE**. The capital of the protected state of the same name, Rajputana. It is perhaps the handsomest and most regularly built of the native towns of India (Map: India, C 3). It lies 150 miles west of Agra. It is built on a plain surrounded by fort-capped hills, except to the southwest, where the plain merges into a desert. It was founded in 1728, is inclosed by a fortified wall, 20 feet thick, pierced by seven gates, and has paved streets 111 feet wide, laid out at right angles. The principal buildings are the Nahargarh, an almost inaccessible fort, dominating the city from the northwest; the palace of the Maharaja with its beautiful pleasure gardens; the Ishwari Minar (minaret piercing heaven); the splendid Maharajan chattris or cenotaphs; the observatory; Hall of the Winds; and the Mayo Hospital. Jaipur has municipal water works supplied by a tributary stream of the Chumbul, is lighted by gas, and its fine public park contains a zoölogical garden covering 70 acres. Its schools include the Maharaja's College, the Oriental College, the Sanskrit College, and a school of art. It is the seat of a British residency and is an important commercial and industrial centre with flourishing bazars and banking and trading establishments. Colored muslins, carpets, cloths, statuary, gold enamel ware, pottery, brass work, and jewelry constitute the chief manufactures. The town has two large cotton compresses. Pop., 1901, 160,167; 1911, 137,098. Amber, the ancient capital of Jaipur, 5 miles distant, has picturesque ruins of a fort, a palace, a mosque, temples, and tombs.

JAK. A tropical tree closely related to the breadfruit tree. See JACK TREE.

JAKIE, jā'kē (South American name). A South American frog (*Pseudis paradoxa*), of the family Cystignathidæ, remarkable for the relatively great size of its tadpoles. It is entirely aquatic and richly colored with bright green, bronze, and black above and shining yellow below, but all these colors disappear in a dull-brown hue immediately after death. The length of the adult is only from 2 to 2½ inches, yet its tadpoles reach a length of more than 10 inches, two-thirds of which consists of a thick, muscular tail. As the transformation proceeds, it shrinks steadily, until, when ready to leave the water, the tadpole is hardly more than 1 inch in length.

JAKJOKERTA, jāk'yō-kēr'tā. A city of Java. See JOKJOKARTA.

JAKOB, yā'kōp, LUDWIG HEINRICH VON (1759-1827). A German economist, born at Wettin. He studied at the University of Halle, where he became professor of philosophy in 1791. When the university was suppressed by Napoleon in 1807, he accepted the chair of political economy at Kharkov, Russia, was appointed to a commission to examine the finances of the Empire, and subsequently held other posts under the Russian government. In 1816 he returned to Halle as professor of political economy. His writings include: *Prolegomena zur praktischen Philosophie* (1787); *Grundriss der allgemeinen Logik* (1788; 4th ed., 1800); *Antimachiavell* (1794; 2d ed., 1796); *Grundsätze der Nationalökonomie* (1805; 3d ed., 1825); *Entwurf eines*

Criminalgesetzbuchs für das russische Reich (1818); *Einleitung in das Studium der Staatswissenschaften* (1819); *Staatsfinanzwissenschaft* (2 vols., 1821).

JAKUNS, jā-kōonz'. A mixed race, inhabiting the protected State of Johore at the extreme south of the Malay Peninsula. They are the offspring of the Malays with the more aboriginal Sakai (q.v.) of the interior. The Jakuns seem rather taller, lighter in color, and finer-featured than the Sakai, who are generally classed as Negritos. Information concerning these people will be found in Stevens, "Anthropologische Bemerkungen über die Eingeborenen von Malacca," in the *Zeitschrift für Ethnologie* (Berlin, 1897).

JAKUTSK, yā-kōot'sk'. Another spelling for the name of a territory and its capital in Siberia. See under YAKUTSK.

JAL, zhāl, AUGUSTE (1795-1873). A French author, born at Lyons. He was educated at the naval school in Brest and led a company of the cadets in the defense of Paris during the Hundred Days (1815). His first literary work was done on *Le Fureteur*, *Le Miroir*, and *La Pandore*, liberal journals. Afterward he became well known as an art critic. In 1831 he received official charge of the marine archives and wrote in this connection a nautical glossary and *L'Archéologie navale* (1839). The fruit of much of his labor is embodied in his great *Dictionnaire critique de biographie et d'histoire* (1864). He also wrote a memoir, published posthumously, *Souvenirs d'un homme de lettres* (1877), and several other works on art and archæology.

JALALABAD, jā-lā'la-bād'. A town of Afghanistan. See JELALABAD.

JALAL-UD-DIN (jā-lāl'-ud-dēn') **MU'-HAMMAD**. See AKBAR.

JALĀL-UD-DĪN RŪMĪ, rōō'mē (1207-73). A Persian philosopher and poet, and the greatest of all the mystics of the Orient. He was born at Balkh in Khorassan, of noble and wealthy parents, and under the careful training of his father, Baha-ud-Din, a scholar of wide repute, early became a visionary and a mystic. He subsequently studied at Aleppo and Damascus and in 1231 succeeded his father as the head of the college at Iconium (Konieh) in Asia Minor. He came for three years under the influence of a wandering dervish, Shams-ud-Din of Tabriz, whose mysterious death in 1247 he commemorated by founding the Maulaw Order of Dervishes, a Sufistic sect. For them he wrote the *Mathnawī*, a collection of tales and moral precepts containing 40,000 couplets, in six books, in imitation of similar poems by Senayi and Farid-ud-Din Attar. This didactic work, which surpasses its models, has been partly translated into English by Redhouse (London, 1881), Whinfield (ib., 1887 and 1901), and Nicholson (1901), and into German by Rosen (Leipzig, 1849). Another work, the *Diwān*, a collection of lyrics of high poetic merit and great originality, has also been preserved and was published, with a translation and notes, by Rosenzweig (Vienna, 1838). Of all the Persian Sufis, Jalāl-ud-Din is the most important. To him the Ego, the world, and the Divine are one (see SUFISM), and in his works for the first time in Persian mysticism we find the doctrine of transmigration taught. Consult: Ethé, "Neupersische Literatur," in Geiger and Kuhn, *Grundriss der iranischen Philologie*, vol. ii (Strassburg, 1896-1904); Browne, *Literary History of Persia* (New York, 1906); Davis, *The Persian Mystics, Jalāl-*

u'd-din Rumi (ib., 1908); Wilson, *The Masnavi, Book II, Translated for the First Time from the Persian into Prose* (London, 1910).

JALANDHAR, jūl'an-dēr, or **JULLUNDER**. A division of the Punjab (q.v.), British India (Map: India, C 2). It comprises the districts of Kangra, Hoshiarpur, Jalandhar, Ludhiana, and Ferozpur, and has an area of 19,394 square miles. Pop., 1901, 4,305,724; 1911, 3,967,724. Capital, Jalandhar.

JALANDHAR, or **JULLUNDER**. The capital of a district and division of the same name in the Punjab, British India, 260 miles northwest of Delhi (Map: India, C 2). It is in a productive agricultural and sporting district and anciently was a fortified place of importance, the capital of the Rajput Katoch Kingdom as early as the fourth century B.C. It manufactures silk, flour, cabinetwork, iron, and brass. Its fine cantonment, where a garrison of two batteries of artillery is stationed, inclosing the public gardens, covers 7½ square miles. Pop., 1901, 67,735; 1911, 69,318.

JAL'AP (Sp. *jalapa*). A well-known purgative medicine. It is the root of *Ipomœa jalapa*, a plant of the natural order Convolvulaceæ. It is found in Mexico, at an elevation of about 6000 feet above the level of the sea, in the neighborhood of the town of Jalapa, or Xalapa, from which its name is derived. It is a perennial twining plant, with large flowers and a turnip-like root, varying from the size of a hazelnut to that of a man's fist. The roots when fresh are white and fleshy and abound in a milky juice. They are prepared for the market by drying. Jalap was long confused with other plants, among them *Mirabilis jalapa*, known in flower gardens as *marvel of Peru*.

Jalap seems to have been first introduced into England as a medicine about 1609.

JALAP.

The dried roots are brown and wrinkled externally and of a deep yellowish-gray color internally; their odor is faint and disagreeable, and their taste is nauseous. The active ingredient is the resinous portion, which contains convolvulin. Jalap resin may be distinguished from common resin by its insolubility in volatile oils. Jalap is a valuable cathartic, but is seldom given alone. It is an ingredient of the compound cathartic pill of the United States Pharmacopœia. Its purgative action is increased by the addition of a little calomel, and its hydragogue action by bitartrate of potash, while its tendency to produce griping is obviated by the addition of a little ginger. In the form of compound jalap powder, which consists of one part of

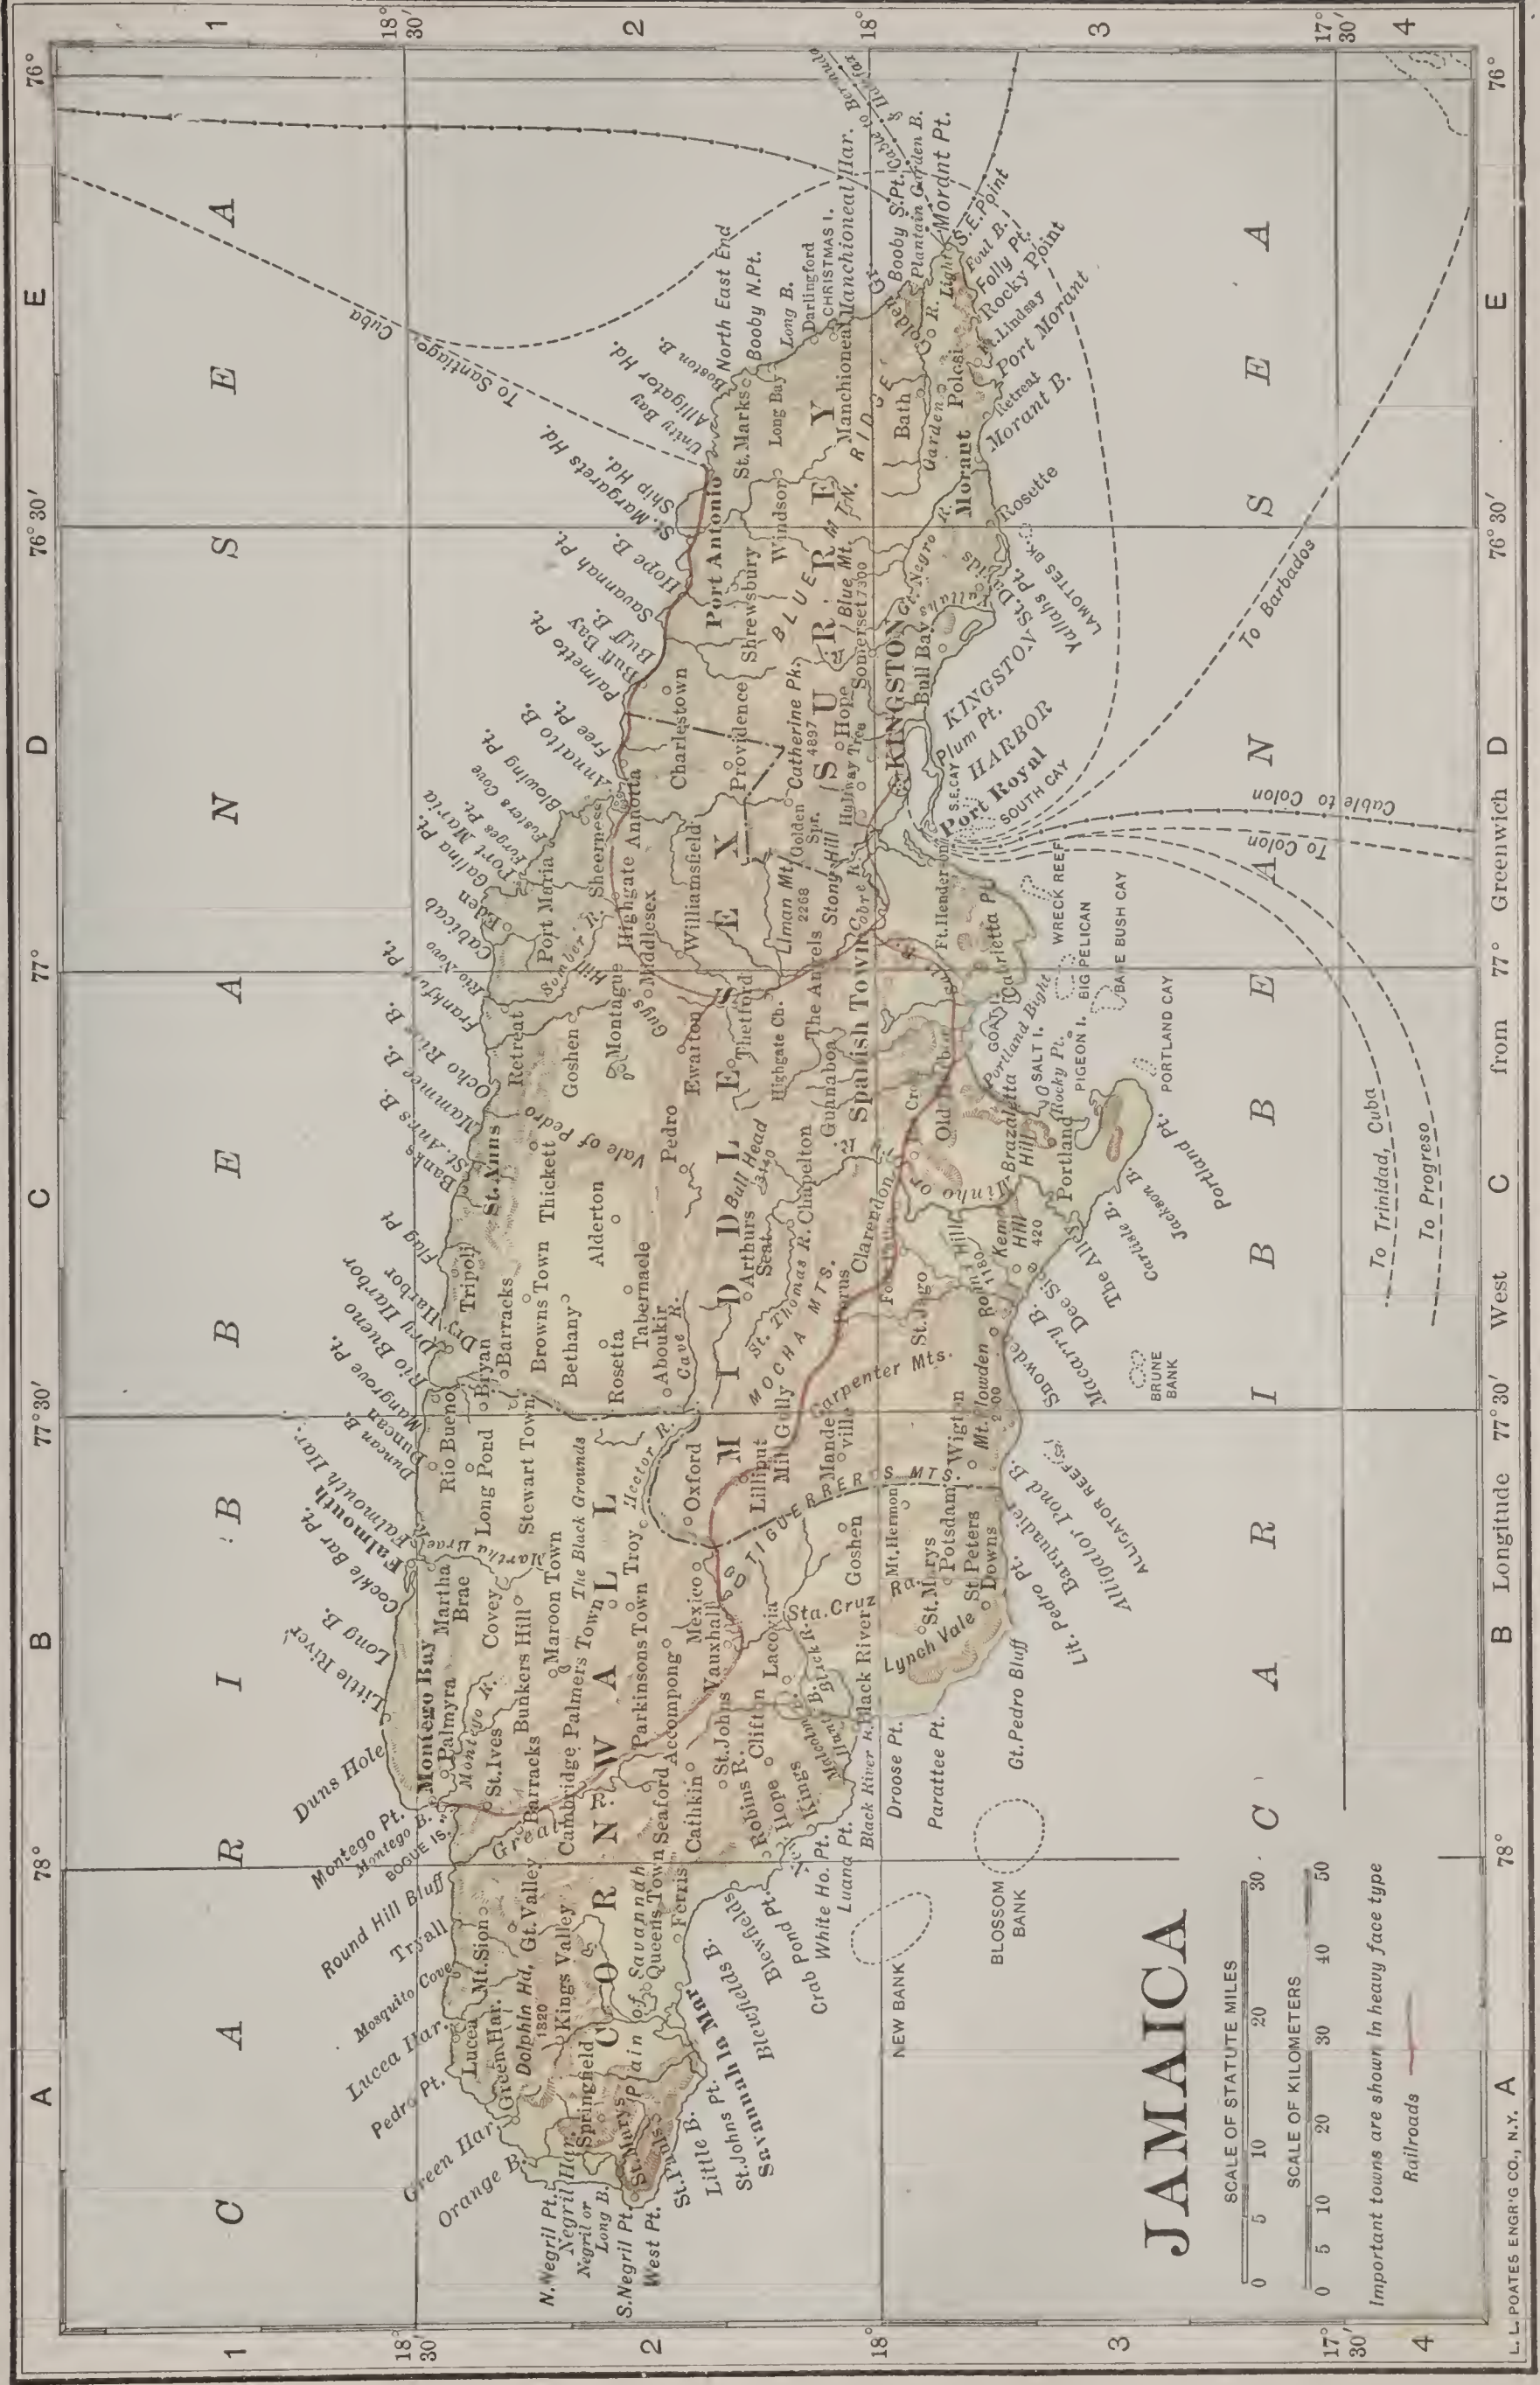

powdered jalap, two parts of bitartrate of potash, and a little ginger, it is of great service in some kinds of dropsy in consequence of its hydragogue action.

JALAPA, or **XALAPA**, há-lä'pä. The capital of the State of Vera Cruz, Mexico, situated at an elevation of 4800 feet on the slope of the extinct volcano of Cofre de Perote, 60 miles northwest of Vera Cruz (Map: Mexico, L 8). The town is surrounded by gardens and is much frequented as a health resort by the people of Vera Cruz. It is well built, with a handsome plaza and beautiful promenades in the suburbs, and has a fine cathedral, containing paintings by the Spanish masters, a Franciscan convent built in 1556, various schools, and hospitals. It has several times been the capital of the state, and prior to the advent of railways had considerable importance, being on the route connecting Mexico City with Vera Cruz. It now carries on some trade in the agricultural products of the region and has a number of small cotton and cigar factories. Pop., 1900, 20,388; 1910, 24,816.

JALISCO, or **XALISCO**, há-lē'skō. One of the states of Mexico, bounded by the Territory of Tepic and the states of Durango, Zacatecas, and Aguas Calientes on the north, Guanajuato and Michoacán on the east, Michoacán and Colima on the south, and the Pacific Ocean on the west (Map: Mexico, G 7). Area, 33,495 square miles. The narrow strip of coast land is low and well indented. The western part of the state rises towards the Sierra Madre in a series of terraced plateaus, on which are scattered a number of volcanic cones and isolated peaks, the two highest of which are the volcano Colima (12,750 feet) and the extinct Nevado (14,854 feet). The central portion is occupied by the Sierra Madre del Pacífico, which divides the state into two parts, the eastern half forming a part of the great Mexican central plateau, Anahuac (q.v.), with an elevation of over 5000 feet. Jalisco has numerous lakes, including the largest lake of Mexico, Chapala (q.v.), drained by the Río Grande de Santiago, which with its tributary, the Verde, is the chief river of the state. The climate is hot and unhealthful in the lowlands of the coast, but moderate in the interior. The soil is very fertile along the rivers and in the eastern part of the state. Corn, wheat, tobacco, cotton, sugar, and indigo are the chief agricultural products. Stock raising is also carried on extensively, and rich silver mines are worked. The chief manufactured products are coarse cotton and woolen goods, pottery, saddlery, tequila (a spirituous liquor), and products of tobacco. Pop., 1910, 1,208,855, consisting largely of Indians. The state is one of the most prosperous and wealthy of Mexico. The capital is Guadalajara (q.v.). Jalisco once formed part of the Kingdom of Nueva Galicia. Consult T. E. Smith, *Handbook of the Mineral Resources of the State of Jalisco* (Guadalajara, 1905).

JALUIT, jä'lōōt. See MARSHALL ISLANDS.

JAMAICA, jä-mā'ká. The largest of the British West Indian Islands, situated 90 miles south of Cuba and 100 miles west of Haiti, between lat. 17° 43' and 18° 32' N. and long. 76° 11' and 78° 21' W. (Map: West Indies, C 3). It is 144 miles in its greatest length and about 50 miles in its widest part. Area, about 4207 square miles. The surface rises gradually from the lowlands of the west coast

towards the mountainous regions of the central part, where some of the peaks are over 7000 feet high. The most important chain is the Blue Mountains, occupying the east end of the island and containing the highest summits. Jamaica is favored with a well-indented coast line. There are about 16 harbors, the most important being on the south coast; besides, there are numerous smaller inlets affording safe anchorage for small vessels. The rivers of the island are numerous and flow north and south, the central mountain range forming the watershed between the two systems. Most of the rivers are unnavigable on account of their turbulence and occasionally cause disastrous floods. The most important are the Plantain Garden River, the Black River, Salt River, and Cabarita. Some of the streams are utilized for irrigating the sugar and fruit plantations. The soil is composed largely of sedimentary deposits derived from the red and white limestone formations which overlie the primitive granite that forms the main structure of the island. Some volcanic rocks in the eastern part of the island and a number of hot mineral springs afford the only evidence of volcanic action.

In the general characteristics of its flora and fauna Jamaica resembles the other West Indian islands. (See WEST INDIES.) Its flora, which is remarkably rich and varied, includes Jamaica cedar, logwood, fustic, plantain, mango, bamboo, cactus, and acacia. The allspice tree (*Pimenta officinalis*) is found almost exclusively here. Venomous snakes are unknown. Bird life includes humming birds, the green tody, cuckoos, tyrant birds, parrots, and buzzards. The climate of Jamaica is, next to its remarkable vegetation, the principal attraction of the island. Although it is quite humid and warm near the coast, the higher regions enjoy a delightfully mild, dry, and equable climate, with an annual range of temperature scarcely exceeding ten degrees, and with especially salutary effect in cases of pulmonary diseases.

The chief industry is agriculture. The mountainous regions are given up largely to pasture, while the plantations are found mostly in the lowlands. Of the total area, about 2,600,000 acres are reported as capable of productivity. The cultivated area in 1911-12 was stated at 941,708 acres; in 1912-13, 922,633 acres. The latter area comprised: tilled lands, 267,276 acres; guinea grass, 152,527; common pasture, 430,064; common pasture and pimento, 72,766. Of the tilled lands, bananas occupied 81,071 acres; ground provisions and mixed crops, 99,632; sugar cane, 31,753; coffee, 22,275; coconuts, 17,377; cacao, 11,236; oranges, 1715; other crops, 2217. The cultivation of sugar has declined in recent years, and that of fruit, especially bananas, has increased. The banana output in 1912 was nearly 13,400,000 bunches, valued at £1,241,000; coffee, £274,700; cacao, £139,800; sugar, £132,800; dyewoods, £88,500; pimento, £78,400; rum, £67,100. The land is divided into small holdings, those of five acres and less numbering over 60,600 out of the total number of about 80,000; but since the resumption of East Indian immigration in 1891, the large estates have been increasing in number. The chief industrial establishments are the sugar mills, oil presses, tanneries, etc.

The trade of the colony is chiefly with the United States and the United Kingdom, Canada ranking third; the former preponderance of the

British trade has been lost in favor of the United States. Imports and exports increased from £2,014,477 and £1,543,267 respectively in the year 1903-04 to £3,050,479 and £2,709,283 in 1912. In the latter year imports from and exports to the United Kingdom were valued at £1,333,352 and £358,516; United States, £1,273,389 and £1,618,614; Canada, £291,363 and £148,943.

The chief exports are fruit, sugar, logwood extract, cacao, rum, coffee, and pimento. The proportion of sugar in the exports of the colony shows a decline from 30.6 per cent in 1879 to 5.1 in 1912; that of rum from 14.4 per cent in 1879 to 2.6 in 1912; coffee declined from 18.3 per cent to 10.7 during the same period; while fruit showed an increase from 2.9 per cent to 54.7 during the same period. The imports are composed chiefly of cotton manufactures, fish, and flour.

Jamaica is administered by a governor, assisted by a privy council, appointed by the crown, and a legislative council consisting of 10 members nominated by the governor, and 14 elected by limited suffrage, besides five ex-officio members and the governor. All financial measures must receive the approval of the governor before they are submitted to the consideration of the Legislative Council. For administrative purposes the island is divided into 15 parishes, administered by elective boards. Administratively attached to Jamaica are the Turks, Caicos, and Cayman islands, and Morant and Pedro cays. Justice is administered by a high court, circuit courts, and by resident magistrates in the parishes. The revenue and expenditure of the colony for the year 1912-13 amounted respectively to £1,432,400 and £1,549,667. A little over 30 per cent of the revenue was derived from customs duties. The public debt in 1912 was £3,843,974. The roads of the island are under the control of the government, which also owns and operates the railways. The railway extends from Kingston to Montego Bay (112.7 miles) and to Ewerton, in the other direction, by a branch from Spanish Town (17.2 miles); also to Port Antonio by a branch from Bogwalk, on the Ewerton branch (54.5 miles); and from May Pen to Chapelton (13 miles); total length open in 1914, 197.4 miles. There are numerous fortifications, and several ships of the royal navy are maintained at the North American and West India naval station.

The population of Jamaica, according to several censuses, is shown below:

YEAR	White	Colored	Black	Others	Total
1861...	13,816	81,065	346,374	441,255
1871...	13,101	100,346	392,707	506,154
1881...	14,432	109,946	444,186	12,240	580,804
1891...	14,692	121,955	488,624	14,220	639,491
1911...	15,605	163,201	630,181	*22,396	831,383

* East Indians, 17,380; Chinese, 2111; not stated, 2905.

Since 1891 there has been a considerable East Indian immigration; in 1912 the East Indians numbered 18,631, of whom 2841 were under indenture. In 1912-13 the birth rate in Jamaica was 38.8; death rate, 25.1; marriage rate, 3.7. The Maroons, the descendants of fugitive slaves, are few in number and do not mix with the other inhabitants of the island. The negroes are engaged principally in agriculture and are to

some extent peasant proprietors. The colored population is represented largely in the trades and professions, while the Chinese are chiefly shopkeepers. Education is optional and to some extent supported by the government. In 1912-13 there were 698 public elementary schools, with an enrollment of 100,179 and an average attendance of 60,900. There is no established church. Accurate religious statistics are not obtainable, but the most numerous churches are Anglican (237), Baptist (200), Wesleyan Methodist (127), and Presbyterian (82). The larger towns are Kingston (q.v.), the capital, with 57,379 inhabitants in 1911; Spanish Town, 7119; Port Antonio, 7074; Montego Bay, 6616; Savanna-la-Mar, 3400.

Jamaica was discovered by Columbus during his second voyage in May, 1494, and was taken possession of by the Spaniards in 1509. The office of governor was held by the descendants of Columbus till the extinction of the line. Under Spanish rule the native population rapidly dwindled away, and before the middle of the seventeenth century had become extinct. In May, 1655, a British expedition under Admirals Penn and Venables captured the island, and England was confirmed in the possession of it by the Treaty of Madrid in 1670. The sugar industry, which had its inception in 1673, soon developed into great importance, and the demand for plantation labor led to the importation of negro slaves. Between 1700 and 1786 more than 600,000 negroes were brought into the island. Many of them escaped to the forests of the interior, where they led a life of semibrigandage and threatened seriously the prosperity of the settlements on the coast. A fierce contest was carried on with them from 1715 to 1738, and they were not subdued completely till 1796. A negro insurrection in 1831 hastened the approach of emancipation, which had been agitated for a long time in England. In 1833 an Emancipation Act was passed, providing for the total extinction of slavery after Aug. 1, 1838, and awarding the sum of \$29,987,000 (£6,161,927) as compensation to the owners of the liberated slaves, who numbered 309,338. The effects of emancipation on the economic condition of the country were disastrous at first. The freedmen abandoned the plantations in large numbers and took possession of the unoccupied lands in the interior. Labor to take their place could be obtained only with great difficulty, and bitter feelings of hostility between whites and blacks resulted. In October, 1865, the negroes at Port Morant, in the eastern part of the island, rose in resistance to the process of the courts; martial law was declared by Governor Eyre, and the insurrection was speedily put down—with excessive cruelty, as was maintained by the negrophiles, or with commendable firmness, as was asserted by a government commission sent out to investigate the affair. As a result of the social conflicts, the old parliamentary government of Jamaica was abolished in December, 1866, and the island was reduced to the grade of a crown colony. Representative government was partially reestablished in 1884. On Jan. 15, 1907, an earthquake caused the death of over 600 persons and the destruction of much property. In November, 1912, a disastrous cyclone visited the western part of the island.

JAMAICA. The county seat of Queens Co., N. Y., comprising the fourth ward of the Borough of Queens, New York City, 10 miles by rail from the centre of Brooklyn, on the Long Island Railroad (Map: New York City, Greater New York, G 6). It is essentially a residential suburb of New York and Brooklyn and contains King's Park, the City Training School, and many fine homes. There are also a number of carriage factories. Jamaica was settled by the Dutch as early as 1656, and several pre-Revolutionary structures still stand.

JAMAICA BARK. See EXOSTEMMA.

JAMAICA BULLACE PLUM. A West Indian fruit. See MELICOCCA.

JAMAICA KINO. A West Indian fruit. See SEASIDE GRAPE.

JAMAICA SORREL. See HIBISCUS.

JAMAK. See JANIZARIES.

JAMALTESA, hä'mäl-tä'sä, or **ESPINTO**, ä-spën'tō. The locality of a group of ruins, situated 20 miles north of Comayagua in Honduras. They exhibit a series of mounds whose summits are reached by flights of steps, above which are remains of considerable edifices. The largest of these mounds stands in the centre of a broad terrace, and the smaller ones are arranged at regular distances from it. Excavations in the surrounding country have brought to light many ancient vases and pieces of sculpture, which indicate, in the excellence of their workmanship, the existence of a high standard of art and marked ability.

JAMBLICHUS. See IAMBlichus.

JAMBOLI. See YAMBOLI.

JAMBRES. See JANNES.

JAMBUDVIPA, jām'bu-dwē'pā (Skt. *jambudvīpa*, rose-apple tree island). In the Mahabharata, the first of the seven dvipas, or continents, into which the world is divided. It is surrounded by seven oceans and contains the dwelling place of the gods, the mountain of Meru, on which grows a great rose-apple tree, which gives the continent its name. Of the nine countries into which it is divided by mountain ranges, Bharata, or India, is the most important and in poetry and Buddhistic works bears the name of the whole continent.

JAMES (Lat. *Jacobus*, Gk. Ἰάκωβος, *Iakōbos*, Heb. *Ya'āqōbh*). The name given certainly to three and probably to four men in the New Testament. Two of them—James, the son of Zebedee, and James, the son of Alphæus—were members of the Twelve (Mark iii. 17, 18). A third was a brother of the Lord (Gal. i. 19). The fourth, according to Luke (vi. 16; Acts i. 13),

was father of one of the Twelve, Judas by name (not Iscariot, John xiv. 22). 1. JAMES, THE SON OF ZEBEDEE, is named only in the Synoptic Gospels and Acts, but is alluded to in the appendix to John (xxi. 2). He was a Galilean fisherman, living in and probably a native of Capernaum, who, with his younger brother John, was called by Jesus to forsake his work and become a fisher of men (Mark i. 16 et seq.), a call which elicited a ready response. His mother's name was Salome, probably a sister of Mary, the mother of Jesus. He was one of the three intimate companions of Jesus in the apostolic circle (Mark i. 29; v. 37; ix. 2; xiii. 3; xiv. 3). This intimacy with Jesus doubtless emboldened Salome to make for him and his brother the ambitious request narrated in Mark x. 35-40. Jesus called James and his brother *Boanerges* (Mark iii. 17, sons of thunder, or noise, tumult), a characterization quite in keeping with the anecdotes related by Luke (ix. 54) and Mark (x. 35 et seq.). He was put to death by Herod in 44 A.D. (Acts xii. 21). (See *BOANERGES*.) According to legend, he preached in Spain, and after his death his body was carried thither and buried there. During the inroads of the Saracens he appeared in shining armor and terrified the Moslem hosts. As St. Iago (Santiago), he became the patron saint of Spain. 2. JAMES, THE SON OF ALPHÆUS, was so named by the Evangelists to distinguish him from James, the son of Zebedee. He holds the first place in the third group of four in all the lists of the Twelve. Beyond this fact we have no definite information, for his name is not certainly mentioned elsewhere in the New Testament. It is possible from Mark ii. 14 that he was a brother of Levi (or Matthew), who is there called son of Alphæus. If the Clopas of John xix. 25 be taken as a translation of Alphæus, then the Mary of Mark xv. 40 may have been the wife of Alphæus, and James the Less and the James mentioned in Mark xvi. 1, Luke xxiv. 10, and Matt. xxvii. 56 this other member of the apostolic circle. 3. JAMES, THE BROTHER OF THE LORD. The facts which are explicitly stated concerning him, or which may be inferred from the statements made, are as follows: According to Paul (1 Cor. xv. 7), he saw the risen Lord; was in Jerusalem three years after Paul's conversion (Gal. i. 19, where he is called the brother of the Lord to distinguish him from the son of Zebedee); was (with Peter and John) a leader in the Church at Jerusalem when Paul, 14 years later, went up thither (Gal. ii. 1-10, where he is called simply James, for the son of Zebedee had already been put to death); was a married man (1 Cor. ix. 5). According to the Book of Acts, he was a believer (i. 14); a leading spirit in the Church at Jerusalem before (xii. 17), at (xv. 13), and after (xxi. 18) the council at Jerusalem. According to the Gospels, he was a brother of Jesus (Mark vi. 3); did not believe in the Lord during His earthly life (John vii. 5); agreed with the family of Jesus in regarding the Lord as demented and came with them to take Him away from His active work (Mark iii. 21). Josephus records his death at the instigation of the Sanhedrin (c.62-63 A.D.). Tradition names him the Just and ascribes to him the homily, in the style of the Wisdom literature, generally known as the Epistle of James (q.v.). Some scholars hold that James was not a son of Joseph and Mary, but a son of Joseph by a former wife; others that this James is the

same as James the Less, a son of Mary and Alphæus (= Clopas), and that the Mary here referred to was a sister of Mary, the mother of Jesus, i.e., that James was a cousin of the Lord. (See *BRETHREN OF THE LORD, THE*.) 4. Of the fourth James nothing is known beyond the fact that he was not the brother of Judas, the Apostle, as stated in the Authorized Version, on the authority of the Latin text of Beza, where the Apostle Judas is confused with the Judas mentioned in the Epistle of Jude, ver. 1, as the brother of James. See *JUDAS, THE LORD'S BROTHER*.

JAMES, Sp. **JAYME**, or **JAÍME**, *hī'mā*, **I**, called **THE CONQUEROR** (1208-76). King of Aragon from 1213 to 1276, son and successor of Pedro II. He was born at Montpellier. On the death of his father (1213), Simon de Montfort, who had charge of James, endeavored to use this position for his own advantage; but the Pope forced him to surrender the boy. James won the surname of *El Conquistador* by wresting the Balearic Islands in 1228-32, by capturing Valencia in 1238 from the Moors, and by achieving other successes over them in Murcia during the last 20 years of his life, in behalf of his son-in-law, Alphonso the Wise of Castile. His possessions were divided between his two legitimate sons by Yolande of Hungary. He wrote his own life in Spanish; there is an English translation by Forster, *The Chronicle of James I, Written by Himself* (London, 1883). Consult also F. D. Swift, *The Life and Times of James I, the Conqueror, King of Aragon* (Oxford, 1894), and Francesch Carreras y Candi, "Espases maravellozes en lo regnat de Jaume lo Conqueridor," in *Revue Hispanique*, vol. xv (Paris, 1906).

JAMES, JAYME, or **JAÍME II**, called **THE JUST** (c.1260-1327). King of Aragon from 1291 to 1327, second son of Pedro III. He succeeded his father in Sicily in 1285. When he succeeded his brother, Alfonso III, in Aragon in 1291, he resigned his claim to Sicily and received in its stead Sardinia. In 1319 he promulgated a constitution by which Aragon, Catalonia, and Valencia were to be under the same laws. So much was he trusted by the people that his royal power was less limited than that of his predecessors, and in 1307 he annulled the decree requiring an annual meeting of the Cortes and replaced it by a biennial act under which the King could name the place of meeting. See *ARAGON*.

JAMES I OF ENGLAND AND VI OF SCOTLAND (1566-1625). He was the son of Mary, Queen of Scots, and her cousin and second husband, Henry Stuart, Lord Darnley, and was born in Edinburgh Castle June 19, 1566. The following year his mother was forced to abdicate, and he became King. There were several regents during the minority, the best of whom was the Earl of Morton, whose fall was brought about by the influence of the Duke of Lennox and that of the Earl of Arran in 1581. Meanwhile James was receiving a thorough scholastic training, especially in Latin and theology, his most famous teacher being George Buchanan. After the fall of Morton there was a series of conspiracies, a French and an English faction each seeking to control the young King. In 1582 James was seized by the Earl of Gowrie and his allies, who were adherents of England. In 1583 James escaped and joined the party hostile to the Presbyterian clergy, but after some minor difficulties

an alliance with Elizabeth of England was signed in 1586. This treaty brought about a complete breach between James and his mother, whom, indeed, he had not seen since infancy. She now disinherited him in favor of Philip II of Spain, who was planning the conquest of England in the interest of Catholicism. But in 1587 she was executed in England, after James had interceded for her with Elizabeth in a half-hearted way. James's marriage to Anne of Denmark, in 1589, brought him into closer relations with the Protestants; but the King, as in everything else, cautious also in his foreign policy, maintained at the same time friendly relations with the Roman Catholic powers. In Scotland itself James had considerable trouble both with the Presbyterian clergy and the great Catholic nobles. There were several conspiracies against him, among which may be mentioned the Gowrie Conspiracy (q.v.) in 1600.

In 1603 James succeeded to the English throne as a descendant of Margaret Tudor, daughter of Henry VII, and one great object of his policy was thereby obtained. James was in favor of peace with Spain, and so he at once dismissed Sir Walter Raleigh (q.v.) from the Council and imprisoned him. He continued Robert Cecil (q.v.), the Minister of Elizabeth, in power, and as a result the old fines continued to be imposed on the Catholics, and the difficulties with them resulted in 1605 in the Gunpowder Plot (q.v.). Moreover, the Puritans also caused trouble. James finally consented to meet their representatives; but the result was unfavorable to the Puritans, on account of the similarity of their doctrines to those of the Presbyterians, with whom James had had so much trouble in Scotland. (See HAMPTON COURT CONFERENCE.) In foreign affairs James broke with the policy of Elizabeth, deserted the Dutch, signed (1604) a treaty with Spain, and began to seek a marriage alliance for his son with its royal house. At home James provoked national prejudices by seeking to bring about the political union of England and Scotland. Though he was unsuccessful in this, he obtained a judicial decision in 1608 whereby Scotchmen born after James's accession to the English throne, the so-called "post-nati," were subjects of the King of England. James believed himself independent of all control, but in reality was continually ruled by favorites. In 1607 a Scotchman named Robert Carr (q.v.) obtained control over James, and in 1616 he gave way to another favorite, George Villiers (q.v.).

With the outbreak of the religious wars in Germany, foreign affairs became all-absorbent. In the Cleves-Jülich troubles in 1609 James had allied himself for a short time with the Dutch, and in 1613 his daughter, Elizabeth, had married the Elector Palatine, the head of the Protestant Union of Germany. In 1617, however, James vigorously reopened negotiations for a Spanish marriage, and as a result the election of his son-in-law, the Elector Palatine, as King Frederick V of Bohemia in 1619, which marked the outbreak of the Thirty Years' War, was extremely annoying to him. The English nation desired to aid Frederick, but James refused to support the Protestants on the Continent. When the fortune of war went against Frederick, grave discontent broke out in England; and James, now that it was too late, sent some slight assistance. Meanwhile the negotiations with Spain went on. In 1623 Charles, who was Prince of

Wales since the death of Prince Henry in 1619, together with Villiers, created in 1624 Duke of Buckingham, went to Spain to prosecute the suit. Buckingham, however, quarreled with the leading men of the Spanish court, the negotiations resulted in a war with Spain, and a marriage alliance was signed instead with France. James died on March 27, 1625. James was known as one of the best scholars of his time, though in him scholarship often assumed the form of ridiculous pedantry. The Authorized Version of the Bible was completed between 1604 and 1611, and the work was encouraged by the King. His vacillating policy and complete subserviency to the will of his favorites caused him to be regarded with contempt, and he was pithily described by the great French statesman Sully as the "wisest fool in Christendom." He believed fully in the divine right of kings and desired an absolute monarchy, but did not know how to manage his parliaments and was compelled to dissolve them on several occasions. Moreover, the House of Commons impeached his ministers, a notable case being that of his great Chancellor, Francis Bacon (q.v.). In Scotland the reign of James was fairly successful, for he understood the temper and spirit of that country better than that of England. The reign of James is also notable for the beginning of permanent English colonization in America and some unsuccessful expeditions, as that of Sir Walter Raleigh to the mouth of the Orinoco in 1616. See *History*, under UNITED STATES.

JAMES II OF ENGLAND AND VII OF SCOTLAND (1633-1701). The son of Charles I and Henrietta Maria, he was born Oct. 14, 1633. While a mere infant, he was created Duke of York and Albany. In 1646 he was surrendered along with his father to the Parliamentary authorities, who held him in custody till he managed to escape to Holland in 1648. He served in several campaigns under Turenne; but as the treaty between Cromwell and Louis XIV provided for the removal of the English royal family from France, James entered the military service of Spain. Appointed Lord High Admiral of England at the Restoration, he twice commanded the English fleet in the ensuing wars with Holland. Although he showed some ability in this office, his weak, inconsistent character stood in the way of much-needed naval reform. On the death of his wife Anne—daughter of Sir Edward Hyde—as an avowed Catholic, he declared himself a convert to her faith. The Test Act of 1673 accordingly compelled him to resign his office. His marriage in this year with Mary

Beatrice, sister of the Duke of Modena, led him to favor close connection with Louis XIV. When great irritation against the Roman Catholics arose in England on the publication of Titus Oates's supposed discoveries, the Duke of York retired for a short time to Holland. The bill for his exclusion from the throne was twice read before the House of Commons and prevented from passing only by the prorogation of Parliament, May 26, 1679. In 1680 the Exclusion Bill passed the House of Commons, but was rejected by the Lords. On his return from abroad, and while this bill was before Parliament, the Duke was sent to govern Scotland. But when Charles II died (Feb. 6, 1685), James succeeded to the crown without opposition. At the beginning of his reign he incurred the hostility of Parliament by favoring Catholics, but, like his brother, Charles II, sought to become somewhat independent of Parliament by allowing himself to be a pensioner of Louis XIV. In Passion Week, 1685, the rites of the Church of Rome were openly celebrated at Westminster with full splendor. In the same year the suppression of the Duke of Monmouth's rebellion in England, and that of the Earl of Argyll in Scotland, was followed by great severities. On the western circuit alone, well known as the Bloody Assize, presided over by the infamous Jeffreys, 320 persons were hanged. When Parliament met (November 9) James requested extra supplies to maintain a standing army; but after a stormy debate he was refused. To aid his endeavors in favor of the Roman Catholics, he resolved to conciliate the Puritans, much as he hated them. On April 4, 1687, appeared the memorable Declaration of Indulgence, in which he announced his intention of protecting dissenters in the free exercise of their religion; and the nation beheld the extraordinary spectacle of the house of Stuart leagued with republican and regicide sects against the old Cavaliers of England. The attempt to conciliate the Puritans, however, was unsuccessful; and in March, 1687, it began to be evident that the war between King and church must soon reach a climax. At that time, a vacancy having occurred in the presidency of Magdalen College, Oxford, a royal letter recommended Anthony Farmer, a Roman Catholic, to the vacant place. For Farmer was afterward substituted Parker, a Bishop of Oxford, who, in addition to other legal disqualifications, was known to be a Roman Catholic, though not avowed. To place him in the office the King resorted to military force. On April 27, 1688, James published a second Declaration of Indulgence, which he ordered to be read in all the churches in the Kingdom. The clergy generally disobeyed, and seven of the bishops, for venturing on a written remonstrance, were committed to the Tower on a charge of seditious libel. On June 10 of the same year James's luckless son, known in history as the Pretender, was born. The certainty that the young heir to the throne would be trained in the Roman Catholic faith determined the country to be rid of the King. Public sentiment compelled the court to acquit the seven bishops, June 30, 1688. That very night an invitation was dispatched to William, Prince of Orange, signed by seven of the leading English politicians, to bring an army into England for the restoration of liberty and for the support of Protestantism. On November 5 William landed at Torbay with 14,000 men. James found himself deserted by the nobility,

gentry, and army; even his own children turned against him. He retired to France, where he was hospitably received by Louis XIV, who settled a revenue upon him. Early in March of the following year he made a hopeless attempt to regain his throne by invading Ireland with a small army, with which he had been furnished by the King of France. He waged war on the island for more than a year, but was finally defeated at the battle of the Boyne, July, 1690. Returning to France, he continued to reside at Saint-Germain till his death, Sept. 6, 1701. During the greater part of his life he was as licentious as others of his rank, but in his last years of retirement he became a religious ascetic.

JAMES I (1394-1437). King of Scotland from 1406 to 1437. He was the third son of Robert III and in 1402 became heir to the throne on the death of his elder brother, the Duke of Rothesay, supposed to have been murdered at the instigation of his uncle, the Duke of Albany. In 1404 or 1406, while on his way to France, the vessel in which he embarked was taken by the English, and James was carried to London and sent to the Tower. He was well treated, but held a prisoner for 18 or 19 years. In 1420 he accompanied Henry V in his expedition to France. On the death of Robert III, in 1406, the government devolved on the Duke of Albany, and on his death, in 1420, his son Murdoch succeeded to the regency. In 1424, James was allowed to return to Scotland on giving hostages for the payment of his ransom, which had been fixed at 60,000 marks (£40,000), but 10,000 marks were deducted because previous to leaving England he married Jane, daughter of the Earl of Somerset, a son of John of Gaunt. To the excellent education which he had received in England James probably was indebted for the development of his very considerable powers of mind. He was the author of *Kingis Quair* (i.e., the King's quire or book), which shows him to have been possessed of high poetic talent. *Christ's Kirk on the Green* and other poems have been attributed to him, but the authorship is disputed. With the acts of his first Parliament, in 1424, the regular series of Scottish

statutes begins. Many excellent laws were passed for the regulation of trade and for the internal economy of the Kingdom, while these were followed up by an executive vigor which Scotland had never known before. No sooner did James feel himself firmly seated on the throne than he resolved to execute vengeance on the Albany family. By a Parliament held at Perth in 1425, the late Regent Murdoch, the Earl of Lennox, and other nobles of their family were found guilty of certain crimes laid to their charge, and four of them were beheaded. The next few years of James's reign are among the most really peaceful in the history of Scotland previous to the union of its crown with that of England; the efforts of the King being entirely directed to the repression of the internal disorders of the Kingdom, especially of the Highlands, where scarcely any law except that of the strongest had hitherto been known. In 1436 James's eldest daughter, Margaret, was married to the Dauphin of France, afterward Louis XI. Among those whom the severe policy of the King had offended was Sir Robert Graham, who had been banished in 1435 and had suffered the loss of his estate. On Feb. 20, 1437, at Perth, the royal chamber was invaded by a band of armed men headed by Graham, and the King was dragged from his hiding place and put to death. James was unquestionably the most able of the Stuart family. Both his intellectual and his practical abilities were of a very high order. His works have been edited by Skeat for the Scottish Text Society (Edinburgh, 1884). Consult Andrew Lang, *History of Scotland from the Roman Occupation*, vol. i (New York, 1900).

JAMES II (1430-60). King of Scotland from 1437 to 1460. He was the son of James I and was crowned at Holyrood in the seventh year of his age. Sir William Crichton, the Chancellor, and Sir Alexander Livingstone competed to get possession of the person of the young King and consequently to wield the royal authority. The power of the house of Douglas was so great as almost to overshadow that of the crown. In the hope of curbing it Crichton had treacherously caused William, the young Earl of Douglas, and his brother to be put to death. The policy of the act proved to be as bad as its spirit, for by the marriage of the heiress of the murdered youth with her cousin the family was restored to more than its former power. The young King, weary of the rule of Crichton, put himself under the control of another Earl of Douglas. Under the rule of the Earl the Kingdom fell into complete anarchy and became a scene of violence and disorder. In 1449 James married Mary of Gelderland and began his real rule. Like most of the Stuarts, he possessed great animal courage; he seems also to have possessed much of his father's clearness of perception in framing laws and of his energy in enforcing their observation. Chafing at the power of Douglas, James treacherously murdered him in Stirling Castle (1452), and Douglas's brother, after a vain resistance, fled. In 1460 James infringed an existing truce with England by laying siege to the castle of Roxburgh, then in the hands of the English. On August 3 he was killed by the bursting of a cannon. Consult Andrew Lang, *History of Scotland from the Roman Occupation*, vol. i (New York, 1900).

JAMES III (1451-88). King of Scotland from 1460 to 1488. He was the son of James II

and Mary of Gelderland. On the death of his father the government appears to have been conducted by his mother, who was under the influence of Archbishop Kennedy. On the death of the latter, in 1466, the young King fell under the control of Lord Boyd and his family. In 1467 they had acquired influence so great that James gave his sister in marriage to Sir Thomas Boyd, son of Lord Robert, Sir Thomas being at the same time created Earl of Arran. Before the King's marriage, however, in 1469, with Margaret of Denmark, power changed hands; Lord Boyd was obliged to flee, and even Arran was driven into exile. Soon after this James seems to have fallen under the influence of favorites. Conspicuous among these was a man named Cochrane, an architect. Through his wiles the Duke of Albany, brother of James, was forced to flee from the Kingdom, having been charged with witchcraft; while the Earl of Mar, also a brother of the King, was imprisoned on the same accusation and probably put to death. The banished Duke of Albany raised an army and invaded Scotland in 1482; a short-lived peace followed, and Albany died in exile in 1485. In 1487 Margaret of Denmark died. James's love of pursuits which for the age in which he lived were intellectual brought upon him the contempt of a warlike and barbarous nobility, on which the weakness of his moral character imposed no check. A conspiracy, the origin of which is obscure, ended in a rebellion having for its avowed object the dethronement of the King. Many of the peers, however, remained loyal, so that James was enabled to put himself at the head of a considerable force. But, mainly through the cowardice of the King, the royal army was defeated at Sauchieburn, June 11, 1488. James escaped from the field, but he was afterward discovered by one of the rebels and murdered. Boece's *Chronicle* is the fullest account. Consult Andrew Lang, *History of Scotland from the Roman Occupation*, vol. i (New York, 1900).

JAMES IV (1473-1513). King of Scotland from 1488 to 1513. The son of James III and Margaret of Denmark, he was born March 17, 1473. He was made the nominal leader of the rebel army by which his father was slain, and although but a youth at his accession he took from the first an active part in public affairs and aided personally in suppressing the rebellion headed by the Earl of Lennox. He won great popularity by his interest in the common people, and throughout his reign he labored to develop commerce and to build up a navy. In 1503 he married Margaret, daughter of Henry VII of England, and made a treaty with his father-in-law which secured peace between the two countries for a few years. Meantime James was passing laws for the better administration of criminal justice, for the annual election of magistrates, for confirming the privileges of the burghs, for the discouragement of beggars, and for the daily session of the council at Edinburgh. This city was now becoming the capital of the Kingdom. Not only is his reign important in the history of Scottish law, but he showed skillful diplomacy in securing friendly relations with the continental powers. From the accession of Henry VIII, however, trouble again arose between England and Scotland. In 1513 the English Parliament declared war against both Scotland and France. The Scottish King, who had long been making preparations, marched

with a large, well-equipped army to meet Surrey, the English commander, at Flodden. It was a "black day" for Scotland; she lost perhaps 10,000 men, a great number of nobles, and her King, who fell fighting in the ranks (Sept. 9, 1513). Though great in the history of Scottish civilization, he was an incompetent general, and the defeat was due chiefly to him. Not till after her union with England did his country recover from the loss. His fickle wavering between France and England also caused Scotland much trouble. James V, his only legitimate child, succeeded him. Consult: *Treasurer's Accounts, Exchequer Rolls, and Acts of Parliament* of his reign; Teulet, *Papiers d'état, pièces et documents inédits ou peu connus, relatifs à l'histoire de l'Ecosse au XVIème siècle, tirés des bibliothèques et des archives de France* (Paris, 1851-60); J. H. Burton, *History of Scotland* (8 vols., London, 1873); Brown, *History of Scotland*, vol. i (Cambridge, 1899); Andrew Lang, *History of Scotland from the Roman Occupation* (4 vols., New York, 1900-07).

JAMES V (1512-42). King of Scotland from 1513 to 1542. The son of James IV and Margaret of England, he was born April 10, 1512. The period of his long minority is one of the gloomiest in Scottish history. Such was the lawless state of the country that it was impossible to travel safely except in armed companies. The Duke of Albany, representing the interests of France, was chosen Regent by Parliament, but his government was almost powerless, owing chiefly to the jealousy and enmity of the Earl of Angus, who was friendly to England and had married the Queen mother. Ultimately Angus prevailed, and the Duke retired to France. For a while the Angus branch of the Douglas family ruled Scotland in the same manner as the elder branch had ruled it in the beginning of the reign of James II. In his seventeenth year the King, resolving no longer to brook the authority of the Earl, escaped from his custody. Angus and his family were banished, and their estates declared forfeited. In 1536 James visited the court of France, and next year married Madeleine, daughter of Francis I. She lived but a few weeks. Soon after her death the King married Mary of Lorraine, daughter of the Duke of Guise. Henry VIII, after declaring his independence of the Pope, wished his nephew to support him in the movement; but James remained true to his ancestral faith and strengthened the laws against heresy. Far from coming to an agreement on the subject of religion, the two Kings went to war against each other. In 1542 the English, while making an incursion across the border, were attacked and defeated with great loss by the Earl of Huntly and Home. To avenge this disaster, Henry sent the Duke of Norfolk into Scotland with an army of 20,000 men, who, however, retired on the approach of James with a superior force. The Scottish King desired thereupon to invade England, but the nobles would not follow him. There had long been strife between the crown and the nobility, but the breach was widening with the progress of the Reformation; for while the Lords adopted the new ideas, the King clung to the Church. He antagonized the nobles further by championing the Commons against them. Finally, Lord Maxwell and a few other western nobles consented to lead an army of 10,000 men across the border, but they were enraged at seeing Sin-

clair, the King's favorite, set over them as commander. In the disorder which followed this appointment the army was disgracefully beaten by a few hundred Englishmen. This dishonor to his arms seems to have broken the heart of James and to have affected his mind. He shut himself up in Falkland Palace, where he died, Dec. 14, 1542, a few days after the birth of his unfortunate daughter Mary. He was a protector of the poor and an excellent administrator, who made his power felt for good throughout Scotland; at the same time he was avaricious and licentious and unable to bear up against misfortune. Consult the bibliography for the preceding subject, and, in addition, for relations with the Pope: Theiner, *Vetera Monumenta Hibernorum et Scotorum Historiam Illustrantia, 1216-1547* (Rome, 1864); J. A. Froude, *History of England* (12 vols., New York, 1874).

JAMES VI OF SCOTLAND. See JAMES I OF ENGLAND AND VI OF SCOTLAND.

JAMES VII OF SCOTLAND. See JAMES II OF ENGLAND AND VII OF SCOTLAND.

JAMES, CHARLES (?-1821). An English soldier and author. He is remembered chiefly for his eyewitness account of the opening scenes of the French Revolution published under the title *Audi Alteram Partem* (1793), wherein he extenuates the conduct of the revolutionists. His other writings diverge widely, from *Petrarch to Laura: A Poetical Epistle* (1787) and *Poems* (2 vols., 1789) to *Hints Founded on Facts, or a View of our Several Military Establishments* (1791) and several other publications on military subjects.

JAMES, DANIEL WILLIS (1832-1907). An American merchant and philanthropist, born in Liverpool, England. In his youth he entered the employ of Phelps, Dodge & Co. in New York City. He became chiefly known for his benefactions, although he gave without ostentation and often anonymously. To Union Theological Seminary he gave \$1,000,000 for the erection of new buildings on Morningside Heights in New York City, and during his lifetime he gave large sums also to Amherst and Oberlin colleges, Hartford Theological Seminary, Columbia University, and the Cathedral of St. John the Divine. By his will he left legacies of \$100,000 each to Union Theological Seminary, Columbia and Yale universities, Amherst College, Cooper Union, the Children's Aid Society of New York, the American Board of Commissioners for Foreign Missions, Hampton Institute, the Cathedral of St. John the Divine, and the Presbyterian Hospital of New York. He presented to the town of Madison, N. J., a public park, a library, and an assembly hall.

JAMES, EDMUND JANES (1855-). An American political economist and university president, born at Jacksonville, Ill. He was educated at Northwestern and Harvard universities and at Halle, where he received the degrees of A.M. and Ph.D. in 1877. For several years he was principal of high schools at Evanston and Normal, Ill. From 1883 to 1895 he was professor of public finance and administration in the Wharton School of Finance and Economy, University of Pennsylvania, at the same time holding the chair of political and social science in the university. For five years (1896-1901) he was professor of public administration and director of the extension division at the University of Chicago. In 1902 he became president of Northwestern University, and in 1904 president

of the University of Illinois. He served as president of the American Economic Association; was a founder, and from 1889 to 1901 president, of the American Academy of Political and Social Science (editor of its *Annals*, 1890-95; associate editor, 1895-98); and from 1891 to 1895 was president of the American Society for the Extension of University Teaching. Among his writings are: *Outline of a Proposed School of Political and Social Science* (1885); *Relation of the Modern Municipality to the Gas Supply* (1886); *The Legal Tender Decisions* (1887); *The Federal Constitution of Germany* (1890); *The Federal Constitution of Switzerland* (1890); *The Education of Business Men in Europe* (1899); *Growth of Great Cities* (1900); *Government of a Typical German City—Halle* (1900); also a large number of papers in transactions of societies. While at the University of Pennsylvania, he edited its Political Economy and Public Law Series of Publications (1886-95).

JAMES, EPISTLE OF. The first of the so-called catholic Epistles of the New Testament. After the signature, address, and greeting (i. 1), the writer at once exhorts his readers to a proper endurance of "trials" (Gk. *πειρασμοί*, testings) and to a proper attitude towards "temptations" (same Gk. word), noting that the latter are not sent of God, but arise from human inclinations (i. 2-18). Next he points out that not only hearing, but doing the word is necessary (i. 19-27), after which comes a trenchant rebuke of the tendency to curry the favor of the rich and neglect the poor (ii. 1-13). This leads to a discussion of the relation between faith (i.e., formal assent to religious truth) and works, showing that faith must exhibit itself in deeds (ii. 14-25). Those eager to become teachers are reminded that it is in word or speech that one is most liable to fail or offend, and the tongue needs strong curbing (iii. 1-12). True wisdom shows itself in good conduct, especially peaceableness (iii. 13-18). He next admonishes against strife and quarrelsomeness (iv. 1-10), against backbiting and judging (iv. 11-12), to proper recognition of Providence (iv. 13-17), that the haughty rich be more considerate of the poor (v. 1-6), to patient waiting and endurance until the reward comes at the Parousia (v. 7-11), against swearing (v. 12), and finally to prayer and labor for the conversion of others (v. 13-20).

This epistle, or homily, is either one of the very earliest or one of the latest of the New Testament writings, and the solution of the problem of its date rests upon the determination of three questions, each of them interesting in itself, and all of them subject to debate among scholars to-day. 1. Is the writer of the Epistle the well-known James, the brother of the Lord, the head of the Jerusalem Church, or an unknown James of postapostolic times? 2. Were the recipients of the letter distinctively Jewish Christians, or Christians generally, Gentile as well as Jewish? 3. Does the situation of the readers betray the primitive condition of the Church before the Judaizing controversy of Acts xv, or the developed condition of the Church after that controversy had been forgotten? As to the first question, it would seem that the naïve way in which the author describes himself ("James, a servant of God and of the Lord Jesus Christ," i. 1) could be better understood of one who, like the Jerusalem

James, was conscious of his recognized authority in the Church (cf. Gal. ii. 9, 12; Acts xv. 13; xxi. 18), and so needed no further titles to commend himself to those to whom he wrote, than of an unknown James who, if he followed the custom of the second century, must have made his message depend upon such titles as he could either honestly or falsely assume. There is naturally the query whether we can suppose the culture evident in the language and diction of the Epistle possible in the case of a Palestinian Jew, as the brother of the Lord must have been; but conclusions here are wholly conjectural and must yield to more definite indications furnished by other points. As to the second question, the wording of the address ("James . . . to the twelve tribes which are of the Dispersion, greeting," i. 1) makes apparently clear the distinctively Jewish character of the readers—an impression which seems to be confirmed by several hints throughout the letter (e.g., ii. 2, 19, 21; v. 4, 11, 17, 18). At the same time we cannot ignore the fact that terms similar to the address are used symbolically, both by Paul (Gal. vi. 16; Phil. iii. 3) and by Peter (1 Pet. i. 1; ii. 9); while the phrases referred to in the body of the letter might be possible with a Gentile readership (cf. Rom. iv. 1, ix. 29; 1 Cor. viii. 6). The third question is really the decisive one; since, if the situation shows itself necessarily that of primitive Christianity, the readers must be considered distinctively Jewish Christian, and the author becomes almost necessarily the Jerusalem James; while, if the situation is that of postapostolic Christianity, the readers cannot be exclusively Jewish, since a group of such churches in the Diaspora is scarcely supposable so long after Gentilism had become part of Christendom. Much less, on the supposition of such a later date, can the author have been the Jerusalem James.

The situation disclosed by the Epistle, however, is clearly that of early Christianity, while the Church was yet almost exclusively Jewish, and before the introduction of Gentiles into its membership had brought about the Judaistic controversy, considered in the Jerusalem Council (Acts xv) and discussed by Paul specifically in his Galatian Epistle. This is shown (1) not so much by the social customs of ii. 1-9 and community conditions of v. 1-6, the commercial life of iv. 13, the term given to their religious assemblies in ii. 2, and the oath formula described in v. 12, all of which indeed disclose a definite situation belonging to the readers that cannot be naturally understood save as Jewish; but rather (2) by the fact that there is such an absence of all reference to Gentile and Jewish differences in the Church as has its only legitimate explanation in the fact that the gospel had not yet been carried outside of Jewish circles to such an extent as to raise the questions which constituted the controversy of Acts xv; and, specifically, (3) by the fact that not only is the faith and works discussion of ii. 14-25 not a polemic against Paul, but it is not even a sympathetic explanation of his position. It belongs distinctively to a period previous to the Pauline propaganda, as is clear from the fact that the idea of "justification" which it embodies is specifically the Old Testament idea of the justification of the just, not the Pauline idea of the justification of the sinner; while its idea of "faith" is distinctively the idea seen in the Old Testament of intellectual belief in

monotheism, not the Pauline idea of spiritual trust in Jesus Christ. Against this uniquely Jewish conception of things it is of little moment to emphasize the moral degeneracy of the times supposed in the Epistle as impossible in the early years of Christianity. As such degeneracy was actual in Judaism itself (cf. Rom. ii. 17-29), the question is simply one of the possibility of the reaction of Jewish Christianity into its previous condition, and it is altogether too bold a claim to make that the 17 years between Pentecost and the Jerusalem Council were too short a period for this. 4. The absence of the conventional Christian terminology common to the Christian writings of the latter part of the first and the early part of the second centuries is also decisively in favor of an early date for this Epistle. The Epistle is, therefore, to be dated some time before 50 A.D., from somewhere in Palestine—most likely Jerusalem, by James, the head of the mother Church. It was addressed as an encyclical letter to the near-by Jewish Christian communities—probably those in the Syrian regions to the north, which were quite likely those first evangelized after the Stephen persecution (cf. Acts viii. 1, 4, 40; ix. 1, 2, 19-25; xi. 19). Its purpose was to encourage the readers in face of their peculiar trials, which were easily possible in the time succeeding the above persecution, and at the same time to warn them against their special degenerating tendencies, which were quite likely to follow upon these trials (cf. especially chaps. i and ii).

Bibliography. A full survey of the literature on James will be found in James Moffatt, *Introduction to the Literature of the New Testament* (New York, 1911), who states the case fairly for the late date and authorship by some unknown writer. The counter position is ably stated by Theodor Zahn in his *Introduction to the New Testament* (Edinburgh, 1909); and by J. B. Mayor in his *Epistle of St. James* (3d ed., London, 1910).

JAMES, GEORGE PAYNE RAINSFORD (1799-1860). An English novelist and historical writer, born in London, Aug. 9, 1799. He attended a school at Putney, where he acquired some knowledge of French and Italian, and subsequently educated himself by wide reading and extensive travel on the Continent. After he had won a place among the contemporary novelists, he was appointed Historiographer Royal under William IV and, later in life, Consul at Boston, at Norfolk, Va., and finally (Consul General) at Venice, where he died May 9, 1860. He began his literary career by writing Eastern tales, which were praised by Washington Irving. In 1829 he published *Richelieu*, an historical novel somewhat in the manner of Scott. Thereafter volume followed volume—and his novels were for the most part historical—in rapid succession, until the number of novels and tales reached almost 100. The best of them is, perhaps, *Mary of Burgundy*. He also wrote, or rather dictated, many biographies and histories, among which are *Memoirs of Great Commanders* (1832), *A History of Chivalry* (1843), and *Life of Richard I* (4 vols., 1842-49). Following the example of Scott, he collected his novels with elaborate prefaces (1844-49). Some of them are still obtainable in cheap editions. While in the United States, he wrote in connection with M. B. Field *Adrian, or the Clouds of the Mind* (1852). James was im-

mensely popular in his own time, but his conventional moralizing and descriptions have long been out of date. His novels are all constructed on the same mechanical plan. They open with two horsemen riding through lovely scenes, or with an invocation to them before they appear, or with the variant of two men talking in subdued tones over their cups. Consult *Works* (new ed., New York, 1903), and A. H. Joline's consideration of James, in his *At the Library Table* (Boston, 1910). A burlesque of the style of G. P. R. James was written by Thackeray under the title of "Barbazure," in his *Novels by Eminent Hands* and first printed in *Punch* (London, 1847); also in Centenary Biographical Edition, vol. i (ib., 1911).

JAMES, GEORGE WHARTON (1858-). An American explorer, ethnologist, and archæologist, born at Gainsborough, Lincolnshire, England. He spent many years in exploration in the Southwest of the United States, especially along the Grand Cañon of the Colorado River, and at the same time made extensive researches among the various Indian tribes of those regions. He became a popular lecturer on these subjects, using pictures made by himself. He was associate editor of the *Craftsman* (1904-05) and editor of the *Basket* (1903-04) and *Out West* (1912-). He is author of *In and Around the Grand Canyon* (1900; rev. ed., 1911); *Indian Basketry* (1900; 3d ed., 1903); *The Indians of the Painted Desert Region* (1903); *In and Out of the Old Missions* (1905); *The Story of Scraggles* (1906); *The Wonders of the Colorado Desert* (1906; 2d ed., 1911); *What the White Race may Learn from the Indian* (1907); *Through Ramona's Country* (1908); *The Grand Canyon of Arizona* (1910; rev. ed., 1912); *The Heroics of California* (1910); *A Little Journey to Strange Places and Peoples* (1911); *The Old Franciscan Missions of California* (1913); *The Prehistoric Cliff Dwellings of the South West* (1913); *California, Romantic and Beautiful* (1914); *Indian Blankets and their Makers* (1914).

JAMES, SIR HENRY (1803-77). An English topographer, born at Rose-in-Vale, near St. Agnes, Cornwall, and educated at the Woolwich Military Academy. He became a probationer for the Corps of Royal Engineers in 1825, in 1826 was made lieutenant of engineers, and went thence into the ordnance department, where he made such good use of his opportunities for scientific study that he was appointed superintendent of the geological survey in Ireland in 1844. Two years later he was appointed to a position at the Portsmouth dockyards, was afterward made chief topographer and statistician of the War Office (1857), and was at the head of the British Ordnance Survey from 1852 to 1875. He published such technical works as *Principal Triangulations of the Earth* (2 vols., 1858), *Abstract of the Principal Lines of Spirit-Levelling in England and Wales* (1861), and *Plans and Photographs of Stonehenge and of Turnisachen in the Island of Lewis, with Notes Relating to the Druids, and Sketehes of Cromlechs in Ireland* (1867). He is credited with having invented photozincography.

JAMES, HENRY (1811-82). An American Swedenborgian theologian, lecturer, and author, father of William (1842-1910) and Henry (1843-1916) James. He was born in Albany, N. Y., graduated at Union College in 1830, studied at Princeton Theological Seminary until

1835, and then traveled abroad, where he met Sandeman, whose *Letters on Theron and Aspasia* he edited in 1839. James's earlier theological views are Unitarian, though he believed in the divinity of Christ. Later he was greatly influenced by Swedenborg, whose doctrines he accepted, but whose ecclesiastical system he combated. He lectured in New York in 1849 and 1852 and published: *Lectures and Miscellanies* (1852); *The Church of Christ not an Ecclesiasticism* (1854); *Christianity the Logic of Creation* (1857); *The Secret of Swedenborg* (1869). His *Literary Remains* were edited by his son William James in 1885.

JAMES, HENRY (1843-1916). A distinguished American novelist and essayist, born in New York City, April 15, 1843, the son of the eminent theologian, Henry James, and the younger brother of William James, the psychologist. He was educated privately in New York, in Switzerland, in England, and in France, and in 1862 he entered the Harvard Law School. He preferred, however, the lectures of James Russell Lowell to the regular work of his courses. After one or two short stories of his had been published, he turned his attention definitely to literature. His contributions to periodicals began as early as 1866. Between 1871 and 1903 he produced more than 40 books, some of them books of essays, but the major part of them works of fiction. Even his early work showed him a resourceful master of language; his style at first was simple, supple, and natural, and the movement of his stories was steady, though not rapid. The substance of his plots was the development of character rather than dramatic incident. The persons whom he chose to portray were selected from the classes that are subject to subtle impressions, and the evanescent emotions of such characters are expressed accurately in Mr. James's work. In his early books, e.g., *Roderick Hudson* (1876), *The American* (1877), *Daisy Miller* (1879), and *The Portrait of a Lady* (1881), he chose as subject the contrast between the vigorous and kindly but simple Americans abroad and the polished arrogance of the members of older races with whom they came in contact. In fact, after 1869 Henry James himself lived abroad, traveling on the Continent and maintaining residences in London and at Rye, Sussex. His popularity increased with *The Bostonians* (1886) and *The Princess Casamassima* (1886), in both of which the subtlety of Mr. James's exposition of character was apparent. In later works, with increased insight into the complexities of the individual and of society and in the effort to render these complexities, there came a development of complexity in the style of the author, exemplified, e.g., in *The Sacred Fount* (1901), which illustrates also a tendency of Mr. James's to turn plot and action into a standing pool of analysis and mystification. In his later works the theme also has changed; the author apparently became interested in the rapid trend towards unconventionality which took place in the last part of the nineteenth century in London, and many of his books dealt with phases of that change. Perhaps the most striking examples of his works which deal with subjects that, treated in a less delicate manner, would be too brutal to seem appropriate for discussion in literature, are *What Maisie Knew* and *The Wings of a Dove*; but the exposition of the rapid change in manners and customs in London is treated most

comprehensively in *The Awkward Age* (1899). He visited the United States in 1905 and published his impressions in *The American Scene* (1906), in which book the author's later style, with what appears to be its perverse obscurity, its incredibly involved syntax, and its tortured diction, reach an amazing and fantastic climax.

Mr. James found his opportunity in the richer and more complex American society which developed after the Civil War; it was this phase of the expanding nation that became the material of much of his fiction, and he chose to present it against an English or continental background and with continual contrasts of American manners, ideals, and types of character with ideals and types that were foreign or cosmopolitan. He became, in fact, the greatest practitioner of the international novel, and as such performed an immense service in bringing the world at large to a better understanding of, and a fuller sympathy with, his compatriots. He performed no less a service in the introduction of his American readers to English aristocratic life, with its prejudices and conventions, and to many phases of continental life, both of which, in their outer aspects and inner spirit, are reflected in his stories with scrupulous fidelity to truth. In making such international studies, Henry James was doing in his day for his countrymen such work as Washington Irving did in a preceding generation with his English and other foreign sketches, or as Longfellow did with his *Outre Mer* and *Hyperion* and in a different way with a not inconsiderable portion of his poetry. In his practice of the realistic method James was strikingly original. It was under the shadow of the prestige of Thackeray, Dickens, and Trollope that he began his work, but he preserved free from outside influence the integrity of his art as he personally conceived it. So distinctive was he in method and manner, so far-reaching in his influence, that he may well be called the inventor of the artistic society novel, the novel that is characterized by minute and faithful observation, refinement and intellectual delicacy, elaborate analysis, subtlety of suggestion, and free form. To Henry James's novels America owes a great debt: they have quickened her vision for beauty in art and nature, they have broadened her social horizons, and they have done much to bring Americans to a better understanding of themselves and of Europe. Mr. James became a member of the American Academy of Arts and Letters. Among his works are: *Watch and Ward* (1871); *Roderick Hudson* (1876); *Transatlantic Sketches* (1875); *A Passionate Pilgrim* (1875); *The American* (1877); *Daisy Miller* (1879); *The Europeans* (1879); *French Poets and Novelists* (1878), a work in which the author's sure taste, subtle insight, and critical discrimination are in evidence; *An International Episode* (1879); *Life of Hawthorne* (1880); *A Bundle of Letters* (1879), in which will be found excellent examples of Mr. James's art in the short story; *Confidence* (1880); *Washington Square* (1881); *The Portrait of a Lady* (1881); *The Siege of London* (1883); *The Point of View* (1883); *Portraits of Places* (1884); *A Little Tour in France* (1885); *Tales of Three Cities* (1884); *The Author of Beltraffio* (1885); *The Bostonians* (1886); *The Princess Casamassima* (1886); *Partial Portraits* (1888); *The Aspern Papers* (1888); *The Reverberator* (1888); *A London Life* (1889); *The Tragic Muse* (1890);

The Pupil (1891); *Terminations* (1895); *The Other House* (1896); *Spoils of Poynton* (1897); *Embarrassments* (1896); *What Maisie Knew* (1897); *The Two Magics* (1898); *In the Cage* (1898); *The Awkward Age* (1899); *The Soft Side* (1900); *The Sacred Fount* (1901); *The Wings of a Dove* (1902); *The Better Sort* (1903); *The Golden Bowl* (1904); *English Hours* (1905); *The Question of our Speech*; *The Lesson of Balzac* (1905); *Julia Bride* (1909); *The Finer Grain* (1910); *The Outcry* (1911); *Notes on Novclists, with Some Other Notes* (1914); the two autobiographical volumes, *A Small Boy and Others* (1913); *Notes of a Son and Brother* (1914). In 1900 a new and revised edition of his novels was published in New York in 24 volumes. Consult E. L. Carey, *The Novels of Henry James* (New York, 1905); Le Roy Phillips, *Bibliography of the Writings of Henry James* (Boston, 1906); W. C. Brownell, *American Prose Masters* (New York, 1909); F. M. Hueffer, *Henry James: A Critical Study* (London, 1913).

JAMES, HENRY JAMES, first BARON (1828–1911). An English jurist, born at Hereford. He was educated at Cheltenham College, studied law, was called to the bar in 1852, and met with much success in the Mayor's Court of London and at Westminster. In 1867 he attained the coveted honor of post man in the Court of Exchequer, and two years afterward became queen's counsel and entered the House of Commons. In 1873 he was appointed Solicitor-General and then Attorney-General. The latter post he received again in 1880, when the Liberals were returned to power, and in it he distinguished himself by introducing and passing the reform bill known as the Corrupt Practices Act. Disagreeing with Gladstone's Irish policy, he refused the lord-chancellorship in 1886. He held the office of attorney-general to the Prince of Wales from 1892 to 1895, and in the latter year was created Baron James of Hereford and was appointed Chancellor of the Duchy of Lancaster.

JAMES, JESSE W. (1847–82). An American outlaw, born in Clay Co., Mo., where his father, Robert James, a Baptist preacher, owned a farm. The family were Southern in their sympathies during the Civil War, and as a consequence were persecuted by their Union neighbors. In order to get revenge, Jesse joined Quantrell's guerrillas and soon earned a name for reckless daring. At the conclusion of peace he surrendered, desperately wounded, and returned to his old home. In 1866, however, he was outlawed, and from that time until his death was constantly pursued by officers of the law. During these years he attained a world-wide notoriety by the crimes he committed or was charged with having committed, by his romantic adventures, and his almost invariable success. These exploits were generally bank or train robberies. Finally Governor Crittenden of Missouri offered a reward of \$10,000 for his capture, dead or alive, and, tempted by this bribe, two members of his own band, Robert and Charles Ford, killed him in his home at St. Joseph, Mo. (April 3, 1882). The murderers then surrendered to the police, and presumably received the reward of their treachery. On the eighteenth of the same month both of the Fords pleaded guilty (at St. Joseph, Mo.) to the charge of having killed James (though it was generally believed that Robert fired the shot) and were sentenced to death, but were pardoned by Governor Crittenden. Frank

James, Jesse's brother, surrendered in the following October; but although he was held in jail more than a year awaiting trial, he was never convicted on any charge. He spent the last 30 years of his life as a farmer and died near Excelsior Springs, Mo., Feb. 18, 1915, at the age of 74. Jesse James's son, in a biography of the outlaw, asserted that James was always anxious to surrender, provided the authorities would guarantee him protection and a fair trial. Consult: Jesse James, Jr., *Jesse James, my Father* (Independence, Mo., 1899); Edwards, *Noted Guerrillas, or the Warfare of the Border* (1877); *American Law Review*, vol. xvi (St. Louis, Mo.).

JAMES, JOHN ANGELL (1785–1859). An English Congregational minister, born at Blandford Forum, Dorsetshire. From his thirteenth till his seventeenth year he was learning the trade of his father, a linen draper, but studied for the ministry too, and was called to Carr's Lane Chapel, Birmingham (1805), where he preached most acceptably to largely increased congregations for more than 50 years. He published a great number of sermons, pastoral letters, and the like; but his best-known books are *Christian Charity* (1829), *The Anxious Enquirer after Salvation* (1843), and *The Church in Earnest* (4th ed., 1851). Consult John Campbell, *John Angell James, his History, Character, and Literary Labours* (London, 1860), and Dale, *Life and Letters* (2d ed., ib., 1861).

JAMES, LOUIS (1842–1910). An American actor, born in Tremont, Ill., Oct. 3, 1842. He made his debut at Louisville in 1864. He was a member of Mrs. John Drew's company (1865–70); then of Daly's (1871–75); and subsequently appeared in support of various noted actors, including Lawrence Barrett and Joseph Jefferson, and as a star, notably with Frederick Warde, in a series of classic revivals (1892–95). Among his Shakespearean characters were Autolycus, Nick Bottom, and Cardinal Wolsey. Consult Clapp and Edgett, *Players of the Present* (Dunlap Society, New York, 1900).

JAMES, OLLIE M. (1871–). An American legislator, born in Crittenden Co., Ky. He received an academic education, studied law under his father, and was admitted to the bar in 1891. He was one of the attorneys of Governor Goebel in his contest for the governorship of Kentucky. He served as chairman of the Kentucky delegation to the Democratic National Convention in 1896, 1904, and 1908, seconded Bryan's nomination for the presidency in 1908, and was chairman of the Democratic National Convention in 1912. He was a member of the Fifty-eighth to the Sixty-second Congresses (1903–13), and in 1912 was elected United States Senator for the term 1913–19.

JAMES, PRINCE, THE OLD PRETENDER. See STUART, JAMES FRANCIS EDWARD.

JAMES, PROTEVANGELIUM OF. See APOCRYPHA.

JAMES, ROBERT (1705–76). An English physician, born in Kinvaston, Staffordshire. He graduated at St. John's College, Oxford, in 1726, was admitted an extralicensiate of the College of Physicians, London, in 1728, and in the same year was granted the degree of M.D. by Cambridge. He practiced successively in Sheffield, Lichfield, and Birmingham before establishing himself in London, where he made himself famous by the invention of a fever powder composed of lime phosphate and oxide of antimony. He was the friend of Dr. Johnson, who helped

him to publish his *Medical Dictionary* (3 vols., 1743-45). James translated the works of other physicians, and his *Vindication of the Fever Powder* was published posthumously in 1778.

JAMES, THOMAS (c.1593-c.1635). An English navigator and explorer. Being an experienced seaman and a scientific navigator versed in all kinds of observations, he was appointed in 1631 by the merchants of Bristol, with the approval of the King, to command an expedition for "the discovery of the North-West Passage to the South Sea, and to proceed to Japan round the world to the westward." Luke Fox sailed on a similar quest from London on May 3, 1631, the same day that James left the Severn, in a 70-ton ship manned by a crew of 22 seamen, and entered Hudson Bay in the latter part of June or the first part of July. Sailing over to the western shore, he turned southward, and on August 29 met Fox. Five days later he named Cape Henrietta Maria after his vessel and then sailed into the bay which is named after him. Wintering on Charlton Island, at the extreme south end of Hudson Bay, where he lost four men, he returned to England in 1632. From 1633 to 1635 he commanded the *Ninth Whelp*, an armed cruiser for the protection of commerce in the Bristol Channel and the Irish Sea, which waters at that period were seriously infested by pirates. Nothing definite is known of his later career. Consult *The Strange and Dangerous Voyage of Captain Thomas James* (London, 1633) and Rundall, *Voyages toward the North-West* (Hakluyt Society, London, 1849).

JAMES, THOMAS LEMUEL (1831-1916). An American banker and cabinet officer, born at Utica, N. Y. He learned the printer's trade and from 1851 to 1861 owned the leading Republican paper in Madison County, to 1856 called the *Madison County Journal* and afterward the *Democrat-Republican*. Between 1854 and 1873 he was collector of canal tolls at Hamilton, customs inspector at New York, weigher, and deputy collector in charge of bonded warehouses. From 1873 to 1881, as postmaster of New York, he introduced reforms in the local mail delivery and had an important influence on the development of this branch of the service throughout the country. He was Postmaster-General for 10 months in 1881-82, and during this short time accomplished various economies and set under way the investigation of the "star route" frauds. In 1882 he became president of the Lincoln National Bank in New York, and he served as president also of the Lincoln Safe Deposit Company and as a director of the Metropolitan Life Insurance Company. In 1896 he was mayor of Tenafly, N. J.

JAMES, THOMAS POTTS (1803-82). An American botanist. He was born at Radnor, Pa., but passed the greater part of his life in Philadelphia, where he was in the wholesale drug business. In 1867 he went to live in Cambridge, Mass., and there devoted himself to botanical research, which had hitherto been his recreation. He wrote several papers for the *Proceedings of the Philadelphia Academy of Natural Sciences* and for the *Proceedings of the American Academy of Arts and Sciences*; prepared the article on "Musci," in the volume on botany of King's *Exploration of the 40th Parallel*, and with Leo Lesquereux wrote *Manual of American Mosses* (1884).

JAMES, WILLIAM (died 1827). An English naval historian. The date and place of his birth

are unknown. Between 1801 and 1813 he was an attorney of the Supreme Court of the island of Jamaica and a proctor in Admiralty. At the outbreak of the War of 1812 he was in the United States and was detained as a prisoner, but escaped to Halifax in 1813. He was much interested in naval affairs and over the signature of "Boxer" wrote a number of articles on the war for the *British Naval Chronicle*. In 1816 he published a bitterly anti-American pamphlet entitled *An Enquiry into the Merits of the Principal Naval Actions between Great Britain and the United States* (enlarged under changed title, 1817). In 1818 he published *A Full and Correct Account of the Military Occurrences of the Late War between Great Britain and the United States of America*, and in 1819 he began his most important work, *The Naval History of Great Britain from the Declaration of War by France in 1793 to the Accession of George IV* (1st ed., 5 vols., 1822-24; reprinted, 6 vols., 1826; ed. in 6 vols., 1837; ed. in 1886; epitomized ed., 1 vol., by Robert O'Beirne, 1888). Accounts of all operations in which the British navy was not victorious are omitted.

James was a fierce partisan. While he carefully sought and examined all British sources of information, he gave no weight to contradictory evidence on the other side, so that his conclusions are often erroneous and very unfair. His contention that the American ships were more powerfully armed and more heavily manned than British vessels of similar rating was in many cases true, but the discrepancy was not so great or so important as he strove to make it appear. J. Fenimore Cooper's *Naval History* (1st ed., 1839) was written in part to refute James's statements; but Cooper's resentment towards Britain and friendliness to his own service led him into erring almost as far on the opposite side, and it was not until the appearance of Theodore Roosevelt's *Naval War of 1812* (1882) that a fair statement of the facts was made.

JAMES, WILLIAM (1842-1910). A distinguished American psychologist and philosopher, son of Henry James, the theologian, and brother of Henry James, the novelist. He was born in New York City, Jan. 11, 1842, was educated in private schools and by tutors in New York and Europe, studied at the Lawrence Scientific School, and graduated from Harvard Medical School in 1870. He received the honorary degree of LL.D. from Princeton, Edinburgh, and Harvard, and that of Ph. et Litt.D. from Padua. Beginning to teach at Harvard in 1872, he was appointed professor in 1881. At first his subjects were anatomy and physiology, then philosophy, later psychology, and then again philosophy. He was Ingersoll lecturer on the immortality of man, at Harvard University (1898); Gifford lecturer on natural religion, at the University of Edinburgh (1899-1901); Lowell Institute lecturer (1906); and Hibbert lecturer on the present situation in philosophy, at Manchester College, Oxford (1909). In 1908 "his colleagues at Columbia University" published in his honor *Essays Philosophical and Psychological*. Besides numerous articles in medical and scientific journals, he published: *Principles of Psychology* (1890); *Psychology, Briefer Course* (1892); *The Will to Believe, and Other Essays in Popular Philosophy* (1897); *Human Immortality: Two Supposed Objections to the Doctrine* (1898); *Talks to Teachers on Psychol-*

ogy, and to Students on Some of Life's Ideals (1899); *The Varieties of Religious Experience* (1902); *Pragmatism* (1907); *A Pluralistic Universe* (1909); *The Meaning of Truth* (1909); *Memories and Studies* (1911); *Some Problems of Philosophy* (1911); *Essays in Radical Empiricism* (1912). He also edited the *Literary Remains of Henry James* (1885).

James's writings are characterized by a fresh and entertaining style and by lucid exposition of abstruse themes. From the publication of the *Principles* until the time of his death his reputation and influence, both in America and in Europe, were probably unequalled by any other American psychologist. His work is especially significant in the field of analytical psychology, in which James has had few equals; several important theories in this field pass under his name. In philosophy his work was notable for keenness and originality. He was perhaps the foremost American expositor, and in a large measure the originator, of the doctrines included under the term "radical empiricism" (q.v.) and "pragmatism" (q.v.; see also DEWEY, JOHN). He entered upon his philosophical studies fresh from his successful work in psychology and brought with him a keen desire to give up all unnecessary theorizing and to confine himself to correct and full description. His radical empiricism was in spirit nothing but an attempt to make experience self-supporting instead of having it depend on assumed extra-experiential factors. His pragmatism was in like measure a revolt against the logic of absolute idealism, developed by Royce and Bradley, and an attempt to make logic a description of our actual thinking processes. His influence was enormous even in remote philosophical circles. Psychological research interested him greatly.

Bibliography. *Essays Philosophical and Psychological in Honor of William James, by his Colleagues at Columbia University* (London, 1908); Flournoy, *La philosophie de William James* (Saint-Blaise, 1911); Josiah Royce, *William James, and Other Essays on the Philosophy of Life* (New York, 1911); Ménard, *Analyse et critique des principes de la psychologie de W. James* (Paris, 1911); K. A. Busch, *William James als Religionsphilosoph* (Göttingen, 1911); Boutroux, *William James* (New York, 1912); R. B. Perry, *Present Philosophical Tendencies* (ib., 1912); James Huneker, "A Philosophy for Philistines," in his *The Pathos of Distance* (ib., 1913); Werner Bloch, *Der Pragmatismus von James und Schiller nebst Exkursen über Weltanschauung und über die Hypothese* (Leipzig, 1913); H. V. Knox, *Philosophy of William James* (London, 1914). Henry James's *A Small Boy and Others* (1913) and *Notes of a Son and Brother* (1914) are full of interesting material.

JAMES BAY. The southern arm of Hudson Bay (q.v.) (Map: America, North, K 4). It is 300 miles long from north to south and 160 miles wide and contains a number of islands, the largest of which, Agomska, is 70 miles long. The bay is shallow except in a narrow channel leading to Moose Factory, at the extreme southwest, the most important station, next to York Factory, of the Hudson's Bay Company on the Canadian coast. James Bay received its name from Thomas James (q.v.), who explored it in 1631-32.

JAMES ISLAND. One of the Sea Islands chain famous for cotton. It constitutes a township in Charleston Co., S. C., south of the city

of Charleston (Map: South Carolina, E 4). Pop., 1900, 2570; 1910, 3147.

JAMES MIL'LIKIN UNIVERSITY. A coeducational institution of learning, comprising Lincoln College at Lincoln, Ill., and Decatur College and Industrial School at Decatur, Ill. Lincoln University was founded in 1865 by the synods of Indiana, Illinois, and Iowa of the Cumberland Presbyterian church. In 1901 certain amendments were made to the charter of the university which provided that it should change its name to Lincoln College and along with the new Decatur College constitute the James Millikin University. The reorganization was made possible by the liberal contributions of the founder, James Millikin, the citizens of Decatur, and the synods of Indiana, Illinois, and Iowa of the Cumberland Presbyterian church. With the union of the Cumberland Presbyterian and the Presbyterian U. S. A. churches the institution passed under the control of the latter denomination, though it is nonsectarian. The college at Lincoln in 1913 had 279 students, a faculty of 18, an endowment of \$120,000, buildings, grounds, and equipment valued at \$100,000, and a library of 7000 volumes. In the same year the college at Decatur reported 1128 students, a faculty of 58, an endowment of \$220,600 with an assured annual income from the trustees of the Millikin estate representing \$600,000 additional, buildings, grounds, and equipment valued at \$594,000, and a library of 7800 volumes. Each college maintains an academic and a collegiate department. Lincoln College offers courses in liberal arts, fine arts, elocution, domestic economy, and music, and Decatur College in liberal arts, domestic economy, fine and applied arts, library science, manual training, commerce and finance, engineering, and music. The president in 1914 was George Emory Fellows, LL.D.

JAMES OF VIRAGGIO, vè-rä-j'ò. See GOLDEN LEGEND.

JAMESON, jām'son, ANNA BROWNELL (MURPHY) (1794-1860). A British author, born in Dublin. She was the daughter of D. Brownell Murphy, the miniature painter, and married Robert Jameson, a barrister, from whom, however, she soon separated. Her first book, *The Diary of an Ennuyée* (1826), was followed by *Loves of the Poets* (1829) and *Characteristics of Women* (1832), a series of essays on Shakespeare's women, which is probably her best work and is still current in various editions. In 1836 she visited New England, where she remained two years. Her *Sacred and Legendary Art* is divided into four volumes: *Legends of the Saints* (1848), *Legends of the Monastic Orders* (1850), *Legends of the Madonna* (1850), and *The History of Our Lord* (1860), completed by Lady Eastlake and the most important of her art writings. Though Mrs. Jameson's work as a critic is of little value, her compilations contain much material not easily obtainable from other sources, and her style is pleasant and readable. Consult Macpherson, *Memoirs of the Life of Anna Jameson* (Boston, 1878), and biography by Richard Garnett in *Dictionary of National Biography*, vol. xxix (London, 1892).

JAMESON, JAMES SLIGO (1856-88). An English naturalist and African explorer, born at Alloa, Clackmannanshire. His early voyages were to Ceylon and Borneo. In 1878 he went to South Africa, succeeded in entering Mashonaland, and discovered the junction of the

Umniati and Umfuli rivers, besides bringing to England valuable ornithological specimens. After travels in the Rocky Mountains (1882), in Spain and Algiers (1884), Jameson joined Stanley's expedition for the relief of Emin Pasha early in 1887 and in June of the same year was left at Yambuya, where Tippu Tib was to reinforce him. These forces were slow to arrive and inadequate when they had come. Barttelot pressed on without Jameson in June of 1888 and was shot at Unaria. Jameson punished the assassin and did all in his power to induce Tippu Tib to accompany him in the search for Stanley, even offering £20,000 from his own funds. To communicate with England, he left Stanley Falls for Bangalas in August and there died of fever. He left a *Diary of the Emin Pasha Expedition* (1890). Stanley's account of Jameson's connection with a cannibal feast, which the latter sketched at Riba Riba, is probably exaggerated; but Jameson, by his own account, cannot be held blameless.

JAMESON, JOHN ALEXANDER (1824-90). An American jurist, born at Irasburg, Vt. He graduated at the State University (1846) and from 1867 to 1868 was professor of law in the University of Chicago. For many years he was assistant editor of the *American Law Register*. He wrote several legal works, including *The Constitutional Convention: Its History, Power, and Modes of Proceeding* (1867; 4th ed., 1887).

JAMESON, JOHN FRANKLIN (1859-). An American historian, born in Boston. He graduated from Amherst College in 1879 and in 1882 from Johns Hopkins University (Ph.D.), where he was an assistant and associate in history until 1888. From then until 1901 he was professor of history at Brown University and in 1901-05 served as professor and head of the department of history at the University of Chicago. In 1905 he became director of the department of historical research and editor of the historical publications of the Carnegie Institution. In 1906-07 Jameson was president of the American Historical Association. He was managing editor of the *American Historical Review* from 1895 to 1901 and again after 1905. He edited the *Correspondence of John C. Calhoun* (1900) and *Original Narratives of Early American History* after 1906 and published, further: *Willem Usselinx, Founder of the Dutch and Swedish West India Companies* (1887); *History of Historical Writing in America* (1891); *Dictionary of United States History* (1894, and published in 1904 in 3 vols. as the *Encyclopedic Dictionary of American History*).

JAMESON, SIR LEANDER STARR (1853-). A British physician, soldier, and administrator, who became prominent as leader of the raid into the Transvaal in December, 1895. A son of R. W. Jameson, writer to the signet, he was born in Edinburgh. He graduated from London University in 1875, received his M.D. in 1877, and in 1878, on account of ill health, went to Kimberley, Cape Colony, to practice his profession. Association with Cecil Rhodes led to his appointment as Administrator of Rhodesia in 1891, under the British South Africa Company. In that capacity he organized an expedition against the Matabele in 1893. In 1894 he was created a C.B. In the course of the discontent and political agitation among the Uitlander element in the Transvaal Republic, a body of troops commanded by Dr. Jameson was placed by Rhodes's orders on the borders of the

Transvaal, prepared to act in case of disturbances. On receipt of a letter from Johannesburg, the seat of disaffection, Jameson, acting on his own judgment, invaded the Transvaal, with 600 men, on Dec. 29, 1895. On January 1, meeting with resistance at Krugersdorp, he shelled the town, but was unable to carry the position. The next day he moved towards Doornkoop, where, after 36 hours of almost continuous fighting, and the loss of 17 killed and 49 wounded, he was forced to surrender to the Boers. The raid was condemned throughout the civilized world. President Kruger handed Jameson and his officers over to the British government for punishment. They were taken to England and tried in London. In May, 1896, Jameson was sentenced to 10 months' imprisonment for an infringement of the Foreign Enlistment Act, but, owing to ill health, was released in December. He fought against the Boers in 1899-1900, was elected to the Cape Legislative Assembly for Kimberley in 1900, from 1904 to 1908 was Premier, and in 1910-12 was a member of the Cape Parliament. He was made first Baronet in 1911. A director after 1900 of the De Beers Consolidated Company, and after 1902 a director of the British South Africa Company, he also became president of the latter. Consult Garrett and Edwards, *The Story of an African Crisis* (Westminster, 1897), and "Cape of Good Hope, House of Assembly, 1897, Report of the Select Committee on the Jameson Raid into the Territory of the South African Republic," in *British Parliamentary Papers* (London, 1897).

JAMESON, ROBERT (1774-1854). A Scottish naturalist, born at Leith. He began the study of medicine, but, manifesting a fondness for natural history, went, in 1800, to Freiberg, Saxony, where he studied geology under Werner. In 1804 he returned to Edinburgh and was given the chair of natural history in the university there, which place he held until his death. The natural history museum of the university was largely indebted to Jameson's care and skill, for not only did he arrange its collections, but he also obtained a grant from the government for its maintenance. He founded the Wernerian Society in Edinburgh in 1808 and was a zealous advocate of the Neptunian theories of his master, which he subsequently abandoned, adopting Hutton's Plutonian or igneous theories of earth origin. With Sir David Brewster he founded, in 1819, the *Edinburgh Philosophical Journal*, and in 1826 the *Edinburgh New Philosophical Journal*, which he edited until his death. The geological articles of the fourth edition of the *Encyclopædia Britannica* were prepared under his supervision. His works include: *System of Mineralogy* (3 vols., 1804-08; 3d ed., 1820); *Elements of Geognosy* (1809); *Manual of Minerals and Mountain Rocks* (1821).

JAMESONE, or JAMESON, GEORGE (c.1587-1644). A Scottish portrait painter. He was born at Aberdeen, the son of an architect. After some practice as a portrait painter at Aberdeen, he went abroad and was a fellow pupil with Van Dyck under Rubens. He was employed by the city of Edinburgh, where he lived after 1630, to copy several portraits of the Scottish King's presentation to Charles I on the occasion of his first visit to Scotland in 1633, and was rewarded by the King with a diamond ring from his own finger. His reputation established, the most celebrated Scotchmen of the day sat to him. But the magistrate of Edinburgh refused to pay

him his price for his portrait of Charles I. His work lacks distinction. Consult Bullock, *George Jamesone* (London, 1885).

JAMESONITE, jām'sūn-īt. A lead sulphantimonite, named after Prof. Robert Jameson, of Edinburgh (1774-1854). It is an occasional ore of lead and is sometimes associated with more important lead ores. It is sometimes called feather ore in reference to its fibrous divergent structure.

JAMESON RAID. See JAMESON, SIR LEANDER STARR.

JAMES (or DAKOTA) RIVER. A navigable stream rising in Wells Co., N. Dak., about 60 miles northeast of Bismarck (Map: South Dakota, G 4). It flows southerly through a fertile country and joins the Missouri River about 9 miles east of Yankton, S. Dak. It is about 400 miles long in its general direction. It falls nearly 600 feet, but the fall is so uniform that the stream is incapable of much development as to water power. Only small tributaries flow into it.

JAMES RIVER. The largest river in Virginia. It is formed by the union of the Jackson and Cowpasture rivers, which rise in the Alleghanies (Map: Virginia, F 4). Its general direction is east-southeast, with many large bends and windings, and after widening into a broad and deep tidal estuary for the last 66 miles of its course, it flows into the lower part of Chesapeake Bay through Hampton Roads near Norfolk. The total length is about 335 miles, and its drainage basin is about 9700 square miles. The main stream and all of its confluents lie entirely within the State of Virginia. There is a nearly uninterrupted channel, about 100 feet wide and 18 feet deep, from Hampton Roads to Richmond Wharf. The western reach of the river opposite Richmond falls about 116 feet in 9 miles, thereby forming rapids which offer ample water power. The old James and Kanawha Canal, which followed the river from Richmond to Buchanan, is now abandoned. The chief tributaries of the James are the Appomattox from the right and the Chickahominy from the left, made famous by campaigns in the Civil War. It was on this river that Jamestown, the first permanent English settlement in America, was founded in 1607.

JAMES'TOWN. The first permanent English settlement within the limits of the United States, founded in May, 1607, by a small company under Captain Newport, in Virginia, on the banks of the James River, about 32 miles from its mouth. Here in 1619 the first legislative assembly in America was held, and here in the same year slavery was first introduced into the original thirteen Colonies. In September, 1676, the town was almost completely destroyed by Nathaniel Bacon. (See BACON'S REBELLION.) Up to 1698, when it was supplanted by Williamsburg, it was the capital of Virginia. The site of the settlement, which was originally a peninsula but is now an island, is owned by the Association for the Preservation of Virginia Antiquities. Ruins are left of a church, built probably between 1676 and 1684, of the fort, and of two or three houses. Near here is the site of the exposition held in 1907 to celebrate the tercentennial (see JAMESTOWN TRICENTENNIAL EXPOSITION) of the first permanent English settlement in the United States.

Bibliography. "Documents Illustrating the History of the Colony of Jamestown," in *Trans-*

actions of the American Antiquarian Society, vol. iv (Worcester, Mass., 1860); M. L. D. Foster, *Colonial Capitals of the Dominion of Virginia* (Lynchburg, 1906); L. G. Tyler, *Cradle of the Republic; Jamestown and James River* (2d ed., Williamsburg, 1906); J. E. Davis, *Round about Jamestown* (Hampton, 1907); R. A. Pryor, *Birth of the Nation; Jamestown, 1607* (New York, 1907); S. H. Yonge, *Site of Old "James Towne," 1607-1698* (Richmond, 1907). For further details concerning the history of Jamestown, see VIRGINIA.

JAMESTOWN. The capital and seaport, on the north coast, of St. Helena (q.v.), a British Admiralty coaling station. It consists of a long street, situated in a deep valley on the northwest coast. Its chief building is the observatory. In its vicinity is situated the tomb and first burial place of Napoleon I. Pop., 1911, 1439.

JAMESTOWN. A city in Chautauqua Co., N. Y., 70 miles by rail south by west of Buffalo, on the outlet of Chautauqua Lake, and on the Erie, and the Jamestown, Chautauqua, and Lake Erie railroads (Map: New York, A 6). Jamestown is a popular summer resort. It is connected by boat and steam and electric railroads with other resorts on the lake. One of the leading attractions of the city is Celoron, on Chautauqua Lake, a popular place of amusement. Among its buildings are the James Prendergast Free Library, the Women's Christian Association Hospital, and the Agnes Home for working girls. Jamestown is the centre of a productive farming district and has large manufacturing interests, including several worsted mills, furniture and lounge factories, saw mills, a cotton mill, and manufactures of metallic goods, voting machines, pianos, towels, bank vaults, and photographic paper. The city government is administered, under the charter of 1886 as revised in 1900, by a mayor, elected every two years, a unicameral council, and subordinate officials. Jamestown was settled in 1810, laid out in 1815, incorporated as a village in 1827, and chartered as a city in 1886. Pop., 1900, 22,892; 1910, 31,297; 1914 (U. S. est.), 34,878.

JAMESTOWN. A city and the county seat of Stutsman Co., N. Dak., 93 miles by rail west of Fargo, on the James River, and on the Northern Pacific and the Midland Continental railroads (Map: North Dakota, F 4). It has the State Hospital for the Insane, St. John's Academy, an Elks Home, Park View Hospital, Roman Catholic Cathedral, the Presbyterian College, a public library, and a fine courthouse. The city is a railroad centre and has farming, dairying, and stock-raising interests. There are grain elevators, flour mills, and other industrial establishments. The water works are owned by the city. Pop., 1900, 2853; 1910, 4358.

JAMESTOWN TRICENTENNIAL EXPOSITION was held on Hampton Roads, Va., from April 26 to Nov. 30, 1907, in commemoration of the three-hundredth anniversary of the first permanent settlement of Anglo-Saxon people in America. The site covered 350 acres at Sewall's Point, along the southern shore of Hampton Roads. The principal group of buildings, eight in number, were arranged around a square called Raleigh Court. Also there were two government buildings in which were shown the exhibits of the government departments. All these buildings were in the Georgian style of architecture. The smaller

buildings included a Porto-Rican, Pan-American, and Mexican building in the Spanish-American Renaissance style. Arranged in a row along the wide street fronting the shore of Hampton Roads were the State buildings, mostly in the Colonial style of architecture and many of them reproducing some historical building. Typical of these may be mentioned the Maryland building, which was a reproduction of the house of Charles Carroll of Carrollton; the Massachusetts building, which was a reproduction of the old State House in Boston; and the Pennsylvania building, which was a replica of Independence Hall. An architectural feature of interest was the government piers, which extended 1600 feet northward into the waters of Hampton Roads and were connected by an arch, 200 feet in width, and elevated in the centre so as to permit the entrance of small vessels. The amusement features were grouped in the western part of the grounds along a continuous street called the War Path. There were about 2500 exhibits, which were classified among the following groups: (1) Historic Art; (2) Education and Social Economy; (3) Manufactures and Liberal Arts (including Graphic Arts); (4) Machinery and Transportation (including Electricity); (5) Agriculture and Horticulture; (6) Food Products and Accessories; (7) Forestry, Fish, and Game; and (8) Mines and Metallurgy. These exhibits were considered by a jury of awards, which awarded 665 gold, 640 silver, and 635 bronze medals. The attendance was between 4000 and 5000 daily, or in all the total admissions were about 2,800,000, of which 1,500,000 were paid. On North Carolina day the attendance was 60,000. The financial results were bad, and at the close of the exposition a statement issued showed the liabilities to be \$3,465,000 and the assets \$710,000, indicating a deficit of \$2,655,000, against which was the ownership of the site. Consult *Final Report of the Jamestown Ter-Centennial Commission* (Washington, 1909) and *The Official Blue Book of the Jamestown Ter-Centennial Exposition, A.D. 1907* (Norfolk, 1909).

JAMESTOWN WEED. A weed of the solanum family. See STRAMONIUM.

JĀMI, jā'mē, NUR-UDDIN 'ABD-URRAHMAN (1414-92). A Persian poet, renowned for his romantic, lyric, and mystic writings, and often spoken of as the last of the transcendental sufi poets. Jāmi was born at the small town of Jam, near Herat, in Khorassan; on this account he is known as Jāmi, although he also plays upon his name in its significant sense as denoting that he was a mystic wine cup (Pers. *jām*, cup) of the divine love of God. His education seems to have been excellent, and his guiding principle in life was the philosophy of Sufism (q.v.), with all its mysticism. His poetic activity must have begun early, if we may judge from the number of works that are his, besides others which are attributed to him. Foremost among his works is a collection of seven poems entitled *Haft Aurang* (Seven Stars of the Great Bear, or Seven Thrones). One of the poems in this series is the tender love story of *Lailā u Majnūn*; another, the *Salāmān u Absāl*, is allegorical and moral in its treatment, and is known in English through Edward FitzGerald's version; a third, *Yūsuf u Zulaikhā* (trans. by Griffith, 1901), in the same collection, is the romantic tale of the passion which Joseph's beauty inspired in Potiphar's wife. Jāmi is likewise the author of a well-

known prose work, *Baharistān* (Garden of Spring), composed about 1487 to give instruction to a son born to him in his old age. He composed also three divans or collections of lyrical poems and odes, written between the years 1479 and 1491. His death occurred at Herat, Nov. 9, 1492.

As a poet, Jāmi's talent is unquestioned; his verse is so polished and his art so finished as to contain almost elements of weakness owing to their refinement and perfection. His works are held in high esteem among the Persians, and some of the manuscripts of his poems are splendid specimens of Oriental calligraphy and illumination. His life and personality, moreover, seem to have been such as to win the favor of princes as well as to endear himself to the people because of his reputation for spiritual exaltation.

Bibliography. Ouseley, *Biographical Notices of Persian Poets* (London, 1846); Robinson, *Persian Poets* (Glasgow, 1883); FitzGerald, *Salāmān and Absāl*, translated (Boston, 1887), which contains a sketch of Jāmi's life after Rosenweig; *The Baharistān Literally Translated* (Benares, 1887); the comprehensive references in Ethé, "Neupersische Literatur," in Geiger and Kuhn, *Grundriss der iranischen Philologie*, vol. ii (Strassburg, 1896-1904); Costello, *Rose Garden of Persia* (Boston, 1901); *Jāmi Lawā'ih: A Treatise on Sūfism* (London, 1906), containing a facsimile of an old manuscript with translation by Whinfield and Kazvīnī; Davis, *The Persian Mystics: Jāmi* (New York, 1908).

JAMIESON, jā'mē-son, JOHN (1759-1838). A Scottish philologist and antiquary. He was born in Glasgow, studied for the ministry at the university there, and in 1781 was ordained pastor of a congregation at Forfar, in connection with the Antiburgher secession body. In 1797 he was called to Edinburgh. His fame rests chiefly upon his *Etymological Dictionary of the Scottish Language* (1808), a work which shows great learning and industry. In 1818 he published an abridgment, and in 1825 two supplementary volumes. The book, while exceedingly valuable in definition and illustration and in its exposition of Scottish customs, was originally weak in its philology. This defect was remedied, however, in a revised edition (1879-87), edited by Dr. Longmuir and Mr. Donaldson. Among his other publications are: *Ancient Culdees of Iona* (1811); *Hermes Scythicus, or the Radical Affinities of the Greek and Latin Languages to the Gothic* (1814); *An Historical Account of the Royal Palaces of Scotland*; *Remarks on Rowland Hill's Journal* (1799).

JAMIN, zhā'mān', JULES CÉLESTIN (1818-86). An eminent French physicist, born at Termes, Ardennes. He was educated at Rheims and at the Ecole Normale Supérieure; taught physics at Caen, at the Collège Bourbon (now Lycée Condorcet), and at the Louis le Grand; and in 1852, after publishing his valuable thesis on the reflection of light from metallic surfaces (1847), became professor at the Ecole Polytechnique, from which he resigned in 1881. On the death of Despretz (1863), Jamin succeeded him at the Sorbonne, where he was director of the physical laboratory until his death. He was elected to Pouillet's place in the Academy of Sciences (1868), of which he was secretary, 1884-86, and followed Milne-Edwards as dean of the faculty of science. An excellent botanist and geologist and a painter of some skill, Jamin was

also a versatile physicist. His contributions to the *Comptes Rendus* of the Academy, numbering more than 80, treat of the critical point of gases, capillarity, hygrometry, compressibility of liquids, and many other subjects. But his fame rests on special studies in optics, magnetism, and electricity. Many of his articles deal with polarization and refraction. As a result of his theory of magnetic distribution, Jamin devised (1873) a very powerful magnet, composed of many laminae, which was adopted for use in Gramme's machine. The Jamin electric light (1879) has carbons side by side, with points down, one fixed and one rotary; in general it resembles those devised by Wilde and Jablochkov, relights automatically, and casts a disadvantageous shadow. *A Cours de physique* (with Boutmy, 4th ed., 1886-91) and a *Petit traité de physique* (1870) were translated into German by Müllner and Recknagel respectively. Jamin published, besides, *Quelques phénomènes atmosphériques* (1880) and wrote essays in the *Revue des Deux Mondes*.

JAMITZER, yä'mīts-ēr, **GAMITZER**, gä'mīts-ēr, or **JAMNITZER**, yäm'nīt-sēr, **WENZEL** (1508-85). The greatest of the German Renaissance goldsmiths. He was born in Vienna, but during his boyhood his family moved to Nuremberg, where he became a master workman in 1534. He was court goldsmith successively to the Emperor Charles V, Ferdinand I, Maximilian II, and Rudolph II. His grave in St. John's Cemetery, Nuremberg, is marked with a bronze epitaph designed by his friend and pupil, Jost Amman. His most famous works are: the silver jewel box in the Green Vault of the Royal Palace of Dresden, 13 inches high by 11 wide; the table centrepiece of gilded silver, 39 inches high, now in the collection of Baron Henri de Rothschild of Paris, made in 1549 for the city of Nuremberg at the price of 1325 gulden, sold in 1880 for 800,000 marks; miniature statues of Flora, Ceres, Bacchus, and Venus, in the Imperial Treasury of Vienna (the surviving part of a centrepiece made for Rudolph II); a jewel box picturing the deeds of Hercules, in the Bavarian Treasury at Munich; a cup with the figure of Maximilian II, now in the possession of the German Emperor. Jamitzer's mark was a lion's head, sometimes accompanied by a W. He made many designs for ornamental gold and silver plate, some of which were reproduced as line engravings, etchings, and wood engravings. There are collections of his drawings in Basel, Coburg, Nuremberg, Erlangen, and Paris. Of the engravings, a number are illustrated by Bergau. Jamitzer was the first German master to break entirely with Gothic and adopt definitely and completely the forms of the Italian Renaissance. Being unable to study the originals, he made much use of Italian engravings, particularly those of Enea Vico and those of Lazarus de Baif. The latter's *De Vaseulis*, published in Paris in 1536, was also a source of inspiration to Du Cerceau, which accounts for the similarity of many of his compositions to Jamitzer's.—**CHRISTOPHER** (1563-1618), Wenzel's grandson, is known as a goldsmith by works now in Vienna, Berlin, and Moscow, and as an engraver by his *Groteskenbuch*. Consult Bergau, *Wenzel Jamitzers Entwürfe* (Berlin, 1879), and, for Nuremberg documents illustrating the history of the family, Frankenburg, *Wenzel Jamnitzer* (Strassburg, 1901).

JAMMU, jüm'oo. A town and fort in the

south of Kashmir, India, 25 miles north of Sialkot by rail (Map: India, C 2). It was the ancient capital of a Rajput kingdom, and it stands amid the Himalayas, on both banks of the Tavi, an affluent of the Chenab—the town on the right side and the fort on the left. Here are the palaces of the Maharajah and his kin, several temples, the Prince of Wales College, and the hospital. Jammu is the terminus of a branch railway, and the starting point of the busy trade route to Srinagar and the Kashmir valley. Jammu at the end of the eighteenth century was said to be a city of 150,000 inhabitants, but new trade routes have robbed it of its importance. Coal mines have been opened in the vicinity, and its prestige may return. Since 1889 a modern system yields a good water supply. Pop., 1901, 35,672; 1911, 31,726.

JAMNA, jüm'nà. A river of India. See **JUMNA**.

JAMNITZER. See **JAMITZER**.

JAMYN, zhä'män', **AMADIS** (c.1530-c.1593). A French poet, born at Chaource (Aube). He was made secretary at the court of Charles IX through the influence of Ronsard, and Sainte-Beuve says his friendship with this poet is his principal claim on our interest. He translated the last 12 books of the *Iliad*, a continuation of the work begun by Hugues Salel, and the first three books of the *Odyssey* (1574), and brought out two volumes of poetry, *Œuvres poétiques* (1575 and 1584). His poems were edited by Brunet, with a life by Colletet (Paris, 1879).

JAN, yän, **KARL VON** (1836-99). A German musical savant, born at Schweinfurt. Although his real profession was philology, he made a special study of the music of the ancient Greeks, and came to be one of the foremost scholars in this field. He began his career as a teacher at the Gymnasium in Berlin, but soon went to Landsberg, where he remained till 1875. From then until 1883 he was in Saargemünd. In that year he was appointed professor at the Lyceum of Strassburg, which position he retained till his death. The results of his researches he published in essays which appeared in various journals. Perhaps the most important of these is *Kitharodik*, giving entirely new and valuable information about the Greek kithara and lyre (1882). His principal work is *Musici Scriptores Græci* (1895), a critical text edition of all Greek writers on music, with an appendix, *Melodiarum Reliquiæ*, containing all known fragments of Greek music in notation (1899).

JANA. See **JANUS**.

JANAUSCHEK, yä'nou-shök, **FANNY**, or **FRANZISKA** (1830-1904). A well-known actress, born at Prague, Bohemia, July 20, 1830. From childhood she gave evidence of dramatic talent, and her first appearance was at her native place. After a successful experience at Cologne she became established as leading actress at Frankfort (1848), remaining till 1860, when she began a series of successful engagements in other German cities. In 1867 she came to America, playing in New York and elsewhere, in the German language. Resolved to play in English, she came again to America in 1873 and very effectively presented Medea, Lady Macbeth, Iphigenia, and other tragic parts. She extended her reputation by further tours in Europe and Australia, but finally settled in the United States, where she appeared in less classic representations, among them *Meg Merrilies* and *The Great Diamond Robbery* (1895-96). After

her retirement she took up her residence in Brooklyn, N. Y.

JANE EYRE, *âr.* A novel by Charlotte Brontë (Currer Bell) (1847). It is partly autobiographical, especially in the school life and early career of the heroine.

JANES, EDMUND STORER (1807-76). An American Methodist Episcopal bishop, born at Sheffield, Mass. He read law while teaching school (1824-30), but instead of becoming a lawyer entered the ministry, joining the Philadelphia conference of his church in 1830. In 1838 he was appointed financial agent of Dickinson College and in 1840 financial secretary of the American Bible Society. He was elected Bishop of the Methodist Episcopal church in 1844, when 37 years old. No other Bishop of the church has ever been elected at so early an age. At the time of his death he was the senior Bishop of the church, and president of the Missionary Society, of the Board of Church Extension, and of the Sunday School Union and Tract Society of the church. He was also one of the managers of the American Bible Society, a director of the American Colonization Society, and trustee of several institutions. After the Civil War he labored in the reconstruction of the work of the church and nation in the South. He represented the American Methodist church abroad in 1865. He died in New York City. Consult H. B. Ridgeway, *The Life of Edmund S. Janes* (New York, 1882).

JANE SHORE. 1. A tragedy by Chettle and Day (1603), founded on the story of the beautiful and unfortunate mistress of Edward IV. 2. A tragedy by Nicholas Rowe (1714), which was popular for a long time and furnished one of Mrs. Siddons's leading rôles.

JANESVILLE. A city and the county seat of Rock Co., Wis., 79 miles by rail west by south of Milwaukee, on the Rock River and on the Chicago and Northwestern and the Chicago, Milwaukee, and St. Paul railroads (Map: Wisconsin, E 6). It is built partly on level and partly on elevated ground and is the seat of the State School for the Blind. The public library, courthouse, city hall, high school, and Y. M. C. A. buildings are all worthy of mention. The city is the centre of a fertile agricultural region, has a considerable trade in tobacco, grain, and sugar beets, grown in the vicinity, and manufactures cotton and woolen goods, shoes, fountain pens, agricultural implements, furniture, barbed wire, carriages, and cement building products. Settled about 1837, Janesville was incorporated in 1853 and adopted the commission form of government in 1912. Pop., 1900, 13,185; 1910, 13,894; 1914 (U. S. est.), 14,195.

JANET, zhâ'nâ', PAUL (1823-99). A French philosophical writer, born in Paris and educated at the Ecole Normale. He was lecturer on philosophy at Bourges (1845-48), was then professor at the University of Strassburg until 1857, at the Lycée Louis le Grand in Paris, and in 1864-97 at the Sorbonne, succeeding Caro. He was elected a member of the Institute in 1864. In general he advocated the principles of Cousin. His peculiarity was a conciliatory method, seeing in various philosophic systems not oppositions, but mere developments of truth; but his eclecticism is very strongly affected by his spiritualistic bias. His numerous works include his *Histoire de la science politique dans ses rapports avec la morale* (1850, 1872); *La famille*:

Leçons de philosophie morale (1855), crowned by the Academy; *Philosophie du bonheur* (1862, 1873); *Le matérialisme contemporain en Allemagne* (1864); *Les problèmes du XIXème siècle* (1872, 1873); *Saint-Simon* (1872); *Les causes finales* (French, 1874; Eng., 1883); *Philosophie de la Révolution française* (1875); *Les maîtres de la pensée moderne* (1883); *Les origines du socialisme contemporain* (1883); *Victor Cousin et son œuvre* (1885); *La philosophie de Lamennais* (1890); *Fénelon* (1892); *Principes de métaphysique et de psychologie* (1896).

JANEWAY, EDWARD GAMALIEL (1841-1911). A distinguished American physician, born near New Brunswick, N. J. He graduated from Rutgers College in 1860 and from the College of Physicians and Surgeons, New York, in 1864, having served as acting medical cadet in the United States Army Hospital at Newark, N. J., from 1862 to 1863. He was on the resident staff of Charity Hospital, Blackwell's Island, New York (1864), and of Bellevue Hospital (1864-66), and then, establishing himself in private practice, soon became a consultant of eminence, especially in the diseases of the organs of the chest and abdomen. For several years, beginning in 1867, he was curator and pathologist to Bellevue Hospital. Janeway's career as a teacher of medicine began in 1872, when he was elected instructor in pathological anatomy in the medical department of New York University. In Bellevue Hospital Medical College he was professor of materia medica and therapeutics from 1873 to 1876, professor of pathological anatomy from 1876 to 1881, associate professor of the principles and practice of medicine from 1881 to 1884, and professor from 1884 to 1891. Six years later he resumed his connection with the college upon the adoption of the plan to consolidate it with the medical department of New York University, as University and Bellevue Hospital Medical College, becoming professor of clinical medicine and president of the faculty; later (1898-1905) he was dean, and after 1898 professor of medicine. He rendered important professional services as visiting or consulting physician to a number of New York hospitals and was president of the Pathological Society, the New York Academy of Medicine, and the Association of American Physicians (1900). From 1875 to 1881 he was commissioner of health of New York City.

JA'NI. See FORUM (at the beginning).

JANIC'ULUM, or MONS JANICULUS. A long ridge or hill on the west bank of the Tiber at Rome, rising to a height of about 300 feet above the sea. The name is derived by tradition from Janus, King of the aborigines, who founded a city on the hill opposite to the Capitoline, then occupied by Saturn. From its argillaceous formation it shares with the Vatican Hill the name of *monti della creta*. It was anciently called Mons Aureus, from the golden color of its sands, whence the modern name Montorio. The commanding position of the hill led to its early fortification by the kings of Rome; but it was not included in the city until the time of Augustus, who made it the fourteenth quarter, under the name of Regio Transtiberina, now Trastevere. In early times it was connected with the east bank only by the Sublician Bridge, which was supplemented in 181 B.C. by the Æmilian Bridge, and in 366 A.D. by the Bridge of Valentinian, represented by the modern Ponte Sisto. The hill commands a magnificent panoramic view of

Rome. Consult Richter, *Topographie der Stadt Rom* (2d ed., Munich, 1901), and Baedeker, *Central Italy and Rome* (15th Eng. ed., Leipzig, 1909).

JANIN, zhá'nǎn', JULES (1804-74). A French critic, born at Saint-Etienne, Feb. 16, 1804. Besides his journalistic cleverness, Janin was skillful as a novelist in knowing what the public would like next. He is perhaps the best representative of the individualistic vagaries of romanticism, both in his style and thought. His earlier novels are ultraromantic and trivial; the later ones, such as *La religieuse de Toulouse* (1850) or *Gaietés champêtres* (1851), are never natural, but often charming. His best journalistic papers, written for the *Journal des Débats*, are collected in a *Histoire de la littérature dramatique*. In 1870 he was elected to the French Academy. His *Œuvres choisies* (12 vols., 1875-78) were edited by A. de la Fitzelière.

JANINA, yá'ně-ná, or **YANINA**. A town of northwestern Greece, situated near the Albanian frontier, on the Lake of Janina (Map: Balkan Peninsula, C 5). Although the splendid buildings of the old city are now in a state of decline, there are still a number of mosques, churches, synagogues, a Greek gymnasium, a library, and a hospital. The chief manufactures are gold ware and silk goods. Pop. (est.), 22,000, including about 15,000 Greeks and about 2500 Jews. Janina is mentioned as early as the ninth century, when it formed a part of the Byzantine Empire. During the eleventh and twelfth centuries it was destroyed by the Normans and fell into the hands of Turkey in 1430, in whose possession it long remained, constituting the capital of the Vilayet of Janina. From 1788 to 1822 it was the seat of the famous Ali Pasha, "the Lion of Janina." On March 6, 1913, after undergoing a protracted siege, Janina was captured by the Greeks, and by the territorial settlements of that year, following the Balkan War (q.v.), especially by the treaties of London and Bucharest, was formally ceded to Greece.

JAN'IS, ELSIE (ELSIE JANIS BIERBOWER) (1889-). An American actress, born at Delaware, Franklin Co., Ohio. She first appeared on the stage at Columbus, Ohio, in 1897, and her first appearance in New York City was in 1900 on the vaudeville stage. She starred in *The Belle of New York* in 1904 and in *The Vanderbilt Cup* in 1906-07. Subsequently she played in *The Hoyden* (1907); *The Fair Co-ed* (1908-09); *The Slim Princess* (1910-11); a play written by herself, *A Star for a Night* (1911); *The Lady of the Slipper* (1913), in which she starred with Montgomery and Stone; *The Passing Show* (1914), in London.

JANITSCHKEK, yá'ně-chěk, HUBERT (1846-93). An Austrian art historian, born at Trop-pau, Silesia. He studied at the university at Graz from 1868 to 1873, then pursued art historical studies in Italy until 1877, when he was appointed custodian of the Austrian Museum of Art and Industry in Vienna. Afterward he became professor, successively, at the universities of Prague (1879), Strassburg (1881), and Leipzig (1891). His sound and scholarly researches in the history of Italian and German art resulted in the publication, among other works, of *Die Gesellschaft der Renaissance in Italien und die Kunst* (1879); *Zwei Studien zur Geschichte der karolingischen*

Malerei (1885); the important volume, *Geschichte der deutschen Malerei*, in Grote's *Geschichte der deutschen Kunst* (1890); *Dantes Kunstlehre und Giotto's Kunst* (1892); and a number of biographies of Italian masters in Dohme's *Kunst und Künstler*.—His wife, MARIA (1859-), a poet and novelist, was born in Vienna. After her husband's death she settled in Berlin and afterward at Rome and Munich. Among her principal works may be mentioned: *Im Kampf um die Zukunft* (1887), an epic poem; *Gesammelte Gedichte* (1892; new ed., 1910); *Aus alten Zeiten* (1900); and the novels and tales *Lichthungrige Leute* (1892), *Gott hat es gewollt* (1895), *Frauenkraft* (1900), *Harter Sieg* (1901), *Ein Stück modernen Lebens* (1903), *Irrende Liebe* (1909), and *Stille Gäste* (1912). Although not always true to nature, her writings attract by reason of their temperamental qualities and their sincere treatment of the problems of modern life.

JANIUAY, hä'ně-wí'. A town of Panay, Philippines, in the Province of Iloilo, situated in a beautiful valley among the mountains in the interior of the island, about 18 miles north-northwest of Iloilo (Map: Philippine Islands, D 5). Oil has been found in the neighborhood. It produces textiles of piña, silk, and cotton. Pop., 1903, 20,738. It was founded in 1578, under the name of Matagub. In 1903, after the census, Lubano (pop., 6661) was annexed.

JANIZARIES, jǎn'í-zâ-ríz, or **JAN'ISSA-RIES** (OF. *jannissaire*, Fr. *janissaire*, It. *gian-nizzero*, from Turk. *yeñieheri*, new troops, from *yeñi*, new + Ar. *askar*, army, soldier). A Turkish military force, first instituted by Orkhan (1326-59), the son and successor of Othman, the founder of the Ottoman Turkish Empire, who levied from the conquered Christian peoples a systematic tribute of young children. These tribute children, always the healthiest and strongest, were trained under Mohammedan tutelage, and, together with Christian captives taken in war and Turkish subjects attracted by the special privileges offered, constituted a special corps of picked troops, which was thus composed of many nationalities. In turn it became the bulwark of the Empire, and, like the Roman prætorians and Russian streltsi, assumed dictatorial power. The corps was more perfectly organized by Amurath I after 1360, when its strength was raised to about 12,000. After the sixteenth century the drafting of Christian children and captives ceased, and the corps was recruited by voluntary enlistment. There were two classes of janizaries—one a standing force, garrisoned in Constantinople and the chief towns and varying in number from 25,000 to 100,000; the other a trained militia known as jamaks, scattered throughout all the towns of the Empire and numbering from 300,000 to 400,000. The janizaries proper were divided into ortas, or regiments. At the head of the whole force was the aga, whose power extended to life and death, for the janizaries were always ready to break out into deeds of violence if their pay or perquisites were withheld. In times of peace they acted as a police force. They served on foot, generally formed the reserves of the Turkish army, and were noted for the wild impetuosity of their attack. The Sultan's bodyguard was formed of them. They became in the course of time very unruly, and their history abounds in conspiracies, assassinations of sultans, viziers, and agas, and

atrocities of every kind; so that by degrees they became more dangerous to the sultans than to foreign enemies. Attempts were made by several sultans to reform or dissolve the corps, but they were always unsuccessful. The reforms of Sultan Mahmud II (q.v.) were bitterly opposed by the janizaries, especially the reorganization of the army on the European model. This opposition broke forth in open revolt, and on June 15, 1825, Mahmud ordered the flag of the Prophet to be unrolled and the Faithful to be arrayed against the mutinous corps. The janizaries, deserted by their aga and other principal officers, were defeated, with the loss of 16,000 men; their barracks were burned and 6000 to 8000 of them were killed in the assault or perished in the flames. A proclamation of June 17, 1826, declared the janizary force dissolved. All opposition was drowned in bloodshed. Thousands were put to death, and more than 20,000 were banished. In the Imperial Museum at Constantinople are 150 life-size figures illustrating the appearance of these famous troops. Consult: M. d'Ohsson, *Tableaux de l'Empire Ottoman* (Paris, 1787-1820); Es'ad Effendi Essejjid Mehemed, *Précis historique de la destruction du corps des Janissaries par le Sultan Mahmoud en 1826* (ib., 1833); A. Djévad Bey, *Etat militaire Ottoman* (Constantinople, 1885); Heinrich Schwartz, "Die Janitscharen," in *Preussischen Jahrbuch*, vol. cxii (Berlin, 1903); Theodor Menzel, "Das Korps der Janitscharen," in *Beiträge Zur Kenntniss der Orients*, vol. i (ib., 1904).

JANIZARY MUSIC. A term applied to music produced by a combination of shrill wood wind and brass instruments, various kinds of drums, and triangles.

JANK, yänk, ANGELO (1868-). A German painter and illustrator. He was born in Munich and studied under Höcker and Löffitz at the Munich Academy, where he was appointed professor in 1907. His best-known paintings are hunting scenes, distinguished by broad brushwork and rhythmic movement, such as "The Hunt" and "The Horsewoman," exhibited in the Metropolitan Museum, New York, in 1909. Other works are "Hurdle Race" (Elberfeld Museum); "Mailed Defense," in the possession of the King of Italy; an equestrian portrait of the Duke of Saxe-Coburg-Gotha; "The Princess and the Swineherd" (Society of Historical Art, Munich). Jank became a contributor to the Munich paper *Jugend*, and his chromolithographs are popular throughout Germany. He was commissioned by the government to paint a large historical composition in the German Reichstag, and in 1905 received the great gold medal at Munich.

JANKÓ, yõp'kõ, PAUL VON (1856-). An Hungarian pianist and inventor of the Jankó keyboard. He was born at Totis, Hungary, and studied music at the Vienna Conservatory, the piano with Ehrlich in Berlin, and mathematics at the University of Berlin. Owing to the smallness of his hands, he had great trouble in playing music which involved octaves, and he turned his attention to constructing a keyboard which would obviate the difficulty. From 1886 to 1890 he made extensive concert tours to demonstrate his new invention. In 1892 he settled in Constantinople. See **JANKÓ KEYBOARD**.

JANKÓ KEYBOARD. A keyboard for the pianoforte invented by Paul von Jankó (q.v.)

in 1882. This was introduced to the English public in 1888 and in New York in October, 1890. The Jankó keyboard consists of six rows or banks of keys, placed in a semicircle and presenting a fanlike appearance. Each note has three different keys, one lower than the other and attached to a key lever, so that each key may be struck in three different rows. Six parallel rows of whole-tone intervals are thus produced. The keyboard slants, the keys are rounded on both sides, and the sharps and flats are distinguished by black bands. A freer use of the fingers is claimed than with the accepted keyboard. By reason of the many rows the hand can maintain its natural position with the long fingers on the upper notes and the shorter ones on the lower. All scales and chords have uniform fingering, the relative position being the same in all keys, and the only necessary change is to raise or lower the entire hand. The octave is brought within the stretch of the sixth on the ordinary keyboard, and half tones may be played legato with one finger. The new keyboard can be adapted to any pianoforte, grand, upright, or square, without harm to the instrument. Chromatic scales in thirds, sixths, and octaves can be executed with as much facility as the ordinary scale on the ordinary pianoforte, because one performer can produce effects that now are obtainable only in four-hand playing. Yet in spite of positive merits, the interest shown by some eminent pianists, and the foundation of a Jankó Society in Vienna in 1905, the new invention has not met with success.

JAN MAYEN (yän mī'en) ISLAND. A volcanic island in the Arctic Ocean, situated between lat. 70° 49' and 71° 9' N. and between long. 7° 53' and 9° 5' W., about 220 miles north-northeast of Iceland (Map: Arctic Regions, J 5). It is oblong in shape and has an area of about 160 square miles. The surface is generally mountainous and reaches in the extinct volcano, Beerenberg, in the north, an altitude of 6000 feet or more. There are some volcanoes on the island, Mount Beerenberg being the highest, and a number of glaciers. The mean annual temperature is somewhat less than 28° F. In the seventeenth century there were seven extensive summer colonies maintained on Jan Mayen for exploiting the valuable whaling fisheries around the island. At present it has no permanent population, but is occasionally visited by sealers and explorers. In 1882-83 Jan Mayen Island was the seat of the Austrian international polar station. Sighted by Hudson in 1607, the island was rediscovered in 1611 by Jan Mayen, after whom it is named. Consult: Wohlgemuth, *Oesterreichische Polarstation Jan Mayen* (Vienna, 1886); Ernesto Lyders y Stamm, *Derrotero de Islandia é instrucción náutica para la Isla Juan de Mayen* (Madrid, 1895); J. B. A. E. Charcot, "Une excursion à Jan-Mayen," in *Géographie*, vol. vi (Paris, 1902).

JANNARIS, yän'ná-rès, ANTHONY (1852-1909). A Cretan scholar and public official. He was head master of the public Gymnasium at Canea in 1883-85 and lectured at the University of Athens in 1889. For taking part in the Cretan insurrection in 1889 he was proscribed by the Sultan of Turkey and was obliged to flee to London, where he remained six years. When he returned to Crete, he was elected a member of the Assembly, was correspondent for the London

Times during the troubles of 1897, and in 1907 became inspector general of education. He compiled Greek grammars and dictionaries, wrote many books and reviews, and is author of Cretan folklore stories.

JANNES, jān'ēz, AND **JAMBRES**, jāmb'rēz, or, according to some authorities, **MAMBRES**. According to an apocryphal story, the names of two Egyptian magicians who withstood Moses (cf. Ex. vii. 11, etc.; 2 Tim. iii. 8). As the names seem to be Hebrew, the story was probably of Jewish origin. Its beginning was as early as the second century B.C., but it was constantly receiving additions until at last in both Jewish and Christian circles there was an extensive cycle of stories concerning these two men. In these Jannes and Jambres are represented as very skillful Egyptian magicians, who were able even to counteract the most severe of the plagues Moses brought upon Egypt. As demonic spirits, they continued their malignant activity against Israel during the wandering in the wilderness, but at last were destroyed through Phinehas' use of the Divine name. One story relates that Jannes died first and went to the deepest place of torment, whence his spirit addressed his brother Jambres, warning him to repent ere it was too late. According to Origen and the *Decretum Gelasii*, there was an apocryphal book of Jannes and Jambres. Origen supposed that Paul depended on this for the statement in 2 Timothy, though the Apostle may have alluded only to a well-known story for the sake of illustration without being acquainted with the book. Consult: Emile Schürer, *Geschichte des jüdischen Volkes*, vol. iii (4th ed., Leipzig, 1901-11); Kohler, in *The Jewish Encyclopædia*, vol. vii (New York, 1901-06); Max Förster, "Das lateinisch-altenglische Fragment der Apokryphe von Jannes und Mambres," in *Archiv für die Studium der neueren Sprachen und Litteratur*, vol. cviii (Brunswick, 1902).

JANNET, zhā'nā', **CLAUDIO** (1844-94). A French publicist, born in Paris. He studied for the bar and afterward became professor of political economy at the Catholic University of Paris. His works include: *De l'état présent et de l'avenir des associations coopératives* (1867); *L'Internationale et la question sociale* (1871); *Les institutions sociales et le droit civile à Sparte* (1874); *Les Etats-Unis contemporains* (1875; 4th ed., 1888), an important work; *Les sociétés secrètes* (1876); *Les pré-ecurseurs de la franemaçonnerie* (1887); *Le socialisme d'état et la réforme sociale* (1889); *Le capital, la spéculation et la finance au XIXème siècle* (1892). In theory Jannet was a disciple of Le Play.

JAN'NEY, SAMUEL MACPHERSON (1801-80). An American Quaker preacher, historical biographer, and poet, born in Loudoun Co., Va. He was a member of the Hicksite Society of Friends and served as a superintendent of Indian affairs in 1869. His publications in prose include: *Conversations on Religious Subjects* (1835); *Historical Sketch of the Christian Church* (1847); *Life of Penn* (1852); *Life of Fox* (1855); *History of the Religious Society of Friends from its Rise to 1828* (1867). His best-known writings in verse are *The Country School House* (1825) and *The Teacher's Gift* (1840).

JANOW, jā'nōv, **MATTHIAS VON** (?-1394). A Catholic prelate, often called a precursor of

Huss. Of his early history little is known. He was educated at the University of Prague and the University of Paris. Visiting Rome, he was appointed in 1381 canon and confessor in the cathedral of Prague and continued to perform the duties of the office until his death. In his book, *Regula Veteris et Novi Testamenti*, he alleges the corruption of the Church in all its parts and explains the causes of it. He advocated the removal of images from the churches, but never revolted from ecclesiastical authority. He died in 1394 and 16 years later his works were burned with those of Wiclif. Consult Lützow, *Life of John Hus* (New York, 1909).

JANS, yāns, **ANNEKE** OR **ANNETJE** (?-1663). An early Dutch colonist of New Netherland, famous because of lawsuits concerning her farm between her heirs and the corporation of Trinity Church, New York City. She emigrated from Holland to New Netherland with her husband, Roeloff Jansen, in 1630. In 1636 the latter obtained a grant of 62 acres of land on Manhattan Island, extending from the present Warren Street to the neighborhood of Desbrosses Street and lying between Broadway and the Hudson River. Soon afterward Jansen died, and she married the Dutch dominie Everardus Bogardus (q.v.). In 1654, after her husband's death, she secured a patent to the farm in her own name and later removed to Albany, where she died, leaving her property to be divided among her eight surviving children. After the English had taken possession, in 1664, all property holders were required to secure new titles for their lands. Accordingly the heirs secured a new patent for the farm from Governor Nicolls, on March 27, 1667. Four years later, March 9, 1671, the property was sold to Governor Lovelace, all of the heirs signing the deed of transfer except the wife and child of Cornelius Bogardus, a son of Anneke and her second husband, who had died in 1666. It is largely upon this omission that the subsequent suits have been based. Upon the recall of Governor Lovelace (q.v.) the government confiscated the Jans farm and subsequently granted it to Trinity Church by a patent sealed on Nov. 23, 1705. In 1749 Cornelius Brower, a descendant of the Cornelius Bogardus whose heirs had not signed, took forcible possession of a portion of the farm and on being evicted began an action against Trinity Church, which was decided against him. In 1757 he made another unsuccessful attempt. Another Cornelius Bogardus took possession of part of the estate in 1784 and held it until he was evicted by the courts in 1786. His son John brought suit in 1830 to secure one-thirtieth of the farm and a proportionate share of back rents. In order to secure the money necessary to carry on this suit, he sent circulars to all the descendants of Anneke Jans, asking them to contribute, which they did most liberally until 1847, when judgment was again given for the church. Since then several other suits have been brought by the heirs, but they have been uniformly decided in favor of the defendants. Consult: Nash, *Anneke Jans Bogardus: Her Farm, and how it Became the Property of Trinity Church, New York* (New York, 1896); *Sandford's Chaneery Reports*, vol. iv, pp. 633-672; Schuyler's *Colonial New York*, vol. ii; *Harper's Monthly Magazine* for May, 1885.

JANS, JANSEN ENIKEL, OR ENENKEL. An Austrian historian and poet of the thirteenth century. He wrote a rhymed *Weltehronik*, en-

tirely worthless as history, but containing many anecdotes and tales which give it a certain literary value (ed., by Strauch in *Monumenta Germaniæ Historica*, vol. ii, part i, 1891), and a *Fürstenbuch* (ed. by Rauch in *Scriptores Rerum Austriacarum*, vol. i, 1790), which, though equally unscientific, describes the reigns of the Austrian dukes Leopold VII and Frederick the Quarrelsome with a good deal of picturesqueness and vigor. Consult Scherer, *Litterarisches Centralblatt* (Leipzig, 1868).

JANSEN, yän'sen, OLAÜS (1714-78). A Swedish naturalist, born at Christianstad. He went to Germany for his education and was appointed professor at Tübingen University. Thence he went to a similar position at Copenhagen, and in 1764 he was ordered by the Danish government to make a study of the natural resources of South America; but his travels extended north to Central America and Florida. In 1772 he visited New England. His published works include: *Aanden i Naturvidenskaben og Naturens almindelige Lære* (1773); *Neue Reisen durch Brasilien und Peru* (1775); *Neue Reisen durch Louisiana und Nueva España* (1776); *Anmärkningar till Historia Naturalis och Klimatet i Nye England och Nye Spanien* (1778).

JANSENISM, jän'sen-iz'm. The name applied to the doctrines of a party in the Church of France which led to bitter controversies in the last half of the seventeenth and the beginning of the eighteenth century. It was a combination of three different tendencies. On the more abstruse theological side it derived from the doctrines of Jansenius, Bishop of Ypres, on the question of grace, and took its name from him; a second equally strong tendency carried the Jansenists into opposition to the current practice in regard to the sacraments and the spiritual life, as a consequence of the influence of the Abbé de Saint-Cyran; while a third characteristic was a spirit of opposition to the government which made them the legitimate heirs of the Fronde. The first two tendencies found determined opponents in the Jesuits, whose stand on the question of grace and whose practice in moral theology were attacked by them; and the third brought the leaders of the party into conflict with the absolute monarchy of Louis XIV.

The Reformation, with its special doctrines as to original sin and justification, had tended to recall attention to the difficult questions of grace and man's free will. Since the famous controversy in the fifth century between St. Augustine on one side and Pelagius and John Cassian on the other, the doctrines of the latter, who exaggerated the part played by the human will (see FREE WILL) at the expense of divine grace, had taken their place in the list of heresies, while that of St. Augustine had held the field. Adopted by St. Thomas Aquinas and the Dominicans in the thirteenth century, it was opposed to some extent by the Franciscan Duns Scotus and became a constant source of controversy between the two orders. In the sixteenth century the discussion became more violent, especially at the University of Louvain, where Michel de Bay, known as Bajus (q.v.), taught what professed to be the Augustinian doctrine, but was actually a violent exaggeration of it, not a little resembling that of Calvin. At the same time the University of Salamanca was agitated by cognate questions, and the theses of the Dominican Bañez and the Jesuit Molina arrayed

the orders against each other. Clement VIII established a special congregation, called De Auxiliis Gratiae, to consider these questions, but his successor, Paul V, finally, for the sake of peace, forbade the two parties to accuse each other of heresy, thus leaving the question, in a sense, open.

The publication, in 1640, of the *Augustinus* of Jansenius (q.v.) added new vigor to the controversy. Its theories about the relation of grace to human nature, singularly close to Calvin's views, were immediately attacked by the Jesuits. By the bull *In eminenti* of 1642, Urban VIII confirmed the prohibition of it by the Inquisition as contravening the decree of Paul V and as renewing some of the condemned propositions of Bajus. But this did not put an end to its influence. Jansenius' friend, Saint-Cyran, had succeeded in grouping around him at Port-Royal a community imbued with similar doctrines; it was small in numbers, but strong in personal character. Besides Antoine Arnauld, who became the leader of the party on Saint-Cyran's death in 1643, and others of his family, it included the learned Lemaître de Sacy, the moralist Nicole, the preacher Singlin, and Pascal. In 1643 Arnauld, in his book *De la fréquente communion*, attacked the practice of the Jesuits in regard to the sacraments; and later, Pascal, in his celebrated *Lettres à un provincial* (1656-57), with the most brilliant irony but with very little regard for the rules of fair controversy, made an onslaught on their moral theology. But the society pursued its end. It had a certain number of propositions from the *Augustinus* submitted to the theological faculty of Paris, and five of them were eventually presented to the holy see for judgment, by 88 bishops. By the bull *Cum occasione* of May 31, 1653, Innocent X declared these five heretical. They were as follows: 1. Certain commandments of God are impossible to just persons even desiring and endeavoring to keep them, according to the strength which they then possess; and such grace as would render them possible is lacking to them. 2. In the state of fallen nature internal grace is never resisted. 3. In order to merit and demerit in the state of fallen nature, freedom from necessity is not required of man, but it suffices that there be freedom from constraint. 4. The Semi-Pelagians admitted the necessity of internal prevenient grace for each separate act, and even for the beginning of faith; their heresy consisted in this, that they considered that grace to be such as the will of man might either resist or obey. 5. It is a Semi-Pelagian error to say that Christ died or shed His blood for all men absolutely.

The Jansenists attempted to evade the force of this bull by contending that the five propositions were not found in the *Augustinus*, or at least not in the sense in which they were condemned, and pointed out that papal infallibility (q.v.) did not extend to questions of fact; therefore, they maintained, the book was not really condemned. The propositions may not have been there—Louis XIV commissioned the Comte de Grammont to read the book and see if they were, and the witty courtier reported that, if they were, they were there incognito—but it was indisputable that they represented the very pith and marrow of the Jansenist position. Alexander VII renewed their condemnation, declaring expressly that they were found in the book, and condemned in the sense there

given to them. Later, he drew up a formulary to be signed by all the bishops and religious of France, in these terms: "I submit myself sincerely to the constitution of our holy Father Innocent X, and I condemn with heart and mouth the doctrine of the five propositions of Cornelius Jansenius, which the Pope and bishops have condemned—a doctrine which is not that of St. Augustine, whom Jansenius has ill explained, and is contrary to the true meaning of that great doctor." The community of Port-Royal refused to sign, in spite of Bossuet's persuasions and severe pressure from the government; and four bishops were willing to sign only with a reservation that they believed themselves to owe nothing more than "respectful silence" to a decision of the Church in matters of fact. They were about to be deposed, when Clement IX came to the pontifical throne in 1667. After complicated negotiations the new Pope managed to arrange a compromise (1668); and the cessation of hostilities, which lasted for 34 years, was known as the Clementine Peace.

During this period the Jansenists strengthened themselves in a number of dioceses and in some religious orders, insisting especially upon strictness in the administration of the sacraments. Their whole attitude, in fact, moral, dogmatic, and political, had many points of resemblance to that of the English Puritans of a generation earlier. On Arnauld's death, in 1694, the former Oratorian Quesnel (q.v.) succeeded to the leadership. The controversy once more revived in an acute form, with the celebrated "Case of Conscience," by which the Jansenists subtly endeavored to make their doctrines appear approved. Clement XI, however, reiterated the disapproval of his predecessors in 1703 and by the bull *Vineam Domini* of 1705. The French parlements, among the legal minds of which Jansenism found many supporters, refused to accept the brief *Universi Dominici* by which, in 1708, the Pope condemned Quesnel's *Réflexions morales*; and the weak character of Cardinal de Noailles, Archbishop of Paris, gave them courage. Louis, who persistently disliked them as preventing the realization of his ideal of perfect unity in church and state, asked the Pope definitely to put an end to these confusions. After two years' further investigation Clement XI issued the constitution *Unigenitus*, which condemned 101 propositions taken from Quesnel's works. Cardinal de Noailles and 15 other bishops made difficulties about its reception; the universities of Paris, Rheims, and Nantes declared against it; the parlements protected the Jansenists; and after the death of Louis XIV the Regent, the Duke of Orléans, took a dubious position. In 1717 Cardinal de Noailles appealed from the bull "to a better-advised Pope and a general council," and several bishops joined him, constituting the party of the Appellants. When he died, after making his submission, in 1729, they gradually lost strength, and not even the miracles supposed to have been wrought by the deacon Pâris (see CONVULSIONARIES) could restore them to their former position. Their spirit, however, remained active up to the Revolution and showed itself especially in the war against the Jesuits. It spread to some extent in Germany and Italy and had its influence on the ecclesiastical innovations proposed by the Emperor Joseph II.

As an organization, it was able to prolong its existence only in Holland, where, at the begin-

ning of the eighteenth century, a formal schism arose. In 1723 the chapter of Utrecht undertook to restore the extinct archbishopric of that city, and they have maintained a succession ever since, claiming this to be the Church of Holland and creating also bishops of Haarlem and Deventer. After the Vatican Council of 1870 they entered into relations with the Old Catholics (q.v.) and consecrated the first bishop of the new sect.

JANSENIIST. See JANSENISM.

JANSENIUS (Latinized form of JANSEN, Dutch pron. yän'sen), CORNELIUS (1585-1638). A Dutch theologian, who gave his name to the Jansenist school. He was born near Leerdam in the Netherlands and made his studies at Utrecht and Louvain, partly under the guidance of the Jesuits, whose society he thought of entering, but was discouraged by them. During his theological studies in the college founded at Louvain by Adrian VI he came under the influence of Jacobus Jansonius, an ardent supporter of Bajus (q.v.), and became intimate with Duvergier de Hauranne (q.v.), better known as the Abbé de Saint-Cyran, whom he followed to Paris and to Bayonne. He came back to Louvain in 1617 as head of the new Dutch College of St. Pulcheria, and acquired much influence as a teacher. In concert with Saint-Cyran he agitated reforms in the Church, especially in the administration of the sacraments, and a discussion of the doctrine of grace which was to have far-reaching consequences. In 1636, on the nomination of Philip IV of Spain, he was made Bishop of Ypres and died there two years later, in good standing and apparently unconscious of the results which were to follow the publication two years later of his great work, *Augustinus, seu Doctrina Sancti Augustini*. Consult Van den Peerenboom, *Cornelius Jansenius septième évêque d'Ypres, sa mort, son testament, ses épitaphes* (Bruges, 1882), and Callawaert and Nols, *Jansenius* (Louvain, 1893). See JANSENISM.

JANSON, yän'son, KRISTOFER NAGEL (1841-). A Norwegian novelist, born at Bergen. He studied theology at the University of Chris-

tiania and afterward interested himself in the advancement of popular education, improving his own by sojourns in Italy. From 1882 till 1892 he was minister to a Unitarian congregation of his countrymen in Minneapolis, Minn., and became editor of the Norwegian periodical, *Saamanden*, published there. He returned to Norway in 1892. Besides poems, his publications include numerous novels, such as: *Fraa Bygdom* (1866); *Han og ho* (1872); *Marit Skjölte* (1868); *Torgrim* (1872); *Fraa Dansketid* (1875); *Den Bergtekne* (1876), translated into English as *The Spell-Bound Fiddler*; *Gjorde hun ret?* (1910); the historical novels *Sara* (1891); *De Fredløse* (1894); *Liv* (1897); *Ensom* (1903); *Alv Pave* (1904); *Bondefortællinger* (1908); and various dramas, among them *En Kvindeskjæbne* (1878). A collection of his *Digte* was published in 1911.

JANSON, zhän'sôn', PAUL (1840-). A Belgian advocate and politician, born at Herstal. He first made himself conspicuous by his speeches on social reform topics delivered at the labor unions in Liège and elsewhere, and in 1877 he was sent to Parliament, where he went at once to the front as a debater, and the following year was made a member of the Liberal cabinet. Afterward he joined some deputies of the Extreme Left in the formation of a radical party, claiming an extension of the suffrage, thus making a split in the Liberals. They reunited in 1889, after M. Janson had been out of Parliament for five years, and he once more began to agitate for universal suffrage. His efforts were finally successful; in 1893 universal suffrage was established. In 1900, as member for Brussels, he reëntered the chamber, after an absence of six years, to take up the struggle for an equal suffrage, and he was active in the Congo debates in 1906. In August, 1912, he received the title of State Minister.

JANSSEN, jän'sen (or JANSEN, or JOHN-SON), CORNELIUS (1593-1664). An English portrait painter. He was probably born in London, and from 1618 was the fashionable portrait painter at court. His patronage declined after the arrival of Van Dyck, and during the Parliamentary wars he migrated to Holland. His portraits include those of Charles I, at Chatsworth; the Duke of Buckingham, at Welbeck Abbey; John Milton as a boy of 10, in private possession, London; "The Magistrates," Hague Museum. Other examples are in the museums of Dresden, Brunswick, Rotterdam, and Lille and in many English private collections. Jansen's portraits are distinguished by clear color, delicate touch, and careful finish, and by dark backgrounds that throw the flesh tints into high relief.

JANSSEN, yän'sen, JOHANNES (1829-91). A German historian. He was born at Xanten on the Rhine, was educated at the universities of Louvain, Bonn, and Berlin, and became a priest of the Roman Catholic church in 1860. He was also professor of history at the city Gymnasium in Frankfort-on-the-Main, and in 1880 became domestic prelate to the Pope. He was strongly ultramontane in his views. His historical works are as follows: *Frankreichs Rheingelüste* (1861; 2d ed., 1883); *Schiller als Historiker* (1863; 2d ed., 1879); *Zur Genesis der ersten Teilung Polens* (1865); *Gustav Adolph in Deutschland* (1865); *Frankfurts Reichskorrespondenz von 1376 bis 1519* (1863-66); *Zeit- und Lebensbilder* (1875; 3d ed., 1879); *Frie-*

drich Leopold, Graf zu Stolberg (1876-77; 2d ed., 1882). *Geschichte des deutschen Volkes seit dem Ausgang des Mittelalters* (1877-86), translated into English in 1905, is his principal work. Consult: Julius Köstlin, *Luther und Janssen* (Halle, 1883); Maximilian Lenz, *Janssens Geschichte des deutschen Volkes* (Munich, 1883); Ludwig Pastor, *J. Janssen* (5th ed., Freiburg, 1893); Mathieu Schwann, *Johannes Janssen und die Geschichte der deutschen Reformation* (Munich, 1892).

JANSSEN, PETER (1844-1908). A German historical painter. He was born at Düsseldorf, son of the engraver Theodor Janssen (1817-94), by whom he was first instructed before studying at the Academy under Karl Sohn and Bendemann. He is principally known through a series of decorative works whose monumental style and sound naturalism won him a reputation as one of the foremost historical painters of modern Germany. He became professor at the Düsseldorf Academy in 1877 and its director in 1895, and was elected a member of the Berlin Academy in 1885. His more important mural paintings include: "The Colonization of the Baltic Coast" (1872), in the Exchange at Bremen; "The Myth of Prometheus," in 12 compositions, in the second Cornelius Room of the National Gallery in Berlin; "Seven Momentous Episodes in the History of Erfurt" (1882), Town Hall, Erfurt; "Human Life," "Imagination," "Beauty," and "Nature," in the Aula of the Düsseldorf Academy. Of his oil paintings, the "Denial of Peter" is in the Academy at Philadelphia; the "Infancy of Bacchus" (1882) excited great admiration at the International Exhibition in Munich; and "Walther Dodde and the Peasants of Berg before the Battle of Worringen, 1288" (Düsseldorf Gallery), a composition of great dramatic power, containing many life-size figures, was awarded the great gold medal in Berlin in 1893.—His brother, KARL (1855-), a sculptor, born at Düsseldorf, was a pupil of the Academy in his native city, where, after studying at Rome, he was appointed professor in 1893. His chief works include the monument to the Kaiser at Düsseldorf, and "Woman Hewing Stone," in the National Gallery, Berlin.

JANSSEN, zhän'sän', PIERRE JULES CÉSAR (1824-1907). A French astronomer, born in Paris. Chosen to report upon natural phenomena in different parts of the globe, he went to Peru in 1857 to locate the magnetic equator, and to Italy (1861-64) to take observations of the solar spectrum. The thesis he wrote for his degree of doctor of science, *L'Absorption de la chaleur rayonnante obscure dans les milieux de l'œil*, made a sensation in 1860. For several years he made a specialty of sun eclipses, and in 1870 he escaped from besieged Paris in a balloon, so as not to miss the Algerian obscurity. As the result of his observations of the solar eclipse at Guntoor, India, in 1868, he announced, almost simultaneously with Lockyer and independently of him, that the solar prominences could be studied without a spectroscope, thus opening up a fruitful field of investigation. The year 1874 found him in Japan, watching the transit of Venus, and the following year he went as astronomer with the English expedition to Siam. In 1875 he was put in charge of the Meudon Observatory, which he had been instrumental in establishing and where he collected his solar photographs in his *Atlas de photographies solaires* (1904). In 1891 he began his

ascents of Mont Blanc, which resulted in the erection of the observatories there. He published volume i of the *Annales de l'observatoire de Meudon* (1896).

JANSSENS, ABRAHAM, called **JANSSENS VAN NUYSSEN**, yän'sëns vãn noi'sen (1575-1632). An eminent Flemish painter, born in Antwerp, where, at the age of 18, he became the pupil of Jan Snellinck. He was admitted as a master into the Guild of St. Luke in 1601, was its dean in 1606-07, and then visited Italy. A contemporary of Rubens, he ranks next to him among the Flemish masters of the seventeenth century, especially as a colorist, and occasionally surpasses him in the correct drawing of his figures. Torchlight and other artificial effects were treated by him with exceptional skill. Of his biblical, allegorical, and mythological subjects there are in the Antwerp Museum a "Madonna," an "Adoration of the Magi," and "Scaldis" (an allegorical representation of the river god of the Scheldt); in the Brussels Museum, "Old Age Resting on Faith and Hope"; in the Cassel Gallery, "Diana and Nymphs Watched by Satyrs"; in the Berlin Museum, "Vertumnus and Pomona" and "Meleager and Atalanta"; and in the Vienna Museum, "Venus and Adonis" and "Day and Night." His finest productions, however, are to be seen in the churches of Flanders, notably an "Entombment" and "Madonna with Saints," in the church of the Carmelites at Antwerp, and an "Ecce Homo" and "Descent from the Cross," in the cathedral of Saint-Bavon at Ghent.

JAN'UA'RIOUS, SAINT, or SAN GENNARO.

A martyr of the Christian faith under Diocletian, and patron saint of Naples. He was Bishop of Benevento, and according to the legend suffered martyrdom by beheading at Puteoli. His day is September 19. His body is preserved at Naples in the crypt of the cathedral, and in a chapel of the same church are also preserved the head of the martyr and two phials (*ampullæ*) said to contain his blood. This blood is affirmed to possess the property of becoming liquid when brought near the head. Should it fail to do so, the event is considered a bad omen by the people. The alleged miracle has commanded much interest, though the phials have never been opened for scientific examination. Consult Cavenne, *Le célèbre miracle de S. Janvier* (Paris, 1909), which, although somewhat uncritical, is a good account.

JANUARY. See MONTH.

JAN'US. An ancient and important Roman god, whose name was invoked at the beginning of all religious ceremonies. Regarding the etymology of the name and its original meaning, two theories are prominent. One considers it a formation from the root *dju*, *djav*, *djev*, by the addition of *-an*, *djav-an*; as we have *Zëvs* and *Záv* in Greek, so, in this view, we have *Iovis* and *Ianus* in Latin; but while in Greek the differentiation in form was not sufficient to lead to the growth of two separate divinities, among the Romans the separation was complete. He is thus the god of the light and heaven, a masculine counterpart to Diana (q.v.), a sun god according to some. This theory of the origin of the name Janus certainly agrees well with the high place of this deity among the gods and with many features of his cult. The other view connects the name of the god with *ianua* (Lat., house door from the street) and considers him as the god of the entrance and the door, whether

of city or house, as Vesta is the goddess of the hearth. This is in accordance with the nature of many Roman gods and explains the peculiar nature of the special shrine of Janus, the *ianus geminus* which formed an entrance to the Forum, at the northeast end. This shrine was simply two parallel arched gateways connected by side walls and furnished with gates. The tradition of later times declared that King Numa Pompilius had built the shrine and ordained that the gates should be closed only in time of peace, and that only once (in 235 B.C.) between Numa and Augustus, who closed them three times during his reign, had such a time been known. If the custom really existed from early times, its origin is probably to be sought in the belief that the Ianus Geminus was the entrance to the sacred hearth, the centre of the city, and that it would be a bad omen to close these gates upon the absent warriors. All doors and gateways were under Janus's protection. Janus is preëminently a god of the beginnings and was therefore invoked at the opening of each prayer. The beginning of the day was sacred to him. To him as well as to Juno offerings seem to have been made on the first day of each month, and his festival, the Agonium, on January 9, was the first of the Roman religious year. The *rex sacrorum* was the special priest of Janus and therefore stood at the head of the Roman priests. (For a different view of the *rex sacrorum*, consult Bessie R. Burchelt, "The Divine Character of the *Rex Sacrorum*," in the *Classical Weekly*, viii, 33-37.) The double-faced head of the god appears on the Roman *as* (q.v.) of the early coinage, and it is possible that this is the earliest representation of the god. In later times his image, with the double face, was set up under the arch in the Forum. Janus, though so ancient and important in the ritual, seems to have played but a small part in the popular religion; his cult is not proved to have existed in early times outside of Rome, and votive inscriptions in his honor are very rare. There are traces of a goddess JANA, the feminine parallel to Janus, but she never became prominent in the state religion. Some ancient authorities apply the name Janus to a King Janus who had a citadel on the Janiculum (q.v.). Consult: Linde, *De Jano Summo Romanorum Deo* (Lund, 1891); Fowler, *The Roman Festivals* (London, 1899); Wissowa, *Religion und Kultus der Römer* (2d ed., Munich, 1912).

JANUS GEM'INUS. See JANUS.

JANUS QUAD'RIFRONS, ARCH OF. An arched passage in the Forum Boarium (q.v.) at Rome. It has four façades and was surmounted by a second story, now destroyed. It is about 40 feet square and 50 feet high; the arches are 33 feet high and 17 wide. Its erection is assigned to the time of Constantine, and it appears to have served as a sort of exchange.

JANVIER, jän'vî-â, MARGARET THOMSON. See JANVIER, THOMAS ALLIBONE.

JANVIER, THOMAS ALLIBONE (1849-1913). An American story-writer and historian, born in Philadelphia, of Provençal descent. With a public-school education he began newspaper work in his native city in 1870 and continued it till 1881. In 1878 he married Catharine Ann Drinker, a lady of literary interests and ability. He spent several years in Colorado and in New and old Mexico, sojourns which provided inspiration and material for much of his literary work. From 1884 to 1894 he lived in the Wash-

ington Square district of New York, for three years was in Provence, and for another three in England. The fruit of his residence in New York was his *Color Studies* (1885), skillfully and charmingly written tales of artist life, originally published in magazines as the "Ivory Black Stories." In France, Janvier became a warm friend of Mistral and was made an honorary member of the Félibrige society. Besides *Color Studies* he wrote: *The Mexican Guide* (1886); *The Aztec Treasure House* (1890); *Stories of Old New Spain* (1891); *The Uncle of an Angel, and Other Stories* (1891); *An Embassy to Provence* (1893); *In Old New York* (1894); *The Women's Conquest of New York* (1894), in which the suffrage movement is fictitiously presented; *In the Sargasso Sea* (1898); *The Passing of Thomas, and Other Stories* (1900); *In Great Waters* (1901); *The Christmas Kalends of Provence* (1902); *The Dutch Founding of New York* (1903); *Legends of the City of Mexico* (1910); *From the South of France* (1912), short stories; *At the Casa Napoleon* (1914), which contains a memoir by Ripley Hitchcock.

Janvier's sister, MARGARET THOMSON JANVIER (1844-1913), was born in New Orleans. Under the pen name Margaret Vandergrift she wrote many juveniles, among which are to be noted: *The Absent-Minded Fairy, and Other Verses* (1884); *The Dead Doll, and Other Verses* (1900); *Under the Dog-Star* (1900); *Umbrellas to Mend* (1905).

JA'OK (name among the Kamchadales). A large, edible sculpin (*Myoxocephalus jaok*), which is one of the most characteristic and useful fishes of both shores of Bering Sea. It is about 2 feet long, reddish above and white beneath. It is very active, has extraordinary tenacity of life, and is extensively caught and smoke cured by the Kamchadales, who call it jaok, and Koriaks, whose name for it is i laal, while the coast Russians call it ramsha.

JAPAN', in Japanese **NIPPON'**, or **NIHON'**. An empire consisting of a chain of islands lying along the east coast of Asia and extending from lat. 21° 45' N. to 50° 56' N. and from long. 119° 18' to 156° 32' E. It is separated from the Philippines by Bashi Channel; from China by Formosa Channel, 70 to 100 miles wide; from Korea by Broughton Channel, less than 25 miles in width; from the Russian portion of the island of Sakhalin by the fiftieth parallel, N. lat.; and from Kamchatka by the Kurile Strait; while the wide, somewhat secluded Sea of Japan lies in the embrace of the main island and Yezo, on the south and east, and of the east coast of Korea and the maritime province of Siberian Manchuria on the west and north.

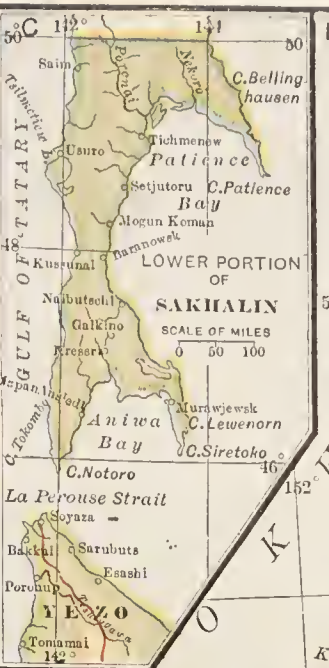

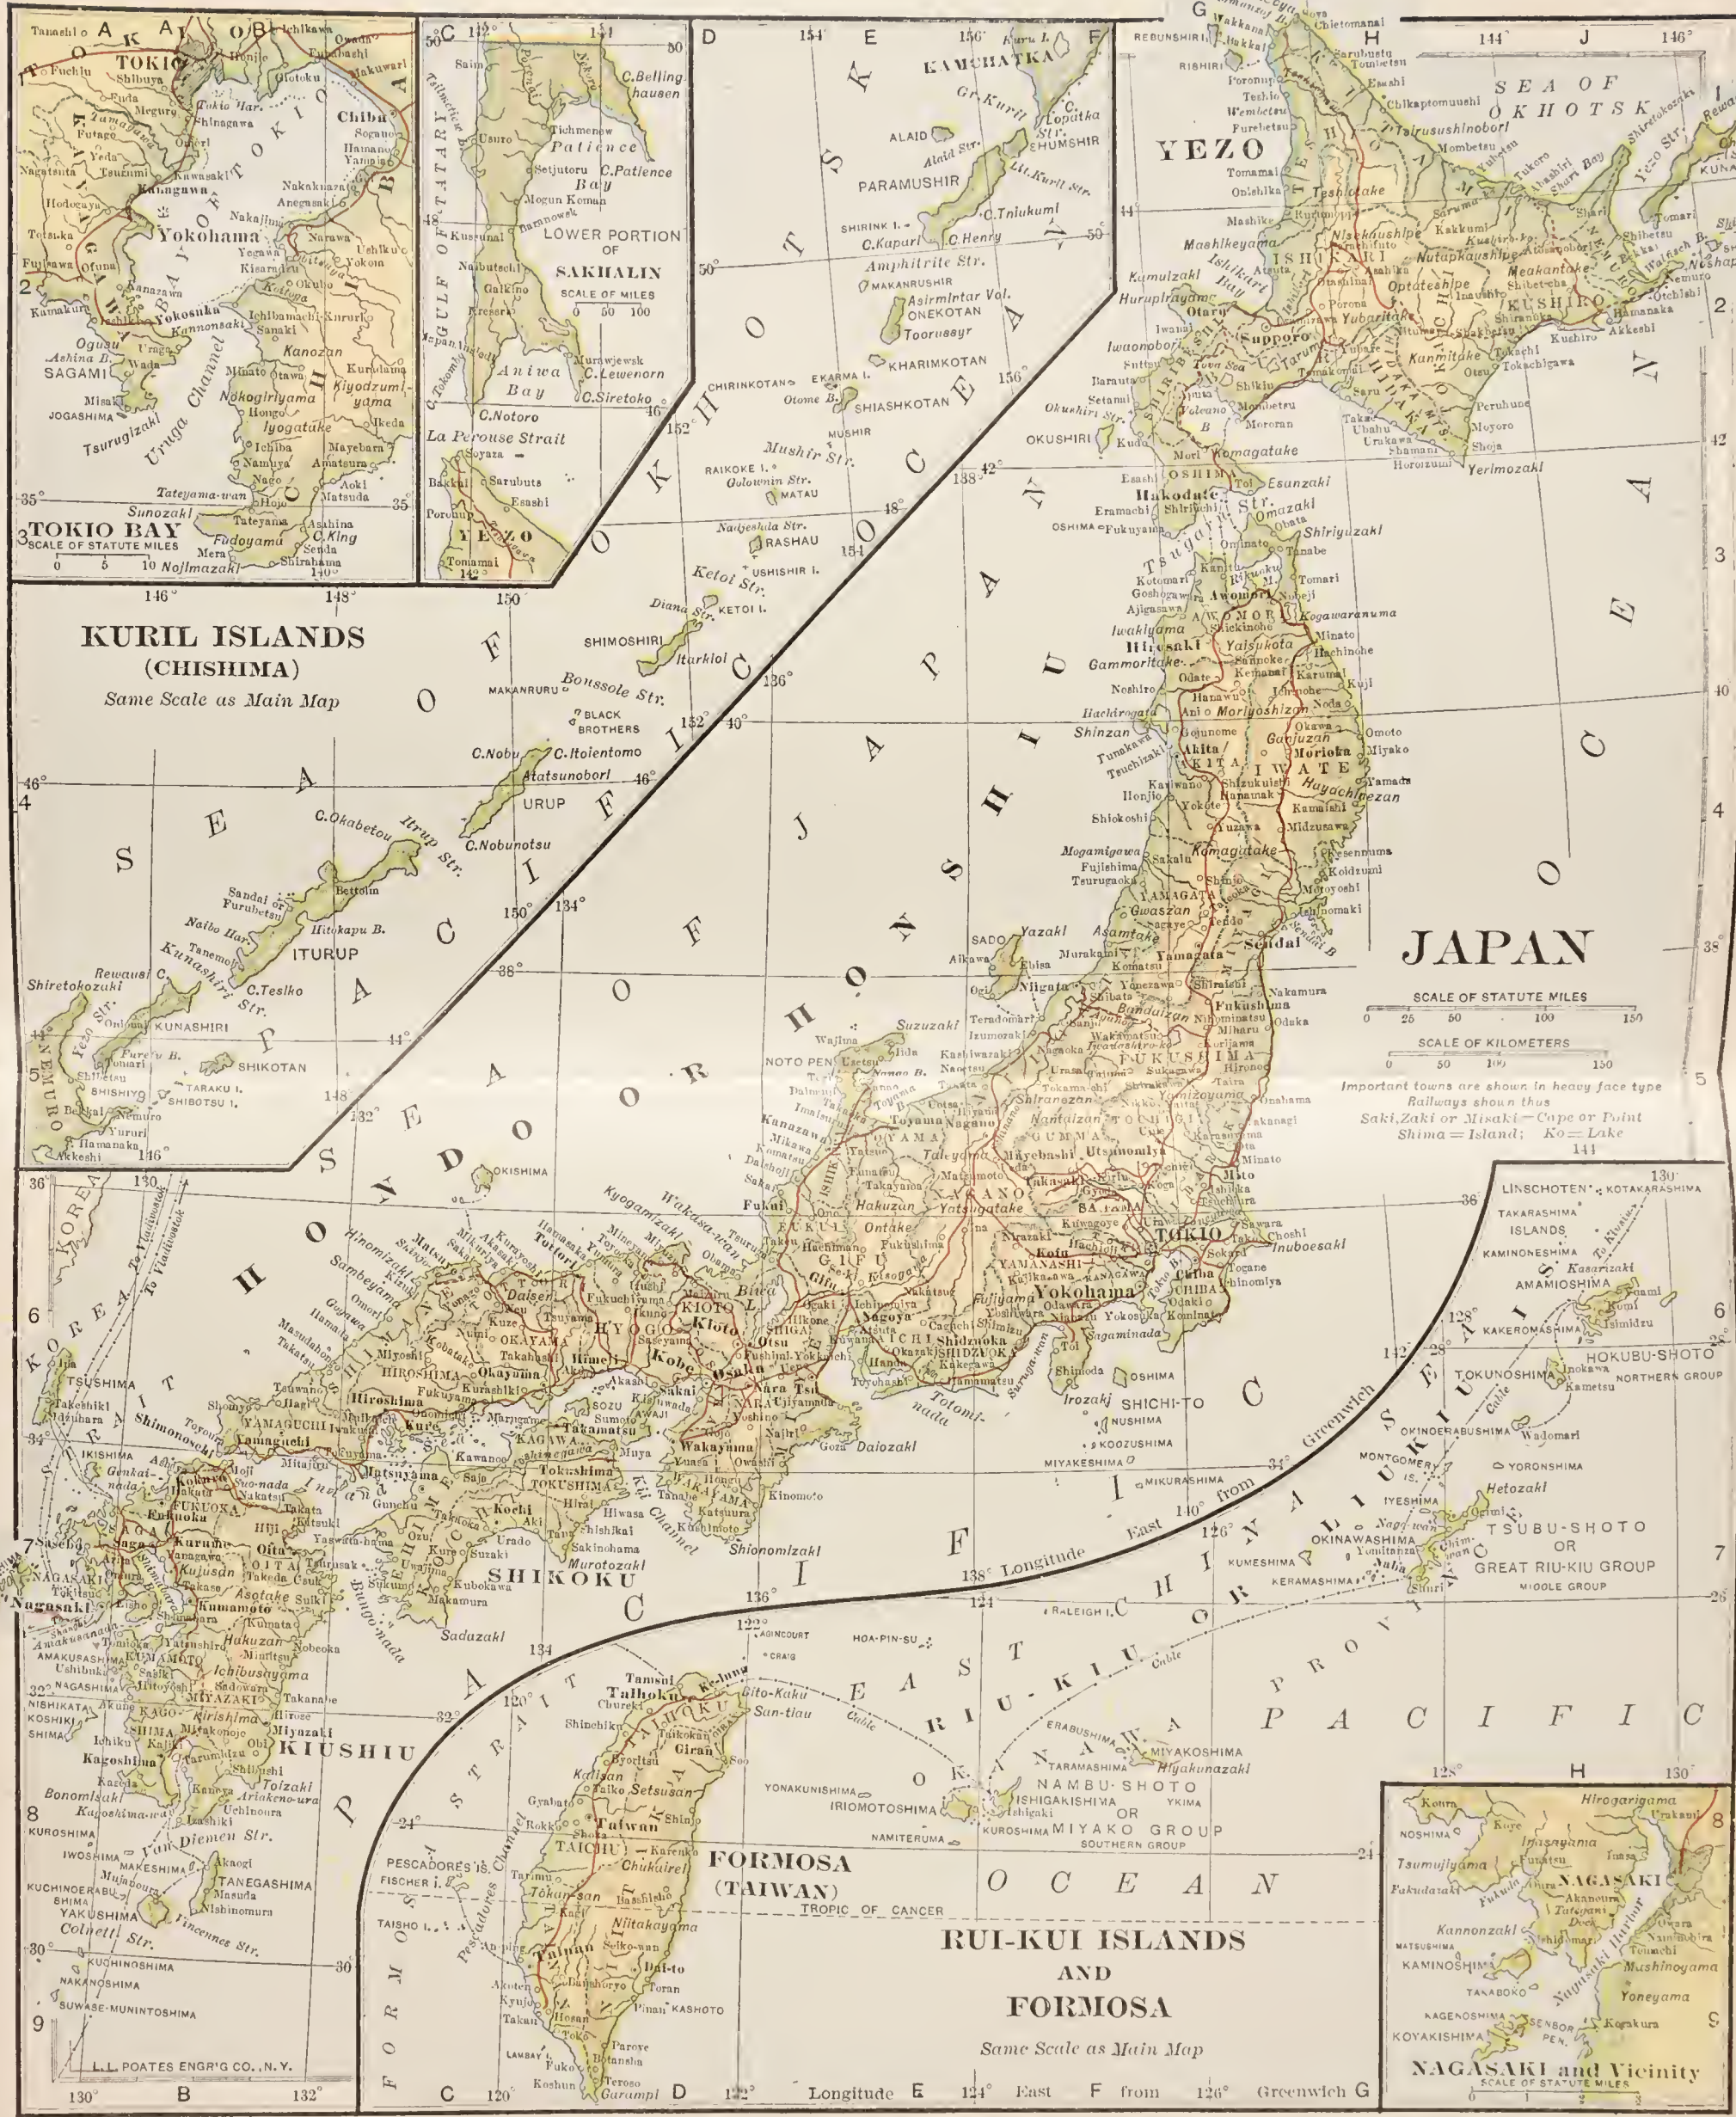

Japan is the name by which the country is known to foreigners, but in Japan itself Nippon or Nihon is used, sometimes with the syllable Dai (great) prefixed and occasionally Te Kokū (empire, or imperial) suffixed to it, so that in its most expanded form the name is Dai Nippon (or Nihon) Te Kokū (i.e., the empire of great Japan). The name Nihon seems to have been adopted about the year 670. Down to that time Yamato was the name, from the province adjoining Kyoto, in which Jimmu Tenno (660 B.C.) and the early mikados ruled. The Chinese have long known the country as Jih-pun-Kwoh, (sun-origin kingdom).

The islands of which the Empire is composed are said to number nearly 4000, but of these

only about 500 are inhabited or have a coast line of over one *ri*, or about 2.44 miles. The remaining islands are mere rocks, sometimes covered with vegetation, as, e.g., the 808 tiny islets of the Bay of Sendai, collectively known as Matsushima, or Pine Islands. The chief islands are five in number: 1. The Hondo, or Main Island, sometimes also designated as Honshu, or the Mainland, and formerly but incorrectly named Nippon, a name which can be applied only to the whole country. With its adjacent small islands, it has an area of 87,426 square miles. In shape it is an irregular crescent, its concave side forming the southeast boundary of the Sea of Japan. Its greatest breadth is less than 200 miles. It is separated from Yezo, on the north, by Tsugaru Strait, 10 miles in width (through which runs a strong current from the Sea of Japan), and from the eastern part of Shikoku, on the southwest, by Kii Channel. 2. Shikoku, with an area of 7083 square miles, lying south of the western part of Hondo, and separated from it by the beautiful landlocked but shallow channel, studded with islets, known to foreigners as the Inland Sea, but to the Japanese by different names in different parts of the length. 3. Kiushu, with an area of 15,703 square miles, separated by the narrow Strait of Shimonoseki from the western point of Hondo, and lying to the west of Shikoku, from which it is divided by Bungo Channel. 4. Yezo, an irregular four-cornered island, with an area of 36,570 square miles, including the Kurile Islands, lying north of the main island, with one long arm or corner stretching north to Siberia and one reaching northeast to the Kurile Islands. 5. Formosa (q.v.), with an area of 13,944 square miles, lying off the coast of China. The other considerable islands or groups of islands are Sado and Oki, in the Sea of Japan, with a combined

LL. POATES ENGR'G CO., N. Y.

The first three of the large islands, viz., Hondo, Shikoku, and Kiushu, with their adjacent islands, together with Sado, Oki, Awaji, Iki, and Tsushima, with their adjacent islands, constitute Oyashima, or Old Japan. With the 55 islands of the Loo-choo group and the 20 of the Bonin group added, there is formed Japan proper—Yezo, with its 12 adjacent islands, the 32 islands of the Kurile group, Formosa, the Pescadores, and Korea, with their numerous adjacent islands, being regarded merely as colonial possessions.

The preceding table shows the different constituent members of the Empire—the chief islands with the number of adjacent islands, the length of coast line of the various groups, and their area in square miles.

Topography. Japan is a land of high mountains and deep valleys, with many small plains. Its scenery is, in the main, pleasing rather than grand or sublime, rounded heights clad with forests, or with the verdure of a remarkably luxuriant vegetation predominating, though a large number of lofty, more or less shattered and craggy volcanic peaks are found.

The level land lies chiefly along the lower courses of the principal rivers, or consists of small extents of coast lowlands or coastal plains, or of plateaus and gentle slopes along the feet of the mountain ranges. The most extensive plains are those which border the Ishikari and Tokachi rivers in Yezo or stretch along the seashore at Kushiro and Nemuro. In the northeast section of Hondo is the Oshu plateau, watered by the swift-flowing Kitakami and extending over portions of four provinces. In the central region is that of the Tonegawa, or plain of the Kwanto, which spreads into the provinces of Musashi, Kodzuke, Hitachi, and Shimosa. Next comes the Kisogawa, which forms part of Mino and Owari. The most extensive of the littoral plains is found in Echigo, along the lower waters of the Shinano River. In the Five Home Provinces are several comparatively wide plains along the Yodo and Yamato rivers and their feeders, while in Shikoku flat lands lie along the Yoshino River and in Kiushu along the Chikugo. In Formosa a plain 20 miles wide, expanding towards the south, lies between the mountains and the western coast.

In general, the mountains follow the trend of the land itself, and the main chains send off various smaller ranges which run parallel or branch out from them, often descending to the sea and forming bays and harbors capable of sheltering large ships. It is at these points that the greatest mountain masses and the most imposing scenery are found. In Formosa, also, the great backbone of the island extends from north to south, several of its peaks exceeding in height those of Japan proper. Beginning with the volcanic elevations of the Kurile group, which form a line of 32 stepping stones from Kamchatka to the island of Yezo, a range of trachytic and basaltic rocks is intersected near the centre of Yezo by a loftier and more massive chain composed of granite and old schists, from Cape Soya on the north (a continuation of the Sakhalin system), the highest peak of which is the Tokachi, with an elevation of 8200 feet. Farther on towards the southwest this volcanic Kurilian Range merges into the west coast range from Cape Soya and is marked by some remarkable volcanoes, the most noted though not the highest of which is

Koma-ga-take, or Foal Mountain (a name of common occurrence in Japan), with a height of nearly 4000 feet. Branching into two lines after the long western arm of the island rounds Volcano Bay, these mountains reappear on the main island in two parallel chains. One, the northern schist range, separates the valley of the Kitakami River from the Pacific; the other, the main chain, continues towards the southwest, forms the backbone of the island until it meets the great complex of massive intersecting ridges which inclose the plateau of Shinano (2550 feet above the sea), and occupies the central portion of the main island where it is widest. It sends out important branches and continuations southeast through the Hakone Range into Idzu; southwest through Yamato and Shikoku to Kiushu; and westerly through the centre of Chugoku to Shimonoseki, forming in its course the dividing line between the group of provinces known as San-yo-do and that called San-in-do.

In this central mountain mass, which covers the provinces of Kaga, Ecchu, Hida, Shinshu, Kosshu, and part of Kodzuke, are found the loftiest peaks of Japan proper. They also offer the grandest scenery and hence are frequently called the Japanese Alps. The principal summits are Haku-san in Kaga, an extinct volcano, with a height of 8920 feet; Yari-ga-take, 10,000 feet, in Hida; Gohonsha, the highest peak of the Tate-yama Range, 9500 feet; Koma-ga-take, 10,384 feet; and scores of others. Farther north in the Nikko Range of Shimotsuke is Shirane-san, 8580 feet; Nantai-san, 8150 feet; and others, each as a rule sacred to some deity and consequently much visited by pilgrims. Snow covers most of them in winter, but, except in a few cases, as, e.g., Haku-san and the peaks of the great mountain masses of Shinano and Hida, it disappears before the end of summer. The Fuji Range is the most noted of the Japanese mountains, and Fujiyama, "the Peerless," 12,395 feet, the highest peak on the islands, is not far from Tokyo. The remarkable grace of the mountain has given it an eminent place in Japanese decorative art. About its base the land is cultivated up to 1500 feet, from this point a grassy moorland extends to 4000 feet, then forests to 8000 feet, and above this is a wide stretch of old ejected lava and ash. Even on Fujiyama only patches of snow remain from year to year. The *toge*, or passes, by which these mountains are crossed are comparatively low, owing to the fact, as Rein points out, that (1) the mountain masses of primitive crystalline rocks and schists do not rise very high, and that (2) the volcanic formations, which have in so many places burst through and overlain them, seldom form long or very high ridges.

It is said that there are in Japan, which is of volcanic origin, 170 volcanoes, most of them, however, regarded as extinct, some merely quiescent, but scores still active, sending forth smoke and steam, or serving as landmarks at night by their fiery glow. Among the more famous volcanoes still reckoned as active are Asama-yama, in Shinano; Koma-ga-take and several others, in Yezo; Chacha-take, in one of the Kuriles; Shirane-yama, in the Nikko Range; Mihara-yama, on Oshima or Vries Island, one of the Seven Islands, lying off the promontory of Idzu; and Suwa-shima in Loo-choo. As late as 1888 Bandai-san (q.v.) was in a state of violent eruption. On Jan. 11, 1914, the volcano

of Sakur-shima on the island of Kiushu after a quiescent period of 130 years broke out violently and thousands of lives were lost. Earthquakes are of frequent occurrence, and even in comparatively recent times some have been very disastrous. The line of greatest seismic disturbance extends from Loo-choo through Kiushu to the northeast. On Oct. 28, 1891, occurred an earthquake, felt in six provinces; 7279 persons lost their lives, 17,393 were injured, and over 200,000 buildings were utterly destroyed.

Thermal springs and solfataras, some of them with curative properties, are exceedingly numerous. In Japan proper, the former, chiefly sulphur, are said to occur in 388 different localities, and almost all are much patronized by the natives. The chief are Kusatsu and Ikao, in Kodzuke; Yumoto, at the foot of Shiraneyama, in the Nikko Range; and Enoyu, on Kirishima-yama, in Kiushu. Chalybeate springs, both hot and cold, are also found. The solfataras are well exemplified by the O-jigoku and Ko-jigoku, or Great and Little Hells, of the Hakone Range.

Hydrography. Owing to the mountainous character of the country and the narrowness of the islands, Japan cannot boast of long rivers, no part being farther distant from the sea than about 100 miles. Yet the country is abundantly watered. Every valley has its stream or its streamlet, and one of the chief charms of the scenery is the rush of the numerous waters, and the beauty of its waterfalls, while the swiftness and torrential character of many of the streams cutting their way through deep rocky gorges, present grave problems to the engineer engaged in railway construction or bridge building. The largest river in the Empire is the Ishikari, in Yezo, which flows into the Sea of Japan, after a course of 275 miles. On the main island the three great *kawa*, or rivers, are the Shinanogawa, the Tonegawa, and the Kisogawa. The Shinano rises in the province of that name, has a course of 215 miles, and flows northwest into the Sea of Japan. The Kitakami, in the northeast, has a course of 146 miles and flows southeast into the Bay of Sendai. The Tonegawa rises in Kodzuke, traverses the plain of Kwanto, and enters the Pacific near Tokyo, after a course of 177 miles. The third great river is the Kisogawa, which pursues a devious course from Shinano and falls into the Pacific. Another important river is the Ten-riu, which rises in Lake Suwa and flows south for 135 miles to the Pacific. Other rivers are the Sumida, flowing through Tokyo into the Gulf of Tokyo, and the Yodogawa, the outlet of Lake Biwa, which enters Osaka Bay. They are all swift, and spread out greatly when they leave the mountains. The streams are rarely navigable for any but the smallest vessels, being very shallow for most of the year; in late summer the torrential rains cause them to rise 15 feet or more, and they become impetuous.

Japan has many lakes, more remarkable for their beauty than their size. Several shallow sheets of water are found in Yezo, and along both the east and the west sides of Hondo or Main Island, but they are of little consequence as lakes and have little beauty. The largest and most noted is Lake Omi, better known as Biwa-ko (ko = lake) from a fancied resemblance in shape to the Chinese guitar (*p'i-pa*). It lies in the centre of the Province of Omi, at no great distance from Kyoto (q.v.), and is much

visited by tourists on account of its "Eight Beauties." It is 37 miles long and 12 miles wide at the widest part and has an area nearly equal to that of Lake Geneva in Switzerland. Northeast of this, in the Province of Shinano, is Suwa Lake, the source of the Ten-riu-gawa, 2600 feet above the level of the sea. In winter it is covered with ice more than a foot thick. Farther north, in the Nikko Mountains, is the beautiful Chuzenji, at the foot of Nantai-san, with an area of nearly 18 square miles, being the highest lake in Japan, 4375 feet above sea level. It is of great depth and contains no fish. Farther north still is Inawashiro, near Bandai-san, with an area of perhaps 90 square miles, and situated about 1840 feet above sea level. It abounds in fish and is said never to be frozen over. Its outlet is the Ikano-gawa, which falls into the Sea of Japan near Niigata. Another well-known lake is that of Hakone, about 50 miles west of Yokohama. It is said to fill the crater of an ancient volcano, at an elevation of 2300 feet above sea level. It is about 10 miles long and is of unknown depth. Its outlet is the Haya-gawa, and by a tunnel at one end it supplies water for irrigating the rice fields of 17 villages on the plain to the west.

Climate. Stretching as the Empire does through nearly 30 degrees of latitude, climatic conditions vary widely in different parts. In the Loo-choo group subtropical conditions prevail; the heat is great, and snow and ice are never seen. In the Kurile Islands, on the other hand, snow and ice never entirely disappear, the sea freezes over in winter, and it is sometimes possible to pass from one island to another on the ice. Omitting Loo-choo, the Bonin Islands, and Formosa, there is scarcely a part of the country that is entirely free from snow in winter. It is heaviest in Yezo and along that part of the main island which lies between the great mountains (which form its backbone) and the Sea of Japan; and so deeply does it cover the country that in many places, especially north of the Shinano, Hida Range, the inhabitants have recourse to continuous porticoes or snow sheds along the streets to afford passageway. To the south and east of this region the snow is somewhat less heavy, and the winter is milder, owing to the influence of the warm current known as the Kuro Shiwo (q.v.). Seldom does more than a few inches of snow fall in Tokyo and Yokohama, though Fujiyama, only 60 miles distant, is covered to its base. The winter temperature hardly ever goes below 22° F., and there are not more than three or four frosty days during the whole winter. Kiushu, Shikoku, San-yo-do, and Tokaido are warm, and snow seldom lies except on the higher mountains. The wind is northerly and dry and the air bracing. The exceptional conditions which prevail in Yezo are due largely to the cold current—the Oyashiwo—and to the strong northeast winds which sweep down upon it from the ice fields of Siberia.

The southwest monsoon brings with it a hot, moist summer. The rainfall is great, and the heat is considerable, much greater than in corresponding latitudes in Europe and America. The rainfall is heaviest in June and September. During September, at the end of the summer heat, tropical cyclones, called typhoons, occur and cause great damage to property, especially to shipping. The annual fall in Yokohama is

about 70 inches; in Nagasaki, 71½; in Tokyo, 65.4; in Hakodate it is only 57.2. It is the great humidity which some of these figures imply, coupled with a temperature which may rise, though rarely, in summer to 95° F. as in Tokyo and Yokohama, that causes so much discomfort and sends to the mountain all who can get away. Yet, as compared with many places on the mainland of China, Japan is a very pleasant summering place. There is a well-equipped and well-managed weather bureau, with many meteorological stations.

Flora. The flora of Japan is exceedingly rich in variety, and its luxuriance is in keeping with the warmth and the moisture of the Japanese summer. In 1876 Franchet and Savatier enumerated no fewer than 2743 species of phanerogamous and the higher cryptogamous plants, distributed among 1035 genera. Since then the number has been increased to over 3000. The ferns are represented by 43 species, the sedge family by 168, and the Ericaceæ by 76. In the plains one meets with pimpernel, the lily of the valley, bluebells, eyebright, various kinds of violets, the gladiolus, or sword lily, and many species of iris, hemerocallis, etc., as well as the characteristically Japanese *Lespedeza striata*, or Japan clover, with its minute purple flower, now well known throughout the southern part of the United States, having been introduced accidentally about 1840, perhaps in tea chests. In April the hillsides of Japan are ablaze with azaleas.

Among trees, evergreens, of which there are said to be 150 varieties, predominate. Savatier enumerates 41 species of Coniferæ alone. One of the most characteristic of Japanese trees is the sugi, or Japanese cedar (*Cryptomeria japonica*), which sometimes attains a height of 150 feet. It is a favorite in temple grounds and is frequently seen lining the highways, but more particularly the approaches to some sacred place, as along the great avenue (nearly 50 miles in length) leading to the tomb of Iyeyasu at Nikko (q.v.). Another beautiful temple tree is the icho (*Salisburia adiantifolia*), or maiden-hair tree. A fine specimen, said to be 1000 years old, stands near the entrance to the temple of Hachiman at Kamakura.

The cypress and the yew, firs of different kinds, the box, the holly, and the myrtle abound. The mulberry tree, the tea plant, the lacquer tree (*Rhus vernicifera*), the camphor tree, and many species of bamboo not only add to the beauty of the landscape, but are of great economic value. Among deciduous trees are the oak (20 species), the maple (24 species), beeches, alders, the ash, the horsechestnut, the birch, and 17 species of willow. The hinoki, or fire cypress, is much prized in the making of lacquer ware; the keyaki, or Japanese elm (*Planera japonica*), in cabinetwork; and the box for combs. The hajimo-ki, or wax tree, grows profusely on the hillsides and round the edges of the cultivated fields in Kiushu, and the coco tree, the banyan tree, and the banana flourish in Loo-choo and the Bonins. The bud and leaves of the ornamental kiri, or *Paulownia imperialis*, form the badge of the Mikado. Among the climbing and twining plants are the *Hydrangea cordifolia*, several species of climbing magnolia, whose coils run from right to left, the *Akebia quinata*, the *Clematis japonica*, and the wistaria, which blossom in June. The plum blossoms in February; the cherry in April.

The tree peony flowers about the first of May, lotuses fill the castle moats and canals in August, and in November the chrysanthemum is the occasion of perhaps the greatest of the Japanese flower festivals. Of the fruits the grape is the best, and those from the Province of Kai are most esteemed. (See KOFU.) The kaki, or persimmon, is a very luscious fruit, and the oranges are the most characteristic of Japanese fruits. The pear, apple, peach, and fig are mostly of inferior value. All attempts at introducing English and other pears have invariably proved unsuccessful; but the apple is now cultivated with good results in Yezo. The strawberry has been successfully introduced. The loquat comes in April.

Fauna. This is not so rich as the flora, yet the country can boast of at least 150 species of mammals, 359 of birds, 300 of reptiles and batrachians, a great number of kinds of fishes, of which 358 species were described by Siebold. Also over 1200 species of mollusca are mentioned in the books; and, according to the best authorities, 26 kinds of sea urchins and 12 species of starfishes are found. At the head of the mammals stands the red-cheeked saru, or monkey (*Inuus speciosus*), which lends its name as a qualifier to the name of many a place and plant, and whose flesh is esteemed a delicacy. The saru is sometimes found as far north as the forty-first parallel of latitude, where in winter snow often lies 15 to 20 feet deep, and the thermometer registers many degrees below zero. Among the 10 species of cheiroptera peculiar to the country are several bats, and of the insect eaters are the mogura, or Japanese mole, and several kinds of shrew mouse. The hedgehog is unknown. The carnivora include three species of bear—the common black bear (*Ursus japonicus*), the red bear, also called the great bear (*Ursus ferox*), much revered by the Ainos, and the ice bear (*Ursus maritimus*), an involuntary visitor brought to Yezo and the Kuriles by the Arctic current. The tanuki, or badger, sometimes called the bamboo bear, whose flesh is eaten, occurs everywhere. The tiger is known only from Chinese literature and art, while the wolf of the country, known as yama-inu, or mountain dog, is not numerous. The fox is found everywhere and, like the monkey and the badger, plays a very important part in folklore and the superstitions of the country. (See FOX.) Among the fur-bearing animals are the marten, the fish otter, the sea otter, and the itachi, or weasel. Rodents are numerous and include two species of ki-nedzumi (tree rats) or squirrels, two flying squirrels, and rats, which are so numerous and so much of a pest that the Japanese government has offered rewards for their extermination. The common house mouse is unknown. Hares exist everywhere. Two species of deer are found.

The avifauna includes many species which are familiar in the Old World, showing very slight differences in color and size, as, e.g., the robin, the cuckoo, the woodpecker, the ice bird, the hoopoe, and the jay. The cuckoo, however, is not very common. The sparrow, the house swallow, and the thrush are the commonest and most numerous. Eagles, falcons, and kites are seen, as well as the woodchat, the magpie, and the Korean raven. There are several species of singing birds, but the uguisu, or Japanese nightingale, and the lark are the most conspicuous. Blackbirds and the singing thrushes are

absent. There are two species of kiji, or pheasant: the *Phasianus versicolor*, called yama dori, or mountain bird, by the Japanese, and the copper pheasant, or *Phasianus sammerringi*. Wild pigeons abound, and quail and snipe are fairly abundant. The wild duck and geese also furnish many a shot for the sportsman. The crane and the silver heron are the most popular of the waders. The former, the symbol of longevity, has a prominent place in Japanese art. The latter faithfully keeps company with the peasant in the rice fields all summer.

The mamushi (*Trionocephalus blomhofi*) is the only poisonous snake of the eight species found in Japan proper. Another, called the habu, exists in Loo-choo. The mamushi, skinned and cooked, is used as a nerve-strengthening food. Four sea snakes make their way to the southern islands in summer. Of the three species of lizard, one, the ya-mori, or house warden, frequents dwellings and is an expert flycatcher. Marine turtles, of which there are three species, are most numerous in the Bonin Islands. The kame, a river tortoise, another symbol of longevity, is one of the four supernatural creatures of Chinese and Japanese mythology. It is found as far north as Yezo, but is not common. There are several species of frogs and toads, but they differ little from those found in Europe and America. The mountain newt (*Lacerta japonica*), when boiled and dried, enriches the Japanese pharmacopœia as a vermifuge. The most remarkable of this class is the giant salamander, extinct elsewhere, but still found in the rivers. It is sometimes captured for the sake of its flesh.

Insects are exceedingly numerous, both in species and individuals, and include many beautiful beetles, 137 species of butterflies, and over 100 species of moths. There are several large silk moths, but only two are used in the silk industry. Except in the mountains, the mosquito is very troublesome and rivals the flea in persistency, but not in numbers. Flies are found everywhere, but are most numerous in the silk-worm-breeding localities. Ants are numerous and troublesome, and crickets, grasshoppers, and cicadas abound. Scorpions exist, but are said to be nonpoisonous. The seas teem with fish, the tai and the maguro being highly esteemed for food. Salmon and trout are found in the northern rivers.

Geology and Mineral Resources. Soon after the opening of the country the government seems to have realized the desirability of exploiting its mineral resources, which were supposed to be very extensive and of great value. To this end geologists and mining engineers were engaged abroad, and to them—Pumpelly, Lyman, and others—as well as to the explorations and observations of later geologists and travelers—Richthofen, Milne, Naumann, Rein, and Wada—the world is indebted for its still very imperfect knowledge of the geology of Japan.

The backbone of the country consists of metamorphic rocks—gneiss, crystalline schists, serpentine, and marble—which are discovered everywhere in great masses, but are best studied in Shikoku. Overlying these are thick Paleozoic strata—probably of the Silurian or Devonian formation—consisting of clay slate, graywacke, quartzite, and limestone. The Carboniferous formation is represented by limestone and by the coal measures of Yezo. The

Permian seems to be entirely unrepresented in Yezo, but Rein seems to have found indications of the occurrence of the lower New Red Sandstones on the main island. Mesozoic strata of the Jurassic formation exist in Kaga, while the Cretaceous formation is exemplified by the coal measures of Takashima, by the gray-white granular and micaceous sandstones of that vicinity, and in Yezo by certain Cretaceous clays. Tertiary and Post-Tertiary conglomerates, sandstone, clay slate, peat, stratified volcanic tuffs rich in coal, lignite, and fossil plants, fringe the country in many places. The oldest eruptions were of granite, which is very widespread.

Japan is not specially rich in minerals, contrary to the views expressed by early geologists. Iron and coal are the most plentiful; next come copper and antimony, gold, silver, lead, sulphur, and petroleum. During 1911 the production was: gold, 10,000 pounds; silver, 300,000 pounds; copper, 580,000 tons; lead, 4500 tons; iron, 60,000 tons; coal, 17,632,000 tons; sulphur, 57,000 tons. The Japanese seem to have been entirely unacquainted with the useful or even the precious metals until after contact with the Chinese and the incoming of the arts, sciences, letters, and religion from China. Silver was first discovered and worked in the year 674, copper in 698, and 10 years later, in imitation of the Chinese cash, a copper coinage was introduced, a fact commemorated in the name of the reign in which this occurred—*Wa-dō* (Japanese copper) (708–714). Gold was discovered in 749. The lodestone had become known somewhat earlier—in 713.

Coal is found in many places, from Formosa to Yezo. The best is that of Takashima (where the seams are 14 feet thick and extend under the sea), Karatsu, Miike, and other places in the island of Kiushu; at Kelung (q.v.) in Formosa; and at Horonai in Yezo. In 1912 the output (exclusive of that of Formosa) was 19,639,000 tons against 3,200,000 tons in 1891. As already indicated, most of it belongs to the Tertiary formations. The coal is of good quality, is much used by the steamships in the Pacific trade, and is also sold at the coaling stations as far south as Hongkong, where it begins to meet the competition of Australian and East Indian coals. Its steaming value is about 75 per cent that of the Welsh coals, which are the standard for steaming purposes on the ocean. Iron is found chiefly as magnetic iron ore, and as iron sand exists in nearly all the provinces. In 1912 the production amounted to approximately 60,000 tons. Copper seems to have been plentiful from the very first. It is said that from 1609 to 1858 no less than 533,332,000 pounds were exported by the Dutch. The product in 1912 amounted to about 140,000,000 pounds. Three silver ores are found, besides galena. The first discovery of silver was on the island of Tsushima, halfway between Kiushu and Korea. It is now worked in many places in Shikoku, and in Hondo from Settsu to Mutsu in the north. In 1912 the product amounted to 39,996,000 mommé (120 mommé = 1 pound).

Gold exists chiefly (1) in the alluvial sands and gravels of Osumi, in Kiushu, and at several places in Yezo; and (2) in auriferous quartz in Satsuma, Koshin, Rikuchiu in Hondo, and at Aikawa, on the island of Sado, in the Sea of Japan. In 1912 the total product was 1,373,000 mommé. Several gold mines are also

worked near Kelung in Formosa. The other mineral products in 1912 were: lead, 11,010,000 pounds; antimony, 176,000 pounds; sulphur, 121,000,000 pounds; iron pyrites, 167,000,000 pounds. The sulphur supply is practically inexhaustible. Petroleum is obtained at Nagaoka and many other places, but the output is far from being enough to supply the needs of the country. In 1912 it amounted to 58,100,000 gallons. The total mineral production of Japan amounted in 1912 to \$65,000,000. It is interesting to note that petroleum was discovered by the Japanese in the Province of Echigo as early as 668. Marble, granite, and other building stones exist in different parts of the country, but are at present little used in building. The number of persons engaged in mining in 1911 was 226,308, of whom 145,412 were engaged in the coal mines, 72,614 in metalliferous mines, and 8282 in nonmetalliferous mines.

✓ **Fisheries.** The Japanese depend on the farmer and the fisherman for their food supplies. The former provides them with the indispensable rice, and the latter with the fish which invariably goes with it. In 1911 about 1,500,000 persons were engaged in fishing and the industries allied to it. The waters, both fresh and salt, teem with fish of every kind, from the whitebait to the bonito and the sturgeon. There is probably no country in the world where the markets are supplied with a greater abundance or variety. The mackerel family is perhaps the largest, both in species and catch; the tai, or golden bream, is perhaps the most prized. The salmon abounds, especially in Yezo, where there are many salmon-curing establishments. The flounder, sole, turbot, trout, haddock, perch, pike, shad, and halibut are all plentiful. In 1912 the value of the take of fresh fish for the entire Empire was over \$51,700,000, and of all fish and fish products \$78,100,000 against \$39,890,000 in 1900. There are a great number of establishments in different parts of the country for the hatching and rearing of fish, and in 1911 there were 71,369 culture beds, aggregating about 475,000,000 square yards. Various kinds of fish oil are made. On the coasts of Yezo immense numbers of a kind of herring or sardine are caught, and the residue, after expressing the oil, is packed and shipped south to the other islands as manure. The value of the dried fish and fish oil, fish guano, and other manufactured products in 1912 was \$48,250,000. The salt used in fish curing and in Japan generally is made by evaporating sea water and then leaching and boiling. The area of beds in 1912 was 14,586 acres, and the value of the salt produced was \$5,840,000.

✓ **Agriculture.** In Japan, as in China, the farming class has always held an honorable position in the community, ranking next after the barons and their military retainers, who were the scholars of the country, and taking precedence of the mechanic and the merchant. Sixty per cent of the population is directly engaged in agriculture.

The soil is largely the product of old shales, granite and trachytic eruptions decomposed by the action of the weather, and is not naturally fertile. It is only by the most careful manuring that it can be made productive, a result to which also the warmth and moisture of the climate contribute largely. As already indicated, the greater portion of the country is

occupied by mountains, largely covered with forests or tall, rank grass, leaving only certain narrow river stretches and plateaus and more or less circumscribed plains for cultivation. It is therefore not surprising that the portion devoted to agriculture is only 17 per cent of the total area. The forests covered 46,300,000 acres in 1913, 42.1 per cent being owned by the state. Rice (of which there are 217 varieties) is the staple food and the most important crop, and rice or "wet" land is worth about three times as much as other arable land. For its cultivation, irrigation is needed, and even the hillsides and gullies are terraced, the water being ingeniously conducted from one terraced plat to another. In 1913, 7,411,000 acres of rice land were under cultivation and yielded 248,463,000 bushels. Much of this is consumed in the manufacture of sake, the beverage of the country, the excise duty on which returns a large revenue to the government. In 1912 over 212,850,000 gallons were produced. The crops next in importance are barley and wheat, the area and the product of which in 1912 were as follows: barley, 1,465,000 acres, yielding 48,012,000 bushels; wheat, 1,216,013 acres, yielding 25,688,000 bushels. The other products are pulse, millet, corn, buckwheat, potatoes of various kinds, all sorts of vegetables, and the soy bean, which is said to approach more nearly in its chemical composition to animal food than any other known vegetable; one-fifth of its weight is fat and nearly two-fifths nitrogenous matter. In 1912, 17,900,000 bushels of this bean were produced. Tobacco (introduced by the Portuguese before 1612, for in that year its production and use were forbidden), cotton (known to the Japanese 150 years before the Chinese), sugar, hemp, and indigo are grown, and great attention is given to silk and tea. The tea plantations in 1913 covered 73,500 acres and produced 71,013,000 pounds of tea.

Since the abolition of the feudal system, the soil has been mostly held by those who work it, the average holding being about one acre. The land tax was transformed in 1873 from a tax in kind (grain), proportioned to area, into a money tax proportioned to the value of the land. It was 2½ per cent of the assessed value until 1899, varied between 3.3 and 5 per cent—according to the class of land—during 1899–1903, and was raised to 5.5 per cent since the war with Russia. In the budget for 1913–14 it was estimated at \$37,501,000, or about 35 per cent more than the estimate from customs.

Until comparatively recent years flocks and herds were not reared, such cattle as were found being used merely as beasts of burden. Milk, butter, and cheese were unknown, and beef was never eaten. This was due partly to the influence of Buddhist teaching and partly to the fact that the grasses of Japan, except perhaps in Yezo, are not adapted for grazing. Since the Restoration (see paragraph on *History*) the government has established numerous experimental farms, under skilled foreign superintendence, including the breeding of horses and cattle and the rearing of sheep. These efforts have been only partially successful. The use of animal food is, however, extending, and dairying has been introduced. In 1912 there were 1,399,498 cattle, 1,581,000 horses, 308,970 hogs, 101,475 goats, and 3308 sheep.

Manufactures. China is the original home of the highly perfected arts of lacquer work,

fine ceramics, chasing and inlaid work, ivory, bone, stone, and wood carving, in most of which Japan now excels its ancient tutor. The most authoritative writers on the industries of Japan agree that the Japanese have regarded China as their model in all these departments for many centuries. They have developed great aptitude for imitating these art products and but very little independent creative power. The fact that Japan now far surpasses its old master in the most extended branches of art handicraft is to be attributed to this very gift of imitation, and most of all to the awakened sense of beauty in nature and art that has been applied to worthy and useful ideas as models which originated on foreign soil.

In the latest development of the industries of Japan the same limitations are observed. It has been shown thus far that while the Japanese artisan has great manipulative skill and can turn out indifferent sewing machines, typewriters, and many other foreign mechanisms with an imitative art in superficialities that amounts almost to genius, still for the fundamental elements of his industry he must yet depend on the assistance of foreigners. The national character in its recent approximation to Western civilization is what it always has been, imitative, not originaive; and is almost wholly devoid of that rude energy of initiative which constitutes such a marked difference between the inhabitants of the East and the West. This detracts nothing from the merit and value of the industries for which the Japanese are famous. In woodwork their buildings lack much in solidity, adaptation, and elegance. It is not as carpenters and architects that they are distinguished, but as joiners, turners, and wood carvers. The frames of their window panes, the wainscoting of the walls of many of their temples, and numerous other works are samples of fine and careful joinery. They make many small wooden wares, excellent in design and utility. Comb cutting is a large house industry, small-toothed combs of the wood of several evergreen trees being used in the native toilet.

Lacquer work takes the first place among the Japanese art industries. In no other branch of art have the Japanese so completely disengaged themselves from their Chinese masters, displayed so much fancy and taste, and won such eminence among all civilized peoples. The lacquer tree is grown chiefly in Hondo or the main island, between the parallels of latitude 35° and 40° north. Its sap is distinguished from all other varnishes by its greater hardness, its high lustre preserved for centuries, and its resistance to agencies that destroy other resinous varnishes. The lacquer varnish is applied to wooden or metal articles. Every layer must be thoroughly dried and polished before another is placed. A fine piece of work, with 20 to 30 coats of lacquer, may be many months in making. The antiquity of the industry is attested by some lacquer boxes in one of the temples where they have been kept, it is said, in a state of perfect preservation for 17 centuries. Among the choicest exhibits of the museums in the Occident are Japanese lacquers fixed on copper, or more frequently on the wood of the *Pinus retinospora*, and ornamented with gold, silver, or mother-of-pearl. The best specimens have a metallic lustre, can scarcely be scratched, and are almost indestructible. In 1912, 17,813 persons in 6234 families were

engaged in the manufacture of lacquered ware. The value of their output was \$4,520,000.

Much broken pottery has been discovered in mounds in Japan dating from prehistoric times, but it was only after contact with China through Korea, and the introduction of Korean potters, that Japan began to progress in an art which has made it renowned. The most famous of the pottery wares are the choice imitation porcelains known as Old Satsuma, which have become extremely rare. All Japanese pottery, however, is traced back to Sedo in Owari, and from this circumstance Sedomono has become the general name for all Japanese ceramic ware. The number of ceramic works was never greater than at present, the art having spread into many new districts. Wares serving the humblest utilities or expensive products for the collections of connoisseurs are produced, many of them being remarkable for richness of color and originality of floral and animal designs. Many of the potters' villages are famous, though they do not differ in appearance from ordinary hamlets. Each workshop comprises the members of a single family, every member watching in his turn over the baking of the materials in the public oven of the commune. The chief manufactories for the finest porcelain ware are at Arita in the Province of Hizen, in Kiushu, where the best clays are found in abundance. It was here that Gorodayu Shonsui set up his first kiln on his return in 1520 from China, where he had learned the art of porcelain making. In 1899 the number of factories engaged in pottery and porcelain making was 4604, the number of persons employed 19,454, and the value of the product \$2,934,000; in 1912 the number of factories was 5657, of persons 34,654, and the value of the product \$8,272,000.

In the making of works of art in bronze, a single artist casts the metal, does the chasing, colors with oxides, incrusts the bronze with precious metals, coral, or pearls, and produces the work from start to finish. The Japanese do not share the predilection of the Indian people for brass utensils, though the few they make are ornamented with great skill and care, but they excel in bronze manufactures.

The Japanese excel in the manufacture of some kinds of paper, of which they use a larger quantity in proportion to population than most other nations. It is made from various species of plants, including the pulp of the paper mulberry, and is used not only for printing and painting, but for many other purposes. Their handkerchiefs, table napkins, windowpanes, the panels forming the movable partitions of their houses, are made of paper. They cover with paper the cushioned stools used as pillows, and paper garments coated with vegetable wax are worn in rainy weather. The papers of Japan always show a yellowish tint when made of the purely native materials and in the purely native way, and in this respect are inferior to the pure white products of the West; but printing paper as white as any made in the United States or Europe is produced in quantity. All attempts to imitate certain of the Japanese native papers have failed. In 1899 Japanese paper was manufactured in 65,514 families, yielding an output valued at \$8,272,754; in 1912, in 53,474 families, the value of the product was \$10,130,000. In addition to this there was produced in 33 factories 324,072,000 pounds of "European" paper valued at \$10,020,000.

The Japanese also excel in wickerwork and in a great variety of straw objects, such as straw toys and mosaics. Ivory is fashioned into curious boxes and cabinets and embellished with carved reliefs involving microscopic work. Ivory carvings, large and small, distinguished for technical skill and inspiration, are sold in all Western countries. The artistic skill of many of the natives, however, has been impaired by the production of great quantities of cheap articles to meet the foreign demand for the artistically worthless articles sold under the name of Japanese china and other cheap products.

Spinning and weaving have for centuries been the most important native industries. The art of weaving heavy linens and silken fabrics and their brocades, interwoven with gold and silver thread, was long ago developed to a high degree; their products still form admirable hangings and festive robes. But the modern brocades are often colored with imported aniline dyes and have neither the brilliancy nor the quality of the old fabrics. Spinning and weaving for everyday utility have always employed most of the textile workers. The returns for 1895 showed that there were then over 1,000,000 weavers, and in nearly every house in rural Japan the spinning wheel and loom were kept going from morning till night. A great revolution, however, was already far advanced. About 1880 an enormous impetus was given to the erection of cotton spinneries, with all modern appliances, and to-day homespun yarn is almost unknown in the Japanese markets. Not only is the domestic market fully supplied by the great spinning mills but large quantities of yarn are produced for exportation. The value of cotton yarn exported in 1913 was \$35,493,000, of which a large proportion went to China for use in the hand industry of weaving cotton cloths. Osaka is the great centre of manufacture both of yarns and cotton goods. It has been compared to Manchester on account of the many spinning mills and other large textile interests centred there. In 1890 the value of raw cotton imported into Japan was \$2,672,000; in 1913 it was \$116,755,000. In 1894 the number of cotton spinning mills was 45, representing a capital investment of \$6,627,000, with 476,000 spindles, producing 121,054,000 pounds of yarn, and employing 8229 male and 26,923 female workers. In 1904 the number of cotton spinning mills was 74, the invested capital was \$17,280,000, the number of spindles was 1,306,000, the yarn produced was 286,235,000 pounds, and the number of employees was 10,967 males and 52,115 females. In 1911 the number of mills was 90, the employees 41,531 men and 707,350 women, machine looms 89,003, hand looms 638,412, value of output \$69,875,000 cotton goods and \$15,091,000 mixed silk and cotton. The exportation of cotton goods has become an important feature of the trade of Japan, the value of cotton shirtings amounting to \$16,645,000 in 1913, and of miscellaneous cotton goods the exports are steadily increasing, especially to China, where cloths from Japan have to a considerable extent displaced those formerly drawn from the United States. Japan draws from the United States a large proportion of the raw cotton used in her mills, though in years of high prices of the raw material a larger share is drawn from India, whose short-staple cotton sells at a less price than the United

States product. The following table, giving the value for a series of years of the silk, cotton, and other textile manufactures, shows the progress of these industries:

1886	1896	1903	1911
\$14,240,000	\$55,492,100	\$68,867,000	\$136,900,000

Silk is also manufactured to a great extent by modern machinery. About half the raw silk is retained at home for the manufacture of the characteristic silk fabrics worn in the country. Large quantities of the exported silk fabrics are now dyed in France and the United States before being placed on the market. Reeled silk, however, is the chief silk export. Silkworm eggs on cards are also exported to Italy.

The policy of Japan has long been to build up a strong navy and a large merchant marine without dependence on foreign yards. Shipbuilding is therefore a large industry, especially at Nagasaki, the open port of Kiushu, where vessels of from 1000 to 8000 tons' burden are turned out. There are also large yards at Kawasaki, Osaka, Ishikawa-jima, and Uraga. They are all equipped with the best appliances for the building of steel and iron ships and have fully demonstrated their ability to turn out ocean-going craft and river steamers of the highest standard. A number of steamers on the Yang-tse River were built in Japan. The merchant marine of Japan on Jan. 1, 1913, was 1981 steamers above 20 tons with a tonnage of 1,430,629; sailing vessels 6443, tonnage 447,307. In many directions Japan is striving to increase her manufactures of iron and steel goods. This necessitates considerable imports of metal, as the local iron-mining industry is not yet adequately developed.

For some years the Japanese have been carrying on the manufacture of many European and American articles that were not even known in their country when it was opened to foreigners. They manufacture enormous quantities of matches, which they sell in China, Hongkong, India, Singapore, Siam, Australia, and other markets. The value exported averages about \$6,000,000 per annum. About 30,000 clocks are made in Kyoto, Osaka, and Nagoya every month and sold at very low prices. Saddlery, glassware, umbrellas, brushes, boots and shoes, rugs, mathematical and surgical instruments, patent medicines, watches, canned fruits, vegetables, and condensed milk are among the articles they are producing with the aid of Western patterns and processes. The wages of the labor employed in these numerous industries are advancing and, while at much lower rates per hour than in Europe or America, are, when judged by the quantity and quality of the product, about as high as those paid in the Western world.

The following tables illustrate the growth of Japanese industry:

1. NUMBER AND KIND OF FACTORIES AND EMPLOYEES

	1904	1912
Factories run by motors.....	4,000	8,710
Total horse power.....	223,930	1,102,782
Factories not run by motors.....	5,234	6,409
Total number of factories.....	9,234	15,119
Operatives employed, male.....	207,951	348,230
" " female.....	318,264	515,217
Total number of operatives.....	526,215	863,447

2. PRINCIPAL BRANCHES OF FACTORY INDUSTRY
IN 1912

	Total number	Nonmotor factories	Total number of employees	Female employees
Textile factories.....	8,119	3,003	513,187	446,283
Raw silk (included in above)	3,056	471	216,833	205,154

Government Industrial Activity. The government of Japan has not only promoted the development of national industry by the establishment of special commissions of scientists and experts, the payment of shipping subsidies, the advancement of capital obtained through foreign loans at a lower rate of interest than can be obtained at home, and in many other ways, but it is also the greatest employer of labor in the country. It owns shipbuilding yards, factories for the manufacture of arms, railway and telegraph material, clothing, etc.

Kure naval arsenal, with 22,276 employees; the Yokosuka naval arsenal, with 9924 employees; and the Sasebo naval arsenal, with 5340 employees. The three factories belonging to the government railway works bureau, situated at Shimbashi, Kobe, and Nagano, employed 4935 persons, and the tobacco factories belonging to the Bureau of Monopolies, 28,664. And while the government's industrial activity during 1904-05 was excessively large, owing to the necessities of war, it should be borne in mind that its taking over of the chief railway lines of the country (see below, *Nationalization of Railways*) still further extended the scope of its industrial activities.

Commerce. The domestic trade has been greatly stimulated by the rapid growth of railways, which render it easy and cheap to distribute the products of the factories throughout the country and particularly in the main island. This fact is causing some decline in the household industries, which, however, still supply a part of the common needs of the people. In the foreign trade the imports have exceeded the exports since 1895, owing to the large railway equipment and other material which Japan has purchased abroad in the development of its many enterprises. About one-third of the imports come from other parts of Asia and two-thirds from Occidental lands. Asiatic countries buy from Japan about one-third of her exports, the remainder being sent to Western countries. The accompanying table showing the total foreign trade (excluding the precious metals) for a series of years will give an idea of the rapid development of foreign commerce (one yen equals \$0.498).

The rapid industrialization of Japan is reflected in the increase, both absolute and relative, of the export of manufactured commodities.

Trade between the United States and Japan has grown rapidly in recent years. The imports into the United States from Japan were, in 1901, \$29,229,443 and, in 1914, \$107,355,847. The exports from the United States to Japan were, in 1901, \$19,000,640 and, in 1914, \$51,205,520. The principal imports into Japan from the United States are flour and wheat, raw ginned cotton and kerosene oil; also engines, locomotives, electrical apparatus, and other kinds of machinery, and leather goods. Nearly all the kerosene oil and most of the lubricating oil and paraffin wax come from the United States. A part of the raw cotton is obtained from British India, the price of whose short staple is usually about 10 per cent lower than that of American cotton. Raw cotton, however, is largely imported from the United States, especially in years of low prices, and the shipments of 1913 were 375,000 bales valued at

	1909	1910	1911	1912	1913
	Yen	Yen	Yen	Yen	Yen
Imports.....	394,198,840	464,233,800	513,805,700	618,992,270	729,431,644
Exports.....	413,112,510	458,428,990	447,433,388	526,981,840	632,460,213

On Dec. 31, 1912, the total number of government factories employed 141,500 operatives and laborers. The Tokyo military arsenal gave employment on the above date to 17,856 persons. Other important establishments are: the Osaka military arsenal, employing 10,900 persons; the

\$25,022,000 against 92,556 bales in 1910 valued at \$6,583,000. The United States supplies nearly all the flour, but Australia competes in supplying wheat. The United States leads in shipments of alcohol, leather, telephones, lumber, and steel and iron materials for bridges

and buildings. Hongkong, Germany, and the Philippine Islands supply nearly half the sugar imported, the remainder coming chiefly from other Asiatic countries, especially Java. The United States buys more than three-fourths of the tea exports and is the heaviest purchaser of raw silk, which constitutes more than one-half of the entire imports from Japan. Japan's cotton yarn and tissues are sold in neighboring countries of Asia. The exports of coal, principally to China and Hongkong, are important, and large quantities of coal are supplied to ocean steamers for bunker use.

The value of the imports from and exports to the leading countries in 1912 and 1913 was as follows:

date, Niigata, and a few minor ones. In January, 1913, Japan had in its merchant marine 1981 steamers above 20 tons and 6443 sailing vessels of the Western type (1,877,936 tons), besides 20,635 sailing vessels of the native type. There are regular lines of Japanese steamers to Europe, America, Australia, British India, China, and Korea. More than 50 steamships, including those of the United States and Canada, ply regularly between the Pacific coast ports of America and the seaports of Japan, some of them going on to Hongkong and Shanghai. Nine steamship companies have vessels in this trade, and they ply between Yokohama, San Francisco, Puget Sound ports, and Vancouver. The government grants liberal sub-

Communications. Japan has exerted every energy for many years to improve transportation facilities throughout the country and to foreign lands. The government is not unmindful of the necessity of supplying good harbors. Yokohama, the most northerly port of first-class importance, has a naturally fine harbor that has been greatly improved by dredging. There are large dock facilities and a substantial breakwater. Yokohama transacts a very large part of the foreign business of the country. It is the centre of the silk trade. The second port in importance is Kobe, one of the centres of the tea trade and other commerce of central Japan. The principal ports utilized in the foreign trade are Yokohama, Kobe, Osaka, Nagasaki, Hako-

Canal, and a line to the eastern coast of South America was established.

The total mileage of railway in operation in Japan in the fiscal year ended June 30, 1912, was 7067. Of this 6008 miles were operated by the government and 1059 miles by private companies. The first railway, 18 miles in length, between Tokyo and Yokohama, was opened in 1872, and now there is direct communication by rail from Awomori at one end of the main island to Shimonoseki at the other, a distance of 1132 miles, and from Moji in Kiushu, less than a mile distant, the lines run south to Kumamoto, 121 miles, and beyond. There are many branch lines, and there is a line of some length in Yezo. There were 844 miles of elec-

tric tramways in operation in Japan in 1912, with 306 miles additional under contract to be built. The post-office system is extended all over the Empire, and the telegraph and telephone have been very widely introduced, their length in 1905 being 16,468 and 3374 miles respectively.

Nationalization of Railways. In 1907 the Japanese government owned and operated about one-third of the total mileage in Japan, and the remainder was operated by private companies. The government then decided to take over the private lines with their subsidiary businesses, paying approximately \$237,100,000 for these lines. In 1910 the mileage owned and operated by the government in Japan proper was 4879 miles, which had cost \$303,978,000, or about \$62,300 per mile. There were at that time 506 miles of privately owned road, capitalized at about \$44,900 per mile. There was considerable opposition in the minority political party in Japan to the acquisition of the privately owned mileage, but this acquisition was hardly as much of a revolutionary change of policy as it was the addition of privately owned lines to already existing state lines.

The average rate of dividends of private railways in 1904—before the large government acquisition—was 8.2 per cent, and of the state railways at that time 9.4 per cent. Lines may be bought at the discretion of the government within 10 years, and the price in each case is to be a sum equal to the capitalized average net profits for the three years 1902–05. New lines and lines which have not paid dividends will be valued by a special commission, from the decisions of which appeal may be made to the Minister of Communications. Payment for cost of construction and equipment is to be made with 5 per cent 30-year bonds at face value, the bonds to be delivered to shareholders at the option of the government within five years from the date of purchase. Payment for supplies on hand is to be made, at their market value, with similar bonds. During the interval between the date of purchase and the delivery of the bonds, shareholders receive the 5 per cent interest on the bonds due to them. The relation of the actual cost of construction and equipment to the face value of the bonds varies greatly in the case of the different lines, the extremes being 34 per cent and 347 per cent. For the six largest companies the ratio of cost to face value of bonds is 40.1 per cent, 41.7 per cent, 49.6 per cent, 52.6 per cent, 87.7 per cent, and 100 per cent respectively. Eight companies will receive bonds, the face value of which is less than cost of construction and equipment; but these are very unimportant companies, only two of them having more than 50 miles of line each. The average of cost to face value of bonds for the 17 lines is 55 per cent. A separate law, similar in its provisions, empowers the government to purchase the railways in Korea, the estimated cost being about 34,000,000 yen.

In 1911–12 the state railways carried 31,501,510 tons of freight and 156,636,964 passengers, and the privately owned roads 4,506,603 tons of freight and 29,325,185 passengers.

The Japanese railways operate at about a 46 per cent ratio of expenses to gross earnings. The average freight rate per ton per mile on Japanese roads is 83 cents, and the average passenger rate per mile is 69 cents.

Banks. The banking business of the country

is carried on (1913) by six great banks (one of them with 16 branch establishments), 46 industrial and agricultural banks, and 1620 ordinary banks, not including the foreign banks at the open ports. The paid-up capital of all banks was, in 1913, 592,031,296 yen, the reserve fund 211,707,667 yen, and the deposits 22,261,751,004 yen. The Bank of Japan is a government institution founded in 1882 and authorized to issue convertible notes, the paper currency of the country down to that time having been "fiat" money. There were also 480 savings banks with deposits in 1913 of 1,047,147,527 yen. Japan adopted a gold standard in 1897, and the yen, in which accounts are kept, is equal to 49.8 cents.

Money, Weights, and Measures. The yen is divided into 100 sen. The subsidiary silver coins are 5, 10, 20, and 50-sen pieces, and there are 5-sen nickel pieces, and 2 sen, 1 sen, and ½ sen of copper. The unit of weight is the kin, equal to 1½ English pounds, or more exactly 1.32277 pounds avoirdupois. Above that is the kwan (or kwamme), equal to 8.267 pounds avoirdupois, or 16 kwan to 100 kin. The lineal foot is divided into 10 inches and is equal to 0.9942119 English foot. For distances, 36 chō equal 1 ri, which equals 2.44034 English miles. For land measures the square chō equals 2.45 acres, and the square ri equals 5.955 square miles. For measures of capacity 1 to = 3.97 English gallons or in dry measure 1.985 pecks. The kokū is equivalent to 39.7033 English gallons, or 4.9629141 English bushels. The English pound and the ton of 2240 pounds are also coming into commercial use. The picul—100 kin, or 132½ pounds avoirdupois—has long been in use in the foreign trade.

Government. The government may be described as a constitutional monarchy with representative institutions based largely on German rather than on British or American models. The constitution on which it rests was promulgated by the Mikado in 1889 in accordance with his oath in 1868 to give the people representative government. In that year the dual government which had existed for centuries reached its end, and the Mikado became the de facto as well as the de jure ruler. The instrument consists of 76 articles, 17 devoted to the Emperor, 15 to the rights and duties of subjects, 22 to the Imperial Diet, 2 to the ministers of state and the Privy Council, 5 to the judiciary, 12 to finance, and 4 to supplementary rules. The Premier, or Minister President of State, presides over the Imperial cabinet. The central government consists of the Imperial cabinet, Privy Council, and the nine ministries—Foreign, Home, Finance, War, Navy, Justice, Education, Agriculture and Commerce, and Communications. There are also a court of accounts, a tribunal of administration, and the administrative bureaus for the Upper and Lower Houses. In the provincial governments division there are the prefecture of the police of Tokyo, the Department of Colonization of Yezo, the fu and ken (the three cities and 43 prefectures into which Japan proper is divided), and the Government of Formosa. Functionaries are in three grades (choku, so, and han), besides many salaried agents.

The Parliament or Diet meets annually and has control over the policy and expenditures not fixed by the constitution. It consists of an Upper and a Lower House. The composition of the Upper House is peculiar, its membership

being made up of five classes: (1) princes of the Imperial family who are 25 years of age or over—they become members for life; (2) princes and marquises of 25 years of age and over—also members for life; (3) a certain number of each of the other classes of peers—counts, viscounts, and barons—over 25 years of age, elected by their own order to serve for seven years; (4) persons who are not peers, nominated by the Emperor for meritorious services to the state, or noted for scholarship—they are members for life; (5) persons over 30 years of age in each fu and ken who are among the 15 largest taxpayers, elected by the 15, and appointed by the Emperor for life. The Upper House contained 369 members in 1914. The Lower House, according to the Election Law of 1900, is composed of 379 members, or one for every 136,522 of the population in 1914.

The Emperor in reality is a mere screen behind which are a powerful group of aristocrats known as the "elder statesmen" who really control the government. It is they who advise the monarch whom to appoint to the cabinet and what policies to recommend. In the fu (first-class cities), Tokyo, Osaka, and Kyoto, and the ken, or prefectures, there are local legislatures, which have general supervision over local affairs, besides paying their own officers. Male subjects who are 25 years old, have lived a year in the voting district, and pay \$5 of direct taxes are allowed to vote for members of the Lower House. The inhabitants of the Colony of Yezo and the inhabitants of the Loo-choo Islands have as yet no part in the parliamentary representation. The franchise is also withheld from functionaries of the Imperial household, ecclesiastics, police, soldiers, sailors, bankrupts, and outlaws. Deputies must be at least 30 years of age and Japanese subjects. The national trend is towards democracy, and the struggle is to secure party government and to make the ministers responsible to the Diet and not, as now, to the Emperor.

Administration of Justice. In preparation for the abolition of the extraterritoriality clause in all the treaties, a new criminal code, based on the Code Napoléon, was put in operation in 1882, with modifications suggested by the old criminal law of Japan. The code of criminal procedure was in 1890 made uniform with the code of civil procedure, according to the provisions of the law of the organization of judicial courts. The civil code, code of civil procedure, and commercial code, published in 1890, went into effect after 1893. The law of the Imperial house, Diet, and finance, laws for the exercise of local self-government, and various miscellaneous subjects, such as the statutes relating to banking and the mechanism of exchange, may also be called codes. Three kinds of crime are classified: (1) crimes against the state or to public detriment; (2) crimes against personal property; and (3) police offenses. Punishments for major crimes are death by hanging; deportation, with or without hard labor, for life or a term of years; imprisonment, with or without hard labor, for life or a term of years. Instead of the 250 crimes calling for the death penalty under the old system, there are but few mentioned which are punishable with death. The principal courts are the high court of cassation (1), courts of appeal (7), and tribunals of the first instance (49).

Finance. The revenue of the Imperial gov-

ernment is derived from many sources. The land tax, which from 1873 until 1899–1903 was 2½ per cent of the market value of the land, was raised after the war with Russia. It produced, in 1913–14, 75,350,000 yen; the taxes on sake and other liquors, about 89,000,000 yen; customs dues, 55,906,000 yen; income tax, 35,471,000 yen; and the receipts from government enterprises—railways, mining, postal and telegraph services, etc.—140,000,000 yen. The chief items of expenditure are (1913–14): army, 78,000,000 yen; navy, 42,000,000 yen; administration of justice, 12,300,000 yen; education, 9,500,000 yen. In 1913–14 the total revenue and expenditure—ordinary and extraordinary—was estimated at 586,807,000 yen each. The public debt stood in 1913 at 2,494,000,000 yen.

In local matters the revenue in 1913–14 was 80,613,558 yen. The revenue of the cities amounted in 1913 to 127,213,000 yen, and the expenditure to 111,970,000 yen.

Prior to 1884 the country was flooded with "fiat" paper money, which had greatly depreciated. In that year the Bank of Japan, a government institution, issued convertible notes in exchange for this depreciated currency, and by 1885 the difference in value between silver and paper had almost disappeared. The following year specie payments were resumed. In 1897 the gold standard was adopted, 74,455,735 yen in gold were coined, and the silver dollars were redeemed as far as received. The currency is now on a gold basis. From the foundation of the mint in 1870 up to 1914 the total coinage issued amounted to about 750,000,000 yen. The coins in circulation Jan. 1, 1913, were 175,090,000 yen. The note issues of the Bank of Japan amounted in 1913 to 408,376,000 yen.

Russo-Japanese War Finance. The methods resorted to by the Japanese government to raise funds for the prosecution of the war against Russia were the usual ones of imposing new taxes or increasing existing ones, diverting funds from the ordinary expenditures to war purposes, and contracting loans at home and abroad. In addition a monopoly was assumed over the salt and tobacco industries. On Dec. 28, 1903, an ordinance was published authorizing the diverting of funds under special accounts, the issuing of Treasury bonds, and the raising of temporary loans for military expenditure. The sums thus obtained amounted to 156,000,000 yen up to March 30, 1904. For the fiscal year 1904–05 the Diet voted 576,201,000 yen for war purposes, and for 1905–06 it voted 780,000,000 yen, including loans of 411,000,000 yen and 571,000,000 yen respectively. The most important special taxes imposed were those on land, sugar, income, and business, and the tobacco and salt monopolies. By the end of March, 1906, by which time all the troops had been repatriated, with the exception of two divisions in Manchuria and two in Korea, the actual outlays for the war amounted to 1,261,161,877 yen, of which sum 1,070,140,000 yen were for the army and 191,021,868 yen were for the navy. The sources of revenue to meet this expenditure were as follows:

Loans and treasury bills	yen 1,127,634,199
War taxes	82,430,129
Capital funds (navy, education, and famine relief)	69,311,977
Voluntary contributions	2,279,899
Sale of state property	5,126,436
Other revenue	5,472,912
Total	yen 1,292,255,552

The loans contracted at home and abroad for war purposes were as follows:

Army. The rapid and progressive development of the military resources of Japan due to her war with China (1894-95), with Russia (1904-05), and to her alliance with Great Britain, signed in 1905 and renewed for 10 years in 1911, combined with her policy of secretiveness in connection with all military affairs, renders it difficult to arrive at an accurate estimate of the ultimate military resources of the nation. It is known, however, that between 1894 and 1904 Japan's fully trained force about doubled, and that this force has again doubled since 1904. At the present time (1914) she has fully realized her national ideal of the "nation in arms," adopted from the continental European countries, and no doubt could rapidly mobilize at least 1,000,000 fully trained men in addition to her regular army, and ultimately put into the field a force of between 3,000,000 and 3,250,000 men, or about 6 per cent of her total population. Her tactical organization, equipment, and methods closely follow European models, particularly that of Germany.

Administration.—The Emperor is supreme commander of the army and navy. He selects his War Minister (a general officer of the army), the chief of staff, the director of military schools, and the members of his military council. The 19 divisions are organized in and recruited from definite territorial districts, which constitute the administrative and command units. In addition to the line troops there are a number of special organizations, military schools, gendarmes, etc., used for educational and administrative purposes. The number of officers performing the semimilitary functions of intendants is estimated at about 1000. The cost of the army amounts to from \$40,000,000 to \$50,000,000 yearly. The military budget for 1913-14, including extraordinary expenditures, was \$49,983,035. Late in 1914 the Premier, on account of Japan's participation in the European War as England's ally, asked for an increased army and larger military appropriations for the fiscal year 1914-15.

Arms.—The Japanese infantry uses the improved Arisaka (modified Mauser) rifle, calibre 0.256 inch; the cavalry, a similar carbine; the field artillery, a rapid-fire shielded Krupp gun, calibre 2.95 inches, projectile 14.3 pounds; the mountain artillery, a gun of same calibre with lighter projectile. The light and heavy field

howitzer batteries use a 4.6-inch and 5.9-inch piece, firing projectiles of about 44 and 80 pounds respectively. A 4-inch gun is also under construction for issue to the heavy artillery.

Service is universal and compulsory, with liability from 17 to 40, actual service beginning at 20. The first line is made up of two classes: the Geneki, or active service with the colors for 2 years in the infantry, 3 in other arms; the Yobi, or reserves for the active army, with service of 5 (or 4) years and 4 months, making a total of 7 years and 4 months in the first line. In the Yobi training of 60 days each is given on two occasions. The reservists then pass to the Kobi, or second line, for 10 years, where they have two periods of 60 days each with the colors; then to the Kokumin, or third line, home-defense army, for 2 years and 8 months, which completes the liability of 20 years' service. The classes just mentioned are filled by the men of highest physical standard. The excess of these, plus the men capable of bearing arms but of a lower physical standard, up to a certain number, are assigned to a category called Hoju, which is a supplementary reserve to replace losses in war. They do not serve continuously with the colors, but are given a first training of 3 months and report for two subsequent trainings of 2 months each during the Hoju period of 7 years and 4 months. They then pass to the Kobi and Kokumin category in the same way and for the same periods as the first-line men. The men composing the Kokumin, or third line, are thus seen to be made up of men of different degrees of military training. It is divided into two classes, or bans: first, the fully trained men of the first line and the partially trained men of the Hoju; second, the untrained men, made up of the excess not required for the Hoju, the men exempted from military service, and the boys between 17 and 20 years. It should be noted that only fully trained men are assigned to the fighting units of the Kobi, or second line, the partially trained being assigned to the transport, supply, and administrative corps on mobilization for war.

Higher Organization.—The division is the highest permanent organization in peace. There are provided in peace, however, the generals and lieutenant generals and staff officers required for the organization and command of field armies composed of from 3 to 5 divisions each in war. In peace there are in Japan proper 19 divisions, 4 independent cavalry brigades, 3 independent brigades of field artillery (each of 12 batteries of 6 guns each), 3 independent battalions of mountain artillery, and 6 regiments of heavy field artillery, each of 24 guns. The normal division consists of 2 brigades of infantry, a regiment of cavalry of 3 squadrons and 4 machine guns, a regiment of light field artillery (6 batteries of 6 guns each), with such heavy and mountain batteries as may be required, with, possibly, 3 Kobi batteries; 1 battalion of engineers, and the necessary communication, supply, and sanitary troops. The total war strength of a normal division is about 19,000 men, 5000 horses, 36 guns, and 1700 vehicles. The field army, of from 3 to 5 divisions, varies in strength from 80,000 to 130,000 men. Total peace strength of the regular army, according to latest information (1914), is estimated at 250,000 men. Upon initial mobilization this regular or standing peace army could at once be expanded to 600,000 fully trained men. In addition there

would still be available about 650,000 fully trained reservists, giving a total trained force of 1,250,000 at the outbreak of war. Adding to these the partially trained and untrained men of the Kokumin, Japan could ultimately mobilize about 3,250,000 men.

Infantry Organization.—Four companies to the battalion of 1000 rifles (war), 3 battalions to the regiment, 2 regiments to the brigade. In 1914 the standing army consisted of 76 regiments (228 battalions), the Kobi of 228 battalions.

Cavalry Organization.—The scarcity of horses in Japan, the demands on the supply, and the expense of maintenance have retarded the development of this arm. There are in the standing army 27 regiments (89 squadrons), in the Kobi 57 squadrons. Peace footing, about 5 officers and 136 men per squadron; war strength but slightly greater. See CAVALRY.

Artillery Organization.—Field artillery, the German system of 6 guns to the battery, 3 batteries to the battalion, 2 battalions to the regiment; in the standing army, 150 field batteries, 9 mountain batteries, 19 battalions of garrison artillery; in the Kobi, 114 field batteries, 12 battalions of garrison artillery. Peace strength, about 5 officers and 120 men; war strength, 5 officers and 154 men.

Technical Troops.—Active army, 19 battalions of engineers, each of 3 companies. Peace strength of a battalion, 21 officers and 374 men; war, 660 men. Kobi, 19 battalions. There is in addition a "communication corps," consisting of railway, telegraph, and aeronautical troops. The strength and equipment of the latter is not definitely known.

Supply Trains.—The train troops are organized into battalions of 2 companies each, to which is added a third company in war. One battalion is assigned to each of the 19 divisions. Peace footing of battalions, 17 officers and 596 men; war footing of a company, 10 officers and 880 men. The total war strength of the train of the 19 divisions is about 51,000 officers and men.

Sanitary Troops.—Six field hospitals accompany each division in war. Peace strength of the medical department is estimated at 1250 officers and 2200 men; the war strength is not known.

Colonial Troops.—In addition to the troops mentioned a division is maintained in Formosa, about 30,000 men in Korea and Manchuria, and small garrisons in Sakhalin and Tsushima.

Navy. The Japanese have always been a sea-going people, and they have had a naval force for many centuries, chiefly as a weapon of defense and offense against the hereditary enemy, China. An old Japanese painting (its date said to be about 1300 A.D.) shows a naval fight with the Chinese in which the ships are wreathed with the smoke of their guns. If the date is correct, this is the first-known naval battle in which guns were used.

The modern Japanese navy may be said to have commenced with the purchase of the armored ram *Stonewall* (renamed *Adzuma*), which was built for the Confederate navy and sold to Japan at the close of the Civil War. From that time the navy increased slowly until 1894, when the war broke out with China. The resistance of the heavy Chinese armor-clads, notwithstanding their defeat, showed the value of such vessels. Japan ordered 2 first-class battleships in England at this time; and during the

next 10 years 4 more battleships and 8 armored cruisers were built or purchased, as were also a number of smaller cruisers and torpedo craft. In the meantime the Japanese navy yards were greatly improved and excellently equipped for building and repair of vessels of all kinds. In 1904 the Japanese navy was in a condition to cope successfully with that of Russia, and the resulting victories not only humbled her antagonist, but added to her fleet 6 battleships, 1 armored cruiser, and 2 coast-defense vessels. Two of her own most powerful battleships were sunk.

The value of a strong navy to an island empire was now fully realized, if it had not been before, and Japan made extensive plans to build one of the great navies of the world. But the cost of the war with Russia and the developing of the conquered territory made such a severe strain upon Japanese finances that the naval construction proceeded much less rapidly than

was desired. Nevertheless 7 battleships were completed or placed under construction between 1904 and 1914, also 4 battle cruisers and 5 large armored cruisers carrying heavy guns. A scandal in the Navy Department in connection with foreign contracts was made a pretext by the Japanese Parliament to cut down the naval appropriations to such an extent that the work on shipbuilding was greatly retarded, and no new keels were to be laid during 1914-15. The lack of money for the navy is likely to be felt until Korea and the other additions to the Empire cease to be a source of expense and afford a revenue.

In 1914 the strength of her fleet placed Japan fifth among naval powers. The numbers of the *personnel* were doubtful, as a considerable portion of the enlisted force had been released

owing to the lack of money. The latest official reports (1913) give 4035 commissioned officers, 1553 warrant officers, and 43,847 enlisted men. The fleet consisted of the ships enumerated in the preceding table, which gives the displacement in tons, number and calibre of principal guns, and maximum speed.

The principal dockyards are at Yokosuka, Kure, Sasebo, Onohama, and Nagasaki. These are well equipped, and most of the vessels of the navy are built in them. The Navy Department is one of the principal departments of the government and is presided over by the Minister of Marine. See NAVIES.

Political Divisions. Omitting Formosa (q.v.) and Korea (q.v.), it may be stated that

Japan is divided (1) into 84 provinces, separated the one from the other by natural boundaries; and (2) for administrative purposes into *fu* and *ken*, or prefectures. The former is the older division and dates back many centuries, though the number has not always been the same. Their names are in more general everyday use than those of the newer divisions. With only one or two exceptions each has both a Japanese and a Chinese name; thus, Yamashiro is also called Joshu, and so on, those ending in *-shu* (which may be translated 'province') being of Chinese origin. Of these 84 provinces two are separate islands (Iki and Tsushima, which lie between the island of Kiushu and Korea). The others are grouped into nine regions, of which eight are named *do*, or circuits. The other is the *Go-kinai*, or Five Home Provinces, which surround the old capital, Kyoto (q.v.). Taken in order from east to west, the eight circuits are as follows: (1) Hokkaido, or North Sea Circuit, comprising the 10 provinces of Yezo (q.v.), and an eleventh added in 1875, made up of the Kurile Islands; (2) Tosando, or Eastern Mountain Circuit, comprising 13 provinces, the most easterly of which lie towards Yezo; (3) Tokaido, or Eastern Sea Circuit, comprising 15 provinces, and stretching along the Pacific from Sendai Bay towards the Five Home Provinces (Fujisan, Tokyo, Yokohama, and other important or well-known places are in this *do*); (4) Hokuroku-do (or riku-do), the Northern Land Circuit, lies along the Sea of Japan and comprises seven provinces; (5) San-in-do, or Mountain Shade Circuit, comprises eight provinces which border the Sea of Japan; (6) San-yo-do, or Mountain Sun Circuit, lying along the south or "sunny" side of the mountains (the last two circuits are frequently spoken of as Chugoku, or the Central Provinces); (7) Nan-kai-do, or the

South Sea Circuit, comprising the four provinces of Shikoku, the island of Awaji, and Kiushu on the main island, six in all; (8) Saikai-do, or the West Sea Circuit, comprising the nine provinces of Kiushu. The subdivisions of the provinces are called *kori*.

For administrative purposes the Empire is divided into *fu*, or municipal prefectures, and *ken*, or rural prefectures. These prefectures are further divided into *gun kori*, or districts, *shi*, or cities, and rural towns, and villages ranked as *cho* and *son*. The preceding table shows the population of the sections of the Empire, with the population according to the census of 1908, and the number of prefectures, rural districts, cities, towns, and villages in 1911.

The capital of the country is Tokyo (q.v.). The pre-Restoration capital was Kyoto.

Population. The first really reliable census of the whole country was taken in 1872. This showed 7,107,841 houses and a total population of 33,110,825—less than that of the main island at the present time. At the end of 1898 the number of houses had increased to 8,281,708, and the population to 43,763,153. Of this total number the nobility claimed 4551, the gentry 2,105,696, and the common people 41,050,568. On Jan. 1, 1909, the number of Japanese proper (i.e., exclusive of the natives of Formosa, the Pescadores, and other dependencies), at home and abroad, divided according to the six statistical divisions, was as follows:

	Population	Pop. per square kilometer
Hondo, central.....	19,004,481	214
Hondo, northern.....	7,480,434	93
Hondo, western.....	10,929,374	217
Total Hondo.....	37,414,889	
Shikoku.....	3,288,310	175
Kiushu.....	7,246,937	181
Hokkaido.....	1,137,455	16
Grand total.....	49,588,804	135

Of this total, 25,046,380 were males and 24,542,424 females. The numerical strength of the various classes was as follows: nobles, 5642; knights or gentry, 2,218,623; common people, 47,382,262, including 18,017 Ainos in Hokkaido. At the end of 1913 the population was estimated at 52,985,423. The percentage of increase has been as follows: 1872, 0.57; 1881, 0.94; 1886, 0.84; 1891, 0.66; 1896, 1.04; 1900, 1.25; 1901, 1.39; 1902, 1.29; 1903, 1.54; 1904, 1.32; 1905, 1.32; 1906, 1.32; 1910, 1.46; 1911, 1.30; 1912, 1.29; 1913, 1.29.

Since the centralization of modern industries there has been a large concentration of population in the cities and towns. The following table shows the number of communes of each

COMMUNES	1898		1908	
	No. of communes	Population	No. of communes	Population
Under 500 population	750	199,712	229	59,950
500 and under 2,000	4,250	5,991,450	2,551	3,778,108
2,000 and under 5,000	8,008	24,427,130	7,649	24,269,615
5,000 and under 10,000	1,069	6,775,503	1,854	10,736,232
10,000 and under 20,000	150	1,991,185	268	3,586,200
20,000 and under 50,000	60	1,747,670	76	2,422,981
50,000 and under 100,000	12	772,481	19	1,352,565
100,000 and under 200,000	3	423,490	4	530,916
200,000 and under 300,000	2	459,925
300,000 and under 400,000	1	353,139	3	1,150,731
400,000 and under 500,000	1	442,462
500,000 and over	2	2,261,356	2	3,412,726
Total.....	14,262	45,403,041	12,456	51,742,486

class, and the aggregate population in each class of communes, according to the censuses of 1898 and 1908.

Education. Since Japan was opened to foreigners much attention has been given to education, and for a time foreign teachers and advisers were in demand, both by the government and by private persons. The present Department of Education was established in 1871, but much organizing had been done before that time. The advisers were mostly from the United States, and as regards the public-school system which the government had determined to establish, United States models were largely followed. Later German influences prevailed, and the system now in vogue is largely patterned after German models. It includes the following grades:

1. Kindergarten work or infant schools, which originated first in 1876 in connection with the normal school, but have since been extended. The age is from three to six. In 1911 there were 475 such schools, employing 1312 women, with 38,125 infants in attendance.

2. Elementary schools, attendance at which is compulsory, as far as the lower division, called "ordinary schools," is concerned. It is for children from 6 years to 10; the school year is 32 weeks long, and the children are taught morals, reading, writing, composition, and arithmetic, and sometimes gymnastics, drawing, and music are provided. The higher grade is optional for children between 10 and 14. The course of instruction includes geography, history, English, agriculture, and commerce.

3. Middle schools, in two grades, ordinary and higher. The ordinary covers a course of five years and includes ethics, Japanese language, English (then French or German), agriculture, geography, history, mathematics, natural history, physics, chemistry, etc. In the higher grade the course covers two years of Latin, zoölogy, botany, geology, mineralogy, dynamics, surveying, philosophy, etc.

4. The university crowns the whole. There are also normal schools and special schools.

Instruction is not gratuitous, and the local school boards, which are elected by the people, have to provide for those too poor to pay. The school age is from 6 to 14. In 1911 the number of children of school age was 8,604,787, of which 4,482,609 were boys and 4,122,178 were girls. In 1911-12 the public and private primary schools numbered 25,750, with 157,536 teachers and 7,021,661 pupils in attendance. In 1880 the rate of attendance per 100 children of school age was 41.06; in 1903 it was 92.23; in 1910-11 it was 98.14, an increase of 0.04 over the previous year. A notable fact is the spread of female education. In 1880 the rate of attendance per 100 children of school age was 57.60 for boys and 23.51 for girls; in 1903 the rate for boys was 96.59 and for girls 89.58; in 1910-11 the rate was 98.83 for boys and 97.38 for girls.

In 1911-12 there were 314 middle schools, with 6092 instructors and 125,304 pupils; 83 normal schools, with 1571 instructors and 27,076 students; 7298 special and technical schools, with 8247 instructors and 394,586 students; 250 superior (or high) schools for girls, with 3300 instructors and 64,809 students; 2266 miscellaneous schools (1910-11), with 7346 instructors and 144,089 pupils.

There were 9 special schools of medicine and pharmacy, with 3389 students; 10 schools of law and politics, with 14,267 students; 241 agri-

cultural schools, with 26,945 students; 108 apprentices' schools, with 10,018 students; 97 commercial schools, with 24,642 students; 12 nautical schools, with 1973 students; 15 fishery schools, with 912 students; 34 schools for the fine arts, languages, etc., embracing 5595. There are numerous preparatory schools for each of the above divisions. The 445 libraries had a total of 2,750,205 volumes in 1911-12, of which 2,600,278 were Japanese and Chinese works and 149,927 European. The Imperial University at Tokyo was founded in 1869 by the consolidation of two schools, the Kai-sei-gakko and the Sho-heiko, and later other colleges were added. In 1911-12 it had 372 professors and instructors (including 15 foreign) and 4984 students. The University of Kyoto was opened in 1889, with one foreign and 69 native professors and 360 students; in 1911-12 it had 158 professors and 1226 students. There are, besides, two universities maintained from private funds, the Keiogi-juku University, founded in 1865, and the Waseda University, founded in 1882 and converted into a university institution in 1902. In 1911-12 there were published 43,153 books, most of them on politics, industry, law, and religion. There were 1793 periodicals in that year.

Religion. Japan has really three religions—Shinto, Buddhism, and Christianity. Under the new constitution of 1889 absolute freedom of speech and freedom of religious opinion and belief are guaranteed. Shinto (the way of the gods) is a purely native cult. It has no creed, no doctrinal system, no moral code, no priests, and no images in its 130,258 (in 1908) temples and shrines, though it has nearly 14,000 gods, before whom, or some of whom, certain offerings are made from time to time; to whom certain prayers are addressed on such occasions, and before whom certain ceremonious dances are performed in a very punctilious and decorous way. It appears to be a mild kind of ancestor and hero worship which has come down from primitive times. The chief deity is Amaterasu (the sun goddess), from whom the mikados are descended. It exerts no particular influence for good on the people, though it does them no harm. From the ninth century onward it became much tinged and corrupted with Buddhism, indeed was practically absorbed by it, Kobo Daishi (q.v.) having apparently convinced everybody that the Shinto gods were merely manifestations or transmigrations of Buddhist deities. It is stated that 13 sects of Shinto now exist.

Buddhism entered Japan by way of Korea in 552 along with the arts, sciences, and letters of China. Its gilded images and its gorgeous temples and ritual appealed to the Japanese mind, and the new religion became popular. It gained both the favor and the patronage of the Imperial court, and in 621 it was by edict proclaimed to be the established religion. Priests went to China, or were sent there by the government to study, and these on their return brought with them new scriptures, new sects, and new ideas which soon began to blossom out into other new sects in Japan. Kobo Daishi in 816 founded the Shingon (q.v.), or the sect with the form of "true words"; the Zen, or "contemplative" sect, was introduced in 1202; the Jodo, or "pure-land" sect (see TS'ING-TU and SUKHAVATI), in 1211; the Shinshu, or "true sect," an offshoot of the preceding, in 1262; the Nichiren in 1282; and many others. Now there are 70 sects and subsects, all based on or developments of the

Mahayana, or Northern School of Buddhism, in which Sakyamuni, the historical Buddha, has little or no place. The most important of these as far as influencing the people is concerned are the Jodo, which finds Nirvana too hard to attain to and provides instead a "Paradise in the West," presided over by Amida Buddha, where the faithful may enjoy a blissful existence through untold ages, and whence, if they have to be reborn, it will be easy to reach the Nirvana state. The Shinshu, an offshoot from Jodo, has been called the "Protestantism of Japan." It teaches that salvation may be obtained merely by faith in the mercy of Amida—the chief of the Buddhas—and his ability to save, without works of any kind. No change of heart or conduct is necessary, and nothing is required beyond loving one another, keeping orderly, and observing the laws of the government. Its priests may marry, and they are free to eat both flesh and fish. This is the most powerful of the Japanese sects; its temples are large and magnificent, are found in the most crowded parts of the cities, and are thronged day and night with silent worshippers. In 1899 its temples numbered 19,213. Buddhism was disestablished in 1871 and disendowed in 1874, and there is now no state religion. The great majority of the people are Buddhists, but there are no organized bodies of church members as there are in Christendom. Among the upper classes agnosticism prevails.

If Shinto can be called a religion, then Christianity comes third. All its churches are enrolled by the government and are protected by law. In 1908 there were 789 Protestant missionaries, including women, 1303 native preachers, ordained or not, men or women, 10,554 churches, 57,830 enrolled members, and 1066 Sunday schools with 84,160 children. The Roman Catholics had 144 European missionaries, 182 church edifices, 62,694 Christians, 93 religious men, and 389 religious women (foreigners and natives). The Greek church had 37 native priests and 129 catechists, and 30,166 baptized Christians according to one reckoning, 13,000 followers according to another. Little has been written about the work of the Russians in Japan; even in Russia almost nothing has ever been published.

In 1908 there were 71,784 Buddhist temples and monasteries, with 73,406 priests and 51,587 preachers and 9976 students. The Shinto temples numbered 130,258, in charge of 14,498 *kannushi*, or priests. The Roman Catholic, Greek, Anglican, and Protestant churches and preaching stations numbered 1290.

Ethnology. The modern Japanese are a very mixed people. The largest factor in the production of the Japanese is to be traced back to the Mongolian race of the adjacent continent, a view confirmed by the physical characteristics of a considerable portion of the population at the present time. Some, indeed, group Japanese and Koreans together as being ancestrally very closely akin, by physical characters as well as by speech. But among the Japanese, as among the Koreans, and in certain parts of China, there are recognizable three physical types—an Ainu type, chiefly characteristic of north Japan; a Manchu-Korean, in the regions nearest Korea; and a Malayo-Mongolic, in the centre and east. The Korean-Manchu type seems to go back, like the primitive Chinese, to a Mongolian ancestry with a strain of proto-Caucasian blood, while the Ainus (see AINO) are perhaps allied to the

most primitive Caucasians; but such opinions must be accepted with caution. The best authorities agree in distinguishing a "fine" and a "coarse" type among the modern Japanese. The former is taller, more slenderly and gracefully built, longer-faced and longer-headed, with better-shaped nose, and, generally, less distinctively Mongolic in form and features, with lighter skin, etc. The "finer" type may be considered to be the descendants of the Japanese immigrants from the continent, who conquered and intermingled with the original inhabitants, or Ainus. This "fine" type has now become the Japanese ideal. The "coarse" type is characterized by shorter stature and thickset body, broader skull and face, more prominent cheek bones, somewhat oblique eyes, large lips, wide mouth, more powerful jaw, flattish nose and wide nostrils, darker skin, and generally more of the Mongolian in form and feature.

The population of Japan may thus be considered to consist of a prehistoric proto-Ainu and later historic Ainu element, upon which the Sibiric ancestors of the Japanese proper imposed themselves by slow degrees until they ultimately became the dominant factor. There has been added, perhaps at several different periods, a Malay or Polynesian element, which is noticeable in central and east Japan, where it is thought to have modified considerably both physical and social characters. Traces of ancient Negrito influence have been seen in Japan by some authorities, but others attach no importance to these alleged proofs of the former existence of a black race in Japan.

Physically the Japanese are not a strongly developed people, but they are capable of great exertion and endurance. A number of somatic peculiarities have been noted in the Japanese, such as the divided molar bone (*os japonicum*), the low, broad upper jaw, without canine fossa, and the so-called "Japanese knee" (due to the practice of sitting so much). In their general physical conformation many of the Japanese males of the better classes have a decidedly feminine or even childlike cast—a character thought by some authorities to belong more or less to the Mongolian race in general.

Intellectually the Japanese have shown a capacity equal to that of any other known people, and their native power is revealed by the fact that while their manners, customs, and certain institutions were modified in ancient times by Chinese culture, and in recent times by European and American civilization, the fundamental traits of their character have not been altered. The mental and moral characters of the Japanese may be summed up as patience and persistence, combined with cheerfulness, a certain versatility and quick-wittedness, enterprise and originality, together with unexcelled powers of imitation, as well as progressiveness, industry, artistic sense, humor, cleanliness, politeness, honor, bravery, kindness, calmness, and ability to conceal the emotions. From the Chinese and some other Mongolian peoples the Japanese differ in the freedom accorded to women from the remotest times down to the present day, their less altruistic ethical system, their high estimation of the warrior and their appreciation of war as a means of national advancement, their national virility, and their power to respond to and accept facts of modern social and historical evolution. The social and moral life of the Japanese offers much that is

interesting in the way of evolution. In sexual relations they are now monogamous, though polygamy was formerly permissible.

As compared with China, and perhaps with Korea, the civilization of Japan is comparatively modern, for the coming of the continental Mongoloid ancestors of the Japanese to the island may be fixed at 2000-1500 B.C. Their conquest of the various islands of the great archipelago was slow and apparently difficult, as the Japanese annals themselves record, for the Ainu and proto-Ainu population was well distributed throughout the group. Relics of Ainu origin are found almost everywhere, but naturally in more abundance towards the north. The amount of Ainu blood in the modern Japanese is considerably more than hitherto supposed, and the liberal policy of the present authorities towards the Ainu of the extreme north is leading to a recognition of the abilities and intellectuality of this ancient and primitive people, pointing to their ultimate disappearance, not by dying out or extermination, but by absorption into the general population. The question of the Malayan or Polynesian element in Japan is more difficult to elucidate. Twice at least in Japanese annals there is mention of swarthy foreigners from the south who made irruptions into east and central Japan. These, according to several authorities, were Malayan or Malayoid tribes, who came by way of Formosa and the Loo-choo Islands, and the physical characteristics of this section of Japan bear testimony to their presence and their numbers. Other evidence of a Malayan influence exists, according to some ethnologists, in the structure of the house, the practice of massage, certain dances, luxury, and love of weapons. Some of these resemblances are too general, however, and others too clearly the product of the Japanese environment, to be conclusive evidence. The introduction of Chinese and Korean civilization into Japan dates back for its beginnings to about the first Christian century, and this influence was strengthened after the transference of Buddhism in the sixth century.

Manners, Customs, etc. The Japanese are a cheerful, contented people, lovers of nature, and always ready for a holiday. Opium growing and the importation of it are forbidden, and government supplies the needs of the medical profession. Courteousness is a distinguishing trait, and their ceremonious politeness is oftentimes most embarrassing to the foreigner, who is not usually given to self-depreciatory remarks, and whose stock of honorifics is small and not always instantly at command. Hand-shaking is not a Japanese custom, and the lowness of the obeisance varies with the rank of the individual, women and the lower classes usually getting down on their knees. Children dress like their elders, and though their footgear is clogs held on by a band passing between the big toe and the next one, they romp and run as much and as fast as European or American children. Their socks—when they wear them—have a separate compartment for the big toe. Their toys and indoor amusements are innumerable. In dress the Japanese are not burdened with much underclothing. Their chief outer garment is the loose-sleeved gown known as the kimono, open in front but bound round the waist with a sash. That of the women is a little longer, differs somewhat in the sleeves, and the sash, or *obi*, is wide and formed into a bow at the

back which varies in style according to age, etc. Married women used to shave off their eye-brows and blacken their teeth with the juice of the persimmon tree. The coiffure is an elaborate construction, with "waterfalls," plastered down with bandoline and decked with stickpins.

Japanese houses are usually of one story. There are no cellars. The floor is about 2½ or 3 feet from the ground and is formed of soft, thickly padded mats measuring 6 feet by 3, and on these the family sit (or rather squat on their heels), eat, and sleep. There are no tables, chairs, or bedsteads, thick wadded quilts serving as mattress and blankets. Heat when wanted is provided by a *hibachi*, or brazier filled with burning charcoal. The pillow was formerly a little paper-covered cylindrical cushion strapped on a narrow stool, and placed under the neck so as not to disturb the hair, but the European pillow is now in general use. Footgear is left in the porch before stepping on the veranda. A single picture, changed with the season, and a small wall vase containing a single sprig, form the only decoration, apart from that of the *shōji*, or sliding paper screens which serve as partitions. Passers-by may get a glimpse through the open screens of a tiny garden at the back, with a miniature rivulet, a stone thrown across it as a bridge, a miniature hillock crowned with a dwarfed pine, and a flowering shrub or two, and perhaps a stone-pillar lantern. A necessary feature of every house is the "god shelf," or family altar, where is the little shrine—Shinto or Buddhist—before which the offerings are placed. Cleanliness is next to godliness, and the bathtub at the back, with its little furnace in one end for boiling the water, is patronized by every member of the family in succession, the water being invariably hot (100° to 115° F.).

Food is served on little lacquered stands about a foot high and is eaten with chopsticks (both of the same material). Rice, with soup of seaweed, beans, vegetables, or hard-boiled egg cut up into pieces, with a little fish with soy, and the like, daintily served, make the meal, sake (their fermented beverage) when used being heated and served in the tiniest of porcelain cups. Tea is the usual beverage. But there is no meal called "tea." Pickled daikon (or radish) is their chief relish.

Married life is usually happy. Cremation was introduced by the Buddhists about 700 A.D. After the Restoration it was forbidden, but a custom of such long standing could not be wiped out with the stroke of a pen. Those who favor the Shinto cult bury their dead in coffins.

History. Japan begins its history with a year corresponding to 660 B.C., when Jimmu Tenno (q.v.), the leader of a band of invaders, settled in Yamato after having conquered several of the tribes who opposed him. Our only source of information in regard to the early history of the dynasty which was founded by him, and which exists to the present day, is found in the *Kojiki*, the oldest extant book of Japan, in which are found the myths and legends written down in Chinese characters in the years 711-712 by one Yasumaro, from the lips of a person named Hiyeda-no-Are, who possessed a most wonderful memory. These myths and legends, under close analysis, show three streams of legends: the Tsukushi or Kiushu cycle; the Idzumo legendary cycle, which covers central and west Japan; and the Yamato cycle,

which covers the central and eastern parts of the main island. The north and east parts of the main island were inhabited by the Emishi savages, or Ainus, who had retired thither before the advancing invaders, leaving their names on rivers, mountains, streams, and other natural landmarks. In the south dwelt aboriginal people, perhaps from the Malay regions. The invaders of the archipelago, whether coming from Tartary or Korea, were without letters or writings, but possessed superior arms, valor, and discipline. They came as immigrants, at various times and to various places, finding people already on the soil, whom they proceeded to put under their control.

There are thus early discerned with clearness, in the morning of the history of Japan, race struggles among various tribes of differing customs and languages, and two types of men, whom we now call Japanese and Ainus, the former living south, the latter north of the thirty-eighth parallel. Gradually the Tsukushi and the Idzumo people became subordinate to the Yamato house or tribe. The conquerors intermarried with the subjugated, and the pacified chiefs were awarded rank and honor, while the power of the Mikado or Yamato chief was consolidated by making the primitive cult, now called Shinto, or Kami-no-michi, a political engine. The whole country was put under a rude feudal system, the conquered or subordinated holding their lands in loyalty to the Yamato chieftain or Mikado. Civilization gradually drifted in from Korea, through teachers, artificers, and men of learning. There are indications that a century or two before the great flood of civilizing influences was borne on the waves of Buddhism, considerable knowledge of Chinese letters, writing, and ethical notions had penetrated to the Yamato court and among some of the chiefs of the southwest. The *Nihongi* (another historical work, compiled in 720 A.D.) states that in the year 405 a Korean scholar was appointed tutor in Chinese classics to one of the Imperial princes, and that about the year 430 "historiographers were appointed." As yet, however, there was no such thing as a settled capital, the Mikado and his household moving from place to place in central Japan. After the death of the Mikado chief, his successor, with a horror of the place of the dead, moved on and built a new palace. There have been thus no fewer than 60 capitals. To-day the provinces of Yamato, Yamashiro, Kawachi, and Settsu "are dotted with places, now mere villages, sometimes indeed empty names, but once in the proud position of capitals of the Empire."

The line between legend and true history is made clear upon the arrival in 552 A.D. of Buddhist missionaries from Korea, who brought with them not only the sutras and images of their cult—the Mahayana northern form of Buddhism—but also letters, writing, calendars, and methods of keeping time. Buddhism took root and became so popular with both court and people that in 621 it was proclaimed by edict to be the established religion of the land. From this time forth we have something like a coherent account of things and can trace with some clearness, through many rebellions and oppositions, the rise to paramountcy of the Yamato house. Nara in Yamato became the fixed capital and remained so for seven reigns between the years 709 and 784. One decade later Kyoto was made the Imperial residence and, with few interrup-

tions, continued to be so until 1868. At the opening of the seventh century Chinese civilization had so far been accepted that in 603 the form of government was changed from feudalism to monarchy; eight boards or departments of state were established, in imitation of the Chinese system; and a new order of nobility, in nine ranks, was created. A great council, called the Dajo-Kwan, which had also been established, superintended the eight boards and ruled the Empire by means of local governors appointed and sent out from the capital.

The practical enforcement of this new centralized system of rule from Kyoto was not acceptable and was in many places long and stoutly resisted. Gradually a military class was formed, which became separate from the agricultural, the latter comprising the farmers and those who permanently tilled the soil. By parallel development the men at arms became professional soldiers. Other great lines of movement may be summarized in the increasing centralization of government and the withdrawal of the Mikado from active service in the field or even in the affairs of government and his comparative seclusion. Under the pretext of religion or a desire to lay aside the cares of government, committing the actual work of administration to his subordinates in order to seek retirement, he became in the national life rather an abstraction than a person.

By means of the superior valor, force, and skill of its soldiers the Empire was extended north, south, east, and west until all Kiushu and Shikoku were subdued and the arms of Japan extended to the far east and north. Meantime in the capital and palace the Fujiwara family, who had come into position and power about the year 670, had developed a bureaucracy, so that they gradually monopolized most of the offices in and about the court and the administrative boards. In other civilian families the particular administration of sacred rites or the cultivation of learning became the specialty or monopoly. The military commands were always given to the rival clans of the Taira and Minamoto. The Taira warriors, fighting under the white crest or banner, gained renown and power in the southwest. The Minamoto, under the red banner or crest, won victory and held power in the east and north; but when once the activities of the field were comparatively things of the past, both clans lusted for power nearer the throne. Then began a struggle in the capital. The Fujiwara, who had formed a ring around the Emperor and by their own henchmen blocked most of the ways of approach by nepotism, were ousted by the Taira, whose star was now in the ascendant. This naturally excited the jealousy of the Minamoto, and in the year 1159 the two rival military clans came to blows. Then began that famous period of the wars of Genji and Heiké, which have since colored all Japanese history, literature, and art, and which in later times, even to this day, have given the standard and motives for games of skill and chance. Kiyomori, the Taira chief, became Premier in 1167. He not only redistributed the offices, civil and military, among his own clansmen, but by marrying his daughter to the Emperor controlled the throne itself. The Minamoto men, their leaders beheaded or banished, were scattered, one line becoming rulers of far-off Loo-choo. In 1181, after Kiyomori's death, Yoritomo led the Minamoto in an

uprising, and under the generalship of Yoshitsuné, his brother, the Taira men were driven out of the capital and from their palaces. After several land battles and a great naval conflict near Shimonoseki (1185) the Taira were annihilated. The divisive evolution between military and civil power had so far proceeded that, leaving Kyoto to be the centre of honor and tradition and of that outward form which in Japan, as in China, saves the "face" of a thing, Yoritomo fixed his seat of authority, in the name of the Emperor, at Kamakura, in the Far East, on the bay of Tokyo. He had himself appointed Shogun, or general (1192), and was hailed as the great peace bringer. Although his line came to an end in 1219, yet the system which he inaugurated was carried out by the Hojo family of regents, who held power until 1333. Obtaining from Kyoto, in the name of the Emperor, nobles who were mere children and puppets, to whom the title of Shogun was given, while they held the power themselves, the Hojo ruled the Empire. It was during their rule at Kamakura that the armada of the Mongol Tatars was destroyed by storms and the valor of the Japanese. Several of the Hojo regents were men of great ability and ruled with justice and vigor.

From the moment of Yoritomo's success feudalism entered upon a new stage of development. Under the Imperial system, from 603 to 1182, the governors sent out from Kyoto to the different provinces under a four years' tenure of office had charge both of the collection of revenue and the repression of crime. Yoritomo had no sooner got control of the east than he obtained from the Emperor a civil title equivalent to that of "high constable of the realm," by which means he had the two departments of revenue and the maintenance of order divided, leaving the Emperor's officers to collect the revenue, while he repressed crime and maintained order. This system of appointing military magistrates seemed to be so excellent that it was gradually extended all over the country. Yet all the time Yoritomo cloaked his military ambition under the guise of his civil title, so that when, in 1192, he was made Shogun, and was thus military commander in chief, he was already the virtual ruler of the country. Seeing this, the Imperial officers in charge of the revenue left Kyoto for Kamakura, and the Shogun thus possessed both purse and sword, leaving Emperor and court, in honor and poverty, dependent on him. Henceforth the functions of government were separated into those of throne and camp—the former the centre of mystery and the fountain of honor, the latter being the actual government. The Hojo were overthrown by the brave warrior Nitta in 1333. Then followed for a while, but for two years only, what may be called the temporary mikadoate, when there was no Shogun and theoretically no feudalism.

That the mikados had not yet, however, vigor enough to enter upon personal rule was shown in the fact that when the adherents of rival nominees to the throne went to war over the division of spoils, the Mikado could not restrain them. Civil war broke out, lasting 56 years, when two rival lines of mikados held the shadow of power, in the period 1336-92, and there were two capitals, though the real rulers were the shoguns of the Ashikaga family. In 1392 one of their envoys persuaded the Mikado,

who had the three Imperial regalia—mirror, crystal ball, and sword—to come to Kyoto and hand over the sacred emblems, and the feud was healed. Now that the Ashikagas had their nominee on the Imperial throne, the second great step in feudalism was taken by them, when they made the military magistracies, established by Yoritomo, hereditary in the families of their own nominees. Thus arose the class of daimyos. (See DAIMYO.) The Ashikaga power lasted until 1573, during which time the Portuguese came to Japan, Mendez Pinto (q.v.) landing in 1542 and Xavier in 1549, beginning a period of intercourse with Europeans which continued until about 1620, during which Christianity and firearms were introduced. In general the period of the Ashikaga rule was one of great refinement of manners, of high art and literary culture, along with the missionary expansion of Buddhism and a remarkable phase of doctrinal evolution. On its political side Buddhism reached a point of wealth, luxury, and menacing military power which made it one of the great forces in the state, calling for some powerful hand to put it down. As the Ashikaga became weaker in their later years, anarchy grew to be more general. The Buddhist abbots and their monks, in arms and armor, possessing closer organization and with fortified monasteries, often turned the scale of power. From 1573 to 1604 was the period of the three famous men Nobunaga (q.v.) (1533-82), Hideyoshi (q.v.) (1536-98), and Iyeyasu (q.v.) (1542-1616). The first humbled the Buddhists, the second reduced the daimyos to submission, and the third consolidated results. The third decisive step in the development of feudalism was taken by Hideyoshi when he rearranged the feudal map of the Empire, marking out the boundaries of the fiefs and appointing to them the daimyos as his own nominees, giving them titles in his own name without reference to the Emperor. During Hideyoshi's time Korea was invaded (1592-98) by his hosts of warriors, who on the return of peace in Japan had been left without occupation. Iyeyasu, his successor, making Yeddo his capital, carried out Hideyoshi's plans, so enlarging them that he and his grandson, Iyemitsu, gave the final form to Japanese feudalism, which early in the middle of the seventeenth century had become settled in routine. It is noteworthy that alongside of elaborate feudal institutions grew up a commercial and industrial system like that contemporaneous with late feudalism in Europe. Yeddo, from a village, became the greatest city in the Empire. The Tokugawa family furnished, from 1603 to 1868, 15 shoguns. Christianity was, as was thought, rooted out. Then began a great development in art, literature, the study of ancient history and the native language, and the revival of pure Shinto (q.v.). The policy followed was that of the exclusion of foreigners and the inclusion of the people of Japan within their island walls, while their intellect was kept within fixed bounds.

Shipwrecks and the casting away of seamen gave the United States government its opportunity to seek a treaty of friendship and, if possible, of commerce. In 1854 Commodore Perry, to whom the task was intrusted, succeeded in establishing treaty relations between Japan and the United States. Four years later other treaties opened several ports to foreign residence and trade. In 1860 a Japanese embassy visited the United States, and in the fol-

lowing year ambassadors were sent to the European courts. Narrow-minded patriots protested, but the great clans of the southwest, always detesting the northern rule of Yeddo, gradually gathered around the court. In 1867 the Shogun was compelled to resign, and when in 1868 he sought to regain power by force of arms, he was driven from the field. Men with new ideas and determined purpose obtained control of the Emperor and the government, moved the capital to Yeddo, had the sovereign swear to rule according to "the right way between heaven and earth" (in deference to public opinion), and began the abolition of feudalism. It was virtually a committee of four men, Iwakura, Okubo, Kido, and Saigo, with their farseeing fellows and helpers, that led the samurai to swing the nation out of ancient routine in order to create the new Japan. They invited educators from the United States to reorganize their educational system, French officers to remodel their army, British seamen to reorganize their navy, and Dutch and other engineers to make internal improvements. These tremendous changes were not accomplished without protest. In 1887 Saigo quarreled with his old friends, led an army "against the Emperor's evil advisers," and the Satsuma Rebellion cost Japan 20,000 lives and \$50,000,000. In 1879 Loo-choo was made an integral part of the Empire, and Sho Tai, the King, brought to Tokyo and made Marquis. Western laws were introduced and codified. In pursuance of the Imperial oath, a Parliament was promised. In 1884 the nobility was organized on the European idea, and many new men were honored with titles. In 1889 the constitution was proclaimed, and the Diet met in 1891. With many an ebb and flow the great tide of progress has kept on. In 1894 war with China broke out in regard to Korea; this resulted in the utter defeat of China, the cession in 1895 of Formosa to Japan, the payment of a large indemnity, and the independence of Korea. The decisive triumph of Japan was notice to the world of the advent of a new power in the East whose voice would be heard in future political arrangements. Even before the outbreak of the war the nation had entered on a series of treaty negotiations which was to admit it to full equality with the Powers through the abolition of the obnoxious consular courts. As a preliminary step a thorough revision was effected of the different legal codes, criminal, penal, judicial, civil, and commercial. Great Britain and the United States were the first to abandon the principle of extraterritoriality (1894), receiving in return the freedom of the entire Empire for their trade. Similar treaties were concluded in 1895-96 with all the European nations of consequence, all the treaties to go into effect in 1899. The sphere of national interest had broadened as a result of the war. The pacification of Formosa, which was made difficult by the activity of Chinese irregular bands or "black flags," was actively carried on. In Korea Japanese influence had to contend with the aspirations of Russia, against whom, naturally, bitter resentment was cherished as the leader in the Triple Alliance of the European Powers which in 1895 had deprived the nation of the greater share of the fruits of victory. In 1898 the two Powers by treaty made formal recognition of the independence of Korea and pledged themselves to abstain from all interference with the internal affairs of that Empire.

During the Boxer uprising the Japanese troops more than held their own among the international forces which marched on Peking. In the diplomatic struggles which followed the occupation of Manchuria by Russia, an act which Japan regarded as portending peculiar danger to its interests, the latter nation found itself again confronted by the 1895 alliance of Russia, Germany, and France. The result was the Anglo-Japanese alliance concluded Jan. 30, 1902, for a period of five years. The two governments, declaring themselves specially interested in maintaining the independence and territorial integrity of the empires of China and Korea, guaranteed to each other the right to take all needful measures for the protection of those interests if threatened by the aggressive action of any power or by disturbances arising within China and Korea. If war was entered into by either of the contracting parties and any other Power, the second party to the agreement pledged itself to maintain an attitude of strict neutrality. In case, however, its ally was involved in hostilities with more than one Power, the other party would come to its aid and wage war and make peace in common. By linking itself with the leading power in the East and the greatest naval power of the world, Japan found its position immeasurably improved. From that time war with Russia was deemed by competent observers to be inevitable, though there was division of opinion as to whether the alliance with Great Britain was only a justifiable measure of self-defense taken in preparation for the conflict which Russian fatuity in Manchuria was bound to evoke, or whether it constituted a challenge and an irritation to Russia and a cause of war in itself.

The developments of the two years preceding the outbreak of hostilities in February, 1904, will be found under CHINA, KOREA, MANCHURIA, and especially RUSSO-JAPANESE WAR. Internal affairs after 1900 were largely concerned with party struggles (see POLITICAL PARTIES) and unsuccessful attempts on the part of the government to cope with the unhappy economic conditions that had followed the war with China. The Katsura ministry, which came to power in June, 1901, found itself confronted by the necessity of satisfying the general demand for the abolition of the onerous land tax instituted in 1898, and at the same time of providing means for the execution of a programme of naval expansion made necessary by the anticipation of war with Russia. A hostile Diet was dissolved in December, 1902, but the House which met in March of the following year was equally recalcitrant. Through the intercession of Marquis Ito a compromise was finally concluded whereby in return for a reduction of the land tax the desired naval credits were voted. In the course of the year relations with Russia over Korea arrived at a critical stage. The Diet which met in December, 1903, expressed its disapproval of the government's conduct of the negotiations and was promptly dissolved. The new House met in March, 1904, after the outbreak of hostilities with Russia (February 8). See RUSSO-JAPANESE WAR.

The history of Japan since the Russo-Japanese War is largely concerned with two great problems, internal reorganization and immigration to the United States. The enormous cost of the war produced a financial stringency which had to be tided over, and the heavy

taxes laid on industry aroused general discontent. Machine production has made rapid strides in Japan, which is now almost as highly industrialized as some of the European countries. The historic friendship between Japan and the United States has several times been strained on account of the question of Japanese immigration. Many Japanese laborers have come to the western part of America, mainly to the States of California, Washington, and Oregon. The white population of these States, particularly the labor unions, were bitterly opposed to the Japanese immigrants and demanded their exclusion by law, as in the case of the Chinese. In 1906 the school board of San Francisco ordered the segregation of Japanese children. This action was regarded by the Japanese as an insult to their race, and a note of protest was sent to the United States government. The sensational press of both countries began an agitation which threatened to rouse the war spirit of both peoples. Moreover, the American government was in a quandary, as it had no power to interfere with the regulations of the local authorities. Mayor Schmitz of San Francisco was called to a conference on the subject by President Roosevelt, and the latter was informed of the intense sentiment against the Japanese on the Pacific coast. A partial settlement was effected by the Japanese government giving an oral assurance that it of itself would restrict the emigration of Japanese laborers to the United States; the objectionable school ordinance was then withdrawn by the authorities of San Francisco.

Japan's emergence as a great Power made her a desirable ally. On Aug. 12, 1905, was signed the famous Anglo-Japanese alliance. Its object was (a) the preservation of peace in eastern Asia and in India, (b) the maintenance of the integrity of China and equal opportunities for trade among all nations, (c) the defense of the territorial rights of each in the regions of eastern Asia and of India; both were to act in common in case of an unprovoked attack or aggressive action. This treaty was renewed for 10 years on July 13, 1911, and a new clause was inserted that "should either High Contracting Party conclude a treaty of general arbitration with a third Power, it is agreed that nothing in this Agreement shall entail upon such Contracting Party an obligation to go to war with the Power with whom such treaty is in force." This clause was put in at the behest of the British government, which became alarmed at the possibility of being forced into a war with the United States on account of Japan. An oral assurance was also given by Japan that she would regulate the emigration of her laborers to Canada.

As a result of the Russo-Japanese War, the paramount interest of Japan in Korea was acknowledged. Great indignation was felt among the Koreans, for it foreshadowed their loss of independence. In 1909 Prince Ito, the famous Japanese statesman, was assassinated at Harbin by a Korean patriot who wished to avenge the wrongs inflicted upon his countrymen by the Japanese. In 1910 Korea was formally annexed to Japan and renamed Chosen, but the commercial rights of foreigners resident there were guaranteed for 10 years. An extensive conspiracy by Koreans against the Japanese government was laid bare in 1912, and many arrests were made. Of the 123 prisoners held

for trial, 106 were sentenced to terms of imprisonment.

The heavy taxation necessary to maintain the army and navy and to pay for the war against Russia resulted in widespread discontent, particularly among the commercial classes, who continually protested against the ever-increasing drain upon industry. In the election of 1908 the Seiyu-kai (Liberal) party obtained an absolute majority in Parliament. As in Germany, the cabinet is responsible to the Emperor, not to Parliament. This was the first time that one party had a majority over all the others, and it was feared by the Conservatives that the principle of ministerial responsibility would be established. In order to prevent this, the Elder Statesmen interfered and ordered the appointment of Prince Katsura as Prime Minister, although he was a member of a small faction known as the Daido Club. The Katsura cabinet took office, promising fiscal reform in harmony with the desires of the commercial classes.

Japan's rapid transformation into a modern nation both politically and industrially brought into existence those revolutionary elements long familiar in Europe, Socialists and even anarchists. For the first time a conspiracy was formed against the life of the Emperor. A Dr. Kotoku and his wife with 12 others were secretly tried and executed in 1911. Twelve others were imprisoned for life. There was much criticism of the government because of the secrecy of the trial. On July 29, 1912, the Emperor Mutsuhito died and was succeeded by the Crown Prince Yoshihito, aged 33. The death of the much beloved Emperor produced great grief among all classes of the population.

The Japanese people have been trying fitfully to shake off the powerful grip that the Elder Statesmen have on the government. In 1913 there occurred a grave constitutional crisis. The Seiyu-kai party, having a majority in Parliament, introduced a resolution of "no confidence" in the Katsura ministry. Urged on by the Elder Statesmen, the Emperor asked that the resolution be withdrawn, but his request was refused. He then prorogued Parliament. A great popular demonstration was the result. Vast mobs collected in the streets, the police were attacked, and the offices of reactionary journals burned. Prince Katsura then resigned and was succeeded by Admiral Yamamoto, a popular naval officer, who promised economy and reform.

The Yamamoto ministry, although it came in on a wave of popularity, was not destined to live long. His naval estimate of February, 1914, was the highest of any year, and it was reduced considerably by both Houses of Parliament. A great naval scandal came to light, which showed widespread corruption among the naval officials in the purchase of supplies, particularly from the armament firms of Germany. Vice Admiral Koichi Fujii was found guilty of bribery and sentenced to one year's penal servitude. But more than all else, there was great dissatisfaction with the ministry because it had not sufficiently protected the rights of the Japanese in the United States. Count Okuma, an old Liberal statesman, succeeded Admiral Yamamoto as Prime Minister. It is significant that Count Okuma is a member of neither the Satsuma nor the Chosu clan, the aristocratic governing elements in Japan.

The relations between the United States and

Japan again became strained in 1913. In that year the State of California passed the alien land ownership law, which excluded from the right to own land all aliens who were not eligible to American citizenship. It was directly aimed at the Japanese, as they are prohibited from becoming naturalized citizens in America. The government of Japan protested vigorously against this discrimination, declaring that the law violated the Treaty of 1911, which guaranteed equal treatment to the citizens of each country. President Wilson, aided by Secretary of State Bryan, made every effort to prevent the law from being passed, but was unsuccessful. See CALIFORNIA.

The Great European War of 1914 brought Japan into the fray. As an ally of Great Britain, Japan issued an ultimatum to Germany ordering her to evacuate Kiaochow within a week. There are several reasons for the Japanese dislike of the Germans. It was Germany who got up the combination of the Powers that ordered Japan out of Port Arthur after her victorious war with China in 1895. It was Kaiser Wilhelm II who first raised the cry of the yellow peril and so raised up a popular feeling against the Japanese. The German government refused to comply with the ultimatum, and war was declared against Germany by Japan, in order "to protect British commerce in the eastern seas." Germany's stronghold in the Far East was the powerful fortress of Tsingtau on the German leased territory of Kiaochow in China. The fortress was attacked by Japanese and British warships and a landing expedition of 50,000 Japanese troops. After a most gallant resistance of 11 weeks the Germans surrendered on Nov. 7, 1914. The Japanese government assured the United States that her intentions were not detrimental to American interests and that she intended to give back Kiaochow to China. See WAR IN EUROPE.

Bibliography. GENERAL; DESCRIPTIVE. Consult Rein, *Japan nach Reisen und Studien* (Leipzig, 1881-86), the first volume of which appeared as *Travels and Resarches Undertaken at the Cost of the Prussian Government* (2d ed., London, 1889) and the second volume as *The Industries of Japan* (ib., 1883; New York, 1889). Especially noteworthy are: Griffis, *The Mikado's Empire* (2d ed., New York, 1883); Chamberlain, *Things Japanese* (4th ed., London, 1904); Brinkley, *Japan: Its History, Arts, and Literature* (8 vols., Boston, 1901-02); Hearn, *Glimpses of Unfamiliar Japan* (ib., 1894); id., *Out of the East: Reveries and Studies in New Japan* (ib., 1895); id., *In Ghostly Japan* (ib., 1899); id., *A Japanese Miscellany* (ib., 1901). JAPANESE ART. The history of Japanese art, as distinguished from Japanese archaeology, begins with the introduction of Buddhism in the sixth century A.D. Along with the new religion came the knowledge of Chinese ideographs (word characters) and the art of the calligraphist that creates them. In Japan, as well as in China, the manual dexterity attained early in life by the use of the brush influences profoundly the manner and method of expression of artists. In both countries painting is often regarded as a mere branch of calligraphy, and both arts are similarly classified according to the nature of the brush strokes. Indispensable to the painter who would acquire a high position in the world of art are complete mastery and consistent use

of a definite style of brushwork. In every painting, print, sculpture, or chased bronze, the Japanese connoisseur looks first of all for individuality of expression, the trace of the living hand of the master. While Japanese art inherits from Chinese, just as Renaissance inherits from Roman, it is interesting to note that all inherit from Greek. The Buddhist art that Chinese pilgrims carried back with them from India to the Far East was still in a measure under the influence of the Greek civilization introduced centuries before by the successors of Alexander the Great. In many an ancient Japanese idol may be found a faint echo of Hellenistic art of the third century B.C.

Painting. Japanese paintings are of three different forms—the *kakemono*, the *makimono*, the *gaku*. The *kakemono* is a tall hanging picture for display on the wall, either singly or in sets of two or three. It is mounted on brocade or paper, at the lower end of which is an ivory-tipped stick around which it is rolled when not on exhibition. The *makimono* is a specially long roll for the presentation of processions, combats, and serial pictures. The *gaku* is a picture framed flat but not glazed. Of Japanese *kakemonos* there exist records and specimens in almost unbroken continuity from the ninth century on. Even of seventh-century paintings there still exist examples, notably the one on the wall of the Kondo in the Horiuji Temple at Nara. With Japanese painters it has always been an axiom to keep materials as much in the background as possible. They work on a surface of ribbed silk or of flat paper, with a brush full of color that does not admit timidity or error. The effect in each picture is confined to narrow limits (usually to a single expression) and is produced with a minimum of manual labor and extreme economy both of line and surface. The principal schools of Japanese painting are:

1. *Chinese and Buddhist*, dating from the sixth century—the former relying on feats of calligraphy, in black and white or dull tones, and intended for the highly cultivated classes; the latter gorgeous in gold, polychrome, and mounting, to attract the masses. The Buddhist subjects were almost entirely religious; the Chinese included history, legend, mythical zoology, landscapes, animals, birds, and flowers, all fashioned after Chinese models.

2. *Yamato and Toza*, dating from the eleventh century—Chinese in basis, but executed with a lighter touch and with decorative coloring, and having subjects commonly connected with Japanese history and legends and court ceremonials.

3. *Kano*, founded by Kano Monotobu (1476-1559), who was contemporary with Raphael and was skillful equally at figures, landscapes, birds, and flowers. His grandson Eitoku was distinguished for boldness of design and brilliancy of coloring. Among the most original of his successors was Tanyu.

4. *Ukiyoye*, founded by Iwasa Matahei (1577-1650), who deserted mediæval and aristocratic subjects for contemporary scenes and figures, corresponding to our genre paintings. Among his numerous successors were Moronobu (1624-95), Chosun (1682-1752), Harunobu (1718-70), Shunso (1726-92), Kiyonaga (1742-1815), Utamaro (1754-1806), Toyokuni (1769-1825), Hokusai (1760-1849), Hiroshige (1797-1858).

5. *Korin*, named after the great artist—a style that originated with Koyetsu (1552-1637),

aimed at an imaginative treatment of nature unfettered by the formalities of the Kano school, and achieved extraordinary decorative values.

6. *Shijo*, a naturalistic school dating from the eighteenth century, named from the street where stood the studio of the founder, Okyo (1733-95), who revolutionized the laws of painting in Kyoto, working closely from nature and preferring washes and quiet tones to sharp lines and strong body colors. Noted masters of the school are Goshun, Sosen (famous for his monkeys), Hoyen, Ganku, Ippo, Gosai, Kuburo, Zeshin.

Color Prints. Printing from wooden blocks was practiced by the Chinese centuries before it was known in Europe, and Japanese prints are extant dating from the thirteenth century. But Japanese color prints of the kind now familiar to Europeans and Americans were originated in the middle of the seventeenth century by Hishigawa Moronobu and used for the multiplication of Ukiyoye pictures. Moronobu was the son of an embroiderer and began life as a pattern designer. There had been woodcut illustrations to books before, but Moronobu was the first to publish picture books and single prints,

FROM THE KWA-CHO GWA-JO (FLOWERS AND BIRDS ILLUSTRATED).

in which the text was quite subsidiary. On Moronobu's prints the outline alone was stamped, the color being applied afterward with the brush. His pupil Kiyonobu (1663-1729) began to apply the color also from blocks, at first rose and green only. Harunobu increased the number of blocks to complete the design with background and atmosphere. He is one of the most seductive artists of Japan, presenting de-

lightfully and delicately the maidens and matrons of his native land. His color is distinguished for force and variety—tender tones of gray, rose, and soft yellow; but also rich apple green, crimson, and chocolate red. Koriusai continued Harunobu's work so closely that their work is often hardly to be distinguished. Shunso produced an infinite array of actors in character. Kiyonaga pictured wonderfully the out-of-door life of Yeddo, its processions and festivals, the countless ceremonies of the New Year, music parties in house boats on the river, and wonderful night scenes. Utamaro is distinguished for strength in figure drawing and versatility of invention. His famous triptych of "Awabi Fishers" is one of the great classics of color printing, and his sets of prints illustrating the life of the strong boy Kintoki have few equals. Kuniyoshi preferred heroic subjects, the feats of old Chinese warriors, the deeds of the Forty-seven Ronins, the civil wars of the Middle Ages. The most various and most puissant spirit of all was Shunso's pupil, Hokusai, who produced a wealth of masterpieces in landscape, and a few great figure subjects in which were concentrated wide knowledge of humanity, mastery of

the human form, and extraordinary resource in composition. Under the name of Shunro, Hokusai produced graceful prints in his master's style. Then, quarreling with his master and being expelled from the studio, he lived for a time from hand to mouth, designing New Year's cards or even peddling small objects through the streets. He was marvelously industrious but equally improvident. During the 90 years of his life he changed his residence 93 times, finding it easier to move, it is said, than to clean house. At the age of 75 he signed himself "The Old Man with a Mania for Drawing," but his thoughts were all of the future. "When I am 80," he wrote, "I shall know more; at 90 I shall have got to the heart of things; at 100 I shall be a marvel; at 110 every line, every blot, of my brush will be alive." On his deathbed he sighed, "Five more years and I should indeed have become a painter." The prints made from his paintings, published in 15 volumes, display a vast range of observation. Mountains, rivers, trees, birds, fishes, animals, insects, breaking waves, flowers, rocks, ships, buildings, utensils, men and women at all kinds of occupations, comic and fantastic figures; even gods, saints, heroes, warriors, dragons, and fabulous beasts, all take life under his restless brush. The sets of prints on which his fame chiefly rests are the "Thirty-six Views of Fuji," the "Bridges," the "Waterfalls," the "Hundred Poems Explained by the Nurse," the "Ten Poets of China and Japan." The landscape work of Hokusai, forming almost an illustrated guidebook to the famous views and favorite resorts of Japan, was

continued by Hiroshige, who is less elemental but more full of charm, and whose influence on European painting has been wider than that of any other Japanese painter. Hiroshige gives us exquisite impressions of twilight, mist, moonrise, snow, and fireworks. It is a Hiroshige motive that Whistler presents in "Battersea Bridge."

Sculpture. Beginning with the sixth century,

JAPANESE ART

1. TERRA COTTA STATUE, polychromatic, at Todaiji, near Nara. VIII Century.
2. WOODEN STATUE, polychromatic, half life size. XII Century.
3. THE HONDO (Chief Temple) of Horiuji, Yamato. VII Century.

Japanese sculptors expressed themselves in wood and metal, but seldom used stone. Noteworthy are the wooden statues dating from the eighth century, preserved at Nara, portraying the Indian Buddhists, Asanga and Vasabandhu, in dignified pose and with stately lines; and the eleventh-century colossal temple guardians of the great gate of Todaiji. The most perfect of the ancient bronzes is the great image of Bhaicha-djyaguru in the temple of Yakushiji at Nara, attributed to a Korean monk of the seventh century. From an early period the ornamentation of arms and armor was elaborate, reaching its height in the twelfth century in the armor of the Japanese Bayard, Yoshitsune, that is still preserved at Nara. In the latter half of the fifteenth century began the elaborate decoration of swords with engraved metal guards (*tsu-bas*) often inlaid with gold and silver. During the seventeenth century the use of tobacco became common, and a kind of button or toggle (*netsuke*) was employed to fasten the pouch to the girdle. The love and expense that the gentry bestowed upon sword hilt and guard were devoted by commoners to pipe and *netsuke*. The name *okimono* is applied to carved animals and decorative objects in metal, wood, and ivory, not having any special use or value.

The Japanese name for bronze, *kara-kane* (Chinese metal), shows whence came knowledge of the alloy. From an early period the Japanese bronze casters have understood how to model in wax and how to employ a hollow removable core, although making colossal statues like that of Lochana Buddha at Nara, 138 feet high and weighing 550 tons, in sections in situ. In the production of rare and exquisitely beautiful patinas the Japanese are unexcelled.

Textiles. Japanese textiles are by no means equal to those of the Chinese. No pile rugs or tapestries of great merit have come down from antiquity. Some of the modern brocades and velvets and embroideries are masterpieces of ingenuity and patience, but by no means to be classed decoratively with the great Chinese and European classic examples. The modern Japanese imitations of Gobelin tapestries made at Kyoto, though praised without reservation by some critics, are unworthy to be named in the same breath with the great products of French-Flemish looms. For Japanese lacquer and ceramics, see LACQUER WORK; POTTERY; PORCELAIN.

Architecture. As compared with that of China, the architecture of Japan is less massive, the great overhanging curved roof forming the chief motive of the design, which, even more than the rounded and swelling cupola in a domed church of Europe, gives character to the whole. The common use of timber even for buildings

meant to be, and sufficiently proved to be, very lasting has deprived Japanese architecture of the monumental possibilities of wall, colonnade, and arch. The building of the country is therefore timber construction very like in principle to that of mediæval Europe, but more dignified than that, because there was in the Eastern land no overmastering style of masonry architecture.

PAGE FROM THE GWA-FU (COLLECTION OF STUDIES) BY HOKUSAI.

like that of the vaulted buildings of Gothic or of neoclassic type, to restrain its development. Whatever was to be done, architecturally speaking, in Japan was perforce done with the trees of the mountain forests; whereas in Europe wood was in general employed only for the less important and less monumental structures. The result of this is that the architecture of Japan seems to a European rather uniform in character, but a profounder examination shows divergences as great in the different forms and characteristics of Japanese buildings as we find in the buildings of any European land. The difference from century to century is less, however; and this because of the admitted slowness of all change among Asiatics, and also because of the deliberate action of so many rulers of Japan in keeping new foreign influences away from the land. In detail there are one or two exceptional

characteristics which result from the custom of building in wood and framework. This framework has its own necessary characteristics; and these are heightened and emphasized by the use the Japanese have made of them. Next to the broad eaves and the exquisitely subtle concave curves of the roofs, one notices the effective use of multiple bracketing of great ingenuity. Very effective also is the decorative treatment of metal holders for the points of support and the points where one timber is secured to another. Just as the floor beams in European buildings are often hung in "stirrups" of wrought iron, so in Japan a metal mount especially affected to the purpose will mark the insertion of one timber into another, the crossing of two timbers of equal size, and also the base and top of a pillar, whether of wood or, as sometimes happens, of stone. The interior of the often represented Phoenix Hall of the Shoguns of the Fujiwara race reigning in the eleventh century of the Christian era has retained almost unchanged the beautiful interior effect produced by this system of construction in wood and metal. These metal mounts are often exquisitely ornamented and gilded in different hues of gold. The wooden members which they strengthen and adorn are lacquered in rich and deep colors, superbly finished. All the framing is executed with extraordinary precision and elegance both of design and fitting.

The chief monuments of Japanese architecture are temple groups, consisting in many cases of a pagoda, temples, halls, and gates; but in others the pagoda is wanting. These groups are built on terraces approached by stairways and planted or surrounded with flowers, trees, and shrubbery. Probably the oldest is the group of Horiuji, near Nara (593 A.D.); that of Yakushiji (680) is even more celebrated. At Kyoto, another important monastic temple centre, are examples of a later and more magnificent style, lacking the charm of the early simplicity. The great monastery of Obaku-san is the finest example of the Zen temple architecture of the Kamakura period, during which loftiness came to be sought after in the interior design; while the Iyeyasu shrine and the temple groups at Nikko display the final flamboyant gorgeousness of the style in its early decline, which began under the Tokugawa dynasty, after 1603. The modern architecture of Japan in part retains the old traditions, but these tend to decay before the persuasive and destructive influence of Western models.

Bibliography. On painting and the decorative arts, consult: William Anderson, *Pictorial Arts of Japan* (London, 1886); id., *Catalogue of Japanese and Chinese Paintings in the British Museum* (ib., 1886). Consult also: Audsley and Bowes, *Ceramic Art of Japan* (2 vols., ib., 1876); Gierke, *Japanische Malereien* (Berlin, 1882); Audsley, *Ornamental Arts of Japan* (2 vols., London, 1882-85); Louis Gonse, *L'Art japonais* (2 vols., Paris, 1883); and especially the folio volume issued by the Japanese Imperial Commission at the Paris Exposition of 1900, *Histoire de l'art du Japon* (ib., 1900); Frank Brinkley, *Art of Japan* (2 vols., Boston, 1901); Sadakachi Hartmann, *Japanese Art* (London, 1904); Strange, *Japanese Illustration: History of the Arts of Wood-Cutting and Color-Printing in Japan* (New York, 1905); Edward Dillon, *Arts of Japan* (Chicago, 1909); W. von Seidlitz, *History of Japanese Color Prints* (Phila-

delphia, 1910); E. F. Fenollosa, *Epochs of Chinese and Japanese Art* (2 vols., New York, 1911); Lawrence Binyon, *Flight of the Dragon: An Essay on the Theory and Practice of Art in China and Japan* (ib., 1911); Oscar Münsterberg, *Japan's Kunst* (Brunswick, 1908); J. F. Blacher, *The A B C of Japanese Art* (London, 1912); M. B. Huish, *Japan and its Art* (3d ed., ib., 1912); Lawrence Binyon, *Painting in the Far East* (2d ed., New York, 1913). There is no book which deals comprehensively with the architecture of Japan. Josiah Conder, in the *Transactions of the Royal Institute of British Architects* (London, 1886-87), treats the subject, and so does McClatchie in the *Reports and Transactions of the Royal Asiatic Society*, vol. vii, part iii. The arrangement and construction of dwelling houses are described by E. S. Morse in *Japanese Homes and their Surroundings* (Boston, 1886). There is a valuable chapter in Dresser, *Japan: Its Architecture, Art, and Art Manufactures* (New York, 1882), and also much in the book of the Japanese Imperial Commission of 1900 (Paris, 1900); also an excellent article by R. A. Cram under the title "Japan," in Sturgis, *Dictionary of Architecture* (New York, 1901); id., *Impressions of Japanese Architecture and the Allied Arts* (ib., 1905).

JAPANESE BEAR. See BEAR.

JAPANESE DEER. The name in England, where this deer has been introduced into parks, of the sika (*Cervus sika*). See SIKA.

JAPANESE LANGUAGE. The most important member of a very small family of languages. Its nearest relatives are Luchuan and the languages spoken in the little islands which lie between Japan and Loo-choo. On the Asiatic continent Korean resembles it in grammatical structure and more remotely in etymology. It is not related to Ainu or to Chinese. Efforts to find other members of the family and to establish more distant relationships have been made in various directions, but with little success. It is called, somewhat vaguely, Altaic; but the identifications are not very convincing, and the results thus far cannot be regarded as scientifically established.

Characteristics. Words and inflections are often formed by loosely joining words and parts of words to other words, and so the language is described as agglutinative. Native grammarians divide its words into two classes, uninflected and inflected. The former includes nouns, pronouns, numerals, postpositions, and some adjectives which are really nouns. The inflected words are most of the adjectives and verbs. Nouns do not distinguish gender, number, or case. The apparent exceptions really conform to the rule, for when the distinction of sex is imperative it is formed by using a special word, and when number must be indicated there is reduplication or the use of words signifying number. There are no personal pronouns; but when, in exceptional cases, a pronoun is required, certain nouns are used which retain in common conversation their ordinary meanings. Relative pronouns are wholly wanting, the relative word or clause being placed before the word qualified, as we may say "the murdered man" for "the man who was murdered." There is no article, and our prepositions are represented by postpositions, the latter having certain uses which have no equivalent in European prepositions. The verb also, in some of its aspects, differs widely from the verb in

languages more familiar to ourselves. It is conjugated in three tenses, past, present, and future, but in a wide range of moods—probable, conditional, concessive, frequentative, imperative. It has, however, neither number nor person, and, one might also add, it has only the present tense; for its past tense denotes primarily certainty and is used, therefore, sometimes of the present and even of the future. The future denotes uncertainty and is used therefore sometimes of the present and even of the past. The past tense is used in its ordinary sense of past time when the emphasis is upon the tense, but often a second verb is introduced in the present showing that it is the dominant point of view, as if one should say "Is it that you have been in Russia?" The moods differ from our own. There is no infinitive, and there are forms not found in our ordinary conjugations—concessive, desiderative, hypothetical, and the like, with negative forms corresponding throughout. The terminations are other verbs, fragments of verbs, or postpositions. Most adjectives are conjugated like verbs, and the adverbs are adjectives with a certain termination. Adjectives are in the positive degree only, though sometimes comparison is indicated by a word corresponding to "than," and the superlative by various words signifying "most." The lack of distinctions of persons is made good in part by the use of honorific prefixes, suffixes, and words which themselves convey differences in the degree of estimation in which persons and things are held. Conjunctions are in part postpositions, and in part they are supplied through inflections of the verb. Two sets of numerals are employed, the Chinese and the native Japanese, but the latter extend only to 10. Auxiliary numbers are common. Similar numerals are used sparingly in English, as sheets of paper, blades of grass, head of cattle, and the like; but the Japanese use such expressions lavishly, certain ones applying to whole classes of objects, so many long, round ones, so many flat ones, and as the usage is fixed a mistake in a numeral produces, as indeed in English, a ludicrous effect. In pronunciation the vowel sounds closely resemble the Italian, and the consonants can be represented by the English letters, *l*, *q*, *v*, and *x* being wanting. In diphthongs each vowel retains its separate value. In many instances "clear" consonants, i.e., surds, are changed to "muddled," i.e., sonants. Syllables are open, and accent is so slight that it may be disregarded. The chief rule of syntax is that the qualifying word or clause precedes the word or clause qualified. The verb is last in the sentence, and as a sentence is supposed to contain a complete statement, however complicated, the mind is often held long in suspense. Most affirmations are without true subjects, active verbs being employed often without a subject, the tendency being to remark "with reference to" somebody or something. It follows that the distinction between active and passive voices and verbs is not precisely the same as in other languages.

The Spoken and Written Forms. The language differs in grammatical forms and in vocabulary in its spoken and written forms, making a twofold series of grammars and dictionaries necessary. In the written language there are also marked distinctions—the archaic, classical, Sinitic-Japanese, epistolary, etc. The oldest specimens we have go back to the eighth century A.D., but they are unintelligible to all

but special students. At a still earlier period the Chinese language had already influenced the Japanese, and many Chinese words are embedded in the Japanese, disguised and naturalized. But from the ninth century onward Chinese has been the language of the learned, taking the place of Latin in Europe. The talk of educated men is unintelligible to the common people, so full is it of Chinese words and phrases. In our day the use of Chinese has increased, since its monosyllables offer unequalled facilities for the coinage of scientific terms, and the whole terminology of modern science has been translated into Chinese compounds by the Japanese. The result is mystifying to a Chinaman, because of the unfamiliar use and collocation of the ideographs, as well as from the retention of the order of the Japanese sentence and its grammatical structure in the ordinary written styles. The pronunciation, too, of Chinese in Japan is traditional, derived from teachers who spoke dialects which have ceased to exist in China. Unfortunately there are two traditions and both in use, complicating a situation which has inherent difficulties enough.

As the Japanese had no writing previous to the introduction of Chinese, the Chinese ideographs are used phonetically, as well as for the expression of ideas. Thus, in Japan names are written with the ideographs without regard to the meaning implied, and originally pure Japanese literature was thus written, certain ideographs being associated with definite sounds. But the result was cumbersome in the extreme, the long, polysyllabic Japanese words not lending themselves to this treatment. In course of time the ideographs were abbreviated and finally took on the form of the *kana*, the syllabary. It is in two forms—the *katakana* and the *hiragana*, the former used chiefly for names. The *katakana* are fashioned out of the square or book form of Chinese characters, the *hiragana* from the cursive. The *kana*, for mnemonic purposes, is arranged in two orders—one composing a verse of Buddhist poetry written by Kōbō Daishi (q.v.) which sets forth the vanity and brevity of life, and the other the table of "50 sounds," though there are really but 47. For convenience in transliterating Chinese, however, a letter representing *n* has been added. All purely Japanese words and syllables end with a vowel sound. The *kana* is thus used as an alphabet, representing syllables instead of consonants and vowels. By the change of surds to sonants in certain instances, and by the distinction of long and short vowels, the number of syllables is considerably increased.

Aston, *Grammar of the Japanese Written Language* (ib., 1904); Hermann Plaut, *Japanische Konversationen—Grammatik* (Heidelberg, 1904); Prentys and Sasamoto, *Japanese for Daily Use* (New York, 1905).

JAPANESE LITERATURE. The literature of Japan falls into three groups corresponding to three periods in the nation's history.

The first represents primitive Japan still feeling foreign influence but slightly. The literature is in archaic Japanese, though already Chinese words and marks of Chinese civilization may be detected. The traditions, hymns, and prayers of Shinto (the way of the gods) came from immemorial antiquity by oral tradition and were reduced to written form in the beginning of the eighth century A.D. The *Ko-ji-ki* (Record of Ancient Matters) is the most important member of this group and perhaps the most important work produced in Japan. It has been called the Bible of the Japanese, although it contains neither doctrine nor ethics. It is a mass of loosely connected and fragmentary legends and annals, setting forth the history of the world, i.e., Japan, from the Divine Age, the beginning. Its first trustworthy date is in the middle of the fifth century A.D., but its materials become scanty in proportion to their historic trustworthiness. The book, however, contains most valuable matter for the critical scholar, being his most important source for the reconstruction of ancient Japan. Even in the eighth century Japan was feeling the mighty influence of the Chinese civilization, and thenceforth scholars studied its language and literature, while they left pure Japanese to romance and poetry and trifles, the amusement of women, and of men in their lighter moods. Archaic Japanese, already unintelligible, gave way to classical forms, and women furnished the models of literary style. This literature reached its culmination in the capital, Kyoto, in the ninth and tenth centuries. It reflects the elegant, trifling, and immoral life of the court in romances which show the customs and manners of the period accurately and tediously. The novels are strings of incidents without unity or attention to the relation of character to event, with supernatural marvels interspersed, and palace intrigue as the chief interest. The poetry is more attractive from its curious unlikeness to other verse. It has neither rhyme nor quantity nor parallelism, but consists simply of alternate lines of five and seven syllables, the usual "poem" containing 31 syllables in all, two pairs of five and seven, with a final seven added. A few poems are longer, and a later form restricts the syllables still more severely to 17. But even within these narrow limits room is found for "pillow words," mere ornaments without significance used as "rests" for other words. The subjects are as few as the syllables—birds, flowers, mountains, the moon, the rain, and snow, the autumn leaves, the wind, and other themes associated with them. Often the verse merely hints a picture which the reader's imagination must complete. There are travels, too, and diaries, and miscellanies filled with reflections and fancies. After the tenth century few additions of value were made to this literature. It continued to be cultivated, but it revolved around the same trite subjects, imitated the same models, and was capable of no further development. In the seventeenth and eighteenth centuries a group of scholars attempted to revive the ancient faith, Shinto, in its pure form. As a part of their endeavor, they wrote in pure Japanese, attempting to exclude all Chinese elements; but the literary fashion never extended very far, nor did it produce important results. In modern times a vast formless literature has been created for the masses, for the greater part novels, in the colloquial or in a simple written style paying little attention to the canons of

classical Japanese literature. Naturally it is ignored by educated men.

Doubtless even the first collections of traditions and rituals were made because Chinese influence was already powerful, and they were put in written form only by the aid of Chinese ideographs. Buddhism won Japan in the sixth and seventh centuries A.D. and brought with it Chinese civilization. Henceforth Chinese literature in form and matter was supreme. The *Ko-ji-ki* was given its written form in archaic Japanese in the year 712 A.D., and it was followed in the year 720 by the *Nihongi*, which covered much the same ground, but was written in Chinese. As Rome in language, ideals, philosophy, law, and literature ruled Europe in the Middle Ages, so did China influence Japan. The Chinese classics were the models of style, as they were the unquestioned authority in religion and morals. Buddhism brought its voluminous works, historical, doctrinal, sectarian, polemic, exegetical, philosophical, with it, and the Japanese set themselves to master and appropriate these riches. Nothing new of importance was produced, if we except possibly the canonical writings of the Shin sect, which is accounted heretical by all the rest and as a matter of fact denies what Buddha affirmed and for the most part affirms what he denied. From the twelfth century until nearly the end of the sixteenth century Japan was tormented by feudal strife. Letters were cultivated by monks, and even in the seventeenth century it required an argument to persuade the higher classes that letters were for others besides priests. With the final restoration of peace under the Tokugawa family (1603–1868) there was a revival of learning. China again gave the impulse, but it was no longer the Buddhistic China of the sixth century, for the literati had by this time rejected the Indian faith and had set forth Confucianism as a fully developed philosophy and cosmogony. Introduced into Japan in the beginning of the seventeenth century, this was thenceforth the religion of the higher classes, and Buddhism was left to priests, women, and the ignorant masses. But, as before, Japan added little to the controlling ideas of the new learning. It imported the varying schools of Chinese thought, fought over anew the same battles with the same arguments and illustrations, but there was no native development. Chinese language, history, literature, and poetry furnished models which satisfied all literary needs. Yet it was not mere copying, nor was the change wholly superficial, for the two empires are animated by different spirits, and these are shown in their respective literatures, so that Sinico-Japanese is entitled to a place by itself and is something more than a mere branch of the greater literature of its more original neighbor.

Again in the present age Japanese literature has undergone a transformation. The style itself has changed, though still held in the bondage of the Sinico-Japanese; but newspapers and reviews with the popularization of knowledge no longer permit the maintenance of the rigid standards of the past. Besides, the acquaintance with the whole range of Chinese literature which the older forms presupposed no longer exists except for specialists. As in the seventeenth century the orthodox Confucian philosophy supplanted the earlier Buddhist teaching, so now have Chinese literature and history given way before the history, philosophy, ethics, theology,

romance, poetry, and, above all, science of the Occident. Judging from the past, we may expect vigorous assimilation of Western literature, and its transformation into forms congenial to this people, who, hospitable to ideas from foreign lands, know how to impress themselves upon the importations and amid all changes to preserve the spirit of Old Japan. See ANTHOLOGY.

G. Aston, *History of Japanese Literature* (New York, 1899); F. V. Dickens (ed. and tr.), *Primitive and Mediæval Japanese Texts* (2 vols., Oxford, 1906); Francis Brinkley, *Japan* (Oriental ser., 8 vols., Boston, 1910); Nitobé, *The Japanese Nation* (New York, 1912).

JAPANESE MUSIC. The music of Japan is almost identical in form with that of China. From the fifth century, when Korean musicians introduced the stronger, more elaborate type, Chinese music has dominated, except in the temples where the priests still preserve the older forms. The only instruments indigenous to the island are the "Yamato" koto, a stringed instrument of 13 strings with a compass of two and a half octaves (pentatonic), and the "Yamato" flute. The few others employed are merely softened modifications of Chinese instruments. From time immemorial the national music has been handed down by certain chosen families, and it is this spirit of conservatism as much as the poverty of their musical instruments which has prevented any original development in Japanese music. In addition they are hampered by a lack of systematized notation, a scale derived from the Chinese, and the unvaried use of common time. The most noticeable characteristics are an extensive use of chromatics, the monotony of their melodies, and the prevalence of the minor key. It is of interest to note that the national hymn was composed by an emperor and written by an empress in the seventh century. Consult: P. T. Piggott, *The Music and Musical Instruments of Japan* (London, 1893); C. Leroux, *La musique classique japonaise* (Paris, 1910); A. Westarp, *Japan Ahead in Music* (London, 1912). A collection of music for koto, both in Japanese and European notation, was published by S. Isawa, at Tokyo in 1888. See also CHINESE MUSIC; KOTO.

JAPANESE POLITICAL PARTIES. See POLITICAL PARTIES, *Japan*.

JAPANESE ROBIN. A dealer's name for one of the East Indian hill tits (q.v.), frequently kept as a cage bird.

JAPANESE SPANIEL. See SPANIEL.

JAPAN'NING. The art of giving a coating of varnish and other materials to certain manufactures, by which a glossy surface is produced. The varnished articles are usually submitted to a high temperature in an oven in order to harden the coating.

JAPAN SEA, BATTLE OF THE. See RUSSO-JAPANESE WAR.

JAPAN VARNISH TREE. A Japanese tree which furnishes a varnish. See SUMACH.

JA'PHETH. According to Gen. x. 2-5, the youngest son of Noah, the brother of Shem and Ham, the father of Gomer, Magog, Madai, Javan, and Tiras. These are clearly the eponymous

ancestors of ancient peoples; and three of them—Gomer, Madai, and Javan—unquestionably represent the Cimmerians, the Medes, and the Greeks. Magog (q.v.), or perhaps originally Gog, seems to have been the name of some Scythian people in the wider sense of the term, and Tiras probably refers to the Tyrrhenians, or Etruscans. Gomer's sons are said to be Ashkenaz, Riphath, and Togarmah. Ashkenaz (see ASHKENAZIM) is the Hebrew form of the Assyrian Ashkuza, the Scolotian Scythians; Riphath is supposed to be the Phrygians, but that is doubtful, as is also the identification of Togarmah as Armenians, or Tilgarunu. The sons of Javan are Elisha, Kittim, Tarshish, and Rodanim. Elisha may be Alashia and represent the Greeks on Cyprus; Kittim may be the Macedonians; Tarshish the Tartessians in Spain or the Dorians around the Etrurian Sea, and Rodanim, which is the probable reading, the Rhodians. The grouping of these peoples together as descendants of Japheth is evidently later than the oracles of Noah in Gen. ix. 25-27, in which the three brothers are Shem, Japheth, and Canaan, who appears as the youngest. Shem here seems to represent a congeries of Hebrew tribes, such as Israel, Judah, and probably Moab, Ammon, Edom, Jerahmeel, Kenaz, Cain, and others. Canaan clearly included a group of kindred Syrian peoples; and Japheth is likely to be the name of the Philistines, the Cherethites, the Pelethites, the Zakkalians, and others. These Japhethites probably came for the most part, as is certainly the case with the Philistines and the Cherethites, from Crete.

Canaan is cursed—let him become a slave of his brothers; Shem is blessed; Japheth also receives a blessing—let the Canaanites be enslaved by Japheth as well as by Shem. The present text reads: "let Japheth dwell in the tents of Shem." That could scarcely mean anything else than a wish that the Japhethites might drive the Shemites out of their dwelling places and occupy them. Such a wish is inconceivable; and it is therefore probable that the original text read: "let Japheth dwell in the tents of Canaan." Such an oracle must be earlier than the invasions by the Philistines of the territory occupied by Israel and Judah. Since the Philistines are first mentioned as falling upon Egypt c.1200 B.C., and they appear to have settled upon the coast of Syria after their defeat by Rameses III (1200-1169), the song is likely to have originated in the twelfth century B.C.

Later some of these terms took on a wider significance. Canaan did not lend itself to expansion; it was naturally limited to Syria. Ham took the place of Canaan as the son of Noah. Shem came to include a number of peoples rightly or wrongly supposed to be akin. Japheth was made the ancestor not only of the nations who had invaded Syria from Crete, but of their assumed kindred. The real kinship of Cimmerians, Scythians, Medes, and Greeks cannot be questioned. As for the Etruscans, if they are indicated by Tiras, their genetic relations have not yet been definitely determined. Japheth is no doubt identical with Iapetos, the father of Prometheus; and there is probably also a connection between Kaphti (Cretan) and Japhti (Japhethite) as well as between Japheth and Joppa. Consult Görres, *Die Japhetiden* (Regensburg, 1845); Knobel, *Die Völkertafel der Genesis* (Giessen, 1850); Eduard Meyer, *Die Israeliten und ihre Nachbarstämme* (Halle,

1906); Nathaniel Schmidt, "The Blessing of Japheth," in *Journal of Biblical Literature*, vol. xxxv (Boston, 1915); and the commentaries on Genesis by Dillmann, Gunkel, Driver, and Skinner.

JAPHET IN SEARCH OF A FATHER.

A novel by Captain Marryat (1836).

JAPIKS, jä'piks, GIJSBERT (1603-66). A Frisian poet, born at Bolsward. His father was a burgomaster, and the son after an excellent education became schoolmaster at Bolsward (1634). In his hands the West Frisian dialect again became a literary tongue. From the French he translated in prose several poems, and he also published versions of the Psalms. His own writing was marked by originality, feeling, and lyric beauty. The *Friesche Rymlerye* was first published in 1668; the edition of Epkema (Leeuwarden, 1821) is supplemented by a grammar and vocabulary (ib., 1825). Consult Halbertsma, *Hulde aan Gijsbert Japiks* (Bolsward, 1824-27).

JAPURÁ, zhä'poo-rä'. A river in Colombia and Brazil. See YAPURÁ.

JAQUES, jäks or jäks, on the stage often pronounced jä'kwēz, *Fr. pron.* zhák. 1. A contemplative character in Shakespeare's *As You Like It* ("the melancholy Jaques"). 2. A son of Sir Rowland de Bois in *As You Like It*. 3. A miser in Ben Jonson's *The Case is Altered*.

JARARACA, zhä'rá-rä'ká (Portug., from the native name). A venomous crotaline serpent (*Lachesis jararaca*), widely distributed over tropical South America and closely related to, if not identical with, the bushmaster (q.v.) or labaria, which it resembles in colors and manner of life.

JARCKE, yär'ke, KARL ERNST (1801-52). A German jurist and conservative publicist. He was born at Danzig and studied at Bonn and Göttingen. In 1824 in Cologne he became a member of the Roman Catholic church after having been professor at Bonn. At Berlin in 1825 he became connected with the university as lecturer and founded the *Politisches Wochenblatt* (in 1831). In 1832 he went to Vienna as Court and State Councilor and as instructor of the Princes of Nassau. Among Jarcke's works are: *Handbuch des gemeinen deutschen Strafrechts* (1827-30); *Die französische Revolution von 1830* (1831, anonymously); *K. L. Sand und sein an Kotzebue verübter Mord* (1831); *Die ständische Verfassung und die deutschen Konstitutionen* (1834); *Vermischte Schriften* (1839-54). With Phillips and Görres he founded in 1839 *Historisch-politische Blätter*.

JARDIN D'ACCLIMATATION, zhär'dän'dä'klé'mä'tä'syôn' (Fr., garden of acclimatization). A garden of 50 acres forming part of the Bois de Boulogne in Paris, designed to acclimatize foreign plants and animals suitable for domestic or ornamental purposes. It contains, besides buildings for the various animals, a permanent exhibition of articles connected with gardening, a dairy, an aquarium, greenhouses, an aviary, a winter garden, establishments for fattening poultry and rearing carrier pigeons, and several cafés. The garden, which was greatly damaged in 1871 during the siege of Paris, is a favorite resort.

JARDIN DES PLANTES, dä plänt (Fr., garden of plants). A botanical and zoölogical garden in Paris, founded at the beginning of the seventeenth century. It was at first called Jardin du Roi.

JARDINE, jär'din, SIR WILLIAM (1800-74). A Scottish naturalist, born in Edinburgh and educated at its university. He succeeded his father in the baronetcy at the age of 20. Ornithology was the first of the natural sciences to claim his attention, but he went on to the study of fishes, monkeys, felidæ, pachyderms, and ruminants, writing himself 14 volumes on these subjects and on birds in a series of books which he edited called *The Naturalist's Library* (40 vols., 1833-45). Sir William made a collection representing 6000 species of birds, was a commissioner on the salmon fisheries, member of the British Association, and author of a *Calendar of Ornithology* (1849); *The Ichnology of Annandale* (1853); *British Salmonidæ* (1861); *The Birds of Great Britain and Ireland* (4 vols., 1876).

JARDIN MABILLE, zhär'dän'mä'bél'. A former very popular resort in Paris, founded in 1840 by a dancer, Mabile. It was a favorite gathering place of the demimonde, and with its brilliant illuminations, fountains, flower beds, and other attractions, became one of the celebrated sights of Paris. The Mabile introduced many novelties in dances, among them the cancan, brought in by Chicard. The place was closed in 1875, and its clientage was absorbed by other similar resorts.

JARGON, jär'gön, or **JARGOON**, jär-göön'. See ZIRCON.

JAR'LEY, MRS. A character in Dickens's *Old Curiosity Shop*, proprietor of a waxworks show, who befriends Little Nell.

JARNAC, zhär'näk'. A town in the Department of Charente, France, known as the scene of a battle fought on March 13, 1569, between 26,000 Catholics under the Duke of Anjou, afterward Henry III, and 15,000 Huguenots under Louis, Prince of Condé. The latter were completely routed, and their leader was killed. See HUGUENOTS.

JARNDYCE, järn'dis, JOHN. A kind-hearted character in Dickens's *Bleak House*, a principal in the famous Chancery suit of Jarndyce v. Jarndyce.

JÄRNEFELT, yër'ne-fält, ARMAS (1869-). A Finnish composer, born at Wiborg. At the Conservatory of Helsingfors he studied piano with Busoni and composition with Wegelius. Later he continued his studies with Massenot in Paris and Becker in Berlin. He began his career as conductor in Magdeburg, then went to Düsseldorf, and from there as principal conductor to the Royal Opera of Stockholm. In 1906 he succeeded Wegelius as director of the Conservatory in Helsingfors. Next to Sibelius (q.v.), he is the most notable among early twentieth-century Finnish composers. His works include a symphonic poem *Korsholm*, two concert overtures, a serenade, a phantasy, and suites for orchestra; choral works with orchestra; male choruses; piano pieces and songs.

JARO, hä'rö. A town of Leyte, Philippines, situated in the north part of the island, 15 miles west-southwest of Tacloban (Map: Philippine Islands, E 5). Pop., 1903, 11,066.

JAROCHOWSKI, yä'rö-köv'ské, KAZIMIR (1829-88). A Polish historian, born at Sokolniki and educated at Posen and Berlin. He took part in the Polish uprising of 1848, but in 1862 entered the Prussian magistracy and resigned in 1882. He died soon after his election to the Prussian Diet. His historical studies deal especially with Poland under the Saxon kings.

Among them the more important are: *Teka Podoskiego* (1854-61); *Wielkopolska w czasie pierwszej wojny szwedzkiej* (1864), dealing with the first Swedish war; *Dzieje panowania Augusta II* (1856-74); *Opowiadania i studia* (1860-84); *Literatura posnańska* (1880).

JAROSLAU, yä'rō-slou'. A town of Galicia, Austria, and an important garrison, on the San (an affluent of the Vistula), 130 miles east of Cracow by rail (Map: Austria, H 1). It has evangelical, Roman Catholic, and Greek churches, and is an industrial centre, with manufactures of textiles, pottery, bricks, tatty, pastry, smoked meats, and spirituous liquors. There is also a considerable trade in agricultural produce, hides, and lumber. Pop., 1900, 22,660; 1910, 23,965, mostly Poles. In the European War, which broke out in 1914, Jaroslau was captured by the Russians, but was later retaken by the Austro-German army. In the second Russian invasion of Galicia it was reoccupied after severe fighting, and the way to Przemysl (captured in March, 1915) and Cracow opened up. See WAR IN EUROPE.

JAROSLAV, yä-rōs'láf. A Russian government and its capital. See YAROSLAV.

JARRAH WOOD. See EUCALYPTUS.

JARRIC, zhá'rék', LOUIS ETIENNE, CHEVALIER DE (1757-91). A West Indian revolutionist, born at Aux Cayes, Haiti. He had no legitimate claim to the name he bore; but his father had him well educated, and he was in France at the time of the Revolution, serving as a captain. A mulatto himself, he started a society in Paris called Friends of the Blacks, but it did not flourish; so he sailed for Haiti in 1790 with a supply of arms. These he distributed among the disaffected negroes, and he headed a band of 700, which, through a victory over the regulars, was increased to 2500; but they were defeated near the river St. Vincent, and Jarric was tortured to death.

JAR'ROW-ON-TYNE. A municipal borough and seaport in Durham, England, on the estuary of the Tyne, 6 miles east of Newcastle (Map: England, E 2). Formerly a small colliery village, it was made a municipality in 1875. Its growth was due to the establishment of large iron shipbuilding and marine-engine works, blast furnaces, iron foundries, gun, paper, and chemical factories. It makes extensive shipments of coal. On the banks of Jarrow Lake are the Tyne docks, with quays, etc., covering about 300 acres. The town maintains quays, an infectious-diseases hospital, and recreation grounds. The Venerable Bede was born in Jarrow and lived and wrote and died in the Benedictine monastery built there in 682, of which there are remains. Pop., 1901, 34,295; 1911, 33,726.

JARVES, jār'vēs, JAMES JACKSON (1820-88). An American author and art collector, born in Boston. In 1851 he went to Europe and settled in Florence, where from 1879 until 1882 he was Vice Consul and acting Consul. He made an important collection of Venetian glass and gave it to the Metropolitan Museum in 1881. But his great collection was of early Italian paintings, and he was the only American of his day (except Thomas J. Bryan, who gave his collection to the New York Historical Society in 1867) who collected primitives. Jarves hoped that his collection might become the nucleus of an American museum for the study of Italian art, but his attempts to interest the American public were unsuccessful. He was finally com-

pelled in 1867 to deposit a large part of his collection with the trustees of Yale College as security for a loan, and, being unable to repay it in the agreed period, the pictures became the property of the college. They form the largest and most important collection of *trecento* pictures in the United States. The balance of Jarves's collection was purchased by L. E. Holden, whose widow in 1912 lent 27 of the pictures to the Metropolitan Museum. Jarves wrote a number of books on art, among them: *Art Hints, Architecture, Sculpture, and Painting* (New York, 1855); *The Art Idea, Sculpture, Painting, and Architecture in America* (Boston, 1864); *Art Thoughts: The Experience and Observations of an American Amateur in Europe* (ib., 1869)—all of which were often reprinted and had an important influence in the right direction, though of course now entirely superseded. His most important work was *Art Studies, the "Old Masters" of Italy, Painting* (New York, 1861), dedicated to his friend Charles Eliot Norton (q.v.), with 43 copperplate illustrations from the pictures of his own collection. The same year Jarves published a *Descriptive Catalogue* of his collection, with explanatory documents. A catalogue of the paintings at New Haven, by Russell Sturgis, Jr., was published in 1868. It was critically treated by Sirén, *Burlington Magazine*, xiv-xv (1908-09), as was the Holden collection by Mrs. Berenson, *Rassegna d'Arte* (January, 1907). The *Bulletin of the Metropolitan Museum* (1911-12) discusses the Holden collection and the Jarves collection of glass.

JAR'VIS, ABRAHAM (1739-1813). A Protestant Episcopal bishop of Connecticut. He was born at Norwalk, graduated at Yale in 1761, and was ordained in England three years afterward. He became rector of Christ Church, Middletown, in 1765, and was regarded as a Tory sympathizer because of his opposition to the independence of the American church during the Revolution. In 1797 he was chosen second Bishop of Connecticut.

JARVIS, EDWARD (1803-84). An American physician, born at Concord, Mass. He graduated at Harvard in 1826 and at the Harvard Medical School in 1830 and subsequently practiced as a physician successively in Concord, Mass., Louisville, Ky., and Dorchester, Mass. He interested himself in the collection of vital statistics and published reports and monographs on this subject, among which are: *Physiology and Health; Elementary Physiology; Reports on the Number and Condition of the Insane and Idiots in Massachusetts*. He was for many years after 1852 president of the American Statistical Association.

JARVIS, JOHN WESLEY (1780-1834). An American portrait painter, born in South Shields, England. He was a nephew and namesake of the famous divine, who kept him till he was five years old and then sent him to join his seafaring father in Philadelphia. As a boy, he made the acquaintance of Stuart and of the aged Matthew Pratt, who greatly encouraged his aspirations to become a painter. Leaving school, he was apprenticed to an engraver named Savage and learned to draw and engrave from an Englishman in Savage's employ, Edwin by name, with whom Jarvis moved to New York. After engraving for a while on his own account, he began to paint portraits, practicing chiefly in New York. He also visited other cities, particularly Baltimore, Charleston, and New Or-

leans, where he painted full-length portraits of Andrew Jackson and other military and naval heroes, earning \$6000 in six months. His principal portraits—of statesmen, churchmen, and naval heroes (1812–15)—are in the City Hall, New York, and in the collection of the New York Historical Society. There are two of his portraits in the Metropolitan Museum, New York. Jarvis was a conspicuous example of the artistic temperament—convivial, improvident, witty, eccentric, vain, observant, a noted story-teller, and practical joker. His work suffered from his manner of life, not so much in lack of finish as in lack of inspiration, and this despite his brilliant talents and the fact that he worked hard to acquire technique, studied anatomy seriously, and became an enthusiast in phrenology, then a novelty. He usually got the character of sitters, but his best work is decidedly inferior to that of Sully.

JARVIS, SAMUEL FARMER (1786–1851). An American Protestant Episcopal clergyman, the son of Abraham Jarvis. He was born at Middletown, Conn., graduated at Yale in 1805, was ordained in 1810, and three years afterward became rector of St. James's, New York. After a year in the chair of biblical criticism in the General Theological Seminary, he was rector of St. Paul's, Boston (1820–26), then traveled and studied in Europe, and lived in Italy until 1835, when he was appointed professor of Oriental literature at Trinity (then Washington) College. He edited the *Gospel Advocate* in 1821–26. As historiographer of the Episcopal church in America, Jarvis wrote *A Chronological Introduction to the History of the Church* (1844). He published, besides: *The Religion of the Indian Tribes of North America* (1820); *No Union with Rome* (1843); *The Church of the Redeemed* (1850).

JASHER, jā'shēr or jāsh'ēr, BOOK OF (Heb. *sepher ha-yashar*). One of the lost books of Hebrew literature. It is quoted twice in the Old Testament (Josh. x. 13; 2 Sam. i. 18). In the first passage the reference to it is lacking in the majority of manuscripts of the Greek version, and the Syriac has *sifra de teshkehata*, 'book of praise songs'; while in the second the Greek has βιβλίον τοῦ εὐθοῦς, *biblion tou euthous*, and the Syriac *sephar ashir*, 'book of Ashir,' or 'book of songs,' Jerome translating in both instances *liber justorum*. It has been maintained by some scholars that the words attributed to Solomon in 1 Kings viii 12, 13, came from this collection. The Greek version states that they were taken from the Book of Songs. It has been conjectured that the translator was misled by a transposition of letters in his text, the Book of Jasher being originally meant. But there is no evidence of this, and the nature of the poetic fragment is such that it is more likely to have come from a book containing songs connected with the temple service. Rather may it be questioned, in view of the textual condition, whether *shir*, 'song' or 'songs,' was not the original reading in the other passages. Both have the appearance of being later interpolations, but there is no reason on this account to doubt their accuracy. As to the meaning of Jasher, many suggestions have been made, chief among them that it signifies 'upright' or 'brave,' and that it refers to Israel, which is also called Jeshurun. The command of Joshua to the sun and the moon to stand still, and the lament over Saul and Jonathan by David, breathe a spirit that accords

with other specimens of early Hebrew poetry. The "lost book" naturally attracted forgers, and in the thirteenth and fourteenth centuries no less than three different works purporting to be the lost book of Jasher seem to have been produced. The most famous of these was published in Naples, 1552, and has passed through many editions. An English translation was printed in London in the year 1750, and a new translation was made by Noch (New York, 1840). The *Book of Jasher* is also the title of a ritualistic treatise by Jacob ben Meir (died 1171) and of several other works of an ethical or legal character written by Jewish scholars.

JASMIN, zhās'mān', JACQUES (1799–1864). A Provençal poet, born at Agen. His real name was Jacques Boé. He was apprenticed to a hairdresser, who had been a soldier of Napoleon. At 18 Jasmin was writing verses and dressing hair. Hence his name "The Barber Poet." His four collections of *Papillotos* or *Curl-Papers* (1825, 1843, 1851, 1853) were naïve little occasional verses, revealing much native power. The *Souvenirs* (1830) are a winning mixture of humor and pathos in their tale of his early struggles for literary recognition. *The Blind Girl of Castel-Cuillé* (1835) is accessible in a good translation by Longfellow. *Françounetto* (1840), a narrative poem, is Jasmin's most sustained work and won general recognition. Jasmin was received into the Legion of Honor in 1846. In 1852 his works were crowned by the Academy. He is the poetic father of Mistral (q.v.) and the Félibres. There is an edition of his *Works*, with a French translation (1860). Consult: Rabain, *Jasmin, sa vie et ses œuvres* (Limoges, 1867); Moutron, *Jasmin, poète d'Agen* (Lille, 1875); Sainte-Beuve, *Portraits contemporains*, vol. iii (Paris, 1881–82); Andrien, *Vie de Jasmin* (Agen, 1882); Smiles, *Barber, Poet, Philanthropist* (New York, 1892).

JASMINE, jās'mīn, or **JESSAMINE**, jēs'-ā-mīn (OF., Fr. *jasmin*, from Ar. *yasmin*, from Pers. *yasmin*, jasmine), *Jasminum*. A genus of plants, chiefly natives of the warm parts of Asia, which belong to the family Oleaceæ, containing about 100 species of shrubs, some of them climbing and many of them having exquisitely fragrant flowers. This genus has the calyx and corolla each five or eight cleft, two sta-

JASMINUM GRANDIFLORUM.

mens attached to and included within the tube of the white or yellow corolla, and a two-lobed berry, one of the lobes generally abortive. The common jasmine (*Jasminum officinale*) is a native of the south of Asia, naturalized in the south of Europe as far north as Tirol and Swit-

zerland. In more northern regions it is much cultivated in gardens, but does not easily endure very severe winters. It is a shrub from 6 to 10 feet high, with pinnate leaves, the terminal leaflet the largest, and very fragrant white flowers. Its slender, deep-green branches

CAPE JASMINE.

give it the appearance of an evergreen. The flowers are used for preparing oil of jasmine, a delicate perfume. It blooms from June to October and requires a light, moist soil to induce free flowering. *Jasminum grandiflorum*, Spanish or Catalonian jasmine, a native of the East Indies, has flowers still more fragrant, from which, and from those of *Jasminum sambac*, oil of jasmine is also made. *Jasminum humile*, a

A PENDENT SPRAY OF YELLOW JASMINE.

very common greenhouse variety, is hardy in the open air as far north as Maryland. The varieties of jasmine are propagated by seeds and layers, but the usual method is starting cuttings of the nearly ripened wood under glass.

Cape Jasmine is a name popularly applied to

plants belonging to the genus *Gardenia*, not related to the true jasmies. They belong to the madder family (*Rubiaceæ*) and are tropical and subtropical shrubs. The genus was named for Dr. Garden, of Charleston, S. C., who was a correspondent of Linnæus. The best-known species is *Gardenia jasminoides*, popularly known as *Gardenia florida*, brought to England from China (not from the Cape) in 1754. A double variety is a very popular greenhouse plant and is common in the Southern States as a hardy outdoor plant. It bears a large, oblong, orange-yellow berry, which is said to be used in China as a dye.

JASMINE, or **JESSAMINE**, CAROLINA, or **YELLOW**. A North American climbing plant, *Gelsemium sempervirens*, of the family Loganiaceæ, which grows in Virginia and southward upon trees and fences and bears a profusion of yellow, funnel-shaped flowers an inch in diameter, with a fragrance similar to that of the true jasmine, the odor on a damp evening or morning being almost overpowering. It has been recently used in medicine as a sedative, antispasmodic, and nervine.

JASON. The leader of the Argonauts (q.v.). See also MEDEA; PELIAS.

JASON (Gk. 'Ιάσων). A tyrant of Pheræ in Thessaly, the successor and the reputed son of Lycophron. He came into prominence early in the fourth century B.C. and undertook to reduce all Thessaly under his dominion. By 374 B.C. he had conquered the chief cities of Thessaly and was recognized as Tagos. He then collected a large army with the object of making himself master of all Greece, but was assassinated in the midst of his preparations (370 B.C.). Consult Kent, *History of Thessaly from the Earliest Historical Times to the Accession of Philip of Macedon* (Lancaster, Pa., 1904).

JASON. A Jewish high priest, son of Simon II, and leader of the Hellenizing party. His real name was Jesus, according to Josephus (*Ant.* xxii, 5, 1). In 174 B.C. he was appointed high priest in place of his brother by Antiochus IV. For this office he is said to have paid a large sum; but he also secured for the citizens of Jerusalem the rights and privileges of Antiochians and was allowed to build a gymnasium and an ephebeum below the acropolis, near Mount Zion. Greek games, Greek caps, and Greek customs were speedily adopted. Even the priests left the altar to take part in the games in the palæstra and artificially concealed their circumcision. Jason sent a large contribution to Tyre for the festival of Hercules. In 171 B.C. he was deposed, and Menelaus raised to the pontificate. But when Antiochus marched against Egypt, in 170 B.C., Jason seized the opportunity of reinstating himself and drove Menelaus away. The King, however, upon his return from Egypt punished the city severely for what he deemed rebellious conduct. Jason was obliged to flee, first to Egypt, then to the Lacedæmonians. Our knowledge of his career depends upon 2 Maccabees and Josephus. The accounts differ in many respects, and neither can be used without great caution. Consult: Willrich, *Juden und Griechen vor der makkabäischen Erhebung* (Göttingen, 1895); Büchler, *Tobiaden und Oniaden* (Vienna, 1899); Willrich, *Judaica* (Göttingen, 1900); Schürer, *Geschichte des jüdischen Volkes* (4th ed., Leipzig, 1901); Wellhausen, *Israelitische und jüdische Geschichte* (7th ed., Berlin, 1914).

JASON OF CYRENE, si-rē'nē. An author whose history in five books is mentioned in 2 Macc. ii. 23. The original work is lost, and known to us only in the epitome made by the author of 2 Maccabees. (See **MACCABEES**, **BOOKS OF THE**.) There is some evidence that it was used by Gorionides. It was unquestionably written in Greek. Whether Jason was a Greek or a Hellenistic Jew is not altogether known. Büchler defends the former opinion and ascribes to him those parts of 2 Maccabees dealing with the Syrian wars under Antiochus IV, Antiochus V, and Demetrius I (qq.v.). But there is reason to believe, as Willrich has shown, that the work comprised the whole history of the Hasmonæan dynasty, and that only the part of it dealing with events that occurred between 175 and 161 B.C. was epitomized. In that case it is more natural to suppose that he was a Jew. He may, however, have had access to written sources not of Jewish origin. This would account for some facts that led Niese to ascribe to 2 Maccabees, and consequently to Jason, a higher age and a greater credibility than to 1 Maccabees. It is not likely that this view will prevail. But even if preference is given to 1 Maccabees, this may not affect Jason so much as the author of 2 Maccabees. The latter has confessedly exercised much freedom. Not only has he abridged, but also added to and probably altered Jason's work. Kusters and Kamphausen have gone so far as to declare Jason a fictitious personage behind whose name the author indulged in polemics against 1 Maccabees. There is no convincing evidence, however, of acquaintance with 1 Maccabees, and such a fiction seems to most scholars wholly improbable. If Jason's work included the whole dynasty, he must have written after 63 B.C. But this is not certain. The allusion to Esther ix. 21 in 2 Macc. xv. 36 points to a time later than 114 B.C., the anti-Hasmonæan bias to a time later than 106 B.C.; but these indications only apply to the epitomizer. The *Ἰάσων κυρήναιος* discovered on a temple wall in Egypt (*Revue des Etudes Grecques*, 1894, p. 297) seems to belong to the third century B.C., but there is no evidence of any connection between this man and the author. Jason may be tentatively considered as having produced his work at Alexandria in the first half of the first century B.C., as 2 Maccabees seems to have been used already by Philo.

Bibliography. Geiger, *Urschrift und Uebersetzungen der Bibel* (Breslau, 1857); Wellhausen, *Pharisäer und Sadducäer* (Greifswald, 1874); Kusters, in *Theologisch Tijdschrift* (Leyden, 1878); Trieber, *Zur Kritik des Gorionides* (Göttingen, 1895); Büchler, *Tobiaden und Oniaden* (Vienna, 1899); Kamphausen, in *Kautzsch's Apokryphen* (Tübingen, 1900); Willrich, *Judaica* (Göttingen, 1900); Schürer, *Geschichte des jüdischen Volkes* (4th ed., Leipzig, 1901); Niese, *Kritik der beiden Makkabäerbücher* (Berlin, 1900); Torrey, article "Maccabees," in *Encyclopædia Biblica* (London, 1902); Laqueur, *Kritische Untersuchungen zum zweiten Makkabäerbuch* (Berlin, 1904); Moffatt, in *Charles, Apocrypha and Pseudepigrapha of the Old Testament* (Oxford, 1913).

JA'SONVILLE. A city in Greene Co., Ind., 25 miles south of Terre Haute, on the Chicago, Terre Haute, and Southeastern Railroad (Map: Indiana, C 6). It is in a farming and productive coal-mining region, and there are brick-yards. Pop., 1910, 3295.

JAS'PER (OF. *jaspre*, *jaspe*, Fr. *jaspe*, It. *jaspide*, from Lat. *jaspis*, Gk. *ἰασπίς*; probably of Semitic origin, cf. Heb. *yāshp'eh*, Ar. *yashb*, *yashb*, *yasf*, jasper). A cryptocrystalline variety of quartz distinguished by its opacity, which is due to the presence of clay and other substances. Jasper was known to the ancients, by whom it was called *iaspis*, and by whom it was used for ornamental purposes, owing to the high polish which it is capable of taking. It is still used for rings and seals and to a certain extent for pillars, mantels, and table tops. The colors of the different varieties of jasper are reddish brown, dark green, grayish blue, and brownish black, according to the impurities present. When the colors appear in layers, the mineral is known as striped or ribbon jasper; the brown and yellow varieties are known as Egyptian jasper. See **GEMS**.

JASPER. A city and the county seat of Walker Co., Ala., 35 miles northwest of Birmingham, on the Alabama Central, the St. Louis and San Francisco, the Illinois Central, and the Northern Alabama railroads (Map: Alabama, B 2). It is the centre of a rich coal field and farming and cotton district and has large saw mills, coke ovens, and some manufactures. Pop., 1900, 1661; 1910, 2509.

JASPER, WILLIAM (c.1750-79). An American soldier, born in South Carolina. He enlisted as a sergeant in the Second South Carolina Regiment in 1775 and at Fort Moultrie, on June 28, 1776, distinguished himself by recovering, through an act of personal bravery, the American colors which had fallen outside the walls. For this Governor Rutledge offered him a commission as lieutenant, but Jasper modestly refused because of his lack of education. He was commissioned by General Moultrie, however, to scour the country and harass the British outposts, and he became the hero of numerous adventures. At last, during the assault on Savannah, Oct. 9, 1779, he fell mortally wounded, while trying to fasten his regimental colors on the parapet. Consult McCrady, *South Carolina in the Revolution* (New York, 1901), and C. C. Jones, "Sergeant William Jasper," in *Magazine of History with Notes and Queries*, vols. viii, ix (ib., 1908-09).

JASPER WARE. A form of porcelain, the invention of Josiah Wedgwood. After a long series of experiments carried on at his manufactory in Burslem, England, he succeeded in 1773 in producing a compact, hard paste, susceptible of taking a very high polish. This he used in producing articles ornamented with cameo-work reliefs, etc. Barium sulphate was employed as a fluxing agent. See **POTTERY**.

JAS'PILITE. A banded metamorphic sedimentary rock (q.v.), made up of alternate layers of iron-stained quartz particles (jasper) and iron oxide (hematite). The bright red of the jasper and the dark brown or black of the oxide of iron give the outcroppings of this rock a brilliant appearance. In the Lake Superior region this rock has considerable economic significance, for the reason that it has a constant geological position at the top of the ore-bearing formation. This upper contact of the formation having been one of accommodation, the jaspilite has been much plicated and fractured. It is capped by a bed of quartzite called the Goodrich quartzite.

JASSY, yās'sē (Rum. **IASI**, yā'shē). The former capital of Moldavia, the northern division of Rumania, on the Bachlui, a tributary

of the Pruth, a few miles from the Russian frontier, in about lat. 47° 25' N. (Map: Balkan Peninsula, F 1). It is irregularly built over a large area. Among its numerous churches the most noteworthy are the newly restored cathedral, the fifteenth-century church of St. Nicholas, and the church of the Three Saints. There are also a number of interesting residences of the boyar families. Jassy is the seat of a Greek Orthodox metropolitan and of a Roman Catholic archbishop. The educational institutions of the city include a university, with 900 students in 1913, a theological seminary, a military school, a school of art, a school of music, and a literary and scientific society. The industries are insignificant, but the commerce is important. The exports consist chiefly of agricultural and animal products, petroleum and salt, while the chief imports are foreign manufactures and coal. Pop., in 1912, 75,882, over a third of whom were Jews. Jassy was created a town in the fourteenth century and became the residence of the Moldavian princes in 1565. A treaty of peace was concluded here between Russia and Turkey on Jan. 9, 1792, by which Russia acquired Otchakov and extended her frontiers to the Dniester. The struggle for Greek independence was inaugurated at Jassy by Alexander Ypsilanti in 1821. The seat of the Rumanian government was transferred to Bucharest in 1861.

JASTROW, yäs'trô, IGNAZ (1856-). A German economist and historian, born in Nakel and educated at Breslau, Berlin, and Göttingen. He became docent at Berlin in 1885 and was Von Ranke's assistant in historical work. He edited the *Jahresberichte der Geschichtswissenschaft* (1881-94); *Sociale Praxis* (1895-97); *Das Gewerbebericht* (1896 et seq.); *Der Arbeitsmarkt* (1897 et seq.); and wrote: *Geschichte des deutschen Einheitstraumes und seiner Erfüllung* (1884; 4th ed., 1891); *Social-liberal* (1893; 2d ed., 1894); *Die Einrichtung von Arbeitsnachweisen und Arbeitsnachweisverbänden* (2d ed., 1900); *Deutsche Geschichte im Zeitalter der Hohenstaufen* (1879-1901), with George Winter; *Kaufmannsbildung und Hochschulbildung* (1907); *Bürgertum und Staatsverwaltung* (1907); *Handelshochschulen* (1909); *Gedächtnisrede auf Dunker* (1911); and many other works. In 1904 he pursued industrial investigations in the United States, and in 1905 became professor of administrative science at Berlin.

JASTROW, jäs'trô, JOSEPH (1863-). An American psychologist, son of Marcus Jastrow. He was born in Warsaw, Poland, but came to Philadelphia in 1866. After graduating at the University of Pennsylvania in 1882 and devoting some time to graduate study there, he was fellow in psychology at Johns Hopkins University (1885-86) and was professor of experimental and comparative psychology at the University of Wisconsin from 1888 to 1903, thereafter being known as professor of psychology. In 1893 he was head of the psychological section at the World's Columbian Exposition and in 1900 he was president of the American Psychological Association. Jastrow contributed to the *Psychological Review*, of which he was associate editor, and to other periodicals. He published: *Time Relations of Mental Phenomena* (1890); *Epitomes of Three Sciences* (1890), with others; *Fact and Fable in Psychology* (1900); *The Subconscious* (1906); *The Quali-*

ties of Men (1910); *Character and Temperament* (1914).

JASTROW, MARCUS (or MORRIS) (1829-1903). An American rabbi and Hebrew scholar. He was born at Rogasen, in Prussian Poland, studied at the Gymnasium there and at the universities of Berlin and Halle, and in 1857 became assistant rabbi in Warsaw. His radical politics forced him from Russia in 1861. He was rabbi in Baden until 1863, at Worms until 1866, and, then coming to America, in Philadelphia until 1892, when he was named pastor emeritus. Prominent in Jewish education and charities, he is best known for his Talmudic learning and as author of *A Dictionary of the Targumim, the Talmud Babli and Yerushalmi, and the Midrashic Literature*, in 16 parts (1904), and as editor of the department of Talmud in the *Jewish Encyclopædia*.

JASTROW, MORRIS, JR. (1861-). An American Orientalist, son of Marcus Jastrow. He was born in Warsaw, Poland, came to Philadelphia in 1866, and, after graduation in 1881 at the University of Pennsylvania, studied Semitic languages and religions in Leipzig and in Paris. Returning to Philadelphia, Dr. Jastrow became professor of Semitic languages and librarian in the University of Pennsylvania. Besides papers for the *Zeitschrift für Assyriologie*, the *American Journal of Semitic Languages*, and the publications of the American Oriental Society, of which he became president in 1915, and the Society of Biblical Literature, he wrote: *The Religion of the Babylonians and Assyrians* (1898; Ger. trans., 1902; new ed., vol. i, 1905, vol. ii, 1912); *The Study of Religion* (1902); *Aspects of Religious Belief and Practice in Babylonia and Assyria* (1911); *Hebrew and Babylonian Traditions*, Haskell Lectures at Oberlin (1913; rev., 1914). He edited the Arabic text of the grammatical treatises of Abu Zakariyya Hayyug (1897); *Selected Essays of James Darmesteter* (with a memoir; translation of the essays by Mrs. Morris Jastrow, Jr., 1895); a series of *Handbooks on the History of Religion*. He contributed articles on Semitic archæology to the NEW INTERNATIONAL ENCYCLOPÆDIA, to the *Britannica*, to the *Jewish Encyclopædia*, and to *Hastings' Dictionary of the Bible* and *Hastings' Encyclopædia of Religion and Ethics*.

JÁSZBERÉNY, yäs'bě-rän-y'. A town of the County of Jász-Nagykun Szolnok, Hungary, on the Zagyva, 40 miles east of Budapest (Map: Austria-Hungary, F 3). It has a city hall with archives, a Franciscan cloister, and several imposing monuments, also an agricultural school. Pop., 1900, 26,791; 1910, 29,675, Magyars and mostly Roman Catholics, employed in agriculture and in trade in corn, cattle, and horses.

JATAKA, jät'a-kà (Skt. *jātaka*, relating to birth, from *jan*, to beget). The name of a Book of Birth Stories, a Buddhist work written in the Pali language and containing 550 stories of incidents in the previous births of Sakyamuni, the Buddha, and to each of these tales is given a religious coloring at the close. This large collection forms a part of that division of Buddhist sacred canon known as the *Sutta-piṭaka*, or Basket of Discourses (see PITAKA), and it is divided into 22 books, roughly classified according to the number of short rhythmical stanzas that are introduced into each narrative regarding some episode in an anterior birth. The Jatakas are of great importance in the study

of folklore. The Pali text of the stories has been edited by Fausbøll, *Jātaka, Together with its Commentary* (7 vols., London, 1879-97); the Pali introduction, sketching Buddhist life, has been translated into English by Rhys Davids (London, 1880), and a valuable translation of the whole is being made by Chalmers, Rouse, Francis, and Neil, under the editorship of Cowell, *The Jātakas, or Stories of the Buddha's Former Births* (7 vols., Cambridge, 1895-1913); Lévi, "Les Jātakas, étapes du Bouddha sur la voie des transmigrations," in the *Annales du Musée Guimet*, vol. xix (Paris, 1906); Foucher, "Les représentations de 'Jātakas' sur les bas-reliefs de Barhut," in the *Annales du Musée Guimet* (ib., 1908); Dutoit, *Jātakam, das Buch der Erzählung aus früherer Existenzen Buddhas*, translated from Pali into German (4 vols., Leipzig, 1908-12); Macdonell, *History of Sanskrit Literature* (London, 1913).

JATHRIP'PA. See MEDINA.

JÁTIVA, hä'tê-vâ, or **XÁTIVA**, formerly SAN FELIPE DE JÁTIVA. A city in the Province of Valencia, Spain, 33 miles south of Valencia, on the railroad between that city and Madrid, in the midst of gardens, vineyards, and olive orchards (Map: Spain, E 3). It was formerly strongly fortified and is still commanded by a castle situated on the brow of a hill. It has several fine promenades, and among its prominent buildings are an old collegiate church, formerly a cathedral, a silk exchange, a theatre, and a bull ring. Its water supply, brought through an aqueduct, is excellent and is utilized in numerous fountains and several public laundries. Játiva was a flourishing town in Roman and Moorish times and famous for its linens. It is the birthplace of Roderigo Borgia (Pope Alexander VI). Pop., 1887, 14,099; 1900, 12,602; 1910, 12,737.

JATS, jats. A people of the Punjab, numbering some 5,000,000, representing the population subjected in the fourth and fifth centuries by the Rajputs, high-caste Hindus. Together with the Rajputs they constitute a definite physical type—dolichocephalic head; straight, finely cut, leptorrhine nose; long, narrow face; well-developed forehead, regular features, tall stature, and light transparent brown skin. They are sturdy, independent farmers and herdsmen, Mohammedan in religion. Consult Sir Herbert Risley, *The People of India* (Calcutta, 1908).

JAUCOURT, zhô'kôôr', ARNAIL FRANÇOIS DE (1757-1852). A French politician, born at Tournon, of a Protestant family. He played some part in the early days of the Revolution, narrowly escaped the massacres of September, and was obliged to leave France because of his moderate views. After his final return he was elected to the Tribunate (1799), became its president (1802), and in 1803 was elected to the Senate. After the departure of Maria Louisa, Jaucourt became a member of the provisional government and at the First Restoration was made a peer, and, while Talleyrand was at Vienna, held the Foreign portfolio. For a short time after the Hundred Days Jaucourt was Minister of Marine and then became Privy Councillor. He voted for Louis Napoleon in 1851 and approved the Coup d'Etat, although he had been a member of the Upper House under Louis Philippe. He was descended from Duplessis Mornay and took much interest in the welfare of Protestant France.

JAUER, you'ër. An old town in the Prus-

sian Province of Silesia, on the Neisse, 38 miles west of Breslau (Map: Prussia, G 3). It has ancient churches, the palace of the former princes of Jauer, a school of commerce, and a Gymnasium. The chief manufactures of the town are machinery, leather, carpets, pens, cloth, cigars, wagons, and gloves. Jauer has a large trade in grain and a reputation for sausages. It was the capital of the Principality of Jauer, which was founded in 1303 and annexed at first to Bohemia (1392) and later to Prussia. Pop., 1900, 13,024; 1910, 13,549, mostly Roman Catholics.

JAUN'DICE (ME. *jaundys*, *jaunes*, from OF. *jaunisse*, *jaulnisse*, Fr. *jaunisse*, yellowness, from OF. *jaune*, *jaulne*, yellow, from Lat. *galbinus*, from *galbus*, yellow), or ICTERUS. The yellow color of the skin, conjunctiva, etc., arising from the presence in the blood and tissues of the coloring matter of the bile. Jaundice is a symptom of disease, not a disease itself. The fæces, from the absence of bile, are of a clay color or light-gray tint; the urine is deep saffron color, and all the other secretions are tinted with bile. The tissues are also stained, as shown at autopsies, the cut surface of the kidneys being especially yellow. The coloring matter of the bile comes from the hæmoglobin of the blood, which is transformed into bilirubin. The transformation takes place in the hepatic cells.

Icterus is due to one of two causes: (1) mechanical obstruction of the flow of bile into the duodenum (see LIVER, DISEASES OF), or *stasis icterus*; and (2) functional alteration of the hepatic cell, resulting in the production of pigmentary polycholia. *Stasis icterus* results from pressure on the gall duct or common bile duct of a tumor or new growth, such as cancer of stomach, of duodenum, of liver, or of pancreas; or fæces in the intestine; or blocking of the gall duct by a gallstone, or blocking of the common bile duct by swelling of the mucous lining and an accumulation of mucus. A gallstone or biliary calculus (see CALCULUS) causes exquisite pain when lodged in or passing through the gall duct. After the endobiliary tension has reached a certain limit the lymphatics begin to absorb the bile and carry it to the thoracic duct, which in turn empties it into the veins. The reabsorption of the bile depends on the bile pressure's being relatively greater than the blood pressure in the portal vein. Jaundice therefore occurs in the newborn babe, in some cases, because ligature of the umbilical cord prevents the blood from flowing from the umbilical to the portal vein. The jaundice of fasting is accounted for by the diminution of pressure in the portal system, owing to insufficient intestinal absorption. Functional alteration of the hepatic cell occurs in phosphorus poisoning and in grave infective conditions, such as yellow fever. In yellow fever there is enormous destruction of the red cells of the blood, but there is also altered biliary function of the liver cells, with a consequent inspissation of the bile. Semmola and Gioffredi classify icterus, according to clinical types, into primary or secondary forms, as follows, without regard to our pathological knowledge of the subject:

- | | | |
|-----------|---|--|
| Primary | { | 1. Catarrhal (acute or chronic).
2. Febrile.
3. Grave (acute yellow atrophy).
4. Emotional.
5. Of the newborn. |
| Secondary | { | 1. To infections.
2. To hepatic disease.
3. To intrinsic or extrinsic stenosis of the bile ducts. |

Two types of jaundice deserve special mention. *Icterus neonatorum* (jaundice of the newborn) results physiologically from the destruction of large numbers of red blood cells during the first few days of life or from interruption of the placental circulation, permitting absorption from the bile capillaries. Pathologically it may arise from septic poisoning through an infected umbilical stump, from syphilis, or rarely from congenital absence of biliary passages. Usually the condition is evanescent and requires no treatment beyond mild purgation.

Weil's Disease (acute febrile jaundice) is most common in the summer and occurs chiefly among laborers, brewers, and butchers. Cold is an exciting cause, but the active agent is believed to be one or more microorganisms. The disease comes on suddenly, with a chill, followed by fever, headache, nausea, and epigastric pain. The liver and spleen are enlarged and tender. The treatment is the same as that for ordinary jaundice, and recovery is the rule. See CHILDREN, DISEASES OF.

During the existence of jaundice changes in the diet should be made, fats being avoided and constipation relieved. Mercury, chloride of ammonium, phosphate of sodium, and hyposulphites are useful drugs.

JAUNPUR, joun-pōōr'. The headquarters of a district of the same name in the United Provinces, British India (Map: India, E 4). It is on the river Gumti, 34 miles northwest of Benares. It has manufactures of perfumes and papier-mâché and a fair trade, but its chief interest is archæological. It was in ancient times the capital of a Mohammedan kingdom. Sultan Feroz III, of Delhi, having ordered a Hindu temple to be demolished, erected in 1370, around its ruins, a fort of solid stone. He sent numerous artificers and others to inhabit the new city, which was completed in 12 years. Pop., 1901, 42,771; 1911, 30,473.

JAUNTING CAR, or JAUNTY CAR. A two-wheeled carriage, very common in Ireland. The seats are extended back to back over low wheels, and at right angles to the wheels, the passengers riding sidewise.

JAURÉGUIBERRY, zhō'rā'gē'bě'rē', JEAN BERNARD (1815-87). A French naval officer. Born at Bayonne, he entered the navy in 1831, was made lieutenant in 1845, commander in 1856, captain in 1860, rear admiral in 1869, and vice admiral in 1870. He served in the Crimean War, in active operations in China, and as Governor of Senegal (1869). Finding no opportunity for service afloat in the Franco-Prussian War, he applied for a command in the army, and his request was granted. He was in command of a division at Coulmiers, Villepion, and Loigny-Poupry, while in the retreat upon Le Mans and in the battle at that place he commanded a corps. In 1871 he became commander in chief of the Toulon fleet and in 1876 was given the command of the Mediterranean evolutionary squadron. He served in many other important naval capacities, including Minister of Marine (1879-80, 1882-83), and in May, 1879, he was elected a senator for life.

JÁUREGUI Y AGUILAR, hou'rā-gē ē ä'gē-lār', JUAN MARTÍNEZ DE (1583-1641). A Spanish poet, born at Seville. He seems to have begun his career as a painter and to have gone to Rome to study art. Some have identified him with the Jáuregui who painted a picture of Cer-

vantes, and whom the latter mentions in the prologue to his *Novelas*. (A portrait, recently discovered and now in the possession of the Real Academia Española, and purporting to be of Cervantes and by Jáuregui, is considered by many critics to be authentic and the very portrait mentioned by Cervantes. See the reproduction thereof in the article CERVANTES SAAVEDRA, MIGUEL DE.) While in Italy he studied Italian literature, and by the publication at Rome, in 1607, of his verse translation of Tasso's *Aminta*, he firmly established his literary reputation. He seems to have returned to Spain late in 1609. In 1618 he published an edition of his verse (*Rimas de Juan de Jáuregui*) at Seville. In the preface to this volume he protested against the baneful mannerisms that Góngora had introduced into Spanish poetry, and his *Discurso poético contra el hablar culto y oscuro* (1624; cf. the reprint of this in Menéndez y Pelayo's *Historia de las ideas estéticas en España*, Madrid, 1884-89) contains so skillful an attack on these same mannerisms that it won him knighthood in the Order of Calatrava. Yet his own *Orfeo*, a poem in five cantos on the well-known classic legend, has some of the stylistic aberrations of Gongorism, and it was published at Madrid the same year. Jáuregui yields entirely to the Gongoristic current in the *Farsalia* (a version of Lucan's Latin poem), published posthumously in 1684. His permanent title to fame must rest upon the translation of the *Aminta* and on one or two of the lyrics contained in the *Rimas*, especially the graceful *silva* on his lady-love bathing. Consult the edition of the *Aminta* in López de Sedano, *Parnaso español*, vol. i (Madrid, 1768-78), and the edition of Jáuregui's poems in *Biblioteca de autores españoles*, in vol. xlii (ib., 1857).

JAURÈS, zhō'rēs', JEAN LÉON (1859-1914). A distinguished French Socialist and writer, born at Castres (Tarn) of well-to-do middle-class parents. He was given an excellent education at the Lycée Louis le Grand and at the Ecole Normale Supérieure. For some years he was a professor of philosophy at the University of Toulouse. In 1885 he was elected to the Chamber of Deputies as a radical Republican, but was defeated four years later by a Monarchist. In 1893 he was returned as a Socialist Deputy, and his great oratorical powers quickly made him one of the leading figures in the Chamber. From that time on he was almost continuously in public life and was regarded as the leading Socialist of France, sharing with August Bebel (q.v.) the leadership of international Socialism. The moderation of Jaurès's Socialism brought upon him the bitter hostility of the revolutionary Marxians led by Jules Guesde (q.v.). The Marxians saw in the Dreyfus affair merely a "bourgeois quarrel" which was of no concern to the worker. To Jaurès it was a great human issue which involved not only the fate of an innocent man but that of the Republic as well. He threw himself into the fray with all his ardor and became one of the stoutest defenders of Captain Dreyfus. When the radical Republican *bloc* was formed in 1899 under Waldeck-Rousseau, he consented to the inclusion of the Socialist Deputy Millerand (q.v.) as a member of the cabinet. Jaurès's support of the *bloc* was the decisive element in the struggle which followed to disestablish the church and to republicanize the army. The followers of Guesde, having denounced Jaurès as a traitor

to Socialist ideals for having compromised with the "bourgeois state," saw to it that the matter was taken up by the International Socialist Congress which met at Amsterdam in 1904. A resolution that no bona fide Socialist should be allowed to hold office in a bourgeois cabinet gave rise to a great debate in which Bebel and Jaurès took the leading parts. In spite of the latter's eloquence the resolution passed the congress, and all Socialist factions in France were ordered to unite. Jaurès, accepting his defeat with good grace, became the leader of a unified Socialist party, which in the election of 1914 returned more than 90 deputies.

Jaurès, although opposed to the main theories of Syndicalism, nevertheless warmly championed the cause of the workers in the great railway strike of 1910. He strongly denounced the Briand ministry for having resorted to mobilization orders to break the general strike. Jaurès favored an agreement with Germany which would do away with militarism by calling a halt on further armament. Socialists, he held, should urge all possible methods of arbitration, but if these failed they should fight willingly the aggressor. He even favored a general strike to stop war, but on condition that it be under *international* direction and not confined to one country. He was the chief opponent of the three years' military law passed by the Chamber in 1913. Just before the Great European War broke out, in 1914 (see WAR IN EUROPE), a meeting of Socialists took place in Brussels, at which Jaurès made a notable attack on militarism. His speech aroused great antagonism, and it was only a few weeks later (July 31) that a semidemented youth, incited by recent attacks on the Socialist leader, assassinated him in front of a café in Paris.

Jaurès was a voluminous writer. For the *Histoire socialiste* (12 vols., 1901-08), to which he was the chief contributor, he wrote vol. i, *La constituante* (1901), vol. ii, *La législative* (1902), vols. iii and iv, *La convention* (1903), vol. x, *Le second empire* (1907), and part of vol. xi, *La guerre franco-allemande* (1908). He also published *Discours parlementaires* (1904); *Etudes socialistes* (1902), translated by Mildred Minturn (1906); and *L'Armée nouvelle* (1911). Jaurès was editor of the Parisian journal *L'Humanité*, which he founded in 1904 and to which he contributed regularly. For description of the personality and ideas of Jaurès, consult S. P. Orth, *Socialism and Democracy in Europe* (New York, 1913); J. S. Schapiro, "The Drift in French Politics," in the *American Political Science Review* (Baltimore, 1913); and the anonymous article in *Current Literature*, February, 1914 (New York). See SOCIALISM.

JAVA, jä'vá (commonly derived from Skt. *yāva*, rich in millet, from *yava*, millet; but it is worthy of note that *Java*, or in the more ancient form *Java-dvipa*, is associable with the proto-Polynesian *Sava* or *Hava*, which, in composition with *Iki*, appears in Polynesian in such widely different names of major geography as Havaiki, Hawaii, Savaii). The most important island of the Dutch East Indies, lying south of the equator, between the parallels of 5° 52' and 8° 59' and between the meridians of 105° 13' and 114° 39' E. (Map: East India Islands, C and D 7). It is bounded on the north by the clear, shallow waters of the Java Sea; on the south by the Indian Ocean; on the west by the

Strait of Sunda, which separates it from Sumatra (also a Dutch possession); and on the east by the Strait of Bali (11 miles wide), separating it from the island of Bali. The south coast is steep and precipitous, with cliffs rising almost perpendicularly to a considerable height, and is bordered by a long line of breakers. The north coast is low and swampy in many places and overgrown with mangrove trees and bushes, particularly towards the west. The island is long and narrow, its greatest length, from west-northwest to east-southeast, being 666 miles, and its breadth from 46 to 121 miles. Area, 48,503 square miles. With Madura and several smaller adjacent islands administratively belonging to it, it is known officially as "Java and Madura." The area of the whole is 50,554 square miles. Java is one of the richest and most populous islands in the world. It is unsurpassed in fertility and in the beauty of its scenery. It has passed through many historical changes and is intensely interesting archæologically.

Topography. Java is very mountainous and is remarkable for the number of its volcanic peaks, 45 in all—ranging in height from 2000 to 12,040 feet above the level of the sea, clad with verdure to their summits and having slopes fertile in nearly all their climatic zones. The general trend is from west to east. A striking difference is noted between the western and eastern halves of the island. In the former the volcanoes are bunched together, forming great masses, without intervals or plateaus. Towards the east the volcanic peaks are for the most part isolated one from the other, with a large number of valleys and plains, deep gorges and rushing streams. Most of the active volcanoes are found in the western end, and of these 14 are found in an area of 20 by 35 miles. During historic ages these volcanoes are known to have destroyed many tens of thousands of human lives, and within recent times several have exploded, spreading devastation on all sides. The peak of Ringghit, once one of the highest, lost much of its form by internal explosions in 1686, destroying, it is estimated, approximately 10,000 lives. In May, 1901, the Kloet, one of the smaller volcanoes, broke into eruption after many years' quiet, enveloping towns 150 to 250 miles distant in thick darkness, destroying the sugar crop and killing several Europeans and about 100 natives. Among the best-known mountains are: Salak, 7000 feet, south of Batavia; Géde, 9718; Tjirmaj, 10,070; Slamet, 11,247; Marbabu, 10,673; Raun, 10,822; and Semeru, 12,040 feet high. The list of eruptions in historic times is a formidable one, that best known in the Western world being that of Krakatoa (q.v.) in the Strait of Sunda. Earthquakes are of common occurrence, though not usually very destructive.

Java abounds in plains, valleys, and forests, the richest alluvial coast land being in the northwest, in the provinces of Bantam, Batavia, Krawang, and Cheribon; yet all through the eastern half are many beautiful and fertile plains, and no part of the island, unless it be the Preanger Residency, which occupies the south half of the western part, and a few provinces in the east half, lacks rivers. As the south coast is relatively high and mountainous, with a long north slope, most of the streams flow into the Java Sea. In the rainy season at least 50 streams can be used for floating rafts to the sea, and five or six are always navigable for some distance

from their mouth. The longest is the Solo, about 300 miles long, on which is situated the city of Surakarta. For most of the year it is navigable for boats and river steamers. The Surabaya River, or Brantes, the next in importance, rising on the west slope of Semeru, forms, with its tributary, a curve with three sides and enters the sea near the Solo, one of its mouths being near the city of Surabaya, where is found the best harbor in Java. The third important river is the Tji Manuk, which nearly traverses the island, and the fourth is the Tji Tarun.

Climate. Though so near the equator, Java is, to those who avoid excess in eating and drinking and avoid exposure to the insect life of the lowland marshes, quite healthful. From April to October there is perpetual sunshine, with only occasional light showers, and the Western white man must avoid the direct rays of the sun during the heat of the day. From October to April there is almost a steady rainfall, except that the sun shines for a while daily, generally during the morning. In the west, however, no part of the year is free from rain. Land and sea breezes render life comfortable all the year round. Violent storms, winds, or hurricanes are unknown, though near the high peaks rains, with terrific lightning and thunder, are frequent. The annual rainfall is about 80 inches, the heaviest rainfall occurring in December, January, and February. The average temperature at Batavia is 78.69° F. (the average of 12 years), and the extreme range on the lowest levels is 26 degrees.

Flora. Java has many botanical zones. The deep black soil produces a richness and an abundance of products in the vegetable kingdom that is without parallel in any other part of the world within an area so limited. Almost all the plants are evergreen, and most of the villages are concealed by the perpetual verdure. The lowest zone, from sea level to 2000 feet, has the most extensive area. Here the heat is tropical, and here we find rice, sugar, cotton, indigo, mangoes, and palm trees. The swamps and plains are covered by cultivated areas, thickets of bamboo, patches of tall grass, and a profusion of flowers. The second level, which extends from 2000 to 4500 feet (the heat is moderate), produces coffee, tea, cinchona, dozens of varieties of palms, fruits, vegetables, teak, mahogany, sandalwood, rubber and camphor trees, rattan, bamboo, many fancy and rare woods, and thousands of vines and flowering shrubs. The third zone, from 4500 to 7500 feet, is moderately cool, and produces maize, tobacco, cabbages, potatoes, etc.; and in the fourth zone (7500 to 12,000 feet) the flora exhibits many genera found in temperate Europe. The fruits are abundant and include oranges, limes, pomelos, the coconut, banana, mango, mangosteen, the duku, the rambutan, and the durian. In the gardens near their houses the natives cultivate fragrant and ornamental flowers. About one-fourth of the area of Java is reckoned as forest, and only in comparatively recent years has this source of wealth been taken advantage of. Teak is the chief wood exported.

Fauna. Fifty species of mammalia are found in Java. Of the larger animals the tiger, leopard, rhinoceros, wild sheep and deer, two species of wild boar, the jackal, wild cat, and many species of monkey are found in the forests. Bats are plentiful, the kalong or "flying fox," a fruit-eating bat, doing much damage to sugar palms, maize, and young coconut trees.

The buffalo, next to the native pony, is the most valuable animal, being used both for draft and for food. Domestic animals, such as sheep, goats, cows, and swine, though below the ordinary size, are not scarce. Horses from Arabia and pigs from China have been introduced and thrive. The smaller game in forest and marsh is numerous. In the watercourses are the crocodiles, from 20 to 30 feet in length, and always ravenous and dangerous. Large troops of wild dogs are found in the jungles. Among birds, the peafowl and pelican are the largest, the former being found in flocks. There are nearly 300 species of land birds, including jungle fowl, various species of woodpeckers and kingfishers, the hornbill, the black and crimson oriole, the minaret flycatcher, the yellow and yellow-green trogon, etc., and the swift (*Collocalia fuciphaga*), which inhabits deep caverns near the sea and cliffs and furnishes the edible birds' nests (see SALANGANE) so much prized by the Chinese for soup. Land and water turtles abound. The varieties of snakes are almost countless. The python is quite common. The insects are without number, but not many of them overtroublesome or venomous. Many rare and beautiful butterflies are found, including the calliper butterfly. The sea abounds in fish, and 600 species are known, besides 34 species of river fish.

Geology and Mineral Resources. Java has been for so many ages under a stress of volcanic action that the strata anciently deposited have been again and again disturbed; yet it appears that the underlying rocks are for the most part granite and syenite, and on these rest sedimentary rocks of the Tertiary period. Though the absence of the fossils of vertebrates is noticeable, the rocks containing the invertebrates are very abundant; but the volcanic deposits have covered up or distorted the older formations in every part of the island. Coal is found in many places, but in thin strata. The best mineral fuel, lignite, is found in Bantam. Asphalt, clay (excellent for bricks and earthenware), limestone, marble, manganese, sulphur, salt, and saltpetre are obtained. The production of petroleum has become important, the quantity produced in 1911 being 425,000,000 gallons. Java is the poorest of the East Indian islands in minerals.

Agriculture. The great majority of the natives are farmers or agricultural laborers. Rice is the chief article of food, and its production the chief industry. By gift from the last Mohammedan Emperor, who abdicated in 1749 in favor of the Dutch, and by purchase from the native princes since then, the Dutch government now owns almost all the land. Along with the Mohammedan gift they secured the right to receive one-fifth of the produce and of the labor of the peasant. This made easy the introduction in 1832 of the "culture system," which has since prevailed. This consists in obligatory service on the part of the peasant, under official superintendence, in the cultivation of tobacco, coffee, sugar, indigo, tea, pepper, etc. Now coffee only is produced by enforced labor. About 8,638,600 acres are under native cultivation. The lands now the property of Europeans cover 1,969,544 acres; of Chinese, 316,209 acres; and of other foreign Orientals, 22,923 acres, and in addition to this there were leases of over 1,000,000 acres to Europeans. The chief products are as follows: sugar (1912), 1,443,584 tons (including the whole of

Dutch India, mostly, however, grown in Java); coffee, including Sumatra (1912), 34,280 tons; cinchona (1911), 21,412,417 pounds; tobacco, including Sumatra (1911), 189,771,968 pounds; tea (1911), 55,697,639 pounds; indigo (1912), 175,504 pounds; cocoa (1911), 3,912,328 pounds; and pepper (1912) 24,071 tons. The tin mines of Banca and Billiton yielded, in 1913, 15,346 tons; the coal mines of Java, Sumatra, and Borneo, 411,000 tons. Java holds third rank among the cane-sugar producers of the world, and second as an exporter of that product. The production of 1912-13 was 1,458,000 tons against 2,492,000 in Cuba and 2,552,000 in India, which latter country, however, produces practically none for the export trade.

Communication. Java is well supplied with good roads. Railway construction began in 1875, and now railways extend across and from end to end of the island. The total length of the railways, state and private, in 1911 was 1393 miles, and of telegraph lines, 10,000 miles. Batavia, Samarang, and Surabaya have been connected by telephone since 1896. The gross receipts of the railways in 1911 were 29,722,000 guilders; passengers carried, 36,867,000.

Commerce. In 1911 the total value of the imports of Java was 373,289,000 guilders (guilder = 40.2 cents); of the exports, 510,612,000 guilders. The chief imports are piece goods, fertilizers, and coal from Wales, Australia, and Japan. Much petroleum from Sumatra and tin from Banca are entered for reexport. The chief exports are sugar, coffee, tobacco, rice, cinchona bark, quinine, which goes mostly to the United States and London, tea (almost entirely to Holland), copra, indigo, kapok (mostly to Australia), hides, timber, rubber, gutta percha, cocoa, tapioca, and spices. With the exception of rice, about one-half of which goes to Borneo and China, nearly four-fifths of the exports go to the Netherlands. There is considerable trade with Penang and Singapore. The only legal coins are those of Holland.

Intercourse with the Outer World. Intercourse with Java, and indeed with the Dutch East Indies generally, is hedged about with many irksome restrictions and regulations. One may land at any of the ports, but cannot stay on shore for more than 24 hours without registering, giving name, age, religion, nationality, place of birth, occupation, name of the ship on which one arrived, the captain's name, etc., and receiving a permit. If travel in the interior is desired, another permit is necessary; sureties have to be provided, the intended route indicated, fees have to be paid, and time is consumed, as every step is taken with true Dutch deliberateness. This pass is not good for more than six months. Should one wish to enjoy sport, however, still another document is needed, entitling the holder to import his gun and ammunition, and more fees, chiefly stamp dues, are demanded. Should one wish to settle in the country, the conditions are still more formidable, the time consumed much greater, and the fees quite considerable. Two sureties, each in a large sum, are needed, and the strictest inquiries are made, and should any inadvertence occur, or any slight discrepancy be found in the initials, the spelling of the name, or the like, it may vitiate the whole proceeding and lead to the rejection of the application; and lastly, when one wishes to leave the island, still another permit is necessary, and it cannot be obtained in a

hurry, as wide inquiries have to be made as to whether all one's debts have been paid, and the like.

Government. "Java and Madura," with the surrounding islets included in the same administration, is divided into 17 residencies, under the control of a Governor-General, who has great executive and even a certain amount of legislative power. He is assisted by a council of five, whose functions are legislative and advisory. In each province there is also a resident, assisted by assistant residents and subordinate officers called controllers. Nevertheless the administration, so far as the Javanese see it, is carried on through a network of native officials, to whom the foreign rulers are "elder brothers." There is daily conference between the Dutch and native chiefs, and in all matters between them the Javanese language is used, Dutch not being allowed to be spoken. Each resident exercises judicial, financial, and administrative functions, dealing with civil and criminal cases. To each assistant resident there is an *afdeeling*, or department. The controller is really the link between the natives and foreign officers. He makes a personal inspection of his district every month, having supervision of everything—observing, advising, and reporting—but with little executive authority. Out of the ancient noble families a native regent is appointed, whose rank and right of precedence are superior even to those of all other European officers except the resident. He is the head of the native officials in his province and receives a salary of 2000 to 3000 florins; but in one or two cases—e.g., the Sultan of Jokja Karta and the Regent of Bandung—the allowance is 84,000 florins. The residents number 17, the assistant residents about three times as many, and the controllers a slightly larger number. The residents and controllers are appointed only after a searching examination in the Javanese language, customs, and conditions. The Governor-General resides in Batavia, the capital. In the administration of justice there is a distinction made between Europeans and natives and Orientals. The former are subject to laws based on those of the Netherlands, while in the regulation and trial of the Javanese and those classed with them, their own traditions, customs, and law, under the direction of the native chiefs, decide questions of equity and law. The High Court of Justice is at Batavia, with lower courts in the five large cities, besides a number of circuit, district, and in some places priestly, courts. For the defense of the colony there is an army of about 35,000 (about two-thirds being natives), with headquarters at Batavia, and a navy, with headquarters at Surabaya. The expenditure for defense was in 1914 about \$19,000,000, of which about one-fourth was disbursed in Netherlands.

Finance. The revenue is derived from land and the usual taxes, licenses, customs dues, the government monopolies of salt, opium, and railways; but the largest item is from the sale of coffee grown under the "culture system" and sold by the government, as well as the sale of quinine and tin. The budget of Java forms a part of that for the Dutch East Indies. The local revenue is derived from land taxes and licenses, customs duties and certain indirect taxes. The revenue of 1914 was 256,957,000 guilders, and the expenditures 335,050,000 guilders.

Population. In 1800 Java, according to a rude census, had 3,000,000, and, in 1813, 6,000,000

inhabitants. In 1896 Java and Madura had 26,125,053 inhabitants, including 51,737 Europeans, 261,080 Chinese, 17,045 Arabs, 3238 other non-indigenous Orientals, and 25,791,953 natives. In 1900 Java and Madura had 28,746,688 inhabitants. In 1905 the population was estimated at 30,098,000, including 75,833 Europeans and Eurasians, 537,316 Chinese, and 27,400 Arabs.

Ethnology. The native inhabitants of Java belong to the Malay race, the alleged Negrito peoples of the interior having no real existence. The Javanese proper dwell in the central portions of the island and towards the east, the Sundanese in the west, and the Madurese in the east and on the adjacent islands of Madura, Bavian, etc. In the mountains of Bantam, in the extreme west, live the Baduwis, and in the mountains of the extreme east the Tenggerese, both of whom are very primitive peoples of the sort sometimes styled Indonesian, or proto-Malay, who, in spite of the influence of their Islamic neighbors, have preserved much of their old "heathen" religion. The much-discussed Kalangs, if at all a separate people, which is improbable, are on present evidence part of the aboriginal Malayan or proto-Malayan stock. Slavery and colonization have added at various periods minor elements to the Javanese population. Thus, there still exists in Batavia a "Bali village," testifying to the fact of deportation from that adjacent island in times past. The Baduwis and Tenggerese are less brachycephalic than the Javanese proper, the Sundanese, and the Madurese, and they are probably of somewhat greater average height, with a rather lighter skin. Outside of the "heathen" tribes of the interior, the Madurese seem to have accepted least the conditions of civilization. The Javanese proper are yielding somewhat to the Madurese on the east, but the Sundanese in the west seem to be becoming more Javanized, and the Javanese may still be looked upon as the average of the island population. The three principal peoples of Java have each their own language, a Malayan dialect with more or less individuality. The marked aristocratic tendencies of the Javanese, which find expression in social and governmental institutions, are reflected also in their language, with its "noble" and "common" forms of speech. The old Javanese of the monuments, inscriptions, etc.—the ancient literary language—is called Kavi (q.v.). Sundanese, though not at all neglected, has received less attention. The puppet plays, or *Wajang*, of Java, to which some authorities have too hastily attributed an entirely Indian origin, and the mask plays, or *topeng*, of which both popular and classical varieties exist, have been recently much studied. The *babads*, or chronicles, are another feature of Javanese folk literature. The Javanese represent perhaps the highest point of Malay culture, and show at the same time its limitations when controlled by Europeans. Not all of Javanese culture was created or suggested by India, probably less than is generally believed. Hindu influence in Java began before the beginning of the fifth century A.D. and had its greatest effects upon the religion, political divisions, language, and literature of the island. The advent of the religion of Islam in the fifteenth century was at first much more rapid and revolutionary in its effects. To-day the great majority of the nearly 30,000,000 Malays of Java are professors in some way or other of Islam, their creed being mixed

here with relics of primitive Shamanism and there with echoes of Hinduism, Buddhism, etc. Besides the loan words in the language, the alphabet in which it is written, and the general influence upon arts of all kinds, Hindu contact has its monument in the great temples to Buddha erected in Java (700–1450 A.D.). One of these, the Great Buddha, or Boro Buddor (q.v.), is by some esteemed the greatest example of Buddhist architecture in existence. The foundation, under Hindu influence, of kingdoms such as those of Madjapahit, led to the extension of Javanese culture into Sumatra, Borneo, and several of the smaller islands of the Malaysian Archipelago, and some have traced it even to Papua and Australia. The great numbers of the Javanese Malays, and the fact that they are not at all moribund, but a rapidly increasing people, make them one of the most important groups of mankind for the historian of human culture. The discovery by Dr. Eugene Dubois (1891–94) of the upper part of a skull, two molars, and a femur, in what is said to be a Pleistocene deposit at Trinil, on the river Bengawan, has given rise to a voluminous literature of study and discussion. See MAN, SCIENCE OF, *Ancient Types*.

Education. Separate school organizations are maintained for natives and Europeans and those assimilated with them. In 1911 there were 706 primary schools for the natives maintained by the state and 507 private schools; the pupils in the two classes were 145,709 and 52,551 respectively. Besides these, there are several middle schools, and normal schools for training native teachers. For the Europeans there were a number of separate schools, both public and private (including several for girls only), besides normal schools at Batavia and Surabaya. There is a gymnasium at Batavia, and there are an agricultural college, a museum, and a botanical garden (one of the finest in the world) at Buitenzorg, the residence of the Governor-General, on the slope of Mount Salak near Batavia.

Religion. Perfect liberty is allowed to all forms of faith. Buddhism was early introduced; but by 414, when Fa Hein, the Chinese Buddhist, visited Java, he wrote that little Buddhism could be found. This was succeeded by Brahmanism, which continued until the Mohammedan conquest in 1475–79 and now lingers only in Bali. Nominally the Javanese are now Mohammedans, and great respect is paid to a returned pilgrim from Mecca, nearly 10,000 pilgrims leaving Java under this pretext of holy visitation annually. The mass of the natives, however, follow the primitive animism of their ancestors and are very religious, in the sense of being under the influence of unseen and mysterious spirits of local importance. About 150 Christian missionaries of various societies, chiefly Netherlandish, labor among them, about 400,000 natives being enrolled in the Roman or Reformed churches.

History. The history of Java, shorn of legend, fable, and mythology, is very simple. Civilization came to the aborigines from India, Buddhism at first being paramount. The Sivaism of the Hindus followed and prevailed for centuries, during which time many Hindu states were set up, that of Madjapahit being chief, with vast power and influence. The struggle between the two faiths introduced from India culminated in a compromise, which is very

marked and easily discernible in their art, antiquities, and ruins, of which the great mass called Boro Buddor (q.v.) furnishes a conspicuous example, superb copies of the sculptures from which were exhibited at the Paris Exposition of 1900. The chief towns containing Hindu remains are Surabaya, Samarang, Solo, Jokjakarta, and Magalang, in the centre and east of the island. The third great epoch was introduced by contact with the Europeans, when the Dutch navigators and their East India Company had trading stations along the coast. The Portuguese made their way to Java early in the sixteenth century, but about the close of the century they were supplanted by the Dutch. The paramount native state at this time was Mataram, and in the early Dutch records its princes are called emperors. The gradual extension of Dutch rule was effected in much the same manner as that of the conquest of India by the British. Their authority was extended over the Preanger Residency in 1705, over the whole northwest coast in 1745, over Surakarta and Jokjakarta by 1755, Bantam coming under their control in 1808. The British held the island from 1811 to 1816, still further asserting and extending European control, and introducing great reforms in the administration under the vigorous government of Sir Stamford Raffles; but on regaining the island the Dutch pressed their claims with increased vigor. Their chief idea seemed to be to use Java simply as an appendage to the Netherlands, to secure revenue and pay off the debts of the "mother country"; but since 1870 the general policy has been to hold the colonies for at least mutual benefit, with increasing purpose to benefit the Javanese in every way as far as possible. The three European names most closely associated with the development of Java are Daendels, Raffles, and Van den Bosch (q.v.). When in 1825 the native chief, Dipa Negara, struggled to regain ascendancy, a war broke out which lasted five years and ended in undisputed control by the Dutch.

Bibliography. Of the older works, Raffles, *History of Java* (2d ed., London, 1830), and Junghuhn, *Java* (trans., Leipzig, 1852-54), are well worth consulting. Veth, *Java, geographisch, ethnologisch, historisch* (2d ed., Haarlem, 1895), is the best book on the general subject. Other valuable works are: Junghuhn, *Topographische und naturwissenschaftliche Reisen durch Java*, ed. by Esenbeck (Magdeburg, 1845); id., *Landschaftsansichten von Java* (trans., Leipzig, 1853); Job Müller, *Beschreibung der Insel Java* (trans., Berlin, 1860); Money, *Java, or How to Manage a Colony* (London, 1861); Gronemann, *In den Kedaton te Jogjakarter* (Leyden, 1888). For a good account of Javanese theatres, dancing, etc.: Van Deventer, *Geschiedenis der Nederlanders op Java* (Haarlem, 1887); Verbeek and Fennema, *Description géologique de Java et Madoura* (Amsterdam, 1890); Bastian, *Indonesien*, vol. v (Berlin, 1894); Mayer, *Een blik in het Javaansche volksleven* (Leyden, 1896); Scidmore, *Java, the Garden of the East* (New York, 1897); Higginson, *Java, the Pearl of the East* (Boston, 1899); Breitenstein, "Java," in *21 Jahren in Indien* (Leipzig, 1899-1900); Giesenhagen, *Aus Java und Sumatra* (Leipzig, 1902); Clive Day, *Policy and Administration of the Dutch in Java* (New York, 1904), contains a bibliography; A. De Wit, *Facts and Fancies about Java* (Philadelphia, 1905); A. Cabaton, *Java and Sumatra and the Other Islands of the*

Dutch East Indics (New York, 1911); A. S. Walcott, *Java and her Neighbours* (London, 1914); Rouffaer and Juynboel, *Die Batik-Kunst in Niederländisch-Indien und ihre Geschichte* (2 vols., Utrecht, 1914), contains a bibliography. For the flora: Blume, *Floræ Javæ* (Brussels, 1858); Van Nooten, *Fleurs, fruits, et feuillages de l'île de Java* (3d ed., ib., 1882). For the natural history: Horsfield, *Zoölogical Researches in Java and the Neighboring Islands* (London, 1824); Wallace, *The Malay Archipelago* (New York, 1869). For anthropology and ethnology: Meyer, *Die Kalangs auf Java* (Leipzig, 1877); Jacobs, *De Badjoes* (The Hague, 1891); Kohlbrugge, "L'Anthropologie des Tenggerois," in *L'Anthropologie* (Paris, 1898); Chailley-Bert, *Java et ses habitants* (ib., 1900). For the ruins: Tissandier, *Camboge et Java, ruines khmères et javanaises* (ib., 1896); J. F. Scheltema, *Monumental Java* (London, 1912), contains a bibliography.

JAVA FOWL. An old-fashioned breed of domestic fowls, white, black, or mottled, with a small, single, upright comb in both cocks and hens. The shanks and toes are yellow and free from feathers. The cocks weigh from 9 to 10 pounds, and the hens about 7½ pounds. They are good, useful fowls and easily kept.

JAV'ANESE LANGUAGE. A language of the Malayo-Polynesian group, which is the vernacular of Java. Largely through Indian influence Javanese became the medium of an important literature as early as the ninth century A.D. In this ancient form Javanese was modified in its vocabulary to a large extent by Sanskrit, and it was accordingly termed Kavi (q.v.) as being preëminently the language of poetry. The direct derivative of Kavi is modern Javanese, which is divided into the courtly or Krama and into the vernacular or Ngoko. Ngoko is used in speaking to an inferior, while Krama is used in addressing a person of superior social station. These two forms of speech differ rather in vocabulary than in morphology. A third language, called Madhya or middle, partakes of the characteristics of both the others, although more closely resembling on the whole the Ngoko. The Javanese are thus bilingualists or even trilingualists, the use of one language in preference to the other being dictated by certain rules of social etiquette. This phenomenon may have its origin in word taboo. Javanese literature consists in great part of translations from the Kavi, and thus ultimately from the Sanskrit. Here belong such works as the *Brata-yuda*, the *Arjuna-sahasrabahu*, and the *Arjuna-vivahana*, all based on the Mahabharata (q.v.), as well as the *Rama*, derived from the Ramayana (q.v.). The *Manik-Maya* is important as a source of Javanese cosmogony and mythology, and the *Babads*, or prose chronicles, are of interest both linguistically and historically. Akin to the *Babads* are a number of historical romances, such as the Damar Wulan and the Raja Pirangon. In drama Javanese is rich in shadow plays (*wayang*), mainly based on old legends, and the beast fable is highly developed. There are also translations and imitations of Arabic religious literature.

Bibliography. Roorda, *Javaansche Grammatika* (Amsterdam, 1855); Favre, *Grammaire javanaise* (Paris, 1866); Abissa, *En javansche Toneelstuk*, Dutch translation by Humme (The Hague, 1878); Van den Broek, *Javansche Vertellingen* (ib., 1878); Gericke, Roorda, and

Breede, *Javaansch-Nederduitsch Woordenboek* (2d ed., Amsterdam, 1883-86); Bohatta, *Praktische Grammatik der javanischen Sprache* (Vienna, 1892); G. A. Wilken, *Handboek voor de Vergelijkende Volkenkunde von Nederlandsch Indien* (Leyden, 1893); Roorda, *Beknopte javansche Grammatika* (4th ed., Amsterdam, 1893); Serrurier, *De Wajang Poerwa* (Leyden, 1896); Veth, *Java, Geographisch, Ethnologisch, Historisch* (2d ed., Harlem, 1896-1903); Hazen, *Bijdrage tot de Kennis van het javaansche Tooneel* (Leyden, 1897); Hansen, *De javaansche Folk: Praktisch Nederlandsch-Javaansch Zak-Woordenboek* (Amsterdam, 1901); Bohatta, "Das javanische Drama," in *Anthropologische Gesellschaft, Mitteilungen*, vol. xxxv (Vienna, 1905); A. De Wit, *Facts and Fancies about Java* (Philadelphia, 1905).

JAVARY, zhä'vá-rē'. A right tributary of the upper Amazon. It rises at the extreme western angle of the boundary of Brazil with Peru and flows north and northeast through the immense and unexplored forests of La Montaña, joining the Amazon in long. 70° W. (Map: Brazil, C 5). It forms nearly half the boundary line between Brazil and Peru and is navigable nearly to its source, a distance of over 300 miles.

JAVA SPARROW. A well-known cage bird (*Munia oryzivora*), known in the East as rice-bird, paddy bird, and by other names. It is one of the weaver birds (Ploceidæ) and has many Oriental and African congeners. This species seems to be indigenous to Java, but was long ago carried abroad and has become naturalized and to some extent a pest in various rice-growing parts of China, Malaya, India, and Africa, where it is often very injurious to grain crops, after the manner of the bobolink. It is about 5 inches in length, plus a tail 2 inches long, of which the central feathers are longest. The beak is conical and swollen, and rosy in hue, as also are the feet. A narrow edging of red surrounds the eye. The body is slate-colored, rump, tail, and crown black, and there is usually a white patch on the cheek, but these white patches may change to black, regardless of sex or age. The lower parts are purplish gray, becoming white towards the vent. The females are rather lighter and the young somewhat mottled. A snow-white breed has been developed in confinement. These birds are sold everywhere as cage birds, their attraction being mainly their beauty, for the song is brief and of little account. See Plate of CAGE BIRDS.

JAVELIN, jäv'lin (OF. *javelin*, *javeline*, Fr. *javeline*, from Bret. *gavlin*, *gavlod*, *javelin*, *gavl*, *gaol*, fork of a tree, Welsh *gafl*, fork of the thighs, Ir. *gabul*, *gabel*, *gable*; connected with OHG. *gabala*, Ger. *Gabel*, AS. *geaful*, Eng. *gable*, Skt. *gabhasti*, *gable*). A long heavy spear, used by ancients for hurling or thrusting. In the Roman legion the first and second lines (the *hastati* and the *principes*) were both armed with two javelins to each man. Each javelin (Lat. *pilum*) was in all about 6¾ feet in length. The shaft was 4½ feet long, of tough wood, an inch in diameter; the remainder was given to the barbed pyramidal head. In action the legionary hurled one javelin on the enemy at the first onset; the second he retained as a defense against cavalry. The Goths and other barbarians used a javelin.

JAVELLE (zhä-vél') **WATER**. See HYPOCHLOROUS ACID.

JAWOROW, yä-vō'rōv. A town in the Austrian Crownland of Galicia, 29 miles northwest of Lemberg (Map: Austria, H 2). It makes pottery, beer, and liquors and has a large farming industry. The castle with its famous Italian gardens was the favorite resort of the Polish King John Sobieski, and here Peter the Great and Catharine were married. At a short distance is the sulphur spring and bath, Szklo. Pop., 1900, 10,090; 1910, 13,160, mostly Ruthenians, Poles, and Jews.

JAWS. The upper jaw is formed by the union of the two superior maxillary bones. The lower jaw or mandible consists of one bone, the inferior maxillary. The superior maxilla is described as consisting of a body, which is roughly cuboidal in shape, and four processes, viz., the malar, which articulates with the cheek bone; the nasal, into which the thin nasal bones fit; the alveolar, which gives lodgment to the teeth; and the palate, which forms the bony roof of the mouth. The body of the maxilla is hollow and contains the antrum of Highmore; its superior surface takes part in the formation of the orbit, and its internal surface forms the wall of the nostril.
